- Disable the Rapid Accelerator target up-to-date check by setting the `sim` command option `RapidAcceleratorUpToDateCheck` to `'off'`.

To satisfy the second condition, you can change parameters only between simulations that do not require a model rebuild. In other words, the structural checksum of the model must remain the same. Hence, you can change only tunable block diagram parameters and tunable run-time block parameters between simulations. For a discussion on tunable parameters that do not require a rebuild subsequent to their modifications, see “Determine If the Simulation Will Rebuild” on page 35-9.

To disable the Rapid Accelerator target up-to-date check, use the `sim` command, as shown in this sample.

```
parpool;
% Load the model and set parameters
model = 'vdp';
load_system(model);
% Build the Rapid Accelerator target
rtp = Simulink.BlockDiagram.buildRapidAcceleratorTarget(model);
% Run parallel simulations
parfor i=1:4
    simOut{i} = sim(model,'SimulationMode', 'rapid',...
                   'RapidAcceleratorUpToDateCheck', 'off',...
                   'SaveTime', 'on',...
                   'StopTime', num2str(10*i));
    close_system(model, 0);
end

close_system(model, 0);
delete(gcf('nocreate'));
```

In this example, the call to the `buildRapidAcceleratorTarget` function generates code once. Subsequent calls to `sim` with the `RapidAcceleratorUpToDateCheck` option off guarantees that code is not regenerated. Data concurrency issues are thus resolved.

When you set `RapidAcceleratorUpToDateCheck` to `'off'`, changes that you make to block parameter values in the model (for example, by using block dialog boxes, by using the `set_param` function, or by changing the values of MATLAB variables) do not affect the simulation. Instead, use `RapidAcceleratorParameterSets` to pass new parameter values directly to the simulation.

Workspace Access Issues

Workspace Access for MATLAB worker sessions

By default, to run `sim` in `parfor`, a parallel pool opens automatically, enabling the code to run in parallel. Alternatively, you can also first open MATLAB workers using the `parpool` command. The `parfor` command then runs the code within the `parfor` loop in these MATLAB worker sessions. The MATLAB workers, however, do not have access to the workspace of the MATLAB client session where the model and its associated workspace variables have been loaded. Hence, if you load a model and define its associated workspace variables outside of and before a `parfor` loop, then neither is the model loaded, nor are the workspace variables defined in the MATLAB worker sessions where the `parfor` iterations are executed. This is typically the case when you define model parameters or external inputs in the base workspace of the client session. These scenarios constitute workspace access issues.

Transparency Violation

When you run `sim` in `parfor` with `srcWorkspace` set to `current`, Simulink uses the `parfor` workspace, which is a transparent workspace. Simulink then displays an error for transparency violation. For more information on transparent workspaces, see “Ensure Transparency in `parfor`-Loops or `spmd` Statements” (Parallel Computing Toolbox).

Data Dictionary Access

When a model is linked to a data dictionary (see “What Is a Data Dictionary?” on page 66-2), to write code in `parfor` that accesses a variable or object that you store in the dictionary, you must use the functions `Simulink.data.dictionary.setupWorkerCache` and `Simulink.data.dictionary.cleanupWorkerCache` to prevent access issues. For an example, see “Sweep Variant Control Using Parallel Simulation” on page 26-20.

Resolving Workspace Access Issues

When a Simulink model is loaded into memory in a MATLAB client session, it is only visible and accessible in that MATLAB session; it is not accessible in the memory of the MATLAB worker sessions. Similarly, the workspace variables associated with a model that are defined in a MATLAB client session (such as parameters and external inputs) are not automatically available in the worker sessions. You must therefore ensure that the model is loaded and that the workspace variables referenced in the model are defined in the MATLAB worker session by using the following two methods.

- In the `parfor` loop, use the `sim` command to load the model and to set parameters that change with each iteration. (Alternative: load the model and then use the `g(s)et_param` command(s) to set the parameters in the `parfor` loop)
- In the `parfor` loop, use the MATLAB `evalin` and `assignin` commands to assign data values to variables.

Alternatively, you can simplify the management of workspace variables by defining them in the model workspace. These variables will then be automatically loaded when the model is loaded into the worker sessions. There are, however, limitations to this method. For example, you cannot store signal objects that use a storage class other than `Auto` in a model workspace. For a detailed discussion on the model workspace, see “Model Workspaces” on page 62-162.

Specifying Parameter Values Using the `sim` Command

Use the `sim` command in the `parfor` loop to set parameters that change with each iteration.

`%Specifying Parameter Values Using the sim Command`

```
model = 'vdp';
load_system(model)

%Specifying parameter values.
paramName = 'StopTime';
paramValue = {'10', '20', '30', '40'};

% Run parallel simulations
parfor i=1:4
    simOut{i} = sim(model, ...
                    paramName, paramValue{i}, ...
                    'SaveTime', 'on'); %#ok
end

close_system(model, 0);
```

An equivalent method is to load the model and then use the `set_param` command to set the `paramName` in the `parfor` loop.

Specifying Variable Values Using the `assignin` Command

You can pass the values of model or simulation variables to the MATLAB workers by using the `assignin` or the `evalin` command. The following example illustrates how to use

this method to load variable values into the appropriate workspace of the MATLAB workers.

```
parfor i = 1:4
    assignin('base', 'extInp', paramValue{i})%#ok
    % 'extInp' is the name of the variable in the base
    % workspace which contains the External Input data
    simOut{i} = sim(model, 'ExternalInput', 'extInp'); %#ok
end
```

Sweep Variant Control Using Parallel Simulation

To use parallel simulation to sweep a variant control (a `Simulink.Parameter` object whose value influences the variant condition of a `Simulink.Variant` object) that you store in a data dictionary, use this code as a template. Change the names and values of the model, data dictionary, and variant control to match your application.

To sweep block parameter values or the values of workspace variables that you use to set block parameters, use `Simulink.SimulationInput` objects instead of the programmatic interface to the data dictionary. See “Optimize, Estimate, and Sweep Block Parameter Values” on page 37-52.

You must have a Parallel Computing Toolbox license to perform parallel simulation.

```
% For convenience, define names of model and data dictionary
model = 'mySweepMdl';
dd = 'mySweepDD.slidd';

% Define the sweeping values for the variant control
CtrlValues = [1 2 3 4];

% Grant each worker in the parallel pool an independent data dictionary
% so they can use the data without interference
spmc
    Simulink.data.dictionary.setupWorkerCache
end

% Determine the number of times to simulate
numberOfSims = length(CtrlValues);

% Prepare a nondistributed array to contain simulation output
simOut = cell(1,numberOfSims);

parfor index = 1:numberOfSims
```

```

% Create objects to interact with dictionary data
% You must create these objects for every iteration of the parfor-loop
dictObj = Simulink.data.dictionary.open(dd);
sectObj = getSection(dictObj,'Design Data');
entryObj = getEntry(sectObj,'MODE');
% Suppose MODE is a Simulink.Parameter object stored in the data dictionary

% Modify the value of MODE
temp = getValue(entryObj);
temp.Value = CtrlValues(index);
setValue(entryObj,temp);

% Simulate and store simulation output in the nondistributed array
simOut{index} = sim(model);

% Each worker must discard all changes to the data dictionary and
% close the dictionary when finished with an iteration of the parfor-loop
discardChanges(dictObj);
close(dictObj);
end

% Restore default settings that were changed by the function
% Simulink.data.dictionary.setupWorkerCache
% Prior to calling cleanupWorkerCache, close the model

spsmd
    bdclose(model)
    Simulink.data.dictionary.cleanupWorkerCache
end

```

Note If data dictionaries are open, you cannot use the command `Simulink.data.dictionary.cleanupWorkerCache`. To identify open data dictionaries, use `Simulink.data.dictionary.getOpenDictionaryPaths`.

Data Concurrency Issues

Data concurrency issues refer to scenarios for which software makes simultaneous attempts to access the same file for data input or output. In Simulink, they primarily occur as a result of the nonsequential nature of the `parfor` loop during simultaneous execution of Simulink models. The most common incidences arise when code is generated or updated for a simulation target of a Stateflow, Model block or MATLAB Function block during parallel computing. The cause, in this case, is that Simulink tries to concurrently

access target data from multiple worker sessions. Similarly, To File blocks may simultaneously attempt to log data to the same files during parallel simulations and thus cause I/O errors. Or a third-party blockset or user-written S-function may cause a data concurrency issue while simultaneously generating code or files.

A secondary cause of data concurrency is due to the unprotected access of network ports. This type of error occurs, for example, when a Simulink product provides blocks that communicate via TCP/IP with other applications during simulation. One such product is the HDL Verifier™ for use with the Mentor Graphics® ModelSim® HDL simulator.

Resolving Data Concurrency Issues

The core requirement of `parfor` is the independence of the different iterations of the `parfor` body. This restriction is not compatible with the core requirement of simulation via incremental code generation, for which the simulation target from a prior simulation is reused or updated for the current simulation. Hence during the parallel simulation of a model that involves code generation (such as Accelerator mode simulation), Simulink makes concurrent attempts to access (update) the simulation target. However, you can avoid such data concurrency issues by creating a temporary folder within the `parfor` loop and then adding several lines of MATLAB code to the loop to perform the following steps:

- 1** Change the current folder to the temporary, writable folder.
- 2** In the temporary folder, load the model, set parameters and input vectors, and simulate the model.
- 3** Return to the original, current folder.
- 4** Remove the temporary folder and temporary path.

In this manner, you avoid concurrency issues by loading and simulating the model within a separate temporary folder. Following are examples that use this method to resolve common concurrency issues.

A Model with Stateflow, MATLAB Function Block, or Model Block

In this example, either the model is configured to simulate in Accelerator mode or it contains a Stateflow, a MATLAB Function block, or a Model block (for example, `sf_bounce`, `sldemo_autotrans`, or `sldemo_mdhref_basic`). For these cases, Simulink generates code during the initialization phase of simulation. Simulating such a model in `parfor` would cause code to be generated to the same files, while the initialization phase is running on the worker sessions. As illustrated below, you can avoid

such data concurrency issues by running each iteration of the parfor body in a different temporary folder.

```
parfor i=1:4
    cwd = pwd;
    addpath(cwd)
    tmpdir = tempname;
    mkdir(tmpdir)
    cd(tmpdir)
    load_system(model)
    % set the block parameters, e.g., filename of To File block
    set_param(someBlkInMdl, blkParamName, blkParamValue{i})
    % set the model parameters by passing them to the sim command
    out{i} = sim(model, mdlParamName, mdlParamValue{i});
    close_system(model,0);
    cd(cwd)
    rmdir(tmpdir,'s')
    rmpath(cwd)
end
```

Note the following:

- You can also avoid other concurrency issues due to file I/O errors by using a temporary folder for each iteration of the parfor body.
- On Windows platforms, consider inserting the `evalin('base', 'clear mex');` command before `rmdir(tmpdir, 's')`. This sequence closes MEX-files first before calling `rmdir` to remove `tmpdir`.

```
evalin('base', 'clear mex');
rmdir(tmpdir, 's')
```

A Model with To File Blocks

If you simulate a model with To File blocks from inside of a parfor loop, the nonsequential nature of the loop may cause file I/O errors. To avoid such errors during parallel simulations, you can either use the temporary folder idea above or use the `sim` command in Rapid Accelerator mode with the option to append a suffix to the file names specified in the model To File blocks. By providing a unique suffix for each iteration of the parfor body, you can avoid the concurrency issue.

```
rtp = Simulink.BlockDiagram.buildRapidAcceleratorTarget(model);
parfor idx=1:4
    sim(model, ...
        'ConcurrencyResolvingToFileSuffix', num2str(idx),...
```

```
        'SimulationMode', 'rapid',...  
        'RapidAcceleratorUpToDateCheck', 'off');  
end
```

Error Handling in Simulink Using MSLException

Error Reporting in a Simulink Application

Simulink allows you to report an error by throwing an exception using the `MSLException` object, which is a subclass of the MATLAB `MException` class. As with the MATLAB `MException` object, you can use a `try-catch` block with a `MSLException` object construct to capture information about the error. The primary distinction between the `MSLException` and the `MException` objects is that the `MSLException` object has the additional property of `handles`. These handles allow you to identify the object associated with the error.

The MSLException Class

The `MSLException` class has five properties: `identifier`, `message`, `stack`, `cause`, and `handles`. The first four of these properties are identical to those of `MException`. For detailed information about them, see “Properties of the `MException` Class” (MATLAB). The fifth property, `handles`, is a cell array with elements that are double array. These elements contain the handles to the Simulink objects (blocks or block diagrams) associated with the error.

Methods of the MSLException Class

The methods for the `MSLException` class are identical to those of the `MException` class. For details of these methods, see `MException`.

Capturing Information about the Error

The structure of the Simulink `try-catch` block for capturing an exception is:

```
try
    Perform one or more operations
catch E
    if isa(E, 'MSLException')
    ...
end
```

If an operation within the `try` statement causes an error, the `catch` statement catches the exception (*E*). Next, an `if isa` conditional statement tests to determine if the

exception is Simulink specific, i.e., an `MSLException`. In other words, an `MSLException` is a type of `MException`.

The following code example shows how to get the handles associated with an error:

```
errHnds = [];  
try  
    sim('ModelName', ParamStruct);  
catch e  
    if isa(e,'MSLException')  
        errHnds = e.handles{1}  
    end  
end
```

You can see the results by examining `e`. They will be similar to the following output:

```
e =  
  
MSLException  
  
Properties:  
    handles: {[7.0010]}  
    identifier: 'Simulink:Parameters:BlkParamUndefined'  
    message: [1x87 char]  
    cause: {0x1 cell}  
    stack: [0x1 struct]  
  
Methods, Superclasses
```

To identify the name of the block that threw the error, use the `getfullname` command. For the present example, enter the following command at the MATLAB command line:

```
getfullname(errHnds)
```

If a block named `Mu` threw an error from a model named `vdp`, MATLAB would respond to the `getfullname` command with:

```
ans =  
vdp/Mu
```

Multiple Simulations

Run Multiple Simulations

For workflows that involve multiple parallel simulations and logging of large amounts of data, you can create simulation sets by using an array of `Simulink.SimulationInput` objects. This is useful in scenarios like model testing, experiment design, Monte Carlo analysis, and model optimization.

Using arrays of `Simulink.SimulationInput` objects simplify the running of multiple simulations and running them in parallel. With the Parallel Computing Toolbox, you can use the `parsim` and `batchsim` commands to run the simulations in parallel.

The `parsim` command distributes each simulation to your workers to decrease your overall simulation time. The `parsim` command automates the creation of a parallel pool, identifying file dependencies and managing build artifacts for accelerator and rapid accelerator simulations.

The `batchsim` command offloads the simulations to the compute cluster. The execution of the simulations takes place on the cluster, giving you the ability to carry out other tasks while the batch job is processing, or close the client MATLAB and access the batch job later.

In the absence of a Parallel Computing Toolbox license, the `parsim` behaves like the `sim` command. The simulations then run in serial.

The `batchsim` command uses the Parallel Computing Toolbox™ license to run the simulations on compute cluster. `batchsim` runs the simulations in serial if a parallel pool cannot be created. If Parallel Computing Toolbox license is not used, `batchsim` errors out.

You can make changes to your model using the `Simulink.SimulationInput` object and run a simulation in parallel with those changes. Changing the `Simulink.SimulationInput` object, overrides the values in the model. The simulation uses the values in the `Simulink.SimulationInput` object rather than the values defined in the model. This way, you can change the model without dirtying it. The `Simulink.SimulationInput` object allows you to change these settings in your model:

- Initial state
- External inputs
- Model parameters
- Block parameters

- Variables

Through the `Simulink.SimulationInput` object, you can also specify MATLAB functions to run at the start and the end of each simulation by using `PreSimFcn` and `PostSimFcn` respectively.

When you use `Simulink.SimulationInput` objects, the model parameters are restored after the simulation ends. See “Run Parallel Simulations Using `parsim`” on page 27-5.

Note When the pool is not already open and simulations are run for the first time, simulations take an additional time to start. Subsequent parallel simulations are faster.

Other Advantages

- Outputs errors in the simulation output object for easier debugging
- Compatible with rapid accelerator and fast restart
- Compatible with file logging (to facilitate big data)
- Compatible with MATLAB Parallel Server in addition to local parallel pools
- Capable of transferring base workspace variables to workers
- Avoids transparency errors

Simulation Manager

The Simulation Manager allows you to monitor multiple parallel simulations. It shows the progress of the runs as they are running in parallel. You can view the details of every run such as parameters, elapsed time, and diagnostics. The Simulation Manager acts as a useful tool by giving you the option to analyze and compare your results in the Simulation Data Inspector. You can also select a run and apply its values to the model. For more information, see [Simulation Manager](#).

Data Logging for Multiple Simulations

The resulting `Simulink.SimulationOutput` object, which contains the simulation outputs, captures error messages and the simulation metadata. When you select the **Data Import/Export > Log Dataset data to file** configuration parameter, Simulink creates a `Simulink.SimulationData.DatasetRef` object for each `Dataset` stored in the resulting MAT file. You can use the `DatasetRef` object to access the data for a `Dataset`

element. For simulations that are run using the `Simulink.SimulationInput` objects, the `DatasetRef` object is returned as part of the `SimulationOutput` object. As a result, you have quicker access to and do not need to create them.

Parallel simulations can produce more logged data than the MATLAB memory can hold. Consider logging to persistent storage for parallel simulations to reduce the memory requirement. When you select the **Data Import/Export > Log Dataset data to file** configuration parameter (`LoggingToFile`), for parallel simulations in Simulink:

- Data is logged in Dataset format in a MAT-file
- A `Simulink.SimulationData.DatasetRef` object is created for each Dataset element (for example, `logouts`) for each simulation

You can use `DatasetRef` objects to access data for a specific signal. You can create `matlab.io.datasetore.SimulationDatastore` objects to use for streaming logged data from persistent storage in to a model.

- “Work with Big Data for Simulations” on page 64-44

Run Parallel Simulations Using parsim

This example shows how to use a `Simulink.SimulationInput` object to change block and model parameters and run simulations in parallel with those changes.

The example model `sldemo_househeat` is a system that models the thermal characteristics of a house, its outdoor environment, and a house heating system. This model calculates heating costs for a generic house.

Set Point block, Thermostat subsystem, Heater subsystem, House subsystem, and Cost Calculator component are the main components. For a detailed explanation of the model, see “Thermal Model of a House”.

Run Multiple Parallel Simulations with Different Set Points

This model uses a Constant block to specify a temperature set point that must be maintained indoors. The default value of set point value is 70 degrees Fahrenheit. This example shows you how to simulate the model in parallel using different values of Set Point.

Open the example model.

```
open_system('sldemo_househeat');
```

Define a set of values for Set Point.

```
SetPointValues = 65:2:85;  
spv_length = length(SetPointValues);
```

Using the defined values, initialize an array of `Simulink.SimulationInput` objects. Use these `Simulink.SimulationInput` objects to specify the Set Point values. In this step, to preallocate the array, the loop index is made to start from the largest value.

```
for i = spv_length:-1:1  
    in(i) = Simulink.SimulationInput('sldemo_househeat');  
    in(i) = in(i).setBlockParameter('sldemo_househeat/Set Point',...  
        'Value',num2str(SetPointValues(i)));  
end
```

This example produces an array of 10 `Simulink.SimulationInput` objects, each corresponding to a different value of Set Point.

Now, run these multiple simulations in parallel using the command `parsim`. To monitor and analyze the runs, open the Simulation Manager by setting the `ShowSimulationManager` argument to `on`. The `ShowProgress` argument when set to `on` shows the progress of the simulations.

```
out = parsim(in, 'ShowSimulationManager', 'on', 'ShowProgress', 'on')
```

The output is generated as a `Simulink.SimulationOutput` object. To see all of the different set point values, open the plot of the Temperatures (Indoor and Outdoor) and the Heat Cost component. The constant block Avg Outdoor Temp specifies the average air temperature outdoors. The Daily Temp Variation Sine Wave block generates daily temperature fluctuations of outdoor temperature. The indoor temperature is derived from the House subsystem. The temperature outdoor varies sinusoidally, whereas the temperature indoors is maintained within 5 degrees Fahrenheit of the set point.

In the absence of the Parallel Computing Toolbox licenses, the `parsim` command behaves like the `sim` command. The simulations run in serial.

View the Runs in the Simulation Manager

Setting the ShowSimulationManager argument to on enables the Simulation Manager. For more information, see Simulation Manager.

You can view the status of all the runs and detailed information about them.

The Simulation Manager window displays the following summary statistics:

Total Simulations	11
Elapsed Time	00:02:08
Number of Active Workers	6
Estimated Time Remaining	00:00:00

Legend: Errors/Aborted (0) | Completed (11) | Active (0) | Queued (0)

Run ID	Status	Progress	Elapsed Time	Machine
1	Completed	100%	00:00:04	ah-cdeshtan
2	Completed	100%	00:00:04	ah-cdeshtan
3	Completed	100%	00:00:04	ah-cdeshtan
4	Completed	100%	00:00:04	ah-cdeshtan
5	Completed	100%	00:00:04	ah-cdeshtan
6	Completed	100%	00:00:04	ah-cdeshtan
7	Completed	100%	00:00:01	ah-cdeshtan
8	Completed	100%	00:00:01	ah-cdeshtan
9	Completed	100%	00:00:01	ah-cdeshtan
10	Completed	100%	00:00:01	ah-cdeshtan

SIMULATION DETAILS

Run ID:	6	Parameters	Timing Info	Diagnostics
Status:	Completed	Type	Name	Value
Progress:	100	Block Parameter	Value	75
Elapsed Time:	00:00:04			

The Simulation Manager enables you to view your results in the Simulation Data Inspector, which in turn allows you to analyze and compare your data. You can view the plot of the Temperatures (Indoor and Outdoor) and the Heat Cost in Simulation Data Inspector. Select the runs for which you want to view the plot and click  icon.

You can now see the heat cost for three simulations.

Using the Simulation Manager, you can apply the parameters of any run to your model. Now, suppose that you want to apply the parameters of Run 3 to your model. Select Run 3 and click the  icon. Your parameters are applied to the model.

- “Run Multiple Simulations” on page 27-2

Multiple Simulation Workflows

When running a set of multiple simulations, you can run them in parallel on multiple MATLAB workers in a parallel pool. To run multiple simulations, you can use `parsim`, `parsim` with `'RunInBackground'` option turned on, or `batchsim`.

The flowchart shows how running multiple simulations with `parsim`, `parsim` with `RunInBackground` and `batchsim` differ.

The `parsim` and `batchsim` commands use the Parallel Computing Toolbox license to run the simulations in parallel. `parsim` runs the simulations in serial if a parallel pool cannot be created or if the Parallel Computing Toolbox license is not available. `batchsim` commands cannot run without Parallel Computing Toolbox license.

parsim Workflow

Using `parsim` command with Parallel Computing Toolbox to run multiple simulations sets up a parallel pool automatically and runs simulations in parallel. The client is always tied to the MATLAB workers.

Basic parsim Workflow

- 1 Create an array of `Simulink.SimulationInput` objects, `in`, to specify changes to the model.
- 2 Specify one-time setup required for running multiple simulations. You can use `SetupFcn` and `TransferBaseWorkspaceVariables` to perform setup on the parallel workers.
- 3 Run `parsim(in)` to execute these multiple simulations in parallel. If a parallel pool does not exist, `parsim` creates it. `parsim` uses default settings.
- 4 You can open Simulation Manager by setting the `'SimulationManager'` argument to `'on'` with `parsim, parsim(in, 'SimulationManager', 'on')`. Simulation Manager enables you to monitor the simulations as they are running and gives you access to outputs of the simulations when they are ready. Simulation Manager provides you with numerous information about the simulations running on the workers. For more information, see **Simulation Manager**.
- 5 Once all the simulations are complete, you get an array of `Simulink.SimulationOutput` objects.

Limitations

- Closing the MATLAB session terminates simulations on the workers, disabling retrieval of partial results.

parsim with RunInBackground Workflow

- 1 Create an array of `Simulink.SimulationInput` objects, `in`, to specify changes to the model.
- 2 Specify one-time setup required for running multiple simulations. You can use `SetupFcn` and `TransferBaseWorkspaceVariables` to perform setup on the parallel workers.
- 3 Run `parsim` with `RunInBackground` option set to `'on'`:
`parsim(in, 'RunInBackground', 'on')`. Setting the `'RunInBackground'` option to `'on'` runs the simulations asynchronously. This keeps the MATLAB command prompt available enabling you to work on other tasks.
- 4 With `'RunInBackground'` option set to `'on'`, `parsim` returns a `Simulink.Simulation.Future` object. You can poll this object to check the status of simulations, fetch the outputs of simulations when they are completed, or cancel simulations. For more information, see `Simulink.Simulation.Future`.

Limitations

- Closing the MATLAB session terminates simulations on the workers, disabling retrieval of partial results. If the `future` object is cleaned, you are subsequently unable to access the results of the simulations.
- Using a `fetchNext` method loop on `Future` objects, along with Simulation Manager causes them to compete for retrieval of `Future` objects. Use either a `fetchNext` next loop or Simulation Manager to get the outputs of completed simulations.

batchsim Workflow

A batch workflow typically means submitting jobs to run simulations on MATLAB workers and subsequently accessing the results of those simulations. When you run simulations in batches, you offload the execution of simulations onto a compute cluster. To learn more about batch processing, see “Simple Batch Processing” (Parallel Computing Toolbox).

- 1 Create an array of `Simulink.SimulationInput` objects, `in`, to specify changes to the model.
- 2 Specify one-time setup required for running multiple simulations. You can use `SetupFcn` and `TransferBaseWorkspaceVariables` to perform setup on the parallel workers.
- 3 To run on a cluster or desktop background, call `batchsim` to offload the execution of simulations. With `batchsim`, you can use most of the arguments that are compatible with `parsim` and `batch` commands. For more information, see `batchsim`.

Using `batchsim`, you offloaded simulations to a MATLAB worker. To run the batch job on multiple workers, specify a pool size, `N`, that is an integer specifying the number of workers to make into a parallel pool for the job: `batchsim(in, 'Pool', N)`. There must be at least `N+1` workers available on the cluster. If the pool size is not specified, `batchsim(in)` runs the simulations on a single worker in the cluster specified by the default cluster profile.

Note `batchsim` errors out when used with a pool size if Parallel Computing Toolbox license is not available.

- 4 `batchsim` offloads simulations to the compute cluster, enabling you to carry out other tasks while the batch job is processing, or close the client MATLAB and access the batch job later.
- 5 On submitting a batch job, `batchsim` returns a job object containing a job ID and other information that you can use to access the batch job at a later time. Access this job again to check the progress of simulations.

Limitations

- Because the client session is not tied to the workers, you cannot access the outputs unless the job is finished.
- `batchsim` does not give you the ability to monitor simulations with Simulation Manager. For batch jobs, you can use a batch job monitor that tells you if the job is queues, in progress, or completed. For more information, see “Job Monitor” (Parallel Computing Toolbox)

Prototype and Debug Models with Scopes

Simulink Scope blocks and Scope viewers offer a quick and lightweight way to visualize your simulation data over time. If you are prototyping a model design, you can attach signals to a Scope block. After simulating the model, you can use the results to validate your design. See “Scope Blocks and Scope Viewer Overview” on page 28-8 and “Model and Validate a System”.

A Scope block or Scope viewer opens to a Scope window where you can display and evaluate simulation data.

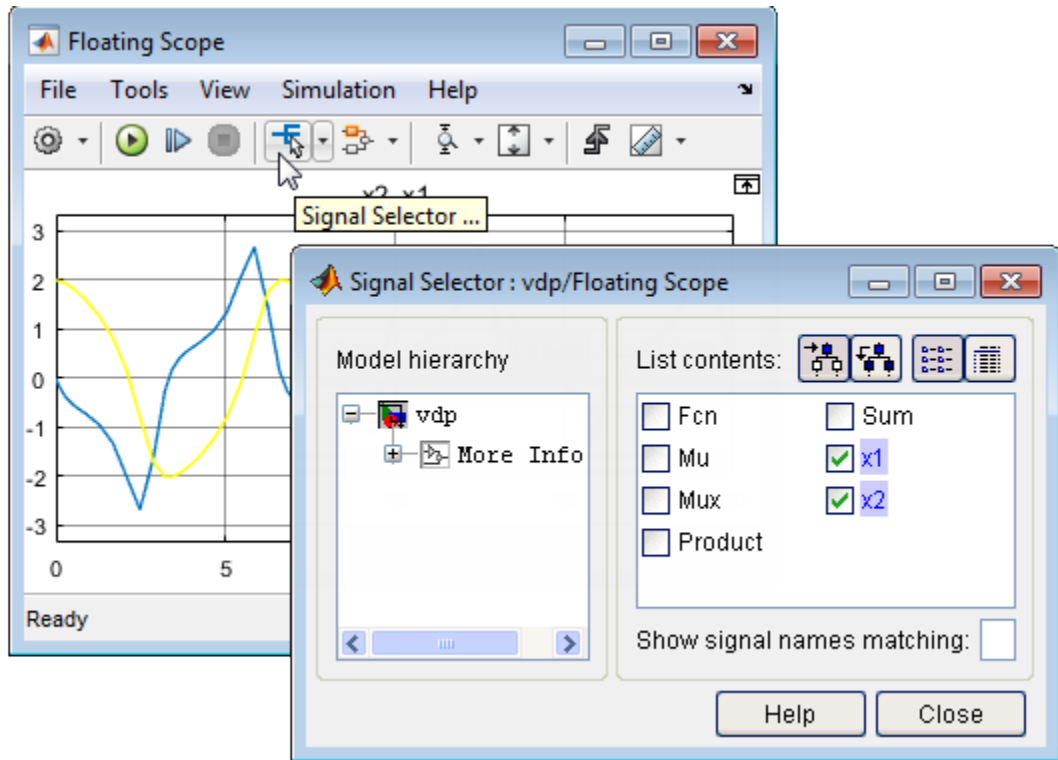

The toolbar contains controls for starting, stopping, and stepping forward through a

simulation . You can use these controls to debug a model by viewing signal data at each time interval. See “How Stepping Through a Simulation Works” on page 2-3.

Connect signal lines to a Scope block using multiple input ports, see “Number of input ports”.

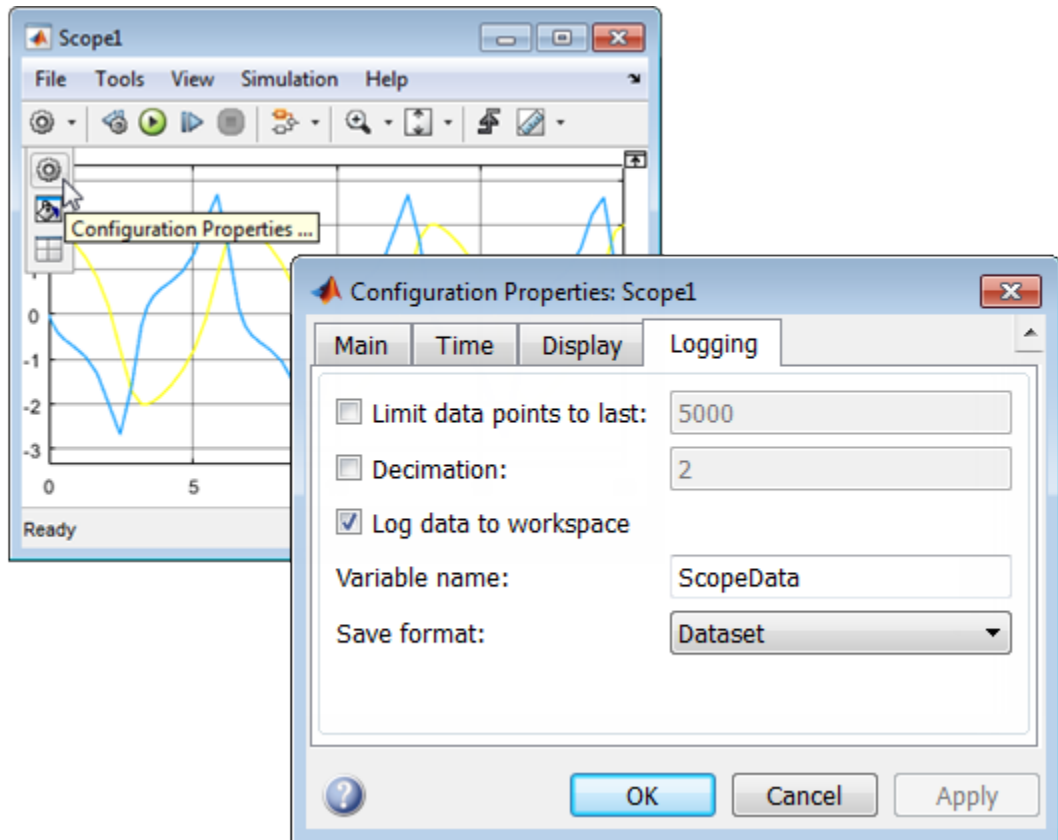

Attach signals to a Floating Scope block or signal viewer directly from the model. See “Connect Signals to Floating Scope Block or Scope Viewer” on page 28-82.

Use the oscilloscope-like tools available with a scope to debug your model. Set triggers to capture events, use interactive cursors to measure signal values at various points, and review signal statistics such as maximum and mean values. See “Scope Triggers Panel” on page 28-16 and “Cursor Measurements Panel” on page 28-30.

Save or log signal data to the MATLAB workspace, and then plot data in a MATLAB figure window. Use MATLAB functions or your own scripts to analyze the data. See “Save Simulation Data Using Floating Scope Block” on page 28-83.

Scope Blocks and Scope Viewer Overview

In this section...

“Overview of Methods” on page 28-8

“Simulink Scope Versus Floating Scope” on page 28-9

“Simulink Scope Versus DSP System Toolbox Time Scope” on page 28-11

Overview of Methods

Simulink scopes provide several methods for displaying simulation data and capturing the data for later analysis. Symbols on your block diagram represent the various data display and data capture methods.

For more information about these methods:

- Scope and Floating Scope blocks — Scope, Floating Scope, “Common Scope Block Tasks” on page 28-63, “Floating Scope and Scope Viewer Tasks” on page 28-81.
- Scope Viewer — “Signal and Scope Manager” on page 28-89, “Floating Scope and Scope Viewer Tasks” on page 28-81.
- Signal Logging — “Save Simulation Data Using Floating Scope Block” on page 28-83.
- Signal Test Point — “Test Points” on page 67-62.

Simulink Scope Versus Floating Scope

Scope blocks and Floating Scope blocks both display simulation results, but they differ in how you attach signals and save data. Simulation behavior for a Floating Scope and a Scope Viewer is identical, but you manage them differently in your model.

Capability	Simulink Scope	Simulink Floating Scope	Simulink Scope Viewer
Attaching signals	Connect signal lines to a Scope block using input ports.	Attach signals interactively from the model before and during a simulation. See “Connect Signals to Floating Scope Block or Scope Viewer” on page 28-82 and “Quickly Switch Visualization of Different Signals on a Floating Scope” on page 28-86.	Attach signals from the Signal Selector, interactively from the model before simulation, or via the signal line context menu.
Access to signals	Because signals lines are connected to a Scope block, access signals at different levels of a model hierarchy using GoTo blocks.	Because signals are attached without signal lines, you do not have to route lines to a Floating Scope block. You can access most signals inside the model hierarchy, including referenced models and Stateflow charts. You cannot access optimized signals.	Scope viewers are attached to signal lines.

Capability	Simulink Scope	Simulink Floating Scope	Simulink Scope Viewer
Data logging	Save data to a MATLAB variable as an array, structure, or object.	Save data to a MATLAB variable as an object.	
Simulation control	Run, forward, and back toolbar buttons.	Run, forward, and back toolbar buttons.	Run, forward, and back toolbar buttons.
Scale axes after simulation	<p>Toolbar buttons to Scale X-axis and Y-axis limits</p> <p>Axes scaling set to Auto for the X-axis and Y-axis.</p>	<p>Toolbar button to scale only the Y-axis limits, and</p> <p>Axes scaling set to Auto for only the Y-axis.</p>	<p>Toolbar buttons to Scale X-axis and Y-axis limits</p> <p>Axes scaling set to Auto for the X-axis and Y-axis.</p>
Add to model	Add block from Simulink sinks library.	Add block from Simulink sinks library.	Add using Signal & Scope Manager. See “Signal and Scope Manager” on page 28-89.
Visual indication in model		Floating Scope block not attached to any signal lines.	Viewer icons located above signal lines for all attached signals.
Manage scopes centrally	No.	No.	Use the Signal & Scope Manager to add or delete viewers, and attach or remove signals.
Manage scopes locally	Attach signal lines to Scope block in ports.	Attach signals from the Floating Scope window.	Add viewers and attach additional signals within a model hierarchy using the context menus.
Simulink Report Generator support	Yes.	Yes.	No.

Capability	Simulink Scope	Simulink Floating Scope	Simulink Scope Viewer
Connecting Constant block with Sample time set to <code>inf</code> (constant sample time)		Plots all data values.	Plots the data value at the first time step and anytime you tune a parameter.

Simulink Scope Versus DSP System Toolbox Time Scope

If you have Simulink and a DSP System Toolbox license, you can use either the Simulink Scope or DSP System Toolbox Time Scope. Choose the scope based on your application requirements, how the blocks work, and the default values of each block.

If you have a DSP System Toolbox license and you have been using Time Scopes, continue to do so in your applications. Using the Time Scope block requires a DSP System Toolbox license.

Feature	Scope	Time Scope
Location in block library	Simulink Sinks library	DSP System Toolbox Sinks library
Trigger and measurement panels	With Simulink only: <ul style="list-style-type: none"> • Trigger • Cursor Measurement With DSP System Toolbox or Simscape license: <ul style="list-style-type: none"> • Signal Statistics • Bilevel Measurements • Peak Finder 	<ul style="list-style-type: none"> • Trigger • Cursor Measurements • Signal Statistics • Bilevel Measurements • Peak Finder

Feature	Scope	Time Scope
Simulation mode support for block-based sample times For block-based sample times, all the inputs of the block run at the same rate.	<ul style="list-style-type: none"> • Normal • Accelerator • Rapid-Accelerator • External 	<ul style="list-style-type: none"> • Rapid-Accelerator • External
Simulation mode support for port-based sample times For port-based sample times, the input ports can run at different rates.	No.	<ul style="list-style-type: none"> • Normal • Accelerator
Frame processing of signals	Included in Scope block with DSP System Toolbox license.	Included in Time Scope block.
Sample time propagation	If the different ports have different sample rates, the scope uses the greatest common divisor of the rates.	When using port-based sample times, the different ports of the Scope block inherit the different rates and plots the signals according to those rates.
Save model to previous Simulink release	If saving to a release before R2015a, the Scope block is converted to a scope with the features available in that release.	No change in features.

This table lists the differences in Configuration Property default values between the Scope and Time Scope blocks.

Property	Scope	Time Scope
Open at start of simulation	Cleared	Selected
Input processing	Elements as channels (sample based)	Columns as channels (frame based)
Maximize Axes	Off	Auto

Property	Scope	Time Scope
Time Units	None	Metric (based on Time Span)
Time-axis labels	Bottom displays only	All
Show time-axis label	Cleared	Selected
Plot Type	Auto	Line
Title	%<Signal Label>	No title
Y label	No label	Amplitude

Debugging a Model with Scope Blocks

There are different types of triggering techniques available in with a Scope block. You can choose one over the other depending on your application. Some of the important triggering techniques available in with a Scope include:

- **Edge Trigger:** Use edge triggering to stabilize a repetitive waveform and search for a occurrence of a particular pattern in the signal. Using the edge triggering technique, one can stabilize a repetitive signal based on occurrence of edge in a signal and then measure important attributes of a signal like Rise Time, Fall Time, Peak to peak voltage, RMS voltage etc.
- **Pulse width triggering:** Using this technique, you can set the Scope to trigger, for example, on the occurrence of a glitch - a pulse which is faster / slower than the reference pulse. This ability can help one investigate the properties of the glitch and do some investigation on the root cause of the glitch
- **Runt triggering:** Using the Runt Triggering, one can set the Scope to trigger for pulses whose amplitude crosses one of the two voltage threshold but not both and whose pulse width lies in a specific predefined time range. This is very useful in debugging the Runt Signals frequently encountered in troubleshooting Digital integrated Circuits.

Runt signals are the signals which typically cross a voltage threshold level but fail to cross a second threshold before re-crossing the first threshold level. Runt signals are frequently encountered in digital circuits.

To look for Runt signals, enable the Trigger, set the Trigger Mode to Normal, set the trigger type as Runt, adjust the voltage threshold and then view if the Scope detects and displays the presence of any runt signals in the incoming data stream.

“What Is the Trigger Panel” on page 28-16
“Main Pane” on page 28-17
“Source/Type and Levels/Timing Panes” on page 28-17
“Hysteresis of Trigger Signals” on page 28-27
“Delay/Holdoff Pane” on page 28-28

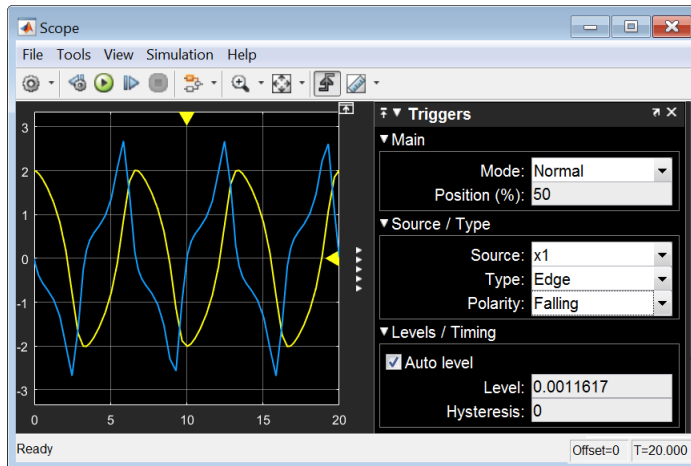

What Is the Trigger Panel

The Trigger panel defines a trigger event to synchronize simulation time with input signals. You can use trigger events to stabilize periodic signals such as a sine wave or capture non-periodic signals such as a pulse that occurs intermittently.

To open the Trigger panel:

- 1 Open a Scope block window.
- 2 On the toolbar, click the Triggers button .
- 3 Run a simulation.

Triangle trigger pointers indicate the trigger time and trigger level of an event. The marker color corresponds to the color of the source signal.

Main Pane

Mode — Specify when the display updates.

- **Auto** — Display data from the last trigger event. If no event occurs after one time span, display the last available data.

Normal — Display data from the last trigger event. If no event occurs, the display remains blank.

- **Once** — Display data from the last trigger event and freeze the display. If no event occurs, the display remains blank. Click the **Rearm** button to look for the next trigger event.
- **Off** — Disable triggering.

Position (%) — Specify the position of the time pointer along the y-axis. You can also drag the time pointer to the left or right to adjust its position.

Source/Type and Levels/Timing Panes

Source — Select a trigger signal. For magnitude and phase plots, select either the magnitude or the phase.

Type — Select the type of trigger.

Trigger Type	Trigger Parameters
<p>Edge — Trigger when the signal crosses a threshold.</p>	<p>Polarity — Select the polarity for an edge-triggered signal.</p> <ul style="list-style-type: none"> • Rising — Trigger when the signal is increasing.  <ul style="list-style-type: none"> • Falling — Trigger when the signal value is decreasing.  <ul style="list-style-type: none"> • Either — Trigger when the signal is increasing or decreasing.

Trigger Type	Trigger Parameters
	<p data-bbox="541 298 1292 357">Level — Enter a threshold value for an edge triggered signal. Auto level is 50%</p> <p data-bbox="541 388 1292 447">Hysteresis — Enter a value for an edge-triggered signal. See “Hysteresis of Trigger Signals” on page 28-27</p>

Trigger Type	Trigger Parameters
<p>Pulse Width — Trigger when the signal crosses a low threshold and a high threshold twice within a specified time.</p>	<p>Polarity — Select the polarity for a pulse width-triggered signal.</p> <ul style="list-style-type: none"> • Positive — Trigger on a positive-polarity pulse when the pulse crosses the low threshold for a second time.  <ul style="list-style-type: none"> • Negative — Trigger on a negative-polarity pulse when the pulse crosses the high threshold for a second time. • Either — Trigger on both positive-polarity and negative-polarity pulses. <p>Note A glitch-trigger is a special type of a pulse width-trigger. A glitch-trigger occurs for a pulse or spike whose duration is less than a specified amount. You can implement a glitch trigger by using a pulse width-trigger and setting the Max Width parameter to a small value.</p> <p>High — Enter a high value for a pulse width-triggered signal. Auto level is 90%.</p> <p>Low — Enter a low value for a pulse width-triggered signal. Auto level is 10%.</p>

Trigger Type	Trigger Parameters
	<p data-bbox="541 296 1329 392">Min Width — Enter the minimum pulse-width for a pulse width triggered signal. Pulse width is measured between the first and second crossings of the middle threshold.</p> <p data-bbox="541 418 1329 480">Max Width — Enter the maximum pulse width for a pulse width triggered signal.</p>

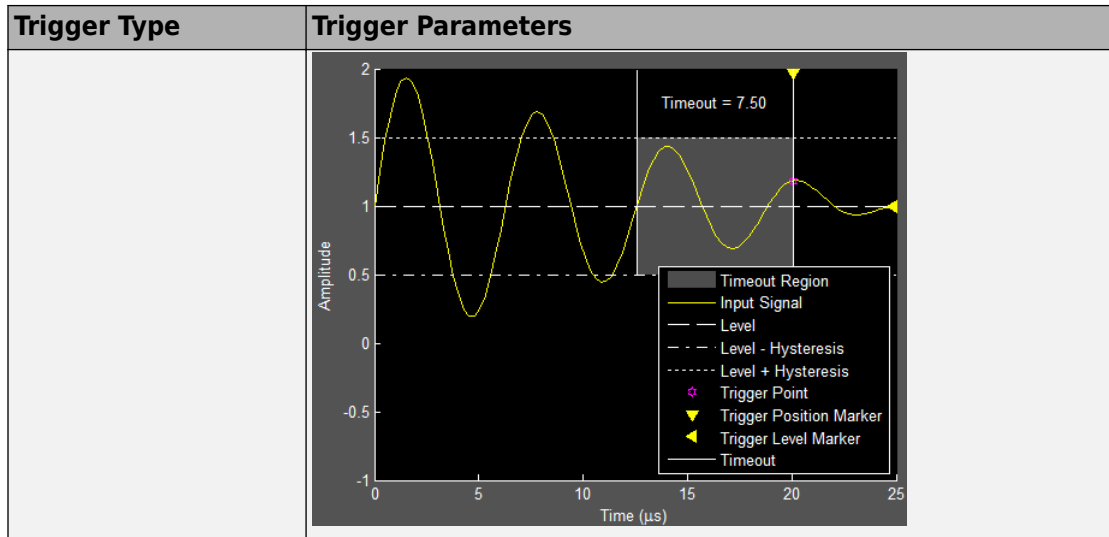

Trigger Type	Trigger Parameters
<p>Transition — Trigger on the rising or falling edge of a signal that crosses the high and low levels within a specified time range.</p>	<p>Polarity — Select the polarity for a transition-triggered signal.</p> <ul style="list-style-type: none"> • Rise Time — Trigger on an increasing signal when the signal crosses the high threshold.  <ul style="list-style-type: none"> • Fall Time — Trigger on a decreasing signal when the signal crosses the low threshold. • Either — Trigger on an increasing or decreasing signal. <p>High — Enter a high value for a transition-triggered signal. Auto level is 90%.</p> <p>Low — Enter a low value for a transition-triggered signal. Auto level is 10%.</p> <p>Min Time — Enter a minimum time duration for a transition-triggered signal.</p> <p>Max Time — Enter a maximum time duration for a transition-triggered signal.</p>

Trigger Type	Trigger Parameters
<p>Runt— Trigger when a signal crosses a low threshold or a high threshold twice within a specified time.</p>	<p>Polarity — Select the polarity for a runt-triggered signal.</p> <ul style="list-style-type: none"> • Positive — Trigger on a positive-polarity pulse when the signal crosses the low threshold a second time, without crossing the high threshold.  <ul style="list-style-type: none"> • Negative — Trigger on a negative-polarity pulse. • Either — Trigger on both positive-polarity and negative-polarity pulses. <p>High — Enter a high value for a runt-triggered signal. Auto level is 90%.</p> <p>Low — Enter a low value for a runt-triggered signal. Auto level is 10%.</p> <p>Min Width — Enter a minimum width for a runt-triggered signal. Pulse width is measured between the first and second crossing of a threshold.</p> <p>Max Width — Enter a maximum pulse width for a runt-triggered signal.</p>

Trigger Type	Trigger Parameters
<p>Window — Trigger when a signal stays within or outside a region defined by the high and low thresholds for a specified time.</p>	<p>Polarity — Select the region for a window-triggered signal.</p> <ul style="list-style-type: none"> <p>Inside — Trigger when a signal leaves a region between the low and high levels.</p>  <p>Outside — Trigger when a signal enters a region between the low and high levels.</p> 

Trigger Type	Trigger Parameters
	<ul style="list-style-type: none"><li data-bbox="541 296 1292 357">• Either — Trigger when a signal leaves or enters a region between the low and high levels. <p data-bbox="541 387 1317 447">High — Enter a high value for a window-triggered signal. Auto level is 90%.</p> <p data-bbox="541 477 1262 538">Low — Enter a low value for a window-trigger signal. Auto level is 10%.</p> <p data-bbox="541 567 1292 628">Min Time — Enter the minimum time duration for a window-triggered signal.</p> <p data-bbox="541 657 1299 718">Max Time — Enter the maximum time duration for a window-triggered signal.</p>

Trigger Type	Trigger Parameters
<p>Timeout — Trigger when a signal stays above or below a threshold longer than a specified time</p>	<p>Polarity — Select the polarity for a timeout-triggered signal.</p> <ul style="list-style-type: none"> • Rising — Trigger when the signal does not cross the threshold from below. For example, if you set Timeout to 7.50 seconds, the scope triggers 7.50 seconds after the signal crosses the threshold.  <ul style="list-style-type: none"> • Falling — Trigger when the signal does not cross the threshold from above. • Either — Trigger when the signal does not cross the threshold from either direction <p>Level — Enter a threshold value for a timeout-triggered signal.</p> <p>Hysteresis — Enter a value for a timeout-triggered signal. See “Hysteresis of Trigger Signals” on page 28-27.</p> <p>Timeout — Enter a time duration for a timeout-triggered signal.</p> <p>Alternatively, a trigger event can occur when the signal stays within the boundaries defined by the hysteresis for 7.50 seconds after the signal crosses the threshold.</p>

Hysteresis of Trigger Signals

Hysteresis (V) — Specify the hysteresis or noise reject value. This parameter is visible when you set **Type** to Edge or Timeout. If the signal jitters inside this range and briefly crosses the trigger level, the scope does not register an event. In the case of an edge trigger with rising polarity, the scope ignores the times that a signal crosses the trigger level within the hysteresis region.

You can reduce the hysteresis region size by decreasing the hysteresis value. In this example, if you set the hysteresis value to 0.07, the scope also considers the second rising edge to be a trigger event.

Delay/Holdoff Pane

Offset the trigger position by a fixed delay, or set the minimum possible time between trigger events.

- **Delay (s)** — Specify the fixed delay time by which to offset the trigger position. This parameter controls the amount of time the scope waits after a trigger event occurs before displaying a signal.
- **Holdoff (s)** — Specify the minimum possible time between trigger events. This amount of time is used to suppress data acquisition after a valid trigger event has occurred. A trigger holdoff prevents repeated occurrences of a trigger from occurring during the relevant portion of a burst.

Related Examples

- “Cursor Measurements Panel” on page 28-30

Cursor Measurements Panel

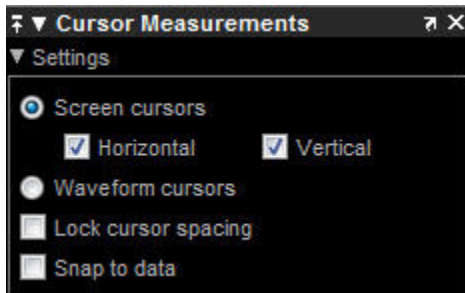

The **Cursor Measurements** panel displays screen cursors. The panel provides two types of cursors for measuring signals. Waveform cursors are vertical cursors that track along the signal. Screen cursors are both horizontal and vertical cursors that you can place anywhere in the display.

Note If a data point in your signal has more than one value, the cursor measurement at that point is undefined and no cursor value is displayed.

Display screen cursors with signal times and values. To open the Cursor measurements panel:

- From the menu, select **Tools > Measurements > Cursor Measurements**.
- On the toolbar, click the Cursor Measurements  button.

In the **Settings** pane, you can modify the type of screen cursors used for calculating measurements. When more than one signal is displayed, you can assign cursors to each trace individually.

- **Screen Cursors** — Shows screen cursors (for spectrum and dual view only).
- **Horizontal** — Shows horizontal screen cursors (for spectrum and dual view only).
- **Vertical** — Shows vertical screen cursors (for spectrum and dual view only).
- **Waveform Cursors** — Shows cursors that attach to the input signals (for spectrum and dual view only).
- **Lock Cursor Spacing** — Locks the frequency difference between the two cursors.

- **Snap to Data** — Positions the cursors on signal data points.

The Measurements pane displays time and value measurements.

	Time (secs)	Value
1	2.500	-9.027e+01
2	7.500	-1.175e+02
ΔT	5.000 s	ΔY 2.722e+01
$1 / \Delta T$		200.000 mHz
$\Delta Y / \Delta T$		5.444 (/s)

- **1** — View or modify the time or value at cursor number one (solid line cursor).
- **2** — View or modify the time or value at cursor number two (dashed line cursor).
- ΔT or ΔX — Shows the absolute value of the time (x-axis) difference between cursor number one and cursor number two.
- ΔY — Shows the absolute value of the signal amplitude difference between cursor number one and cursor number two.
- $1/\Delta T$ or $1/\Delta X$ — Shows the rate. The reciprocal of the absolute value of the difference in the times (x-axis) between cursor number one and cursor number two.
- $\Delta Y/\Delta T$ or $\Delta Y/\Delta X$ — Shows the slope. The ratio of the absolute value of the difference in signal amplitudes between cursors to the absolute value of the difference in the times (x-axis) between cursors.

Related Examples

- “Scope Triggers Panel” on page 28-16

Scope Signal Statistics Panel

Note The Signal Statistics panel requires a DSP System Toolbox or Simscape license.

Display signal statistics for the signal selected in the **Trace Selection** panel. To open the Signal Statistics panel:

- From the menu, select **Tools > Measurements > Signal Statistics**.
- On the toolbar, click the Signal Statistics  button.

	Value	Time (secs)
Max	1.000e+00	0.000e+00
Min	-1.000e+00	1.000
Peak to Peak	2.000e+00	
Mean	1.117e-05	
Median	2.945e-04	
RMS	7.084e-01	

The statistics shown are:

- **Max** — Maximum or largest value within the displayed portion of the input signal.
- **Min** — Minimum or smallest value within the displayed portion of the input signal.
- **Peak to Peak** — Difference between the maximum and minimum values within the displayed portion of the input signal.
- **Mean** — Average or mean of all the values within the displayed portion of the input signal.
- **Median** — Median value within the displayed portion of the input signal.
- **RMS** — Root mean squared of the input signal.

When you use the zoom options in the scope, the Signal Statistics measurements automatically adjust to the time range shown in the display. In the scope toolbar, click the **Zoom In** or **Zoom X** button to constrict the x-axis range of the display, and the statistics

shown reflect this time range. For example, you can zoom in on one pulse to make the **Signal Statistics** panel display information about only that particular pulse.

The Signal Statistics measurements are valid for any units of the input signal. The letter after the value associated with each measurement represents the appropriate International System of Units (SI) prefix, such as *m* for *milli-*. For example, if the input signal is measured in volts, an *m* next to a measurement value indicates that this value is in units of millivolts. The SI prefixes are shown in the following table:

Bilevel Measurements

Note The Bilevel Measurements panel requires a DSP System Toolbox or Simscape license.

Display information about signal transitions, overshoots, undershoots, and cycles. To open the Bilevel Measurements panel:

- From the menu, select **Tools > Measurements > Bilevel Measurements**.
- On the toolbar, click the Bilevel Measurements  button.

Settings

The **Settings** pane enables you to modify the properties used to calculate various measurements involving transitions, overshoots, undershoots, and cycles. You can modify the high-state level, low-state level, state-level tolerance, upper-reference level, mid-reference level, and lower-reference level.

Bilevel Measurements	
▶ Settings	
▼ Transitions	
High	9.900e-01
Low	-9.900e-01
Amplitude	1.980e+00
+ Edges	1459
+ Rise Time	258.516 μ s
+ Slew Rate	8.296 (/ms)
- Edges	1459
- Fall Time	257.387 μ s
- Slew Rate	-8.309 (/ms)
▼ Overshoots / Undershoots	
+ Preshoot	-0.243 %
+ Overshoot	-0.271 %
+ Undershoot	24.163 %
+ Settling Time	--
- Preshoot	-0.250 %
- Overshoot	24.424 %
- Undershoot	-0.276 %
- Settling Time	--
▼ Cycles	
Period	1.739 ms
Frequency	575.040 Hz
+ Pulses	1458
+ Width	867.458 μ s
+ Duty Cycle	49.647 %
- Pulses	1459
- Width	873.184 μ s
- Duty Cycle	50.290 %

- **Auto State Level** — When this check box is selected, the Bilevel measurements panel detects the high- and low- state levels of a bilevel waveform. When this check box is cleared, you can enter in values for the high- and low- state levels manually.
- **High** — Used to specify manually the value that denotes a positive polarity, or high-state level.

- **Low** — Used to specify manually the value that denotes a negative polarity, or low-state level.

- **State Level Tolerance** — Tolerance within which the initial and final levels of each transition must be within their respective state levels. This value is expressed as a percentage of the difference between the high- and low-state levels.
- **Upper Ref Level** — Used to compute the end of the rise-time measurement or the start of the fall time measurement. This value is expressed as a percentage of the difference between the high- and low-state levels.
- **Mid Ref Level** — Used to determine when a transition occurs. This value is expressed as a percentage of the difference between the high- and low- state levels. In the following figure, the mid-reference level is shown as the horizontal line, and its corresponding mid-reference level instant is shown as the vertical line.

- **Lower Ref Level** — Used to compute the end of the fall-time measurement or the start of the rise-time measurement. This value is expressed as a percentage of the difference between the high- and low-state levels.
- **Settle Seek** — The duration after the mid-reference level instant when each transition occurs used for computing a valid settling time. This value is equivalent to the input parameter, `D`, which you can set when you run the `settlingtime` function. The settling time is displayed in the **Overshoots/Undershoots** pane.

Transitions Pane

Display calculated measurements associated with the input signal changing between its two possible state level values, high and low.

A positive-going transition, or rising edge, in a bilevel waveform is a transition from the low-state level to the high-state level. A positive-going transition has a slope value greater than zero. The following figure shows a positive-going transition.

When there is a plus sign (+) next to a text label, the measurement is a rising edge, a transition from a low-state level to a high-state level.

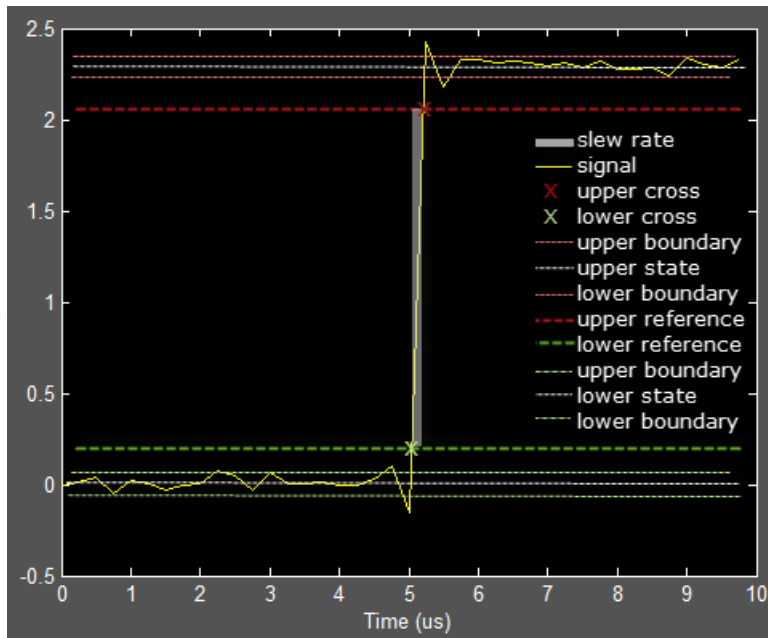

A negative-going transition, or falling edge, in a bilevel waveform is a transition from the high-state level to the low-state level. A negative-going transition has a slope value less than zero. The following figure shows a negative-going transition.

When there is a minus sign (-) next to a text label, the measurement is a falling edge, a transition from a high-state level to a low-state level.

The Transition measurements assume that the amplitude of the input signal is in units of volts. For the transition measurements to be valid, you must convert all input signals to volts.

- **High** — The high-amplitude state level of the input signal over the duration of the **Time Span** parameter. You can set **Time Span** in the **Main** pane of the Visuals—Time Domain Properties dialog box.
- **Low** — The low-amplitude state level of the input signal over the duration of the **Time Span** parameter. You can set **Time Span** in the **Main** pane of the Visuals—Time Domain Properties dialog box.
- **Amplitude** — Difference in amplitude between the high-state level and the low-state level.
- **+ Edges** — Total number of positive-polarity, or rising, edges counted within the displayed portion of the input signal.
- **+ Rise Time** — Average amount of time required for each rising edge to cross from the lower-reference level to the upper-reference level.
- **+ Slew Rate** — Average slope of each rising-edge transition line within the upper- and lower-percent reference levels in the displayed portion of the input signal. The region in which the slew rate is calculated appears in gray in the following figure.

- - **Edges** — Total number of negative-polarity or falling edges counted within the displayed portion of the input signal.
- - **Fall Time** — Average amount of time required for each falling edge to cross from the upper-reference level to the lower-reference level.
- - **Slew Rate** — Average slope of each falling edge transition line within the upper- and lower-percent reference levels in the displayed portion of the input signal.

Overshoots / Undershoots Pane

The **Overshoots/Undershoots** pane displays calculated measurements involving the distortion and damping of the input signal. Overshoot and undershoot refer to the amount that a signal respectively exceeds and falls below its final steady-state value. Preshoot refers to the amount before a transition that a signal varies from its initial steady-state value.

This figure shows preshoot, overshoot, and undershoot for a rising-edge transition.

The next figure shows preshoot, overshoot, and undershoot for a falling-edge transition.

- **+ Preshoot** — Average lowest aberration in the region immediately preceding each rising transition.
- **+ Overshoot** — Average highest aberration in the region immediately following each rising transition.
- **+ Undershoot** — Average lowest aberration in the region immediately following each rising transition.
- **+ Settling Time** — Average time required for each rising edge to enter and remain within the tolerance of the high-state level for the remainder of the settle-seek duration. The settling time is the time after the mid-reference level instant when the signal crosses into and remains in the tolerance region around the high-state level. This crossing is illustrated in the following figure.

You can modify the settle-peek duration parameter in the **Settings** pane.

- - **Preshoot** — Average highest aberration in the region immediately preceding each falling transition.
- - **Overshoot** — Average highest aberration in the region immediately following each falling transition.
- - **Undershoot** — Average lowest aberration in the region immediately following each falling transition.
- - **Settling Time** — Average time required for each falling edge to enter and remain within the tolerance of the low-state level for the remainder of the settle-peek duration. The settling time is the time after the mid-reference level instant when the signal crosses into and remains in the tolerance region around the low-state level. You can modify the settle-peek duration parameter in the **Settings** pane.

Cycles Pane

The **Cycles** pane displays calculated measurements pertaining to repetitions or trends in the displayed portion of the input signal.

Properties to set:

- **Period** — Average duration between adjacent edges of identical polarity within the displayed portion of the input signal. The Bilevel measurements panel calculates period as follows. It takes the difference between the mid-reference level instants of the initial transition of each positive-polarity pulse and the next positive-going transition. These mid-reference level instants appear as red dots in the following figure.

- **Frequency** — Reciprocal of the average period. Whereas period is typically measured in some metric form of seconds, or seconds per cycle, frequency is typically measured in hertz or cycles per second.
- **+ Pulses** — Number of positive-polarity pulses counted.
- **+ Width** — Average duration between rising and falling edges of each positive-polarity pulse within the displayed portion of the input signal.
- **+ Duty Cycle** — Average ratio of pulse width to pulse period for each positive-polarity pulse within the displayed portion of the input signal.
- **- Pulses** — Number of negative-polarity pulses counted.
- **- Width** — Average duration between rising and falling edges of each negative-polarity pulse within the displayed portion of the input signal.
- **- Duty Cycle** — Average ratio of pulse width to pulse period for each negative-polarity pulse within the displayed portion of the input signal.

When you use the zoom options in the Scope, the bilevel measurements automatically adjust to the time range shown in the display. In the Scope toolbar, click the **Zoom In** or **Zoom X** button to constrict the x-axis range of the display, and the statistics shown reflect this time range. For example, you can zoom in on one rising edge to make the **Bilevel Measurements** panel display information about only that particular rising edge. However, this feature does not apply to the **High** and **Low** measurements.

- “Scope Triggers Panel” on page 28-16

Peak Finder Measurements Panel

The **Peak Finder** panel displays the maxima, showing the x -axis values at which they occur. Peaks are defined as a local maximum where lower values are present on both sides of a peak. Endpoints are not considered peaks. This panel allows you to modify the settings for peak threshold, maximum number of peaks, and peak excursion.

- From the menu, select **Tools > Measurements > Peak Finder**.
- On the toolbar, click the Peak Finder  button.

The **Settings** pane enables you to modify the parameters used to calculate the peak values within the displayed portion of the input signal. For more information on the algorithms this pane uses, see the `findpeaks` function reference.

Properties to set:

- **Peak Threshold** — The level above which peaks are detected. This setting is equivalent to the `MINPEAKHEIGHT` parameter, which you can set when you run the `findpeaks` function.
- **Max Num of Peaks** — The maximum number of peaks to show. The value you enter must be a scalar integer from 1 through 99. This setting is equivalent to the `NPEAKS` parameter, which you can set when you run the `findpeaks` function.
- **Min Peaks Distance** — The minimum number of samples between adjacent peaks. This setting is equivalent to the `MINPEAKDISTANCE` parameter, which you can set when you run the `findpeaks` function.

- **Peak Excursion** — The minimum height difference between a peak and its neighboring samples. Peak excursion is illustrated alongside peak threshold in the following figure.

The peak threshold is a minimum value necessary for a sample value to be a peak. The peak excursion is the minimum difference between a peak sample and the samples to its left and right in the time domain. In the figure, the green vertical line illustrates the lesser of the two height differences between the labeled peak and its neighboring samples. This height difference must be greater than the **Peak Excursion** value for the labeled peak to be classified as a peak. Compare this setting to peak threshold, which is illustrated by the red horizontal line. The amplitude must be above this horizontal line for the labeled peak to be classified as a peak.

The peak excursion setting is equivalent to the `THRESHOLD` parameter, which you can set when you run the `findpeaks` function.

- **Label Format** — The coordinates to display next to the calculated peak values on the plot. To see peak values, you must first expand the **Peaks** pane and select the check boxes associated with individual peaks of interest. By default, both x-axis and y-axis values are displayed on the plot. Select which axes values you want to display next to each peak symbol on the display.

- X+Y — Display both x-axis and y-axis values.
- X — Display only x-axis values.
- Y — Display only y-axis values.

The **Peaks** pane displays the largest calculated peak values. It also shows the coordinates at which the peaks occur, using the parameters you define in the **Settings** pane. You set the **Max Num of Peaks** parameter to specify the number of peaks shown in the list.

The numerical values displayed in the **Value** column are equivalent to the `pks` output argument returned when you run the `findpeaks` function. The numerical values displayed in the second column are similar to the `locs` output argument returned when you run the `findpeaks` function.

The Peak Finder displays the peak values in the **Peaks** pane. By default, the **Peak Finder** panel displays the largest calculated peak values in the **Peaks** pane in decreasing order of peak height.

Use the check boxes to control which peak values are shown on the display. By default, all check boxes are cleared and the **Peak Finder** panel hides all the peak values. To show or hide all the peak values on the display, use the check box in the top-left corner of the **Peaks** pane.

The Peaks are valid for any units of the input signal. The letter after the value associated with each measurement indicates the abbreviation for the appropriate International System of Units (SI) prefix, such as *m* for *milli-*. For example, if the input signal is measured in volts, an *m* next to a measurement value indicates that this value is in units of millivolts.

Related Examples

- “Scope Triggers Panel” on page 28-16

Spectrum Analyzer Cursor Measurements Panel

The **Cursor Measurements** panel displays screen cursors. The panel provides two types of cursors for measuring signals. Waveform cursors are vertical cursors that track along the signal. Screen cursors are both horizontal and vertical cursors that you can place anywhere in the display.

Note If a data point in your signal has more than one value, the cursor measurement at that point is undefined and no cursor value is displayed.

In the Scope menu, select **Tools > Measurements > Cursor Measurements**.

Alternatively, in the Scope toolbar, click the Cursor Measurements  button.

The **Cursor Measurements** panel for the spectrum and dual view:

	Freq. (kHz)	Power (dBm)
1	29.125	-31.098
2	87.375	-32.501
Δ	58.250	1.402 dB
Channel Power:		27.000 dBm

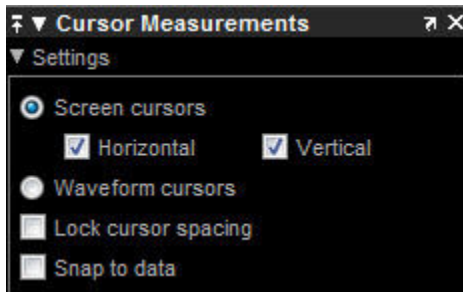

The **Cursor Measurements** panel for the spectrogram view. You must pause the spectrogram display before you can use cursors.

	Freq. (kHz)	Time (s)	Pwr. (dBm)
1	29.125	0.074	-35.383
2	87.375	0.223	-32.001
Δ	58.250	148.712 m	3.383

You can use the mouse or the left and right arrow keys to move vertical or waveform cursors and the up and down arrow keys for horizontal cursors.

In the **Settings** pane, you can modify the type of screen cursors used for calculating measurements. When more than one signal is displayed, you can assign cursors to each trace individually.

- **Screen Cursors** — Shows screen cursors (for spectrum and dual view only).
- **Horizontal** — Shows horizontal screen cursors (for spectrum and dual view only).
- **Vertical** — Shows vertical screen cursors (for spectrum and dual view only).
- **Waveform Cursors** — Shows cursors that attach to the input signals (for spectrum and dual view only).
- **Lock Cursor Spacing** — Locks the frequency difference between the two cursors.
- **Snap to Data** — Positions the cursors on signal data points.

The **Measurements** pane displays the frequency (Hz), time (s), and power (dBm) value measurements. Time is displayed only in spectrogram mode. **Channel Power** shows the total power between the cursors.

- **1** — Shows or enables you to modify the frequency, time (for spectrograms only), or both, at cursor number one.
- **2** — Shows or enables you to modify the frequency, time (for spectrograms only), or both, at cursor number two.
- **Δ** — Shows the absolute value of the difference in the frequency, time (for spectrograms only), or both, and power between cursor number one and cursor number two.
- **Channel Power** — Shows the total power in the channel defined by the cursors.

The letter after the value associated with a measurement indicates the abbreviation for the appropriate International System of Units (SI) prefix.

Spectrum Analyzer Channel Measurements Panel

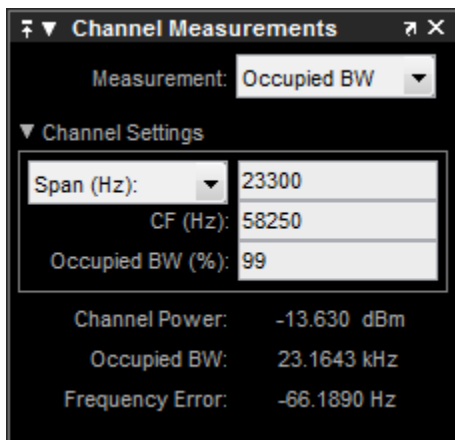

The **Channel Measurements** panel displays occupied bandwidth or adjacent channel power ratio (ACPR) measurements.

- From the menu, select **Tools > Measurements > Channel Measurements**.
- On the toolbar, click the Channel Measurements  button.

In addition to the measurements, the **Channel Measurements** panel has an expandable **Channel Settings** pane.

- **Measurement** — The type of measurement data to display. Available options are Occupied BW or ACPR. See “Algorithms” (DSP System Toolbox) for information on how Occupied BW is calculated. ACPR is the adjacent channel power ratio, which is the ratio of the main channel power to the adjacent channel power.

When you select Occupied BW as the **Measurement**, the following fields appear.

- **Channel Settings** — Modify the parameters for calculating the channel measurements.

Channel Settings for Occupied BW

- Select the frequency span of the channel, **Span (Hz)**, and specify the center frequency **CF (Hz)** of the channel. Alternatively, select the starting frequency,

FStart (Hz), and specify the starting frequency and ending frequency (**FStop (Hz)**) values of the channel.

- **CF (Hz)** — The center frequency of the channel.
- **Occupied BW (%)** — The percentage of the total integrated power of the spectrum centered on the selected channel frequency over which to compute the occupied bandwidth.
- **Channel Power** — The total power in the channel.
- **Occupied BW** — The bandwidth containing the specified **Occupied BW (%)** of the total power of the spectrum. This setting is available only if you select **Occupied BW** as the **Measurement** type.
- **Frequency Error** — The difference between the center of the occupied band and the center frequency (**CF**) of the channel. This setting is available only if you select **Occupied BW** as the **Measurement** type.

When you select ACPR as the **Measurement**, the following fields appear.

- **Channel Settings** — Enables you to modify the parameters for calculating the channel measurements.

Channel Settings for ACPR

- Select the frequency span of the channel, **Span (Hz)**, and specify the center frequency **CF (Hz)** of the channel. Alternatively, select the starting frequency, **FStart (Hz)**, and specify the starting frequency and ending frequency (**FStop (Hz)**) values of the channel.
- **CF (Hz)** — The center frequency of the channel.
- **Number of Pairs** — The number of pairs of adjacent channels.
- **Bandwidth (Hz)** — The bandwidth of the adjacent channels.
- **Filter** — The filter to use for both main and adjacent channels. Available filters are None, Gaussian, and RRC (root-raised cosine).
- **Channel Power** — The total power in the channel.
- **Offset (Hz)** — The center frequency of the adjacent channel with respect to the center frequency of the main channel. This setting is available only if you select ACPR as the **Measurement** type.
- **Lower (dBc)** — The power ratio of the lower sideband to the main channel. This setting is available only if you select ACPR as the **Measurement** type.
- **Upper (dBc)** — The power ratio of the upper sideband to the main channel. This setting is available only if you select ACPR as the **Measurement** type.

Spectrum Analyzer Distortion Measurements Panel

The **Distortion Measurements** panel displays harmonic distortion and intermodulation distortion measurements.

- From the menu, select **Tools > Measurements > Distortion Measurements**.
- On the toolbar, click the Distortion Measurements  button.

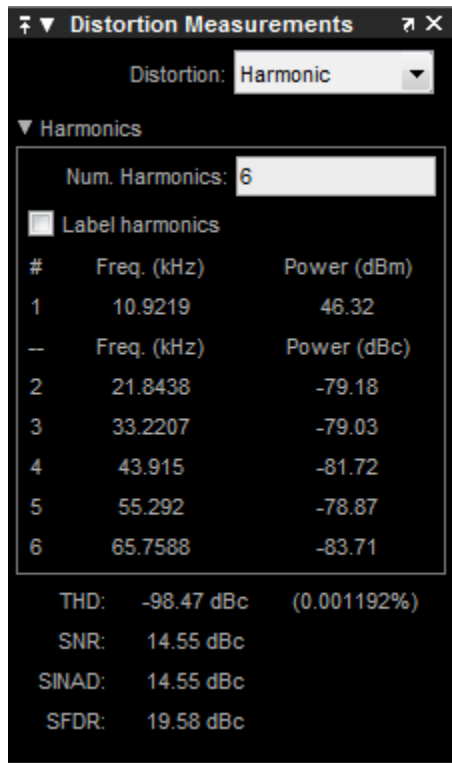

The **Distortion Measurements** panel has an expandable **Harmonics** pane, which shows measurement results for the specified number of harmonics.

Note For an accurate measurement, ensure that the fundamental signal (for harmonics) or primary tones (for intermodulation) is larger than any spurious or harmonic content. To do so, you may need to adjust the resolution bandwidth (RBW) of the spectrum analyzer. Make sure that the bandwidth is low enough to isolate the signal and harmonics from spurious and noise content. In general, you should set the RBW so that there is at least a 10dB separation between the peaks of the sinusoids and the noise floor. You may also need to select a different spectral window to obtain a valid measurement.

- **Distortion** — The type of distortion measurements to display. Available options are **Harmonic** or **Intermodulation**. Select **Harmonic** if your system input is a single sinusoid. Select **Intermodulation** if your system input is two equal amplitude sinusoids. Intermodulation can help you determine distortion when only a small portion of the available bandwidth will be used.

See “Distortion Measurements” (DSP System Toolbox) for information on how distortion measurements are calculated.

When you select **Harmonic** as the **Distortion**, the following fields appear.

The harmonic distortion measurement automatically locates the largest sinusoidal component (fundamental signal frequency). It then computes the harmonic frequencies and power in each harmonic in your signal. Any DC component is ignored. Any harmonics that are outside the spectrum analyzer's frequency span are not included in the measurements. Adjust your frequency span so that it includes all the desired harmonics.

Note To view the best harmonics, make sure that your fundamental frequency is set high enough to resolve the harmonics. However, this frequency should not be so high that aliasing occurs. For the best display of harmonic distortion, your plot should not show skirts, which indicate frequency leakage. Also, the noise floor should be visible.

For a better display, try a Kaiser window with a large sidelobe attenuation (e.g. between 100-300 db).

- **Num. Harmonics** — Number of harmonics to display, including the fundamental frequency. Valid values of **Num. Harmonics** are from 2 to 99. The default value is 6.
- **Label Harmonics** — Select **Label Harmonics** to add numerical labels to each harmonic in the spectrum display.
- **1** — The fundamental frequency, in hertz, and its power, in decibels of the measured power referenced to 1 milliwatt (dBm).
- **2, 3, ...** — The harmonics frequencies, in hertz, and their power in decibels relative to the carrier (dBc). If the harmonics are at the same level or exceed the fundamental frequency, reduce the input power.
- **THD** — The total harmonic distortion. This value represents the ratio of the power in the harmonics, D , to the power in the fundamental frequency, S . If the noise power is too high in relation to the harmonics, the THD value is not accurate. In this case, lower the resolution bandwidth or select a different spectral window.

$$THD = 10 \cdot \log_{10}(D/S)$$

- **SNR** — Signal-to-noise ratio (SNR). This value represents the ratio of power in the fundamental frequency, S , to the power of all nonharmonic content, N , including spurious signals, in decibels relative to the carrier (dBc).

$$SNR = 10 \cdot \log_{10}(S/N)$$

If you see — as the reported SNR, the total non-harmonic content of your signal is less than 30% of the total signal.

- **SINAD** — Signal-to-noise-and-distortion. This value represents the ratio of the power in the fundamental frequency, S to all other content (including noise, N , and harmonic distortion, D), in decibels relative to the carrier (dBc).

$$SINAD = 10 \cdot \log_{10} \left(\frac{S}{N + D} \right)$$

- **SFDR** — Spurious free dynamic range (SFDR). This value represents the ratio of the power in the fundamental frequency, S , to power of the largest spurious signal, R , regardless of where it falls in the frequency spectrum. The worst spurious signal may or may not be a harmonic of the original signal. SFDR represents the smallest value of a signal that can be distinguished from a large interfering signal. SFDR includes harmonics.

$$SNR = 10 \cdot \log_{10}(S/R)$$

When you select Intermodulation as the **Distortion**, the following fields appear.

The intermodulation distortion measurement automatically locates the fundamental, first-order frequencies (F1 and F2). It then computes the frequencies of the third-order intermodulation products ($2 \cdot F1 - F2$ and $2 \cdot F2 - F1$).

- **Label frequencies** — Select **Label frequencies** to add numerical labels to the first-order intermodulation product and third-order frequencies in the spectrum analyzer display.
- **F1** — Lower fundamental first-order frequency
- **F2** — Upper fundamental first-order frequency

- **2F1 - F2** — Lower intermodulation product from third-order harmonics
- **2F2 - F1** — Upper intermodulation product from third-order harmonics
- **TOI** — Third-order intercept point. If the noise power is too high in relation to the harmonics, the TOI value will not be accurate. In this case, you should lower the resolution bandwidth or select a different spectral window. If the TOI has the same amplitude as the input two-tone signal, reduce the power of that input signal.

Spectrum Analyzer Spectral Mask

The **Spectral Mask** panel enables you to add upper and lower masks, modify the mask, and monitor mask statistics. Use spectral masks to:

- Enhance visualizing spectrum limits.
- Compare spectrum values to specification values.

To open the Spectral mask panel, in the toolbar, select the spectral mask button, .

Set Up Spectral Masks

In the Spectrum Analyzer window:

- 1 In the Spectral Mask panel, select a **Masks** option.
- 2 In the **Upper limits** or **Lower limits** box, enter the mask limits as a constant scalar, an array, or a workspace variable name.
- 3 (Optional) Select additional properties:
 - **Reference level** — Set a reference level for the mask. Enter a specific value or select `Spectrum peak`.
 - **Channel** — Select a channel to use for the mask reference.
 - **Frequency offset** — Set a frequency offset for mask.

Check Spectral Masks

In the Spectrum Analyzer window, select the spectral mask button, . In the **Spectral Mask** panel, the **Statistics** section shows statistics about how often the masks fail, which channels fail the mask, and which masks are failing. To perform an action every time the mask fails, use the `MaskTestFailed` event. To trigger a function when the mask fails, create a listener to the `MaskTestFailed` event and define a callback function to trigger. For more details about using events, see “Events” (MATLAB).

Spectrum Analyzer CCDF Measurements Panel

The **CCDF Measurements** panel displays complimentary cumulative distribution function measurements. CCDF measurements in this scope show the probability of a signal's instantaneous power being a specified level above the signal's average power. These measurements are useful indicators of a signal's dynamic range.

To compute the CCDF measurements, each input sample is quantized to 0.01 dB increments. Using a histogram 100 dB wide (10,000 points at 0.01 dB increments), the largest peak encountered is placed in the last bin of the histogram. If a new peak is encountered, the histogram shifts to make room for that new peak.

To open this dialog box:

- From the menu, select **Tools > Measurements > CCDF Measurements**
- In the toolbar, click the CCDF Measurements  button.

- **Plot Gaussian reference** — Show the Gaussian white noise reference signal on the plot.
- **Probability (%)** — The percentage of the signal that contains the power level above the value listed in the **dB above average** column
- **dB above average** — The expected minimum power level at the associated **Probability (%)**.
- **Average Power** — The average power level of the signal since the start of simulation or from the last reset.

Max Power — The maximum power level of the signal since the start of simulation or from the last reset.
- **PAPR** — The ratio of the peak power to the average power of the signal. PAPR should be less than 100 dB to obtain accurate CCDF measurements. If PAPR is above 100 dB, only the highest 100 dB power levels are plotted in the display and shown in the distribution table.
- **Sample Count** — The total number of samples used to compute the CCDF.
- **Reset** — Clear all current CCDF measurements and restart.

Common Scope Block Tasks

In this section...

- “Connect Multiple Signals to a Scope” on page 28-63
- “Save Simulation Data Using a Scope Block” on page 28-66
- “Pause Display While Running” on page 28-68
- “Copy Scope Image” on page 28-69
- “Plot an Array of Signals” on page 28-70
- “Scopes in Referenced Models” on page 28-71
- “Scopes Within an Enabled Subsystem” on page 28-74
- “Show Signal Units on a Scope Display” on page 28-75
- “Select Number of Displays and Layout” on page 28-79
- “Dock and Undock Scope Window to MATLAB Desktop” on page 28-79

To visualize your simulation results over time, use a Scope block or Time Scope block

Connect Multiple Signals to a Scope

To connect multiple signals to a scope, drag additional signals to the scope block. An additional port is created automatically.

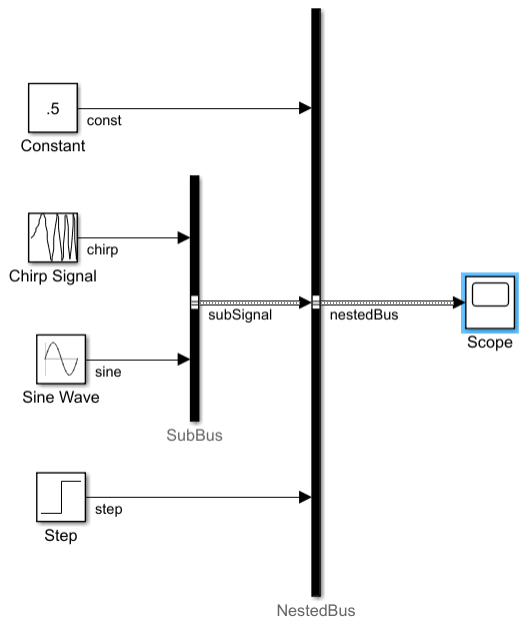

To specify the number of input ports:

- 1 Open a scope window.
- 2 On the toolbar, select **File > Number of Input Ports > More**.
- 3 Enter the number of input ports, up to 96.

Signals from Nonvirtual Buses and Arrays of Buses

You can connect signals from nonvirtual buses and arrays of buses to a Scope block. To display the bus signals, use normal or accelerator simulation mode. The Scope block displays each bus element signal, in the order the elements appear in the bus, from the top to the bottom. Nested bus elements are flattened. For example, in this model the `nestedBus` signal has the `const`, `subSignal`, and `step` signals as elements. The `subSignal` sub-bus has the `chirp` and `sine` signals as its bus elements. In the Scope block, the two elements of the `subSignal` bus display between the `const` and `step` signals.

Save Simulation Data Using a Scope Block

This procedure uses the model `vdp` to demonstrate saving signals to the MATLAB Workspace.

- 1 Add a Scope block to your model. See “Add Scope and Time Scope Blocks to Model” on page 28-97.
- 2 Connect signals to scope input ports. See “Connect Multiple Signals to a Scope” on page 28-63. For example, connect the signals `x1` and `x2` to a scope.
- 3 Open the Scope window. From the toolbar, click the Parameters button .

- 4 Click the **Logging** tab, and then select the **Log data to workspace** check box. In the **Variable name** box, enter a variable name for saving the data or use the default name ScopeData. From the **Save format** list, select Dataset. Click **OK**.

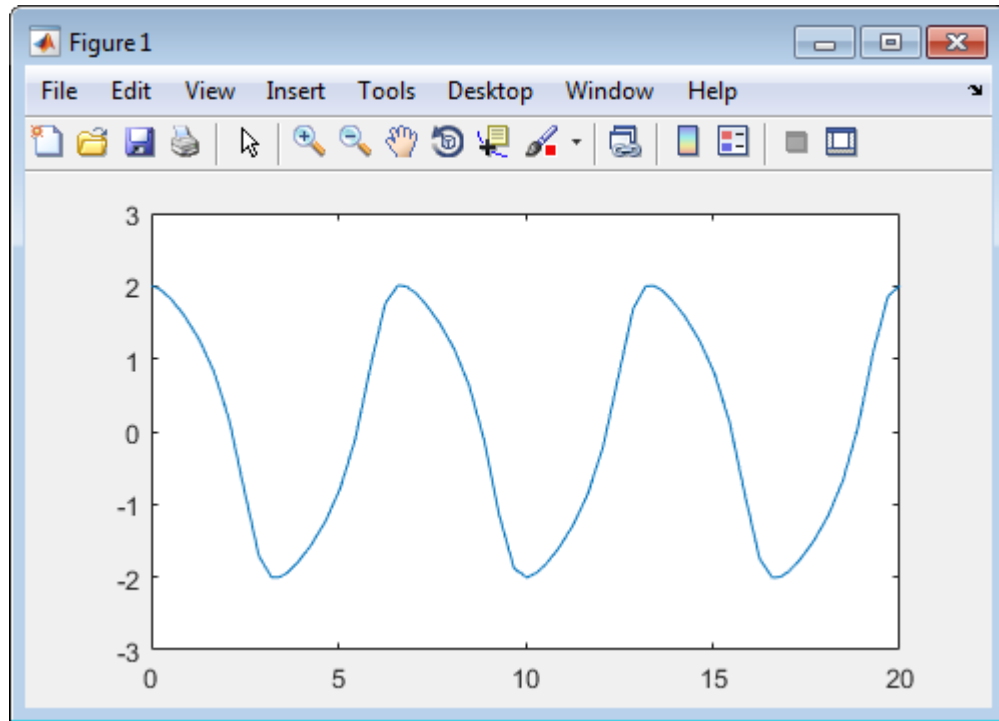

Alternatively, you can set **Save format** to a format other than Dataset (for example, Array).

When saving data from a Scope block, you do not have to select the **Log signal data** property for a signal or the **Signal logging** parameter on the **Model Configuration Parameters > Data Import/Export** pane.

Note To log signals from nonvirtual buses or arrays of buses attached to a Scope block, set the **Save format** parameter to Dataset.

- 5 Run a simulation. Simulink saves data to the MATLAB Workspace in a Dataset object with two elements, one element for each signal.
- 6 In the Command Window, enter these commands to view the logged data from ScopeData, where x1 is the name of a signal:

```
x1_data = ScopeData.getElement('x1').Values.Data
x1_time = ScopeData.getElement('x1').Values.Time
plot(x1_time,x1_data)
```

For information about the `Dataset` object, see `Simulink.SimulationData.Dataset`.

Pause Display While Running

Use the Simulink Snapshot to pause the scope display while the simulation keeps running in the background.

- 1 Open a scope window and start the simulation.
- 2 Select **Simulation > Simulink Snapshot**.

The scope window status in the bottom left is **Frozen**, but the simulation continues to run in the background.

- 3 Interact with the paused display. For example, use measurements, copy the scope image, or zoom in or out.
- 4 To unfreeze the display, select **Simulation > Simulink Snapshot** again.

Copy Scope Image

This example uses the model vdp to demonstrate how to copy and paste a scope image.

- 1 Add a scope block to your model. See “Add Scope and Time Scope Blocks to Model” on page 28-97.
- 2 Connect signals to scope ports. See “Connect Multiple Signals to a Scope” on page 28-63. For example, in the vdp model, connect the signals x1 and x2 to a scope.
- 3 Open the scope window and run the simulation.

- 4 Select **File > Copy to Clipboard**.
- 5 Paste the image into a document.

The van der Pol Equation results from my model:

By default, **Copy to Clipboard** saves a printer-friendly version of the scope with a white background and visible lines. If you want to paste the exact scope plot displayed, select **View > Style**, then select the **Preserve colors for copy to clipboard** check box.

Plot an Array of Signals

This example takes an array of four sine-wave signals and plots them on a scope display.

- 1 Connect a Sine Wave block to a scope block.
- 2 Open the Scope Configuration Properties dialog box. On the **Display** pane, select the **Legends** check box.
- 3 Set the **Amplitude** parameter for the Sine Wave block to [10 20;30 40].
- 4 Set the **Signal name** property for the signal to SignalArray.

- 5 Simulate the model.

The Scope window displays the four signals in the matrix order (1,1), (2,1), (1,2), (2,2).

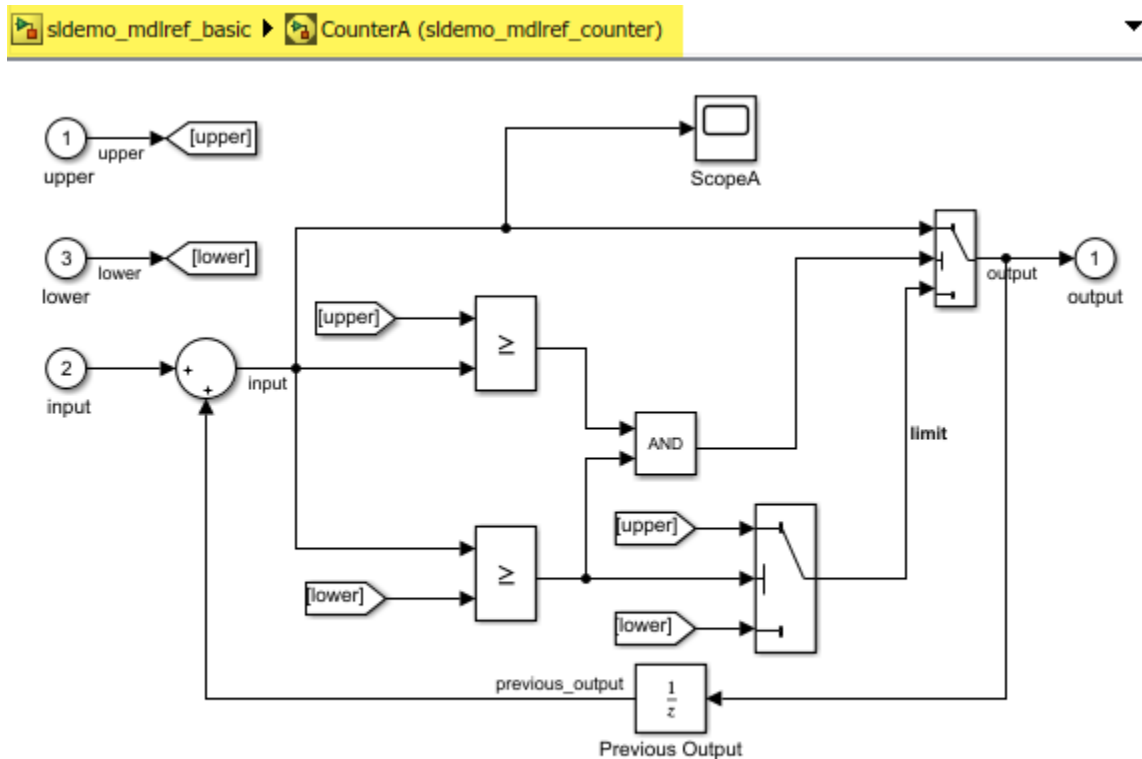

Scopes in Referenced Models

This example shows the behavior of scopes in referenced models. When you use a scope in a referenced model, you see different output in the scope depending on where you started the simulation: from the top model or the scope in the referenced model.

Note Scope windows display simulation results for the most recently opened top model. Playback controls in scope blocks and viewers simulate the model containing that block or viewer.

This example uses the `sldemo_mdref_counter` model both as a top model and as a referenced model from the `sldemo_mdref_basic` model.

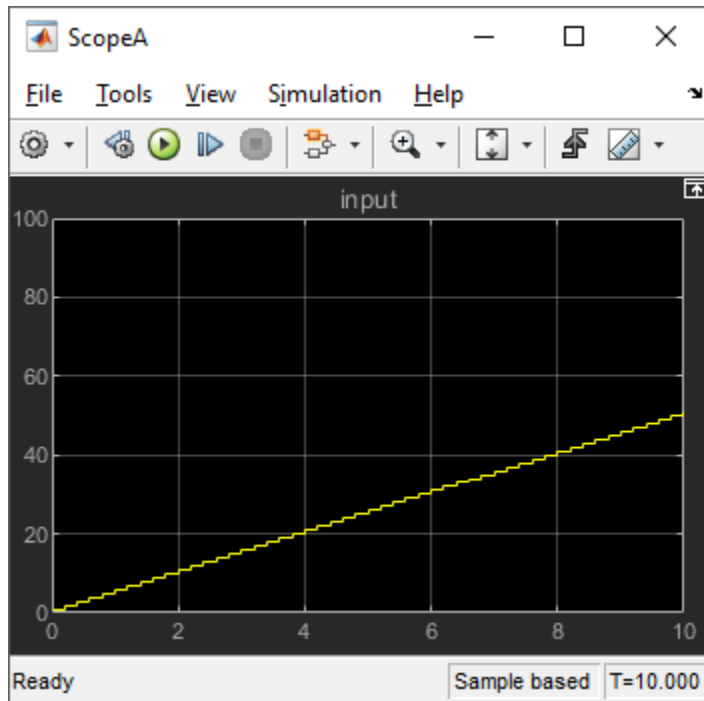

Open the `sldemo_mdref_basic` model and double-click the CounterA block. The `sldemo_mdref_counter` model opens as a reference model, as evidence by the breadcrumb above the canvas.

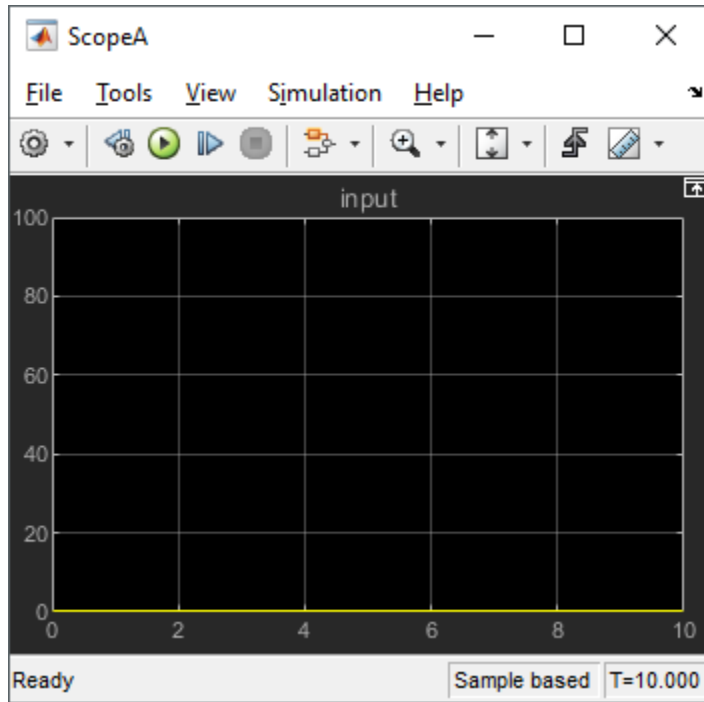

Copyright 1990-2014 The MathWorks, Inc.

Run the simulation using the main run button, then open up the ScopeA scope. The scope visualizes the data from the entire model.

If you rerun the simulation using the run button in the scope, the scope only visualizes data as if the referenced model is opened in isolation. Playback controls in scope blocks and viewers simulate the model containing that block or viewer. In this case, the referenced model input, without the top model, is zero the entire time.

Note If you click run from the scope, the model does not show that the model is running in the background. For the simulation status, look at the status bar in the scope.

Scopes Within an Enabled Subsystem

When placed within an Enabled Subsystem block, scopes behave differently depending on the simulation mode:

- Normal mode — A scope plots data when the subsystem is enabled. The display plot shows gaps when the subsystem is disabled.

- External, Accelerator, and Rapid modes — A scope plots data when the subsystem is enabled. The display connects the gaps with straight lines.

Show Signal Units on a Scope Display

You can specify signal units at a model component boundary (Subsystem and Model blocks) using Inport and Outport blocks. See “Unit Specification in Simulink Models” on page 9-2 . You can then connect a Scope block to an Outport block or a signal originating from an Outport block. In this example, the **Unit** property for the Out1 block was set to m/s.

Show Units on a Scope Display

- 1 From the Scope window toolbar, select the Configuration Properties button .
- 2 In the Configuration Properties: Scope dialog box, select the **Display** tab.
- 3 In the **Y-label** box, enter a title for the y-axis followed by (%<SignalUnits>). For example, enter
Velocity (%<SignalUnits>)
- 4 Click **OK** or **Apply**.

Signal units display in the y-axis label as meters per second (m/s) and in the Cursor Measurements panel as millimeters per second (mm/s).

You can also select **Display > Signals & Ports > Ports Units**. You do not have to enter (%<SignalUnits>) in the **Y-Label** property.

Show Units on a Scope Display Programmatically

- 1 Get the scope properties. In the Command Window, enter

```
load_system('my_model')
s = get_param('my_model/Scope', 'ScopeConfiguration');
```

- 2 Add a y-axis label to the first display.

```
s.ActiveDisplay = 1
s.YLabel = 'Velocity (%<SignalUnits>);'
```

You can also set the model parameter ShowPortUnits to 'on'. All scopes in your model, with and without (%<SignalUnits>) in the **Y-Label** property, show units on the displays.

```
load_system('my_model')
get_param('my_model', 'ShowPortUnits')
```

```
ans =
off

set_param('my_model', 'ShowPortUnits','on')

ans =
on
```

Determine Units from a Logged Data Object

When saving simulation data from a scope with the Dataset format, you can find unit information in the DataInfo field of the timeseries object.

Note Scope support for signal units is only for the Dataset logging format and not for the legacy logging formats Array, Structure, and Structure With Time.

- 1 From the Scope window toolbar, select the Configuration Properties button .
- 2 In the Configuration Properties: Scope dialog box, select the **Logging** tab.
- 3 Select the **Log data to workspace** check box. In the text box, enter a variable name for saving simulation data. For example, enter ScopeData.
- 4 From the Scope window toolbar, select the run button .
- 5 In the Command Window, enter

```
ScopeData.getElement(1).Values.DataInfo

Package: tldata
Common Properties:
    Units: m/s (Simulink.SimulationData.Unit)
    Interpolation: linear (tldata.interpolation)
```

Connect Signals with Different Units to a Scope

When there are multiple ports on a scope, Simulink ensures that each port receives data with only one unit. If you try to combine signals with different units (for example by using a Bus Creator block), Simulink returns an error.

Scopes show units depending on the number of ports and displays:

- **Number of ports equal to the number of displays** — One port is assigned to one display with units for the port signal shown on the y-axis label.

- **Greater than the number of displays** — One port is assigned to one display, with the last display assigned the remaining signals. Different units are shown on the last y-axis label as a comma-separated list.

Select Number of Displays and Layout

- 1 From a Scope window, select the Configuration Properties button .
- 2 In the Configuration Properties dialog box, select the **Main** tab, and then select the **Layout** button.
- 3 Select the number of displays and the layout you want.

You can select more than four displays in a row or column. Click within the layout, and then drag your mouse pointer to expand the layout to a maximum of 16 rows by 16 columns.

- 4 Click to apply the selected layout to the Scope window.

Dock and Undock Scope Window to MATLAB Desktop

- 1 In the right corner of a Scope window, click the Dock Scope button.

The Scope window is placed above the Command Window in the MATLAB desktop.

- 2 Click the Show Scope Actions button, and then click **Undock Scope**.

Floating Scope and Scope Viewer Tasks

In this section...

“Add Floating Scope Block to Model” on page 28-81

“Add Scope Viewer with Signal & Scope Manager” on page 28-81

“Connect Signals to Floating Scope Block or Scope Viewer” on page 28-82

“Save Simulation Data Using Floating Scope Block” on page 28-83

“Run Simulation from Floating Scope Window” on page 28-85

“Delete Scope Viewer” on page 28-85

“Quickly Switch Visualization of Different Signals on a Floating Scope” on page 28-86

Add Floating Scope Block to Model

To add a Floating Scope block from the Simulink block library:

- 1 From the Simulink Editor menu, click the Library Browser button .
- 2 From the Simulink Sinks library, drag a copy of the Floating Scope block to the Simulink Editor.

To add a Floating Scope block by searching from the model diagram:

- 1 In the Simulink Editor, click the model diagram, and then start typing `floating scope`.
- 2 From the list, select `Floating Scope Simulink/Sinks`.

Add Scope Viewer with Signal & Scope Manager

- 1 From the Simulink Editor menu, select **Diagram > Signals & Ports > Signal & Scope Manager**.
- 2 In the Signal & Scope Manager, in the **Types** pane and under the **Viewers** node, expand a product node to show the available viewers.
- 3 Select a **Scope**, and then click **Attach to model**. The viewer is added to a table on the **Viewers** tab in the **Generators/Viewers in model** pane.

Connect Signals to Floating Scope Block or Scope Viewer

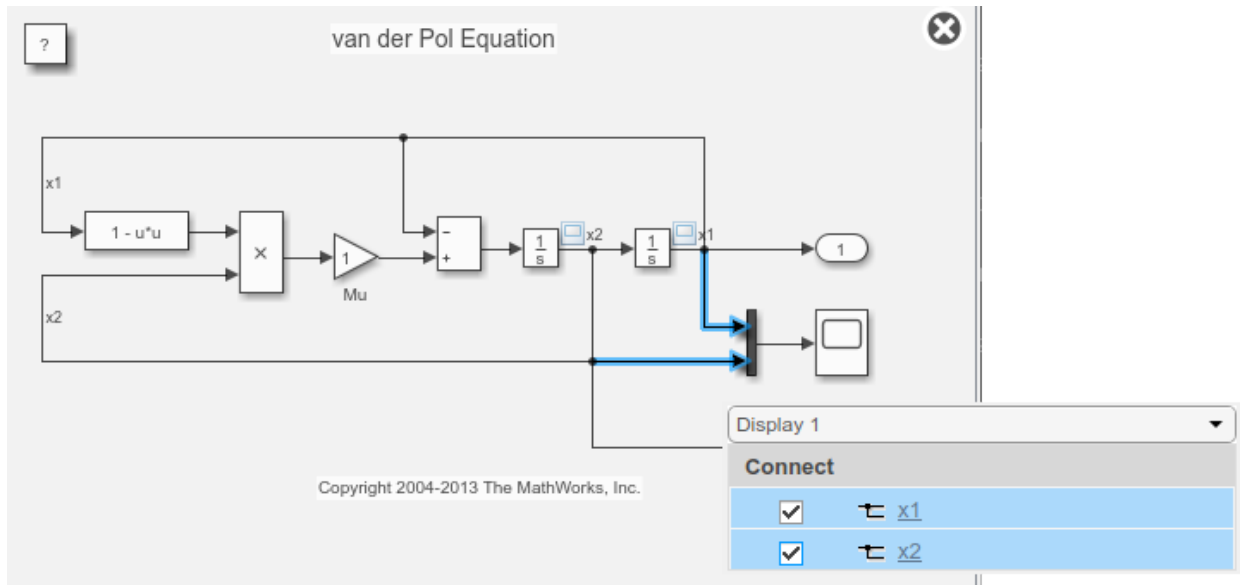

Connect signals to a Floating Scope block or Scope viewer.

- 1 Open the scope by double-clicking a Floating Scope block or Scope viewer icon .
- 2 In the scope window toolbar, click the signal selection button . You may need to select the lock dropdown to see the button.

The Simulink canvas grays, indicating you can interactively select signals to connect to the scope.

- 3 Select the signals you want to connect to the scope. For multiple signals, click and drag multiple signals.
- 4 In the **Connect** pop-up, select the check box next to the signals you want to connect.

- 5 For scopes with multiple displays, select a display from the drop-down and connect the signals.
- 6 Click the **X** in the upper-right of the Simulink canvas and then run a simulation.

Save Simulation Data Using Floating Scope Block

This procedure uses the model vdp to demonstrate saving signals to the MATLAB Workspace.

- 1 Add a Floating Scope or Scope Viewer to your model. See “Add Floating Scope Block to Model” on page 28-81 or “Add Scope Viewer with Signal & Scope Manager” on page 28-81.
- 2 Connect signals to the scope, see “Connect Signals to Floating Scope Block or Scope Viewer” on page 28-82. For example, select the signals x1 and x2.
- 3 Open a Floating Scope or Scope Viewer window. From the toolbar, click the Parameters button .

- 4 Click the **Logging** tab, and then select the **Log/Unlog Viewed Signals to Workspace** button.

This selection also sets the **Log signal data** parameter check box for the connected signals. The Simulink Editor places logging symbols  on the signals.

- 5 Open the **Configuration Parameters** dialog box by selecting **Simulation > Model Configuration Parameters**. In the Configuration Parameters, select **Data Import/Export**.
- 6 Select the **Signal logging** check box. Use the default Dataset object name `logsout` or enter your own name. Click **OK**.
- 7 Run a simulation. Simulink saves data to the MATLAB Workspace in a Dataset object with two elements, one element for each signal.
- 8 In the MATLAB Command Window, enter these commands to view the logged data from `logsout`, where `x1` is the name of a signal:

```
x1_data = logsout.get('x1').Values.Data  
x1_time = logsout.get('x1').Values.Time  
plot(x1_time,x1_data)
```

Run Simulation from Floating Scope Window

- 1 From a Simulink model, double-click a Floating Scope block.
- 2 From the toolbar, click the **Run** button .

For information on using toolbar buttons to control a simulation, see “Step Through a Simulation” on page 2-15.

Delete Scope Viewer

- 1 Right-click any signal line with a viewer attached or click the viewer symbol  attached to a signal line.
- 2 Select **Delete Viewer**, and then select a viewer name.

Quickly Switch Visualization of Different Signals on a Floating Scope

- 1 Open a Floating Scope window.
- 2 On the toolbar, click the Lock button  so that the icon is unlocked .
- 3 On the model, click a signal line to select and highlight the signal line. To select multiple signals, hold down the **Shift** key while selecting signals.

After clicking on the canvas, the selected display clears any previous signal connections.

- 4 Run a simulation. As long as the unlock  icon is showing, you can click between signals to switch which signal appears in the Floating Scope.

Signal Generator Tasks

In this section...

“Attach Signal Generator” on page 28-87

“Attach and Remove Signal Generator” on page 28-87

Attach Signal Generator

Using the Context Menu

- 1 In the Simulink Editor, right-click the input to a block.
- 2 From the context menu, select **Create & Connect Generator**, the product, and then the generator you want as input to the block.

The name of the generator you choose appears in a box connected to the block input.

- 3 Right-click the generator name and select **Generator Parameters**. In the Generator Parameters dialog box, enter values for parameters that are specific to this generator.

Using the Signal and Scope Manager

- 1 Right-click the input to a block and select **Signal & Scope Manager**.
- 2 In the **Types** pane and under the Generators node, expand a product node to show the available generators.
- 3 Select a generator and click **Attach to model**.

The generator is added to a table in the **Generators** tab in the **Generators/Viewers in model** section. The table lists the generators in your model.

Attach and Remove Signal Generator

- 1 Right-click a generator icon on a signal line.
- 2 From the context menu, select **Disconnect Generator**.

More About

- “Signal and Scope Manager” on page 28-89

Signal and Scope Manager

About the Signal & Scope Manager

Using the Signal & Scope Manager you can manage viewers and generators from a central point.

Note The Signal and Scope Manager requires that you have Java enabled when you start MATLAB.

Viewer and Generator

Viewers and generators are not blocks. Blocks are dragged from the Library browser and managed with block dialog boxes. Viewers and generators are added and managed through the Signal & Scope Manager.

Symbols identify a viewer attached to a signal line and signal names identify generators. Manage viewers and generators using the Signal & Scope Manager.

Change Scope Viewer Parameters

- 1 Open the Signal & Scope Manager. Right-click the input to a block and select **Signal & Scope Manager**.
- 2 In the list of **Generators/Viewers in model**, double-click the generator or viewer you want to change.
 - For a generator, the Generator Parameters dialog box opens.

- For a viewer, a Viewer opens. From the viewer toolbar, select the parameters button . The Viewer parameters dialog box opens.
- 3 Review and change parameters.

Connect Viewers and Generators

Connect signals to new viewer or generator using the Signal & Scope Manager.

- 1 Open the Signal & Scope Manager window. Right-click a signal line, and then select **Signal & Scope Manager**.
- 2 From the **Types** pane, select a viewer or generator.
- 3 Click **Attach to model**.
- 4 Use the “Signal Selector” on page 28-93 to connect the viewer or generator to a signal.

View Test Point Data

Use a Scope viewer available from the Signal and Scope Manager to view any signal that is defined as a test point in a referenced model. A test point is a signal that you can always see when using a Scope viewer in a model.

Note With some viewers (for example, XY Graph, To Video Display, Matrix Viewer), you cannot use the Signal Selector to select signals with test points in referenced models.

For more information, see “Test Points” on page 67-62.

Customize Signal & Scope Manager

You can add custom signal viewers or generators so that they appear in the Signal & Scope Manager. The following procedure assumes that you have a custom viewer named `newviewer` that you want to add.

- 1 Open a new Simulink library by selecting **File > New > Library**.
- 2 Save the library as `newlib`.
- 3 In the MATLAB Command Window, set the library type to a viewer library:

```
set_param('newlib', 'LibraryType', 'SSMgrViewerLibrary')
```

To set the library type for generators, use the type 'SSMgrGenLibrary'. For example:

```
set_param('newlib', 'LibraryType', 'SSMgrGenLibrary')
```

- 4 Set the display name of the library:

```
set_param('newlib', 'SSMgrDisplayString', 'My Custom Library')
```

- 5 Add the viewer or generator to the library.

Note If the viewer is a compound viewer, such as a subsystem with multiple blocks, make the top-level subsystem an atomic one.

- 6 Set the `iotype` of the viewer. For example:

```
set_param('newlib/newviewer', 'iotype', 'viewer')
```

- 7 Save the library `newlib`.

- 8 Using the MATLAB editor, create a file named `sl_customization.m`. In this file, enter a directive to incorporate the new library as a viewer library.

For example, to save `newlib` as a viewer library, add the following lines:

```
function sl_customization(cm)
cm.addSigScopeMgrViewerLibrary('newlib')
%end function
```

To add a library as a generator library, add a line like the following:

```
cm.addSigScopeMgrGeneratorLibrary('newlib')
```

- 9 Add a corresponding `cm.addSigScope` line for each viewer or generator library you want to add.
- 10 Save the `sl_customization.m` file on your MATLAB path. Edit this file to add new viewer or generator libraries.
- 11 To see the new custom libraries, restart MATLAB and start the Signal & Scope Manager.

Signal Selector

In this section...

“About the Signal Selector” on page 28-93

“Select Signals” on page 28-94

“Model Hierarchy” on page 28-94

“Inputs/Signals List” on page 28-95

Note To connect signals interactively to Floating Scopes and Scope Viewers, see “Connect Signals to Floating Scope Block or Scope Viewer” on page 28-82.

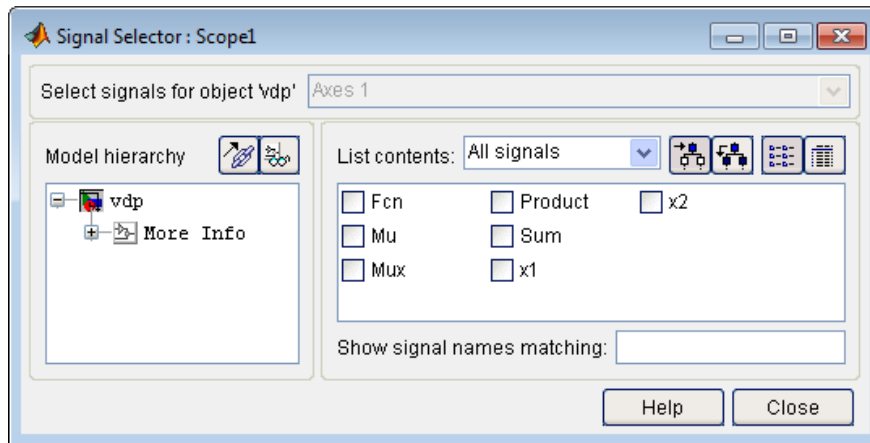

About the Signal Selector

The signal selector adds signals to a Scope Viewer. You can also add signals interactively from the model, see “Connect Signals to Floating Scope Block or Scope Viewer” on page 28-82.

To open the Signal Selector,

- 1 From the Simulink menu, select **Diagram > Signal & Ports > Signal & Scope Manager**.
- 2 Select the viewer or generator.
- 3 On the right side of the Signal & Scope Manager, click the Signal Selector button .

The Signal Selector that appears when you click the **Edit signal selection** button applies only to the currently selected generator or viewer. If you want to connect blocks to another generator or viewer object, select the object in the Signal & Scope Manager and then open another instance of the Signal Selector.

Select Signals

This list box allows you to select the owner output port (in the case of signal generators) or display axis (in the case of viewers) to which you want to connect blocks in your model.

The list box is enabled only if the signal generator has multiple outputs or the viewer has multiple axes.

Model Hierarchy

This tree-structured list lets you select any subsystem in your model.

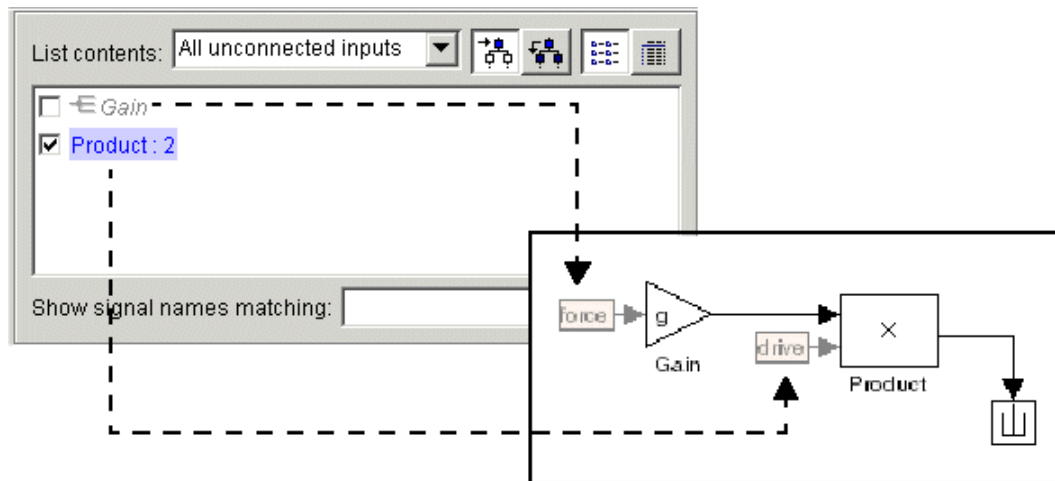

Selecting a subsystem causes the adjacent port list to display the ports available for connection in the selected subsystem. To display subsystems included as library links in

your model, click the **Follow links** button at the top of the **Model hierarchy** control. To display subsystems contained by masked subsystems, click the **Look under masks** button at the top of the panel.

Inputs/Signals List

The contents of this panel displays input ports available for connection to the Signal Selector owner if the owner is a signal generator or signals available for connection to the owner if the owner is a viewer.

If the Signal Selector owner is a signal generator, the inputs/signals list by default lists each input port in the system selected in the model hierarchy tree that is either unconnected or connected to a signal generator.

The label for each entry indicates the name of the block of which the port is an input. If the block has more than one input, the label indicates the number of the displayed port. A greyed label indicates that the port is connected to a signal generator other than the Signal Selector owner. Selecting the check box next to a port entry in the list connects the Signal Selector owner to the port, replacing, if necessary, the signal generator previously connected to the port.

To display more information on each signal, click the **Detailed view** button at the top of the pane. The detailed view shows the path and data type of each signal and whether the signal is a test point. The controls at the top and bottom of the panel let you restrict the amount of information shown in the ports list.

- To show named signals only, select **Named signals only** from the **List contents** control at the top of the pane.
- To show only signals selected in the Signal Selector, select **Selected signals only** from the **List contents** control.
- To show test point signals only, select **Testpointed/Logged signals only** from the **List contents** control.
- To show only signals whose signals match a specified string of characters, enter the characters in the **Show signals matching** control at the bottom of the **Signals** pane and press the **Enter** key.
- To show the selected types of signals for all subsystems below the currently selected subsystem in the model hierarchy, click the **Current and Below** button at the top of the **Signals** pane.

To select or clear a signal in the **Signals** pane, click its entry or use the arrow keys to move the selection highlight to the signal entry and press the **Enter** key. You can also move the selection highlight to a signal entry by typing the first few characters of its name (enough to identify it uniquely).

Note You can continue to select and clear signals on the block diagram with the Signal Selector open. For example, shift-clicking a line in the block diagram adds the corresponding signal to the set of signals that you previously selected with the Signal Selector.

Control Scope Blocks Programmatically

In this section...

“Use Simulink Configuration Object” on page 28-97

“Scope Configuration Properties” on page 28-99

Use Simulink Configuration Object

Use a Scope Configuration object for programmatic access to scope parameters.

- Modify the title, axis labels, and axis limits
- Turn on or off the legend or grid
- Control the number of inputs
- Change the number of displays and which display is active

In this example, the variable `myConfiguration` stores the mask object obtained using `get_param`. The example also shows how to change the value of a Scope parameter.

Create a New Model

```
mdl='myModel';
new_system(mdl);
```

Add Scope and Time Scope Blocks to Model

```
add_block('simulink/Sinks/Scope', [mdl '/myScope']);
add_block('dpsnks4/Time Scope', [mdl '/myTimeScope']);
```

Get a Scope Configuration Object

Many of the scope configuration properties correspond to Scope block parameters.

```
myConfiguration = get_param([mdl '/myScope'],'ScopeConfiguration')
```

```
myConfiguration =
```

```
Scope Configuration with properties:
```

```
    Name: 'myScope'
    Position: [680 390 560 420]
```

```
        Visible: 0
    OpenAtSimulationStart: 0
        DisplayFullPath: 0
    PreserveColorsForCopyToClipboard: 0
        NumInputPorts: '1'
        LayoutDimensions: [1 1]
        SampleTime: '-1'
    FrameBasedProcessing: 0
        MaximizeAxes: 'Off'
        MinimizeControls: 0
        AxesScaling: 'Manual'
    AxesScalingNumUpdates: '10'
        TimeSpan: 'Auto'
    TimeSpanOvverrunAction: 'Wrap'
        TimeUnits: 'none'
    TimeDisplayOffset: '0'
        TimeAxisLabels: 'Bottom'
    ShowTimeAxisLabel: 0
        ActiveDisplay: 1
            Title: '%<SignalLabel>'
        ShowLegend: 0
        ShowGrid: 1
    PlotAsMagnitudePhase: 0
        YLimits: [-10 10]
        YLabel: ''
    DataLogging: 0
    DataLoggingVariableName: 'ScopeData'
    DataLoggingLimitDataPoints: 0
    DataLoggingMaxPoints: '5000'
    DataLoggingDecimateData: 0
    DataLoggingDecimation: '2'
    DataLoggingSaveFormat: 'Dataset'
```

Set a Property

```
myConfiguration.DataLoggingMaxPoints = '10000';
```

Find Scope and Time Scope Blocks

```
find_system mdl, 'LookUnderMasks', 'on', 'IncludeCommented', 'on', ...
'AllBlocks', 'on', 'BlockType', 'Scope')
```

```
ans =  
    'myModel/myScope'  
    'myModel/myTimeScope'
```

Find Only Simulink Scope Blocks

```
find_system mdl, 'LookUnderMasks', 'on', 'IncludeCommented', 'on', ...  
    'AllBlocks', 'on', 'BlockType', 'Scope', 'DefaultConfigurationName', ...  
    'Simulink.scopes.TimeScopeBlockCfg')
```

```
ans =  
    'myModel/myScope'
```

Find Only DSP System Toolbox Time Scope Blocks

```
find_system mdl, 'LookUnderMasks', 'on', 'IncludeCommented', 'on', ...  
    'AllBlocks', 'on', 'BlockType', 'Scope', 'DefaultConfigurationName', ...  
    'spbscopes.TimeScopeBlockCfg')
```

```
ans =  
    'myModel/myTimeScope'
```

Plot Circle with XY Graph

This example plots a circle in Simulink using an XY Graph block.

The `ex_xygraph_block_circle` model computes a circle of radius 4, centered at the origin of x-y plane.

The plotted functions are:

$$x = 4 \cos(\theta)$$

$$y = 4 \sin(\theta)$$

When you simulate the model, a figure window appears showing the plotted circle.

ans =

```

Simulink.SimulationOutput:
      tout: [101x1 double]

SimulationMetadata: [1x1 Simulink.SimulationMetadata]
  ErrorMessage: [0x0 char]

```

- “Inspect and Analyze Models in Simulink” on page 29-137

View Data with the Simulation Data Inspector

The Simulation Data Inspector can visualize many kinds of data that you generate throughout your design process, including complex, event, and frame data. You can log your data to the Simulation Data Inspector from a Simulink model, or you can import data from the base workspace or a MAT-, CSV-, or MDF-file. Visualizing your data with the Simulation Data Inspector supports design, debugging, and verification workflows. You can also create custom visualizations of data during simulations using data access. For more information see, “Access Data in a MATLAB Function During Simulation” on page 29-35.

View Logged Data

By default, Simulink sends data for logged signals to the workspace and to the Simulation Data Inspector. To log data only to the Simulation Data Inspector, clear the **Signal Logging** check box in the **Data Import/Export** pane of the **Model Configuration Parameters**.

Open the model `slexAircraftExample` by typing its name at the MATLAB command line.

To log the `q`, `rad/sec` and `alpha`, `rad` signals, select the signals. Right-click the selected signals, and select **Log Selected Signals** from the context menu. The logging

badge  marks the signals in the model.

Alternatively, you can select signals to log using one of the several methods described in [Mark a Signal for Logging](#) on page 64-73.

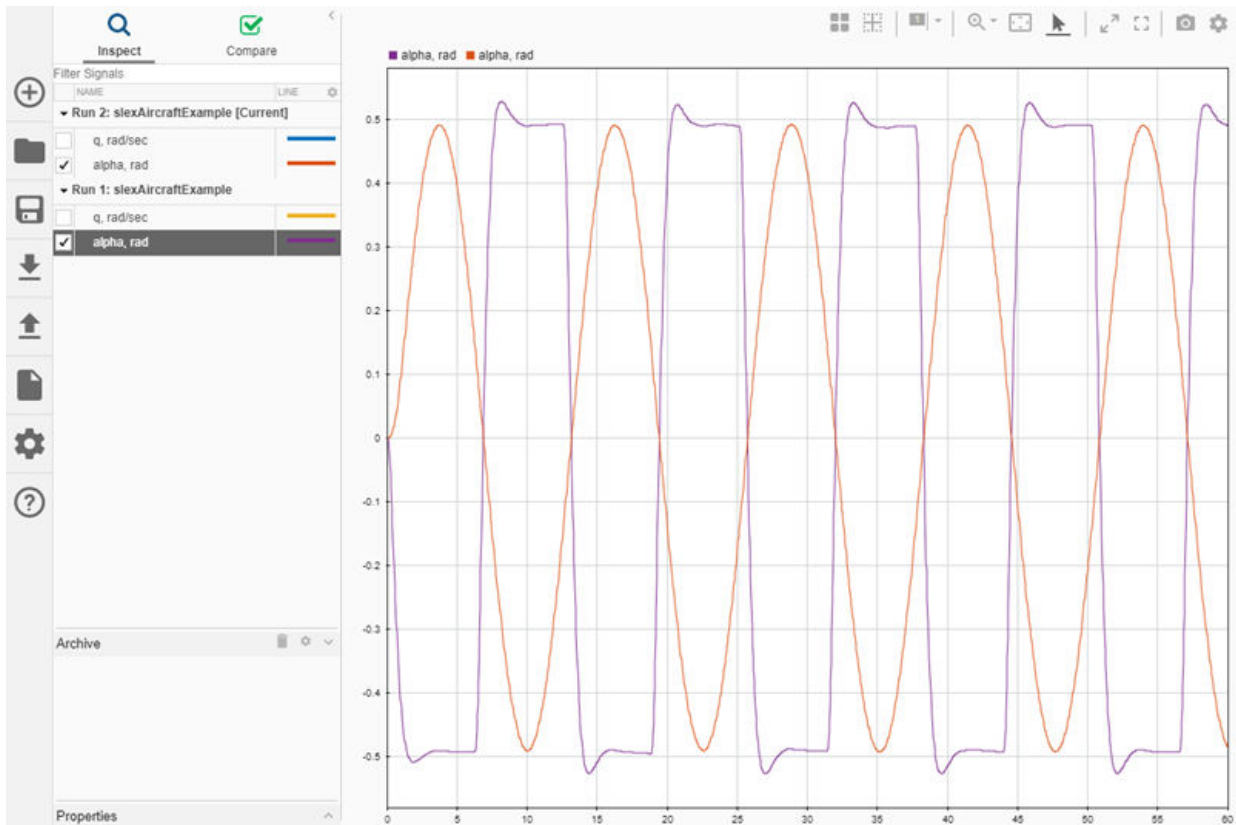

Run a simulation. Change the Pilot block's **Wave form** to `sine`, and simulate the model again. Then, open the Simulation Data Inspector by clicking the **Simulation Data Inspector** button on the Simulink editor toolbar.

The Simulation Data Inspector creates a **Run** for the data from each simulation. The two runs and their signals are listed on the left in the **Inspect** pane. By default, the Simulation Data Inspector automatically archives previous simulation runs, and the run for the first simulation is in the **Archive**. You can plot signals from the archive, or you can move runs of interest from the archive into the work area. Drag Run 1 into the work area.

The Simulation Data Inspector keeps signal line styles and colors consistent for every run. Click the lines next to the signals in Run 1 in the **Inspect** pane, and change the colors. Then, select the check boxes next to the `alpha, rad` signals in both runs.

You can also select signals to plot in your model. When you click the logging badge for a signal during or after a simulation, the Simulation Data Inspector plots the signal on the active subplot.

States and Simscape data do not log directly to the Simulation Data Inspector and can be recorded instead. Recorded data accumulates during simulation and then automatically imports into the Simulation Data Inspector when the simulation pauses or completes. Data must be logged to the workspace to record to the Simulation Data Inspector. To configure logged data for recording, select **Record logged workspace data in Simulation Data Inspector** in the **Data Import/Export** pane of the **Model Configuration Parameters**.

Note To record **States**, **Dataset** is the recommended **Format**. You can also set **Format** to **Structure** with **time** or **Array**. If **Format** is configured as **Array**, you must also log **Time** for **States** to record to the Simulation Data Inspector.

View Data from the Workspace or a File

You can import data to view in the Simulation Data Inspector from the base workspace or a MAT, CSV, or Microsoft Excel file. For information about how to format the data in CSV and Microsoft Excel files for import into the Simulation Data Inspector, see “Simulation Data Inspector Import and Export File Format” on page 29-22. You can also import MDF-files with `mdf`, `mf4`, `mf3`, `data`, and `dat` file extensions. The Simulation Data Inspector allows up to 8000 channels per signal in a run created from imported workspace data.

This example shows how to import a MAT-file containing saved data from a previous simulation to view alongside a current simulation. You can also import data created outside of Simulink, like measured test data, for example.

To import data, you have to open the Simulation Data Inspector. Type `Simulink.sdi.view` in the MATLAB Command Window, or you can click the **Simulation Data Inspector** button in the Simulink editor.

Then, to import data:

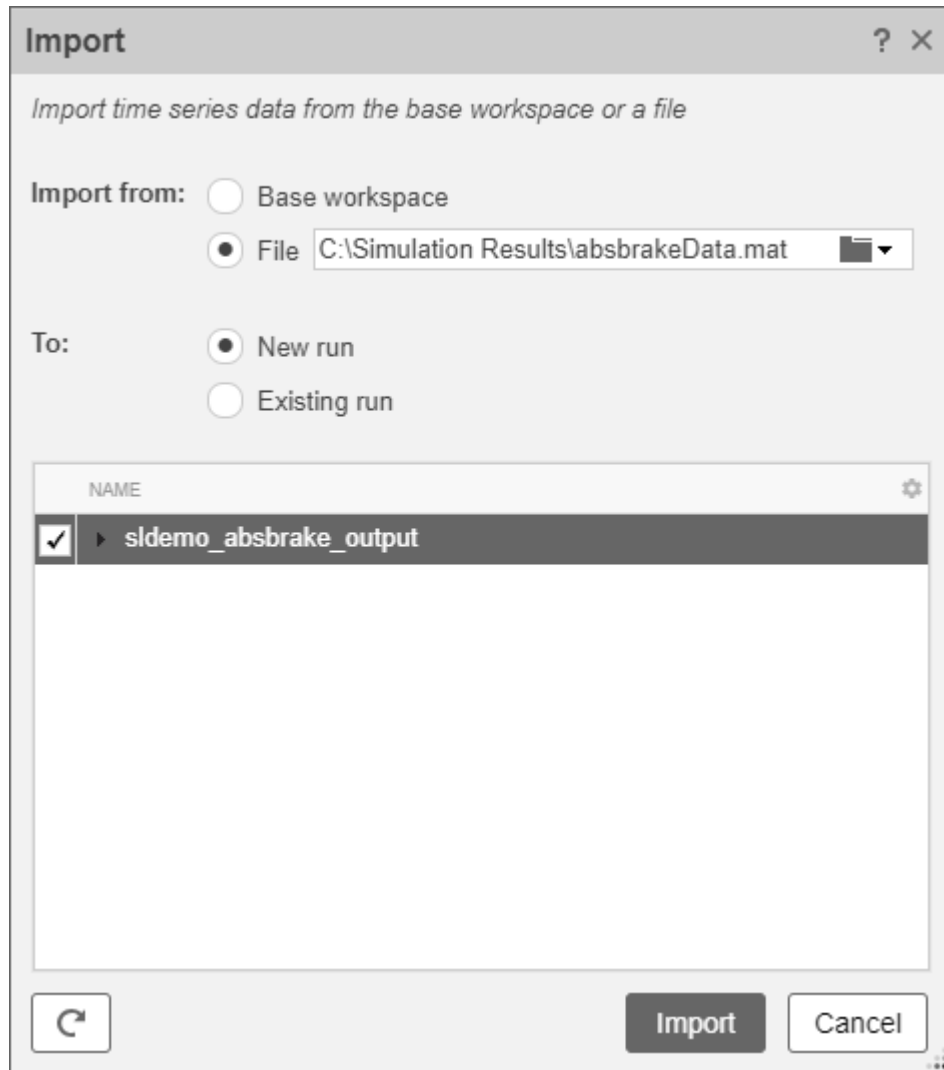

1

Click the Import button on the left sidebar.

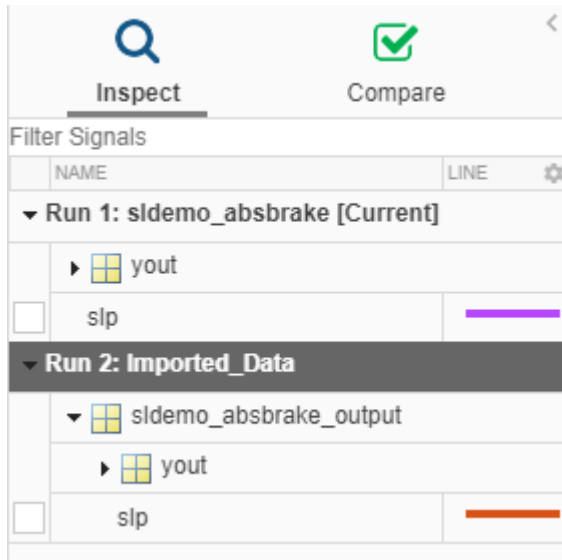

2 Select import from **File**.

3 To import the previous simulation data to a new run, select **New run**. You can also import data to an existing run.

- 4 Click **Import**.

The imported run appears in the work area, with the current simulation run. The Simulation Data Inspector always puts imported data in the work area, and you can manually move imported runs to the archive.

Tip To work with data vectors, the Simulation Data Inspector requires at least an associated time vector for your data. In general, the **Array** and **Structure** data formats are not supported unless **Time** is logged. The **Timeseries** data format is preferred because some of the Simulation Data Inspector features work best with metadata that is missing from other formats.

Select the check boxes next to the `slp` signal in each run to view the signals.

View Complex Data

To view complex data in the Simulation Data Inspector, import the data or log the signals to the Simulation Data Inspector. You can control how to visualize the complex signal using the **Properties** pane in the Simulation Data Inspector and in the **Instrumentation Properties** for the signal in the model. To access the **Instrumentation Properties** for a signal, right-click the logging badge for the signal and select **Properties**.

You can specify the **Complex Format** as Magnitude, Magnitude-Phase, Phase, or Real-Imaginary. If you select Magnitude-Phase or Real-Imaginary for the **Complex Format**, the Simulation Data Inspector plots both components of the signal when you select the check box for the signal. For signals in Real-Imaginary format, the **Line Color** specifies the color of the real component of the signal, and the imaginary component is a different

shade of the **Line Color**. For example, the Rectangular QAM Modular Baseband signal on the lower graph displays the real component of the signal in light blue, matching the **Line Color** parameter, and the imaginary component is shown in a darker shade of blue.

For signals in Magnitude-Phase format, the **Line Color** specifies the color of the magnitude component, and the phase is displayed in a different shade of the **Line Color**.

View String Data

You can log and view string data with your signal data in the Simulation Data Inspector. For example, consider this simple model. The value of the sine wave block controls whether the switch sends a string reading **Positive** or **Negative** to the output.

The plot shows the results of simulating the model. The string signal is shown at the bottom of the graphical viewing area. The value of the signal is displayed inside a band, and transitions in the string signal's value are marked with criss-crossed lines.

You can use cursors to inspect how the string signal values correspond with the sine signal's values.

When you plot multiple string signals on a plot, the signals stack in the order they were simulated or imported, with the most recent signal positioned at the top. For example, you might consider the effect of changing the phase of the sine wave controlling the switch.

View Frame-Based Data

Processing data in frames rather than point by point provides a performance boost needed in some applications. To view frame-based data in the Simulation Data Inspector, you have to specify that the signal is frame-based in the **Instrumentation Properties** for the signal. You can access the **Instrumentation Properties** dialog for a signal by right-clicking the signal's logging badge, and selecting **Properties**. To specify a signal as frame-based, select **Columns as channels (frame based)** for **Input processing**.

View Event-Based Data

You can log or import event data to the Simulation Data Inspector. To view the logged event-based data, select the check box next to **Send: 1**. The Simulation Data Inspector

displays the data as a stem plot, with each stem representing the number of events that occurred for a given sample time.

View and Replay Map Data

You can add a map to your layout in the Simulation Data Inspector to view routes of longitude and latitude data. The map data is synchronized with signal data in the Simulation Data Inspector, allowing you to analyze signal activity throughout the route. To analyze the relationship between the route and signal values, you can replay the data. When you replay data in the Simulation Data Inspector, synchronized cursors and markers move across the plots in the view.

To view map data in the Simulation Data Inspector, you must have an active internet connection.

If your model includes latitude and longitude signals, you can log data to the Simulation Data Inspector and visualize it during simulation. You can also import the data from the workspace or a file using the instructions in “View Data from the Workspace or a File” on page 29-4 or the `Simulink.sdi.createRun` function. For this example, import a file of recorded map and speed data using `Simulink.sdi.createRun`. Then, open the Simulation Data Inspector.

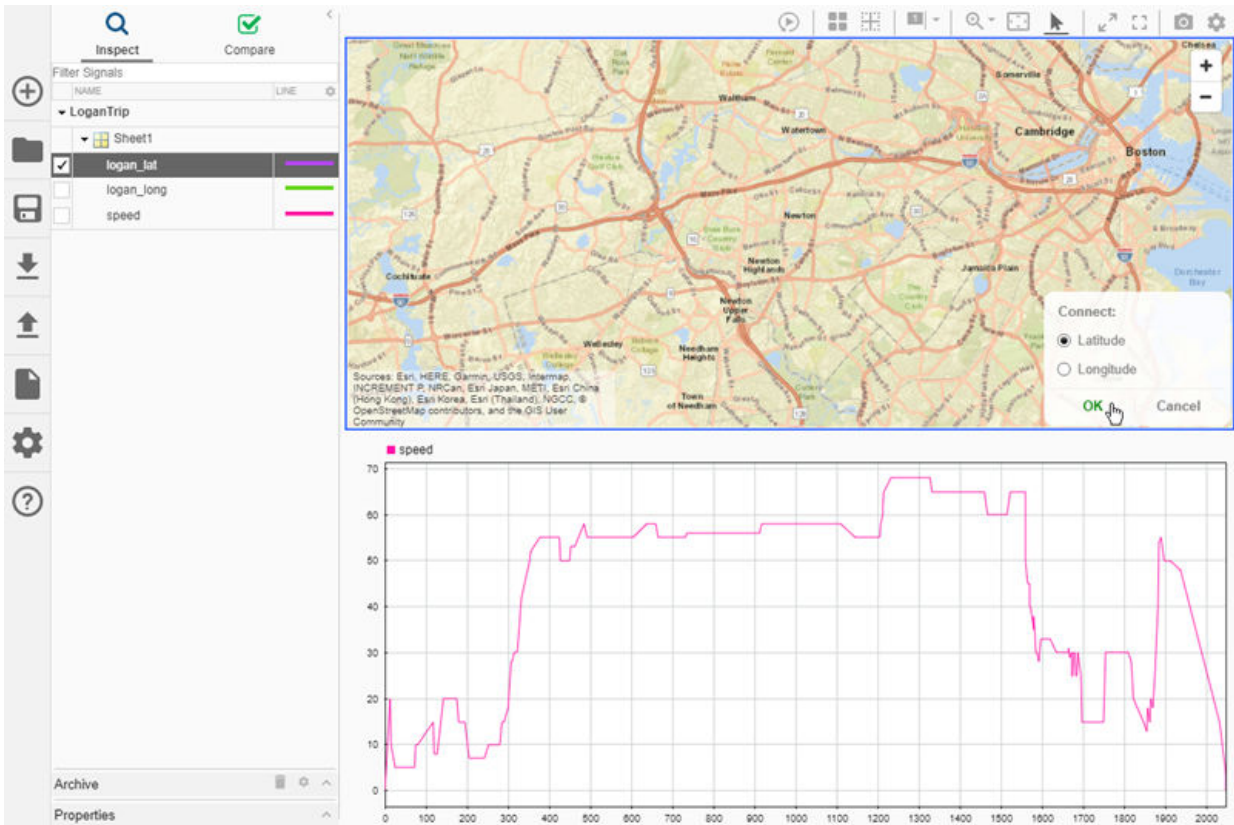

```
mapRun = Simulink.sdi.createRun('LoganTrip','file','logan_ah_gps_data.xlsx');  
Simulink.sdi.view
```

View Map Data

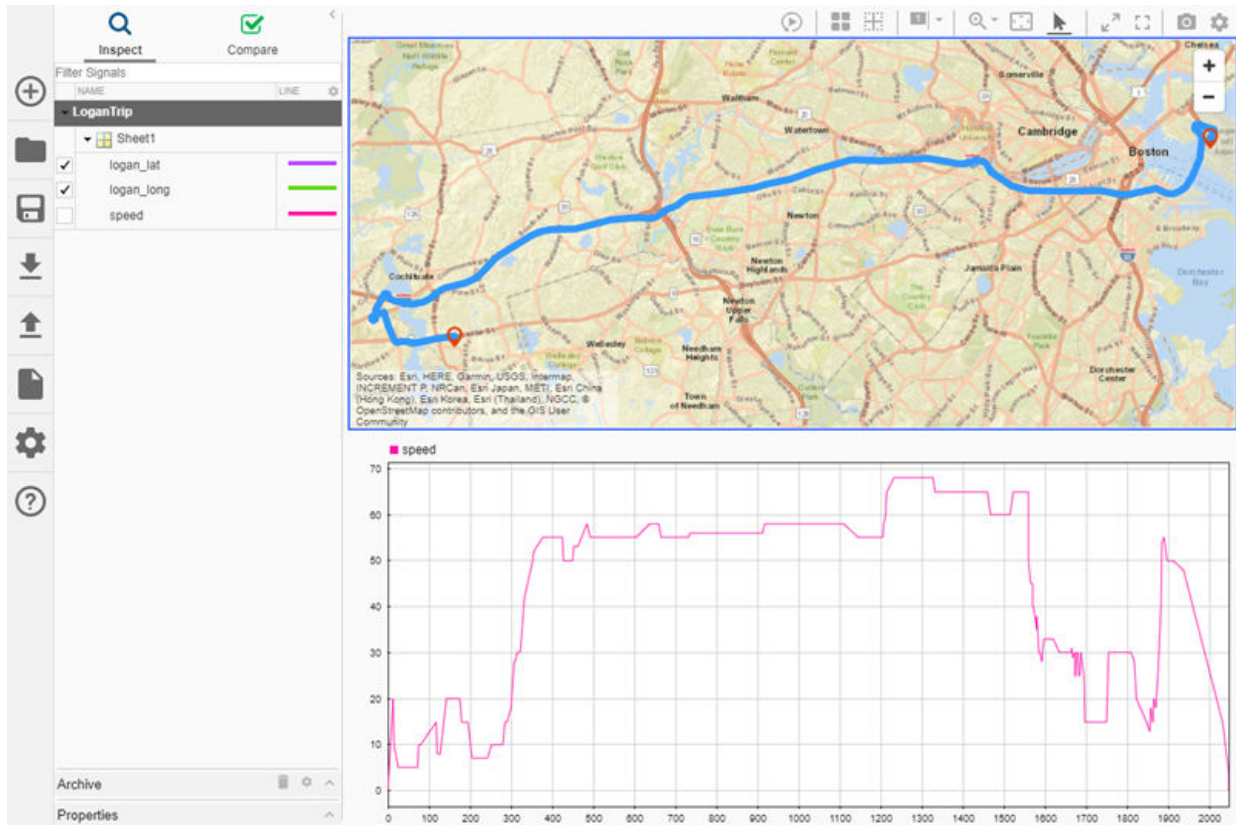

Configure the plot area in a 2x1 layout so you can view the speed data and map data together. To plot the speed data on the lower plot, select the plot and then select the check box next to the speed signal. To add a map to the layout, open the **Visualization Gallery** by clicking **Edit View** on the **Layout** menu.

From the visualization gallery, drag a map onto the top subplot in the layout. Check the `logan_lat` signal and click **OK** on the dialog in the bottom-right of the map to use the signal to specify the latitude data on the map.

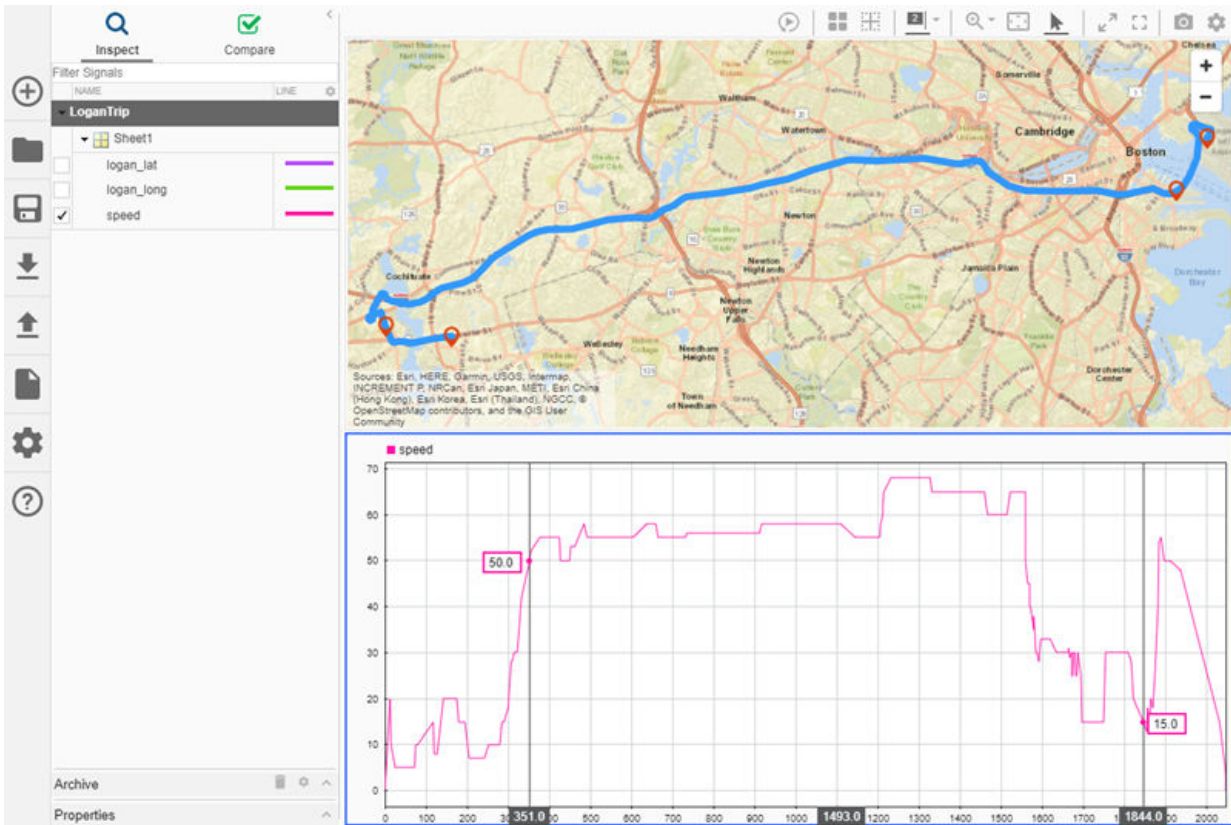

Then, check the `logan_long` signal and click **OK** to use the signal as longitude data on the map.

You can also plot map data by selecting multiple signals while holding **Ctrl** and then dragging those signals onto the map. The menu in the lower-right shows drop-downs you can use to specify which signal to use for the latitude data and which to use for the longitude data.

You can add cursors to the plots to analyze the relationship between the speed signal and the route shown on the map. To add two cursors to the layout, click the drop-down arrow on the cursors button in the toolbar and select **Two Cursors**. Move the cursor on the left. The marker on the right of the map moves as you move the left cursor because the route starts in Boston and moves East to West with time.

To remove the cursors from the plot, click the **Show/hide data cursors** button.

Replay Map Data

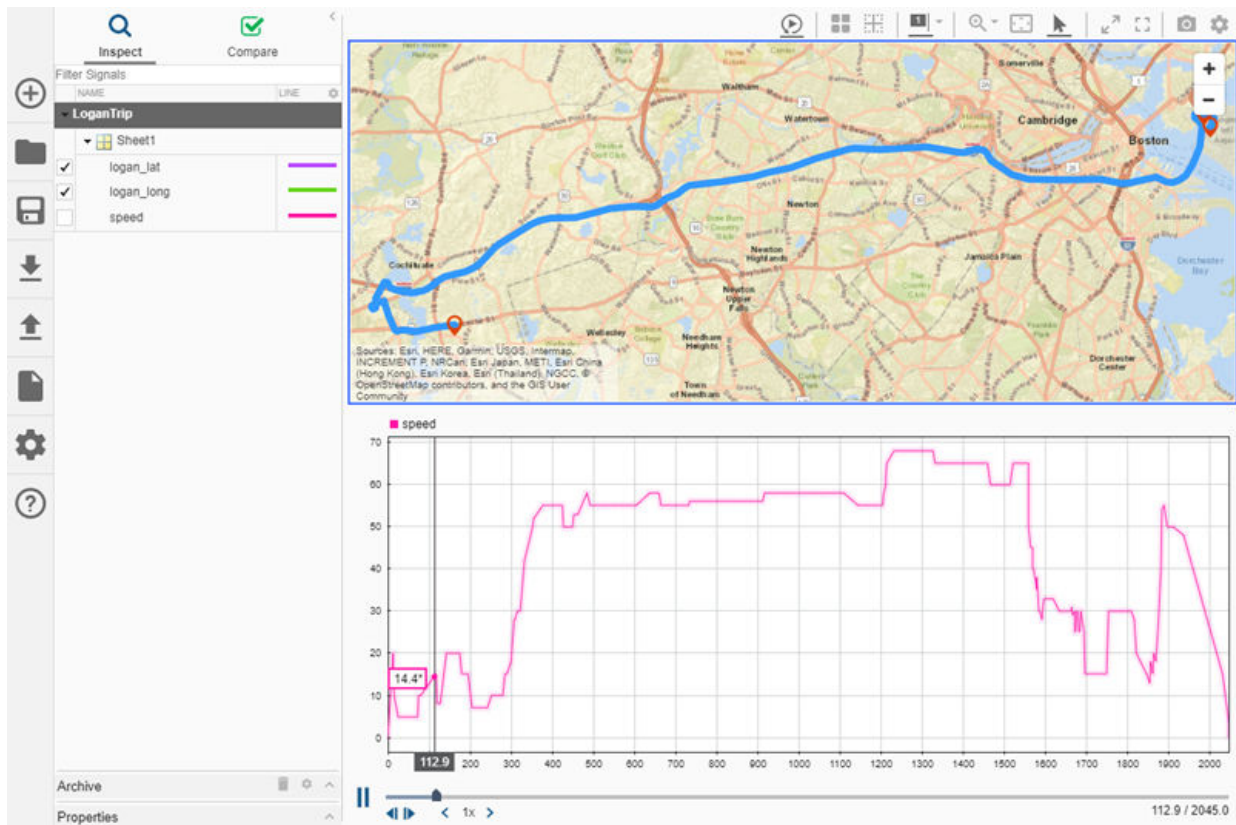

You can replay data in the Simulation Data Inspector to automate moving cursors across the visualizations in your view. To add the replay controls to the view, click the **Show/hide replay controls** button.

Then, press the **Replay** button.

A data marker on the map and a cursor on the time plot sweep synchronously across the screen. The synchronous replay facilitates an intuitive understanding of the relationship between speed and position throughout the trip.

By default, the Simulation Data Inspector replays data at one second per second, meaning that the cursor moves through one second of data in one second of clock time. The data for this trip spans approximately 34 minutes. You can increase the replay speed using the arrow to the right of the label or by clicking the label and typing the desired speed. Increase the replay speed to 32x using the arrow.

For another example, see “Replay Data in the Simulation Data Inspector” on page 29-80.

Simulation Data Inspector Import and Export File Format

You can import data stored in CSV and Microsoft Excel files into the Simulation Data Inspector to view and analyze. You can also export data from the Simulation Data Inspector to a Microsoft Excel file. The format required for import is the same as the format generated by exporting data from the Simulation Data Inspector. The file always contains time and signal data and can optionally include metadata associated with each signal.

Basic File Format

In the simplest format for CSV and Microsoft Excel files, the first row is a header listing the names of the signals, and the first column is time. The name for the time vector must be `time`. Subsequent rows list the signal values corresponding to each monotonically increasing time step.

	A	B	C	D
1	time	signal1	signal2	signal3
2	0	1	1	4
3	1	2	4	8
4	2	3	9	15
5	3	3	9	16
6	3	4	16	23
7	4	5	25	42

```

myData - Notepad
File Edit Format View Help
time,signal1,signal2,signal3
0,1,1,4
1,2,4,8
2,3,9,15
3,3,9,16
3,4,16,23
4,5,25,42
  
```

The Simulation Data Inspector does not support time vectors that include `Inf` and `NaN` values or signals that include `Inf` sample values. `NaN` or empty sample values render as missing data. All built-in data types are supported, as well as `enum` types. When your signal has an `enum` data type, specify the name of the enumeration class in the row between the signal name and first data point with the label `Enum:`, for example, `Enum: myEnum`. The definition for the enumeration class must be on the MATLAB path.

Multiple Time Vectors

When your data includes signals with different time vectors, the file can include more than one time vector. Every time vector name must be `time`. Time vectors specify the time steps for signals to the right, up to the next time vector. For example, the first time column defines the time for `signal1` and `signal2`, and the second time column defines the time steps for `signal3`.

	A	B	C	D	E	
1	time	signal1	signal2	time	signal3	
2		0	1	1	0	4
3		1	2	4	2	8
4		2	3	9	3	15
5		3	3	9	5	16
6		3	4	16		
7		4	5	25		

```

myData - Notepad
File Edit Format View Help

1,2,4,2,8
2,3,9,3,15
3,3,9,5,16
3,4,16
4,5,25

```

Signal columns must have the same number of data points as the associated time vector.

Signal Metadata

The file can include metadata for signals to indicate the data type, units, interpolation method, block path, and port index for each signal. Metadata for each signal is listed in rows between the signal names and the signal data. Each piece of metadata is labeled, according to this table.

Property Descriptions

Property Name	Value
Data type	Type:
Units	Unit:
Interpolation method	Interp:
Block Path	BlockPath:
Port Index	PortIndex:

When an imported file does not specify signal metadata, the Simulation Data Inspector assumes double data type and linear interpolation. You can specify the interpolation

method as `linear` or `zoh` (for zero-order hold). If you do not specify units for the signals in your file, after importing the file, you can assign units to the signals in the Simulation Data Inspector. For a list of supported units, enter `showunitslist` at the MATLAB command line.

You can specify any combination of metadata for each signal in your file. Leave a blank cell for signals with less specified metadata.

	A	B	C	D	E
1	time	signal1	signal2	time	signal3
2		Interp: zoh			Interp: zoh
3		Type: int8	Type: int32		
4		Unit: m			Unit: m/s
5	0	1	1	0	4
6	1	2	4	2	8
7	2	3	9	3	15
8	3	3	9	5	16
9	3	4	16		
10	4	5	25		

```

```

Complex, Multidimensional, and Bus Signals

You can import and export complex, multidimensional, and bus signals using CSV and Microsoft Excel files. The signal name for a column of data indicates whether that data is part of a complex, multidimensional, or bus signal.

Multidimensional signals include index information in parentheses. For example, the signal name for a column might be `signal1(2,3)`. When you import data from a file that includes multidimensional signal data, elements in the data not included in the file take zero sample values with the same data type and complexity as the other elements.

Complex signal data is always in real-imaginary format. Signal names for columns containing complex signal data include `(real)` and `(imag)` to indicate the columns corresponding to the real and imaginary data. When you import data from a file that includes imaginary signal data without specifying values for the real component of that signal, the real component for the signal values default to zero.

Multidimensional signals can contain complex data. The signal name includes the indication for the index within the multidimensional signal and the real or imaginary tag. For example, `signal1(1,3)(real)`.

Dots in signal names specify the hierarchy for bus signals. For example:

- `busSignal.x`
- `busSignal.y.a`

Bus signals with a bus data type specification can also include a metadata row indicating the name of the `Simulink.Bus` object that defines the bus, with the label `Bus:`.

Iterate Model Design Using the Simulation Data Inspector

The Simulation Data Inspector facilitates iterative design, debugging, and optimization by providing easy access to visualizations of logged data during simulation. Using the Simulation Data Inspector archive, you can maintain a focused work area and control data retention for multiple simulations. When you automatically archive simulation runs, you can create a view that is automatically applied to subsequent simulation runs. With **Browse Mode** enabled, you can inspect large amounts of logged signals more quickly.

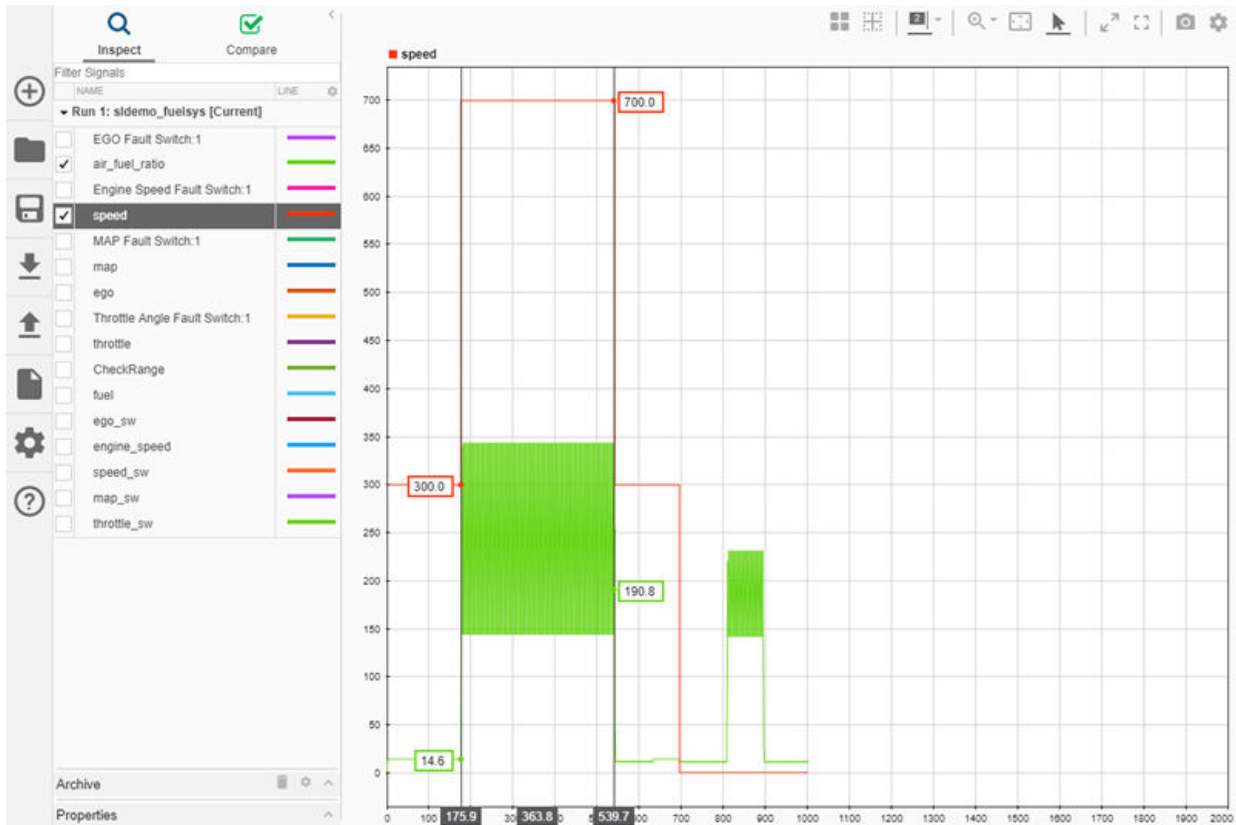

View and Inspect Signals During Simulation

You can plot logged signals in the Simulation Data Inspector during simulation. Viewing signals during a simulation can help build understanding of the model and allow you to make decisions about model parameters without waiting for a simulation to complete.

To closely examine signals throughout design iteration, add data cursors to your plots. You can add a data cursor to the plot during simulation, while a simulation is paused, or

after the simulation has finished. To add a data cursor, click the cursor button . Drag the data cursor across the plot to inspect signal values. When you display multiple signals on a plot, the data cursor indicates the value for each signal in a color-coded box.

Click the drop-down on the cursors button and select **Two Cursors** to add a second data cursor and explore temporal characteristics of your data. You can move each cursor independently, or you can move them together. The number between the two cursors displays the time difference between the cursors.

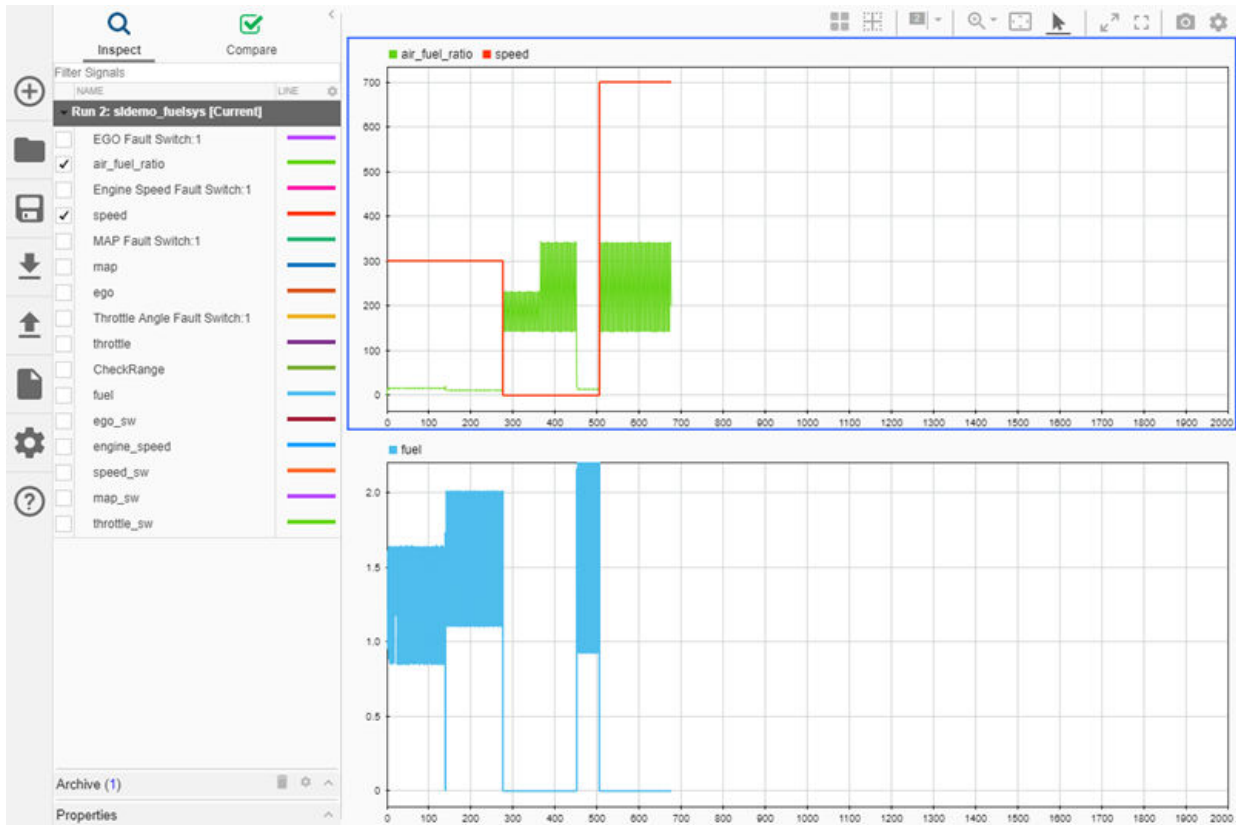

You can type directly into the box to specify a desired cursor separation. To move the cursors together, click and hold the middle number indicator, and drag it across the graphical viewing area to your desired position. For more information about using data cursors, see “Inspect Simulation Data” on page 29-58.

Automatically Transfer View to Current Simulation

By default, the Simulation Data Inspector is configured to automatically archive simulation runs and transfer a view from the previous run to the current simulation. When you run a new simulation, the Simulation Data Inspector moves the prior simulation run to the archive and updates the view to show aligned signals from the current run. You can control the **Automatically archive** setting on the **Archive** settings pane.

For example, create a view of signals from the `sldemo_fuelsys` model. Then, simulate the `sldemo_fuelsys` model again. The signals from the previous run clear from the plots, and the Simulation Data Inspector plots data from the current simulation as the simulation runs. The previous run also moves into the archive, reducing clutter in the work area.

You can access and plot data from previous runs from within the archive, and you can drag runs of interest into the work area from the archive.

Control Data Retention

Running many simulations with logged signals can create a lot of data, especially during iterative design and debugging workflows. To limit the amount of disk space occupied by logged data, you can limit the amount of data the Simulation Data Inspector stores in the archive on the **Archive** settings pane.

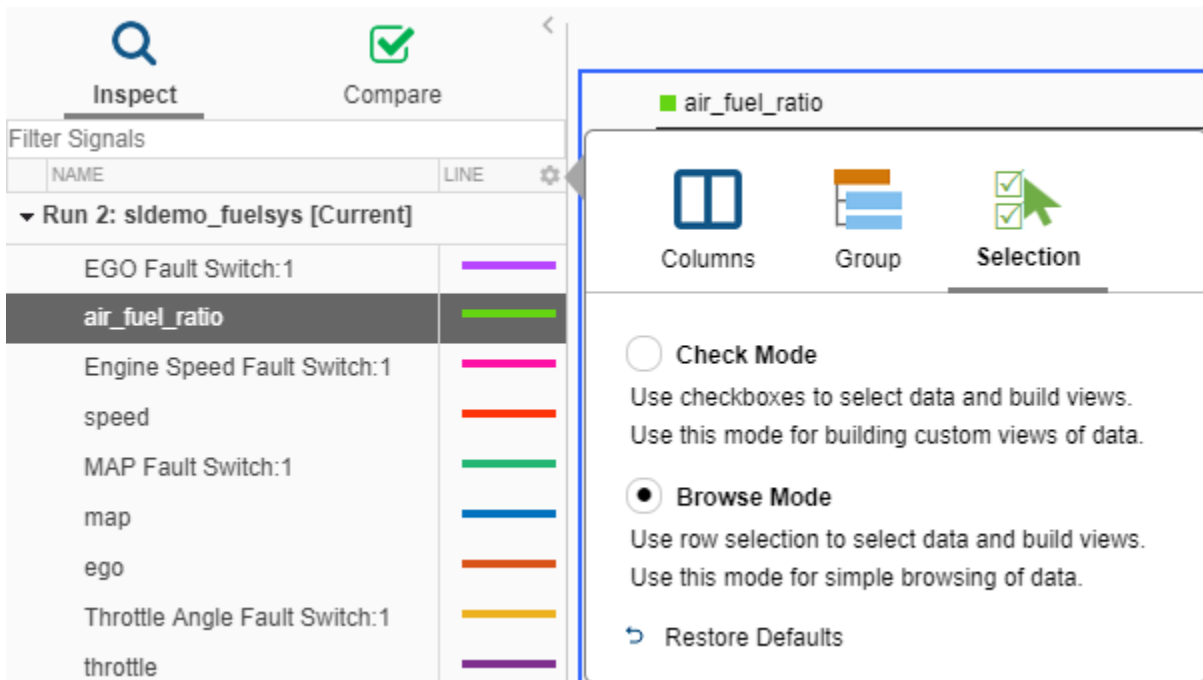

By default, the Simulation Data Inspector does not limit the number of runs stored in the archive. To impose a limit, select the **Last runs** radio button, and specify the desired limit. When the number of runs in the archive reaches the limit, the Simulation Data Inspector deletes the run that has been in the archive the longest. If the archive contains more runs than the limit you specify, the Simulation Data Inspector provides a warning before deleting your run data.

Tip When you do not want the Simulation Data Inspector to store run data, specify an archive limit of 0. With an archive limit of 0 and **Automatically archive** enabled, the

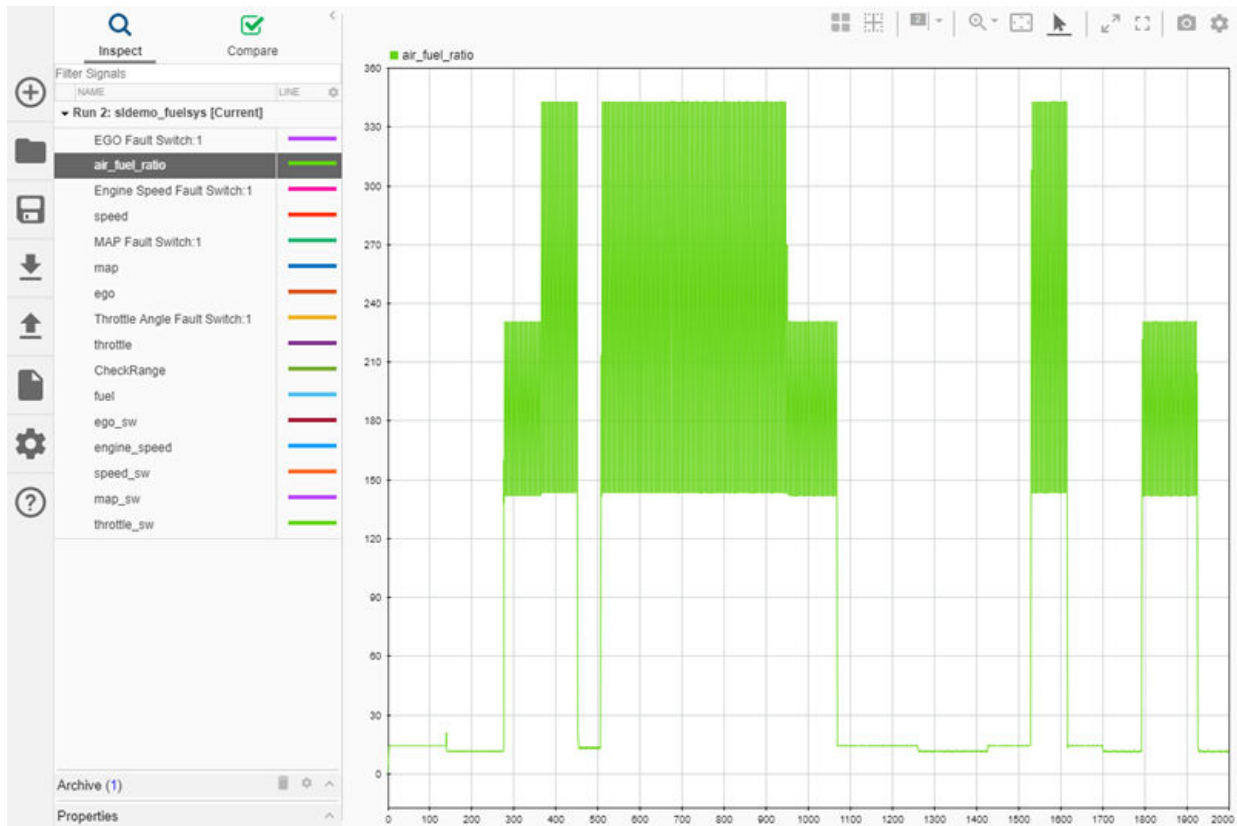

Simulation Data Inspector automatically transfers your configured view to the current simulation and only retains the current simulation data.

Visualize Many Logged Signals

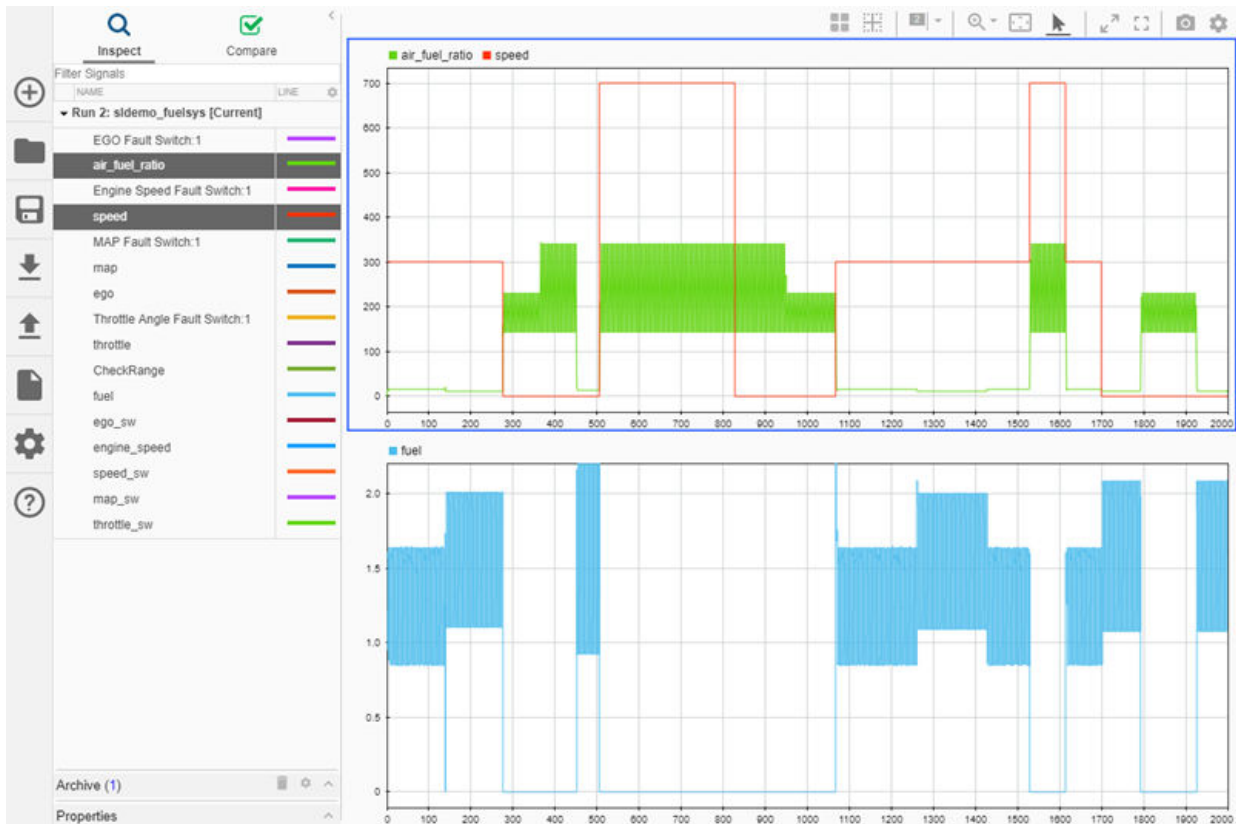

You can use **Browse Mode** to inspect many signals quickly. To enable **Browse Mode**, click the gear icon in the navigation pane, and navigate to the **Selection** pane. Click the radio button next to **Browse Mode**.

In **Browse Mode**, signals selected in the navigation pane are plotted in the graphical viewing area. You can use the arrow keys on your keyboard to change the selected signals, and you can select multiple signals by holding the **Shift** or **Ctrl** keys. When you select a row for a run or hierarchical organization, no signals are displayed in the graphical viewing area.

You can also use plot layouts in **Browse Mode** to make more complex visualizations. When the graphical viewing area contains multiple subplots, selecting new signals using the mouse or keyboard changes only the active plot.

When you finish browsing your simulation results, enable **Check Mode** on the **Selection** pane of the work area settings to build plots that showcase your data. For more information about creating plots with the Simulation Data Inspector, see “Create Plots Using the Simulation Data Inspector” on page 29-45.

Access Data in a MATLAB Function During Simulation

You can stream signal data to a MATLAB callback function during simulation using the **Data Access** functionality in the **Instrumentation Properties** for a signal. The function you provide receives data in packets asynchronously throughout the simulation. The callback function executes each time it receives new data. You can write a callback function to process signal data during simulation or to create a custom visualization of a signal. The callback function does not affect signal values in your model. Data access does not support Rapid Accelerator mode or string, fixed-point, or bus signals and only supports 1-D and 2-D matrix signals. This example illustrates the steps required to access signal data during simulation using a simple callback function that plots the signal.

Write a Callback Function for Data Access

The data access callback function always receives signal data as the first argument. You can choose to send the simulation time and a parameter. When you include all three arguments, simulation time is the second argument. Your callback function can be specific to a single signal, or you can use the same callback to process and visualize multiple signals. The callback function only has access to data for a single signal at a time. This example creates a callback function that receives signal data, time, and a parameter used to identify which signal the function is processing for a given call.

Author your callback function in an m-file with the same name as your function. For more information about writing MATLAB functions, see “Create Functions in Files” (MATLAB). The example callback function uses the optional parameter to assign a numerical identifier to each signal. The parameter is used to create a unique figure for each signal and assign each signal a different line color. To accumulate signal data on the plot, the callback includes `hold on`. For each call to the callback, the function receives a portion of the signal data. You can use the callback to accumulate the packets if desired.

```
function plotSignals(y,time,sigNum)

    figure(sigNum)

    if isequal(sigNum,1)
        marker = 'ro-';
    elseif isequal(sigNum,2)
        marker = 'go-';
    else
        marker = 'bo-';
    end
```

```
hold on;  
plot(time,y,marker);
```

```
end
```

The callback function provides no return values. If you specify the function with returns, the return data is discarded.

Tip Use `assignin` to access data from the callback function in the base workspace.

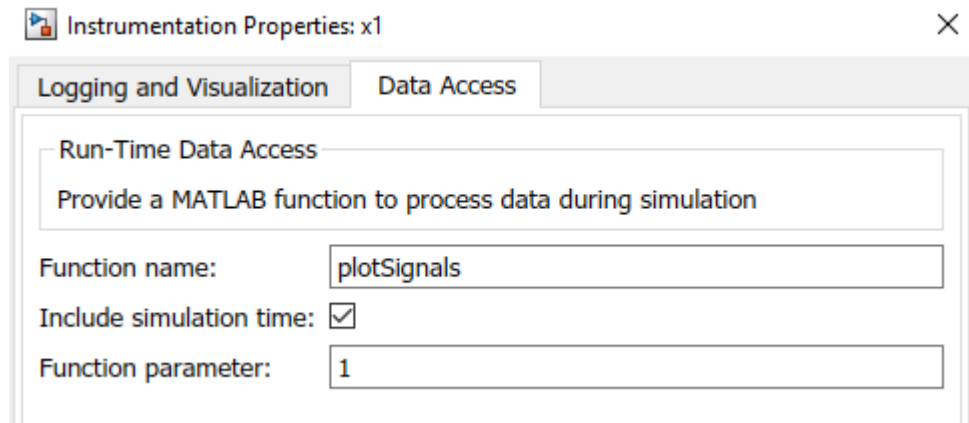

Save the callback function in a location on the MATLAB path. If the location where you save the callback is not on the path, you can add it to the path. Right-click the directory containing the callback in the **Current Folder** section in MATLAB and select **Add to Path**.

Configure Signals for Data Access

To access data for a signal with the data access callback, you need to log the signal. To mark a signal for logging, right-click the signal in your model and select **Log Selected Signals**. To configure data access for the signal, right-click the logging badge and select **Properties**. On the **Data Access** tab of the **Instrumentation Properties**, you can specify the name of your callback function, whether the callback function takes time as an argument, and the optional parameter value.

For example, open the `vdp` model and configure the `x1` and `x2` signals to use the callback from the previous section.

- 1 Enter `vdp` in the MATLAB **Command Window**.
- 2 Select the `x1` and `x2` signals. Then, right-click the selected signals and choose **Log Selected Signals** from the context menu.
- 3 To open the **Instrumentation Properties**, right-click the logging badge for `x1` and select **Properties**.
- 4 On the **Data Access** pane, enter the name of the callback, check **Include simulation time**, and enter 1 as the **Function parameter**.

- 5 Open the **Instrumentation Properties** for x2 and configure the **Data Access** pane to use the `plotSignals` callback with a **Function parameter** value of 2.

Simulate the `vdp` model. The callback generates Figures 1 and 2 to display the `x1` and `x2` signals during simulation.

You can modify the callback function to create a custom visualization or to create a plot of processed signal data. Errors related to the data access callback function do not interrupt simulation. The errors surface in the **Diagnostic Viewer** as a warning.

- “View Data with the Simulation Data Inspector” on page 29-2

Save and Share Simulation Data Inspector Data and Views

After you inspect, analyze, or compare your data in the Simulation Data Inspector, you can share your results with others. The Simulation Data Inspector provides several options for sharing and saving your data and results, depending on your needs. With the Simulation Data Inspector, you can:

- Save your data and layout modifications in a Simulation Data Inspector session.
- Share your layout modifications in a Simulation Data Inspector view.
- Share images and figures of plots you create in the Simulation Data Inspector.
- Create a Simulation Data Inspector report.
- Export your data from the Simulation Data Inspector.

Save and Load Simulation Data Inspector Sessions

If you want to save or share data along with a configured view in the Simulation Data Inspector, save your data and settings in a Simulation Data Inspector session. You can save sessions as MAT- or MLDATX-files. The default format is MLDATX. When you save a Simulation Data Inspector session, the session file contains:

- All runs, data, and properties from the **Inspect** pane, including which run is the current run and which runs are in the archive.
- Plot display selection for signals in the **Inspect** pane.
- Subplot layout and line style and color selections.

Note Comparison results and global tolerances are not saved in Simulation Data Inspector sessions.

To save a Simulation Data Inspector session:

- 1 Hover over the save icon on the left side bar. Then, click **Save As**.

- 2 Name the file.
- 3 Browse to the location where you want to save the session, and click **Save**.

For large datasets, a status overlay in the bottom right of the graphical viewing area displays information about the progress of the save operation and allows you to cancel the save operation.

The **Save** tab of the Simulation Data Inspector preferences menu on the left side bar allows you to configure options related to save operations for MLDATX-files. You can set a limit as low as 50MB on the amount of memory used for the save operation. You can also select one of three **Compression** options:

- **None**, the default, applies no compression during the save operation.
- **Normal** creates the smallest file size.
- **Fastest** creates a smaller file size than you would get by selecting **None**, but provides a faster save time than **Normal**.

To load a Simulation Data Inspector session, click the open icon on the left side bar. Then, browse to select the MLDATX-file you want to open, and click **Open**.

Alternatively, you can double-click the MLDATX-file. MATLAB and the Simulation Data Inspector open if they are not already open.

When the Simulation Data Inspector already contains runs and you open a session, all of the runs in the session move to the archive. The view updates to reflect show plotted signals from the session file. You can drag runs between the work area and archive as desired.

When the Simulation Data Inspector does not contain runs and you open a session, the Simulation Data Inspector puts runs in the work area and archive as specified in the file.

Share Simulation Data Inspector Views

When you have different sets of data that you want to visualize the same way, you can save a view. A view saves the layout and appearance characteristics of the Simulation Data Inspector without saving the data. Specifically, a view saves:

- Plot layout, axis ranges, linking characteristics, and normalized axes.
- Location of signals in the plots, including plotted signals in the archive.
- Signal grouping and columns on display in the **Inspect** pane.
- Signal color and line styling.

To save a view:

- 1 Click the layout button .
- 2 Click **Save current view**.
- 3 In the dialog box, specify a name for the view and browse to the location where you want to save the MLDATX-file.
- 4 Click **Save**.

To load a view:

- 1 Click the layout button .
- 2 Click **Open saved view**.
- 3 Browse to the view you would like to load, and click **Open**.

Share Simulation Data Inspector Plots

Use the snapshot feature to share the plots you generate in the Simulation Data Inspector. You can export your plots to the clipboard to paste into a document, as an image file, or to a MATLAB figure. You can choose to capture the entire plot area, including all subplots in the plot area, or to capture only the selected subplot.

Click the camera icon  on the toolbar to access the snapshot menu. Use the radio buttons to select the area you want to share and how you want to share the plot. After you make your selections, click **Snapshot** to export the plot.

Snapshot

Take snapshot of:

Entire plot area

Selected plot only

Send to:

Clipboard

Image File

MATLAB Figure

Snapshot

If you create an image, select where you would like to save the image in the file browser.

You can create snapshots of your plots in the Simulation Data Inspector programmatically using `Simulink.sdi.snapshot`.

Create a Simulation Data Inspector Report

To generate documentation of your results quickly, create a Simulation Data Inspector report. You can create a report of your data in either the **Inspect** or the **Compare** pane. The report is an HTML file that includes information about all the signals and plots in the active pane. The report includes all signal information displayed in the signal table in the navigation pane. For more information about configuring the table, see “Inspect Metadata” on page 29-70.

To generate a Simulation Data Inspector Report:

1

Click the create report icon on the left side bar.

2

Under **Include in report**, specify the type of report you want to create.

- Select **Inspect Signals** to include the plots and signals from the **Inspect** pane.
- Select **Compare Runs** to include the data and plots from the **Compare** pane. When you generate a **Compare Runs** report, you can choose to **Report only mismatched signals** or to **Report all signals**. If you select **Report only mismatched signals**, the report shows only signal comparisons that are not within the specified tolerances.

The image shows a 'Create Report' dialog box with the following fields and options:

- Create Report** (Title bar)
- Create a report of the runs or comparison plots* (Subtitle)
- Include in report**
 - Inspect Signals
 - Compare Runs
 - Report only mismatched signals
 - Report all signals
- Report output options**
 - File name:
 - Folder:
 - If report exists, increment file name to prevent overwriting
 - Display partial block path (modelname/.../blockname)
- Create Report** (Button)
- Cancel** (Button)

3

Specify a **File name** for the report, and navigate to the **Folder** where you want to save the report.

4 Click **Create Report**.

The generated report automatically opens in your default browser.

Export Data from the Simulation Data Inspector

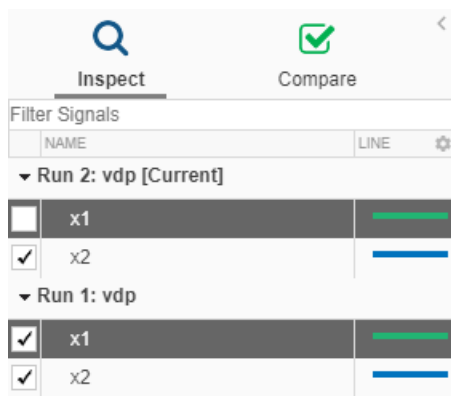

You can use the Simulation Data Inspector to export data to the base workspace, a MAT-file, or a Microsoft Excel file. You can export a selection of runs and signals, runs in the work area, or all runs in the **Inspect** pane, including the **Archive**.

When you export a selection of runs and signals, make the selection of data to export

before clicking the export button.

Only the selected runs and signals are exported. In this example, only the x1 signals from Run 1 and Run 2 are exported. The check box selections for the plotting area do not affect whether a signal is exported.

When you export a single signal, the signal is stored in `timeseries` format in the workspace variable or MAT-file. Exported data for a run or multiple signals is stored in `Simulink.SimulationData.Dataset` format.

Note When you export a run that contains logged parameter data, the exported `Simulink.SimulationData.Dataset` contains a `Simulink.SimulationData.Parameter` element for each logged parameter.

To export data to a file, select the **File** option in the **Export** dialog. You can specify a file name and browse to the location where you want to save the exported file. When you export data to a MAT-file, a single exported signal is stored in `timeseries` format, and runs or multiple signals are stored in `Simulink.SimulationData.Dataset` format. When you export data to a Microsoft Excel file, the data is stored in the format described in “Simulation Data Inspector Import and Export File Format” on page 29-22.

To export to a Microsoft Excel file, select the XLSX extension from the drop-down. When you export data to a Microsoft Excel file, you can specify additional options for the format of the data in the exported file. If the file name you provided already exists, you can choose to overwrite the entire file or to only overwrite sheets containing data that corresponds to the exported data. You can also choose which metadata to include and whether signals with identical time data share a time column in the exported file.

Create Plots Using the Simulation Data Inspector

Plots can help showcase important features or trends in your data and share your findings with others. The Simulation Data Inspector allows you to select from a variety of visualization types and layouts and customize plot and signal appearances to present your data most effectively. This topic uses simulation data generated from a simulation of the `slexAircraftExample` model that logs the output of the Actuator Model block and the Stick, α , rad, and q , rad/sec signals.

Plot Layouts

The Simulation Data Inspector allows you to select from three types of layouts under the layout menu  .

Basic Layouts:

Overlays:

Grid:

Rows: Columns:

- **Basic Layouts** includes templates for two or three subplot layouts.
- **Overlays** options have overlay subplots in two corners of the main plot.
- **Grid** layouts create a grid of subplots from 1×1 to 8×8 .

You can select the plot layout that best highlights the characteristics of your data. For example, with a basic three plot layout, you can use the large plot to show a main result and show intermediate signals on the smaller plots.

Moving Between Subplot Layouts

When you plot a signal on a subplot, the Simulation Data Inspector links the signal to the subplot, identifying the subplot with a number. As you move between subplot layouts, the association between the signal and subplot remains, even as the shape or visibility of the subplot may change. The **Basic Layouts** and **Overlays** subplot numbering are based on the columnwise numbering used for the grids layout.

Subplots of **Grid** layouts follow columnwise numbering, from 1 at the top left subplot to 8 in the bottom left, to 64 at the bottom right. The number system is fixed, regardless of

which subplot configuration you select. For example, if you display four subplots in a 2×2 configuration, the bottom right subplot of the configuration is numbered 10, not 4. The number is 10 because in the largest possible 8×8 matrix, that subplot is numbered 10 when you count the subplots in a columnwise manner.

Basic Layouts subplots also use the fixed 8×8 columnwise numbering as a base. For example, the top plot in this three-subplot layout is subplot 1, and the two subplots below it are 2 and 10.

In this three-subplot layout, the index for the right subplot is 9, and the indices for the two subplots on the left are 1 and 2.

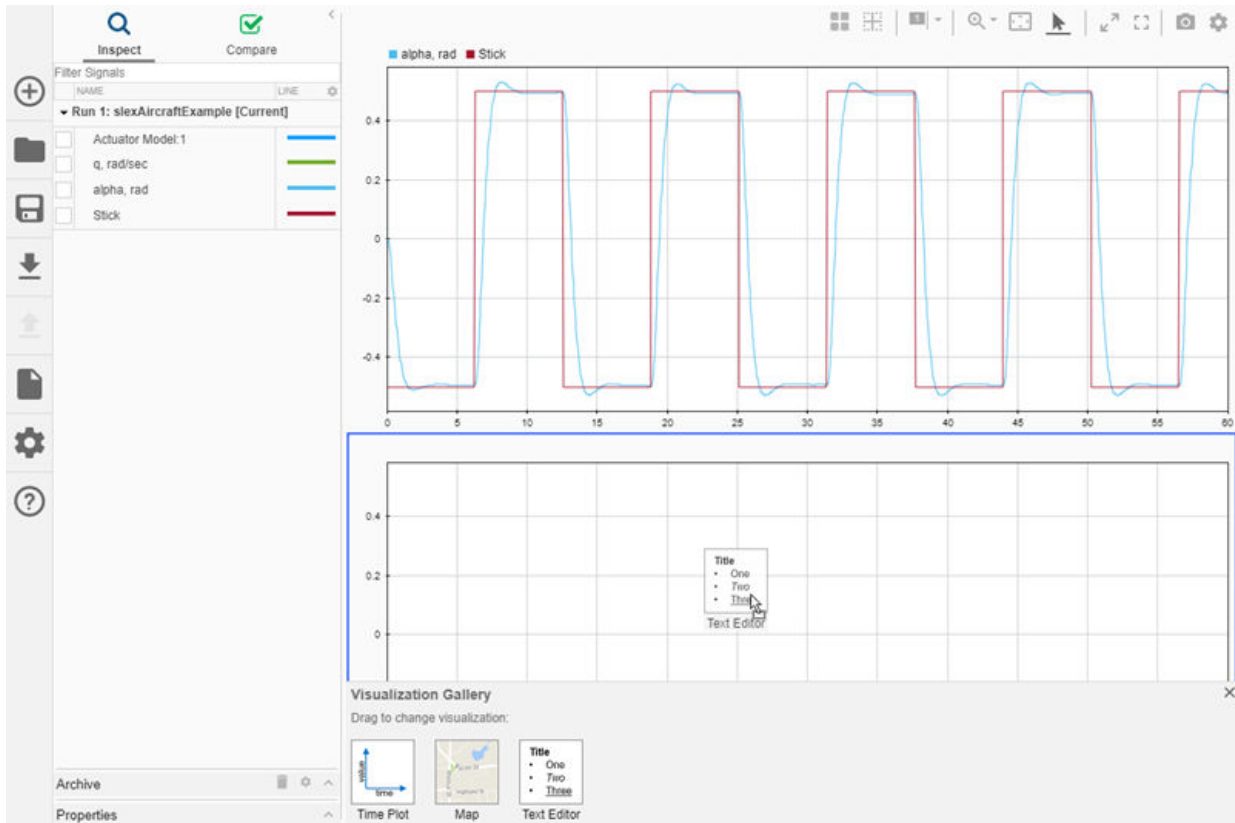

For the **Overlays** layouts, the index for the main plot is always 1, and the indices for the overlaid plots are 2 and 9.

Visualizations

You can choose from several visualizations to use for your data in the Simulation Data Inspector. To view available visualizations, open the **Visualization Gallery** by clicking **Edit View** on the layout menu.

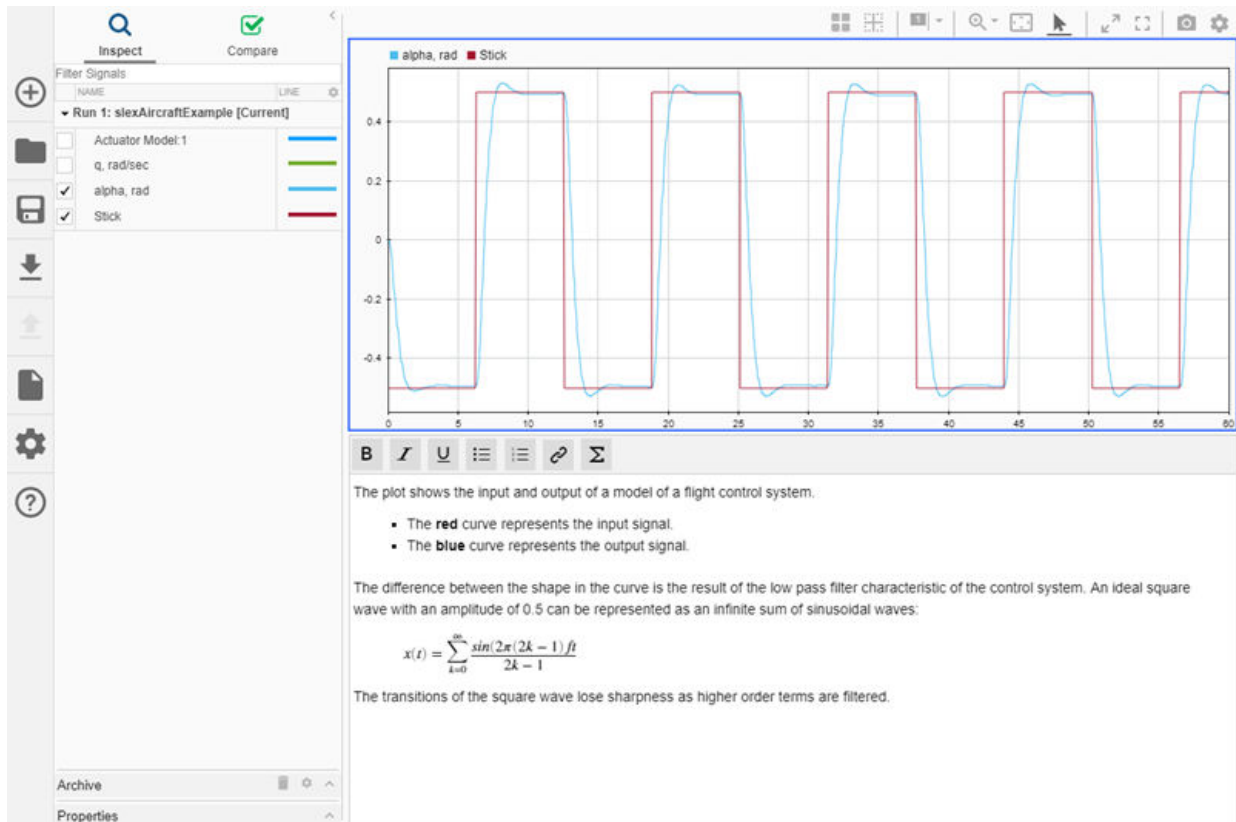

You can drag the visualization you want to add to your layout to the plot where you want to add it. You can choose a time plot, map, or text editor for each subplot in your layout. For more information about using map visualizations, see “View and Replay Map Data” on page 29-15.

Add a text editor to your plot layout when you want to present conclusions, descriptions, or observations alongside your data. The text editor includes a toolbar for rich text formatting, including:

- Bullet points
- Numbered lists
- Hyperlinks
- LaTeX equations

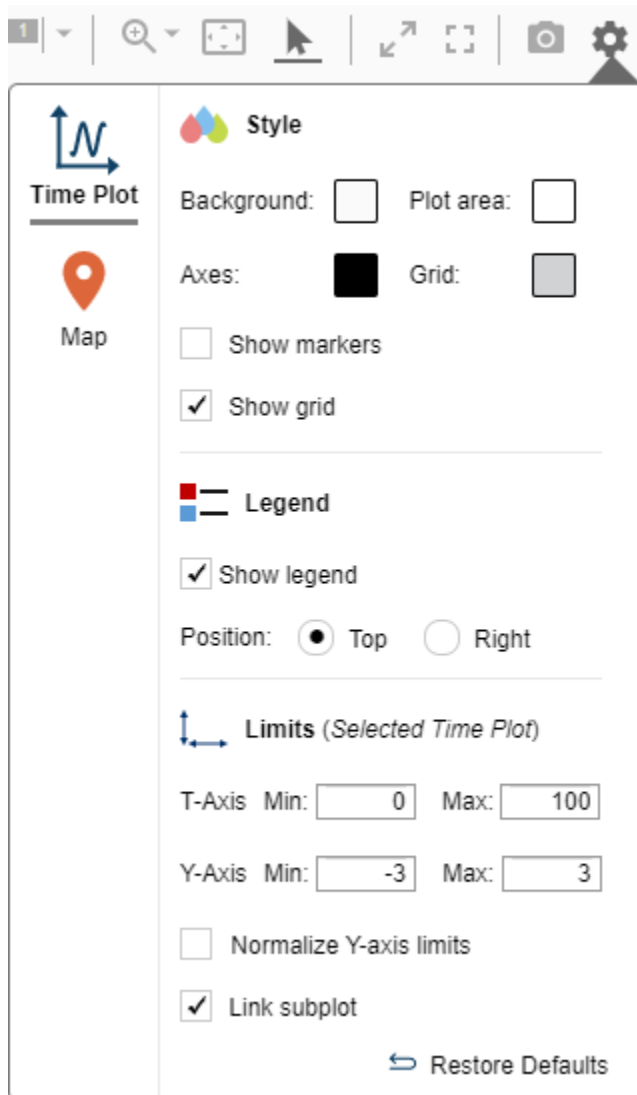

Customize Plot Appearance

After you choose a plot layout, you can customize the appearance of each visualization using the visualization settings menu . The number of menu tabs depends on the visualizations present in your layout. When your layout does not include a map visualization, the **Map** tab is not shown.

On the **Map** tab, you can select between a street view and a satellite view for your map visualization.

The **Time plot** tab includes sections for modifying the style, legend, and limits for time plots in your layout. In the **Style** section, you can specify a color for each aspect of the plot. For example, you might change the **Background** of a layout you want to print to white to save printer ink. Use the **Show markers** check box to specify whether you want to show markers on plotted signals. You can show or hide the grid using the **Show grid** option. In the **Legend** section, you can control the legend location and visibility. The selections on the **Style** and **Legend** tabs apply to all subplots in the Simulation Data Inspector.

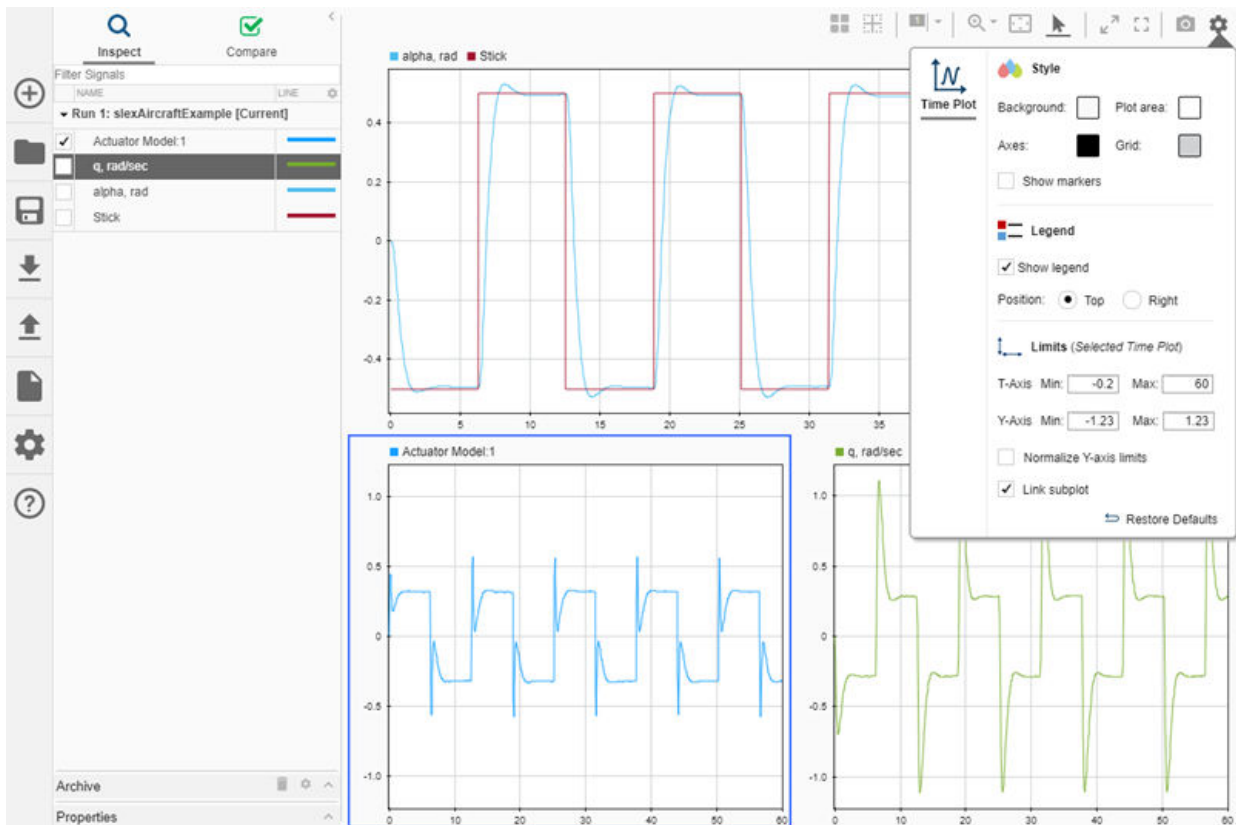

The **Limits** section gives you control over the limits of the t - and y -axes for individual subplots. You may also choose to normalize the y -axis. Except for the t -axis limits, the settings you configure in the **Limits** section apply to the active subplot. To configure t -

axis limits individually for a subplot, unlink the subplot. For more information, see “Linked Subplots” on page 29-63.

To improve the basic layout plot created in the previous section, change the y-axis limits of the left graph to match those on the right.

- 1 Select the q , rad/sec plot to view its y-axis limits in the **Limits** tab.
- 2 Select the Actuator Model: 1 plot as the active plot.
- 3 In the **Limits** section, change the y-axis limits of the Actuator Model: 1 plot to match the limits of the q , rad/sec plot.

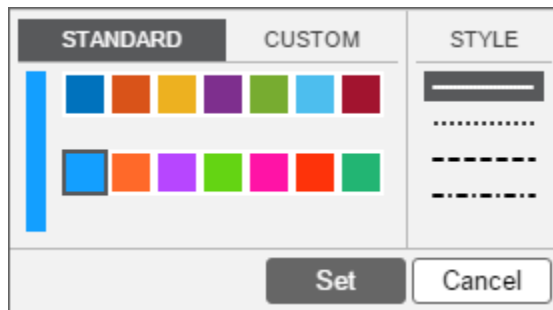

You can clear the active subplot or all subplots using the clear subplots menu on the

toolbar. 

Customize Signal Appearance

The Simulation Data Inspector allows you to modify the color and style of each signal individually. For each signal, you can select from a palette of standard colors or specify a custom color with RGB values.

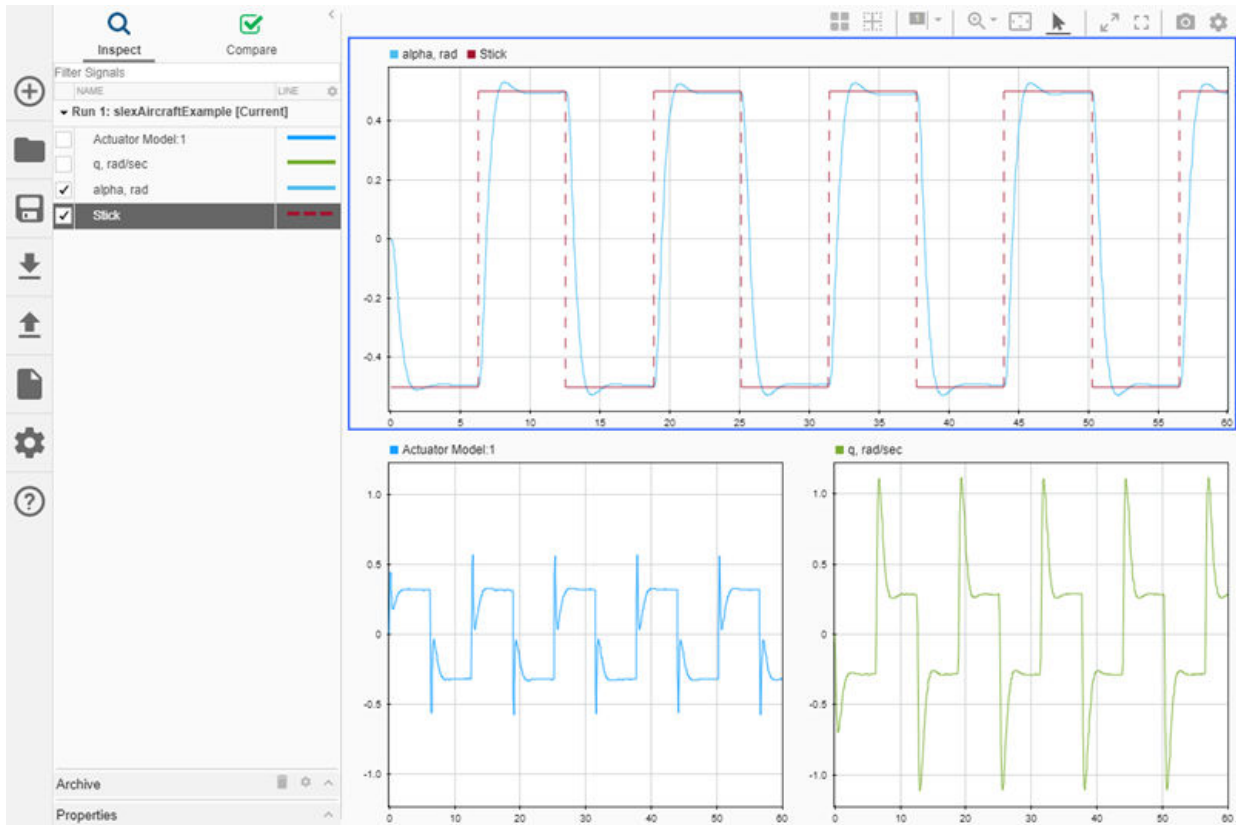

You can access the line style menu for a signal from several places:

- Click the graphic representation in the **Line** column of the navigation pane.
- From the Simulink Editor, right-click the logging badge, and select **Properties** to open the **Visualization Properties** dialog. Then, click the graphic representation of the **Line**.

From the **Visualization Properties** dialog, you can also select subplots where you want to plot the signal. Changes made through the **Visualization Properties** dialog box take effect for subsequent simulations.

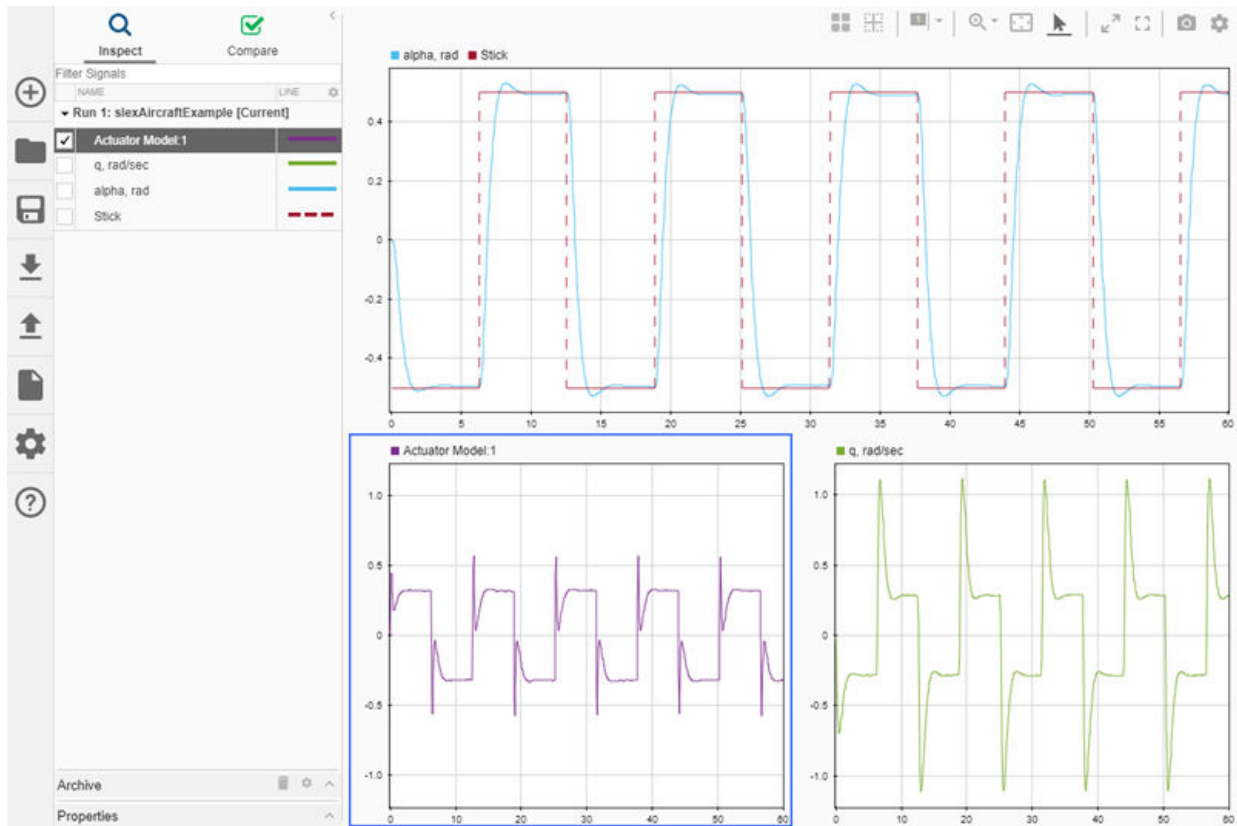

Line style customization can help emphasize differences between signals in your plot. For example, change the line style of the `Stick` signal to dashed to visually indicate that it is an ideal, rather than simulated, signal.

- 1 Click the **Line** column for the `Stick` signal.
- 2 Select the dashed option (third in the list).
- 3 Click **Set**.

The `alpha, rad` and `Actuator Model: 1` signals are very close in color. You can select bold, easily distinguishable colors for all of the signals in your plot.

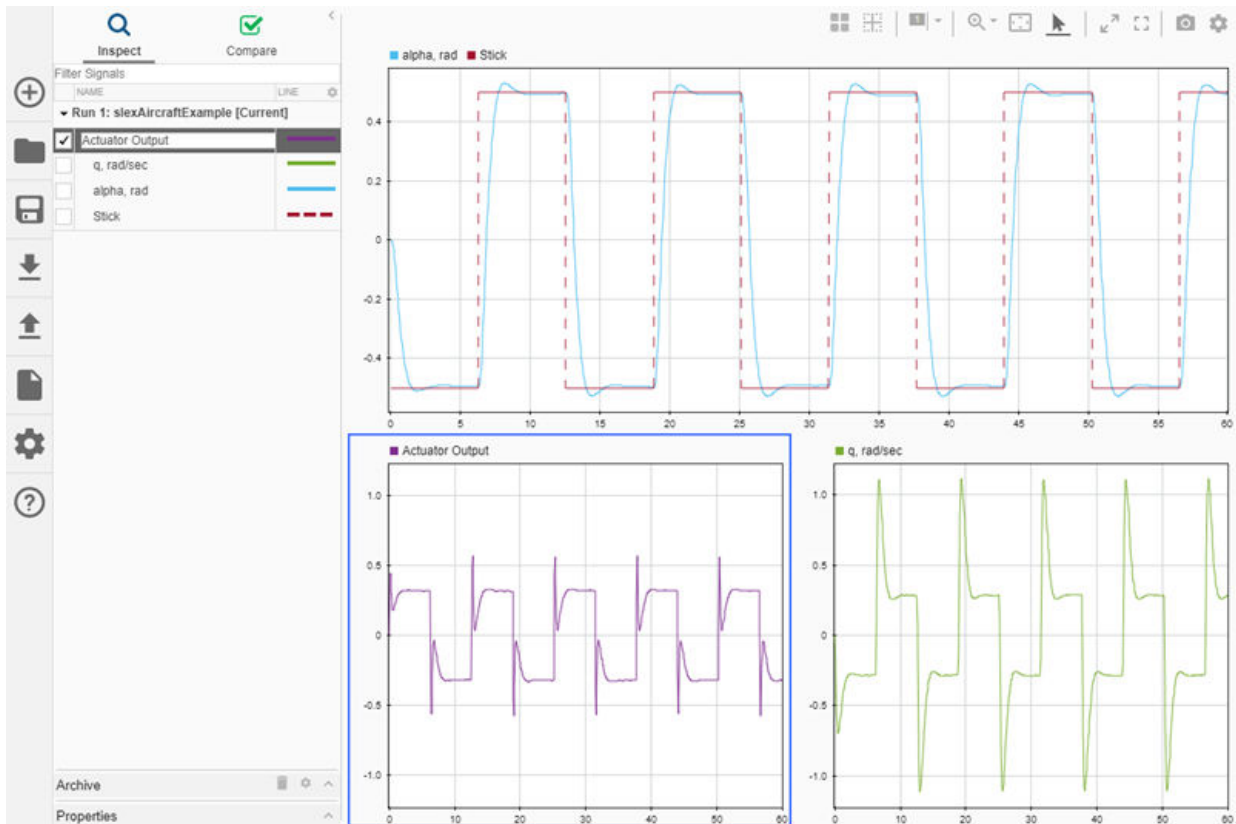

- 1 Select the `Actuator Model: 1` signal in the navigation pane.
- 2 Click the **Line** row entry in the properties pane.
- 3 Specify your desired color.
- 4 Click **Set**.

Rename Signals

You can rename signals in the Simulation Data Inspector when a more descriptive name can help convey information. Changing a signal name in the Simulation Data Inspector does not affect signal names used in models. You cannot rename bus signals in the Simulation Data Inspector.

To change a signal name, you can double-click the signal name in the work area or archive, or you can edit the **Name** field in the **Properties** pane. Change the name of the Actuator Model: 1 signal to Actuator Output.

More About

- “Save and Share Simulation Data Inspector Data and Views” on page 29-38
- “Inspect Simulation Data” on page 29-58
- “Compare Simulation Data” on page 29-86

Inspect Simulation Data

You can use the Simulation Data Inspector to view and inspect signals from simulations or imported data. The Simulation Data Inspector provides a comprehensive view of your data by allowing you to group data from multiple simulations and sources on multiple subplots. You can zoom and pan within plots and use data cursors for close examination of signal values, and you can replay data to analyze signal relationships.

This example shows you how to view and inspect signal data from the `slexAircraftExample` model using the Simulation Data Inspector.

Configure Signals for Logging

This example uses signal logging to send data to the Simulation Data Inspector. You can also import signal data from the base workspace or a CSV, MDF, Microsoft Excel, or MAT-file. For more information, see “View Data with the Simulation Data Inspector” on page 29-2.

Open the `slexAircraftExample` model, mark several signals for logging, and run a simulation.

- 1 To open the model, enter `slexAircraftExample` in the MATLAB Command Window.
- 2 To log the `q`, `rad/sec`, the `Stick`, and the `alpha`, `rad` signals to the Simulation Data Inspector, select the signals in the model. Then, click the **Simulation Data Inspector** drop-down, and select **Log Selected Signals**.

The logging badge  appears above each signal marked for logging.

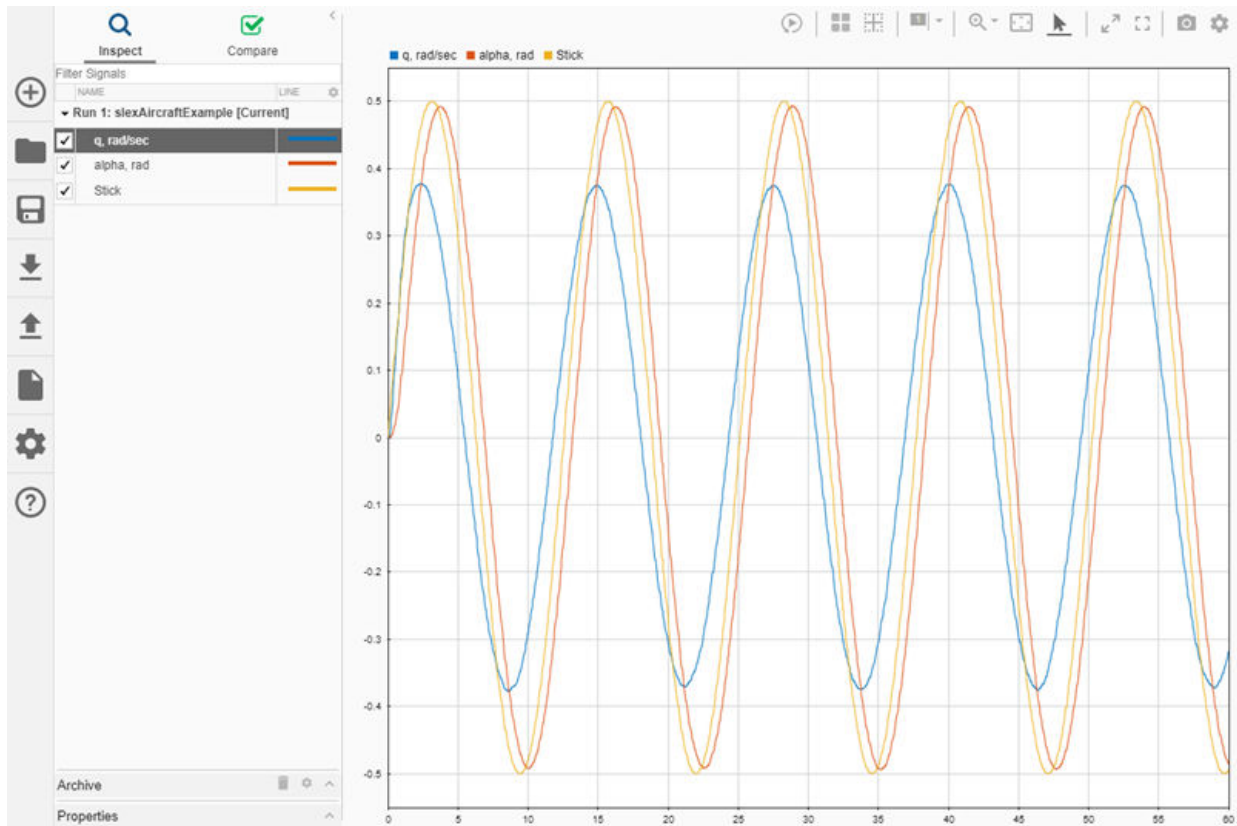

- 3 Double-click the Pilot block. Set **Wave form** to sine, and click **OK**.

- 4 In the Simulink Editor, click the **Simulation Data Inspector** button to open the Simulation Data Inspector.
- 5 Simulate the model. The simulation run appears in the Simulation Data Inspector.

By default, the **Inspect** pane lists all logged signals in rows, organized by simulation run. You can expand or collapse any of the runs to view the signals in a run. For more information on signal grouping, see “Organize Your Simulation Data Inspector Workspace” on page 29-105.

View Signals

To select signals you want to plot, use the check boxes next to the signals in the navigation pane. Select the check boxes next to the `q`, `rad/sec`, `Stick`, and `alpha`, `rad` signals. When the signal you want to plot is easier to find in your model, you can click the logging badge for the signal to plot it in the Simulation Data Inspector.

You can also use signal browsing mode to quickly view all the signals in your run. For more information about how to enable and use **Browse Mode**, see “Visualize Many Logged Signals” on page 29-31.

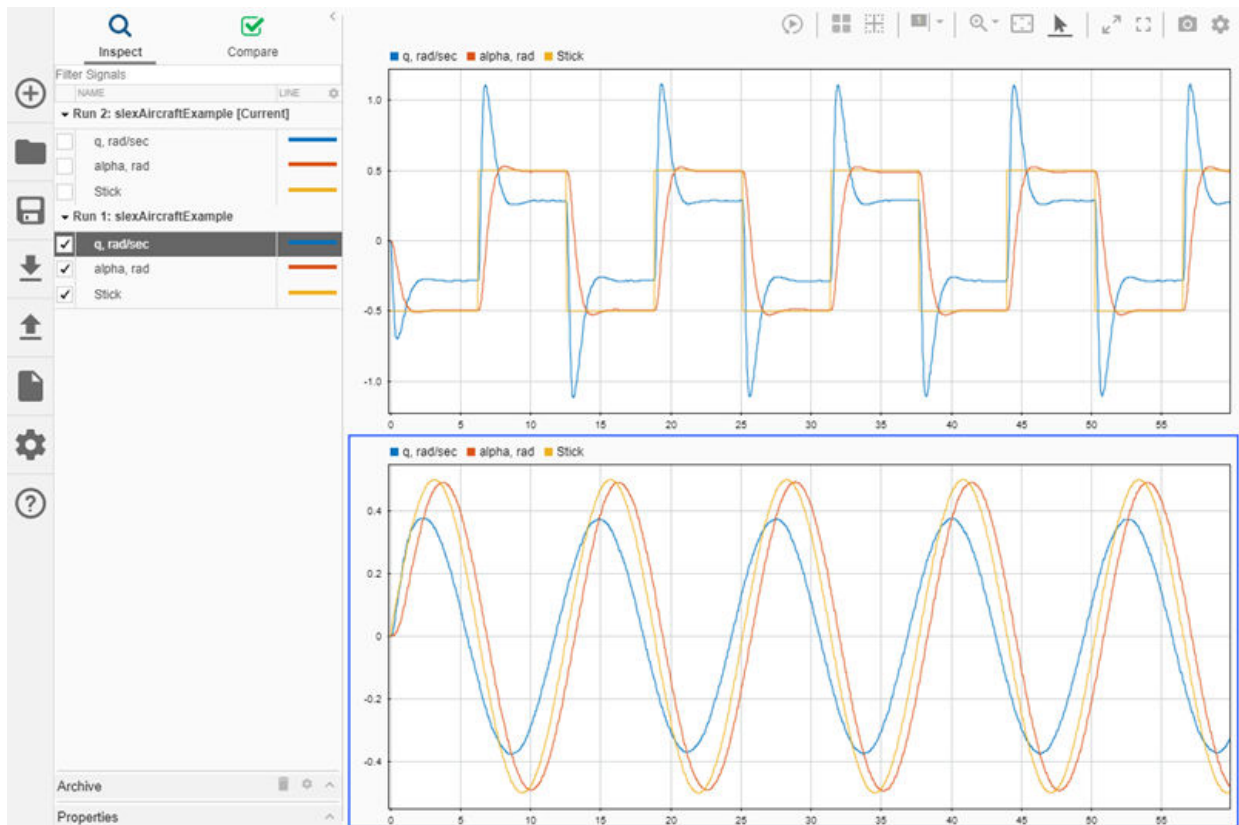

View Signals on Multiple Plots

You can use subplot layouts to view groups of signals on different subplots. For example, you can group the same signal from different simulation runs or group signals that have a similar range of values.

- 1 In the model, double-click the Pilot block. Set **Wave form** to square, and click **OK**.
- 2 Simulate the model.

- 3 By default, the Simulation Data Inspector automatically moves prior runs into the **Archive** and transfers the view to the current run. Drag Run 1 from the **Archive** into the work area.
- 4 Click the **Layout** button and select the 2×1 plot layout.
- 5 Click the lower subplot in the viewing area. In the **Inspect** pane, select the check boxes for the q , rad/sec, α , rad, and Stick , and α , rad signals under Run 1.

The check boxes in the **Inspect** pane indicate the signals plotted in the selected subplot, outlined in blue.

You can also move signals graphically, rather than using the check boxes. Click and drag the signal from the **Inspect** pane or another subplot to the subplot where you want to plot it.

For more information on working with plots, see “Create Plots Using the Simulation Data Inspector” on page 29-45.

Zoom, Pan, and Resize Plots

You can closely inspect signals in a larger viewing area using the **Maximize** and **Full Screen** options on the toolbar above the viewing area.

-  — Click the **Maximize** button to expand the active subplot to occupy the entire graphical viewing area.
-  — Click the **Full Screen** button to view your entire layout using your whole screen. The Simulation Data Inspector automatically collapses the navigation pane so your layout is as large as possible.

You can zoom and pan within subplots that use a time plot visualization to inspect signal values and the relationships between signals. The zoom and pan controls in the Simulation Data Inspector are on the toolstrip above the graphical viewing area. Each icon allows you to control the aspects of the plot using your mouse.

- You can select the zoom action for the zoom button from the drop-down.

-  When you select the zoom-in option, all the mouse actions zoom in on both the y - and t -axes. You can click the graphical viewing area to zoom in a fixed amount on

both axes. You can also click and drag to select an area to define the y - and t -axes. Scrolling with the mouse wheel zooms in and out on both axes.

-  Click the zoom-out option to zoom out a fixed amount.
-  The t -axis zoom option makes all the mouse actions zoom on the t -axis. You can click the graphical viewing area to zoom in a fixed amount. You can click and drag the graphical viewing area to select a portion of the plot as the limits for the t -axis. Scrolling with the mouse wheel zooms in and out on the t -axis.
-  When you select the y -axis zoom option, all the mouse actions zoom on the y -axis. You can click in the graphical viewing area to zoom in a fixed amount. You can also click and drag to select a portion of the plot as the limits for the y -axis. Scrolling with the mouse wheel zooms in and out on the y -axis.
-  With the mouse pointer selected, you can select signals by clicking them and pan by clicking anywhere on the plot and dragging the mouse.
-  Click the fit-to-view option to scale the axes to accommodate your plotted data.

Linked Subplots

Subplots are linked by default. Linked plots have a synchronized response when you:

- Click a plot and drag to pan.
- Perform any zoom operation.
- Fit to view.
- Adjust **T-Axis** limits.

To inspect data independently in a subplot, you can unlink the subplot.

- 1 Select the subplot you want to unlink.
- 2 Click the **Visualization Settings** button in the upper right of the viewing area.
- 3 In the **Limits** section, clear the **Link Subplot** option.

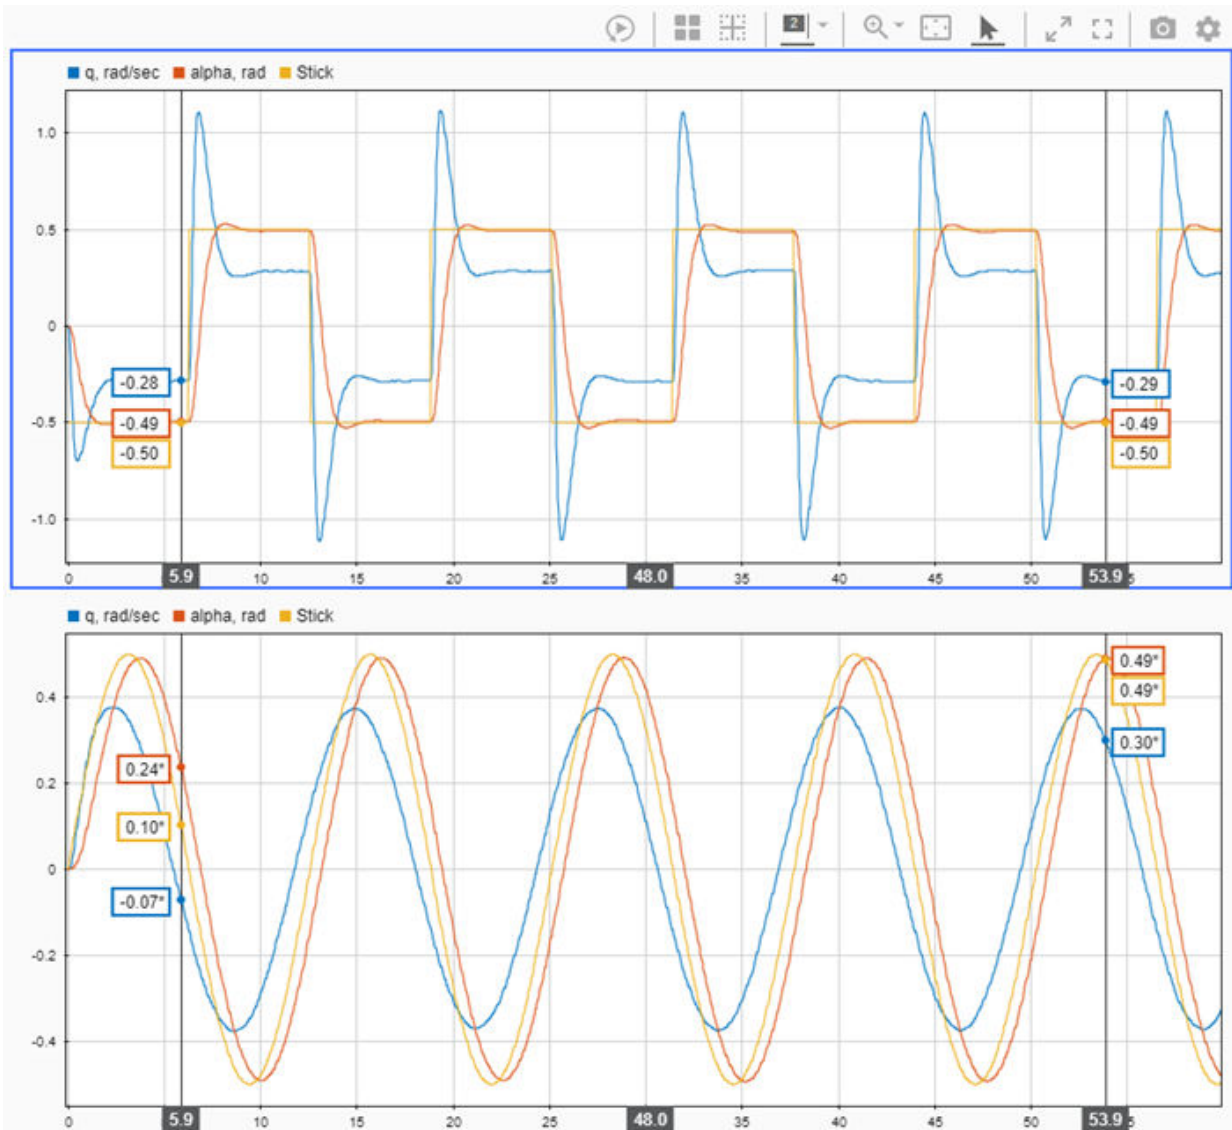

The broken link symbol  appears on the unlinked subplot.

Inspect Simulation Data Using Cursors

In the Simulation Data Inspector, you can inspect signals using data cursors. You can use one or two cursors to inspect your data. To add two cursors, select **Two Cursors** from the **Show/hide data cursors** drop-down.

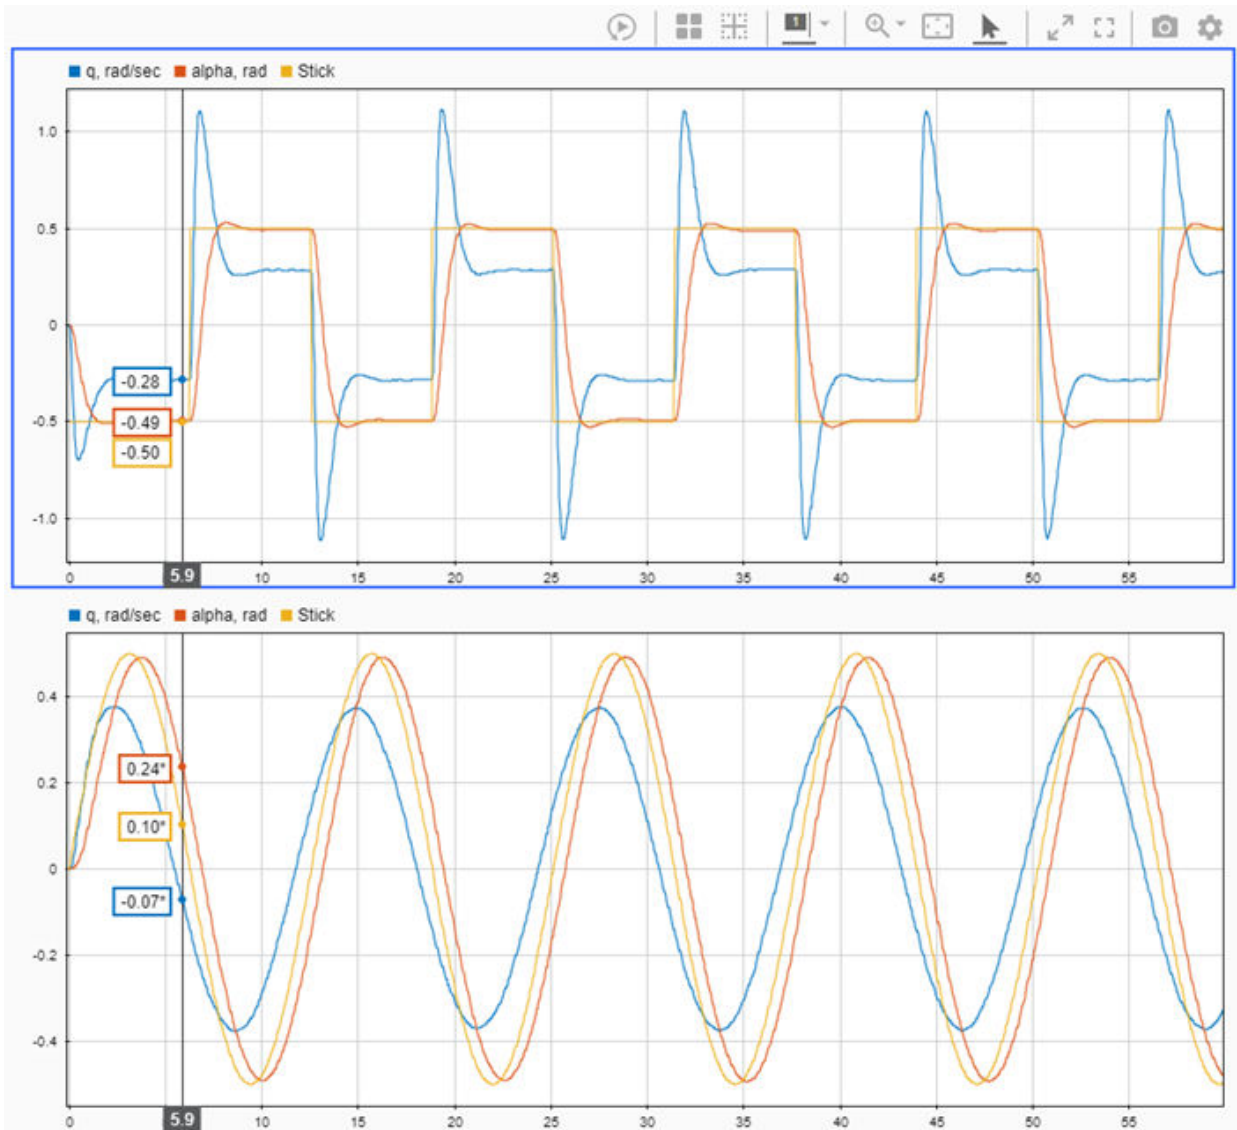

With two cursors, three time values are displayed: the time corresponding to each cursor position and the time spanned by the cursors. You can move the two cursors together by dragging the span label between the two cursors. You can also set the span by typing the desired value into the label field.

Practice inspecting data with cursors using one cursor.

- 1 Select **One Cursor** from the **Show/hide data cursors** drop-down.

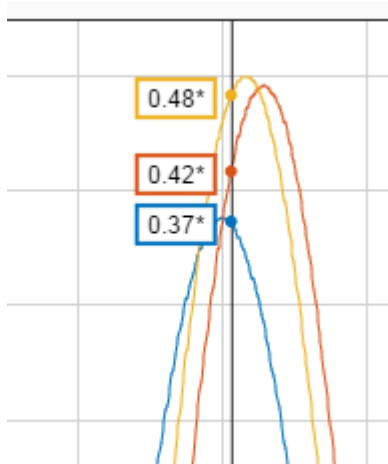

- 2 Drag the data cursor left or right to a point of interest. You can also use the arrow keys to move the data cursor from sample to sample.

To inspect the data at a specific point in time, click the cursor time field and enter the desired time value, for example 40.33.

If the signal does not have a sample at the point of interest, the Simulation Data Inspector interpolates the value for the indicated time. An asterisk in the data cursor label indicates that the displayed value is interpolated. For information regarding interpolation methods, see “Interpolation” on page 29-101.

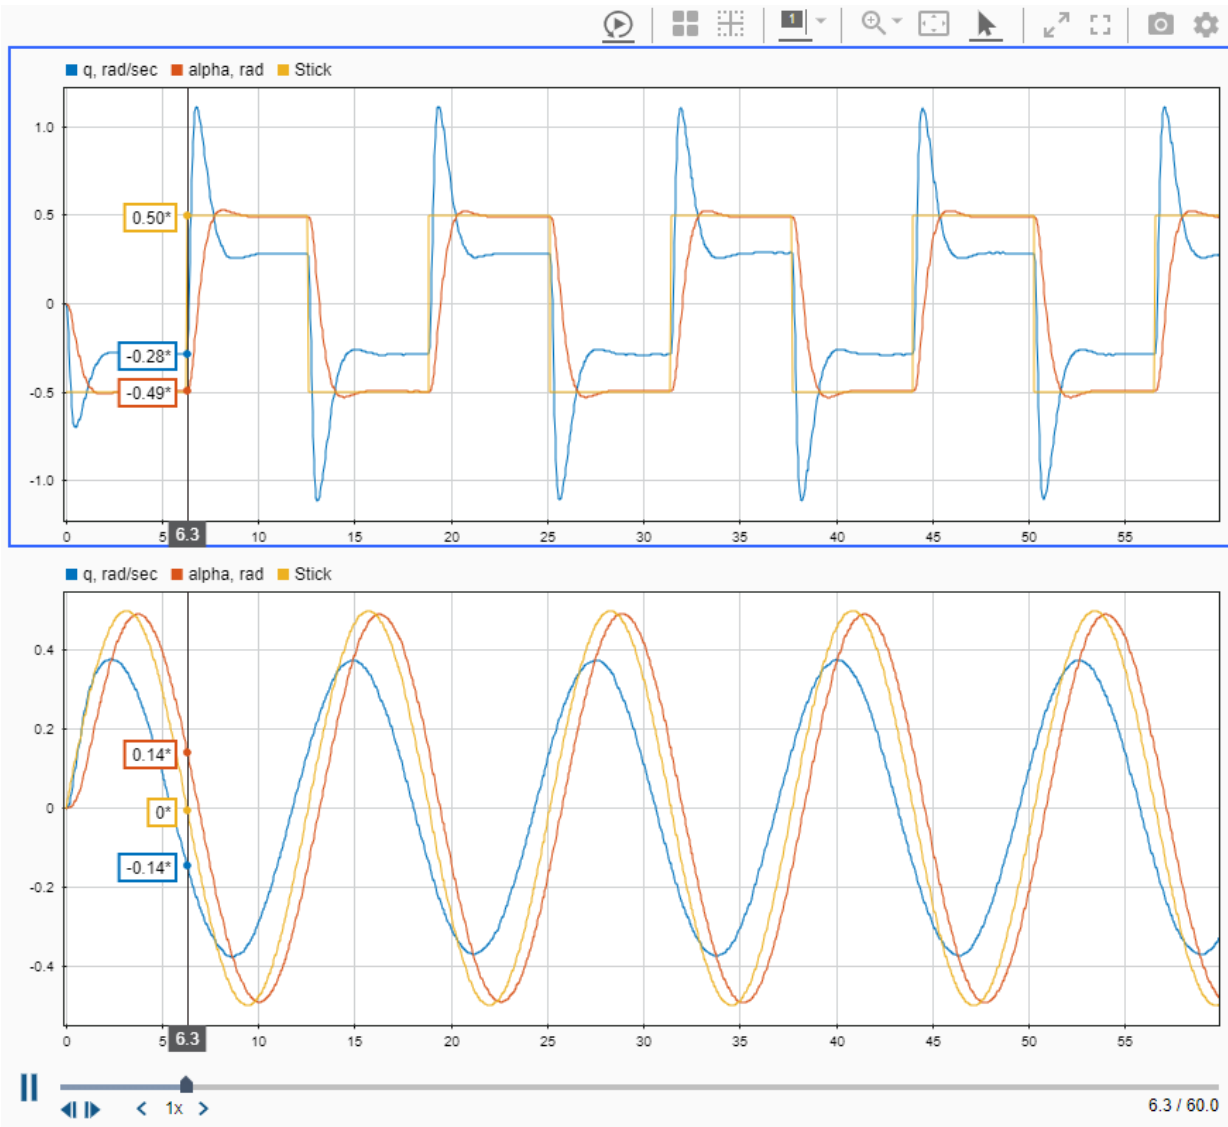

- 3 When you have finished inspecting the data, click the cursor button to remove the cursor from the viewing area.

Replay Data

You can replay data in the Simulation Data Inspector to inspect signal value changes and relationships between signals. Replaying data in the Simulation Data Inspector has no effect on any models or simulations. To replay data, first show the replay controls by

clicking the **Show/hide replay controls** button.  Then, press the **Replay** button.

The Simulation Data Inspector synchronously sweeps a cursor displaying the signal value across all subplots in the view. By default, data replays at a rate of one second per second, which means that replaying one second of data takes one second of clock time. You can adjust the replay speed using the arrows on either side of the label or by clicking the label to type the desired speed. You can also pause the replay and use the **Step forward** and **Step backward** buttons to inspect signal values, sample by sample. For a detailed example, see “Replay Data in the Simulation Data Inspector” on page 29-80.

Inspect Metadata

The Simulation Data Inspector allows you to view run and signal metadata. You can view signal metadata in the **Properties** pane or in the table of signals under each run. You can view run data only in the **Properties** pane.

The **Properties** pane displays the metadata for the selected run or signal. You can edit properties using the white box in the **Values** column. When you view a comparison, the Simulation Data Inspector highlights metadata differences in red.

Properties	
Name	q, rad/sec
Line	
Units	rad/s
Data Type	double
Complexity	Real
Complex Format	Real-Imaginary
Sample Time	Continuous
Model	slexAircraftExample
Block Name	Aircraft Dynamics Model
Block Path	slexAircraftExample/Ai...

Override Global Tolera...	no
Absolute Tolerance	0
Relative Tolerance	0.00%
Time Tolerance	0
Interp Method	linear
Sync Method	union

Columns in the navigation pane allow you to display signal properties in the table of signals under each run. To add or remove columns in the table, select the columns you want to display from the list on the **Columns** tab of the navigation pane's **Preferences** menu. Columns appear in the table in the order in which you select them.

The screenshot shows the 'Inspect' tool interface. At the top, there are 'Inspect' and 'Compare' tabs. Below them is a 'Filter Signals' section with a table of signals for two runs. The 'Columns' panel is open on the right, showing a legend for signal types (q, alpha, Stick) and a list of columns to display. The 'Line' column is checked.

Run	Signal Name	Unit	Color
Run 2: slexAircraftExample [Current]	<input checked="" type="checkbox"/> q, rad/sec	rad/sec	Blue
	<input type="checkbox"/> alpha, rad	rad	Orange
	<input type="checkbox"/> Stick		Yellow
Run 1: slexAircraftExample	<input type="checkbox"/> q, rad/sec	rad/sec	Blue
	<input type="checkbox"/> alpha, rad	rad	Orange
	<input type="checkbox"/> Stick		Yellow

- Restore Defaults

Property Descriptions

Property Name	Value
Line	Signal line style and color
Units	Signal measurement units
Data Type	Signal data type
Complexity	Signal type — real or complex
Complex Format	Format for visualizing complex data
Sample Time	Type of sampling
Model	Name of the model that generated the signal
Block Name	Name of the signal's source block
Block Path	Path to the signal's source block
Port	Index of the signal on the block's output port
Dimensions	Dimensions of the matrix containing the signal
Channel	Index of signal within matrix
Run	Name of the simulation run containing the signal
Absolute Tolerance	User-specified, positive-valued absolute tolerance for the signal
Relative Tolerance	User-specified, positive-valued relative tolerance for the signal
Override Global Tolerance	User-specified property that determines whether signal tolerances take priority over global tolerances
Time Tolerance	User-specified, positive-valued time tolerance for the signal
Interp Method	User-specified interpolation method used to plot the signal
Sync Method	User-specified synchronization method used to coordinate signals for comparison

Property Name	Value
Time Series Root	Name of the variable associated with signals imported from the MATLAB workspace
Time Source	Name of the array containing the time data for signals imported from the MATLAB workspace
Data Source	Name of the array containing the data for signals imported from the MATLAB workspace

On the **Compare** pane, many parameters have a **Baseline** column and a **Compare To** column that you can display independently. If the **Baseline** and **Compare to** signals both have a property, but you can only display one property column, the column shows the **Baseline** property. In addition to the parameters listed for the **Inspect** pane, the **Compare** pane has columns specific to comparisons.

- **Max Difference** — The maximum difference between the **Baseline** and **Compare to** signals
- **Align By** — Primary signal alignment criterion specified in the **Alignment** tab of the Simulation Data Inspector **Preferences** menu

By default, the table displays the baseline name column and a column indicating whether the comparisons passed or failed.

- “Save and Share Simulation Data Inspector Data and Views” on page 29-38

Modify Signal Properties in the Simulation Data Inspector

You can modify signal units, data type, and names in the Simulation Data Inspector. When you modify the units and data type metadata for a signal, the Simulation Data Inspector converts the signal values. Changes made to signal properties in the Simulation Data Inspector do not affect any models, files, or workspace variables. You may want to save the original signal data or export modified signal data to use as simulation input. You can export data from the Simulation Data Inspector to the workspace or a file. For more information, see “Export Data from the Simulation Data Inspector” on page 29-43.

This example uses data from a simulation of the `slexAircraftExample` model. To generate the data for this example:

- 1 Enter `slexAircraftExample` in the MATLAB Command Window.
- 2 To log the `q`, `rad/sec`, the `Stick`, and the `alpha`, `rad` signals to the Simulation Data Inspector, select the signals in the model. Then, right-click the selection, and choose **Log Selected Signals** from the context menu.
- 3 Double-click the Pilot block. Set **Wave form** to `sine`, and click **OK**.
- 4 Simulate the model.

Modify Signal Units

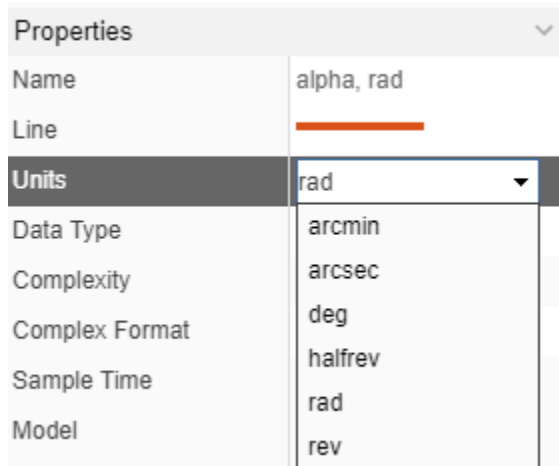

You can specify and modify signal units in the Simulation Data Inspector. The units you specify are properties of the signals in the Simulation Data Inspector only and do not affect the signal properties in models. To learn how to specify units in a model, see “Unit Specification in Simulink Models” on page 9-2.

The `slexAircraftExample` model does not specify units for its signals. However, some signal names indicate the intended units.

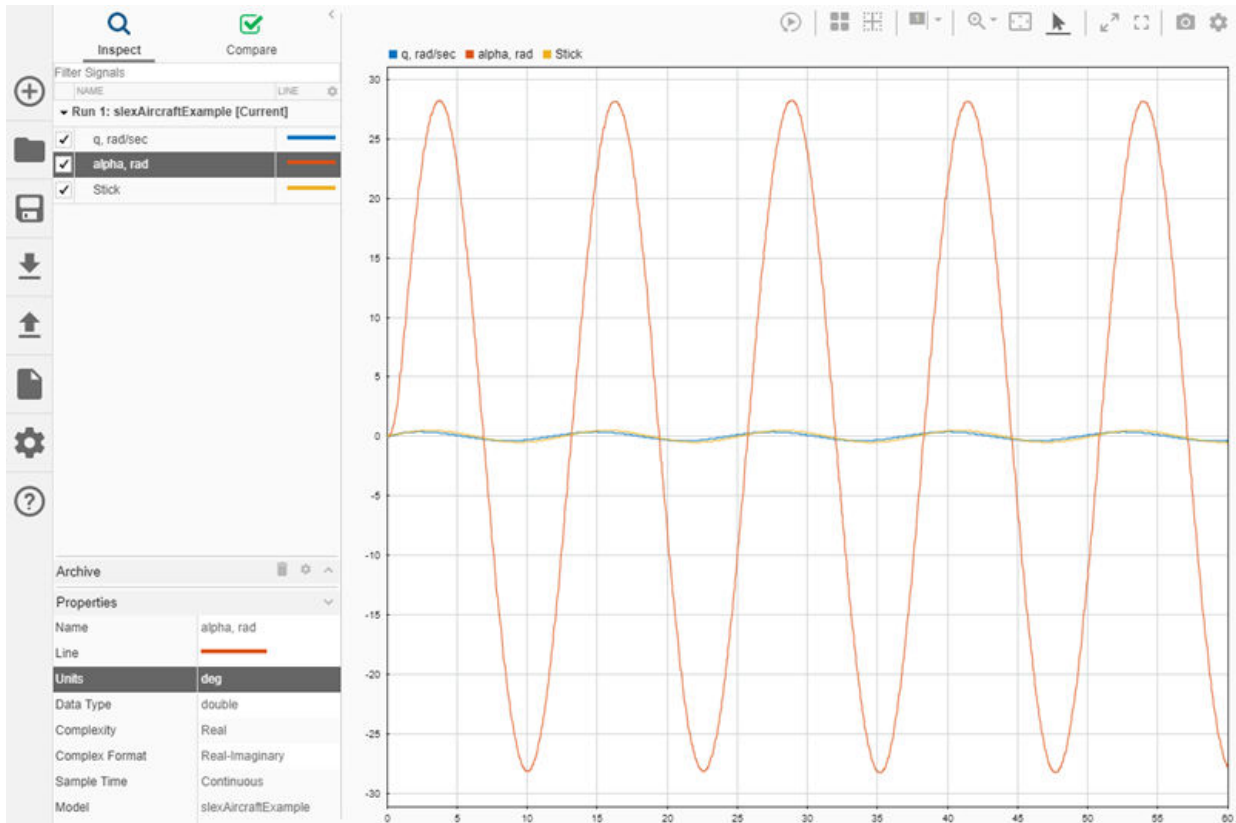

- 1 Select the `alpha`, `rad` signal in the **Inspect** pane.
- 2 To view the properties for the selected signal, expand the **Properties** pane.
- 3 To specify units of radians for the signal, type `rad` into the white text box next to the **Units** property in the **Properties** pane.

For a list of units supported by Simulink, enter `showunitslist` at the MATLAB Command Window.

Now, the Simulation Data Inspector interprets the data for the `alpha, rad` signal as having units of `rad`. Once a signal has units Simulink recognizes, you can convert the signal to supported compatible units using the Simulation Data Inspector. When you click the **Units** text box to modify the units, the Simulation Data Inspector provides a drop-down list of compatible units for converting the signal.

Change the `alpha, rad` signal units to `deg` either using the drop-down or by typing the new units into the **Units** field for the signal. When you change the units, the Simulation Data Inspector performs the conversion, and the plot updates to show the converted signal values.

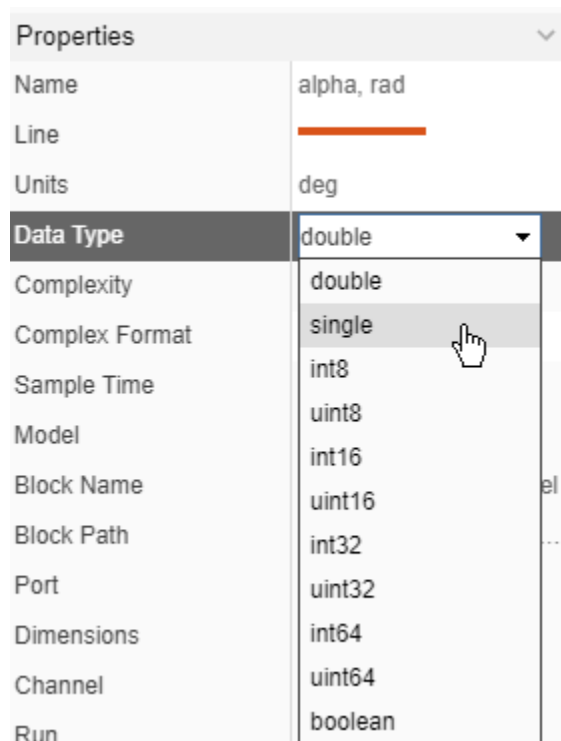

Modify Signal Data Type

You can modify the data type for a signal to analyze the effect on signal values or to create a signal to use as simulation input. Converting the data type in the Simulation Data Inspector does not affect any signal properties in the model. You can convert signal data types to all built-in data types. If you have a license for Fixed-Point Designer, you can also convert to fixed-point data types. For a list of built-in data types, see “Data Types Supported by Simulink” on page 62-6.

Note When you convert to a lower precision data type, you lose precision in the data that cannot be recovered. You can save a copy of the data in the Simulation Data Inspector

before changing signal data types. For more information, see “Save and Share Simulation Data Inspector Data and Views” on page 29-38.

The data type for the `alpha, rad` signal is `double`. Suppose you want to convert the data type to `single`. First, select the `alpha, rad` signal. Then, expand the **Properties** pane and click the white text field next to the **Data Type** property. You can type `single` or select it from the drop-down of data types. The Simulation Data Inspector converts the data when you click outside the drop-down.

Because the `single` data type has less precision than the `double` data type, the Simulation Data Inspector returns a warning about irreversible precision loss. Click **Continue**. The plot shows no visible difference in the signal. If you saved the data for the original signal, you can compare the converted signal to analyze the effect of changing the data type. For more information on comparing data in the Simulation Data Inspector, see “Compare Simulation Data” on page 29-86.

Fixed-Point Conversions

If you have a license for Fixed-Point Designer, you can convert signal data types to fixed-point data types in the Simulation Data Inspector. Specify the data type in the **Data Type** property text box using the `fixdt` function.

Modify Signal Names

You can modify the names of signals in the Simulation Data Inspector. Changing the name of a signal in the Simulation Data Inspector does not affect signal names specified in the model. You can specify a new name from the work area, the **Archive**, or the **Properties** pane. To modify the signal name, click the signal name and type the new name. For example, change the name of the `alpha, rad` signal to `a_lpha` because the **Units** property has the units information, now.

	NAME	LINE	
▼ Run 1: slexAircraftExample [Current]			
<input checked="" type="checkbox"/>	q, rad/sec		—
<input checked="" type="checkbox"/>	alpha		—
<input checked="" type="checkbox"/>	Stick		—

When you export data from the Simulation Data Inspector after modifying the name, the exported data uses the new name.

- “Compare Simulation Data” on page 29-86
- “Create Plots Using the Simulation Data Inspector” on page 29-45

Replay Data in the Simulation Data Inspector

This example shows how to replay data in the Simulation Data Inspector to inspect and build intuitive understanding of your data. When you replay data, a cursor sweeps synchronously across all the subplots in your view, displaying signal values. You can control the replay speed, pause to move the cursor sample-by-sample, and zoom to inspect your data. You can replay imported data and data logged from a simulation.

This example uses logged simulation data saved in a session. The session contains two runs containing data logged from the `ex_vdp_mu` model. Data from Run 1: `ex_vdp_mu` is plotted in the viewing area.

Load the session and open the Simulation Data Inspector to view the data.

```
Simulink.sdi.load('ex_vdp_mu.mldatx');  
Simulink.sdi.view
```

Replay Data

When you replay data, the Simulation Data Inspector animates synchronized cursors to move through a time period defined by the maximum time among the plotted signals. Replaying and pausing in the Simulation Data Inspector has no effect on any models or simulations.

To show the replay controls in the Simulation Data Inspector, click the **Show/hide replay controls** button.

Click the **Replay** button.

Synchronized cursors sweep across the subplots, indicating the signal value as the cursor moves in time. By default, the Simulation Data Inspector replays data at a rate of one second per second, meaning that the cursor moves through one second of data in the span of one second of clock time. You can adjust the replay speed to suit the data you want to inspect. To change the speed, click one of the arrows on either side of the label or click the label and type your desired replay speed.

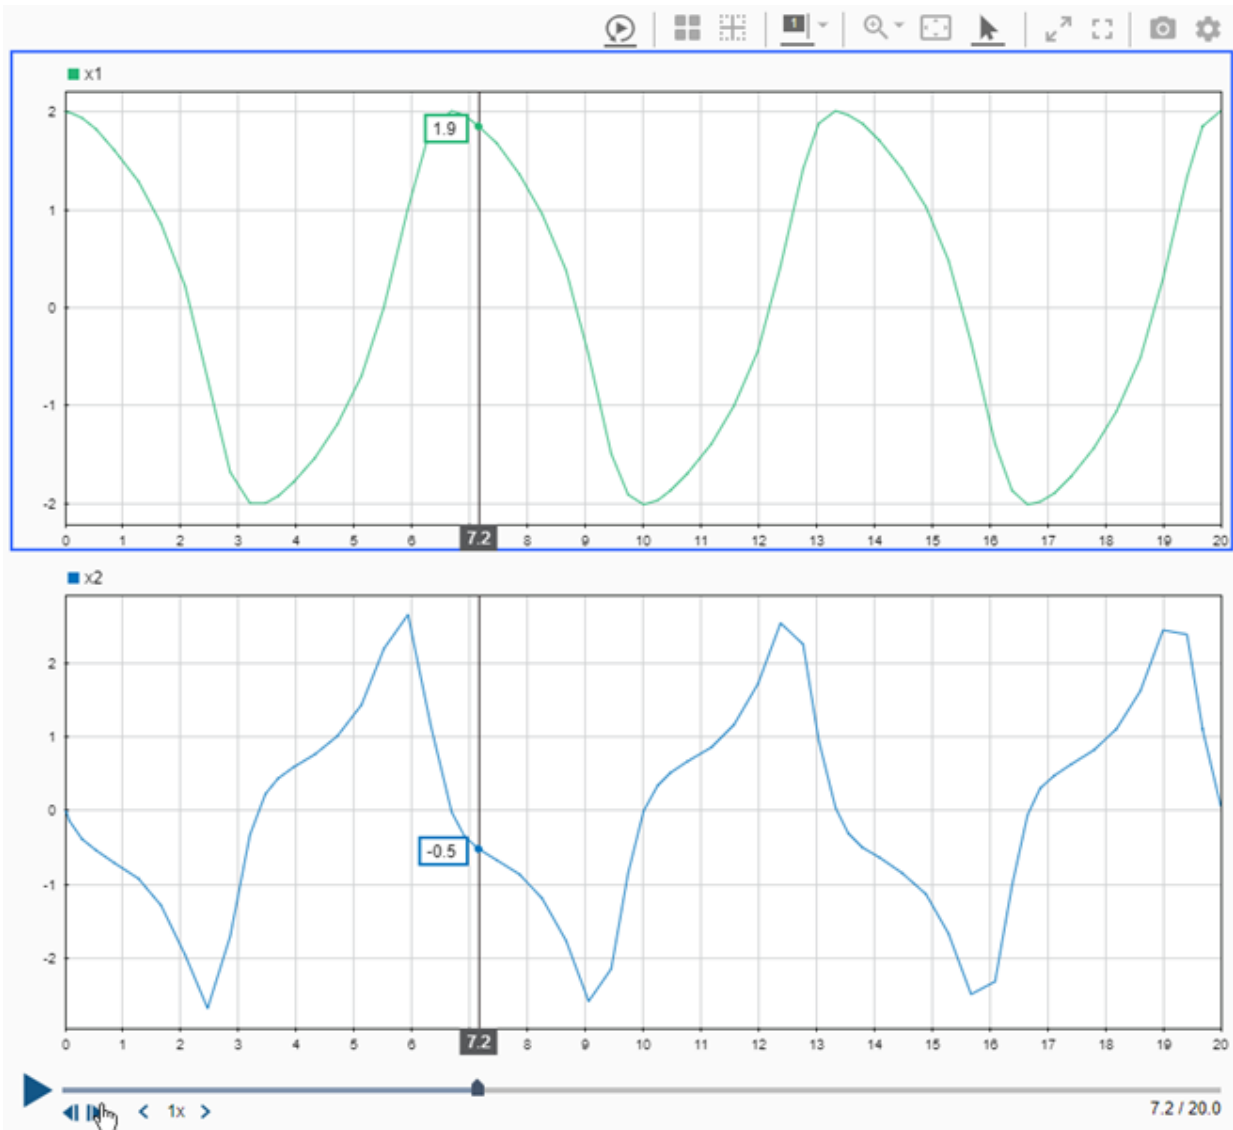

The Simulation Data Inspector moves the cursor based on the maximum time in the plotted signals and the replay speed. The position of the cursor at a given time during replay does not depend on the time values for samples in the plotted signals. When the

cursor position does not correspond with a sample in a plotted signal, the Simulation Data Inspector interpolates a value to display, based on the **Interpolation** property of the signal. An asterisk at the end of the cursor value indicates that the value is interpolated.

Inspect Data Values During Replay

To inspect sample values in your data, you can pause the replay. When the replay is paused, you can use the **Step forward** and **Step backward** buttons to move the cursor sample-by-sample. The cursors move to the next time point among all plotted signals. When a plotted signal does not have a sample, the Simulation Data Inspector interpolates the value.

Pause the replay and use the **Step forward** and **Step backward** buttons to view the signal values.

Zoom During Replay

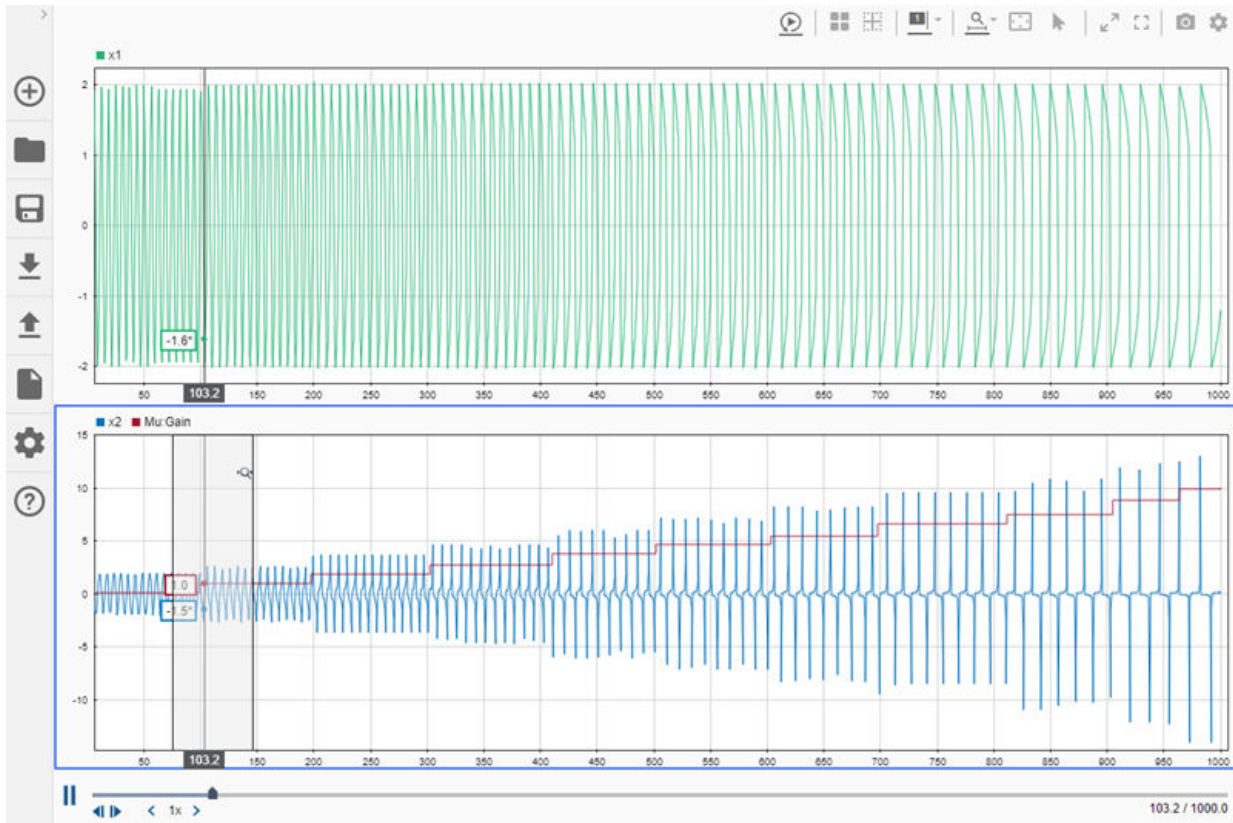

You can zoom in on a region of your data during replay to inspect signal values and relationships more closely. Viewing a portion of your signal can be particularly useful

when your data spans a long duration with a high sample rate. For example, plot the signals from Run 2: `ex_vdp_mu`.

The data in run 2 corresponds to a much longer simulation of the `ex_vdp_mu` model, where the value of `Mu` changed over the course of the simulation. Viewing the entire signal at once makes analyzing the changing characteristics of the curve difficult. Before replaying the data, change the limits for the time plots in the **Visualization settings** to show the first 100 seconds. You can also collapse the navigation pane to allow the viewing area to occupy more space. Then, replay the data.

When the cursor nears the end of the zoomed portion of the data, click the **Fit to view** button to show the complete signal. Then, you can use the **Zoom in time** option to select another region of the signal to inspect more closely during the replay.

When replaying a long simulation, you can also adjust the replay speed or drag the time marker to replay data in an area of interest.

Compare Simulation Data

The Simulation Data Inspector can compare the data and metadata for runs and individual signals. You can analyze comparison results using tolerances, and you can control aspects of the comparison through comparison settings. For more information about tolerance calculations and the comparison settings, see “How the Simulation Data Inspector Compares Data” on page 29-98.

The runs and signals used in this example are relatively small and simple. When you compare long signals or runs containing many signals, the Simulation Data Inspector displays incremental progress indicators during the comparison, and the **Compare** button becomes a **Cancel** button you can click to cancel the comparison at any point. For hierarchical data, the **Results** column in the comparison view summarizes the results on each hierarchical node.

 37 Within tolerance 82 Out of tolerance

This example uses data generated in “Inspect Simulation Data” on page 29-58.

Setup

This example continues from “Inspect Simulation Data” on page 29-58. You can also use this script to generate the data required for the example.

```
load_system('slexAircraftExample')
```

```
% Configure signals to log
```

```
Simulink.sdi.markSignalForStreaming('slexAircraftExample/Pilot', 1, 'on')
```

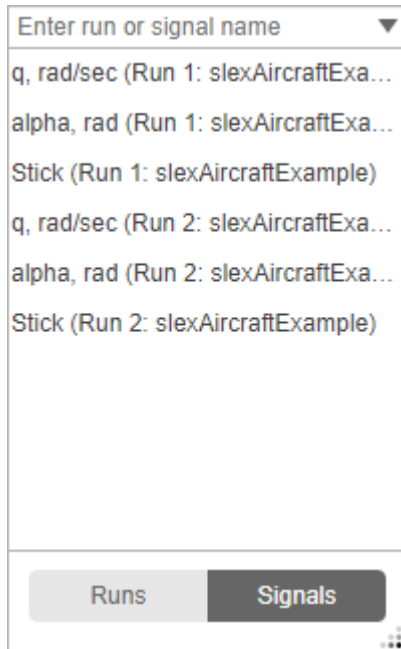

```
Simulink.sdi.markSignalForStreaming('slexAircraftExample/Aircraft Dynamics Model', 3,  
Simulink.sdi.markSignalForStreaming('slexAircraftExample/Aircraft Dynamics Model', 4,  
  
% Change Pilot signal to sine  
set_param('slexAircraftExample/Pilot', 'WaveForm', 'sine')  
  
% Simulate model  
sim('slexAircraftExample')  
  
% Change Pilot signal to square  
set_param('slexAircraftExample/Pilot', 'WaveForm', 'square')  
  
% Simulate Model  
sim('slexAircraftExample')
```

Compare Signals

You can compare signals to analyze the relationship between your model's inputs and outputs. For example, compare the `Stick` input signal to the output observed at `alpha, rad`. Then, specify tolerance values to analyze the result.

To compare the `alpha, rad` signal to the `Stick` signal:

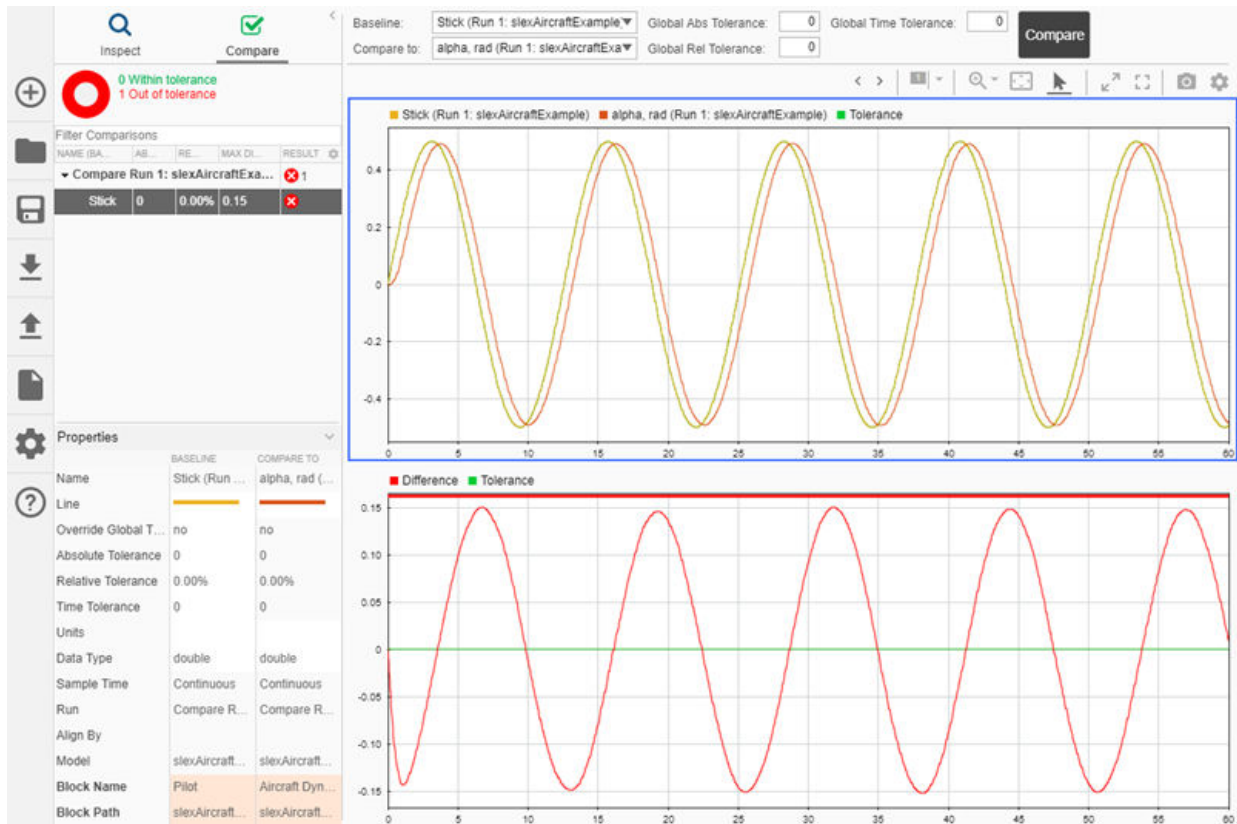

- 1 Navigate to the **Compare** pane.
- 2 To view a list of signals available for comparison, click the **Baseline** text box, and select **Signals**.

- 3 Select Stick (Run 1: slexAircraftExample).
- 4 Click the **Compare to** text box, and select **Signals**.
- 5 Select alpha, rad (Run 1: slexAircraftExample).
- 6 Click **Compare**.

Alternatively, you can select the **Baseline** and **Compare to** signals through the context menu by right-clicking the signal in the **Inspect** pane.

The signals do not match within the absolute, relative, and time tolerances, all set to 0 by default.

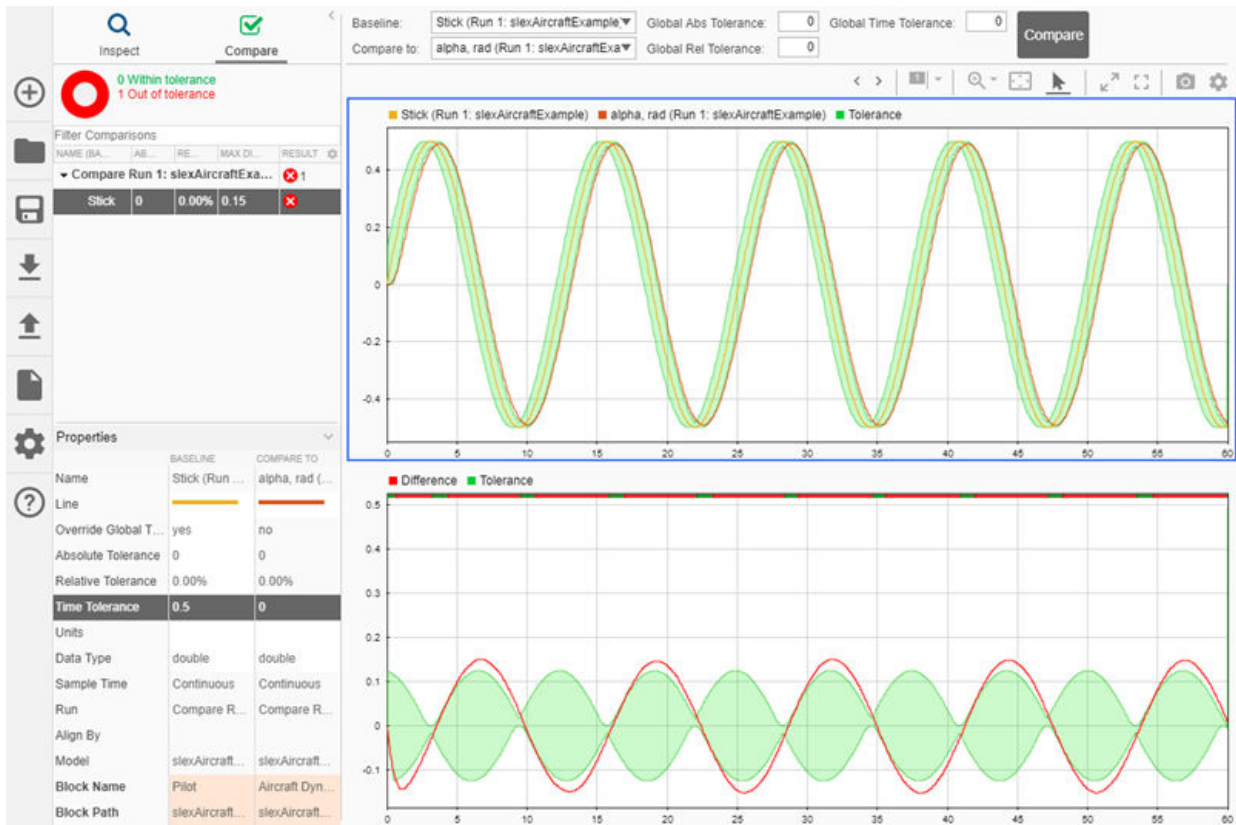

Signal Time Tolerance

Looking at the top plot in the comparison view, you can see the α , rad signal lags the Stick signal. For signal comparisons, the Simulation Data Inspector uses tolerance values for the **Baseline** signal. Add a time tolerance to the Stick signal to account for the lag.

Select the Stick signal and enter 0.5 in the **Time Tolerance** field of the **Properties** pane. When you specify a tolerance for a **Baseline** signal, its **Override Global Tolerance** field automatically changes to yes. When you click away from the **Time Tolerance** field, the comparison runs again, using the signal-level tolerance you specified. If you want to use global tolerance values for the signal, click the **Override Global Tolerance** field and select no from the drop-down.

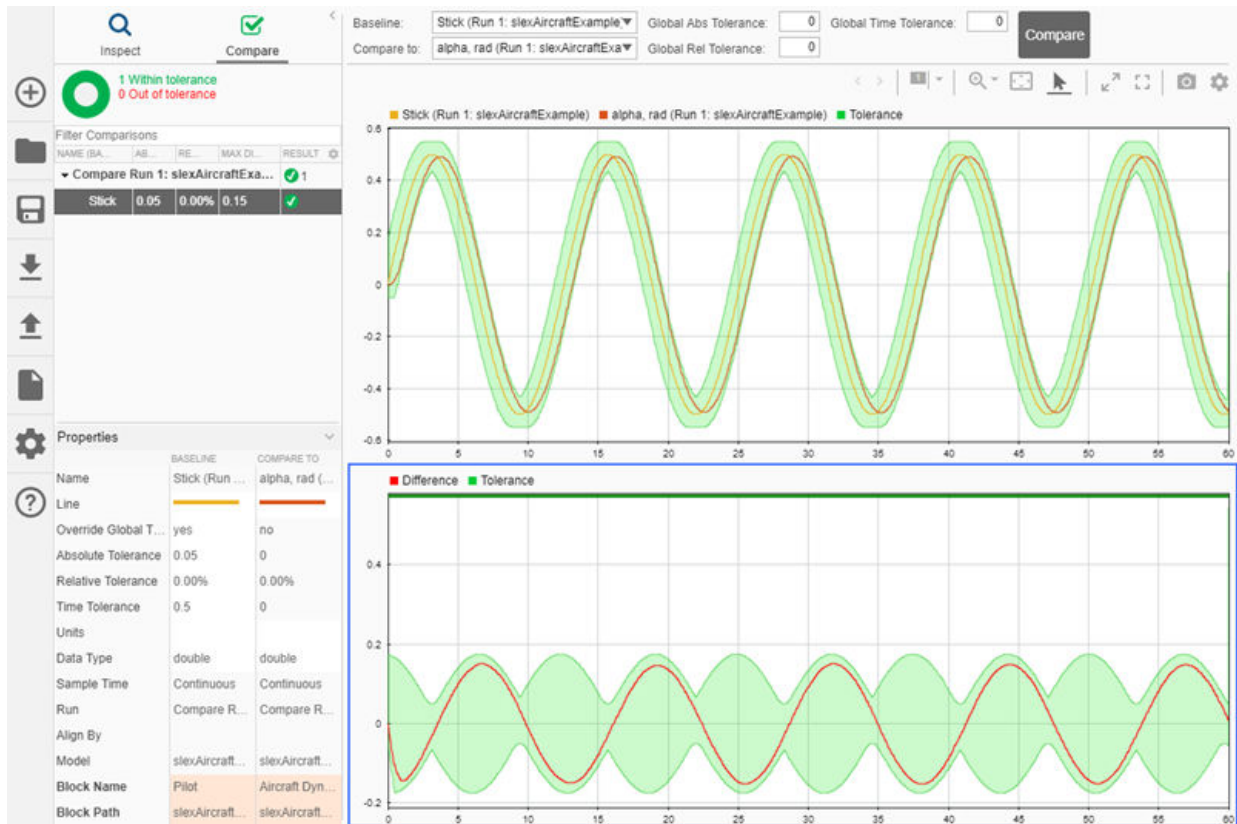

The Simulation Data Inspector draws the tolerance band around the plotted **Baseline** signal and around the signed difference signal displayed in the bottom subplot. The bar along the top of the difference plot shows regions within tolerance and out of tolerance for the comparison in green and red.

Signal Magnitude Tolerance

The time tolerance covers the phase difference between the two signals, but the comparison still includes regions out of tolerance due to the amplitude difference. You can add a magnitude tolerance as either an **Absolute Tolerance** or **Relative Tolerance**.

To add an absolute tolerance to the **Stick** signal, enter 0.05 into the **Absolute Tolerance** field in the properties pane. With the combination of the absolute and time tolerances, the signal comparison passes.

Note The Simulation Data Inspector draws the tolerance region with the most lenient interpretation of the specified tolerances for each point. For more information on how the Simulation Data Inspector calculates the tolerance band, see “Tolerance Specification” on page 29-102.

Compare Runs

You can also use the Simulation Data Inspector to compare signals in a run at once. Run comparisons can provide useful information about the effects of changing model parameters. For example, change the frequency cutoff of the filter for the control stick

input signal. Then, evaluate the effect on the output signal with the Simulation Data Inspector.

- 1 Click the **Model Explorer** button  to access the **Model Workspace** variables.
- 2 Change the value of Ts in the **Model Workspace** from 0.1 to 1 and close the **Model Explorer**.
- 3 Simulate the model with the new filter.
- 4 On the **Compare** pane in the Simulation Data Inspector, click the **Baseline** text box, and select **Runs**.
- 5 From the list of runs, select Run 2: `slexAircraftExample`.
- 6 Click the **Compare to** text box, and select **Runs**.
- 7 Select Run 3: `slexAircraftExample` and click **Compare**.

The **Compare** pane lists all signals from the compared runs and summarizes the results of the comparison in the **Results** column. In this example, all three signals aligned, and none matched within the specified tolerance values, all of which are set to zero.

NAME (BA...	AB...	RE...	MAX DI...	RESULT 
▼ Compare Run 3: <code>slexAircraftExa...</code>				 3
q, rad/s	0	0.00%	1.00	
alpha, r	0	0.00%	0.49	
Stick	0	0.00%	0.78	

Note The Simulation Data Inspector only compares signals from the **Baseline** run that align with a signal from the **Compare To** run. If a signal from the **Baseline** run does not align with a signal from the **Compare To** run, the signal is listed in the **Compare** pane

with a warning. . For more information on signal alignment, see “Signal Alignment” on page 29-98.

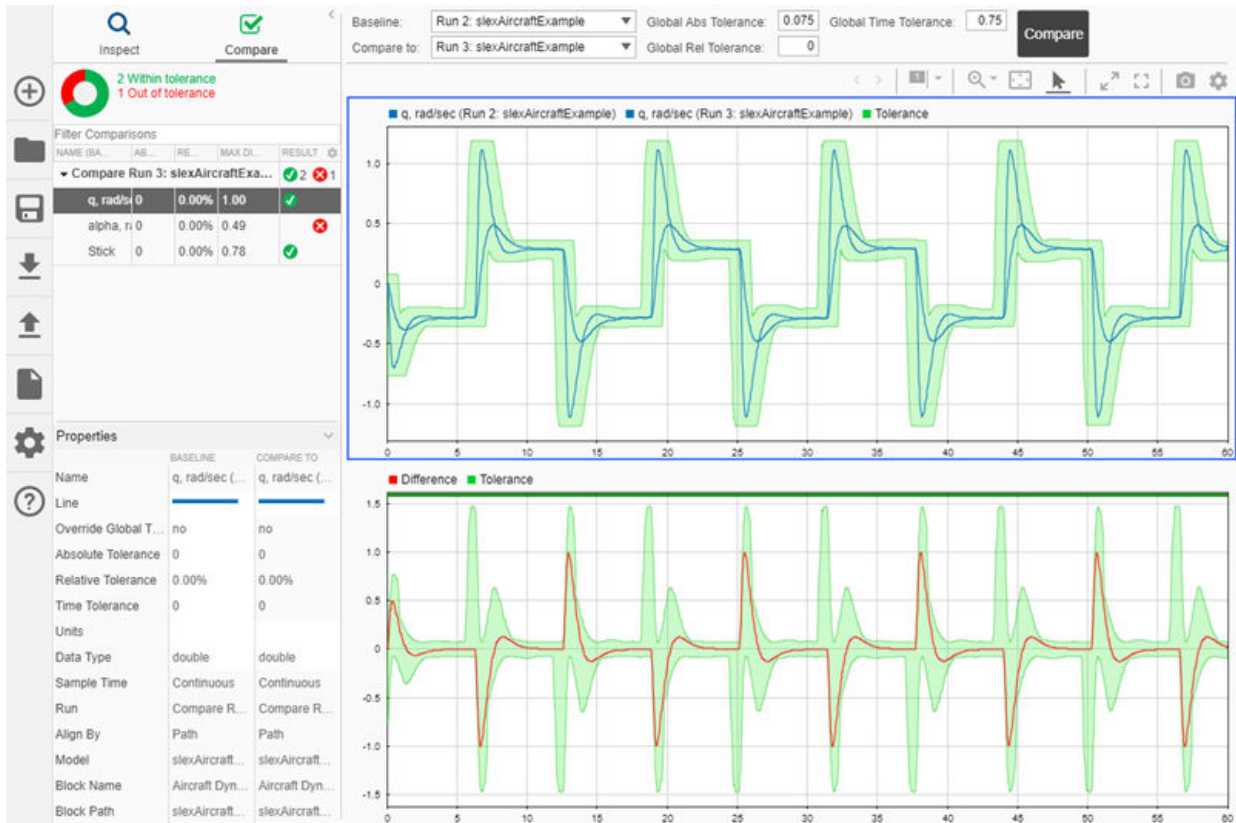

To plot comparison data, select the signal you want to see in the **Compare** pane. Here, the top plot shows the q , rad/sec signals from the **Baseline** and **Compare To** runs. The bottom plot shows the difference between the signals and a graphical representation of the tolerance.

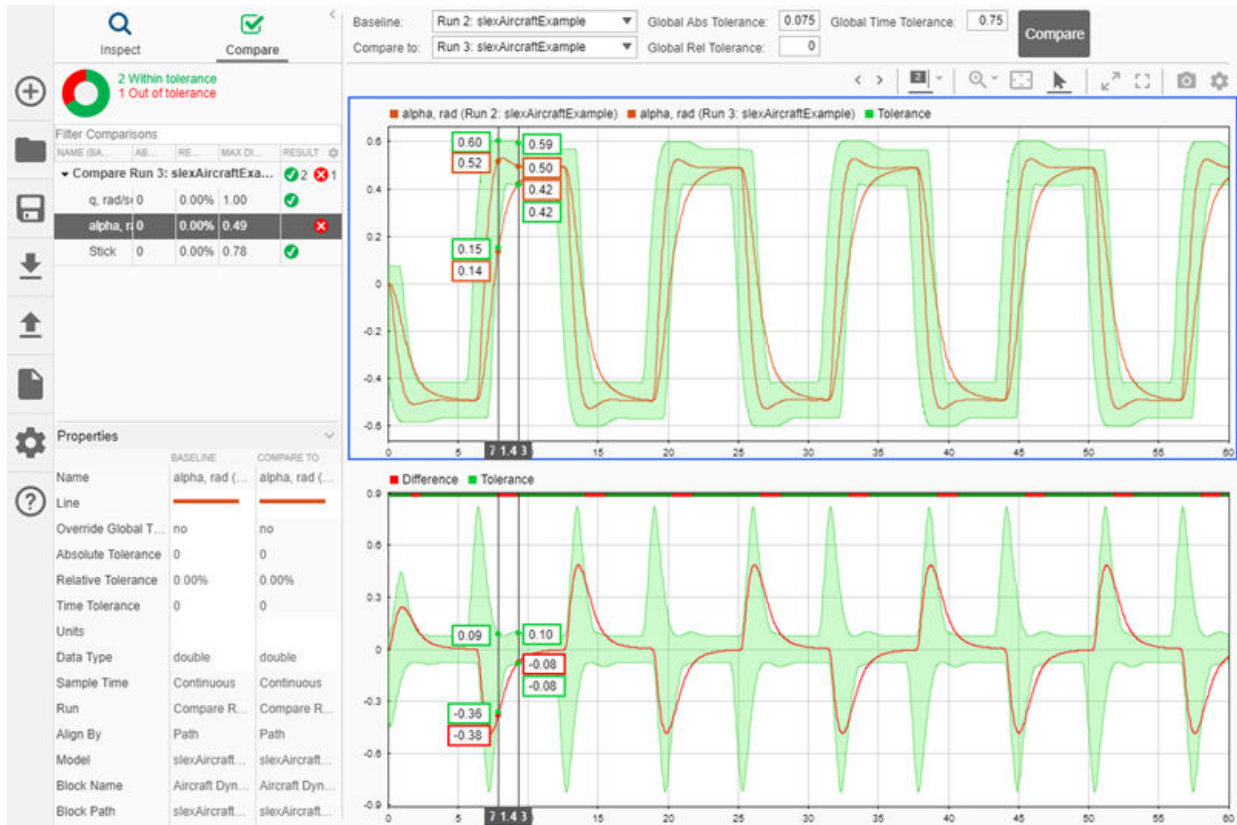

Global Tolerances

To qualify signals in the run comparison, you can add global tolerances to the comparison. Change the **Global Time Tolerance** to 0.75 and the **Global Abs Tolerance** to 0.075,

and click the **Compare** button to run the comparison. The Simulation Data Inspector draws the tolerance band around the **Baseline** signal and on the signed difference plot on the lower half of the graphical viewing area. With the new tolerance values, the Stick and q , rad/sec signals pass the comparison.

View the α , rad signal to analyze the comparison's out of tolerance regions. Click the arrow buttons   in the tool strip to navigate through the out of tolerance regions. Two cursors on the plot show the beginning and end of the first out of tolerance region. You can use your keyboard arrows to explore the signal and tolerance values throughout each out of tolerance region. To view the next out of tolerance region, click the right arrow button in the tool strip.

To resolve the out of tolerance regions, you can choose to modify the global tolerance values or to add a signal specific tolerance to the α , rad signal using the signal properties.

How the Simulation Data Inspector Compares Data

You can tailor the Simulation Data Inspector comparison process to fit your requirements in multiple ways. When comparing runs, the Simulation Data Inspector:

- 1 Aligns signal pairs in the **Baseline** and **Compare To** runs based on the **Alignment** settings.

The Simulation Data Inspector does not compare signals that it cannot align.

- 2 Synchronizes aligned signal pairs according to the specified **Sync Method**.

Values for time points added in synchronization are interpolated according to the specified **Interpolation Method**.

- 3 Computes the difference of the signal pairs.
- 4 Compares the difference result against specified tolerances.

When the comparison run completes, the results of the comparison are displayed in the navigation pane.

Status	Comparison Result
	Difference falls within the specified tolerance.
	Difference violates specified tolerance.
	The signal does not align with a signal from the Compare To run.

When you compare signals with differing time intervals, the Simulation Data Inspector compares the signals on their overlapping interval.

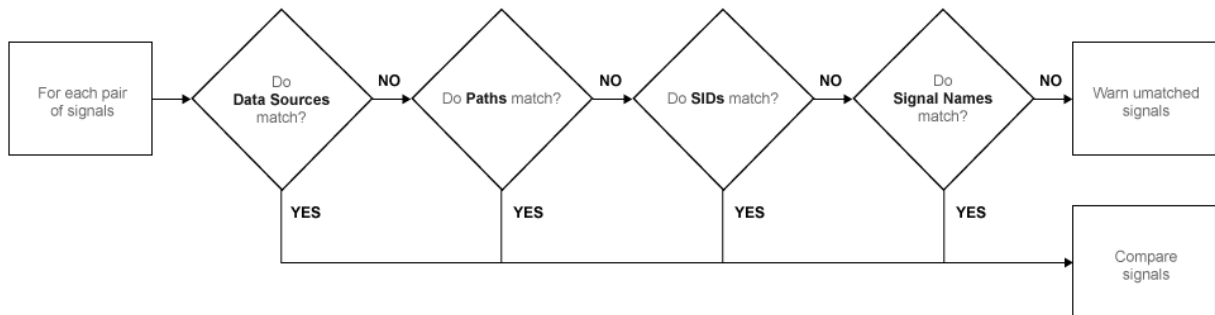

Signal Alignment

In the alignment step, the Simulation Data Inspector decides which signal from the **Compare To** run pairs with a given signal in the **Baseline** run. When you compare signals with the Simulation Data Inspector, you complete the alignment step by selecting the **Baseline** and **Compare To** signals.

The Simulation Data Inspector aligns signals using a combination of their Data Source, Path, SID, and Signal Name properties.

Property	Description
Data Source	Path of the variable in the MATLAB workspace for data imported from the workspace
Path	Block path for the source of the data in its model
SID	Simulink identifier For more information about SIDs, see “Locate Diagram Components Using Simulink Identifiers” on page 1-18
Signal Name	Name of the signal in the model

With the default alignment settings, the Simulation Data Inspector aligns signals between runs according to this flow chart.

You can specify the priority for each of the signal properties used for alignment in the Simulation Data Inspector **Preferences**. The **Align By** field specifies the highest priority property used to align signals. The priority drops with each subsequent **Then By** field. You must specify a primary alignment property in the **Align By** field, but you can leave any number of the **Then By** fields blank.

Synchronization

Often, signals that you want to compare don't contain the exact same set of time points. The synchronization step in Simulation Data Inspector comparisons resolves discrepancies in signals' time vectors. You can choose **union** or **intersection** as the synchronization method.

When you specify **union** synchronization, the Simulation Data Inspector builds a time vector that includes every sample time between the two signals. For each sample time not originally present in either signal, the Simulation Data Inspector interpolates the value. The second graph in the illustration shows the union synchronization process, where the Simulation Data Inspector identifies samples to add in each signal, represented by the unfilled circles. The final plot shows the signals after the Simulation Data Inspector has interpolated values for the added time points. The Simulation Data Inspector computes the difference using the signals in the final graph, so that the computed difference signal contains all the data points between the signals.

When you specify `intersection` synchronization, the Simulation Data Inspector uses only the sample times present in both signals in the comparison. In the second graph, the Simulation Data Inspector identifies samples that do not have a corresponding sample for comparison, shown as unfilled circles. The final graph shows the signals used for the comparison, without the samples identified in the second graph.

The choice between the synchronization options involves a trade off between speed and accuracy. The interpolation required by `union` synchronization takes time, but provides a more precise result. When you use `intersection` synchronization, the comparison finishes quickly because the Simulation Data Inspector computes the difference for fewer data points and does not interpolate. However, some data is discarded and precision lost with `intersection` synchronization.

Interpolation

The interpolation property of a signal determines how the Simulation Data Inspector displays the signal and how additional data values are computed in synchronization. You can choose to interpolate your data with a zero-order hold (`zoh`) or a linear approximation.

When you specify **zoh** for the **Interpolation Method**, the Simulation Data Inspector replicates the data of the previous sample for interpolated sample times. When you specify **Linear** interpolation, the Simulation Data Inspector uses samples on either side of the interpolated point to linearly approximate the interpolated value. Typically, discrete signals use **zoh** interpolation, and continuous signals use **Linear** interpolation. You can specify the **Interpolation Method** for your signals in the signal properties.

Tolerance Specification

The Simulation Data Inspector allows you to specify the scope and value of the tolerance for your signal. You can define a tolerance band using any combination of absolute, relative, and time tolerance values, and you can specify whether the specified tolerance applies to an individual signal or to all the signals in a run.

Tolerance Scope

In the Simulation Data Inspector, you can specify the tolerance for your data globally or for an individual signal. Global tolerance values apply to all signals in a run that do not have **Override Global Tol** set to **yes**. You can specify global tolerance values for your data at the top of the graphical viewing area in the **Compare** view. To specify signal specific tolerance values, edit the signal properties and ensure the **Override Global Tol** property is set to **yes**.

Tolerance Computation

In the Simulation Data Inspector, you can specify a tolerance band for your run or signal using a combination of absolute, relative, and time tolerance values. When you specify the tolerance for your run or signal using multiple types of tolerances, each tolerance can yield a different answer for the tolerance at each point. The Simulation Data Inspector computes the overall tolerance band by selecting the most lenient tolerance result for each data point.

When you define your tolerance using only the absolute and relative tolerance properties, the Simulation Data Inspector computes the tolerance for each point as a simple maximum.

```
tolerance =
max(absoluteTolerance, relativeTolerance*abs(baselineData));
```

The upper boundary of the tolerance band is formed by adding tolerance to the **Baseline** signal. Similarly, the Simulation Data Inspector computes the lower boundary of the tolerance band by subtracting tolerance from the **Baseline** signal.

When you specify a time tolerance, the Simulation Data Inspector evaluates the time tolerance first, over a time interval defined as $[(t_{\text{samp}} - \text{tol}), (t_{\text{samp}} + \text{tol})]$ for each sample. The Simulation Data Inspector builds the lower tolerance band by selecting the minimum point on the interval for each sample. Similarly, the maximum point on the interval defines the upper tolerance for each sample.

If you specify a tolerance band using an absolute or relative tolerance in addition to a time tolerance, the Simulation Data Inspector applies the time tolerance first, and then applies the absolute and relative tolerances to the maximum and minimum points selected with the time tolerance.

$\text{upperTolerance} = \text{max} + \max(\text{absoluteTolerance}, \text{relativeTolerance} * \text{max})$

$\text{lowerTolerance} = \text{min} - \max(\text{absoluteTolerance}, \text{relativeTolerance} * \text{min})$

Organize Your Simulation Data Inspector Workspace

You can modify the layout and content of the panels in the Simulation Data Inspector to help you organize your data. You can set new run naming rules, change how signals are grouped within runs in the navigation pane, and use filters to find the signal you want to inspect.

Modify the Layout

You can collapse and expand the navigation, archive, and Properties panes in the Simulation Data Inspector using the chevrons in the upper-right corner of each pane, highlighted in the image.

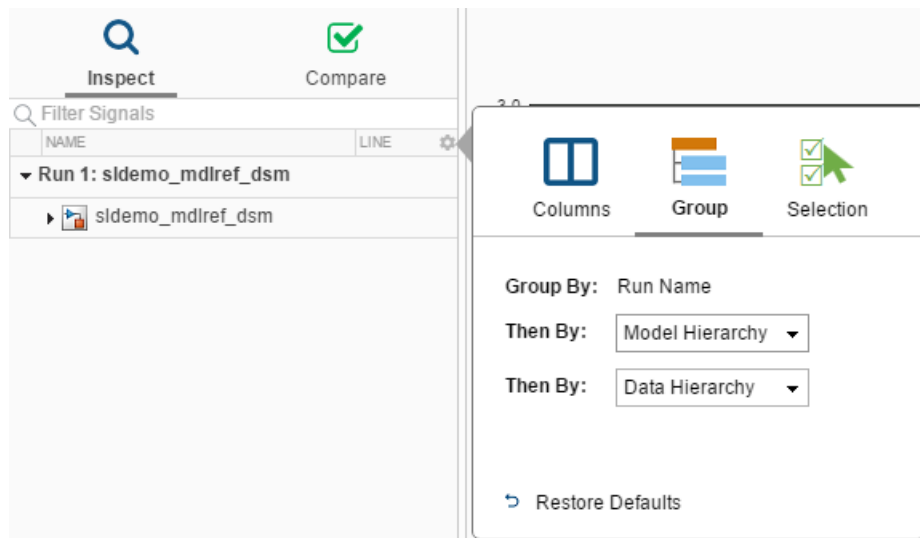

Modify Signal Grouping

You can customize the hierarchy for how your data is grouped in the **Inspect** and **Compare** panes. The data is grouped first by run name, which cannot be modified. You can then group your data by data or model hierarchy. If you have a Simscape license, you can also group your data by physical system hierarchy. Changes to signal grouping apply

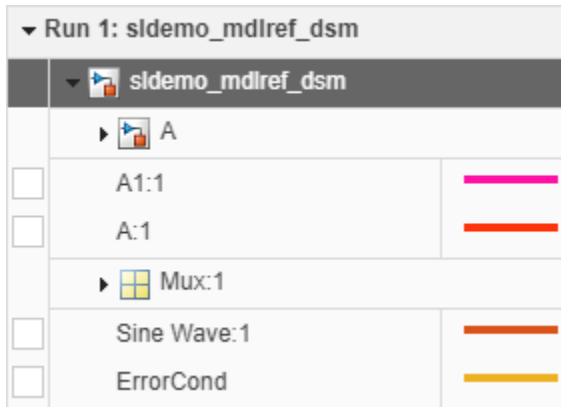

to both the **Inspect** and **Compare** panes, regardless of the pane from which you edit the grouping.

As an example, change the Simulation Data Inspector settings to group signals by run name, then by model hierarchy, and then by data hierarchy.

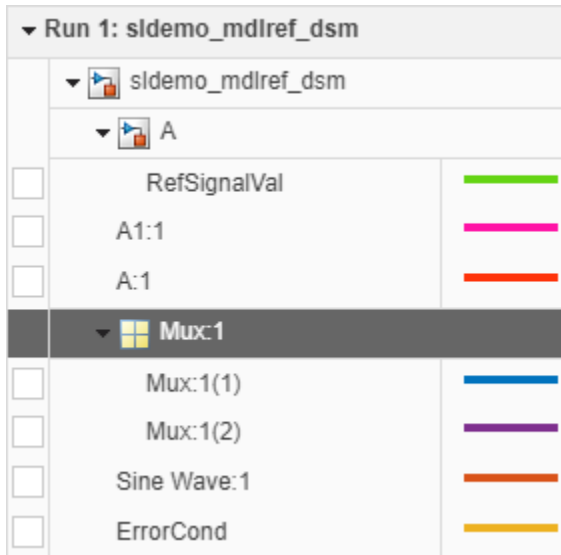

- 1 Click the **Preferences** button in the upper right of the navigation pane.
- 2 On the **Group** pane, select Model Hierarchy in the first **Then By** list.
- 3 In the second **Then By** list, select Data Hierarchy.

The Simulation Data Inspector groups the signals by run name, then by model hierarchy, and then by data hierarchy. By default, all hierarchies within the run are collapsed. You can expand the model group to see the logged signals.

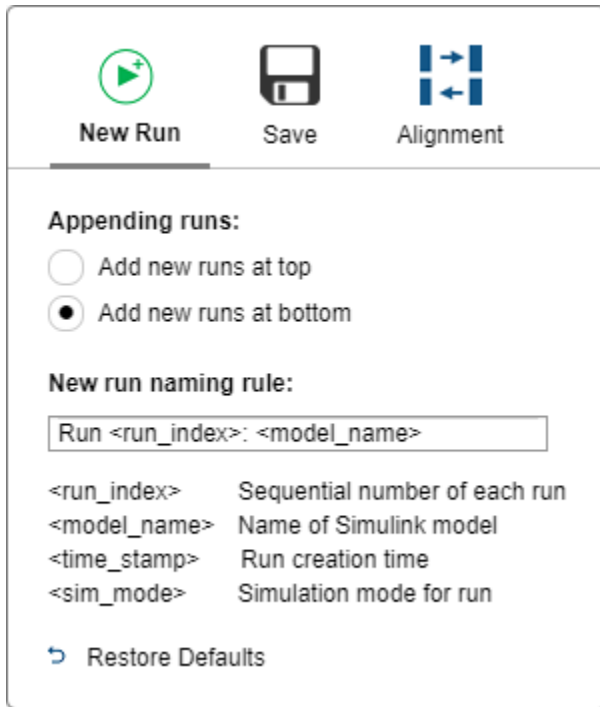

Signals inside subsystem A are still collapsed under A, and the signals in the Mux block output are grouped under Mux: 1. You can expand these groups to see the rest of the signals in the run. The check boxes for signals remain on the left side of the navigation pane, and the signal names indent to indicate the level of hierarchy.

To remove the hierarchy and display a flat list of signals in each run, select None from both **Then By** lists on the **Group** pane.

You can also specify whether to add new runs to the top or bottom of the runs list in the **Inspect** pane. The **New Run** tab in the **Preferences** window allows you to configure how new runs are added to the **Inspect** pane. The default configuration adds new runs to the bottom of the runs list.

Specify How the Simulation Data Inspector Names Runs

You can specify how existing and future runs are named in the Simulation Data Inspector.

To rename an existing run double-click the run row, type the new run name, and press **Enter**. Alternatively, you can select the run you want to rename and type the new name into the **Name** row of the properties pane.

To specify how you would like the Simulation Data Inspector to name future runs, open

the **New Run** tab on the **Preferences** menu. The default value for the **New run naming rule** is Run <run_index>: <model_name>.

To change the run naming rule, enter your desired options from the list of available parameters along with any other regular characters. For example, to include the simulation mode in subsequent run names, enter Run <run_index>: <model_name>:

<sim_mode> in the **New run naming rule** box. With this rule, simulating model `slexAircraftExample` in normal mode, the name of the first run appears as `Run 1: slexAircraftExample: normal`.

Filter Runs and Signals in the Work Area

You can filter runs and signals displayed in the work area of the **Inspect** pane and in the **Compare** pane to help search through large amounts of data in the Simulation Data Inspector. You can filter the data by text contained in the run or signal names and properties.

To show only signals named `alpha, rad`, type `alpha` into the filter signals text box. Matches for the search criteria are highlighted in the filter results displayed in the pane. The filter dialog box suggests completions for the text typed into the search query.

The screenshot shows the Simulation Data Inspector interface. The top bar has a search icon and a checkmark icon. Below the search icon is the text "alpha". The interface is divided into two panes: "Inspect" and "Compare". The "Inspect" pane shows a table of results for the search query "alpha". The table has columns for NAME, LINE, UNITS, and DATA... The results are grouped by run. Run 1: slexAircraftExample has a checked checkbox and the signal "alpha, rad" is highlighted in yellow. Run 2: slexAircraftExample has an unchecked checkbox and the signal "alpha, rad" is not highlighted. The "Compare" pane shows a plot of three signals: "q, rad/sec" (blue), "alpha, rad" (orange), and "Stick" (yellow). The plot shows three curves that are all highlighted in yellow, indicating they match the search criteria. The plot has a legend at the top and a search box on the left. The search box contains "alpha, rad" and has a dropdown arrow. Below the search box are the words "Plotted" and "ADVANCED >". The plot has a y-axis with a tick mark at -0.3 and an x-axis with tick marks at 0, 5, and 10.

NAME	LINE	UNITS	DATA...
▼ Run 1: slexAircraftExample			
<input checked="" type="checkbox"/>	alpha, rad	rad	double
▼ Run 2: slexAircraftExample			
<input type="checkbox"/>	alpha, rad	rad	double

To filter for a signal or run property, use colons to separate the property name and filter value. For example, `port:1` filters for signals that use port 1 in the model. Because the property column is not visible in the **Inspect** pane, the result is not highlighted.

You can also construct more complicated filter queries that include multiple properties using the **Advanced** section of the filter dialog box.

- 1 Open the **Advanced** section of the filter dialog box.
- 2 Select a column to add to the filter, and enter the value.

Note Filters work by matching text. For example, an absolute tolerance filter for a value of 00.1 does not return signals with an absolute tolerance of 0.1 .

For convenience, you can save filter configurations. To save the filter, enter a name in the **Save Search As** box and click **Save** on the filter dialog box. Saved filters show as options in the filter list.

Inspect and Compare Data Programmatically

You can harness the capabilities of the Simulation Data Inspector from the MATLAB command line using the Simulation Data Inspector API.

The Simulation Data Inspector organizes data in runs and signals, assigning a unique numeric identification to each run and signal. Some Simulation Data Inspector API functions use the run and signal IDs to reference data, rather than accepting the run or signal itself as an input. To access the run IDs in the workspace, you can use `Simulink.sdi.getAllRunIDs` or `Simulink.sdi.getRunIDByIndex`. You can access signal IDs through a `Simulink.sdi.Run` object using the `Simulink.sdi.Run.getSignalIDByIndex` method.

The `Simulink.sdi.Run` and `Simulink.sdi.Signal` classes provide access to your data and allow you to view and modify run and signal metadata. You can modify the Simulation Data Inspector preferences using functions like `Simulink.sdi.setSubPlotLayout`, `Simulink.sdi.setRunNamingRule`, and `Simulink.sdi.setMarkersOn`. To restore the Simulation Data Inspector's default settings, use `Simulink.sdi.clearPreferences`.

Create a Run and View the Data

This example shows how to create a run, add data to it, and then view the data in the Simulation Data Inspector.

Create Data for the Run

This example creates `timeseries` objects for a sine and a cosine. To visualize your data, the Simulation Data Inspector requires at least a time vector that corresponds with your data.

```
% Generate timeseries data
time = linspace(0, 20, 100);

sine_vals = sin(2*pi/5*time);
sine_ts = timeseries(sine_vals, time);
sine_ts.Name = 'Sine, T=5';

cos_vals = cos(2*pi/8*time);
cos_ts = timeseries(cos_vals, time);
cos_ts.Name = 'Cosine, T=8';
```

Create a Simulation Data Inspector Run and Add Your Data

To give the Simulation Data Inspector access to your data, use the `create` method and create a run. This example modifies some of the run's properties to help identify the data. You can easily view run and signal properties with the Simulation Data Inspector.

```
% Create a run
sinusoidsRun = Simulink.sdi.Run.create;
sinusoidsRun.Name = 'Sinusoids';
sinusoidsRun.Description = 'Sine and cosine signals with different frequencies';

% Add timeseries data to run
sinusoidsRun.add('vars', sine_ts, cos_ts);
```

Plot Your Data Using the `Simulink.sdi.Signal` Object

The `getSignalByIndex` method returns a `Simulink.sdi.Signal` object that can be used to plot the signal in the Simulation Data Inspector. You can also programmatically control aspects of the plot's appearance, such as the color and style of the line representing the signal. This example customizes the subplot layout and signal characteristics.

```
% Get signal, modify its properties, and change Checked property to true
sine_sig = sinusoidsRun.getSignalByIndex(1);
sine_sig.LineColor = [0 0 1];
sine_sig.LineDashed = '-.';
sine_sig.Checked = true;

% Add another subplot for the cosine signal
Simulink.sdi.setSubPlotLayout(2, 1);

% Plot the cosine signal and customize its appearance
cos_sig = sinusoidsRun.getSignalByIndex(2);
cos_sig.LineColor = [0 1 0];
cos_sig.plotOnSubPlot(2, 1, true);

% View the signal in the Simulation Data Inspector
Simulink.sdi.view
```

Close the Simulation Data Inspector and Save Your Data

```
Simulink.sdi.close('sinusoids.mat')
```

Compare Signals Within a Simulation Run

This example uses the `slexAircraftExample` model to demonstrate the comparison of the input and output signals for a control system. The example marks the signals for streaming then gets the run object for a simulation run. Signal IDs from the run object specify the signals to be compared.

```
% Load model slexAircraftExample and mark signals for streaming
load_system('slexAircraftExample')
Simulink.sdi.markSignalForStreaming('slexAircraftExample/Pilot',1,'on')
Simulink.sdi.markSignalForStreaming('slexAircraftExample/Aircraft Dynamics Model',4,'on')

% Simulate model slexAircraftExample
sim('slexAircraftExample')

% Get run IDs for most recent run
allIDs = Simulink.sdi.getAllRunIDs;
runID = allIDs(end);

% Get Run object
aircraftRun = Simulink.sdi.getRun(runID);

% Get signal IDs
signalID1 = aircraftRun.getSignalIDByIndex(1);
signalID2 = aircraftRun.getSignalIDByIndex(2);

if (aircraftRun.isValidSignalID(signalID1))
    % Change signal tolerance
    signal1 = Simulink.sdi.getSignal(signalID1);
    signal1.AbsTol = 0.1;
end

if (aircraftRun.isValidSignalID(signalID1) && aircraftRun.isValidSignalID(signalID2))
    % Compare signals
    sigDiff = Simulink.sdi.compareSignals(signalID1,signalID2);

    % Check whether signals match within tolerance
    match = sigDiff.match
end
```

```
match = logical  
    0
```

Compare Simulation Data Inspector Runs Programmatically

This example shows how to compare runs of simulation data and analyze the comparison results with the Simulation Data Inspector programmatic interface.

Generate Runs of Simulation Data

Simulate the model with different `Desired relative slip` values to create runs of simulation data to analyze with the Simulation Data Inspector programmatic interface.

```
% Open model  
load_system('ex_sldemo_absbrake')  
  
% Set the desired slip ratio to 0.24 and simulate  
set_param('ex_sldemo_absbrake/Desired relative slip','Value','0.24')  
sim('ex_sldemo_absbrake');  
  
% Change the desired slip ratio to 0.25 and simulate  
set_param('ex_sldemo_absbrake/Desired relative slip','Value','0.25')  
sim('ex_sldemo_absbrake');
```

Compare Runs with a Global Tolerance

Get the run IDs for the runs you just created with the `Simulink.sdi.getAllRunIDs` function. Then, compare the runs using a global relative tolerance and a global time tolerance to analyze whether your data meets specifications.

```
% Get run IDs for last two runs  
runIDs = Simulink.sdi.getAllRunIDs;  
runID1 = runIDs(end - 1);  
runID2 = runIDs(end);  
  
% Compare runs  
runResult = Simulink.sdi.compareRuns(runID1,runID2,'reltol',0.2,'timetol',0.5);
```

Create a Plot of a Comparison Result

Use the `Simulink.sdi.DiffRunResult` object you created in the previous step with `Simulink.sdi.compareRuns` to access the data for the `Ww` signal result to plot it in a figure.

```
% Plot the |Ww| signal difference
signalResult_Ww = runResult.getResultByIndex(1);
figure(1)
plot(signalResult_Ww.Diff)
```

Analyze Simulation Data with Signal Tolerances

You can change tolerance values on a signal-by-signal basis to evaluate the effect of a model parameter change. This example uses the `slexAircraftExample` model and the Simulation Data Inspector to evaluate the effect of changing the time constant for the low-pass filter following the control input.

Setup

Load the model, and mark the `q`, `rad/sec` and `alpha`, `rad` signals for logging. Then, simulate the model to create the baseline run.

```
% Load example model
load_system('slexAircraftExample')

% Mark the q, rad/sec and alpha, rad signals for logging
Simulink.sdi.markSignalForStreaming('slexAircraftExample/Aircraft Dynamics Model',3,'on')
Simulink.sdi.markSignalForStreaming('slexAircraftExample/Aircraft Dynamics Model',4,'on')

% Simulate system
sim('slexAircraftExample')
```

Modify Model Parameter

Modify the model parameter Ts in the model workspace to change the time constant of the input low-pass filter.

```
% Change input filter time constant
modelWorkspace = get_param('slexAircraftExample','modelworkspace');
modelWorkspace.assignin('Ts',1)

% Simulate again
sim('slexAircraftExample')
```

Compare Runs and Inspect Results

Use the `Simulink.sdi.compareRuns` function to compare the data from the simulations. Then, inspect the `match` property of the signal result to see whether the signals fell within the default tolerance of 0.

```
% Get run data
runIDs = Simulink.sdi.getAllRunIDs;
runID1 = runIDs(end - 1);
runID2 = runIDs(end);

% Compare runs
diffRun1 = Simulink.sdi.compareRuns(runID1,runID2);

% Get signal result
sig1Result1 = diffRun1.getResultByIndex(1);
sig2Result1 = diffRun1.getResultByIndex(2);

% Check whether signals matched
sig1Result1.Match
```

```
ans = logical
      0
```

```
sig2Result1.Match
```

```
ans = logical
      0
```

Compare Runs with Signal Tolerances

The signals did not match within the default tolerance of 0. To further analyze the effect of the time constant change, add signal tolerances to the comparison with the baseline signal properties to determine the tolerance required for a pass. This example uses a combination of time and absolute tolerances.

```
% Get signal object for sigID1
run1 = Simulink.sdi.getRun(runID1);
sigID1 = run1.getSignalIDByIndex(1);
sigID2 = run1.getSignalIDByIndex(2);

sig1 = Simulink.sdi.getSignal(sigID1);
sig2 = Simulink.sdi.getSignal(sigID2);

% Set tolerances for q, rad/sec
sig1.AbsTol = 0.1;
sig1.TimeTol = 0.6;

% Set tolerances for alpha, rad
sig2.AbsTol = 0.2;
sig2.TimeTol = 0.8;

% Run the comparison again
diffRun2 = Simulink.sdi.compareRuns(runID1, runID2);
sig1Result2 = diffRun2.getResultByIndex(1);
sig2Result2 = diffRun2.getResultByIndex(2);

% Check the result
sig1Result2.Match

ans = logical
      1

sig2Result2.Match
```

```
ans = logical
      1
```

Generate a Simulation Data Inspector Report Programmatically

This example shows how to create reports using the Simulation Data Inspector programmatic interface. You can create a report for plotted signals in the Inspect pane or for comparison data in the Compare pane. This example first generates data by simulating a model, then shows how to create an Inspect Signals report. To run the example exactly as shown, ensure that the Simulation Data Inspector repository starts empty with the `Simulink.sdi.clear` function.

Generate Data

This example generates data using model `ex_slldemo_absbrake` with two different desired slip ratios.

```
% Ensure Simulation Data Inspector is empty
Simulink.sdi.clear

% Open model
load_system('ex_slldemo_absbrake')

% Set slip ratio and simulate model
set_param('ex_slldemo_absbrake/Desired relative slip','Value','0.24')
sim('ex_slldemo_absbrake')

ans =
  Simulink.SimulationOutput:

      slldemo_absbrake_output: [1x1 Simulink.SimulationData.Dataset]

      SimulationMetadata: [1x1 Simulink.SimulationMetadata]
      ErrorMessage: [0x0 char]

% Set new slip ratio and simulate model again
set_param('ex_slldemo_absbrake/Desired relative slip','Value','0.25')
sim('ex_slldemo_absbrake')
```

```
ans =
  Simulink.SimulationOutput:

      sldemo_absbrake_output: [1x1 Simulink.SimulationData.Dataset]

      SimulationMetadata: [1x1 Simulink.SimulationMetadata]
      ErrorMessage: [0x0 char]
```

Plot Signals in the Inspect Pane

The `Inspect Signals` report includes all signals plotted in the graphical viewing area of the `Inspect` pane and all displayed metadata for the plotted signals.

```
% Get Simulink.sdi.Run objects
runIDs = Simulink.sdi.getAllRunIDs;
runID1 = runIDs(end-1);
runID2 = runIDs(end);

run1 = Simulink.sdi.getRun(runID1);
run2 = Simulink.sdi.getRun(runID2);

% Get Simulink.sdi.Signal objects for slp signal
run1_slp = run1.getSignalByIndex(4);
run2_slp = run2.getSignalByIndex(4);

% Plot slp signals
run1_slp.plotOnSubPlot(1, 1, true)
run2_slp.plotOnSubPlot(1, 1, true)
```

Create a Report of Signals Plotted in Inspect Pane

You can include more data in the report by adding more columns using the `Simulation Data Inspector` UI, or you can specify the information you want in the report programmatically with Name-Value pairs and the enumeration class `Simulink.sdi.SignalMetaData`. This example shows how to specify the data in the report programmatically.

```
% Specify report parameters
reportType = 'Inspect Signals';
reportName = 'Data_Report.html';

signalMetadata = [Simulink.sdi.SignalMetaData.Run, ...
```

```
Simulink.sdi.SignalMetaData.Line, ...  
Simulink.sdi.SignalMetaData.BlockName, ...  
Simulink.sdi.SignalMetaData.SignalName];  
  
Simulink.sdi.report('ReportToCreate', reportType, 'ReportOutputFile', ...  
    reportName, 'ColumnsToReport', signalMetadata);
```

Save and Restore a Set of Logged Signals

This example shows the capability of using the `Simulink.HMI.InstrumentedSignals` object to save a set of logged signals to restore after running a simulation with a different set of signals.

Load Model and Save Initial Configuration

Load the `sldemo_fuelsys` model, and save the initial set of logged signals.

```
% Load model  
load_system sldemo_fuelsys  
  
% Get Simulink.HMI.InstrumentedSignals object  
initSigs = get_param('sldemo_fuelsys', 'InstrumentedSignals');  
  
% Save logging configuration to file for future use  
save initial_instSigs.mat initSigs
```

Remove All Logging Badges

Return to a baseline of no logged signals so you can easily select a different configuration of signals to log.

```
% Clear all logging signals  
set_param('sldemo_fuelsys', 'InstrumentedSignals', [])
```

Restore Saved Logging Configuration

After working with a different set of logged signals, you can easily restore a saved configuration with the `Simulink.HMI.InstrumentedSignals` object.

```
% Load the saved configuration  
load initial_instSigs.mat
```

```
% Restore logging configuration  
set_param('sldemo_fuelsys', 'InstrumentedSignals', initSigs)
```

Keyboard Shortcuts for the Simulation Data Inspector

You can use several keyboard shortcuts to facilitate working with the Simulation Data Inspector. In the table, where the shortcut looks like **Ctrl+N**, to use the shortcut, you hold down the **Ctrl** key and then press the **N** key.

Note On Macintosh platforms, use the **command** key instead of **Ctrl**.

General Actions

Task	Shortcut
Start a new session	Ctrl+N
Open a session	Ctrl+O
Save a session	Ctrl+S
Compare	Ctrl+E
Link/Unlink a subplot	Ctrl+U
Delete a run or signal	Delete

Plot Zooming

Task	Shortcut
Zoom in T (time)	Ctrl+Shift+T
Zoom in Y	Ctrl+Shift+Y
Zoom in T and Y	Ctrl++ (Numeric keypad only)
Zoom out	Ctrl+- (Numeric keypad only)
Fit to view	Spacebar
Cancel zoom operation or signal dragging	Esc

Data Cursors

Task	Shortcut
Show a data cursor	Ctrl+I
Hide all data cursors	Shift+Del
Move a selected data cursor to next data point	Right arrow
Move a selected data cursor to previous data point	Left arrow
Activate first (left) cursor	Ctrl+1
Activate second (right) cursor	Ctrl+2

Import Dialog Box

These actions pertain to the import table.

Task	Shortcut
Expand all nodes	Ctrl+=
Collapse all nodes	Shift+Ctrl+=
Select a node	Space
Expand a single node	Right arrow
Collapse a single node	Left arrow

The Simulation Data Inspector Archive

The archive in the Simulation Data Inspector stores runs in a collapsible pane, allowing you to manage the contents of your work area without deleting run data. You can configure the Simulation Data Inspector to automatically move prior simulation runs to the archive or not, and you can limit the number of runs stored in the archive.

Manage Runs in the Archive

By default, the Simulation Data Inspector automatically archives simulation runs. When you simulate a model, the Simulation Data Inspector automatically moves the prior simulation run to the archive and updates the view to show aligned signals from the current run.

The archive does not impose any functional limitations on the runs and signals it contains. You can plot signals from the archive, and you can use runs and signals in the archive in comparisons. You can drag runs of interest from the archive to the work area and vice versa. You can manually move runs between the work area and archive whether the **Automatically Archive** check box is enabled or disabled. If you want to manage the data in the archive entirely manually, clear the **Automatically Archive** check box on the **Archive** settings pane.

When you import runs into the Simulation Data Inspector, the imported runs appear in the work area, and the **Current** tag remains on the most recent simulation run. You can import signals to existing runs in the work area and in the archive.

To delete all the runs in the archive, click the trash  icon.

Limit Data Retention

To reduce the amount of data retained by the Simulation Data Inspector, you can configure a limit for the number of runs stored in the archive. When the number of runs in the archive reaches the **Archive Size Limit**, the Simulation Data Inspector starts to delete runs on a first in first out basis. By default, the Simulation Data Inspector has no limit on the number of runs stored in the archive. To specify the maximum number of runs stored in the archive, select the **Last n runs** radio button, and enter your desired limit. If you enter a limit that would delete runs already in the archive, the Simulation Data Inspector gives a warning. You can also delete the contents of the archive manually, using the trash  icon.

Tune and Visualize Your Model with Dashboard Blocks

In this section...

“Explore Connections Within the Model” on page 29-131

“Simulate Changing Model States” on page 29-132

“View Signal Data” on page 29-133

“Tune Parameters During Simulation” on page 29-135

The blocks in the Dashboard library help you control and visualize your Simulink model during simulation and while the simulation is paused. This example uses the Fault-Tolerant Fuel Control System model to showcase the control and visualization capabilities of Dashboard blocks.

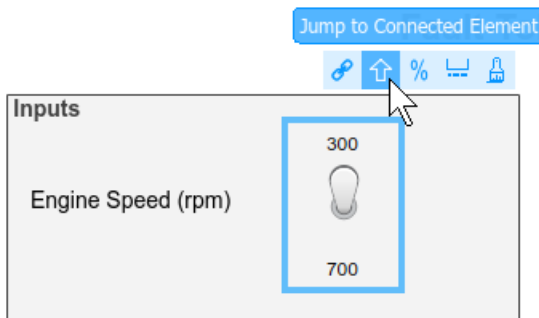

To open the model, enter `sldemo_fuel_sys` into the MATLAB command window. To open the Dashboard subsystem, double-click it or click the Open the Dashboard link.

Note Dashboard blocks cannot connect to signals inside referenced models.

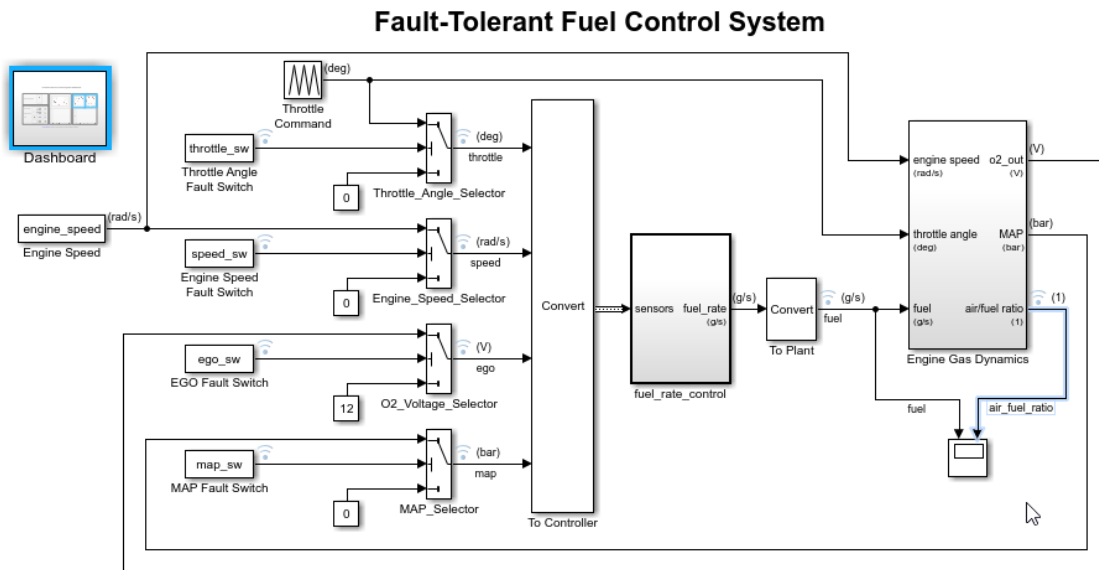

Explore Connections Within the Model

The Dashboard subsystem contains blocks for controlling and visualizing signals in the Fault-Tolerant Fuel Control System model. Explore the connections between the signals and Dashboard blocks. Click either a signal or a Dashboard block to highlight the connections.

From the Dashboard subsystem, click the Toggle Switch in the Fuel panel. Hover the mouse over the ellipsis above the block and then click the arrow above it to jump to the connected block or signal.

From the top level of the model, click the `air_fuel_ratio` signal and see the Dashboard subsystem, Quarter Gauge, and Half Gauge highlighted.

[Open the Dashboard](#) subsystem to simulate any combination of sensor failures.

Copyright 1990-2016 The MathWorks, Inc.

Simulate Changing Model States

In the Dashboard subsystem, switches provide control over the state of the throttle angle, engine speed, EGO, and MAP signals. For each sensor signal, the switch toggles between

normal and fail, allowing you to simulate the system response to each single-point failure. Clicking any one of these switches before simulation, during simulation, or while a simulation is paused changes the state in the model.

Run the simulation and observe the control system response to each single-point failure.

- 1 Start the simulation.
- 2 As the simulation runs, click one of the switches to simulate a component failure.

Observe the changes in the fuel and air_fuel_ratio signals in the Dashboard Scope and Gauge blocks when you flip each switch.

- 3 Stop the simulation when you are finished.

Fault-Tolerant Fuel Control System Dashboard

[Update Diagram](#) (Ctrl+D) to bind switches to model workspace variables.

View Signal Data

Dashboard blocks allow you to view signal data using gauges, lamps, and dashboard scopes. In this example, the Dashboard blocks provide visual feedback about the fuel input and air-to-fuel ratio during simulation, after simulation, and while a simulation is paused.

To capture different types of information and more effectively visualize a signal, connect multiple Dashboard blocks to a single signal. For example, you can visualize the `air_fuel_ratio` signal using the Gauge, Quarter Gauge, and Dashboard Scope blocks.

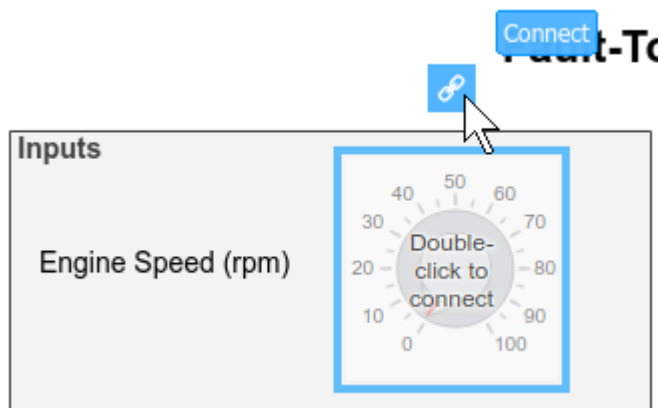

Use the Quarter Gauge block, labeled Normal Range in the example, to see small fluctuations in the instantaneous `air_fuel_ratio` signal while its value lies within the normal operational range. The Gauge block, labeled Full Range, allows you to see the behavior of the instantaneous `air_fuel_ratio` signal outside of the normal range. The Dashboard Scope block shows the variations of the `air_fuel_ratio` signal over time.

Note If you disable logging for a signal connected to a Dashboard block, the connection breaks, and signal data does not stream to the block. To view the signal again, double-click the Dashboard block and reconnect the signal.

Tune Parameters During Simulation

Dashboard blocks allow you to tune parameters in your model during a simulation. To explore the tuning capability within the fuel system model, replace the engine speed Toggle Switch block with a Knob:

- 1 Delete the engine speed Toggle Switch.
- 2 Add a Knob block from the Dashboard library.
- 3 Click the **Connect** button that appears when you pause on the Knob block. When you click the **Connect** button, the Simulink editor enters connect mode, which facilitates connecting Dashboard blocks to signals and parameters in your model.

- 4 Navigate to the top level of the model and select the Engine Speed block. The Engine Speed block is a Constant block whose **Constant value** parameter you can tune with the Knob block.

When you select the Engine Speed block, the names of tunable parameters associated with the block appear in a table.

- 5 Select the option button next to `engine_speed` in the table. Then, to exit connect mode, click the **Exit** button in the upper-right of the model canvas.

Now that the Knob block is connected to the `engine_speed` parameter, you can set the tick interval and range to values that make sense for the simulation. Double-click the Knob block to access the block parameters. In this example, set **Minimum** to 75, **Maximum** to 750, and **Tick Interval** to 75. Then, click **OK**.

Simulate the model and tune the `engine_speed` parameter using the Knob.

- 1 Start the simulation.
- 2 As the simulation runs, drag the pointer on the Knob to adjust the value of `engine_speed`.

Notice as you use the Knob to adjust the value of `engine_speed`, the `air_fuel_ratio` value displayed on the Gauge blocks and in the Dashboard Scope block changes.

- 3 Stop the simulation when you have finished tuning the parameter.

Inspect and Analyze Models in Simulink

The Simulink environment provides model-level visualization tools that can probe your system at any connection. Use these tools to stream, record, and analyze signals in your model. To open a model-level visualization tool, choose one of the following options:

-  — **Simulation Data Inspector**
-  — **Logic Analyzer** (requires DSP System Toolbox)
-  — **Bird's-Eye Scope** (requires Automated Driving Toolbox™)

The toolbar displays only the most recently chosen visualization tool. To open the tool not displayed, click the arrow next to the button and select the tool from the menu.

Choose a Visualization Tool

- Use the **Simulation Data Inspector** to compare variable-step data, fixed-step solver data from Simulink and Simulink Coder, and fixed-step output with external data. For more information, see **Simulation Data Inspector**.
- Use the **Logic Analyzer** to visualize, measure, and analyze transitions and states over time.
- Use the **Bird's-Eye Scope** to visualize and analyze sensor coverages, detections, and tracks.

“Signal Logging Without Blocks” on page 30-9

Visualizing Simulation Data

During the modeling process, you run simulations to learn about the behavior of your model. To observe that behavior, view and plot signal values during and after a simulation. Some common modeling tasks that include simulations are:

- **Prototype** — Quickly model a design and compare design alternatives.
- **Validate** — Compare simulated data with functional requirements to validate that you built your model correctly.
- **Optimize** — Compare simulated data between simulations to check if changes to your model remain within a specified design tolerance.
- **Verify** — Compare simulated data from a model with measured data from the modeled system to verify that your model gives the correct answer.

In Simulink you can view simulation data using several approaches. Some approaches display signal data during a simulation. Other approaches save signal data to the MATLAB workspace where you can post process the data. Learn about each of these approaches so you can choose one suitable for your application.

Port Value Displays

When debugging a model to isolate a particular issue, a common task is to observe signal values at each time step during a simulation. To observe a signal value, right-click a signal line, and then select **Show Value Label of Selected Port**.

Displaying port values for a bus signal allows you to monitor the signal values at each time step during a simulation.

Scope Blocks and Scope Viewers

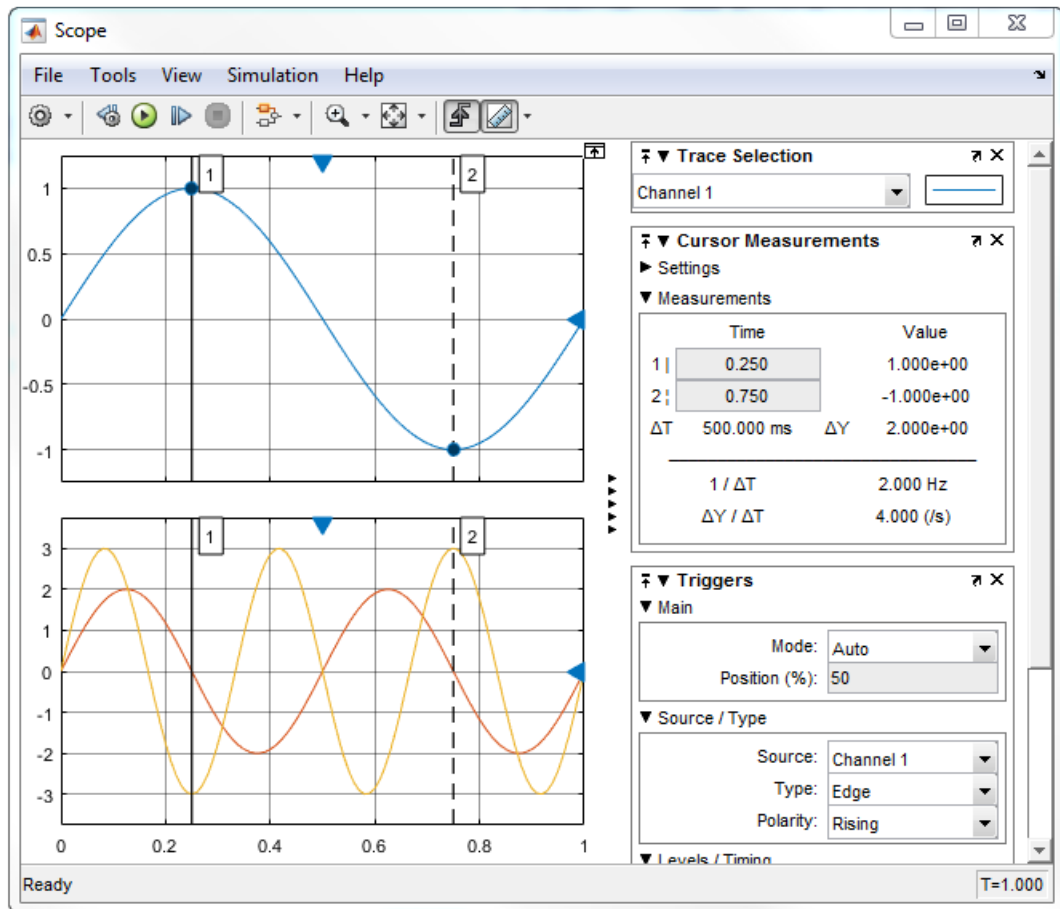

Scope blocks and scope viewers offer a way to visualize your simulation data over time. If you are prototyping a model design, you can attach signals to a Scope block, and then simulate your model to test and validate the design. Use the oscilloscope-like tools (triggers and measurements) available with a scope to debug your model.

A Scope block or scope viewer opens to a scope window where you can display and evaluate simulation data. In the Scope window, you can:

- **Select signals** — Connect signal lines to a Scope block using input ports. Attach signals to a Floating Scope block using the signal selector tool that hierarchically displays all signals in a model.
- **View signals** — Compare selected signals by grouping them on multiple displays.
- **Prototype and debug** — Set triggers to capture events, use interactive cursors to measure signal values at various points, and review signal statistics such as maximum and mean values. Also, control simulations and step through simulations to validate a design.

- Save signal data — Save signal data to the MATLAB workspace using a dataset object, array, or structure format.
- Supported data types — All data types supported by Simulink including variable-size, fixed-point, sample-based, and frame-based signals.

For more information, see “Scope Blocks and Scope Viewer Overview” on page 28-8.

Simulation Data Inspector

If you run your simulation more than once and want to inspect or compare data between simulations, you can use the Simulation Data Inspector. You can stream and store signals from the model and compare data between multiple simulations. For example, you can check to see if the difference between two signals is within a certain design tolerance. In the Simulation Data Inspector, you can:

- View signals — Inspect signal data while your model is simulating.
- Import data — Import time series data from MAT-files or the base workspace.
- Compare signal data — Compare multiple simulation outputs to check the difference between runs.
- Export data and generate reports — Export plots and comparison data to share or archive results.

For more information, see **Simulation Data Inspector**.

Dashboard Controls and Displays

Create an interactive display of controls and displays within your model diagram using blocks from the Dashboard library. Connect block parameters to control blocks (Knobs, Buttons, and Switches) and signals to displays blocks (Scopes and Gauges).

While a simulation is running, you can change parameter values using the controls. Signal values are updated continuously in the displays.

For more information, see “Tune and Visualize Your Model with Dashboard Blocks” on page 29-131.

Output Block

Use Output blocks to save simulation data from the top-level of your model to the MATLAB workspace. Select and define the variables for saving data in the **Data Import/Export** pane of the Configuration Parameters dialog box. For example, select the **Time** and **Output** check boxes.

After running a simulation, you can use MATLAB plotting commands to display the simulation results. The variables `tout` and `yout` are the default variables returned by the solver after a simulation.

```
plot(tout,yout)
```

For more information, see “Model Configuration Parameters: Data Import/Export”.

To Workspace Block

Use To Workspace blocks to save simulation data from anywhere in your model to the MATLAB workspace. Store a time vector by connecting a Clock block to a To Workspace block. You can also get a time vector using the `sim` command.

During a simulation, the blocks write data to an internal buffer. When you pause the simulation or it reaches the end time, data is written to the workspace and saved in the variables `y` and `t`.

For more information, see “Model Configuration Parameters: Data Import/Export”.

Signal Logging Without Blocks

You can save simulation data to the MATLAB workspace without using blocks.

- 1 Select signals for logging. Right-click a signal line, select **Properties**, and then select the **Log signal data** check box.
- 2 Enable signal logging during a simulation. In the **Data Import/Export** pane of the Configuration Parameters dialog box, select the **Signal logging** check box and enter a variable name.

For more information, see Export Signal Data Using Signal Logging on page 64-69.

Linearizing Models

In this section...

“About Linearizing Models” on page 30-11

“Linearization with Referenced Models” on page 30-13

“Linearization Using the 'v5' Algorithm” on page 30-15

About Linearizing Models

The Simulink product provides the `linmod`, `linmod2`, and `dlinmod` functions to extract linear models in the form of the state-space matrices A , B , C , and D . State-space matrices describe the linear input-output relationship as

$$\begin{aligned}\dot{x} &= Ax + Bu \\ y &= Cx + Du,\end{aligned}$$

where x , u , and y are state, input, and output vectors, respectively. For example, the following model is called `lmod`.

To extract the linear model of this system, enter this command.

```
[A,B,C,D] = linmod('lmod')
```

```
A =
    -2    -1    -1
     1     0     0
     0     1    -1
```

```
B =  
    1  
    0  
    0  
C =  
    0    1    0  
    0    0   -1  
D =  
    0  
    1
```

Inputs and outputs must be defined using Inport and Outport blocks from the Ports & Subsystems library. Source and sink blocks do not act as inputs and outputs. Inport blocks can be used in conjunction with source blocks, using a Sum block. Once the data is in the state-space form or converted to an LTI object, you can apply functions in the Control System Toolbox product for further analysis:

- Conversion to an LTI object

```
sys = ss(A,B,C,D);
```

- Bode phase and magnitude frequency plot

```
bode(A,B,C,D) or bode(sys)
```

- Linearized time response

```
step(A,B,C,D) or step(sys)  
impulse(A,B,C,D) or impulse(sys)  
lsim(A,B,C,D,u,t) or lsim(sys,u,t)
```

You can use other functions in the Control System Toolbox and the Robust Control Toolbox™ products for linear control system design.

When the model is nonlinear, an operating point can be chosen at which to extract the linearized model. Extra arguments to `linmod` specify the operating point.

```
[A,B,C,D] = linmod('sys', x, u)
```

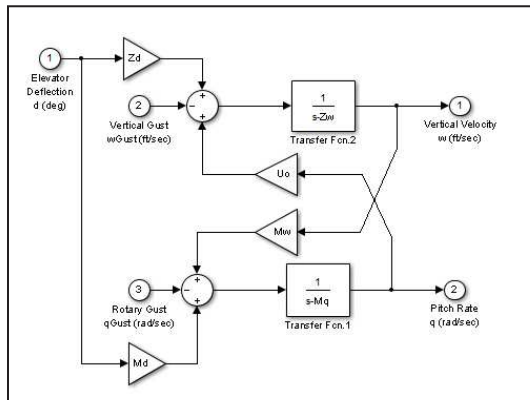

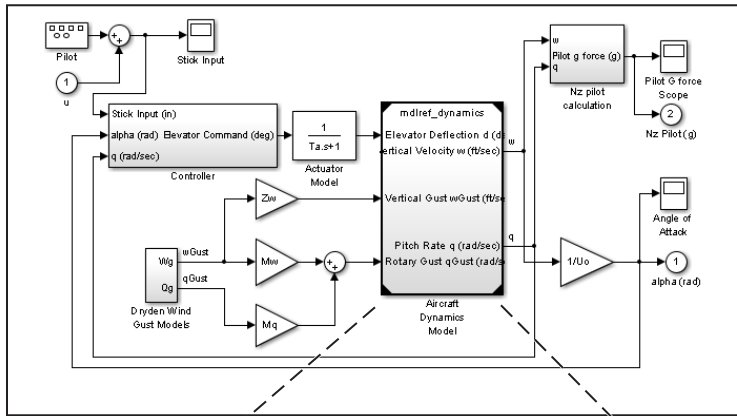

For discrete systems or mixed continuous and discrete systems, use the function `dlinmod` for linearization. This function has the same calling syntax as `linmod` except that the second right-hand argument must contain a sample time at which to perform the linearization.

Linearization with Referenced Models

You can use `linmod` to extract a linear model from a Simulink environment that contains Model blocks.

Note In Normal mode, the `linmod` command applies the block-by-block linearization algorithm on blocks inside the referenced model. If the Model block is in Accelerator mode, the `linmod` command uses numerical perturbation to linearize the referenced model. Due to limitations on linearizing multirate Model blocks in Accelerator mode, you should use Normal mode simulation for all models referenced by Model blocks when linearizing with referenced models. For an explanation of the block-by-block linearization algorithm, see the Simulink Control Design™ documentation.

For example, consider the f14 model `mdlref_f14`. The Aircraft Dynamics Model block refers to the model `mdlref_dynamics`.

To linearize the `mdlref_f14` model, call the `linmod` command on the top `mdlref_f14` model as follows.

```
[A,B,C,D] = linmod('mdlref_f14')
```

The resulting state-space model corresponds to the complete `f14` model, including the referenced model.

You can call `linmod` with a state and input operating point for models that contain Model blocks. When using operating points, the state vector x refers to the total state vector for the top model and any referenced models. You must enter the state vector using the structure format. To get the complete state vector, call

```
x = Simulink.BlockDiagram.getInitialState(topModelName)
```

Linearization Using the 'v5' Algorithm

Calling the `linmod` command with the 'v5' argument invokes the perturbation algorithm created prior to MATLAB software version 5.3. This algorithm also allows you to specify the perturbation values used to perform the perturbation of all the states and inputs of the model.

```
[A,B,C,D]=linmod('sys',x,u,para,xpert,upert,'v5')
```

Using `linmod` with the 'v5' option to linearize a model that contains Derivative or Transport Delay blocks can be troublesome. Before linearizing, replace these blocks with specially designed blocks that avoid the problems. These blocks are in the Simulink Extras library in the Linearization sublibrary.

You access the Extras library by opening the Blocksets & Toolboxes icon:

- For the Derivative block, use the Switched derivative for linearization.

When using a Derivative block, you can also try to incorporate the derivative term in other blocks. For example, if you have a Derivative block in series with a Transfer Fcn block, it is better implemented (although this is not always possible) with a single Transfer Fcn block of the form

$$\frac{s}{s+a}$$

In this example, the blocks on the left of this figure can be replaced by the block on the right.

See Also

`dlinmod` | `linmod`

Finding Steady-State Points

The Simulink `trim` function uses a model to determine steady-state points of a dynamic system that satisfy input, output, and state conditions that you specify. Consider, for example, this model, called `ex_lmod`.

You can use the `trim` function to find the values of the input and the states that set both outputs to 1. First, make initial guesses for the state variables (x) and input values (u), then set the desired value for the output (y).

```
x = [0; 0; 0];
u = 0;
y = [1; 1];
```

Use index variables to indicate which variables are fixed and which can vary.

```
ix = [];      % Don't fix any of the states
iu = [];     % Don't fix the input
iy = [1;2];  % Fix both output 1 and output 2
```

Invoking `trim` returns the solution. Your results might differ because of roundoff error.

```
[x,u,y,dx] = trim('lmod',x,u,y,ix,iu,iy)
```

```
x =
    0.0000
    1.0000
    1.0000
u =
     2
y =
```

```
1.0000
1.0000
dx =
1.0e-015 *
-0.2220
-0.0227
0.3331
```

Note that there might be no solution to equilibrium point problems. If that is the case, `trim` returns a solution that minimizes the maximum deviation from the desired result after first trying to set the derivatives to zero. For a description of the `trim` syntax, see `trim`.

How Optimization Techniques Improve Performance and Accuracy

The design of a model and choice of configuration parameters can affect simulation performance and accuracy. Solvers handle most model simulations accurately and efficiently with default parameter values. However, some models yield better results when you adjust solver parameters. Information about the behavior of a model can help you improve simulation performance, particularly when you provide this information to the solver. Use optimization techniques to better understand the behavior of your model and modify the model settings to improve performance and accuracy.

To optimize your model and achieve faster simulation automatically using Performance Advisor, see “Automated Performance Optimization”.

To learn more about accelerator modes for faster simulation, see “Acceleration”.

More About

- “Modeling Techniques That Improve Performance” on page 31-13

Speed Up Simulation

Several factors can slow simulation. Check your model for some of these conditions.

- Your model includes an Interpreted MATLAB Function block. When a model includes an Interpreted MATLAB Function block, the MATLAB execution engine is called at each time step, drastically slowing down the simulation. Use the built-in Fcn block or the Math Function block whenever possible.
- Your model includes a MATLAB file S-function. MATLAB file S-functions also call the MATLAB execution engine at each time step. Consider converting the S-function either to a subsystem or to a C-MEX file S-function.
- Your model includes a Memory block. Using a Memory block causes the variable-order solvers (ode15s and ode113) to reset back to order 1 at each time step.
- The maximum step size is too small. If you changed the maximum step size, try running the simulation again with the default value (`auto`).
- Your accuracy requirements are too high. The default relative tolerance (0.1% accuracy) is usually sufficient. For models with states that go to zero, if the absolute tolerance parameter is too small, the simulation can take too many steps around the near-zero state values. See the discussion of this error in “Maximum order” “Maximum order” in the online documentation.
- The time scale is too long. Reduce the time interval.
- The problem is stiff, but you are using a nonstiff solver. Try using ode15s. For more information, see “Stiffness of System” on page 31-17.
- The model uses sample times that are not multiples of each other. Mixing sample times that are not multiples of each other causes the solver to take small enough steps to ensure sample time hits for all sample times.
- The model contains an algebraic loop. The solutions to algebraic loops are iteratively computed at every time step. Therefore, they severely degrade performance. For more information, see “Algebraic Loop Concepts” on page 3-38.
- Your model feeds a Random Number block into an Integrator block. For continuous systems, use the Band-Limited White Noise block in the Sources library.
- Your model contains a scope viewer that displays too many data points. Try adjusting the viewer property settings that can affect performance. For more information, see Scope Viewer.
- You need to simulate your model iteratively. You change tunable parameters between iterations but do not make structural changes to the model. Every iteration requires

the model to compile again, thus increasing overall simulation time. Use fast restart to perform iterative simulations. In this workflow, the model compiles only once and iterative simulations are tied to a single compile phase. See “How Fast Restart Improves Iterative Simulations” on page 73-2 for more information.

How Profiler Captures Performance Data

In this section...

“How Profiler Works” on page 31-5

“Start Profiler” on page 31-7

“Save Profiler Results” on page 31-10

How Profiler Works

Profiler captures performance data while your model simulates. It identifies the parts of your model that require the most time to simulate. Use the profiling information to decide where to focus your model optimization efforts.

Note You cannot use Profiler in Rapid Accelerator mode.

Simulink stores performance data in the *simulation profile report*. The data shows the time spent executing each function in your model.

The basis for Profiler is an execution model that this pseudocode summarizes.

```

Sim()
  ModelInitialize().
  ModelExecute()
    for t = tStart to tEnd
      Output()
      Update()
      Integrate()
        Compute states from derivs by repeatedly calling:
          MinorOutput()
          MinorDeriv()
        Locate any zero crossings by repeatedly calling:
          MinorOutput()
          MinorZeroCrossings()
      EndIntegrate
    Set time t = tNew.
  EndModelExecute
  ModelTerminate
EndSim

```

According to this conceptual model, Simulink runs a model by invoking the following functions zero, one, or many times, depending on the function and the model.

Function	Purpose	Level
sim	Simulate the model. This top-level function invokes the other functions required to simulate the model. The time spent in this function is the total time required to simulate the model.	System
ModelInitialize	Set up the model for simulation.	System
ModelExecute	Execute the model by invoking the output, update, integrate, etc., functions for each block at each time step from the start to the end of simulation.	System
Output	Compute the outputs of a block at the current time step.	Block
Update	Update the state of a block at the current time step.	Block
Integrate	Compute the continuous states of a block by integrating the state derivatives at the current time step.	Block
MinorOutput	Compute block output at a minor time step.	Block
MinorDeriv	Compute the state derivatives of a block at a minor time step.	Block
MinorZeroCrossings	Compute zero-crossing values of a block at a minor time step.	Block
ModelTerminate	Free memory and perform any other end-of-simulation cleanup.	System

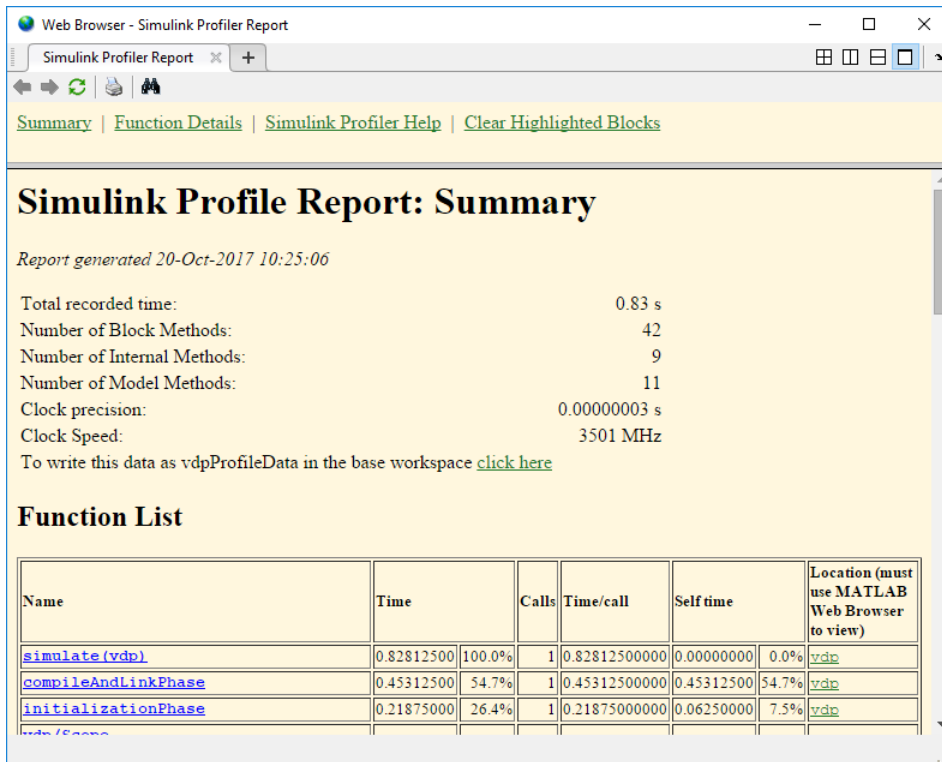

Function	Purpose	Level
Nonvirtual Subsystem	Compute the output of a nonvirtual subsystem at the current time step by invoking the output, update, integrate, etc., functions for each block that it contains. The time spent in this function is the time required to execute the nonvirtual subsystem.	Block

Profiler measures the time required to execute each invocation of these functions. After the model simulates, Profiler generates a report that describes the amount of simulation time spent on each function.

Start Profiler

- 1 Open the model.
- 2 Select **Analysis > Performance Tools > Show Profiler Report**.
- 3 Simulate the model.

When simulation is complete, Simulink generates and displays the simulation profile for the model in a MATLAB web browser.

Summary Section

The summary file displays the following performance totals.

Item	Description
Total Recorded Time	Total time required to simulate the model
Number of Block Methods	Total number of invocations of block-level functions (e.g., <code>Output()</code>)
Number of Internal Methods	Total number of invocations of system-level functions (e.g., <code>ModelExecute</code>)
Number of Model Methods	Number of methods called by the model
Number of Nonvirtual Subsystem Methods	Total number of invocations of nonvirtual subsystem functions

Item	Description
Clock Precision	Precision of the profiler's time measurement
Clock Speed	Speed of the profiler's time measurement

The function list shows summary profiles for each function invoked to simulate the model. For each function listed, the summary profile specifies this information.

Item	Description
Name	Name of function. This item is a hyperlink. Click it to display a detailed profile of this function.
Time	Total time spent executing all invocations of this function as an absolute value and as a percentage of the total simulation time.
Calls	Number of times this function was invoked.
Time/Call	Average time required for each invocation of this function, including the time spent in functions invoked by this function.
Self Time	Total time required to execute this function, excluding time spent in functions called by this function.
Location	Specifies the block or model executed for which this function is invoked. This item is a hyperlink. Click it to highlight the corresponding element in the model diagram.

Detailed Profile Section

This section of the report contains detailed profiles for each function that Simulink invoked to simulate the model. In addition to the information in the summary profile for the function, the detailed profile displays the function (parent function) that invoked the profiled function and the functions (child functions) invoked by the profiled function. Click the name of the parent or a child function to see the detailed profile for that function.

Note Enabling Profiler on a parent model does not enable profiling for referenced models. You must enable profiling separately for each referenced model. Profiling occurs only if the referenced model executes in Normal mode. See “Normal Mode” on page 35-4 for more information.

Reports for the referenced models are different from that of the parent model.

Save Profiler Results

You can save the Profiler report to a variable in the MATLAB workspace, and after that, to a `mat` file. At a later time, you can regenerate and review the report.

Save the Profiler report for a model `vdp` to the variable `profile1` and to the data file `report1.mat`.

1 In the **Simulink Profiler Report** window, in the **Summary** section, click **click here** link. Simulink saves the report data to the variable `vdpProfileData`.

2 Review the report. At the MATLAB command prompt, enter:

```
slprofreport(vdpProfileData)
```

3 Save the data to a variable named `profile1` in the base workspace.

```
profile1 = vdpProfileData;
```

4 Save the data to a `mat` file named `report1`.

```
save report1 profile1
```

To view the report later, at the MATLAB command prompt, enter:

```
load report1  
slprofreport(profile1);
```

Check and Improve Simulation Accuracy

Check Simulation Accuracy

- 1 Simulate the model over a reasonable time span.
- 2 Reduce either the relative tolerance to $1e-4$ (the default is $1e-3$) or the absolute tolerance.
- 3 Simulate the model again.
- 4 Compare the results from both simulations.

If the results are not significantly different, the solution has converged.

If the simulation misses significant behavior at the start, reduce the initial step size to ensure that the simulation does not step over that behavior.

Unstable Simulation Results

When simulation results become unstable over time,

- The system can be unstable.
- If you are using the `ode15s` solver, try restricting the maximum order to 2 (the maximum order for which the solver is A-stable). You can also try using the `ode23s` solver.

Inaccurate Simulation Results

If simulation results are not accurate:

- For a model that has states whose values approach zero, if the absolute tolerance parameter is too large, the simulation takes too few steps around areas of near-zero state values. Reduce this parameter value in the **Solver pane** of model configuration parameters or adjust it for individual states in the function block parameters of the Integrator block.
- If reducing the absolute tolerances does not improve simulation accuracy enough, reduce the size of the relative tolerance parameter. This change reduces the acceptable error and forces smaller step sizes and more steps.

Certain modeling constructs can also produce unexpected or inaccurate simulation results.

- A Source block that inherits sample time can produce different simulation results if, for example, the sample times of the downstream blocks are modified (see “How Propagation Affects Inherited Sample Times” on page 7-38).
- A Derivative block found in an algebraic loop can result in a loss in solver accuracy.

Modeling Techniques That Improve Performance

In this section...

“Accelerate the Initialization Phase” on page 31-13

“Reduce Model Interactivity” on page 31-14

“Reduce Model Complexity” on page 31-15

“Choose and Configure a Solver” on page 31-16

“Save the Simulation State” on page 31-18

Accelerate the Initialization Phase

Speed up a simulation by accelerating the initialization phase, using these techniques.

Simplify Graphics Using Mask Editor

Complex graphics and large images take a long time to load and render. Masked blocks that contain such images can make your model less responsive. Where possible, remove complex drawings and images from masked blocks.

If you want to keep the image, replace it with a smaller, low-resolution version. Use mask editor and edit the icon drawing commands to keep the image that is loaded by the call to `image()`.

For more information on mask editor, see “Mask Editor Overview”.

Consolidate Function Calls

When you open or update a model, Simulink runs the mask initialization code. If your model contains complicated mask initialization commands that contain many calls to `set_param`, consolidate consecutive calls into a single call with multiple argument pairs. Consolidating the calls can reduce the overhead associated with these function calls.

To learn more, see “Mask Callback Code” on page 39-18.

Load Data Using MAT-file

If you use MATLAB scripts to load and initialize data, you can improve performance by loading MAT-files instead. The data in a MAT-file is in binary and can be more difficult to

work with than a script. However, the load operation typically initializes data more quickly than the equivalent MATLAB script.

For more information, see “MAT-Files for Signal Data” on page 64-12.

Reduce Model Interactivity

In general, the more interactive a model is, the longer it takes to simulate. Use these techniques to reduce the interactivity of your model.

Disable Debugging Diagnostics

Some enabled diagnostic features can slow simulations considerably. Consider disabling them in the model configuration parameters **Diagnostics** pane.

Note Running **Array bounds exceeded** and **Solver data inconsistency** can slow down model runtime performance. For more information, see “Array bounds exceeded” and “Solver data inconsistency”.

Disable MATLAB Debugging

After verifying that your MATLAB code works correctly, disable these checks in the model configuration parameters **Simulation Target** pane.

- **Enable debugging/animation**
- **Detect wrap on overflow (with debugging)**
- **Echo expressions without semicolons**

For more information, see “Model Configuration Parameters: Simulation Target”.

Use BLAS Library Support

If your simulation involves low-level MATLAB matrix operations, use the Basic Linear Algebra Subprograms (BLAS) libraries to make use of highly optimized external linear algebra routines.

Disable Stateflow Animations

By default, Stateflow charts highlight the current active states in a model and animate the state transitions that take place as the model simulates. This feature is useful for debugging, but it slows the simulation.

To accelerate simulations, either close all Stateflow charts or disable the animation. Similarly, consider disabling animation or reducing scene fidelity when you use:

- Simulink 3D Animation
- Simscape Multibody visualization
- FlightGear
- Any other 3D animation package

To learn more, see “Speed Up Simulation” (Stateflow).

Adjust Scope Viewer Properties

If your model contains a scope viewer that displays a high rate of logging and you cannot remove the scope, adjust the viewer properties to trade off fidelity for rendering speed.

However, when you use decimation to reduce the number of plotted data points, you can miss short transients and other phenomena that you can see with more data points. To have more precise control over enabling visualizations, place viewers in enabled subsystems.

For more information, see Scope Viewer.

Reduce Model Complexity

Use these techniques to improve simulation performance by simplifying a model without sacrificing fidelity.

Replace Subsystems with Lower-Fidelity Alternatives

Replace a complex subsystem with one of these alternatives:

- A linear or nonlinear dynamic model that was created from measured input-output data using the System Identification Toolbox™.
- A high-fidelity, nonlinear statistical model that was created using the Model-Based Calibration Toolbox™.

- A linear model that was created using Simulink Control Design.
- A lookup table. For more information, see A lookup table.

You can maintain both representations of the subsystem in a library and use variant subsystems to manage them. Depending on the model, you can make this replacement without affecting the overall result. For more information, see “Optimize Generated Code for Lookup Table Blocks” on page 38-44.

Reduce Number of Blocks

When you reduce the number of blocks in your model, fewer blocks require updates during simulations and simulation is faster.

- Vectorization is one way to reduce your block count. For example, if you have several parallel signals that undergo a similar set of computations, try to combine them into a vector using a Mux block and perform a single computation.
- You can also enable the **Block Reduction** parameter in the **Configuration Parameters** dialog.

Use Frame-Based Processing

In frame-based processing, Simulink processes samples in batches instead of one at a time. If a model includes an analog-to-digital converter, for example, you can collect output samples in a buffer. Process the buffer in a single operation, such as a fast Fourier transform. Processing data in chunks this way reduces the number of times that the simulation needs to invoke blocks in your model.

In general, the scheduling overhead decreases as frame size increases. However, larger frames consume more memory, and memory limitations can adversely affect the performance of complex models. Experiment with different frame sizes to find one that maximizes the performance benefit of frame-based processing without causing memory issues.

Choose and Configure a Solver

Simulink provides a comprehensive library of solvers, including fixed-step and variable-step solvers, to handle stiff and nonstiff systems. Each solver determines the time of the next simulation step. A solver applies a numerical method to solve ordinary differential equations that represent the model.

The solver you choose and the solver options you select can affect simulation speed. Select and configure a solver that helps boost the performance of your model using these criteria. For more information, see “Choose a Solver” (Global Optimization Toolbox).

Stiffness of System

A stiff system has continuous dynamics that vary slowly and quickly. Implicit solvers are particularly useful for stiff problems. Explicit solvers are better suited for nonstiff systems. Using an explicit solver to solve a stiff system can lead to incorrect results. If a nonstiff solver uses a very small step size to solve a model, this is a sign that your system is stiff.

Model Step Size and Dynamics

When you are deciding between using a variable-step or fixed-step solver, keep in mind the step size and dynamics of your model. Select a solver that uses time steps to capture only the dynamics that are important to you. Choose a solver that performs only the calculations needed to work out the next time step.

You use fixed-step solvers when the step size is less than or equal to the fundamental sample time of the model. With a variable-step solver, the step size can vary because variable-step solvers dynamically adjust the step size. As a result, the step size for some time steps is larger than the fundamental sample time, reducing the number of steps required to complete the simulation. In general, simulations with variable-step solvers run faster than those that run with fixed-step solvers.

Choose a fixed-step solver when the fundamental sample time of your model is equal to one of the sample rates. Choose a variable-step solver when the fundamental sample time of your model is less than the fastest sample rate. You can also use variable-step solvers to capture continuous dynamics.

Decrease Solver Order

When you decrease the solver order, you reduce the number of calculations that Simulink performs to determine state outputs, which improves simulation speed. However, the results become less accurate as the solver order decreases. Choose the lowest solver order that produces results with acceptable accuracy.

Increase Solver Step Size or Error Tolerance

Increasing the solver step size or error tolerance usually increases simulation speed at the expense of accuracy. Make these changes with care because they can cause Simulink to miss potentially important dynamics during simulations.

Disable Zero-Crossing Detection

Variable-step solvers dynamically adjust the step size, increasing it when a variable changes slowly and decreasing it when a variable changes rapidly. This behavior causes the solver to take many small steps near a discontinuity because this is when a variable changes rapidly. Accuracy improves, but often at the expense of long simulation times.

To avoid the small time steps and long simulations associated with these situations, Simulink uses zero-crossing detection to locate such discontinuities accurately. For systems that exhibit frequent fluctuations between modes of operation—a phenomenon known as chattering—this zero-crossing detection can have the opposite effect and thus slow down simulations. In these situations, you can disable zero-crossing detection to improve performance.

You can enable or disable zero-crossing detection for specific blocks in a model. To improve performance, consider disabling zero-crossing detection for blocks that do not affect the accuracy of the simulation.

For more information, see “Zero-Crossing Detection” on page 3-24.

Save the Simulation State

In the classic workflow, a Simulink model simulates repeatedly for different inputs, boundary conditions, and operating conditions. In many situations, these simulations share a common startup phase in which the model transitions from the initial state to another state. For example, you can bring an electric motor up to speed before you test various control sequences.

Using `SimState`, you can save the simulation state at the end of the startup phase and then restore it for use as the initial state for future simulations. This technique does not improve simulation speed, but it can reduce total simulation time for consecutive runs because the startup phase needs to be simulated only once.

See “Save and Restore Simulation Operating Point” on page 25-36 for more information.

Use Performance Advisor to Improve Simulation Efficiency

Use Performance Advisor to check for conditions and configuration settings that can cause inefficient simulation performance. Performance Advisor analyzes a model and produces a report with suboptimal conditions or settings that it finds. It suggests better model configuration settings where appropriate, and provides mechanisms for fixing issues automatically or manually.

Improve Simulation Performance Using Performance Advisor

In this section...
“Performance Advisor Workflow” on page 32-2
“Prepare Your Model” on page 32-3
“Create a Performance Advisor Baseline Measurement” on page 32-5
“Run Performance Advisor Checks” on page 32-6
“View and Respond to Results” on page 32-8
“View and Save Performance Advisor Reports” on page 32-10

Whatever the level of complexity of your model, you can make systematic changes that improve simulation performance. Performance Advisor checks for configuration settings that slow down your model simulations. It produces a report that lists the suboptimal conditions or settings it finds and suggests better configuration settings where appropriate.

You can use the Performance Advisor to fix some of these suboptimal conditions automatically or you can fix them manually.

Note Use Performance Advisor on top models. Performance Advisor does not traverse referenced models or library links.

To learn about faster simulation using acceleration modes, see “Acceleration”.

Performance Advisor Workflow

When the performance of a model is slower than expected, use Performance Advisor to help identify and resolve bottlenecks.

- 1 Prepare your model.
- 2 Create a baseline to compare measurements against.
- 3 Select the checks you want to run.
- 4 Run Performance Advisor with the selected checks and see recommended changes.

- 5 Make changes to the model. You can either:
 - Automatically apply changes.
 - Generate advice, and review and apply changes manually.
- 6 After applying changes, Performance Advisor performs a final validation of the model to see how performance has improved.
 - If the performance improves, the selected checks were successful. The performance check is complete.
 - If the performance is worse than the baseline, Performance Advisor reinstates the previous settings of the model.
- 7 Save your model.

Caution Performance Advisor does not automatically save your model after it makes changes. When you are satisfied with the changes to the model from Performance Advisor, save the model.

Prepare Your Model

Before running checks using Performance Advisor, complete the following steps:

- “Start Performance Advisor” on page 32-3
- “Enable Data Logging for the Model” on page 32-4
- “Select How Performance Advisor Applies Advice” on page 32-4
- “Select Validation Actions for the Advice” on page 32-4
- “Specify Runtime for Performance Advisor” on page 32-5

Start Performance Advisor

To get started with Performance Advisor:

- 1 Make a backup of the model.
- 2 Verify that the model can simulate without error.
- 3 Close all applications, including web browsers. Leave only the MATLAB Command Window, the model you want to analyze, and Performance Advisor running.

Running other applications can hinder the performance of model simulation and the ability of Performance Advisor to measure accurately.

- 4 Open Performance Advisor. In the Simulink Editor, select **Analysis > Performance Tools > Performance Advisor**.

Enable Data Logging for the Model

Make sure the model configuration parameters are set to enable data logging.

- 1 In the model, select **Simulation > Model Configuration Parameters**.
- 2 In the Configuration Parameters dialog box, click **Data Import/Export** in the left pane.
- 3 Set up signal logging. The model must log at least one signal for Performance Advisor to work. For example, select the **States** or **Output** check box.
- 4 Click **Configure Signals to Log** and select the signals to log.

Note Select only the signals you are most interested in. Minimizing the number of signals to log can help performance. Selecting too many signals can cause Performance Advisor to run for a longer time.

- 5 Click **OK** in the Configuration Parameters dialog box.
- 6 Run the model once to make sure that the simulation is successful.

Select How Performance Advisor Applies Advice

Choose from these options to apply advice to the model:

- **Use check parameters.** Select the checks for which you want Performance Advisor to automatically apply advice. You can review the remaining checks and apply advice manually.
- **Automatically for all checks.** Performance Advisor automatically applies advice to all selected checks.
- **Generate advice only.** Review advice for each check and apply changes manually.

Select Validation Actions for the Advice

For the checks you want to run, validate an improvement in simulation time and accuracy by comparing against a baseline measurement. Each validation action requires the model to simulate. Use these validation options as global settings for the checks you select:

- **Use check parameters.** From the checks you want to run, select the ones for which you want to validate an improvement in performance. Specify validation action for fixes using individual settings for these checks.
- **For all checks.** Performance Advisor automatically validates an improvement in performance for the checks you select.
- **Do not validate.** Performance Advisor does not validate an improvement in performance. Instead, you can validate manually. When you select this option and also specify for Performance Advisor to apply advice automatically, a warning appears before Performance Advisor applies changes without validation.

These global settings for validation apply to all checks in the left pane except the Final Validation check. The Final Validation check validates the overall performance improvement in a model after you have applied changes. In case you do not want to validate changes resulting from other check results, you can run the Final Validation check to validate model changes for simulation time and accuracy.

Specify Runtime for Performance Advisor

You can specify a **Time Out** value in minutes if you want to limit the runtime duration of Performance Advisor. Use this option when running Performance Advisor on models with long simulation times.

If Performance Advisor times out before completing the checks you specify, in the left pane you can see the checks that failed.

Create a Performance Advisor Baseline Measurement

A baseline measurement is a set of simulation measurements that Performance Advisor measures check results against.

Note Before creating a baseline measurement, set the model configuration parameters to enable data logging. For more information, see “Enable Data Logging for the Model” on page 32-15.

- 1 In the model, select **Analysis > Performance Tools > Performance Advisor** to start Performance Advisor.
- 2 In the left pane, in the Baseline folder, select **Create Baseline**.

- 3 In the right pane, under **Input Parameters**, enter a value in the **Stop Time** field for the baseline.

When you enter a Stop Time value in Performance Advisor, this overrides the value set in the model. A large stop time can create a simulation that runs longer.

If you do not enter a value, Performance Advisor uses values from the model. Performance Advisor uses values from the model that are less than 10. Performance Advisor rounds values from the model larger than 10 to 10.

- 4 Select the **Check to view baseline signals and set their tolerances** check box to start the Signal Data Inspector after Performance Advisor runs a check. Using the Signal Data Inspector, you can compare signals and adjust tolerance levels.
- 5 Click **Run This Check**.

When a baseline has been created, a message like the following appears under **Analysis**:

After the baseline has been created, you can run Performance Advisor checks.

Run Performance Advisor Checks

- 1 After you have created a baseline measurement, select checks to run.
 - In the left pane of Performance Advisor, expand a folder, such as **Simulation** or **Simulation Targets**, to display checks related to specific tasks.
 - In the folder, select the checks you want to run using the check boxes.

Tip If you are unsure of which checks apply, you can select and run all checks. After you see the results, clear the checks you are not interested in.

- 2 Specify input parameters for selected checks. Use one of these methods:

- Apply global settings to all checks to take action, validate simulation time and validate simulation accuracy.
- Alternatively, for each check, in the right pane, specify input parameters.

Input Parameter	Description
Take action based on advice	<p>automatically — Allow Performance Advisor to automatically make the change for you.</p> <p>manually — Review the change first. Then manually make the change or accept Performance Advisor recommendations.</p>
Validate and revert changes if time of simulation increases	Select this check box to have Performance Advisor rerun the simulation and verify that the change made based on the advice improves simulation time. If the change does not improve simulation time, Performance Advisor reverts the changes.
Validate and revert changes if degree of accuracy is greater than tolerance	Select this check box to have Performance Advisor rerun the simulation and verify that, after the change, the model results are still within tolerance. If the result is outside tolerance, Performance Advisor reverts the changes.
Quick estimation of model build time	Select this check box to have Performance Advisor use the number of blocks of a referenced model to estimate model build time.

- 3 To run a single check, click **Run This Check** from the settings for the check. Performance Advisor displays the results in the right pane.

You can also select multiple checks from the left pane and click **Run Selected Checks** from the right pane. Select **Show report after run** to display the results of the checks after they run.

- 4 To limit the run time of Performance Advisor, specify a **Time Out** value in minutes. Use this option for models with long simulation times. The default setting for this option is 60 minutes.

Note The **Time Out** setting does not apply to a Quick Scan diagnosis.

Performance Advisor also generates an HTML report of the current check results and actions in a file with a name in the form *model_name\report_#.html*

To view this report in a separate window, click the **Report** link in the right pane.

Note If you rename a system, you must restart Performance Advisor to check that system.

View and Respond to Results

After you run checks with Performance Advisor, the right pane shows the results:

The screenshot displays the 'Identify simulation target settings' window, divided into 'Analysis' and 'Action' sections. An arrow labeled 'Analysis' points to the top section, and an arrow labeled 'Action' points to the bottom section.

Analysis Section:

- Analysis:** Disabling simulation target settings, such as 'Echo expression without semicolons', can improve simulation speed.
- Input Parameters:** Take action based on advice: (dropdown menu)
- Validate and revert changes if time of simulation increases
- Validate and revert changes if degree of accuracy is greater than tolerance
-
- Result:** ⚠ Warning
- The simulation target setting 'Echo expressions without semicolons' is enabled. Disabling this setting might improve simulation speed. Review the following settings in the Model Configuration of model 'vdp'.
- Performance Advisor has taken the necessary actions. For details, see the Action Results section.

Severity	Diagnostics checked	Original Value	New Value
⚠	Simulation Target > Echo expressions without semicolons	on	off

Action Section:

- Action:** Review the action results
-
- Result:**

Summary of performance validations			
	Before this check	After this check	Improvement
Performance			✓
Accuracy	Within given tolerance	Within given tolerance Click to view	✓
Simulation Time	00:00:34.970	00:00:02.036	94.18%

To view the results of a check, in the left pane, select the check you ran. The right pane updates with the results of the check. This pane has two sections.

The **Analysis** section contains:

- Information about the check
- Option to run the simulation
- Settings to take action based on advice from Performance Advisor
- Result of the check (Passed, Failed or Warning)

The **Action** section contains:

- A setting to manually accept all recommendations for the check
- Summary of actions taken based on the recommendations for the check

Respond to Results

Use the **Take action based on advice** parameter in the **Analysis** section to select how to respond to changes that Performance Advisor suggests.

Value	Response
automatically	<ul style="list-style-type: none"> • Performance Advisor makes the change for you. • You can evaluate the changes using the links in the summary table. • The Modify All button in the Action section is grayed out since Performance Advisor has already made all recommended changes for you.
manually	<ul style="list-style-type: none"> • Performance Advisor does not make the change for you. • The links in the summary table show recommendations. • Use the Modify All button in the Action section to implement all recommendations after reviewing them. Depending on how you set your validation input parameters before you ran the check, the button label can change to Modify All and Validate.

Review Actions

The **Action** section contains a summary of the actions that Performance Advisor took based on the **Input Parameters** setting. If the tool also performed validation actions, this

section lists the results in a summary table. If performance has not improved, Performance Advisor reports that it reinstated the model to the settings it had before the check ran.

Action

Review the action results

Result:

Summary of performance validations			
	Before this check	After this check	Improvement
Performance			
Accuracy	Within given tolerance	Within given tolerance Click to view	
Simulation Time	00:00:04.276	00:00:02.412	43.59%

Summary of actions

Actions:

Severity	Description
	The actions succeeded. The table lists the percentage of improvement.
	The actions failed. For example, if Performance Advisor cannot make a recommended change, it flags it as failed. It also flags a check as failed if performance did not improve and reinstates the model to the settings it had before the check ran.

Caution Performance Advisor does not automatically save your model after it makes changes. When you are satisfied with the changes to the model from Performance Advisor, save the model.

View and Save Performance Advisor Reports

When Performance Advisor runs checks, it generates HTML reports of the results. To view a report, select a folder in the left pane and click the link in the **Report** box in the right pane.

As you run checks, Performance Advisor updates the reports with the latest information for each check in the folder. Time stamps indicate when checks ran.

In the pane for global settings, when you select **Show report after run**, Performance Advisor displays a consolidated set of check results in the report.

Simulink Performance Advisor Report - vdp.slx

Simulink version: 8.3
System: vdp
Model version: 1.7
Current run: 24-Oct-2013 06:57:14

Performance Advisor

1 Baseline 01 00 00 00

2 Simulation 02 00 02 08

2.1 Checks Occurring Before Update 01 00 02 06

Identify resource-intensive diagnostic settings

Some diagnostics incur run-time overhead during simulation. Review the following parameters in the Model Configuration of model 'vdp' and the suggested changes for these parameters.

Click link(s) to make changes manually. Alternatively, click the 'Modify all' button below to have Performance Advisor take necessary actions for you.

Severity	Diagnostics checked	Original Value	New Value
Solver	Diagnostics > Solver data inconsistency	none	none
Signals	Diagnostics > Data Validity > Signal resolution	Explicit and warn implicit	Explicit only
	Diagnostics > Data Validity > Division by singular matrix	none	none
	Diagnostics > Data Validity > Inf or nan block output	none	none
	Diagnostics > Data Validity > Simulation range checking	none	none
	Diagnostics > Data Validity > Array bounds exceeded	none	none
DSM Blocks	Diagnostics > Data Validity > Detect read before write	UseLocalSettings	DisableAll
	Diagnostics > Data Validity > Detect write after read	UseLocalSettings	DisableAll

You can perform these actions using the Performance Advisor report:

- Use the check boxes under **Filter checks** to view only the checks with the status that you are interested in viewing. For example, to see only the checks that failed or gave warnings, clear the **Passed** and **Not Run** check boxes.
- Perform a keyword search using the search box under **Filter checks**.
- Use the tree of checks under **Navigation** to jump to the category of checks or a specific check result that interests you.
- Expand and collapse content in the right pane of the report to view or hide check results.

Some checks have input parameters that you specify in the right pane of Performance Advisor. For example, **Identify resource intensive diagnostic settings** has several input parameters. When you run checks that have input parameters, Performance Advisor displays the values of the input parameters in the report.

Identify resource-intensive diagnostic settings

Some diagnostics incur run-time overhead during simulation. Review the following parameters in the Model Configuration of model 'vdp' and the suggested changes for these parameters.

Performance Advisor has taken the necessary actions. For details, see the Action Results section.

Severity	Diagnostics checked	Original Value	New Value
Solver	Diagnostics > Solver data inconsistency	none	none
Signals	Diagnostics > Data Validity > Signal resolution	Explicit and warn implicit	Explicit only
	Diagnostics > Data Validity > Division by singular matrix	none	none

v More (8 rows)

Input Parameters Selection

Name	Value
Take action based on advice	automatically
Validate and revert changes if time of simulation increases	true
Validate and revert changes if degree of accuracy is greater than tolerance	true

Save Performance Advisor Reports

You can archive a Performance Advisor report by saving it to a new location. Performance Advisor does not update the saved version of a report when you run checks again. Archived reports serve as good points of comparison when you run checks again.

- 1** In the left pane of the Performance Advisor window, select the folder of checks for the report you want to save.
- 2** In the **Report** box, click **Save As**.
- 3** In the **Save As** dialog box, navigate to where you want to save the report, and click **Save**. Performance Advisor saves the report to the new location.

Perform a Quick Scan Diagnosis

Quick Scan is a fast method to diagnose settings in a model and deliver an approximate analysis of performance. A model can compile and simulate several times during a normal run in Performance Advisor. Quick Scan enables you to review performance issues without compiling or changing the model or validating any fixes. In models with long compile times, use Quick Scan to get a rapid analysis of possible improvements.

When you perform a Quick Scan diagnosis, Performance Advisor

- Does not perform a baseline measurement.
- Does not automatically apply advice to the model.
- Does not validate any changes you make to the model.
- Does not time out if the Quick Scan diagnosis takes longer than the **Time Out** duration you specify.

Run Quick Scan on a Model

- 1 Select checks to run.

Tip If you are unsure of which checks apply, you can select and run all checks. After you see the results, clear the checks you are not interested in.

- In the left pane of Performance Advisor, expand a folder, such as **Simulation** or **Simulation Targets**, to display checks related to specific tasks.
 - In the folder, select the checks you want to run using the check boxes.
- 2 Select the **Show report after run** checkbox to display the results of the checks after they run.
 - 3 Click **Quick Scan** on the right pane.

Checks in Quick Scan Mode

- “Identify resource-intensive diagnostic settings”
- “Check optimization settings”
- “Identify inefficient lookup table blocks”

- “Check MATLAB System block simulation mode”
- “Identify Interpreted MATLAB Function blocks”
- “Identify simulation target settings”

Improve vdp Model Performance

In this section...

“Enable Data Logging for the Model” on page 32-15

“Create Baseline” on page 32-15

“Select Checks and Run” on page 32-16

“Review Results” on page 32-17

“Apply Advice and Validate Manually” on page 32-19

This example shows you how to run Performance Advisor on the vdp model, review advice, and make changes to improve performance.

Enable Data Logging for the Model

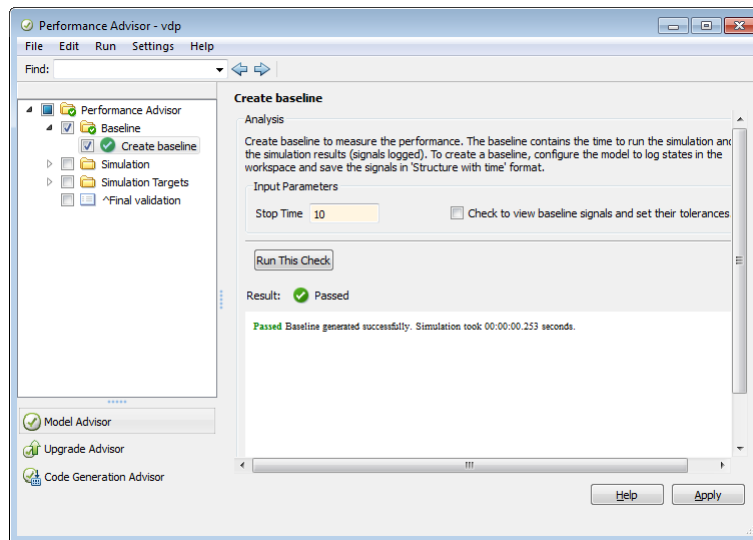

- 1 In the vdp model, select **Simulation > Model Configuration Parameters**.
- 2 In the Configuration Parameters dialog box, click **Data Import/Export** in the left pane.
- 3 Set up signal logging. The model must log at least one signal for Performance Advisor to work. For example, select the **States** or **Output** check box.
- 4 Click **Configure Signals to Log**.
- 5 To select signals to log, select a signal in vdp. Right click and select **Properties**.
- 6 In the Signal Properties dialog box, check the **Log signal data** option and click **OK**.
- 7 Click **OK** in the Configuration Parameters dialog box.
- 8 Run the model once to make sure that the simulation is successful.

Create Baseline

- 1 Open Performance Advisor. In the vdp model, select **Analysis > Performance Tools > Performance Advisor**.
- 2 In the right pane, under **Set Up**, select a global setting for **Take Action**. To automatically apply advice to the model, select **automatically** for all checks.
- 3 Select global settings to validate any improvements in simulation time and accuracy after applying advice. To select the default setting for validation, for **Validate simulation time** and **Validate simulation accuracy**, select use check parameters.

Note To validate any improvements automatically, change the global settings to **For all checks**. However, this can increase simulation time as validating all checks requires more simulation runs.

- 4 Select **Show report after run**. This opens an HTML report of check results.
- 5 In the left pane, select the **Create baseline** check. Clear the other checks.
- 6 In the **Create baseline** pane, set **Stop Time** to 10. Click **Apply**.
- 7 Click **Run This Check**. The right pane updates to show that the baseline was created successfully.

Select Checks and Run

Note The global input parameters to take action and validate improvement apply to all the checks you select.

- 1 In the left pane, clear the baseline check. Select these checks:
 - In **Simulation > Checks Occurring Before Update**, select **Identify resource-intensive diagnostic settings**.

- In **Simulation > Checks that Require Update Diagram**, select **Check model reference parallel build**.
 - In **Simulation Targets > Check Compiler Optimization Settings**, select **Select compiler optimizations on or off**.
 - Select **Final validation**.
- 2 For every check that you have selected in the left pane, select options in the right pane to validate any improvements in simulation time and accuracy. Note that **Take Action based on advice** is set to automatically, a result of **Take Action** being set to automatically for all checks.
 - 3 Select a value for **Time Out** if you want to limit the runtime duration of Performance Advisor.
 - 4 Click **Run Selected Checks**.

Performance Advisor runs the checks you selected and opens an HTML report with check results.

Review Results

- 1 In the HTML report, filter the results to see only the checks that passed.

✔ Final validation

All of the selected checks passed successfully.

- 2 Navigate to the results for a particular check, for example **Check model reference parallel build**. Use the navigation tree in the left pane or scroll to the results for this check in the right pane.
- 3 Performance Advisor gives you information about this check, advice for performance improvement, as well as a list of related model configuration parameters.

✔ **Check model reference parallel build**

Passed

There are less than two reference models in your model. Parallel building is unnecessary. However, consider using model reference for large models. Use more than one model reference to take advantage of parallel building.

Input Parameters Selection

Name	Value
Quick estimation of model build time	true
Parallel build overhead time estimation factor	0.5

- 4 Filter the results to display warnings. See results for the **Identify resource-intensive diagnostic settings** check.

Performance Advisor identified diagnostic settings that incur runtime overhead during simulation. It modified values for some of these diagnostics. A table in the report shows the diagnostics checked and whether Performance Advisor suggested a change to the value.

If the performance of the model improved, the HTML report gives you information about this improvement. If the performance has deteriorated, Performance Advisor discards all changes and reinstates the original settings in the model.

- 5 See details for the **Final Validation** check.

✓ Final validation

Summary of performance validations			
	Before this check	After this check	Improvement
Performance			✓
Accuracy	Within given tolerance	Within given tolerance Click to view	✓
Simulation Time	00:00:00.253	00:00:00.100	60.38%

Passed

Overall, Performance advisor has improved the performance of the model.

Input Parameters Selection

Name	Value
Take action based on advice	automatically
Validate and revert changes if time of simulation increases	true
Validate and revert changes if degree of accuracy is greater than tolerance	true

This check validates the overall performance improvement in the model. The check results show changes in simulation time and accuracy, depending on whether performance improved or degraded.

Apply Advice and Validate Manually

Generate advice for a check, apply it, and validate any improvements manually.

- 1 In the left pane, click **Performance Advisor**. Select these settings and click **Apply**:
 - Set **Take Action** to generate advice only.
 - Set **Validate simulation time** to use check parameters.
 - Set **Validate simulation accuracy** to use check parameters.
- 2 For every check that you have selected in the left pane, select options in the right pane to validate any improvements in simulation time and accuracy. Note that **Take Action based on advice** is set to manually, a result of **Take Action** being set to generate advice only.
- 3 Select **Performance Advisor** in the left pane. Click **Run Selected Checks** in the Performance Advisor pane.

If the performance of the model has improved, the **Final Validation** check results show the overall performance improvement.

- 4 In the results for **Identify resource-intensive diagnostic settings**, Performance Advisor suggests new values for the diagnostics it checked. Review these results to accept or reject the values it suggests.

Alternatively, click **Modify all and Validate** to accept all changes and validate any improvement in performance.

Performance Advisor Window

When you open Performance Advisor, it displays two panes.

In the left pane, the performance checks you can run are stored in folders. Expand the folders to see the checks within and select checks to run. You can search for folders and checks using **Find** above the pane.

Use the right pane to:

- Understand the Performance Advisor workflow
- Set up the model to run checks
- Select actions to apply generated advice and validate check results
- Learn more about each check
- Specify input parameters
- Run checks
- View and save reports
- View Performance Advisor results

After you run a check, Performance Advisor displays the results in the right pane. The right pane changes depending on the check you have selected.

Selection	Right Pane Display
Folder	<p>Analysis pane, containing:</p> <ul style="list-style-type: none"> • Run Selected Checks button — Click to run the selected checks in the folder and its subfolders. • Show report after run check box — Select to display an HTML report of the check results in a separate window. <p>Report pane, containing:</p> <ul style="list-style-type: none"> • Link to HTML report of check results • Save As button — Click to export the HTML report to a specific location <p>Tips and Legend panes, containing brief descriptions on using the checks.</p>
Check	<p>Analysis pane, containing:</p> <ul style="list-style-type: none"> • Input Parameters section — Before running checks, specify how you want checks to run (for more information, see “Run Performance Advisor Checks” on page 32-6). • Result section — Display results after a check runs. <p>Action pane, containing:</p> <ul style="list-style-type: none"> • Modify button — After the check runs, Performance Advisor suggests actions to take to improve performance. Click here to accept the recommendations and modify the model. • Result section — Display results after performing recommended actions.

From Performance Advisor, you can also run:

- **Model Advisor** — Check a model or subsystem for conditions that result in inaccurate or inefficient simulation of the system. See “Run Model Checks”.
- **Upgrade Advisor** — Upgrade and improve models with the current release. See “Consult the Upgrade Advisor” on page 6-2.

- **Code Generation Advisor** — Configure the model to meet code generation objectives. See “Application Objectives Using Code Generation Advisor” (Simulink Coder).

Examine Model Dynamics Using Solver Profiler

When model simulation slows down or stops responding, a close examination of the dynamics of the model can help you identify the factors affecting the simulation.

Understanding solver behavior enables you to interpret how the model simulates and what causes the solver to take small steps.

The Solver Profiler analyzes a model for patterns that affect its simulation. The Solver Profiler presents graphical and statistical information about the simulation, solver settings, events, and errors. You can use this data to identify locations in the model that caused simulation bottlenecks.

In addition, there are multiple factors that can limit the simulation speed. The Solver Profiler logs and reports all the major events that occur when simulating a model:

- Zero-crossing events
- Solver exception events
- Solver reset events
- Jacobian computation events

These events are common and necessary for an accurate simulation. However, they do incur computational cost and frequent occurrences can slow down or even stall the simulation.

To examine model dynamics and identify causes that affect the simulation:

- 1 Open the model that is simulating slowly or unsuccessfully.

- 2 Open the Solver Profiler by clicking the hyperlink in the lower-right corner of the Simulink Editor.

- 3 The Solver Profiler provides smart logging and diagnostics of continuous model states and Simscape states. To enable this, select the **Continuous States** or **Simscape States** option before a run. Disable these options only if you are running out of memory. After the run, access the States Explorer or Simscape Explorer to examine those states.
- 4 Click **Run**. The profiler simulates the model and starts capturing solver performance data.

When the simulation ends, the profiler displays the statistics and exceptions it captured over the duration of the simulation.

Tip You can pause or stop the simulation at any time to view the information captured until that point.

- 5 Use the profiler plot to highlight the parts of the model that caused generate the most events.
- 6 Click **Save** to capture your profiling session, or exit without saving.

Understand Profiling Results

If you have a large model, it can be challenging to identify which parts of your model cause the solver to take small steps. The Solver Profiler logs and reports events when the solver attempts to take large steps. This report of events helps you identify which parts of your model to focus on to improve solver performance.

This topic presents simple examples that illustrate various events that the profiler reports.

Zero-Crossing Events

This example simulates a ball bouncing on a hard surface.

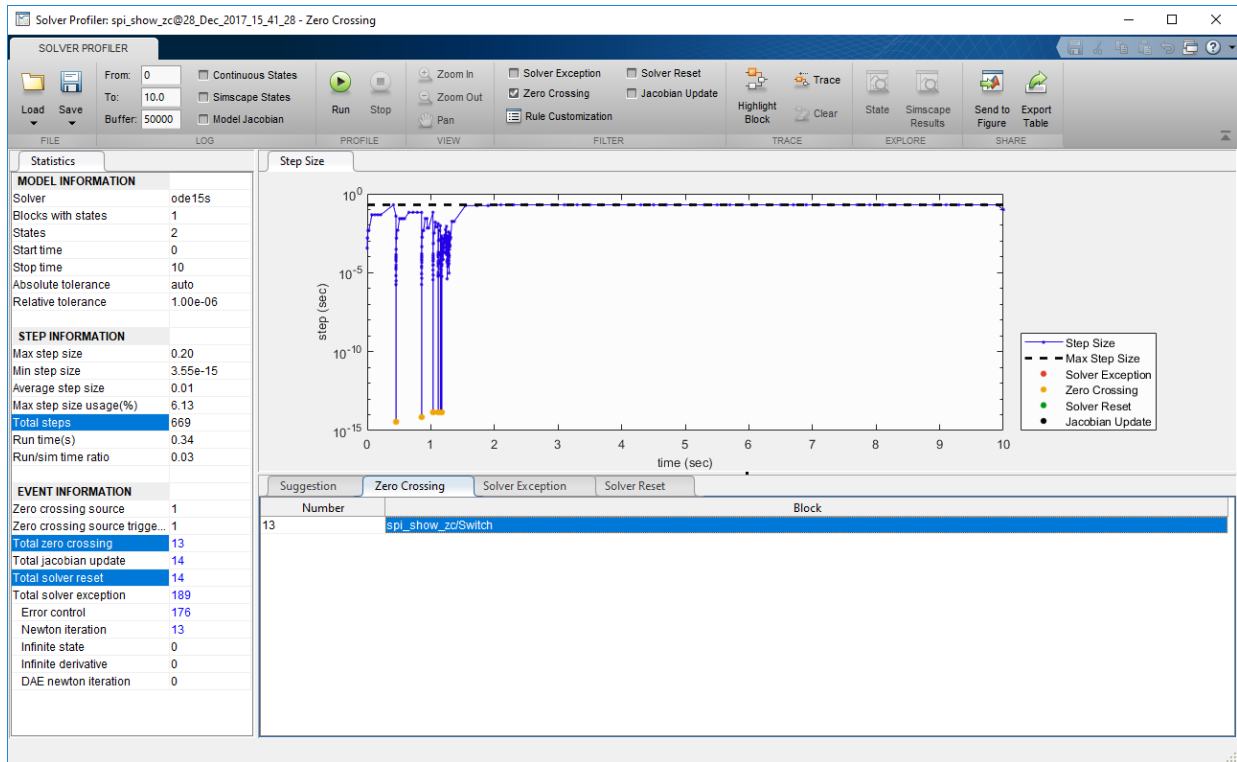

When you run the Solver Profiler on this model, the model simulates in 2898 steps and that it triggers 67 zero crossing events. To highlight the zero crossing events on the step size plot, click the **Zero Crossing** tab and select the block that is causing the event.

The result indicates that when the ball drops on the hard surface, it bounces 67 times before coming to a stop. The solver resets after each bounce, increasing the computational load. Having many resets improves accuracy at the cost of computation load. Therefore, it is important to know this tradeoff when modeling.

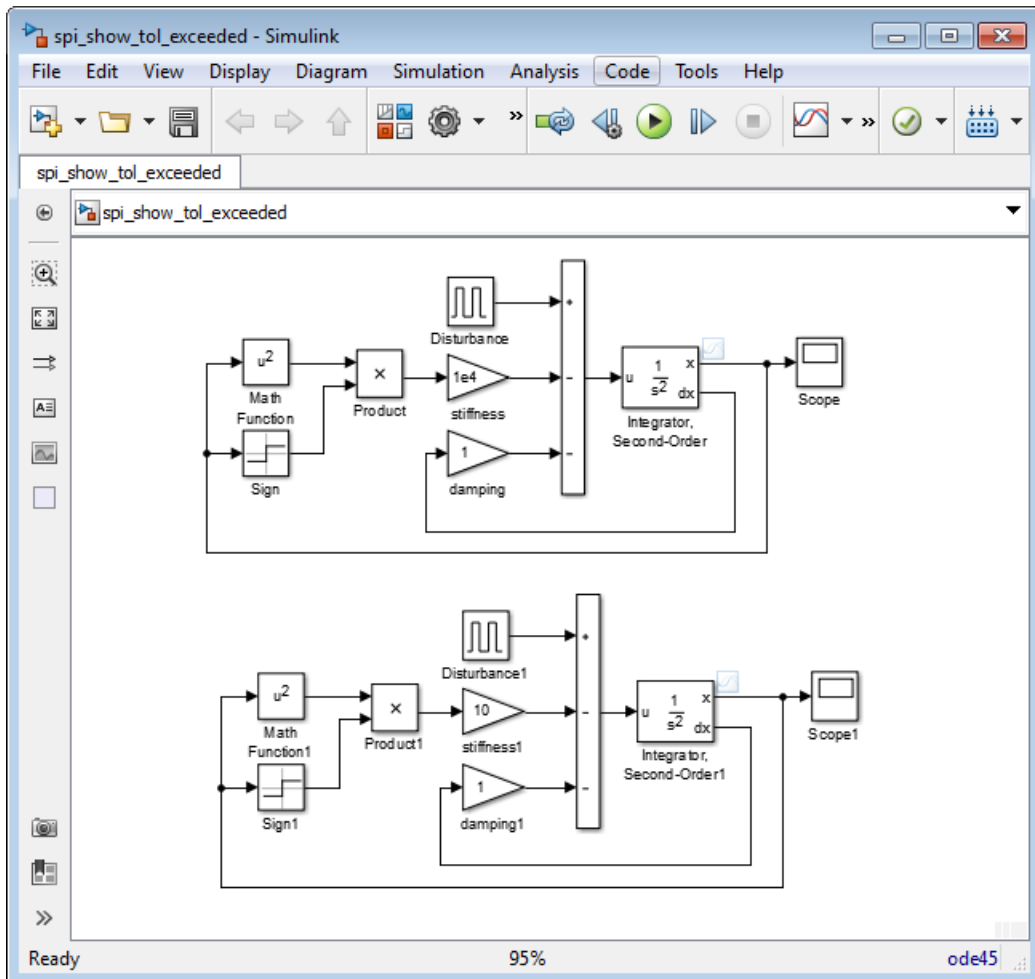

If this modeling construct belonged to a larger model, the Solver Profiler would help you locate it. You could then modify the model to improve solver performance. For example, you can decide to reduce the accuracy of the contact dynamic by increasing the damping factor, which would reduce the number of bounce events. Increasing the damping from 100 to 500 makes the ball bounce only 13 times, allowing the simulation to complete in only 669 steps.

Solver Exception Events

Tolerance-Exceeding Events

This example simulates two identical nonlinear spring-damping systems. The two systems have different spring stiffness.

When you run the Solver Profiler on this model, you can see the tolerance-exceeding events in the **Solver Exception** tab.

The result indicates that the stiffer spring causes the solver tolerance to exceed the limit. Typically, model states that change the fastest tend to be closest to the solver tolerance limit.

The solver attempts to take the largest possible steps while optimally trading off between speed and accuracy. Occasionally, this tradeoff causes the solver to take steps that exceed the tolerance limit and forces it to reduce the step size. Exceeding the tolerance limit is not a poor modeling practice in itself. This profiler statistic is not meant to help you reduce tolerance exceeding events to zero.

This statistic can help you identify parts of your model that are close to exceeding the tolerance limit. You can identify model components that change the fastest or are the stiffest. You can decide to retain this model dynamic in the simulation or simplify it to speed up simulation.

The tolerance-exceeding statistic can also help you identify modeling errors. If you do not expect the highlighted states to change as fast, you can examine your model for errors. In this example, the modeling error could be that the stiffness of the stiffer spring is specified in N/m instead of N/mm. This error makes the spring 1000 times stiffer than expected.

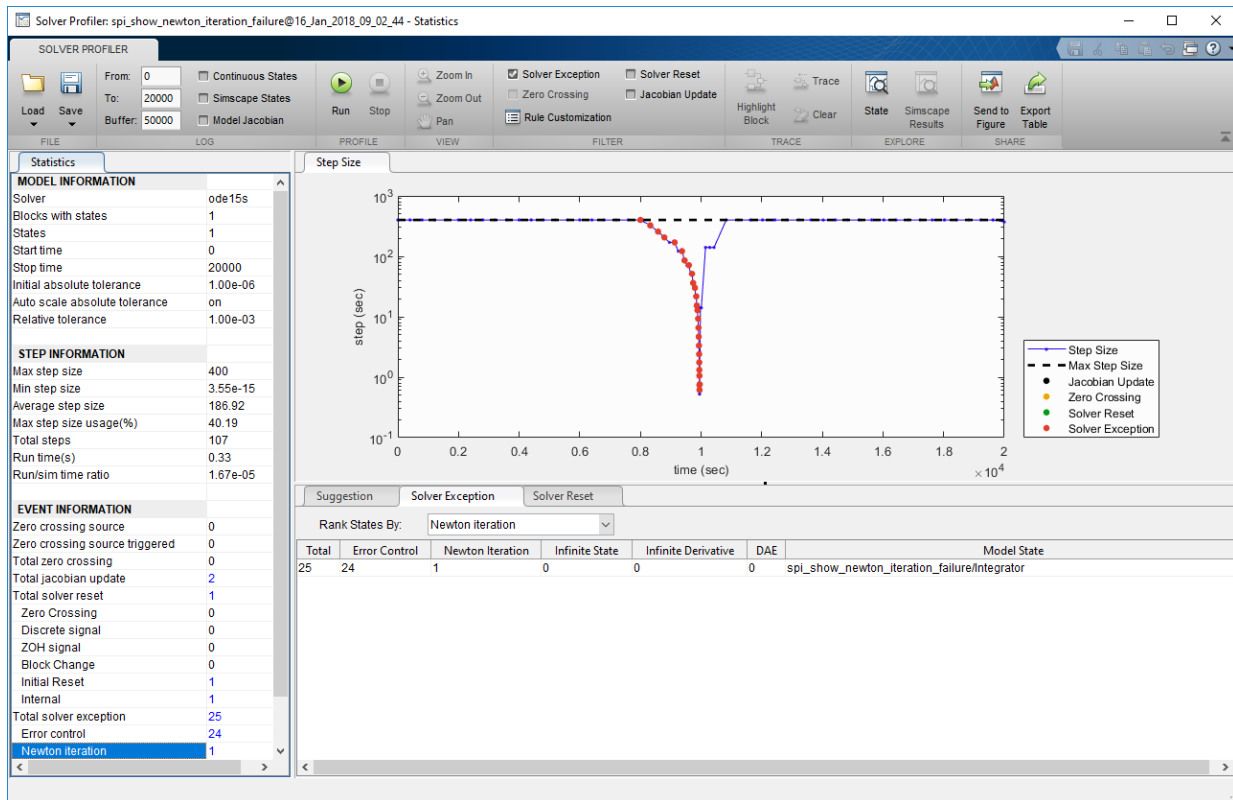

Newton Iteration Failures

Newton iteration failures are specific to implicit solvers like `ode15s` and `ode23t`, and they result from Newton iterations not converging after a few trials. Similar to tolerance-exceeding events, these failures tend to occur when a system changes quickly.

This example simulates how the radius of a ball of flame changes when you strike a match. The ball of flame grows rapidly until it reaches a critical size, when the amount of oxygen consumed balances the growth in ball surface.

When you run the Solver Profiler on this model, you can see the Newton iteration failures in the **Solver Exception** tab.

The result indicates that when the combustion begins, the solver tolerance is exceeded multiple times. When equilibrium is attained, the system appears different, and a Newton iteration failure occurs. The Jacobian of the system is recomputed, and the solver continues to move forward.

Newton failures are not indicative of poor modeling practices. This profiler statistic is not meant to help you reduce these failures to zero. In this example, you can reduce the solver tolerance to prevent this failure. But the solver then takes small steps unnecessarily, which is counterproductive. Therefore, in this example, this failure is acceptable.

This type of failure becomes problematic when it occurs in large numbers over a short period, especially in Simscape models. Dense failures indicate that your model is not

robust numerically. One way to improve numerical robustness is to tighten the solver tolerance. Another way is to modify the model to avoid rapid changes.

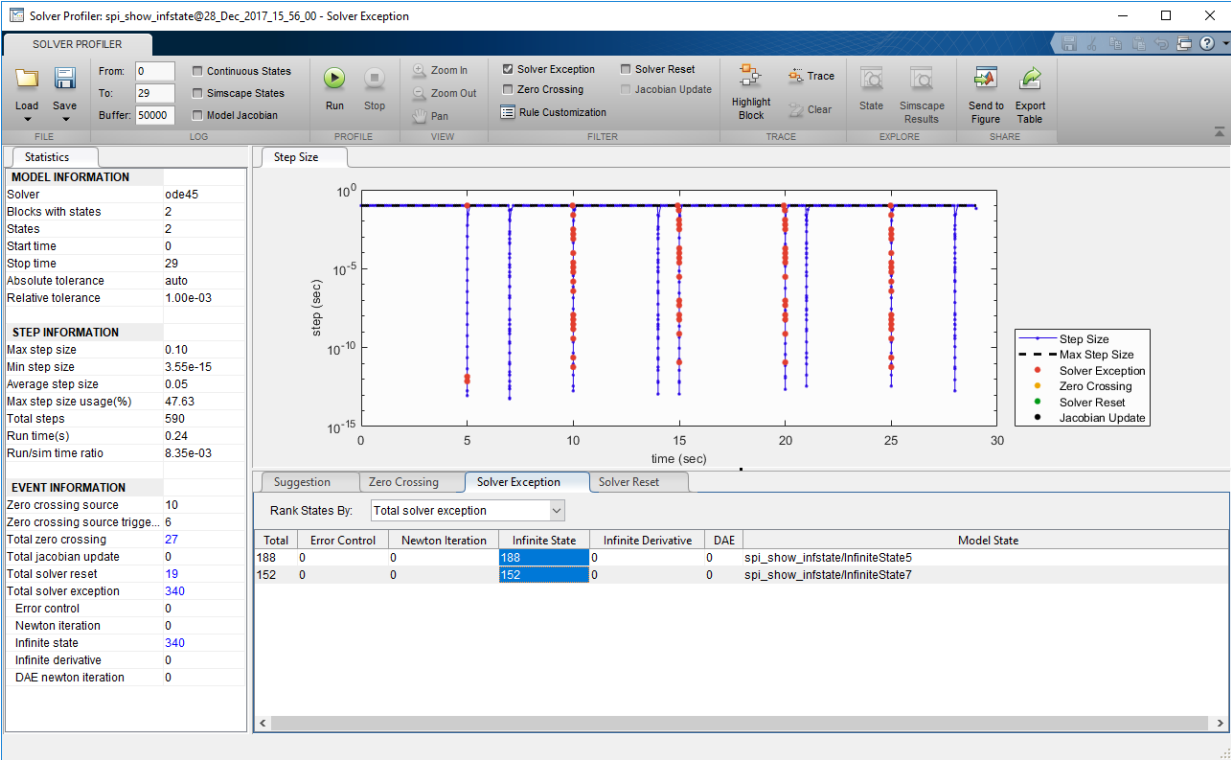

Infinite State and Infinite Derivative Exceptions

An infinite state exception occurs when the magnitude of a state approaches infinity. Similarly, when the magnitude of the derivative of a state approaches infinity, an infinite derivative exception occurs. The solver reduces the step size and makes another attempt at integration.

This example shows a set of two Integrator Limited blocks that have initial conditions slightly less than `realmax`. As they integrate the Constant input of `1e305`, the solver quickly reaches the infinite state exception.

When you run the Solver Profiler for this model, you can see that the InfiniteState5 and InfiniteState7 blocks have 188 and 152 infinite state exceptions in the **Solver Exceptions** tab.

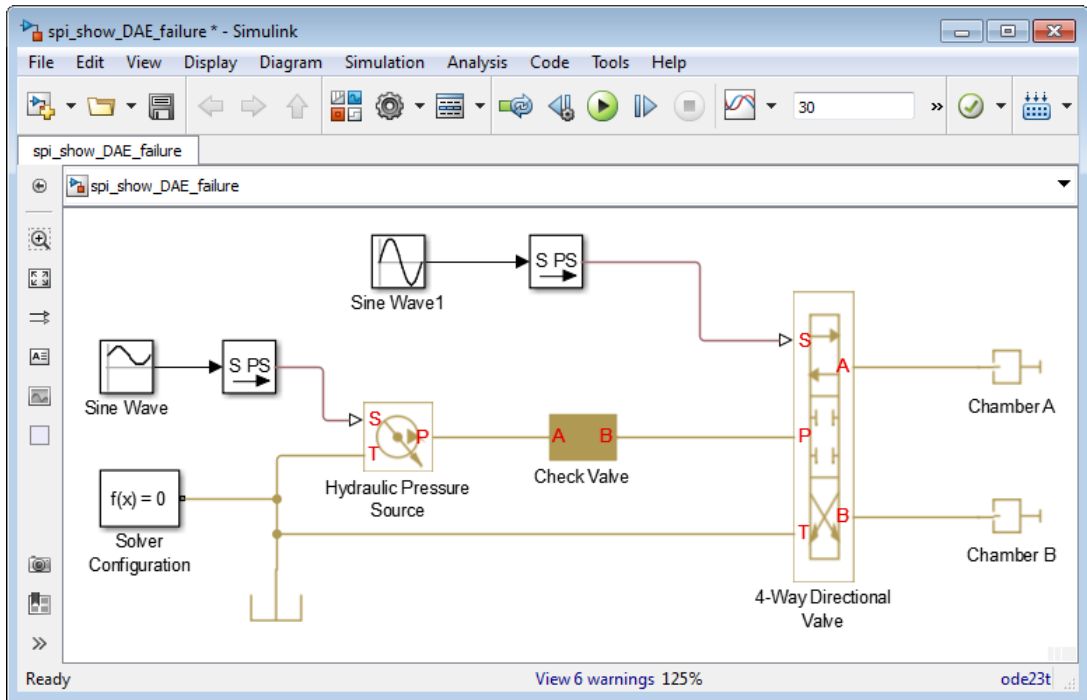

Differential Algebraic Equation Failures

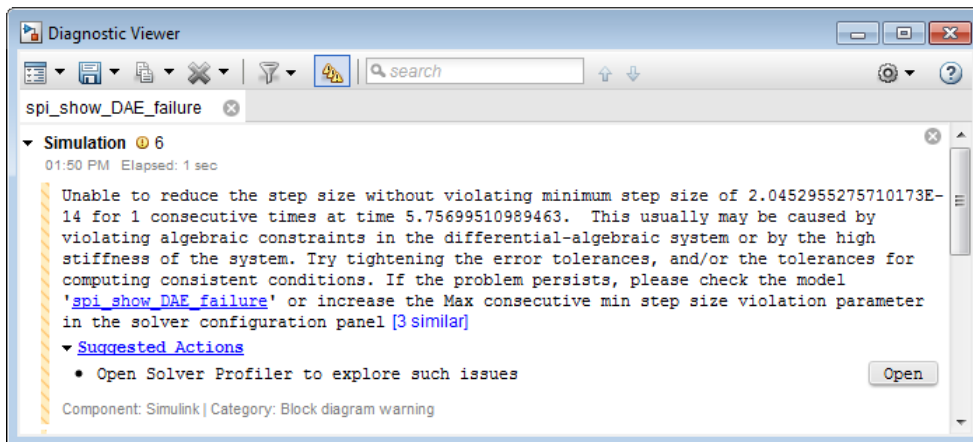

Most Simscape models use differential algebraic equations (DAEs), in contrast to Simulink models, which use ordinary differential equations.

The use of DAEs adds complexity to Simscape models. Solvers like `ode15s` and `ode23t` can handle many types of DAEs. However, when the algebraic constraints between Simscape components are complex and changing fast, the Newton iteration process fails to resolve to those constraints.

This example simulates a pressure source that can be directed toward one of two hydraulic chambers.

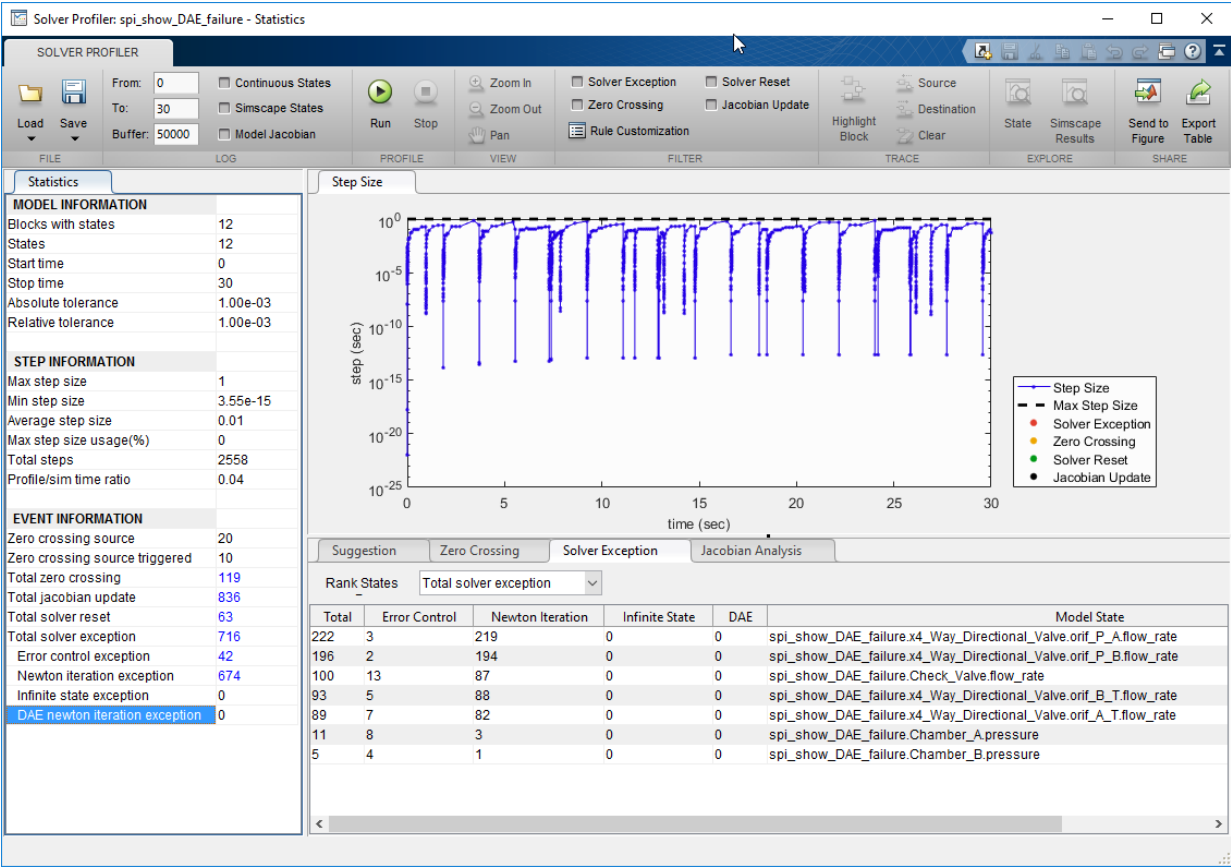

When you simulate this model, Simulink displays several warnings.

Typically, small models can handle such warnings and simulate to completion. However, this warning indicates that the model is not robust numerically. Minor changes to the model, or integration into a larger model, can result in errors.

When you run the Solver Profiler on this model, you can see the DAE failures in the **Solver Exception** tab.

In this case, the exception results from large solver tolerance. Tightening the solver tolerance forces the solver to take smaller steps and better capture the changes in algebraic constraints.

Alternatively, this exception can be avoided by removing the algebraic constraint. In this example, the **Check Valve** and the **4-Way Directional Valve** are directly connected.

When their pressure-flow relationship changes rapidly, the solver is unable to capture the changes. Inserting a **Hydraulic Chamber** between those two components makes them compliant. To learn more about dry nodes, see Simscape documentation.

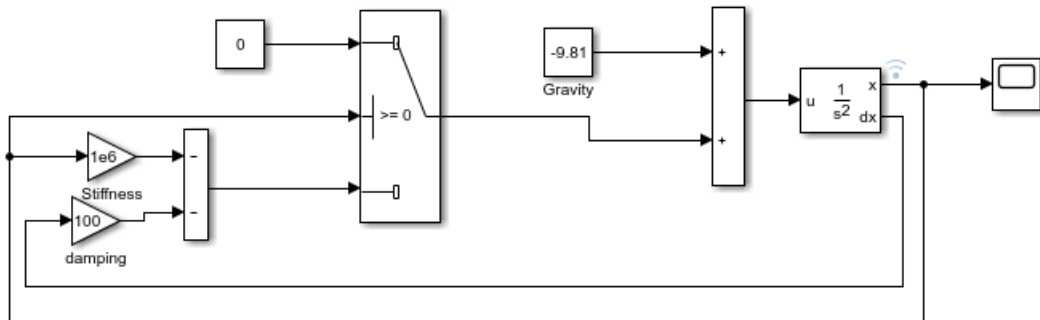

Solver Resets

The Solver Profiler logs events that cause the solver to reset its parameters because solver resets do incur computational cost. In addition to the total number of resets, you can also see a breakdown by type of reset event.

Note A solver reset event can have multiple causes. As a result, the number of **Total solver reset** events in the **Statistics** pane may be less than the sum of the solver resets of each type.

Zero-Crossing

Some zero crossing events occur at discontinuities in the signal. Consider the example model of a bouncing ball from the “Zero-Crossing Events” on page 33-6 section.

The Solver Profiler records 67 solver resets caused by zero crossings from the Switch block in the model. Compare the step-size and the **Solver Reset** highlighting with the output x of the Second-Order Integrator block, which is the height of the ball from the ground. Observe that the solver resets occur when the ball bounces off the ground.

Discrete Signal

Solver resets also occur when your model has a discrete signal driving a block with continuous states, as seen in this example model.

The discrete Sine Wave block outputs a 1 rad/s sine wave with a discrete sample time $t_s = 2$.

The Solver Profiler report shows that four solver resets occur due to discrete signals driving a continuous block. These resets occur at every execution of the Sine Wave block.

ZOH Signal

This type of solver reset occurs when a block output is not executed during a trial or minor time step and gets updated only during the integration or major time step. As a result, the block output changes discontinuously from one major time step to the other. As a result the solver resets. See “Fixed-in-Minor-Step” on page 7-16 sample time.

This example model shows a simple plant and controller that tracks a sinusoidal reference signal. The source of this signal is a Sine Wave block whose sample time is specified to be fixed-in-minor-step.

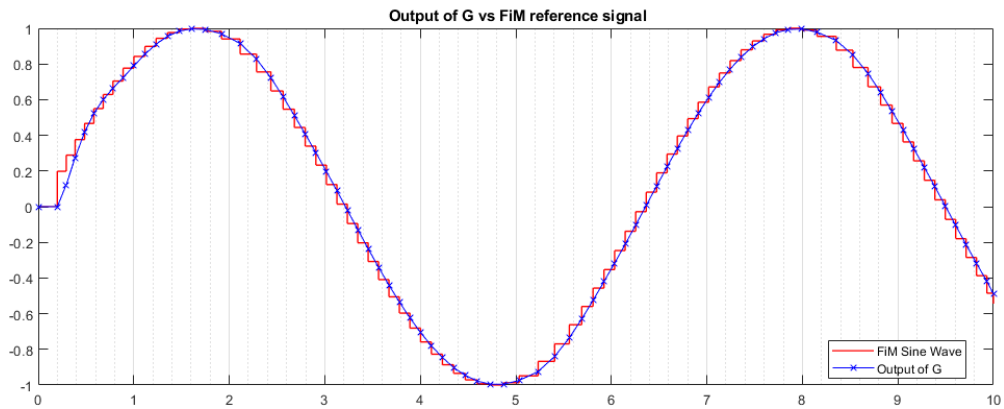

Observe from the results of the profiling session that there are **80 ZOH Signal** solver resets in the simulation.

Note When you select **Continuous States** for logging or enable the SaveStates parameter, the derivative of a continuous block driven by a Fixed-in-Minor-Step signal is NaN.

This is because the driving “Fixed-in-Minor-Step” on page 7-16 block updates its value only at every major time step. The signal driven to the continuous block is therefore discontinuous and the state is non differentiable.

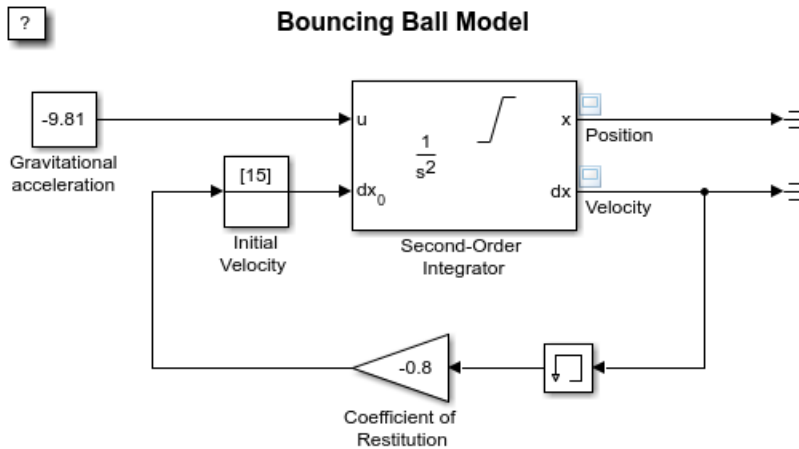

The plot shows the outputs of the Sine Wave and Integrator blocks in the example model.

Tip Solver resets caused due to ZOH signals are serious compared to solver reset events caused by discrete signals and can significantly slow down the simulation. This is because ZOH signal reset events occur at every major step of the solver. Reconfigure your simulation to avoid these resets, if needed.

Block Signal

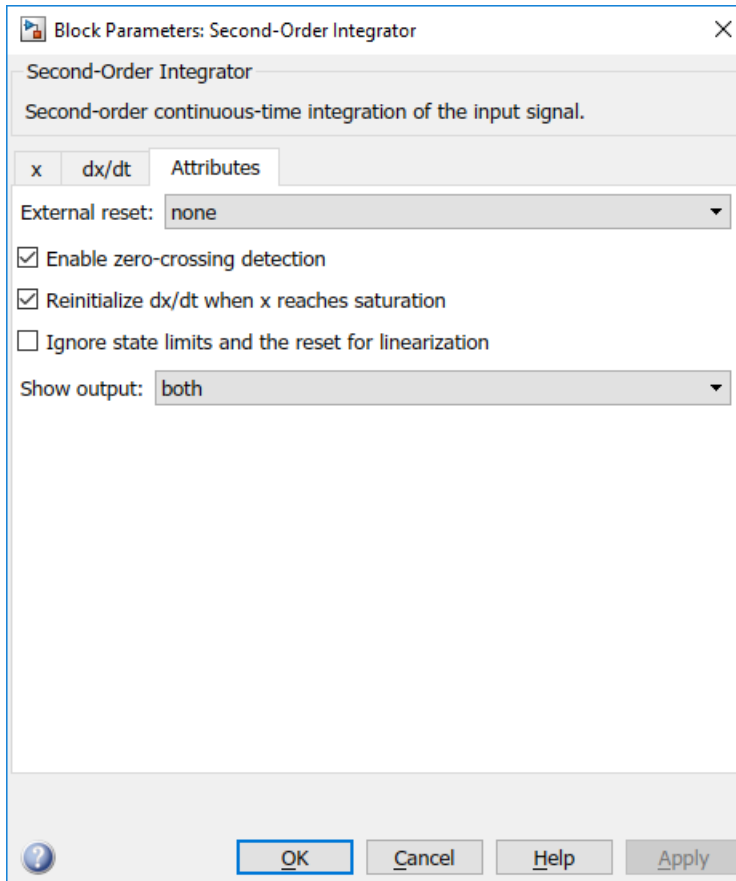

Sometimes, the block can be configured to reset the solver when certain conditions are satisfied during its execution. Consider the `sldemo_bounce` model of a bouncing ball.

Observe from the profiling results that there are 130 solver resets triggered by a block. A solver reset event can have multiple causes. In this case, zero crossings and block changes cause a solver reset event.

One setting that causes the **Block Change** solver reset event is the **Reinitialize dx/dt when x reaches saturation** parameter. This setting is necessary to properly simulate the dynamics of a bouncing ball.

Initial Reset

When you run a simulation, the solver needs to reset its parameters for the first time. This event is shown as the **Initial Reset** event in the Solver Profiler report. It occurs once at the start of the simulation.

Internal

There are some reset events that are internal to the Simulink engine. These reset events are necessary for the engine to correctly configure itself for accurate simulation.

Jacobian Logging and Analysis

The Solver Profiler supports Jacobian logging and analysis for ode15s and ode23t solvers only.

You can select the **Model Jacobian** checkbox in the Solver Profiler to log updates to the Jacobian matrix for the model. When you run the Solver Profiler on a model, you can see the logs in the **Jacobian Analysis** tab.

The **Jacobian Analysis** tab indicates the states in the model that are likely slowing down the solver.

To investigate the cause of each limiting state, select a row in the **Jacobian Analysis** tab and click **Highlight Block**.

Modify Solver Profiler Rules

You can customize the suggestions that appear in the Solver Profiler in these ways:

- Change the thresholds of the Solver Profiler rules that detect failure patterns.
- Select which rules to apply during a profiling run.
- Author your own rule set as a MATLAB script.

Change Thresholds of Profiler Rules

Click **Rule Customization** in the Solver Profiler to access the rule set. You can change the thresholds for most of these rules and also select which rules you want to apply selectively during a simulation run.

The screenshot shows a dialog box titled "Rule Set: ssc_pneumatic_actuator" with a "Restore to Default" button. It is divided into three sections:

- If simulation hangs or pauses, show suggestions when:**
 - Ratio of solver exceptions to number of steps exceeds %
 - Ratio of zero crossing events to number of steps exceeds %
 - Ratio of solver reset events to number of steps exceeds %
- Over the entire simulation, show suggestions when:**
 - There are any DAE newton iteration exceptions during simulation
 - There is coupling between continuous and discrete rates
 - Ratio of solver reset events to number of steps exceeds %
 - Number of solver exception in one second simulation time exceeds
 - Number of zero crossing in one second simulation time exceeds
 - Percentage of steps with max step size exceeds %
- Custom Rule Set:**
 - ...

Develop Profiler Rule Set

You can override the settings on the **Rule Set** dialog box by specifying a custom rule set.

Create a rule set as a MATLAB script and specify the path to the script in the **Custom Rule Set** section of the **Rule Set** dialog box.

A simple rule set example looks as follows:

```
function diagnosticsString = customRule(profilerData)
    if isempty(profilerData.zcEvents)
        diagnosticsString{1} = 'No zero crossing event detected.';
    else
        diagnosticsString{1} = 'Zero-crossing events detected.';
    end
end
```

The input to the function is an array of structures called `profilerData`. This array of structures organizes all the information that the Solver Profiler collects during a profiling run. It contains the following substructures.

Substructure	Fields
<code>stateInfo</code> : Stores information on block states	<ul style="list-style-type: none"> • <code>name</code>: Block name • <code>value</code>: State values • <code>blockIdx</code>: Block ID
<code>blockInfo</code> : Cross-reference of blocks and state IDs	<ul style="list-style-type: none"> • <code>name</code>: Block name • <code>stateIdx</code>: State ID
<code>zcSrcInfo</code> : Stores information on blocks causing zero crossing events	<ul style="list-style-type: none"> • <code>name</code>: Block name • <code>blockIdx</code>: Block ID
<code>zcEvents</code> : Cross-reference of the time stamps of zero crossing events and the corresponding state IDs	<ul style="list-style-type: none"> • <code>t</code>: Event timestamp • <code>srcIdx</code>: Block ID
<code>exceptionEvents</code> : Cross-reference of exception event timestamps, the ID of the corresponding state that caused the event, and the cause.	<ul style="list-style-type: none"> • <code>t</code>: Event timestamp • <code>stateIdx</code>: State ID • <code>cause</code>: Cause of exception

Substructure	Fields
resetTime: Stores timestamps of solver resets.	None
tout: Stores simulation times.	None

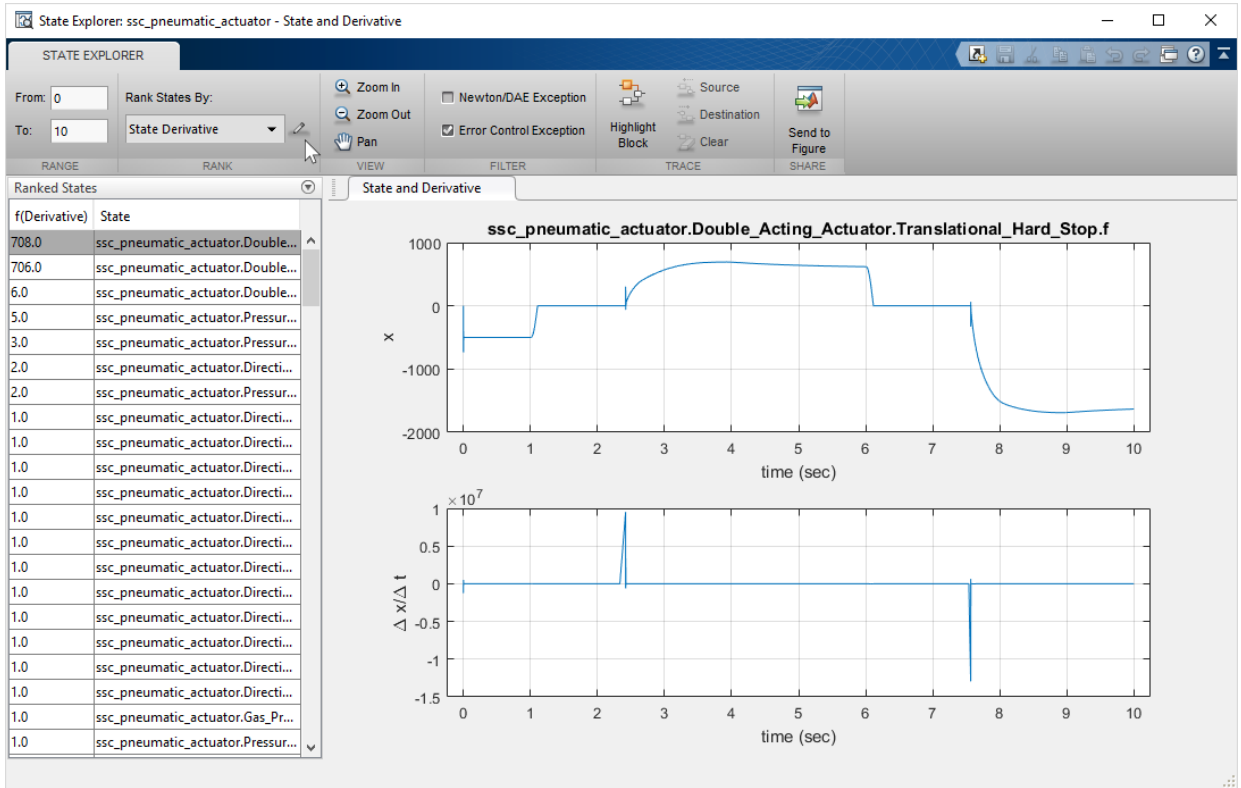

Customize State Ranking

If you log continuous states in the Solver Profiler, you can open the State Explorer to investigate each continuous state. The State Explorer ranks continuous states by the following metrics:

- State Derivative
- Newton/DAE Exception
- State Value
- Error Control Exception
- State Name
- State Chatter

In addition to these ranking metrics, you can write and upload your own algorithm to determine how continuous states are ranked in the State Explorer.

- 1 Click the edit button next to the **Rank States By** dropdown.

- 2 In the Custom Algorithm dialog box that appears, click **Add** and upload a MATLAB script that contains your ranking algorithm.

A simple algorithm that ranks states by value looks as follows:

Note The structures referenced in this example organize information that the Solver Profiler collects during a profiling run. For more information on the structures, see “Develop Profiler Rule Set” on page 33-31.

```
function [index,score] = customRank(sd,tl,tr)
```

```
% Allocate storage for index and score list
nStates = length(sd.stateInfo);
index = 1:nStates;
```

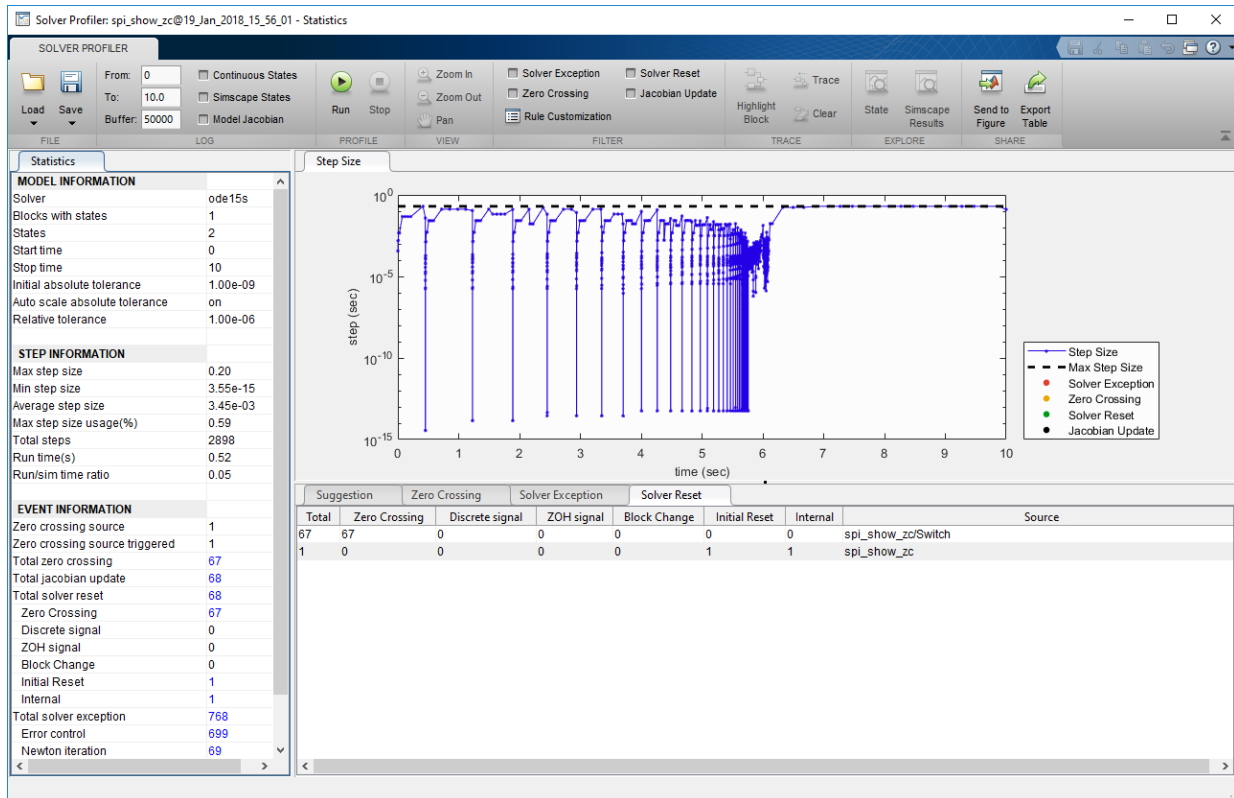

```
score = zeros(nStates,1);

% Loop through each state to calculate score
for i = 1:nStates
    x = sd.stateInfo(i).value;
    % apply time range constraints
    x = x(sd.tout>=tl & sd.tout<=tr);
    if max(x) > 1
        score(i) = 1;
    else
        score(i) = 0;
    end
end

% Rank the states
[score, order] = sort(score, 'descend');
index = index(order);

end
```

Solver Profiler Interface

The Solver Profiler enables you to:

- Start a profiling session, save a session, or open a saved session.
- Customize and filter the results displayed.
- Interact with the model and trace and highlight the states that contain exceptions.
- Open Simscape Explorer or States Explorer to analyze simulation data further.
- Customize profiler suggestions using your own rules.

Statistics Pane

The statistics pane displays information on model parameters, including:

- **Average step size** — A measure of how fast the solver advances. It is calculated as the total simulation time divided by the number of steps the solver used. It is bounded by the model configuration parameters **Max step size** and **Min step size**.
- **Max step size usage** — The percentage of maximum step sizes used by the solver among all step sizes.
- **Zero crossing** — A solver-specific event that affects model dynamics. During simulation, the solver detects zero crossing. Zero crossing detection incurs computation cost. For more information, see “Zero-Crossing Detection” on page 3-24.
- **Solver reset** — An event that causes the solver to reset its parameters. Solver reset detection incurs computation cost. The solver reset statistics are broken down into **Zero Crossing**, **Discrete Signal**, **ZOH Signal**, **Block Change**, **Initial Reset**, and **Internal** solver reset events. For more information, see “Solver Resets” on page 33-19
- **Solver exception** — An event that renders the solver unable to solve model states to meet accuracy specifications. To solve model states accurately, the solver has to run a few adjusted trials, which incur computation cost.
- **Error control exception** — An event where a solution obtained by the solver has an error that is greater than the tolerance specification.
- **Newton iteration exception** — An event specific to implicit solvers. Newton iterations do not converge after a few trials.
- **Infinite state exception** — An event where one or more states solved by the solver are infinite.
- **DAE newton iteration exception** — An event specific to implicit solvers for Simscape models. The Newton iteration does not converge even though the solver violates the minimum step size constraint.

Suggestions and Exceptions Pane

The suggestions and exceptions pane displays information on exceptions, including:

- **Zero crossing** — A solver-specific event that affects model dynamics. During simulation, the solver detects zero crossing. Zero crossing detection incurs computation cost. For more information, see “Zero-Crossing Detection” on page 3-24.
- **Solver reset** — An event that causes the solver to reset its parameters. Solver reset detection incurs computation cost. The solver reset statistics are broken down into **Zero Crossing**, **Discrete Signal**, **ZOH Signal**, **Block Change**, **Initial Reset**, and **Internal** solver reset events. For more information, see “Solver Resets” on page 33-19

- **Solver exception** — An event that renders the solver unable to solve model states to meet accuracy specifications. To solve model states accurately, the solver has to run a few adjusted trials, which incur computation cost.
- **Error control exception** — An event where a solution obtained by the solver has an error that is greater than the tolerance specification.
- **Newton iteration exception** — An event specific to implicit solvers. Newton iterations do not converge after a few trials.
- **Infinite state exception** — An event where one or more states solved by the solver are infinite.
- **DAE newton iteration exception** — An event specific to implicit solvers for Simscape models. The Newton iteration does not converge even though the solver violates the minimum step size constraint.

Introduction to the Debugger

With the debugger, you run your simulation method by method. You can stop after each method to examine the execution results. In this way, you can pinpoint problems in your model to specific blocks, parameters, or interconnections.

Note Methods are functions that the Simulink software uses to solve a model at each time step during the simulation. Blocks are made up of multiple methods. “Block execution” in this documentation is shorthand for “block methods execution.” Block diagram execution is a multi-step operation that requires execution of the different block methods in all the blocks in a diagram at various points during the process of solving a model at each time step during simulation, as specified by the simulation loop.

The debugger has both a graphical and a command-line user interface. The graphical interface allows you to access the most commonly used features of the debugger. The command-line interface gives you access to all of the capabilities in the debugger. If you can use either to perform a task, the documentation shows you first how to use the graphical interface, “Debugger Graphical User Interface” on page 34-3, and then the command-line interface, “Debugger Command-Line Interface” on page 34-10.

All functions such as `atrace` and `ashow` can only be used within the debugger.

Debugger Graphical User Interface

In this section...

“Displaying the Graphical Interface” on page 34-3

“Toolbar” on page 34-4

“Breakpoints Pane” on page 34-5

“Simulation Loop Pane” on page 34-5

“Outputs Pane” on page 34-7

“Sorted List Pane” on page 34-7

“Status Pane” on page 34-8

Displaying the Graphical Interface

Select **Debug Model** from a model window **Simulation > Debug** menu to display the debugger graphical interface.

Note The debugger graphical user interface does not display state or solver information. The command line interface does provide this information. See “Display System States” on page 34-31 and “Display Solver Information” on page 34-32.

Toolbar

The debugger toolbar appears at the top of the debugger window.

From left to right, the toolbar contains the following command buttons:

Button	Purpose
	Step into the next method (see “Stepping Commands” on page 34-20 for more information on this command, and the following stepping commands).
	Step over the next method.
	Step out of the current method.
	Step to the first method at the start of next time step.
	Step to the next block method.
	Start or continue the simulation.
	Pause the simulation.
	Stop the simulation.
	Break before the selected block.

Button	Purpose
	Display inputs and outputs of the selected block when executed (same as trace gcb).
	Display the current inputs and outputs of selected block (same as probe gcb).
	Display help for the debugger.
	Close the debugger.

Breakpoints Pane

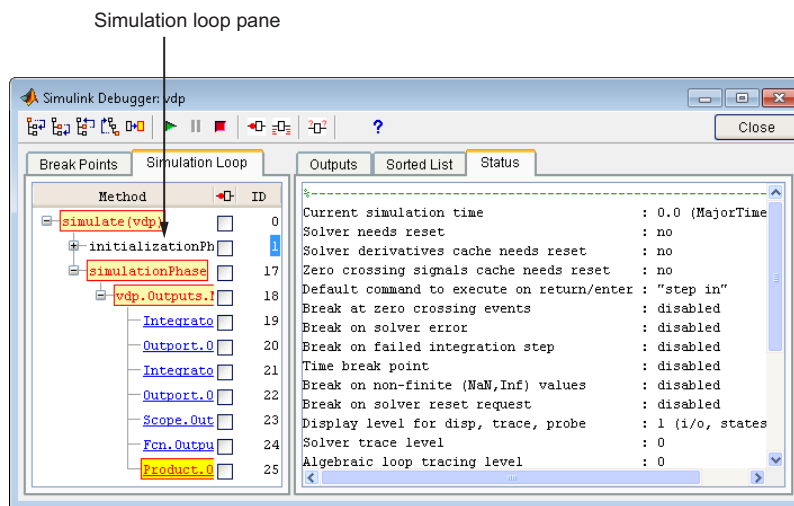

To display the **Breakpoints** pane, select the **Break Points** tab on the debugger window.

The **Breakpoints** pane allows you to specify block methods or conditions at which to stop a simulation. See “Set Breakpoints” on page 34-23 for more information.

Simulation Loop Pane

To display the **Simulation Loop** pane, select the **Simulation Loop** tab on the debugger window.

The **Simulation Loop** pane contains three columns:

- Method
- Breakpoints
- ID

Method Column

The **Method** column lists the methods that have been called thus far in the simulation as a method tree with expandable/collapsible nodes. Each node of the tree represents a method that calls other methods. Expanding a node shows the methods that the block method calls. Clicking a block method name highlights the corresponding block in the model diagram.

Whenever the simulation stops, the debugger highlights the name of the method where the simulation has stopped as well as the methods that invoked it. The highlighted method names indicate the current state of the method call stack.

Breakpoints Column

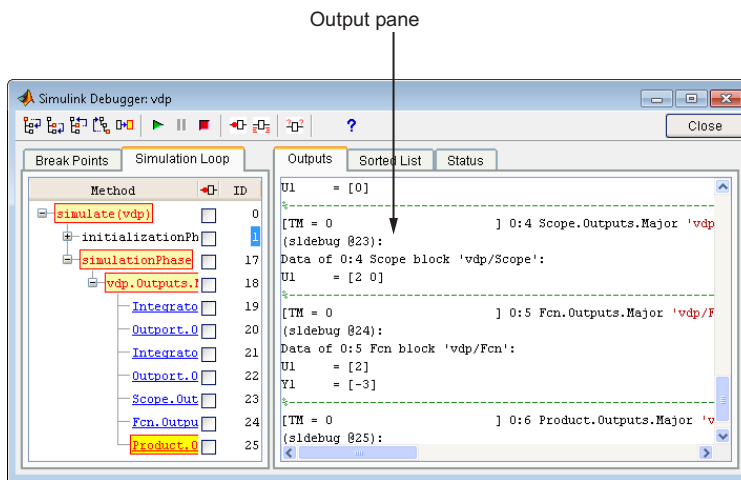

The breakpoints column consists of check boxes. Selecting a check box sets a breakpoint at the method whose name appears to the left of the check box. See “Setting Breakpoints from the Simulation Loop Pane” on page 34-25 for more information.

ID Column

The ID column lists the IDs of the methods listed in the **Methods** column. See “Method ID” on page 34-10 for more information.

Outputs Pane

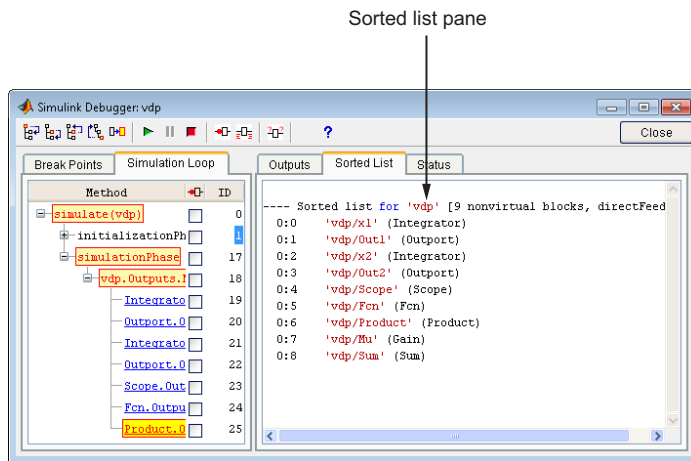

To display the **Outputs** pane, select the **Outputs** tab on the debugger window.

The Outputs pane displays the same debugger output that would appear in the MATLAB command window if the debugger were running in command-line mode. The output includes the debugger command prompt and the inputs, outputs, and states of the block at whose method the simulation is currently paused (see “Block Data Output” on page 34-19). The command prompt displays current simulation time and the name and index of the method in which the debugger is currently stopped (see “Block ID” on page 34-10).

Sorted List Pane

To display the **Sorted List** pane, select the **Sorted List** tab on the debugger window.

The **Sorted List** pane displays the sorted lists for the model being debugged. See “Display Model’s Sorted Lists” on page 34-34 for more information.

Status Pane

To display the **Status** pane, select the **Status** tab on the debugger window.

The **Status** pane displays the values of various debugger options and other status information.

Debugger Command-Line Interface

In this section...

“Controlling the Debugger” on page 34-10
--

“Method ID” on page 34-10

“Block ID” on page 34-10

“Accessing the MATLAB Workspace” on page 34-11
--

Controlling the Debugger

In command-line mode, you control the debugger by entering commands at the debugger command line in the MATLAB Command Window. To enter commands at the debugger command line, you must start the debugger programmatically and not through the GUI. Use `sldb` for this purpose. The debugger accepts abbreviations for debugger commands. For more information on debugger commands, see “Simulink Debugger”.

Note You can repeat some commands by entering an empty command (i.e., by pressing the **Enter** key) at the command line.

Method ID

Some of the Simulink software commands and messages use method IDs to refer to methods. A method ID is an integer assigned to a method the first time the method is invoked. The debugger assigns method indexes sequentially, starting with 0.

Block ID

Some of the debugger commands and messages use block IDs to refer to blocks. Block IDs are assigned to blocks while generating the model's sorted lists during the compilation phase of the simulation. A block ID has the form `sysIdx:blkIdx`, where `sysIdx` is an integer identifying the system that contains the block (either the root system or a nonvirtual subsystem) and `blkIdx` is the position of the block in the system's sorted list. For example, the block ID `0:1` refers to the first block in the model's root system. The `slist` command shows the block ID for each debugged block in the model.

Accessing the MATLAB Workspace

You can enter any MATLAB expression at the `sldebug` prompt. For example, suppose you are at a breakpoint and you are logging time and output of your model as `tout` and `yout`. The following command creates a plot.

```
(sldebug ...) plot(tout, yout)
```

You cannot display the value of a workspace variable whose name is partially or entirely the same as that of a debugger command by entering it at the debugger command prompt. You can, however, use the `eval` command to work around this problem. For example, use `eval('s')` to determine the value of `s` rather than `step` the simulation.

Debugger Online Help

You can get online help on using the debugger by clicking the **Help** button on the debugger toolbar. Clicking the **Help** button displays help for the debugger in the MATLAB product Help browser.

In command-line mode, you can get a brief description of the debugger commands by typing `help` at the debug prompt.

Start the Simulink Debugger

In this section...

“Starting from a Model Window” on page 34-13

“Starting from the Command Window” on page 34-13

You can start the debugger from either a Simulink model window or from the MATLAB Command Window.

Starting from a Model Window

- 1 In a model window, select **Simulation > Debug > Debug Model**.

The debugger graphical user interface opens. See “Debugger Graphical User Interface” on page 34-3.

- 2 Continue selecting toolbar buttons.

Note When running the debugger in graphical user interface (GUI) mode, you must explicitly start the simulation. For more information, see “Start a Simulation” on page 34-15.

Note When starting the debugger from the GUI, you cannot enter debugger commands in the MATLAB command window. For this, you must start the debugger from the command window using the `sim` or `sldebug` commands.

Starting from the Command Window

- 1 In the MATLAB Command Window, enter either
 - the `sim` command. For example, enter

```
sim('vdp', 'StopTime', '10', 'debug', 'on')
```
 - or the `sldebug` command. For example, enter

```
sldebug 'vdp'
```

In both cases, the example model vdp loads into memory, starts the simulation, and stops the simulation at the first block in the model execution list.

- 2 The debugger opens and a debugger command prompt appears within the MATLAB command window. Continue entering debugger commands at this debugger prompt.

- “Debugger Online Help” on page 34-12

Start a Simulation

To start the simulation, click the **Start/Continue** button on the debugger toolbar.

The simulation starts and stops at the first simulation method that is to be executed. It displays the name of the method in its **Simulation Loop** pane. At this point, you can

- Set breakpoints.
- Run the simulation step by step.
- Continue the simulation to the next breakpoint or end.
- Examine data.
- Perform other debugging tasks.

The debugger displays the name of the method in the Simulation Loop pane, as shown in the following figure:

The following sections explain how to use the debugger controls to perform these debugging tasks.

Note When you start the debugger in GUI mode, the debugger command-line interface is also active in the MATLAB Command Window. However, to prevent synchronization errors between the graphical and command-line interfaces, you should avoid using the command-line interface.

Run a Simulation Step by Step

In this section...
“Introduction” on page 34-18
“Block Data Output” on page 34-19
“Stepping Commands” on page 34-20
“Continuing a Simulation” on page 34-21
“Running a Simulation Nonstop” on page 34-21

Introduction

The debugger provides various commands that let you advance a simulation from the method where it is currently suspended (the next method) by various increments (see “Stepping Commands” on page 34-20). For example, you can advance the simulation

- Into or over the next method
- Out of the current method
- To the top of the simulation loop.

After each advance, the debugger displays information that enables you to determine the point to which the simulation has advanced and the results of advancing the simulation to that point.

For example, in GUI mode, after each step command, the debugger highlights the current method call stack in the **Simulation Loop** pane. The call stack comprises the next method and the methods that invoked the next method either directly or indirectly. The debugger highlights the call stack by highlighting the names of the methods that make up the call stack in the **Simulation Loop** pane.

In command-line mode, you can use the `where` command to display the method call stack.

Block Data Output

After executing a block method, the debugger prints any or all of the following block data in the debugger **Output** panel (in GUI mode) or, if in command line mode, the MATLAB Command Window:

- $U_n = v$
where v is the current value of the block's n th input.
- $Y_n = v$
where v is the current value of the block's n th output.
- $CSTATE = v$
where v is the value of the block's continuous state vector.
- $DSTATE = v$
where v is the value of the block's discrete state vector.

The debugger also displays the current time, the ID and name of the next method to be executed, and the name of the block to which the method applies in the MATLAB Command Window. The following example illustrates typical debugger outputs after a step command.

```

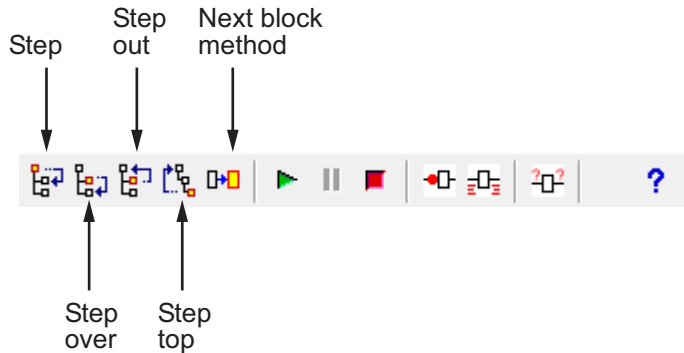

Current time                                Next method
  ↓                                           ↓
-----*-----*-----*-----*-----*-----*-----*-----*-----*-----*
[Tm = 2.009509145207664e-05 ] 0:2 Integrator.Derivatives 'vdp/x2'
(slidebug @49):
Data of 0:2 Integrator block 'vdp/x2':
U1      = [-1.9998794294512876]
Y1      = [-4.0190182904153282e-05]
CSTATE  = [-4.0190182904153282e-05]
-----*-----*-----*-----*-----*-----*-----*-----*-----*-----*
[Tm = 3.014263717811496e-05 ] vdp.Outputs.Minor
  
```

Stepping Commands

Command-line mode provides the following commands for advancing a simulation incrementally:

This command...	Advances the simulation...
step [in into]	Into the next method, stopping at the first method in the next method or, if the next method does not contain any methods, at the end of the next method
step over	To the method that follows the next method, executing all methods invoked directly or indirectly by the next method
step out	To the end of the current method, executing any remaining methods invoked by the current method
step top	To the first method of the next time step (i.e., the top of the simulation loop)
step blockmth	To the next block method to be executed, executing all intervening model- and system-level methods
next	Same as step over

Buttons in the debugger toolbar allow you to access these commands in GUI mode.

Clicking a button has the same effect as entering the corresponding command at the debugger command line.

Continuing a Simulation

In GUI mode, the **Stop** button turns red when the debugger suspends the simulation for any reason. To continue the simulation, click the **Start/Continue** button. In command-line mode, enter `continue` to continue the simulation. By default, the debugger runs the simulation to the next breakpoint (see “Set Breakpoints” on page 34-23) or to the end of the simulation, whichever comes first.

Running a Simulation Nonstop

The `run` command lets you run a simulation to the end of the simulation, skipping any intervening breakpoints. At the end of the simulation, the debugger returns you to the command line. To continue debugging a model, you must restart the debugger.

Note The GUI mode does not provide a graphical version of the `run` command. To run the simulation to the end, you must first clear all breakpoints and then click the **Start/Continue** button.

Set Breakpoints

In this section...

“About Breakpoints” on page 34-23

“Setting Unconditional Breakpoints” on page 34-23

“Setting Conditional Breakpoints” on page 34-26

About Breakpoints

The debugger allows you to define stopping points called breakpoints in a simulation. You can then run a simulation from breakpoint to breakpoint, using the debugger `continue` command. The debugger lets you define two types of breakpoints: unconditional and conditional. An unconditional breakpoint occurs whenever a simulation reaches a method that you specified previously. A conditional breakpoint occurs when a condition that you specified in advance arises in the simulation.

Breakpoints are useful when you know that a problem occurs at a certain point in your program or when a certain condition occurs. By defining an appropriate breakpoint and running the simulation via the `continue` command, you can skip immediately to the point in the simulation where the problem occurs.

Note When you stop a simulation at a breakpoint of a MATLAB S-function in the debugger, to exit MATLAB, you must first quit the debugger.

Setting Unconditional Breakpoints

You can set unconditional breakpoints from the:

- Debugger toolbar
- **Simulation Loop** pane
- MATLAB product Command Window (command-line mode only)

Setting Breakpoints from the Debugger Toolbar

To enable the **Breakpoint** button,

- 1 Simulate the model.
- 2 Click the **Step over current method** button until `simulationPhase` is highlighted.
- 3 Click the **Step into current method** button.

The debugger displays the name of the selected block in the **Break/Display points** panel of the **Breakpoints** pane.

Note Clicking the **Breakpoint** button on the toolbar sets breakpoints on the invocations of a block's methods in major time steps.

You can temporarily disable the breakpoints on a block by deselecting the check box in the breakpoints column of the panel. To clear the breakpoints on a block and remove its entry from the panel,

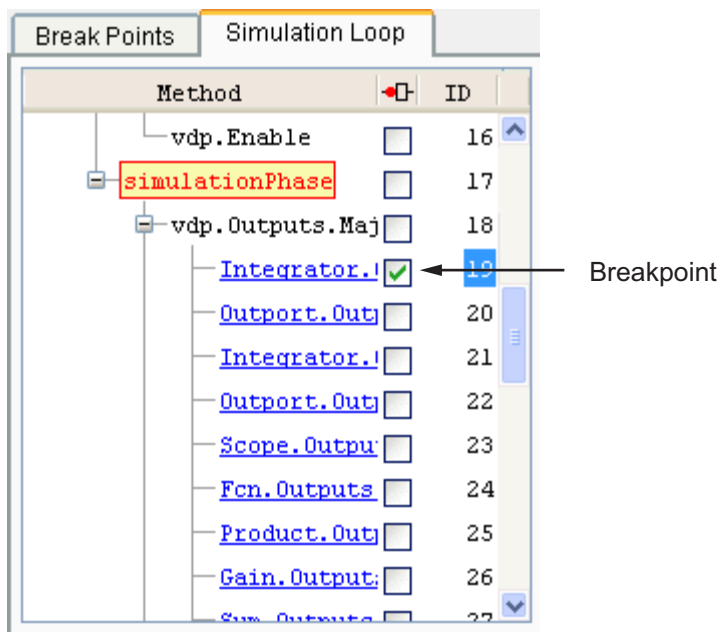

- 1 Select the entry.
- 2 Click the **Remove selected point** button on the panel.

Note You cannot set a breakpoint on a virtual block. A virtual block is purely graphical: it indicates a grouping or relationship among a model's computational blocks. The debugger warns you if you try to set a breakpoint on a virtual block. You can get a listing of a

model's nonvirtual blocks, using the `sl list` command (see “Displaying a Model's Nonvirtual Blocks” on page 34-35).

Setting Breakpoints from the Simulation Loop Pane

To set a breakpoint at a particular invocation of a method displayed in the Simulation Loop pane, select the check box next to the method's name in the breakpoint column of the pane.

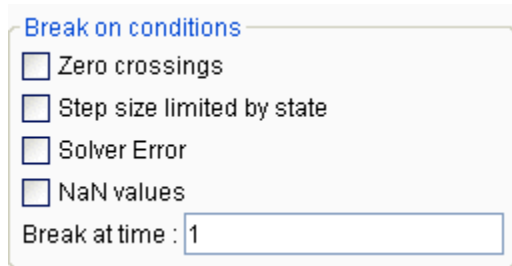

To clear the breakpoint, deselect the check box.

Setting Breakpoints from the Command Window

In command-line mode, use the `break` and `bafter` commands to set breakpoints before or after a specified method, respectively. Use the `clear` command to clear breakpoints.

Setting Conditional Breakpoints

You can use either the **Break on conditions** controls group on the debugger **Breakpoints** pane

or the following commands (in command-line mode) to set conditional breakpoints.

This command...	Causes the Simulation to Stop...
<code>tbreak [t]</code>	At a simulation time step
<code>ebreak</code>	At a recoverable error in the model
<code>nanbreak</code>	At the occurrence of an underflow or overflow (NaN) or infinite (Inf) value
<code>xbreak</code>	When the simulation reaches the state that determines the simulation step size
<code>zcbreak</code>	When a zero crossing occurs between simulation time steps

Setting Breakpoints at Time Steps

To set a breakpoint at a time step, enter a time in the debugger **Break at time** field (GUI mode) or enter the time using the `tbreak` command. This causes the debugger to stop the simulation at the `Outputs.Major` method of the model at the first time step that follows the specified time. For example, starting `vdp` in debug mode and entering the commands

```
tbreak 2
continue
```

causes the debugger to halt the simulation at the `vdp.Outputs.Major` method of time step `2.078` as indicated by the output of the `continue` command.

```
%-----%
[TM = 2.034340153847549      ] vdp.Outputs.Minor
(sldebug @37):
```

Breaking on Nonfinite Values

Selecting the debugger **NaN values** option or entering the `nanbreak` command causes the simulation to stop when a computed value is infinite or outside the range of values that is supported by the machine running the simulation. This option is useful for pinpointing computational errors in a model.

Breaking on Step-Size Limiting Steps

Selecting the **Step size limited by state** option or entering the `xbreak` command causes the debugger to stop the simulation when the model uses a variable-step solver and the solver encounters a state that limits the size of the steps that it can take. This command is useful in debugging models that appear to require an excessive number of simulation time steps to solve.

Breaking at Zero Crossings

Selecting the **Zero crossings** option or entering the `zcbreak` command causes the simulation to halt when a nonsampled zero crossing is detected in a model that includes blocks where zero crossings can arise. After halting, the ID, type, and name of the block in which the zero crossing was detected is displayed. The block ID (`s:b:p`) consists of a system index `s`, block index `b`, and port index `p` separated by colons (see “Block ID” on page 34-10).

For example, setting a zero-crossing break at the start of execution of the `zeroxing` example model,

```
>> sldebug zeroxing
%-----%
%
[TM = 0                      ] zeroxing.Simulate
(sldebug @0): >> zcbreak
Break at zero crossing events      : enabled
```

and continuing the simulation

```
(sldebug @0): >> continue
```

results in a zero-crossing break at

```
Interrupting model execution before running mdlOutputs at the left post of
(major time step just before) zero crossing event detected at the following location:
  6[-0]  0:5:2  Saturate  'zeroxing/Saturation'
%-----%
[TzL= 0.3435011087932808      ] zeroxing.Outputs.Major
(sldebug @16): >>
```

If a model does not include blocks capable of producing nonsampled zero crossings, the command prints a message advising you of this fact.

Breaking on Solver Errors

Selecting the debugger **Solver Errors** option or entering the `ebreak` command causes the simulation to stop if the solver detects a recoverable error in the model. If you do not set or disable this breakpoint, the solver recovers from the error and proceeds with the simulation without notifying you.

Display Information About the Simulation

In this section...

“Display Block I/O” on page 34-29

“Display Algebraic Loop Information” on page 34-31

“Display System States” on page 34-31

“Display Solver Information” on page 34-32

Display Block I/O

The debugger allows you to display block I/O by clicking the appropriate buttons on the debugger toolbar

or by entering the appropriate debugger command.

This command...	Displays a Blocks I/O...
probe	Immediately
disp	At every breakpoint any time execution stops
trace	Whenever the block executes

Note The two debugger toolbar buttons, Watch Block I/O () and Display Block I/O () correspond, respectively, to `trace gcb` and `probe gcb`. The `probe` and `disp` commands do not have a one-to-one correspondence with the debugger toolbar buttons.

Displaying I/O of a Selected Block

To display the I/O of a block, select the block and click  in GUI mode or enter the `probe` command in command-line mode. In the following table, the `probe gcb` command has a corresponding toolbar button. The other commands do not.

Command	Description
<code>probe</code>	Enter or exit probe mode. Typing any command causes the debugger to exit probe mode.
<code>probe gcb</code>	Display I/O of selected block. Same as  .
<code>probe s:b</code>	Print the I/O of the block specified by system number <code>s</code> and block number <code>b</code> .

The debugger prints the current inputs, outputs, and states of the selected block in the debugger **Outputs** pane (GUI mode) or the Command Window of the MATLAB product.

The `probe` command is useful when you need to examine the I/O of a block whose I/O is not otherwise displayed. For example, suppose you are using the `step` command to run a model method by method. Each time you step the simulation, the debugger displays the inputs and outputs of the current block. The `probe` command lets you examine the I/O of other blocks as well.

Displaying Block I/O Automatically at Breakpoints

The `disp` command causes the debugger to display a specified block's inputs and outputs whenever it halts the simulation. You can specify a block by entering its block index and entering `gcb` as the `disp` command argument. You can remove any block from the debugger list of display points, using the `undisp` command. For example, to remove block `0:0`, enter `undisp 0:0`.

Note Automatic display of block I/O at breakpoints is not available in the debugger GUI mode.

The `disp` command is useful when you need to monitor the I/O of a specific block or set of blocks as you step through a simulation. Using the `disp` command, you can specify the blocks you want to monitor and the debugger will then redisplay the I/O of those blocks on every step. Note that the debugger always displays the I/O of the current block when

you step through a model block by block, using the `step` command. You do not need to use the `disp` command if you are interested in watching only the I/O of the current block.

Watching Block I/O

To watch a block, select the block and click  in the debugger toolbar or enter the `trace` command. In GUI mode, if a breakpoint exists on the block, you can set a watch on it as well by selecting the check box for the block in the watch column  of the **Break/Display points** pane. In command-line mode, you can also specify the block by specifying its block index in the `trace` command. You can remove a block from the debugger list of trace points using the `untrace` command.

The debugger displays a watched block's I/O whenever the block executes. Watching a block allows you obtain a complete record of the block's I/O without having to stop the simulation.

Display Algebraic Loop Information

The `atrace` command causes the debugger to display information about a model's algebraic loops (see “Algebraic Loop Concepts” on page 3-38) each time they are solved. The command takes a single argument that specifies the amount of information to display.

This command...	Displays for each algebraic loop...
<code>atrace 0</code>	No information
<code>atrace 1</code>	The loop variable solution, the number of iterations required to solve the loop, and the estimated solution error
<code>atrace 2</code>	Same as level 1
<code>atrace 3</code>	Level 2 plus the Jacobian matrix used to solve the loop
<code>atrace 4</code>	Level 3 plus intermediate solutions of the loop variable

Display System States

The `states` debug command lists the current values of the system states in the MATLAB Command Window. For example, the following sequence of commands shows the states of the bouncing ball example (`sldemo_bounce`) after its first, second, and third time steps. However, before entering the debugger, open the Configuration Parameters dialog box and clear the **Block reduction** and **Signal storage reuse** check boxes.

```

sldebug sldemo_bounce
%-----%
[TM = 0                               ] simulate(sldemo_bounce)
(sldebug @0): >> step top
%-----%
[TM = 0                               ] sldemo_bounce.Outputs.Major
(sldebug @16): >> next
%-----%
[TM = 0                               ] sldemo_bounce.Update
(sldebug @23): >> states

Continuous States:
Idx Value                               (system:block:element Name 'BlockName')
  0  10                                (0:4:0 CSTATE 'sldemo_bounce/Second-Order Integrator')
  1. 15                                (0:4:1)

(sldebug @23): >> next
%-----%
[TM = 0                               ] solverPhase
(sldebug @26): >> states

Continuous States:
Idx Value                               (system:block:element Name 'BlockName')
  0  10                                (0:4:0 CSTATE 'sldemo_bounce/Second-Order Integrator')
  1. 15                                (0:4:1)

(sldebug @26): >> next
%-----%
[TM = 0.01                             ] sldemo_bounce.Outputs.Major
(sldebug @16): >> states

Continuous States:
Idx Value                               (system:block:element Name 'BlockName')
  0  10.1495095                        (0:4:0 CSTATE 'sldemo_bounce/Second-Order Integrator')
  1. 14.9019                            (0:4:1)

```

Display Solver Information

The `strace` command allows you to pinpoint problems in solving a models differential equations that can slow down simulation performance. Executing this command causes the debugger to display solver-related information at the command line of the MATLAB product when you run or step through a simulation. The information includes the sizes of the steps taken by the solver, the estimated integration error resulting from the step size, whether a step size succeeded (i.e., met the accuracy requirements that the model specifies), the times at which solver resets occur, etc. If you are concerned about the time required to simulate your model, this information can help you to decide whether the solver you have chosen is the culprit and hence whether choosing another solver might shorten the time required to solve the model.

Display Information About the Model

In this section...

“Display Model’s Sorted Lists” on page 34-34

“Display a Block” on page 34-35

Display Model’s Sorted Lists

In GUI mode, the debugger **Sorted List** pane displays lists of blocks for a model’s root system and each nonvirtual subsystem. Each list lists the blocks that the subsystems contains sorted according to their computational dependencies, alphabetical order, and other block sorting rules. In command-line mode, you can use the `slist` command to display a model’s sorted lists.

```

---- Sorted list for 'vdp' [9 nonvirtual blocks, directFeed=0]
 0:0  'vdp/x1' (Integrator)
 0:1  'vdp/Out1' (Outputport)
 0:2  'vdp/x2' (Integrator)
 0:3  'vdp/Out2' (Outputport)
 0:4  'vdp/Scope' (Scope)
 0:5  'vdp/Fcn' (Fcn)
 0:6  'vdp/Product' (Product)
 0:7  'vdp/Mu' (Gain)
 0:8  'vdp/Sum' (Sum)

```

These displays include the block index for each command. You can use them to determine the block IDs of the model’s blocks. Some debugger commands accept block IDs as arguments.

Identifying Blocks in Algebraic Loops

If a block belongs to an algebraic list, the `slist` command displays an algebraic loop identifier in the entry for the block in the sorted list. The identifier has the form

```
algId=s#n
```

where `s` is the index of the subsystem containing the algebraic loop and `n` is the index of the algebraic loop in the subsystem. For example, the following entry for an Integrator block indicates that it participates in the first algebraic loop at the root level of the model.

```
0:1 'test/ss/I1' (Integrator, tid=0) [algId=0#1, discontinuity]
```

When the debugger is running, you can use the `ashow` command at the debugger command-line interface to highlight the blocks and lines that make up an algebraic loop. See “Displaying Algebraic Loops” on page 34-36 for more information.

Display a Block

To determine the block in a models diagram that corresponds to a particular index, enter `bshow s:b` at the command prompt, where `s:b` is the block index. The `bshow` command opens the system containing the block (if necessary) and selects the block in the systems window.

Displaying a Model's Nonvirtual Systems

The `systems` command displays a list of the nonvirtual systems in the model that you are debugging. For example, the `sldemo_clutch` model contains the following systems:

```
open_system('sldemo_clutch')
set_param(gcs, 'OptimizeBlockIOStorage','off')
sldebug sldemo_clutch
(sldebug @0): %-----%
[TM = 0                               ] simulate(sldemo_clutch)
(sldebug @0): >> systems
  0  'sldemo_clutch'
  1  'sldemo_clutch/Locked'
  2  'sldemo_clutch/Unlocked'
```

Note The `systems` command does not list subsystems that are purely graphical. That is, subsystems that the model diagram represents as Subsystem blocks but that are solved as part of a parent system. are not listed. In Simulink models, the root system and triggered or enabled subsystems are true systems. All other subsystems are virtual (that is, graphical) and do not appear in the listing from the `systems` command.

Displaying a Model's Nonvirtual Blocks

The `slist` command displays a list of the nonvirtual blocks in a model. The listing groups the blocks by system. For example, the following sequence of commands produces a list of the nonvirtual blocks in the Van der Pol (vdp) example model.

```
sldebug vdp
%-----%
[TM = 0                               ] simulate(vdp)
sldebug @0): >> slist
```

```

---- Sorted list for 'vdp' [9 nonvirtual blocks, directFeed=0]
 0:0  'vdp/x1' (Integrator)
 0:1  'vdp/Out1' (Output)
 0:2  'vdp/x2' (Integrator)
 0:3  'vdp/Out2' (Output)
 0:4  'vdp/Scope' (Scope)
 0:5  'vdp/Fcn' (Fcn)
 0:6  'vdp/Product' (Product)
 0:7  'vdp/Mu' (Gain)
 0:8  'vdp/Sum' (Sum)

```

Note The `slist` command does not list blocks that are purely graphical. That is, blocks that indicate relationships between or groupings among computational blocks.

Displaying Blocks with Potential Zero Crossings

The `zclist` command displays a list of blocks in which nonsampled zero crossings can occur during a simulation. For example, `zclist` displays the following list for the clutch sample model:

```

(sldebug @0): >> zclist
 0 0:4:0 F HitCross 'sldemo_clutch/Friction Mode Logic/Lockup
Detection/Velocities Match'
 1 0:4:1 F
 2 0:10:0 F Abs 'sldemo_clutch/Friction Mode Logic/Lockup
Detection/Required Friction for Lockup/Abs'
 3 0:12:0 F RelationalOperator 'sldemo_clutch/Friction Mode
Logic/Lockup Detection/Required Friction for Lockup/Relational Operator'
 4 0:19:0 F Abs 'sldemo_clutch/Friction Mode Logic/Break Apart
Detection/Abs'
 5 0:20:0 F RelationalOperator 'sldemo_clutch/Friction Mode
Logic/Break Apart Detection/Relational Operator'
 6 2:3:0 F Signum 'sldemo_clutch/Unlocked/slip direction'

```

Displaying Algebraic Loops

The `ashow` command highlights a specified algebraic loop or the algebraic loop that contains a specified block. To highlight a specified algebraic loop, enter `ashow s#n`, where `s` is the index of the system (see “Identifying Blocks in Algebraic Loops” on page 34-34) that contains the loop and `n` is the index of the loop in the system. To display the loop that contains the currently selected block, enter `ashow gcb`. To show a loop that contains a specified block, enter `ashow s:b`, where `s:b` is the block's index. To clear algebraic-loop highlighting from the model diagram, enter `ashow clear`.

Displaying Debugger Status

In GUI mode, the debugger displays the settings of various debug options, such as conditional breakpoints, in its **Status** panel. In command-line mode, the `status` command displays debugger settings. For example, the following sequence of commands displays the initial debug settings for the `vdp` model:

```
sim('vdp', 'StopTime', '10', 'debug', 'on')
%-----%
[TM = 0                               ] simulate(vdp)
(sldebug @0): >> status
%-----%
Current simulation time                : 0.0 (MajorTimeStep)
Solver needs reset                     : no
Solver derivatives cache needs reset   : no
Zero crossing signals cache needs reset : no
Default command to execute on return/enter : ""
Break at zero crossing events          : disabled
Break on solver error                  : disabled
Break on failed integration step       : disabled
Time break point                       : disabled
Break on non-finite (NaN,Inf) values  : disabled
Break on solver reset request          : disabled
Display level for disp, trace, probe  : 1 (i/o, states)
Solver trace level                     : 0
Algebraic loop tracing level          : 0
Animation Mode                         : off
Execution Mode                         : Normal
Display level for etrace                : 0 (disabled)
Break points                           : none installed
Display points                         : none installed
Trace points                           : none installed
```

- “How to Improve Performance in Acceleration Modes” on page 35-39

What Is Acceleration?

Acceleration is a mode of operation in the Simulink product that you can use to speed up the execution of your model. The Simulink software includes two modes of acceleration: accelerator mode and the rapid accelerator mode. Both modes replace the normal interpreted code with compiled target code. Using compiled code speeds up simulation of many models, especially those where run time is long compared to the time associated with compilation and checking to see if the target is up to date.

The accelerator mode works with any model, but performance decreases if a model contains blocks that do not support acceleration. The accelerator mode supports the Simulink debugger and profiler. These tools help with debugging and determining relative performance of various parts of your model. For more information, see “Run Accelerator Mode with the Simulink Debugger” on page 35-33 and “How Profiler Captures Performance Data” on page 31-5.

The rapid accelerator mode works with only those models containing blocks that support code generation of a standalone executable. For this reason, rapid accelerator mode does not support the debugger or profiler. However, this mode generally results in faster execution than the accelerator mode. When used with dual-core processors, the rapid accelerator mode runs Simulink and the MATLAB technical computing environment from one core while the rapid accelerator target runs as a separate process on a second core.

For more information about the performance characteristics of the Accelerator and rapid accelerator modes, and how to measure the difference in performance, see “Comparing Performance” on page 35-35.

To optimize your model and achieve faster simulation automatically using Performance Advisor, see “Automated Performance Optimization”.

To employ modeling techniques that help achieve faster simulation, see “Manual Performance Optimization”.

How Acceleration Modes Work

In this section...
“Overview” on page 35-4
“Normal Mode” on page 35-4
“Accelerator Mode” on page 35-5
“Rapid Accelerator Mode” on page 35-7

Overview

The Accelerator and rapid accelerator modes use portions of the Simulink Coder product to create an executable.

The Accelerator and rapid accelerator modes replace the interpreted code normally used in Simulink simulations, shortening model run time.

Although the acceleration modes use some Simulink Coder code generation technology, you do not need the Simulink Coder software installed to accelerate your model.

Note The code generated by the accelerator and rapid accelerator modes is suitable only for speeding the simulation of your model. Use Simulink Coder to generate code for other purposes.

Normal Mode

In normal mode, the MATLAB technical computing environment is the foundation on which the Simulink software is built. Simulink controls the solver and model methods used during simulation. Model methods on page 3-16 include such things as computation of model outputs. Normal mode runs in one process.

One Process

Accelerator Mode

By default, the accelerator mode uses Just-in-Time (JIT) acceleration to generate an execution engine in memory instead of generating C code or MEX files. You can also have your model fall back to the classic accelerator mode, in which Simulink generates and links code into a C-MEX S-function.

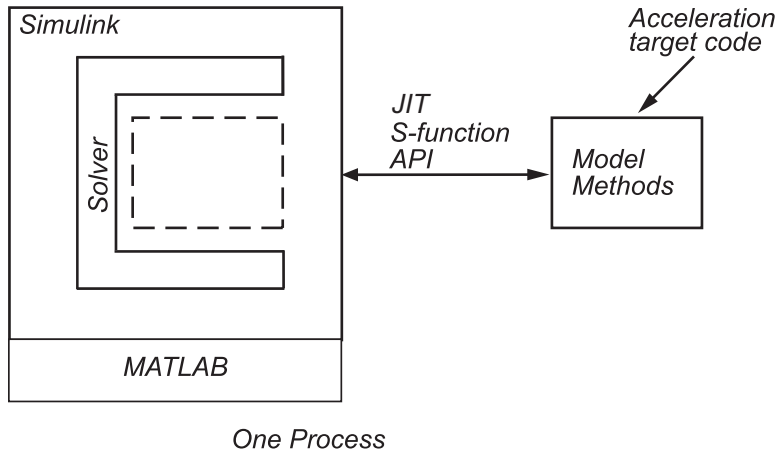

In the accelerator mode, the model methods are separate from the Simulink software and are part of the *acceleration target code*, which is used in later simulations.

Simulink checks that the acceleration target code is up to date before reusing it. For more information, see “Code Regeneration in Accelerated Models” on page 35-9 .

There are two modes of operation in accelerator mode.

Just-In-Time Accelerator Mode

In this default mode, Simulink generates an execution engine in memory for the top-level model only and not for referenced models. As a result, a C compiler is not required during simulation.

One Process

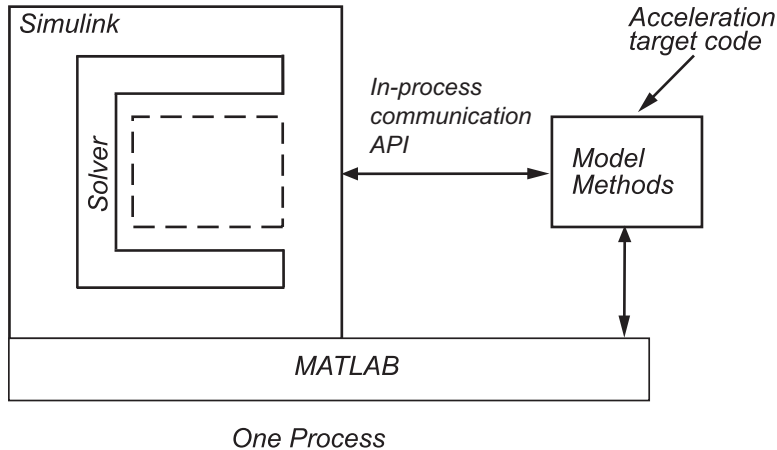

Because the acceleration target code is in memory, it is available for reuse as long as the model is open. Simulink also serializes the acceleration target code so that the model does not need rebuilding when it is opened.

Classic Accelerator Mode

If you want to simulate your model using the classic, C-code generating, accelerator mode, run the following command:

```
set_param(0, 'GlobalUseClassicAccelMode', 'on');
```

In this mode, Simulink generates and links code into a shared library, which communicates with the Simulink software. The target code executes in the same process as MATLAB and Simulink.

Rapid Accelerator Mode

The rapid accelerator mode creates a *Rapid Accelerator standalone executable* from your model. This executable includes the solver and model methods, but it resides outside of MATLAB and Simulink. It uses external mode (see “External Mode Communication” (Simulink Coder)) to communicate with Simulink.

MATLAB and Simulink run in one process, and if a second processing core is available, the standalone executable runs there.

Code Regeneration in Accelerated Models

In this section...

“Determine If the Simulation Will Rebuild” on page 35-9

“Parameter Tuning in Rapid Accelerator Mode” on page 35-9

Changing the structure of your model causes the Rapid Accelerator mode to regenerate the standalone executable, and for the Accelerator mode to regenerate the target code and update (overwrite) the existing MEX-file. Changing the value of a tunable parameter does not trigger a rebuild.

Determine If the Simulation Will Rebuild

The Accelerator and Rapid Accelerator modes use a checksum to determine if the model has changed, indicating that the code should be regenerated. The checksum is an array of four integers computed using an MD5 checksum algorithm based on attributes of the model and the blocks it contains.

- 1 Use the `Simulink.BlockDiagram.getChecksum` command to obtain the checksum for your model. For example:

```
cs1 = Simulink.BlockDiagram.getChecksum('myModel');
```
- 2 Obtain a second checksum after you have altered your model. The code regenerates if the new checksum does not match the previous checksum.
- 3 Use the information in the checksum to determine why the simulation target rebuilt.

For a detailed explanation of this procedure, see the example model `slAccelDemoWhyRebuild`.

Parameter Tuning in Rapid Accelerator Mode

In model rebuilds, Rapid Accelerator Mode handles block diagram and runtime parameters differently from other parameters.

Tuning Block Diagram Parameters

You can change some block diagram parameters during simulation without causing a rebuild. Tune these parameters using the `set_param` command or using the **Model Configuration Parameters** dialog box. These block diagram parameters include:

Solver Parameters		
AbsTol	MaxNumMinSteps	RelTol
ConsecutiveZCsStepRelTol	MaxOrder	StartTime
ExtrapolationOrder	MaxStep	StopTime
InitialStep	MinStep	ZCDetectionTol
MaxConsecutiveMinStep	OutputTimes	
MaxConsecutiveZCs	Refine	

Loading and Logging Parameters		
ConsistencyChecking	MinStepSizeMsg	SaveTime
Decimation	OutputOption	StateSaveName
FinalStateName	OutputSaveName	TimeSaveName
LimitDataPoints	SaveFinalState	
LoadExternalInput	SaveFormat	
MaxConsecutiveZCsMsg	SaveOutput	
MaxDataPoints	SaveState	

Tuning Runtime Parameters

To tune runtime parameters for maximum acceleration in Rapid Accelerator mode, follow this procedure which yields better results than using `set_param` for the same purpose:

- 1 Collect the runtime parameters in a runtime parameter structure while building a rapid accelerator target executable using the `Simulink.BlockDiagram.buildRapidAcceleratorTarget` function.
- 2 To change the parameters, use the `Simulink.BlockDiagram.modifyTunableParameters` function.
- 3 To specify the modified parameters to the `sim` command, use the `RapidAcceleratorParameterSets` and `RapidAcceleratorUpToDateCheck` parameters.

All other parameter changes can necessitate a rebuild of the model.

Parameter Changes	Passed Directly to sim command	Passed Graphically via Block Diagram or via set_param command
Runtime	Does not require rebuild	Can require rebuild
Block diagram (logging parameters)	Does not require rebuild	Does not require rebuild

For information about parameter tunability limitations with accelerated simulation modes, see “Tunability Considerations and Limitations for Other Modeling Goals” on page 37-49.

Choosing a Simulation Mode

In this section...
"Simulation Mode Tradeoffs" on page 35-12
"Comparing Modes" on page 35-14
"Decision Tree" on page 35-15

Simulation Mode Tradeoffs

In general, you must trade off simulation speed against flexibility when choosing either Accelerator mode or Rapid Accelerator mode instead of Normal mode.

Normal mode offers the greatest flexibility for making model adjustments and displaying results, but it runs the slowest.

Accelerator mode lies between Normal and Rapid Accelerator modes in performance and in interaction with your model. Accelerator mode does not support runtime diagnostics.

Rapid Accelerator mode runs the fastest, but this mode does not support the debugger or profiler, and works only with those models for which C code or MEX file is available for all of the blocks in the model.

Note An exception to this rule occurs when you run multiple simulations, each of which executes in less than one second in Normal mode. For example:

```
for i=1:100
sim(model); % executes in less than one second in Normal mode
end
```

For this set of conditions, you will typically obtain the best performance by simulating the model in Normal mode.

Tip To gain additional flexibility, consider using model referencing to componentize your model. If the top-level model uses Normal mode, then you can simulate a referenced model in a different simulation mode than you use for other portions of a model. During the model development process, you can choose different simulation modes for different portions of a model. For details, see “Simulate Model Hierarchies” on page 8-54.

Comparing Modes

The following table compares the characteristics of Normal mode, Accelerator mode, and Rapid Accelerator mode.

If you want to...	Then use this mode...		
	Normal	Accelerator	Rapid Accelerator
Performance			
Run your model in a separate address space			✓
Efficiently run batch and Monte Carlo simulations			✓
Model Adjustment			
Change model parameters such as solver, stop time without rebuilding	✓	✓	✓
Change block tunable parameters such as gain	✓	✓	✓
For more information on configuration set parameters which can be modified without requiring rebuild, see “Code Regeneration in Accelerated Models” on page 35-9			
Model Requirement			

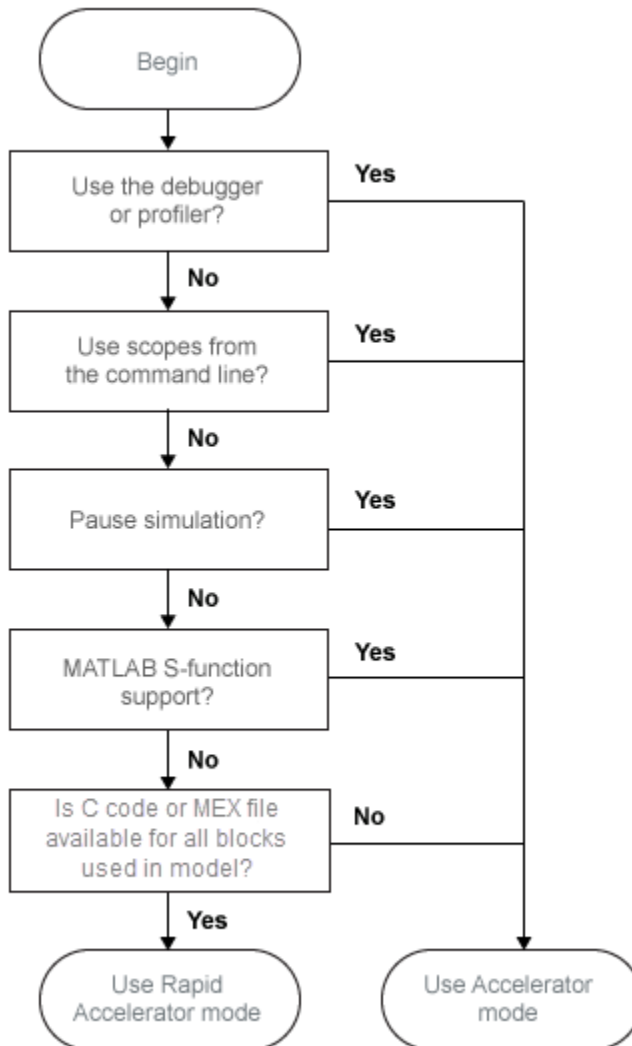

If you want to...	Then use this mode...		
	Normal	Accelerator	Rapid Accelerator
Accelerate your model even if C code or MEX file are not used for all blocks		✓	
Support Interpreted MATLAB Function blocks	✓	✓	
Support Non-Inlined MATLAB language or Fortran S-Functions	✓	✓	
Permit algebraic loops in your model	✓	✓	
Have your model work with the debugger or profiler	✓	✓	
Have your model include C++ code	✓	✓	
Data Display			
Use scopes and signal viewers	✓	✓	See “Behavior of Scopes and Viewers with Rapid Accelerator Mode” on page 35-21
Use scopes and signal viewers when running your model from the command line	✓	✓	

Note Scopes and viewers do not update if you run your model from the command line in Rapid Accelerator mode.

Decision Tree

Use this decision tree to select between Normal, Accelerator, or Rapid Accelerator modes.

See “Comparing Performance” on page 35-35 to understand how effective the accelerator modes will be in improving the performance of your model.

“Behavior of Scopes and Viewers with Rapid Accelerator Mode” on page 35-21
“Factors Inhibiting Acceleration” on page 35-22

Select Blocks for Accelerator Mode

The Accelerator simulation mode runs the following blocks as if you were running Normal mode because these blocks do not generate code for the accelerator build. Consequently, if your model contains a high percentage of these blocks, the Accelerator mode may not increase performance significantly. All of these Simulink blocks use interpreted code.

- Display
- From File
- From Workspace
- Inport (root level only)
- Interpreted MATLAB Function
- Outport (root level only)
- Scope
- To File
- To Workspace
- XY Graph

Note In some instances, Normal mode output might not precisely match the output from Accelerator mode because of slight differences in the numerical precision between the interpreted and compiled versions of a model.

The following blocks can cause poor simulation runtime performance when run in the default JIT Accelerator mode.

- Transport Delay
- Variable Transport Delay

Select Blocks for Rapid Accelerator Mode

Blocks that do not support code generation (such as SimEvents) or blocks that generate code only for a specific target cannot be simulated in Rapid Accelerator mode.

Additionally, Rapid Accelerator mode does not work if your model contains any of the following blocks:

- Interpreted MATLAB Function
- Device driver S-functions, such as blocks from the Simulink Real-Time product, or those targeting Freescale™ MPC555

Note In some instances, Normal mode output might not precisely match the output from Rapid Accelerator mode because of slight differences in the numerical precision between the interpreted and compiled versions of a model.

Control S-Function Execution

Note In the default JIT Accelerator mode, inlining of user-written TLC S-Functions is not supported. If you run a model containing TLC S-Functions in the JIT Accelerator mode, there is a possibility of the execution speed reducing. The code generation speed, however, will be high due to JIT acceleration.

Inlining S-functions using the Target Language Compiler increases performance with the classic Accelerator mode by eliminating unnecessary calls to the Simulink API. By default, however, the classic Accelerator mode ignores an inlining TLC file for an S-function, even though the file exists. The Rapid Accelerator mode always uses the TLC file if one is available.

A device driver S-Function block written to access specific hardware registers on an I/O board is one example of why this behavior was chosen as the default. Because the

Simulink software runs on the host system rather than the target, it cannot access the targets I/O registers and so would fail when attempting to do so.

To direct the classic Accelerator mode to use the TLC file instead of the S-function MEX-file, specify `SS_OPTION_USE_TLC_WITH_ACCELERATOR` in the `mdlInitializeSizes` function of the S-function, as in this example:

```
static void mdlInitializeSizes(SimStruct *S)
{
/* Code deleted */
ssSetOptions(S, SS_OPTION_USE_TLC_WITH_ACCELERATOR);
}
```

The Rapid Accelerator mode will make use of the MEX file if the S-Function's C file is not present in the same folder.

Note to use the `.c` or `.cpp` code for your S-Function, ensure that they are in the same folder as the S-Function MEX-file, otherwise, you can include additional files to an S-function or bypass the path limitation by using the `rtwmakecfg.m` file. For more information, see [Use `rtwmakecfg.m` API to Customize Generated Makefiles \(Simulink Coder\)](#).

Accelerator and Rapid Accelerator Mode Data Type Considerations

- Accelerator mode supports fixed-point signals and vectors up to 128 bits.
- Rapid Accelerator mode supports fixed-point parameters up to 128 bits.
- Rapid Accelerator mode supports fixed-point root inputs up to 32 bits
- Rapid Accelerator mode supports root inputs of Enumerated data type
- Rapid Accelerator mode does not support fixed-point data for the From Workspace block.
- Rapid Accelerator mode ignores the selection of the **Log fixed-point data as a fix object** (FixptAsFi) check box for the To Workspace block.
- Rapid Accelerator mode supports bus objects as parameters.
- The Accelerator mode and Rapid Accelerator mode store integers as compactly as possible.

- Fixed-Point Designer does not collect min, max, or overflow data in the Accelerator or Rapid Accelerator modes.
- Accelerator mode supports a limited set of runtime diagnostics, including the assertion block.
- Rapid Accelerator mode supports a limited set of runtime diagnostics, including the assertion block.

Behavior of Scopes and Viewers with Rapid Accelerator Mode

Running the simulation from the command line or the menu determines the behavior of scopes and viewers in Rapid Accelerator mode.

Scope or Viewer Type	Simulation Run from Menu	Simulation Run from Command Line
Simulink Scope blocks	Same support as Normal mode	<ul style="list-style-type: none"> • Logging is supported • Scope window is not updated
Simulink signal viewer scopes	Graphics are updated, but logging is not supported	Not supported
Other signal viewer scopes	Support limited to that available in External mode	Not supported
Signal logging	Supported, with limitations listed in “Signal Logging in Rapid Accelerator Mode” on page 64-70	Supported, with limitations listed in “Signal Logging in Rapid Accelerator Mode” on page 64-70.
Multirate signal viewers	Not supported	Not supported
Stateflow Chart blocks	Same support for chart animation as Normal mode	Not supported

Rapid Accelerator mode does not support multirate signal viewers such as the DSP System Toolbox spectrum scope or the Communications Toolbox™ scatterplot, signal trajectory, or eye diagram scopes.

Note Although scopes and viewers do not update when you run Rapid Accelerator mode from the command line, they do update when you run the model from the menu. “Run

Acceleration Mode from the User Interface” on page 35-25 shows how to run Rapid Accelerator mode from the menu. “Interact with the Acceleration Modes Programmatically” on page 35-29 shows how to run the simulation from the command line.

Factors Inhibiting Acceleration

- You cannot use the Accelerator or Rapid Accelerator mode if your model:
 - Passes array parameters to MATLAB S-functions that are not numeric, logical, or character arrays, are sparse arrays, or that have more than two dimensions.
 - Uses Fcn blocks containing trigonometric functions having complex inputs.
- In some cases, changes associated with external or custom code do not cause Accelerator or Rapid Accelerator simulation results to change. These include:
 - TLC code
 - S-function source code, including `rtwmakecfg.m` files
 - Integrated custom code
 - S-Function Builder

In such cases, consider force regeneration of code for a top model. Alternatively, you can force regeneration of top model code by deleting code generation folders, such as `s_lprj` or the generated model code folder.

Note With JIT acceleration, the acceleration target code is in memory. It is therefore available for reuse as long as the model is open, even if you delete the `s_lprj` folder.

Rapid Accelerator Mode Limitations

- Rapid Accelerator mode does not support:
 - Algebraic loops.
 - Targets written in C++.
 - Interpreted MATLAB Function blocks.
 - Noninlined MATLAB language or Fortran S-functions. You must write S-functions in C or inline them using the Target Language Compiler (TLC) or you can also use the MEX file. For more information, see “Write Fully Inlined S-Functions” (Simulink Coder).

- Debugger or Profiler.
- Run time objects for Simulink.RunTimeBlock and Simulink.BlockCompOutputPortData blocks.
- Model parameters must be one of these data types:
 - `boolean`
 - `uint8` or `int8`
 - `uint16` or `int16`
 - `uint32` or `int32`
 - `single` or `double`
 - Fixed-point
 - Enumerated
- You cannot pause a simulation in Rapid Accelerator mode.
- If a Rapid Accelerator build includes referenced models (by using Model blocks), set up these models to use fixed-step solvers to generate code for them. The top model, however, can use a variable-step solver as long as the blocks in the referenced models are discrete.
- In certain cases, changing block parameters can result in structural changes to your model that change the model checksum. An example of such a change is changing the number of delays in a DSP simulation. In these cases, you must regenerate the code for the model. See “Code Regeneration in Accelerated Models” on page 35-9 for more information.
- For root inports, Rapid Accelerator mode supports only base as the `Srcworkspace`.
- For root inports, when you specify the minimum and maximum values that the block should output, Rapid Accelerator mode does not recognize these limits during simulation.
- In Rapid Accelerator mode, To File or To Workspace blocks inside function-call subsystems do not generate any logging files if the function-call port is connected to Ground or unconnected.

Reserved Keywords

Certain words are reserved for use by the Simulink Coder code language and by Accelerator mode and Rapid Accelerator mode. These keywords must not appear as function or variable names on a subsystem, or as exported global signal names. Using the reserved keywords results in the Simulink software reporting an error, and the model cannot be compiled or run.

The keywords reserved for the Simulink Coder product are listed in “Construction of Generated Identifiers” (Simulink Coder). Additional keywords that apply only to the Accelerator and Rapid accelerator modes are:

<code>muDoubleScalarAbs</code>	<code>muDoubleScalarCos</code>	<code>muDoubleScalarMod</code>
<code>muDoubleScalarAcos</code>	<code>muDoubleScalarCosh</code>	<code>muDoubleScalarPower</code>
<code>muDoubleScalarAcosh</code>	<code>muDoubleScalarExp</code>	<code>muDoubleScalarRound</code>
<code>muDoubleScalarAsin</code>	<code>muDoubleScalarFloor</code>	<code>muDoubleScalarSign</code>
<code>muDoubleScalarAsinh</code>	<code>muDoubleScalarHypot</code>	<code>muDoubleScalarSin</code>
<code>muDoubleScalarAtan,</code>	<code>muDoubleScalarLog</code>	<code>muDoubleScalarSinh</code>
<code>muDoubleScalarAtan2</code>	<code>muDoubleScalarLog10</code>	<code>muDoubleScalarSqrt</code>
<code>muDoubleScalarAtanh</code>	<code>muDoubleScalarMax</code>	<code>muDoubleScalarTan</code>
<code>muDoubleScalarCeil</code>	<code>muDoubleScalarMin</code>	<code>muDoubleScalarTanh</code>

“Making Run-Time Changes” on page 35-27

Customize the Build Process

Compiler optimizations are off by default. This results in faster build times, but slower simulation times. You can optimize the build process toward a faster simulation.

- 1 From the **Simulation** menu, select **Model Configuration Parameters**.
- 2 In the Configuration Parameters dialog box, from the **Compiler optimization level** drop-down list, select **Optimizations on (faster runs)**.

Code generation takes longer with this option, but the model simulation runs faster.

- 3 Select **Verbose accelerator builds** to display progress information using code generation, and to see the compiler options in use.

Changing the Location of Generated Code

By default, the Accelerator mode places the generated code in a subfolder of the working folder called `slprj/accel/modelname` (for example, `slprj/accel/f14`). To change the name of the folder into which the Accelerator Mode writes generated code:

- 1 In the Simulink editor window, select **File > Simulink Preferences**.

The Simulink Preferences window appears.

- 2 In the Simulink Preferences window, navigate to the **Simulation cache folder** parameter.
- 3 Enter the absolute or relative path to your subfolder and click **Apply**.

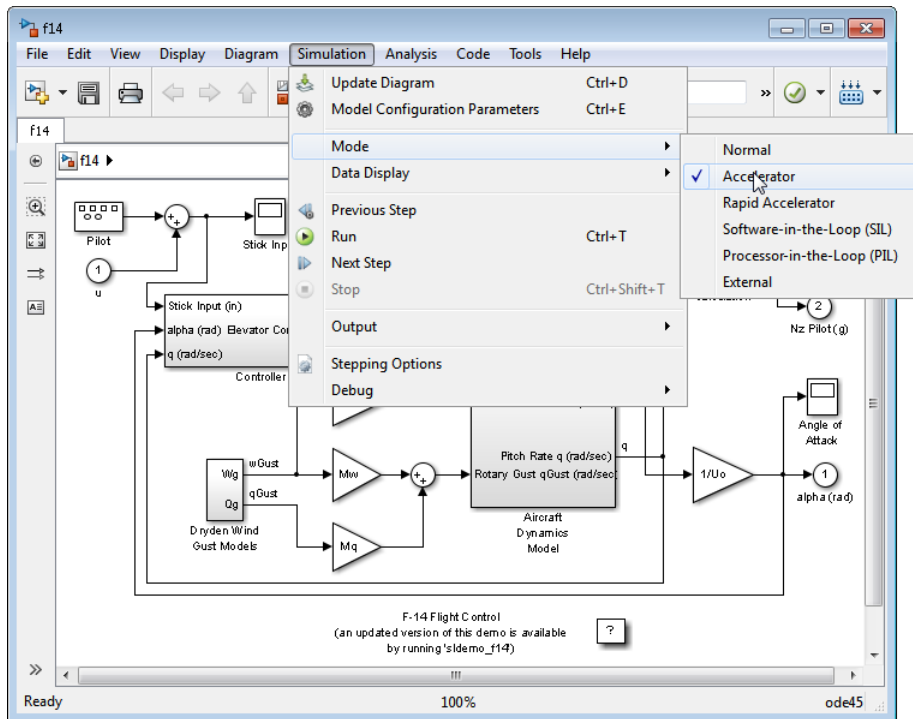

Run Acceleration Mode from the User Interface

To accelerate a model, first open it, and then from the **Simulation > Mode** menu, select either **Accelerator** or **Rapid Accelerator**. Then start the simulation.

The following example shows how to accelerate the already opened f14 model using the Accelerator mode:

- 1 From the **Simulation > Mode** menu, select **Accelerator**.

Alternatively, you can select Accelerator from the Simulink Editor toolbar.

- 2 From the **Simulation** menu, select **Run**.

The Accelerator and Rapid Accelerator modes first check to see if code was previously compiled for your model. If code was created previously, the Accelerator or Rapid Accelerator mode runs the model. If code was not previously built, they first generate and compile the C code, and then run the model.

For an explanation of why these modes rebuild your model, see “Code Regeneration in Accelerated Models” on page 35-9.

The Accelerator mode places the generated code in a subfolder of the working folder called `slprj/accel/modelname` (for example, `slprj/accel/f14`). If you want to change this path, see “Changing the Location of Generated Code” on page 35-25.

The Rapid Accelerator mode places the generated code in a subfolder of the working folder called `slprj/raccel/modelname` (for example, `slprj/raccel/f14`).

Note The warnings that blocks generate during simulation (such as divide-by-zero and integer overflow) are not displayed when your model runs in Accelerator or Rapid Accelerator mode.

Making Run-Time Changes

A feature of the Accelerator and Rapid Accelerator modes is that simple adjustments (such as changing the value of a Gain or Constant block) can be made to the model while the simulation is still running. More complex changes (for example, changing from a `sin` to `tan` function) are not allowed during run time.

The Simulink software issues a warning if you attempt to make a change that is not permitted. The absence of a warning indicates that the change was accepted. The warning does not stop the current simulation, and the simulation continues with the previous values. If you wish to alter the model in ways that are not permitted during run time, you must first stop the simulation, make the change, and then restart the simulation.

In general, simple model changes are more likely to result in code regeneration when in Rapid Accelerator mode than when in Accelerator mode.

Interact with the Acceleration Modes Programmatically

In this section...

“Why Interact Programmatically?” on page 35-29

“Build JIT Accelerated Execution Engine” on page 35-29

“Control Simulation” on page 35-29

“Simulate Your Model” on page 35-30

“Customize the Acceleration Build Process” on page 35-31

Why Interact Programmatically?

You can build an accelerated model, select the simulation mode, and run the simulation from the command prompt or from MATLAB script. With this flexibility, you can create Accelerator mode MEX-files in batch mode, allowing you to build the C code and executable before running the simulations. When you use the Accelerator mode interactively at a later time, it will not be necessary to generate or compile MEX-files at the start of the accelerated simulations.

Build JIT Accelerated Execution Engine

With the `accelbuild` command, you can build a JIT accelerated execution engine without actually simulating the model. For example, to build an Accelerator mode simulation of `myModel`:

```
accelbuild myModel
```

Control Simulation

You can control the simulation mode from the command line prompt by using the `set_param` command:

```
set_param('modelName', 'SimulationMode', 'mode')
```

The simulation mode can be `normal`, `accelerator`, `rapid`, or `external`.

For example, to simulate your model with the Accelerator mode, you would use:

```
set_param('myModel', 'SimulationMode', 'accelerator')
```

However, a preferable method is to specify the simulation mode within the `sim` command:

```
simOut = sim('myModel', 'SimulationMode', 'accelerator');
```

You can use `bdroot` to set parameters for the currently active model (that is, the active model window) rather than *modelName* if you do not wish to explicitly specify the model name.

For example, to simulate the currently opened system in the Rapid Accelerator mode, you would use:

```
simOut = sim(bdroot, 'SimulationMode', 'rapid');
```

Simulate Your Model

You can use `set_param` to configure the model parameters (such as the simulation mode and the stop time), and use the `sim` command to start the simulation:

```
sim('modelName', 'ReturnWorkspaceOutputs', 'on');
```

However, the preferred method is to configure model parameters directly using the `sim` command, as shown in the previous section.

You can substitute `gcs` for *modelName* if you do not want to explicitly specify the model name.

Unless target code has already been generated, the `sim` command first builds the executable and then runs the simulation. However, if the target code has already been generated and no significant changes have been made to the model (see “Code Regeneration in Accelerated Models” on page 35-9 for a description), the `sim` command executes the generated code without regenerating the code. This process lets you run your model after making simple changes without having to wait for the model to rebuild.

Simulation Example

The following sequence shows how to programmatically simulate `myModel` in Rapid Accelerator mode for 10,000 seconds.

First open `myModel`, and then type the following in the Command Window:

```
simOut = sim('myModel', 'SimulationMode', 'rapid'...  
'StopTime', '10000');
```

Use the `sim` command again to resimulate after making a change to your model. If the change is minor (adjusting the gain of a gain block, for instance), the simulation runs without regenerating code.

Customize the Acceleration Build Process

You can programmatically control the Accelerator mode and Rapid Accelerator mode build process and the amount of information displayed during the build process. See “Customize the Build Process” on page 35-25 for details on why doing so might be advantageous.

Controlling the Build Process

Use `SimCompilerOptimization` to set the degree of optimization used by the compiler when generating code for acceleration. The permitted values are `on` or `off`. The default is `off`.

Enter the following at the command prompt to turn on compiler optimization:

```
set_param('myModel', 'SimCompilerOptimization', 'on')
```

When `SimCompilerOptimization` is set to `on` in JIT accelerated mode, the simulation time for some models improves, while the build time can become slower.

Controlling Verbosity During Code Generation

Use the `AccelVerboseBuild` parameter to display progress information during code generation. The permitted values are `on` or `off`. The default is `off`.

Enter the following at the command prompt to turn on verbose build:

```
set_param('myModel', 'AccelVerboseBuild', 'on')
```

Run Accelerator Mode with the Simulink Debugger

In this section...

“Advantages of Using Accelerator Mode with the Debugger” on page 35-33

“How to Run the Debugger” on page 35-33

“When to Switch Back to Normal Mode” on page 35-33

Advantages of Using Accelerator Mode with the Debugger

The Accelerator mode can shorten the length of your debugging sessions if you have large and complex models. For example, you can use the Accelerator mode to simulate a large model and quickly reach a distant break point.

For more information, see “Accelerator Mode” on page 35-5.

Note You cannot use the Rapid Accelerator mode with the debugger.

How to Run the Debugger

To run your model in the Accelerator mode with the debugger:

- 1 From the **Simulation > Mode** menu, select **Accelerator**.
- 2 At the command prompt, enter:

```
sldebug modelName
```
- 3 At the debugger prompt, set a time break:

```
tbreak 10000  
continue
```
- 4 Once you reach the breakpoint, use the debugger command **emode** (execution mode) to toggle between Accelerator and Normal mode.

When to Switch Back to Normal Mode

You must switch to Normal mode to step through the simulation by blocks, and when you want to use the following debug commands:

- trace
- break
- zcbreak
- nanbreak

Comparing Performance

In this section...
“Performance of the Simulation Modes” on page 35-35
“Measure Performance” on page 35-37

Performance of the Simulation Modes

The Accelerator and Rapid Accelerator modes give the best speed improvement compared to Normal mode when simulation execution time exceeds the time required for code generation. For this reason, the Accelerator and Rapid Accelerator modes generally perform better than Normal mode when simulation execution times are several minutes or more. However, models with a significant number of Stateflow or MATLAB Function blocks might show only a small speed improvement over Normal mode because in Normal mode these blocks also simulate through code generation.

Including tunable parameters in your model can also increase the simulation time.

The figure shows in general terms the performance of a hypothetical model simulated in Normal, Accelerator, and Rapid Accelerator modes.

Performance When the Target Must Be Rebuilt

The solid lines in the figure show performance when the target code must be rebuilt (“all targets out of date”). For this hypothetical model, the time scale is on the order of minutes, but it could be longer for more complex models.

As generalized in the figure, the time required to compile the model in Normal mode is less than the time required to build either the Accelerator target or Rapid Accelerator executable. It is evident from the figure that for small simulation stop times Normal mode results in quicker overall simulation times than either Accelerator mode or Rapid Accelerator mode.

The crossover point where Accelerator mode or Rapid Accelerator mode result in faster execution times depends on the complexity and content of your model. For instance, those models running in Accelerator mode containing large numbers of blocks using interpreted

code (see “Select Blocks for Accelerator Mode” on page 35-18) might not run much faster than they would in Normal mode unless the simulation stop time is very large. Similarly, models with a large number of Stateflow Chart blocks or MATLAB Function blocks might not show much speed improvement over Normal mode unless the simulation stop times are long.

For illustration purposes, the graphic represents a model with a large number of Stateflow Chart blocks or MATLAB Function blocks. The curve labeled “Normal” would have much smaller initial elapsed time than shown if the model did not contain these blocks.

Performance When the Targets Are Up to Date

As shown by the broken lines in the figure (“all targets up to date”) the time for the Simulink software to determine if the Accelerator target or the Rapid Accelerator executable are up to date is significantly less than the time required to generate code (“all targets out of date”). You can take advantage of this characteristic when you wish to test various design tradeoffs.

For instance, you can generate the Accelerator mode target code once and use it to simulate your model with a series of gain settings. This is an especially efficient way to use the Accelerator or Rapid Accelerator modes because this type of change does not result in the target code being regenerated. This means the target code is generated the first time the model runs, but on subsequent runs the Simulink code spends only the time necessary to verify that the target is up to date. This process is much faster than generating code, so subsequent runs can be significantly faster than the initial run.

Because checking the targets is quicker than code generation, the crossover point is smaller when the target is up to date than when code must be generated. This means subsequent runs of your model might simulate faster in Accelerator or Rapid Accelerator mode when compared to Normal mode, even for short stop times.

Measure Performance

You can use the `tic`, `toc`, and `sim` commands to compare Accelerator mode or Rapid Accelerator mode execution times to Normal mode.

- 1 Open your model.
- 2 From the **Simulation > Mode** menu, select **Normal**.
- 3 Use the `tic`, `toc`, and `sim` commands at the command line prompt to measure how long the model takes to simulate in Normal mode:

```
tic,[t,x,y]=sim('myModel',10000);toc
```

`tic` and `toc` work together to record and return the elapsed time and display a message such as the following:

```
Elapsed time is 17.789364 seconds.
```

- 4 Select either **Accelerator** or **Rapid Accelerator** from the **Simulation > Mode** menu, and build an executable for the model by clicking the **Run** button. The acceleration modes use this executable in subsequent simulations as long as the model remains structurally unchanged. “Code Regeneration in Accelerated Models” on page 35-9 discusses the things that cause your model to rebuild.
- 5 Rerun the compiled model at the command prompt:

```
tic,[t,x,y]=sim('myModel',10000);toc
```

- 6 The elapsed time displayed shows the run time for the accelerated model. For example:

```
Elapsed time is 12.419914 seconds.
```

The difference in elapsed times (5.369450 seconds in this example) shows the improvement obtained by accelerating your model.

How to Improve Performance in Acceleration Modes

In this section...

“Techniques” on page 35-39

“C Compilers” on page 35-39

Techniques

To get the best performance when accelerating your models:

- Verify that the Configuration Parameters dialog box settings are as follows:

Set...	To...
Solver data inconsistency	none
Array bounds exceeded	none
Signal storage reuse	selected

- Disable Stateflow debugging and animation.
- When logging large amounts of data (for instance, when using the Workspace I/O, To Workspace, To File, or Scope blocks), use decimation or limit the output to display only the last part of the simulation.
- Customize the code generation process to improve simulation speed. For details, see “Customize the Build Process” on page 35-25.

C Compilers

On computers running the Microsoft Windows operating system, the Accelerator and Rapid Accelerator modes use the default 64-bit C compiler supplied by MathWorks to compile your model. If you have a C compiler installed on your PC, you can configure the mex command to use it instead. You might choose to do this if your C compiler produces highly optimized code since this would further improve acceleration.

Note For an up-to-date list of 32- and 64-bit C compilers that are compatible with MATLAB software for all supported computing platforms, see:

https://www.mathworks.com/support/compilers/current_release/

Nonvirtual and Virtual Blocks

When creating models, you need to be aware that Simulink blocks fall into two basic categories: nonvirtual blocks and virtual blocks. Nonvirtual blocks play an active role in the simulation of a system. If you add or remove a nonvirtual block, you change the model's behavior. Virtual blocks, by contrast, play no active role in the simulation; they help organize a model graphically. Some Simulink blocks are virtual in some circumstances and nonvirtual in others. Such blocks are called conditionally virtual blocks. The table lists Simulink virtual and conditionally virtual blocks.

Block Name	Condition Under Which Block Is Virtual
Bus Assignment	Virtual if input bus is virtual.
Bus Creator	Virtual if output bus is virtual.
Bus Selector	Virtual if input bus is virtual.
Demux	Always virtual.
Enable	Virtual unless connected directly to an Outputport block.
From	Always virtual.
Goto	Always virtual.
Goto Tag Visibility	Always virtual.
Ground	Always virtual.
Inport	Virtual <i>unless</i> the block resides in a conditionally executed or atomic subsystem <i>and</i> has a direct connection to an Outputport block.
Mux	Always virtual.
Outputport	Virtual when the block resides within any subsystem block (conditional or not), and does <i>not</i> reside in the root (top-level) Simulink window.
Selector	Virtual only when Number of input dimensions specifies 1 and Index Option specifies Select all, Index vector (dialog), or Starting index (dialog).
Signal Specification	Always virtual.

Block Name	Condition Under Which Block Is Virtual
Subsystem	Virtual unless the block is conditionally executed or the Treat as atomic unit check box is selected. You can check if a block is virtual with the <code>IsSubsystemVirtual</code> block property. See “Block-Specific Parameters”.
Terminator	Always virtual.
Trigger	Virtual when the output port is <i>not</i> present.

- “Display Port Values for Debugging” on page 36-20
- “Control and Display the Sorted Order” on page 36-31
- “Access Block Data During Simulation” on page 36-50
- “Block Libraries”

Specify Block Properties

For each block in a model, you can set general block properties, such as:

- A description of the block
- The block execution order
- A block annotation
- Block callback functions

To set block properties, use the Property Inspector. You can set properties in the **Properties** and **Info** tabs of the Property Inspector when the block is selected. Alternatively, you can use the Block Properties dialog box. For more information on setting properties, see “Setting Properties and Parameters” on page 1-52.

Set Block Annotation Properties

In the Property Inspector, use the **Block Annotation** section to display the values of selected block parameters in an annotation. The annotation appears below the block icon.

Enter the text of the annotation in the text box. You can use a block property token in the annotation. The value for the property replaces the token in the annotation in the model. To display a list of tokens that you can use in an annotation, type % in the text box. The parameters that are valid for the selected block appear. See “Common Block Properties” and “Block-Specific Parameters”.

Suppose that you specify the following annotation text and tokens for a Product block:

```
Multiplication = %<Multiplication>
Sample time = %<SampleTime>
```

In the Simulink Editor, the block displays this annotation:

You can also create block annotations programmatically. See “Create Block Annotations Programmatically” on page 36-6.

Specify Block Callbacks

Use the **Callbacks** section to specify block callbacks. Callbacks are MATLAB commands that execute when a specific model action occurs, such as when you select or delete a block. For more information on callbacks, see “Callbacks for Customized Model Behavior” on page 4-50.

- 1 Select the block whose callback you want to set.
- 2 In **Properties** tab of the Property Inspector, in the **Callbacks** section, select the function that you want to assign the callback to. For example, select **OpenFcn** to specify a behavior for double-clicking a block.
- 3 In the text box, enter the command that you want to execute when that block function occurs.

After you assign a callback to a function, the function displays an asterisk next to it in the list. The asterisks helps you to see the functions that have callbacks assigned to them.

Note After you add an **OpenFcn** callback to a block, double-clicking the block does not open the block dialog box. Also, the block parameters do not appear in the Property Inspector when the block is selected. To set the block parameters, select **Block Parameters** from the block context menu.

Set a Block Callback Programmatically

This example shows how to use the **OpenFcn** callback to execute MATLAB scripts when you double-click a block. For example, in a MATLAB script you can define variables or open a plot of simulated data.

To create a callback programmatically, select the block to which you want to add this property. Then, at the MATLAB command prompt, enter a command in this form:

```
set_param(gcf, 'OpenFcn', 'myfunction')
```

In this example, `myfunction` represents a valid MATLAB command or a MATLAB script on your MATLAB search path.

Specify Block Execution Priority and Tag

In the **Advanced Properties** section of the block properties, you can specify the block priority and identify the block by assigning a value to the **Tag** property.

- **Priority** — Specify the execution priority of the block relative to other blocks in the model. For more information, see “Assign Block Priorities” on page 36-45.
- **Tag** — Specify an identifier for the block. Specify text to assign to the block Tag parameter. Setting this property is useful for finding the block in the model by searching or programmatically using `find_system`. See “Find Model Elements in Simulink Models” on page 12-45.

Use Block Description to Identify a Block

The **Info** tab displays information about the block type. The block author provides this description.

You can also enter a description in the **Description** box to provide information about the block instance.

- If you add a description, you can set up your model display so that the description appears in a tool tip when you hover over the block. Use **Display > Blocks > Tool Tip Options > Description** to enable this tool tip.
- The **Description** property can help you to find a block by searching. See “Find Model Elements in Simulink Models” on page 12-45.

Create Block Annotations Programmatically

You can use a block `AttributesFormatString` parameter to display specified block parameter values below the block. “Common Block Properties” and “Block-Specific Parameters” describe the parameters that a block can have. Use the Simulink `set_param` function to set this parameter to the attributes format that you want.

The attributes format can be any text that has embedded parameter names. An embedded parameter name is a parameter name preceded by `%<` and followed by `>`, for example, `%<priority>`. Simulink displays the attributes format text below the block icon, replacing each parameter name with the corresponding value. You can use line-feed characters (`\n`) to display each parameter on a separate line. For example, select a Gain block and enter this command at the MATLAB command prompt:

```
set_param(gcb, 'AttributesFormatString', 'pri=%<priority>\ngain=%<Gain>')
```

The Gain block displays this block annotation:

If a parameter value is not text or an integer, N/S (for not supported) appears in place of the value. If the parameter name is not valid, Simulink displays ??? in place of the value.

- “Assign Block Priorities” on page 36-45

Adjust Visual Presentation to Improve Model Readability

As you build a model, you can adjust block positions, change block and background color, adjust fonts, and add elements that help to improve model readability. These changes can help to organize the model visually and help others understand the model when you share it.

You can make these types of changes to improve model readability:

- Improve the model layout. See “Improve Model Layout” on page 36-8.
- Flip or rotate blocks or groups of blocks. These adjustments help blocks to fit in the model and connect with other blocks. See “Flip or Rotate Blocks” on page 36-9.
- Reposition or hide block names. See “Manage Block Names” on page 36-13.
- Add colors to blocks and to the background. See “Specify Model Colors” on page 36-14.
- Adjust aesthetics by changing fonts and deepening the intensity of drop shadows. See “Specify Fonts in Models” on page 36-15 and “Increase Drop Shadow Depth” on page 36-16.
- Surround groups of blocks with a box to show that the blocks are related. See “Box and Label Areas of a Model” on page 36-17.
- Copy formatting from a block, line, or area to another model element. See “Copy Formatting Between Model Elements” on page 36-18.
- Document a model using text, image, and math annotations. See “Describe Models Using Annotations” on page 4-5.
- Annotate a block. See “Set Block Annotation Properties” on page 36-4.
- Change the block icon, for example, display a graphic on the block. Use a mask to achieve this effect. A mask also enables you to design a custom interface for a block. To learn about masks, see “Masking Fundamentals” on page 39-2.

Improve Model Layout

To improve your diagram layout and appearance, select **Diagram > Arrange > Arrange Automatically**. This option:

- Aligns blocks in your model from left to right, starting with inputs and ending with outputs.

- Resizes blocks, such as the Constant block, to display long parameter values.
- Standardizes block size among similar blocks.
- Straightens signal lines by moving blocks.

Alternatively, you can try improving the shapes of signal lines. To try to improve the shape of a single line, select it and, from the action bar, select **Auto-route Line**. The line redraws if a better route between model elements is possible.

You can try to improve multiple lines using **Auto-route Lines**. To access **Auto-route Lines** from the action bar, select either a block or multiple model elements using a drag box.

Flip or Rotate Blocks

You can change the orientation of a block or a group of blocks by rotating in 90-degree increments or by flipping. Rotate or flip blocks to fit better in the model, for example, in feedback loops. You might also need to rotate so that inports align with outports or to make better use of the model canvas.

The figure shows a Gain block flipped to simplify a feedback loop diagram.

- To rotate or flip a block, select the block and select a command from the **Diagram > Rotate & Flip** menu. You can rotate clockwise (**Ctrl+R**) or counterclockwise.

With a single block selected, the **Flip Block** command flips the block based on the orientation of its ports. For example, if the ports are on the sides, the block flips left to right.

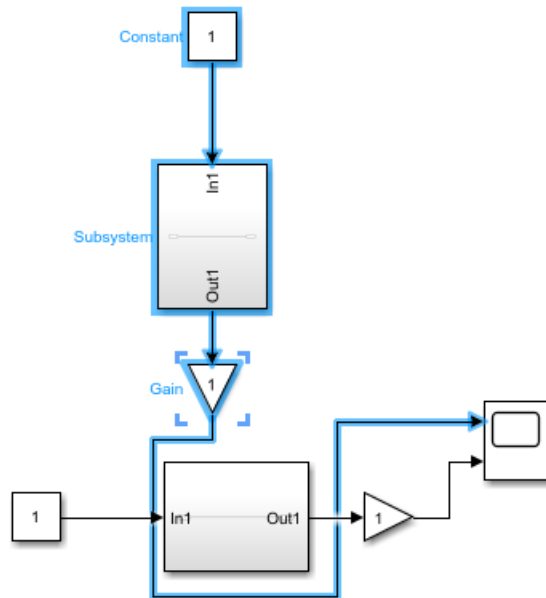

- Blocks rotate when you place them on a signal line that has an orientation other than left to right. For example, if the signal goes from bottom to top and you place a block on it, the block rotates with its ports up.
- To rotate or flip a group of blocks, select multiple blocks, and then select the rotate or flip command. The rotation or flip occurs as a group. The group of blocks flip only left to right when you flip blocks as a group.

After you rotate or flip a group of blocks, you can improve the readability of the model by editing the signal lines. The **Auto-route Line** command on the action bar might improve the appearance of signals. (For information on rotation with multiple ports, see “Port Location After Rotating or Flipping” on page 36-12.)

For example, suppose you rotate these selected blocks.

After you rotate the blocks and move them to fix overlapping, the model looks like this model.

In this case, select the line that connects the Gain block to the scope, and then select **Auto-route Line** to improve the shape of the signal line.

Port Location After Rotating or Flipping

Rotating moves block ports from the sides to top and bottom or the reverse, depending on the placement of the ports. The resulting positions of the block ports depend on the block port rotation type.

Rotating can reposition the ports on some blocks to maintain left-to-right or top-to-bottom port numbering order. A block whose ports are reordered after a rotation have the default port rotation type. This policy helps to maintain the left-right and top-down block diagram orientation convention used in control system modeling applications. Blocks by default use this rotation policy. The figure shows the effect of clockwise rotation on a block with the default port rotation policy.

A masked block can specify for ports to keep their order after rotation (see “Port rotation”). These blocks have a physical port rotation type. This policy helps when designing blocks to use in mechanical and hydraulic systems modeling and other applications where diagrams do not have a preferred orientation. The figure shows the effect of clockwise rotation on a block with a physical port rotation type.

Flipping a block moves the ports to the opposite side of the block, creating a mirror image, regardless of port rotation type.

Manage Block Names

You can manage block names by displaying or hiding them and by changing their location on the block.

Hide or Display Block Names

The Simulink Editor names blocks when you create them. The first occurrence of the block is the library block name, for example, Gain. The next occurrence is the block name with a number appended. Each new block increments the number, for example, Gain1, Gain2, and so on. These names are called automatic names. By default, the Editor hides these names.

You can choose whether to hide or display block names. You can:

- Display all the hidden automatic names. Select the **Display** menu, and clear the **Hide Automatic Names** check box.
- Temporarily display a hidden automatic block name by selecting the block.
- Name the block explicitly, for example, by its purpose in the model. The **Hide Automatic Names** setting does not affect blocks that you name explicitly. To name a block, select it, double-click the name, and type the new name.

In addition, you can explicitly hide or display any block name. Explicitly hidden or displayed blocks are not affected by the **Hide Automatic Names** setting. To explicitly

hide or display a block name, select the block, select **Diagram > Format > Show Block Name** and then select:

- **On** to always display the block name.
- **Off** to always hide the block name.
- **Auto** to return to the default state. If the block has an automatic name, **Hide Automatic Names** affects the block.

To display and hide block names programmatically, use `set_param` with the `'HideAutomaticNames'` option for models and the `'HideAutomaticName'` and `'ShowName'` options for blocks. For more information on these parameters, see “Model Parameters” and “Common Block Properties”. The table shows how these parameters interact.

'ShowName' (block setting)	'HideAutomaticName' (block setting)	'HideAutomaticNames' (model setting)	Result
'off'	Any	Any	Name is hidden
'on'	'on'	'on'	Name is hidden
'on'	'off'	Any	Name is shown
'on'	'on'	'off'	Name is shown

Move Block Names

By default, block names appear below blocks whose ports are on the sides and to the left on blocks whose ports are on the top and bottom. To change the location of a block name, you can:

- Drag the block name to the opposite side of the block.
- Select the block and then select **Diagram > Rotate & Flip > Flip Block Name**.

Specify Model Colors

You can specify the outline and interior colors of any block, and you can change the background color for any system in a model. You can also change text color and background color for annotations and fill color for areas.

This subsystem uses color to identify the inports.

slidemo_fuelsys ▶ fuel_rate_control ▶ fuel_calc ▶ switchable_compensation ▶

Loop Compensation and Filtering

- To change outline color on a block, text color in an annotation, or interior color for an area, select the element, and then select **Diagram > Format > Foreground Color**. Changing the foreground color of a block also changes the color of its output signals.
- To change interior color on a block or background color in an annotation, select the element, and then select **Diagram > Format > Background Color**.
- To change a background color in a system, open the system, and then select **Diagram > Format > Canvas Color**.

You can select a color from the menu or select **Custom** to open the color picker and define your own color.

You can also use the Property Inspector to change color for an area or an annotation. To specify colors programmatically, see “Specify Colors Programmatically” on page 1-22

Specify Fonts in Models

Change font family, style, and size for any model element to make your model easier to read or to comply with company standards. You can modify the font for selected blocks,

signal labels, areas, and annotations. Changing a block's font changes the font for the name and for text that appears on the block.

You can also change the default font for the model. The default font affects any elements whose font you have not changed and any new elements you create. If you want to use the same default font in all new models, change the default model font in your default template. See "Use Customized Settings When Creating New Models" on page 1-8.

- To change the font of a block, signal label, area, or annotation, select the element, and then select **Diagram > Format > Font Style for Selection**. Use the dialog box to specify the font information.
- To change the default font for the model, with no selection, select **Diagram > Format > Font Style for Model**. Use the dialog box to specify the font information.

You can also use the Property Inspector to change font for an area or an annotation.

Select Font Dialog Box on Linux Machines

On Linux machines configured for English, the **Font style** list in the Select Font dialog box can appear out of order and in another language in some fonts. If the characters in your **Font style** list appear in another language, set the LANG environment variable to `en_US.utf-8` before you start MATLAB. For example, at a Linux terminal, enter:

```
setenv LANG en_US.utf-8
matlab
```

Increase Drop Shadow Depth

By default, blocks have a drop shadow. To make the block stand out more against the background, you can increase the depth of the drop shadow.

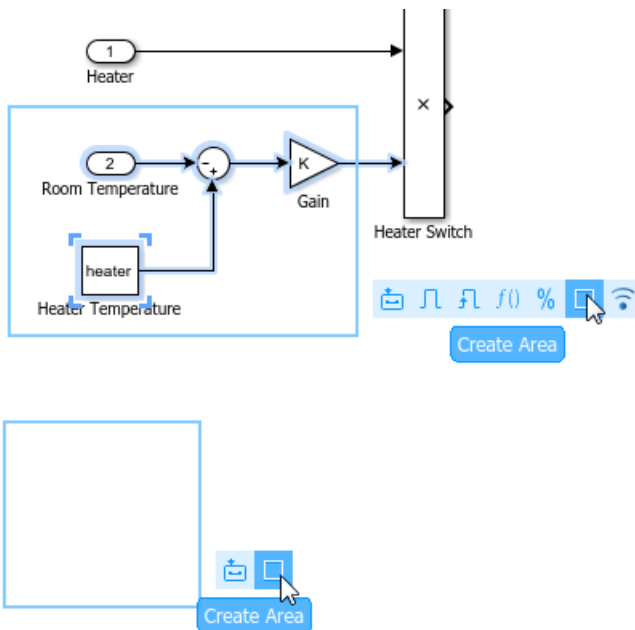

Select the blocks whose drop shadow depth you want to increase, and then select **Diagram > Format > Shadow**.

Tip To remove the default drop shadow for all blocks, select the Simulink Editor preference **Use classic diagram theme**.

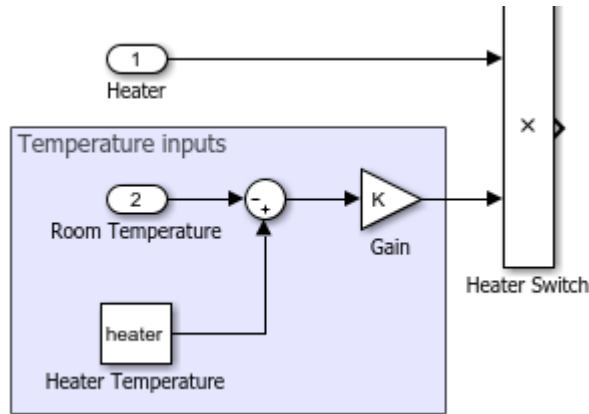

Box and Label Areas of a Model

Add an area to your model to visually group related model elements in a box. An area can move with the blocks it surrounds. You can add text to an area to briefly describe or label the area.

- 1 Drag a box around the area of interest in the model. Or, drag on a blank area of the canvas to draw the area shape.
- 2 From the action bar, select **Create Area**.

- 3 Type the name of the area. The name appears in the upper-left corner of the area.

To enter the name later, select the area, click the **?**, and start typing, or use the **Name** property in the Property Inspector.

- 4 Optionally, add a description of the area contents using the Property Inspector.
- 5 To move the area and its contents, drag the area near the border.

Tip To move an area without moving its contents, hold **Alt** (**option** on a Mac) and drag.

Convert Area to a Subsystem

An area is similar to a subsystem in that it is a way to group related blocks. However, a subsystem creates a hierarchy, replacing multiple blocks in a model with a single block. You can initially group related blocks in an area and later decide to put those blocks in a subsystem by converting the area. The resulting subsystem has the same name, blocks, description, and requirements traceability information as the area.

To convert an area to a subsystem, right-click the area and select **Create Subsystem from Area**.

Copy Formatting Between Model Elements

If you have applied formatting to a block, signal line, or area in a model, you can copy the formatting and apply it to another model element. Examples of formatting include font changes, foreground and background color, and drop shadow effects.

- 1 Select the block, line, or area whose formatting you want to copy.
- 2 From the ellipsis menu, select **Copy Formatting**. The cursor becomes a paintbrush.

- 3 Using the paintbrush, click each element that you want to copy the formatting to.
- 4 To cancel the paintbrush cursor, click a blank spot on the canvas or press **Esc**.

Display Port Values for Debugging

In this section...

“Display Port Values for Easy Debugging” on page 36-20

“Display Value for a Specific Port” on page 36-24

“Display Port Values for a Model” on page 36-27

“Port Value Display Limitations” on page 36-28

Display Port Values for Easy Debugging

For many blocks whose signals carry data, Simulink can display signal values (block output) as port value labels (similar to tool tips) on the block diagram during and after a simulation. Port value labels display block output values when Simulink runs block output methods. This model shows a port value label for the port on the Fcn block, an output value of -3.03 .

If the port value label appears empty, this means that no port value is currently available. For example, toggling a port value label on a continuous block when paused during simulation does not display any values in the label.

Port value labels are also empty when you have not yet simulated the model. This is because the block output methods do not run when the model does not simulate.

If you toggle or hover on a block that Simulink optimizes out of a simulation (such as a virtual subsystem block), while you simulate, the model displays the text `optimized`.

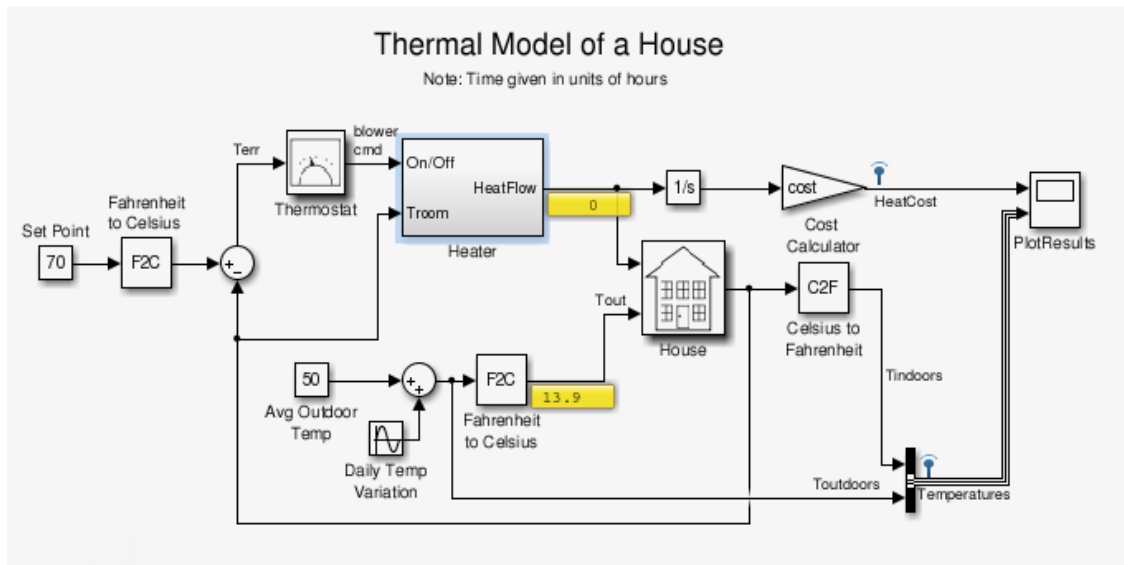

Displaying port value data tips can help during interactive debugging of a model. For example, the figure shows the output of a thermal model for a house.

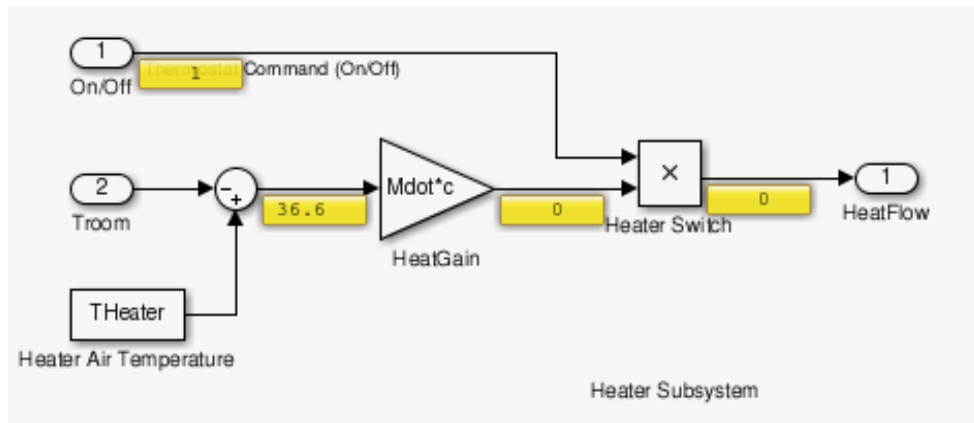

These results suggest a problem with the model because:

- The heating cost is 0 at all temperatures.
- The temperature inside the house matches ambient temperature almost exactly.

In such cases, debugging the blocks in the model interactively can help isolate the error. Port value labels provide information at the output of every block in the model. So in this example, if you step forward using Simulation Stepper, you can see that the output of the Heater subsystem is 0 at every time step.

To learn more, you can enable port value labels for blocks inside the Heater subsystem. Using Simulation Stepper, if you step forward again to display the values, you can see that there is an issue with the HeatGain block. The output is constant at 0.

This technique helps you isolate the issue.

To simplify debugging, you can turn on and off port value labels during simulation. Besides providing useful information for debugging, port value displays can help you

monitor a signal value during simulation. However, these labels are not saved with a model.

For nonnumeric data display, Simulink uses these values:

Message	Explanation
action	The signal executes action subsystems.
fcn-call	The signal is a function-call signal, e.g., Function Call Generator output.
ground	The signal is coming from a Ground block.
not a data signal	The signal does not contain valid data, e.g., the signal is from a block that is commented out.

In some cases:

- The port value display may not be able to acquire the value signal or
- The signal's value cannot be easily displayed

In such cases, Simulink uses these values.

Message	Explanation
...	The signal dimension exceeds the maximum number of elements Simulink can display. For more information, see "Display Port Values for a Model" on page 36-27.
(no message)	The simulation data available is insufficient. Step forward or press play to obtain more data.
click to add signals	You have enabled a port value label on a bus. However, you have not selected a signal to display. Click the label to select bus signals.
inaccessible	Simulink cannot obtain the port value. For an example, see "Signal Storage Reuse" on page 36-28.
[m*n]	This is a nonvector signal. Simulink cannot display the actual values of the matrix. It displays the matrix dimension instead.

Message	Explanation
no data yet	This message appears when: <ul style="list-style-type: none"> • The simulation data is not available. Start the simulation to see values. • If the model contains subsystems (for example, an enabled subsystem) and model references and they are not executed during a simulation.
not used	Simulink cannot obtain the signal value due to optimization.
removed	Simulink cannot obtain the signal value due to block reduction.
optimized	Simulink cannot obtain the signal value due to optimization. In Normal mode, this message appears for blocks with Conditional input branch execution enabled. For more information, see “Conditionally Executed Subsystems Overview” on page 10-3.
unavailable	The simulation data available is insufficient. For example, see “Simulation Stepper” on page 36-29.

Note You can force a value label to display the signal value by designating the signal as a test point. Use the **Properties** dialog box to do this.

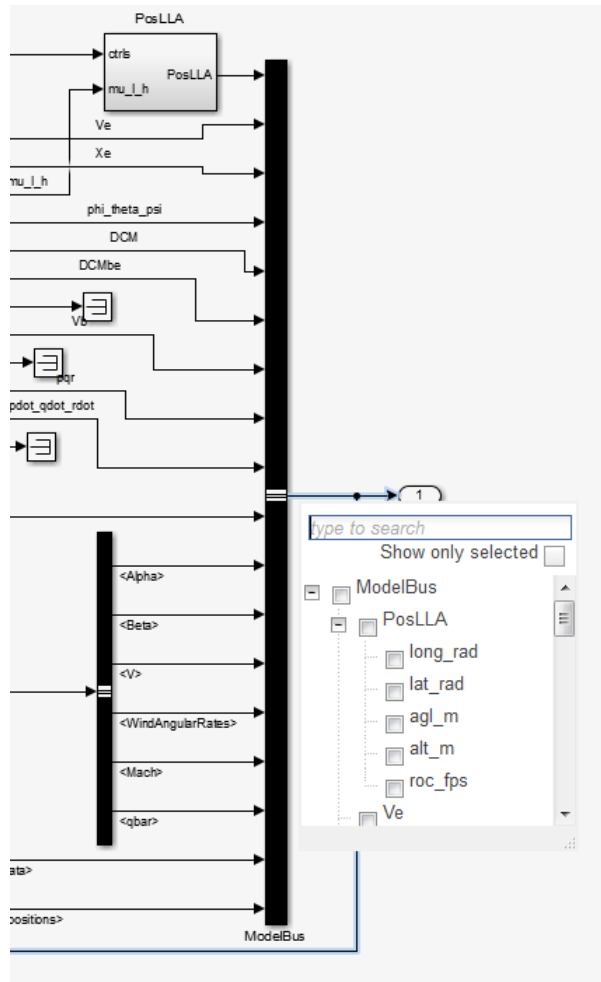

Display Value for a Specific Port

To display the value of a specific port or port values for a block before simulation, select one or more signals, right-click the selection, and select **Show Value Label of Selected Port**.

By default, Simulink displays the value of a signal when you click on it during simulation. You can control this behavior in **Display > Data Display in Simulation > Options > Display values > Enable by default during simulation**.

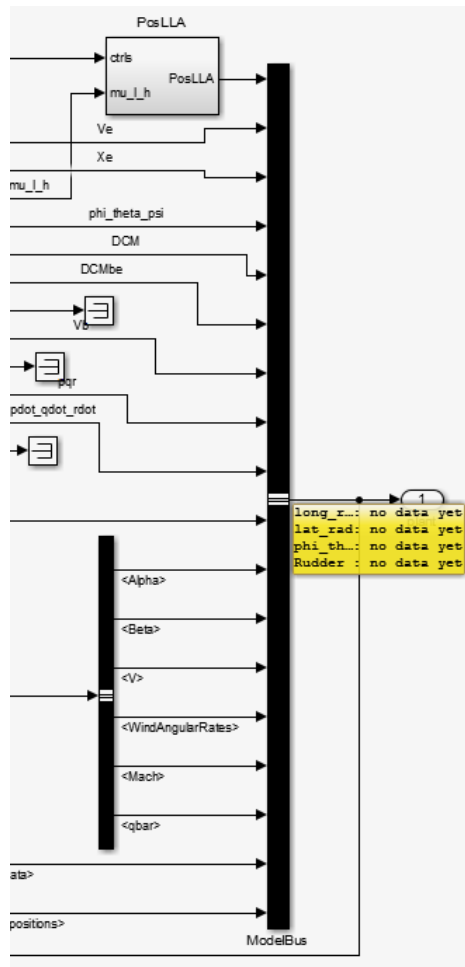

Note To remove all data tips, select **Display > Data Display in Simulation > Remove All Value Labels**.

For bus signals, the **Show Value Label of Selected Port** option opens a dialog box where you can select from all signals in the bus. For example, in this model, you can see the dialog box for all signals that are contained in ModelBus.

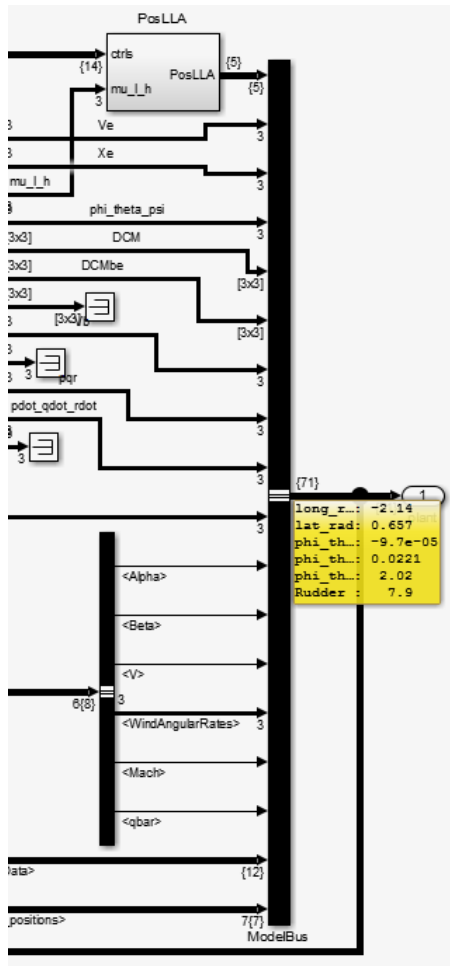

You can search for a signal by name or filter through the hierarchy. Select a parent signal to include all of the signals it contains. You can also filter the display to view only those signals you have selected.

Click anywhere outside the dialog box to close it. The port value label appears. The label has no data; it displays values when you simulate the model.

When you simulate the model, the port value label displays the names and values of the signals you chose. To change the signals to display, click on the port value label to reopen the dialog. You can also click on another signal to display its value.

Note Simulink does not save the values of a signal when you remove the port value label.

Display Port Values for a Model

Specify port value display formatting and the frequency of updates. The Value Label Display Options dialog box controls these settings on the entire model.

- 1 In the model whose port values you want to display, select **Display > Data Display in Simulation > Options**.
- 2 In the Value Label Display Options dialog box, specify your preferences for:
 - The display options, including font size, the refresh frequency, and the number of elements displayed for vector signals with signal widths greater than 1
 - The display mode
 - Floating-point or fixed-point format

Port Value Display Limitations

Performance

Enabling the hovering option for a model or setting at least one block to **Toggle Value Labels When Clicked** slows down simulation.

Accelerated Modes

Port values work in Normal and Accelerator modes only. They do not work in Rapid Accelerator and External modes. The table shows how accelerator modes affect the display of port values.

Accelerated Mode	Port Values
Accelerator	<ul style="list-style-type: none"> • Signals not optimized in Accelerator mode display port values as in Normal mode. Signals optimized in Accelerator mode display port values as optimized. For more information, see “Display Port Values for Easy Debugging” on page 36-20. • Model reference blocks simulated in Accelerator mode do not get their port value displays updated.
Rapid Accelerator	Incompatible. The limitation exists whether the model or its parent specifies accelerated simulation. For more information, see “Accelerate, Refine, and Test Hybrid Dynamic System on Host Computer by Using RSim System Target File” (Simulink Coder).

Signal Storage Reuse

If the output port buffer of a block is shared with another block through the optimization of signal storage reuse, the port value displays as *inaccessible*. You can disable signal

storage reuse using the **Signal storage reuse** check box. However, disabling signal storage reuse increases the memory used during simulation.

Signal Data Types

- Simulink displays the port value for ports connected to most kinds of signals, including signals with built-in data types (such as `double`, `int32`, or `Boolean`), `DYNAMICALLY_TYPED`, and several other data types.
- Simulink shows the floating format for only noncomplex signal value displays.
- Simulink displays the port value of fixed point data types based on the converted double value.
- Simulink does not display data for signals with some composite data types, such as bus signals.

Subsystems

- You cannot display port values for subsystems contained in a variant subsystem when there are no signal lines connecting to them. In such cases, during simulation, Simulink automatically determines block connectivity based on the active variant. However, you can display port values within the subsystems contained in the variant subsystem. You can also display values on signal lines outside of the variant subsystem.
- When you disable a conditionally executed subsystem, the port value display for a signal that goes into an Output block displays the value of the Output block, depending on the **Output when disabled** setting.
- Simulink does not display data for the ports of an enabled subsystem that is not enabled.

Simulation Stepper

If you do not enable port value display when stepping forward, the display will not be available when stepping back. When stepping back, if the port value is unavailable, the `unavailable` label is displayed.

Refine Factor

Port value displays do not honor refine factor values (**Configuration Parameters > Data Import/Export > Additional parameters > Refine factor**) because Simulink updates port value displays only during major time steps.

Signal Specification Block and Inport Block

When you display port values on Signal Specification and Inport blocks in a subsystem, the value that is driving the blocks displays instead of the block values.

Command-Line Simulations

For efficiency, Simulink does not support port value displays during a command-line simulation using the `sim` command.

Merge Block

Simulink does not display the input values to the merge block. To see this value, refer to the source block.

Command Line Interface

You cannot specify port value displays through the command line interface.

Non-Simulink signals

You cannot place port values on non-Simulink signals, such as Simscape or SimEvents signals. This limitation applies to conditional breakpoints as well.

Control and Display the Sorted Order

In this section...

“What Is Sorted Order?” on page 36-31
“Display the Sorted Order” on page 36-31
“Sorted Order Notation” on page 36-32
“How Simulink Determines the Sorted Order” on page 36-42
“Assign Block Priorities” on page 36-45
“Rules for Block Priorities” on page 36-45
“Block Priority Violations” on page 36-48

What Is Sorted Order?

During the updating phase of simulation, Simulink determines the order in which to invoke the block methods during simulation. This block invocation ordering is the *sorted order*.

You cannot set this order, but you can assign priorities to nonvirtual blocks to indicate to Simulink their execution order relative to other blocks. Simulink tries to honor block priority settings, unless there is a conflict with data dependencies. To confirm the results of priorities that you have set, or to debug your model, display and review the sorted order of your nonvirtual blocks and subsystems.

Note For more information about block methods and execution, see:

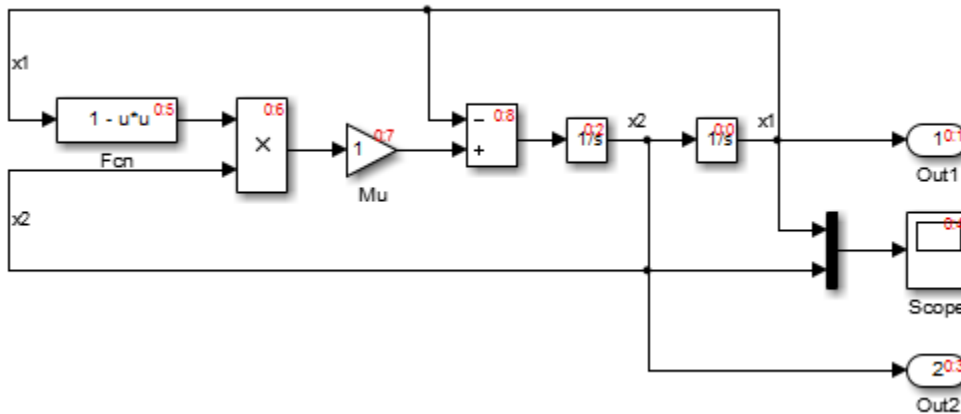

- “Block Methods” on page 3-15
 - “Conditionally Executed Subsystems Overview” on page 10-3
-

Display the Sorted Order

To display the sorted order of the vdp model:

- 1 Open the van der Pol equation model:
vdp

2 In the model window, select **Display > Blocks > Sorted Execution Order**.

Simulink displays a notation in the top-right corner of each nonvirtual block and each nonvirtual subsystem. These numbers indicate the order in which the blocks execute. The first block to execute has a sorted order of 0.

For example, in the van der Pol equation model, the Integrator block with the sorted order 0:0 executes first. The Out1 block, with the sorted order 0:1, executes second. Similarly, the remaining blocks execute in numeric order from 0:2 to 0:8.

You can save the sorted order setting with your model. To display the sorted order when you reopen the model, select **Simulation > Update diagram**.

Sorted Order Notation

The sorted order notation varies depending on the type of block. The following table summarizes the different formats of sorted order notation. Each format is described in detail in the sections that follows the table.

Block Type	Sorted Order Notation	Description
“Nonvirtual Blocks” on page 36-36	$s : b$	<ul style="list-style-type: none"> s is the system index of the model or subsystem the block resides in. For root-level models, s is always 0.

Block Type	Sorted Order Notation	Description
	$s:b \{x, y\}$	<ul style="list-style-type: none"> b specifies the block position within the sorted order for the designated execution context. x, y are the system indices of the subsystems whose execution is controlled by this block.
“Nonvirtual Subsystems” on page 36-36 (not including function-call and action subsystems)	$s:b$	<ul style="list-style-type: none"> s is the system index of the model or subsystem. b specifies the block position within the sorted order for the designated execution context.
“Virtual Blocks and Subsystems” on page 36-38	Not applicable	Virtual blocks do not execute.
Action Subsystems	$s:b'$	<ul style="list-style-type: none"> s is the system index of the model or subsystem the block resides in. For root-level models, s is always \emptyset. b' is the block index of the action block (but not of the action subsystem).
“Function-Call Subsystems” on page 36-39 and Function-Call models	One non-grounded initiator: $s:b^i$	<ul style="list-style-type: none"> s is the system index of the model or subsystem the block resides in. For root-level models, s is always \emptyset. b^i is the block index of the root initiator in the subsystem’s hierarchy.
	Two or more initiators: <ul style="list-style-type: none"> $s:b^{i1}, s:b^{i2}, \dots, s:b^{in}$ where n is the number of non-grounded initiators. 	<ul style="list-style-type: none"> s is the system index of the model or subsystem the block resides in. For root-level models, s is always \emptyset. b^{i_n} is the block index of the n-th root initiator in the subsystem’s hierarchy.

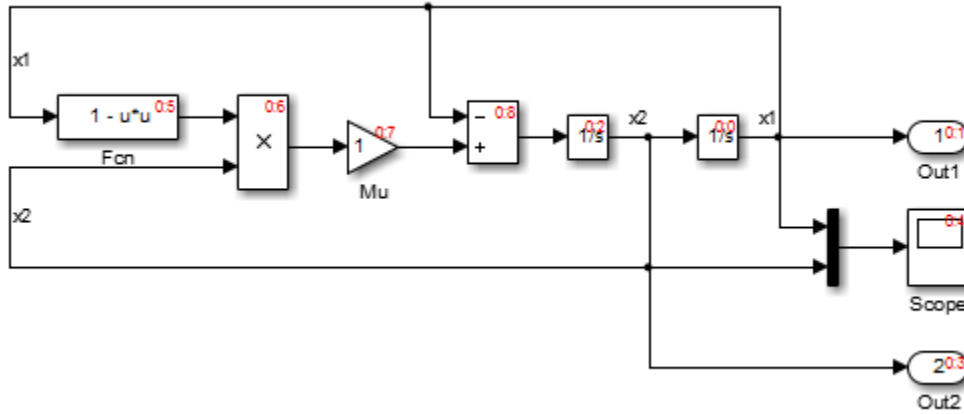

Block Type	Sorted Order Notation	Description
	Initiators are either Ground blocks or are unconnected: <ul style="list-style-type: none"> • $s : G$ 	<ul style="list-style-type: none"> • s is the system index of the model or subsystem the block resides in. For root-level models, s is always \emptyset. • G indicates that all function-call initiators are grounded.
“Branched Function-Call Signals” on page 36-41	$s : b^i [B_k]$	<ul style="list-style-type: none"> • s is the system index of the model or subsystem the block resides in. For root-level models, s is always \emptyset. • b^i is the block index of the root initiator in the subsystem’s hierarchy. • B_k indicates that it is a branched function-call subsystem with branch index k.
Function-Call Feedback Latch Blocks	$s : b^i [B_m]$	<ul style="list-style-type: none"> • s is the system index of the model or subsystem the block resides in. For root-level models, s is always \emptyset. • b^i is the block index of the root initiator in the subsystem’s hierarchy. • B_m indicates that it is a branched subsystem with branch index m.
Blocks in a model with asynchronous function-call inputs	Function-call root-level Inport and Outport blocks: F_i	<ul style="list-style-type: none"> • F indicates that it is executed in a function-call context. • i is the function-call index.
	Root-level data Inport blocks: If they drive a function-call subsystem, it is the function-call index of the subsystem. If they are part of the model that is not driven by asynchronous function-call inputs, then no function-call index is displayed.	

Block Type	Sorted Order Notation	Description
	Root-level function-call blocks: F_i Root-level branched function-call blocks: $F_i[B_k]$	<ul style="list-style-type: none"> F indicates that it is executed in a function-call context. i is the function-call index.
Blocks inside Export Function Models (See “Execution Order for Root-Level Function-Call Inport Blocks” on page 10-125)	Function-call root-level Inport and Output blocks: F_i	<ul style="list-style-type: none"> F indicates that it is a function-call block. i is the execution order for the function-call root-level Inport or Output block in normal simulation mode.
	Root-level function-call subsystems: F_i Root-level branched function-call subsystems: $F_i[B_k]$	<ul style="list-style-type: none"> F indicates that it is a function-call block. i is the execution order for the function-call root-level Inport block in normal simulation mode. B_k indicates a branched function-call subsystem with index k.
	Merge and Data Store Memory blocks: F_i, F_j, \dots	<ul style="list-style-type: none"> F indicates that it is a function-call block. i is the block execution index.
	Root-level data Inport and Output blocks: Same execution order as the function-call subsystems they are connected to.	
“Bus-Capable Blocks” on page 36-42	$s : B$	<ul style="list-style-type: none"> s is the system index of the model or subsystem the block resides in. For root-level models, s is always \emptyset. B indicates a bus-capable block.

- “Nonvirtual Blocks” on page 36-36
- “Nonvirtual Subsystems” on page 36-36
- “Virtual Blocks and Subsystems” on page 36-38
- “Function-Call Subsystems” on page 36-39
- “Branched Function-Call Signals” on page 36-41
- “Bus-Capable Blocks” on page 36-42

Nonvirtual Blocks

In the van der Pol equation model, all the nonvirtual blocks in the model have a sorted order. The system index for the top-level model is 0, and the block execution order ranges from 0 to 8.

Nonvirtual Subsystems

The following model contains an atomic, nonvirtual subsystem named Discrete Cruise Controller.

When you enable the sorted order display for the root-level system, Simulink displays the sorted order of the blocks.

The Scope block in this model has the lowest sorted order, but its input depends on the output of the Car Dynamics subsystem. The Car Dynamics subsystem is virtual, so it does not have a sorted order and does not execute as an atomic unit. However, the blocks

within the subsystem execute at the root level, so the Integrator block in the Car Dynamics subsystem executes first. The Integrator block sends its output to the Scope block in the root-level model, which executes second.

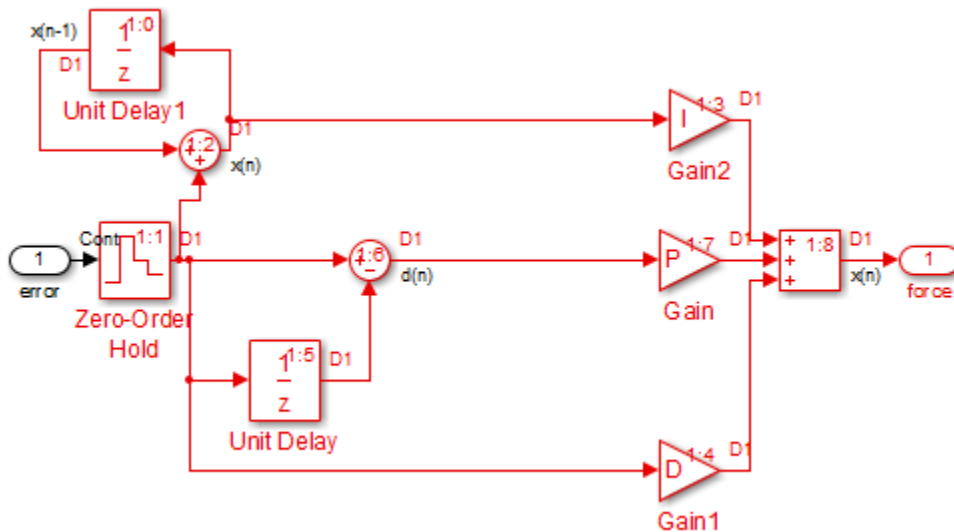

The Discrete Cruise Controller subsystem has a sorted order of $0:5$:

- 0 indicates that this atomic subsystem is part of the root level of the hierarchical system comprised of the primary system and the two subsystems.
- 5 indicates that the atomic subsystem is the sixth block that Simulink executes relative to the blocks within the root level.

The sorted order of each block inside the Discrete Cruise Controller subsystem has the form $1:b$, where:

- 1 is the system index for that subsystem.
- b is the block position in the execution order. In the Discrete Cruise Controller subsystem, the sorted order ranges from 0 to 8 .

Note Depending on your model configuration, Simulink can insert hidden, nonvirtual subsystems in your model. As a result, the visible blocks inside the hidden subsystem block can have a system index that is different from the current system index. For example, if you select **Conditional input branch execution**, Simulink creates hidden, nonvirtual subsystems, which can affect the sorted execution order.

Virtual Blocks and Subsystems

Virtual blocks, such as the Mux block, exist only graphically and do not execute. Consequently, they are not part of the sorted order and do not display any sorted order notation.

Virtual subsystems do not execute as a unit, and like a virtual block, are not part of the sorted order. The blocks inside the virtual subsystem are part of the root-level system sorted order, and therefore share the system index.

In the model in “Nonvirtual Subsystems” on page 36-36, the virtual subsystem Car Dynamics does not have a sorted order. However, the blocks inside the subsystem have a sorted order in the execution context of the root-level model. The blocks have the same system index as the root-level model. The Integrator block inside the Car Dynamics

subsystem has a sorted order of $0:0$, indicating that the Integrator block is the first block executed in the context of the top-level model.

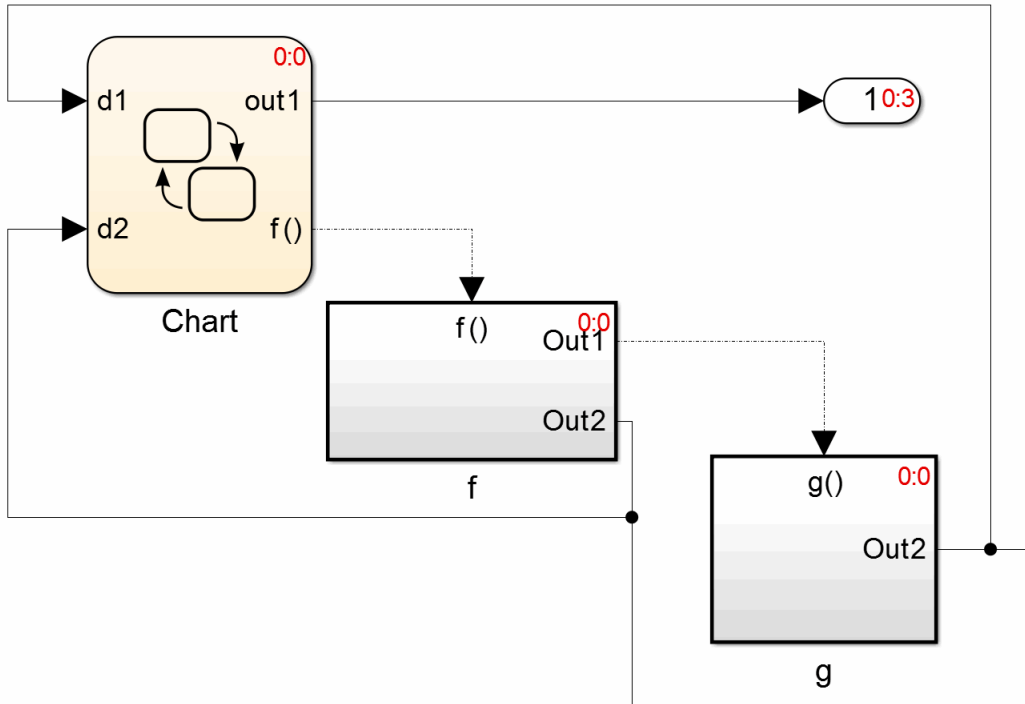

Function-Call Subsystems

Single Initiator

A function-call subsystem (or model) executes when the initiator invokes the function-call subsystem (or model) and, therefore, does not have a sorted order independent of its initiator. Specifically, for a subsystem that connects to one initiator, Simulink uses the notation $s:b^i$, where s is the index of the system that contains the initiator and b^i is the block index of the root initiator in the subsystems hierarchy.

For example, the sorted order for the subsystems f and g is $0:0$, since the sorted order of their root initiator, Chart, is $0:0$.

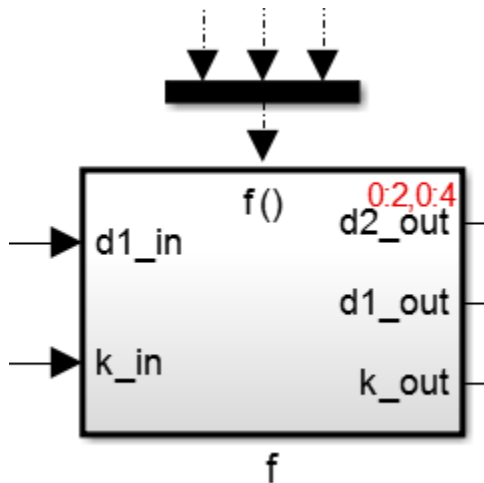

Multiple Initiators

For a function-call subsystem that connects to more than one initiator, the sorted order notation is $s:b^{i_1}, s:b^{i_2}, \dots, s:b^{i_n}$ where n is the number of non-grounded initiators, s is the system index of the model or subsystem the block resides in, and b^{i_n} is the block index of the n -th root initiator in the subsystem's hierarchy.

For example, open the `sl_subsys_fcncall6` model. The `f` subsystem has three initiators from the same level in the subsystem's hierarchy. Two are from the Stateflow chart, `Chart1`, and one from the Stateflow chart, `Chart`.

Because `Chart1` has a sorted order `0:2` and `Chart` has a sorted order of `0:4`, the function-call subsystem `f` has a sorted order notation of `0:2, 0:4`.

Branched Function-Call Signals

When a function-call initiator is branched using a Function-Call Split block, Simulink displays the order in which subsystems or models that are connect to the branches execute. Simulink uses the notation $s : b^i [B_k]$ to indicate this order. s is the system index of the subsystem or model the block resides in, b^i is the block index of the root initiator in the subsystem hierarchy, and B_k indicates that it is a branched function-call subsystem with branch index k .

In the following example, the sorted order indicates subsystem f with branch index 0 executes before the subsystem g with branch index 1 .

Bus-Capable Blocks

A bus-capable block with a virtual bus input does not execute as a unit and therefore does not have a unique sorted order. Such a block displays its sorted order as $s : B$ where B stands for bus.

For example, the sorted order for this Unit Delay block with a virtual bus input is $0 : B$.

For a list of bus-capable blocks, see “Bus-Capable Blocks” on page 68-49.

How Simulink Determines the Sorted Order

Direct-Feedthrough Ports Impact on Sorted Order

To ensure that the sorted order reflects data dependencies among blocks, Simulink categorizes block input ports according to the dependency of the block outputs on the block input ports. An input port whose current value determines the current value of one of the block outputs is a *direct-feedthrough* port. Examples of blocks that have direct-feedthrough ports include:

- Gain
- Product
- Sum

Examples of blocks that have non-direct-feedthrough inputs:

- Integrator — Output is a function of its state.
- Constant — Does not have an input.
- Memory — Output depends on its input from the previous time step.

Rules for Sorting Blocks

To sort blocks, Simulink uses the following rules:

- If a block drives the direct-feedthrough port of another block, the block must appear in the sorted order ahead of the block that it drives.

This rule ensures that the direct-feedthrough inputs to blocks are valid when Simulink invokes block methods that require current inputs.

- Blocks that do not have direct-feedthrough inputs can appear anywhere in the sorted order as long as they precede any direct-feedthrough blocks that they drive.

Placing all blocks that do not have direct-feedthrough ports at the beginning of the sorted order satisfies this rule. This arrangement allows Simulink to ignore these blocks during the sorting process.

Applying these rules results in the sorted order. Blocks without direct-feedthrough ports appear at the beginning of the list in no particular order. These blocks are followed by blocks with direct-feedthrough ports arranged such that they can supply valid inputs to the blocks which they drive.

The following model, from “Nonvirtual Subsystems” on page 36-36, illustrates this result. The following blocks do not have direct-feedthrough and therefore appear at the beginning of the sorted order of the root-level system:

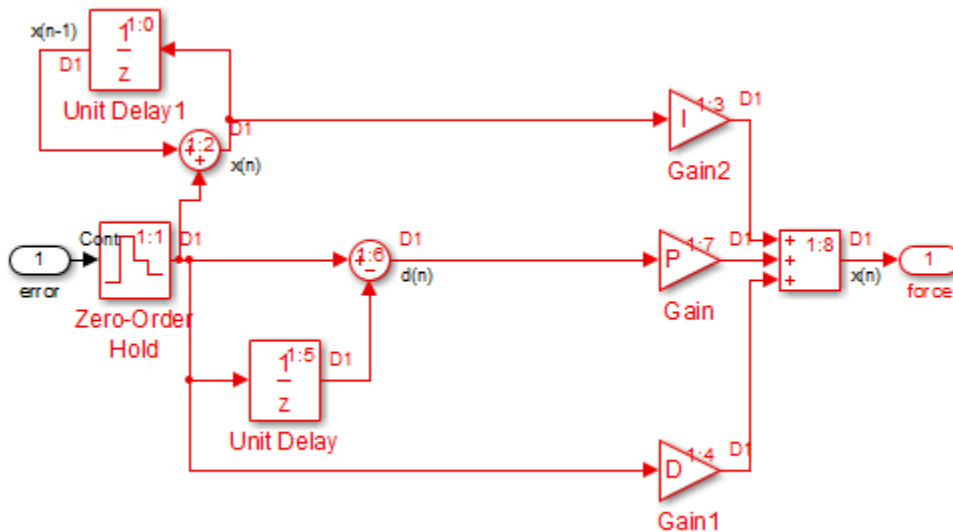

- Integrator block in the Car Dynamics virtual subsystem

- Speed block in the root-level model

Inside the Discrete Cruise Controller subsystem, all the Gain blocks, which have direct-feedthrough ports, run before the Sum block that they drive.

Assign Block Priorities

You can assign a priority to a nonvirtual block or to an entire subsystem. Higher priority blocks appear before lower priority blocks in the sorted order. The lower the number, the higher the priority. Set the block priority in the **General** tab of the Block Properties dialog.

Rules for Block Priorities

Simulink honors the block priorities that you specify unless they violate data dependencies. (“Block Priority Violations” on page 36-48 describes situations that cause block property violations.)

In assessing priority assignments, Simulink attempts to create a sorted order such that the priorities for the individual blocks within the root-level system or within a nonvirtual subsystem are honored relative to one another.

Three rules pertain to priorities:

- “Priorities Are Relative” on page 36-46

- “Priorities Are Hierarchical” on page 36-47
- “Lack of Priority May Not Result in Low Priority” on page 36-48

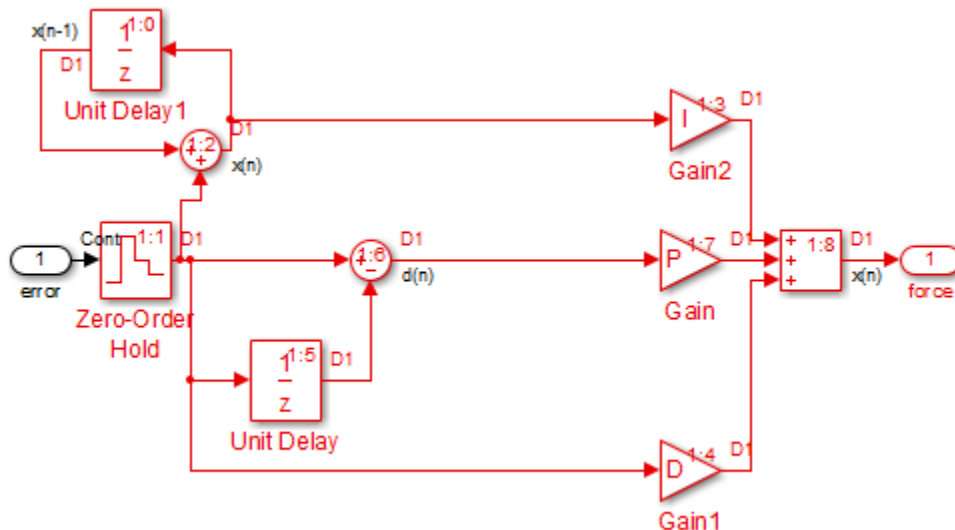

Priorities Are Relative

Priorities are relative; the priority of a block is relative to the priority of the blocks within the same system or subsystem.

For example, suppose you set the following priorities in the Discrete Cruise Controller subsystem in the model in “Nonvirtual Subsystems” on page 36-36.

Block	Priority
Gain	3
Gain1	2
Gain2	1

After updating the diagram, the sorted order for the Gain blocks is as follows.

The sorted order values of the Gain, Gain1, and Gain2 blocks reflect the respective priorities assigned: Gain2 has highest priority and executes before Gain1 and Gain; Gain1

has second priority and executes after Gain2; and Gain executes after Gain1. Simulink takes into account the assigned priorities relative to the other blocks in that subsystem.

The Gain blocks are not the first, second, and third blocks to execute. Nor do they have consecutive sorted orders. The sorted order values do not necessarily correspond to the priority values. Simulink arranges the blocks so that their priorities are honored relative to each other.

Priorities Are Hierarchical

In the Car Dynamics virtual subsystem, suppose you set the priorities of the Gain blocks as follows.

Block	Priority
Gain	2
Gain1	1

After updating the diagram, the sorted order for the Gain blocks is as illustrated. With these priorities, Gain1 always executes before Gain.

You can set a priority of 1 to one block in each of the two subsystems because of the hierarchical nature of the subsystems within a model. Simulink never compares the priorities of the blocks in one subsystem to the priorities of blocks in any other subsystem.

For example, consider this model again.

The blocks within the Car Dynamics virtual subsystem are part of the root-level system hierarchy and are part of the root-level sorted order. The Discrete Cruise Controller subsystem has an independent sorted order with the blocks arranged consecutively from 1:0 to 1:7.

Lack of Priority May Not Result in Low Priority

A lack of priority does not necessarily result in a low priority (higher sorting order) for a given block. Blocks that do not have direct-feedthrough ports execute before blocks that have direct-feedthrough ports, regardless of their priority.

If a model has two atomic subsystems, A and B, you can assign priorities of 1 and 2 respectively to A and B. This priority causes all the blocks in A to execute before any of the blocks in B. The blocks within an atomic subsystem execute as a single unit, so the subsystem has its own system index and its own sorted order.

Block Priority Violations

Simulink software honors the block priorities that you specify unless they violate data dependencies. If Simulink is unable to honor a block priority, it displays a Block Priority Violation diagnostic message.

As an example:

- 1 Open the `sldemo_bounce` model.

Notice that the output of the Memory block provides the input to the Coefficient of Restitution Gain block.

- 2 Set the priority of the Coefficient of Restitution block to 1, and set the priority of the Memory block to 2.

Setting these priorities specifies that the Coefficient of Restitution block execute before the Memory block. However, the Coefficient of Restitution block depends on the output of the Memory block, so the priorities you just set violate the data dependencies.

- 3 In the model window, enable sorted order by selecting **Format > Block displays > Sorted Order**.
- 4 Select **Simulation > Update Diagram**.

The block priority violation warning appears in the **Diagnostic Viewer**. To open the **Diagnostic Viewer** window, click **View > Diagnostic Viewer**. The warning includes the priority for the respective blocks:

```
Warning: Unable to honor user-specified priorities.  
'sldemo_bounce/Memory' (pri=[2]) has to execute  
before 'sldemo_bounce/Coefficient of Restitution'  
(pri=[1]) to satisfy data dependencies
```

- 5 Remove the priorities from the Coefficient of Restitution and Memory blocks and update the diagram again to see the correct sorted order.

Access Block Data During Simulation

In this section...

“About Block Run-Time Objects” on page 36-50

“Access a Run-Time Object” on page 36-50

“Listen for Method Execution Events” on page 36-51

“Synchronizing Run-Time Objects and Simulink Execution” on page 36-52

About Block Run-Time Objects

Simulink provides an application programming interface, called the block run-time interface, that enables programmatic access to block data, such as block inputs and outputs, parameters, states, and work vectors, while a simulation is running. You can use this interface to access block run-time data from the MATLAB command line, the Simulink Debugger, and from Level-2 MATLAB S-functions (see “Write Level-2 MATLAB S-Functions” in the online Simulink documentation).

Note You can use this interface even when the model is paused or is running or paused in the debugger.

The block run-time interface consists of a set of Simulink data object classes (see “Data Objects” on page 62-75) whose instances provide data about the blocks in a running model. In particular, the interface associates an instance of `Simulink.RunTimeBlock`, called the block's run-time object, with each nonvirtual block in the running model. A run-time object's methods and properties provide access to run-time data about the block's I/O ports, parameters, sample times, and states.

Access a Run-Time Object

Every nonvirtual block in a running model has a `RuntimeObject` parameter whose value, while the simulation is running, is a handle for the blocks' run-time object. This allows you to use `get_param` to obtain a block's run-time object. For example, the following statement

```
rto = get_param(gcb, 'RuntimeObject');
```

returns the run-time object of the currently selected block. Run-time object data is read-only. You cannot use run-time objects to change a block's parameters, input, output, and state data.

Note Virtual blocks (see “Nonvirtual and Virtual Blocks” on page 36-2) do not have run-time objects. Blocks eliminated during model compilation as an optimization also do not have run-time objects (see “Block reduction”). A run-time object exists only while the model containing the block is running or paused. If the model is stopped, `get_param` returns an empty handle. When you stop a model, all existing handles for run-time objects become empty.

Listen for Method Execution Events

One application for the block run-time API is to collect diagnostic data at key points during simulation, such as the value of block states before or after blocks compute their outputs or derivatives. The block run-time API provides an event-listener mechanism that facilitates such applications. For more information, see the documentation for the `add_exec_event_listener` command. For an example of using method execution events, enter

```
sldemo_msfcn_lms
```

at the MATLAB command line. This Simulink model contains the S-function `adapt_lms.m`, which performs a system identification to determine the coefficients of an FIR filter. The S-function's `PostPropagationSetup` method initializes the block run-time object's `DWork` vector such that the second vector stores the filter coefficients calculated at each time step.

In the Simulink model, double-clicking on the annotation below the S-function block executes its `OpenFcn`. This function first opens a figure for plotting the FIR filter coefficients. It then executes the function `add_adapt_coef_plot.m` to add a `PostOutputs` method execution event to the S-function's block run-time object using the following lines of code.

```
% Add a callback for PostOutputs event
blk = 'sldemo_msfcn_lms/LMS Adaptive';

h    = add_exec_event_listener(blk, ...
    'PostOutputs', @plot_adapt_coefs);
```

The function `plot_adapt_coefs.m` is registered as an event listener that is executed after every call to the S-function's `Outputs` method. The function accesses the block run-time object's `DWork` vector and plots the filter coefficients calculated in the `Outputs` method. The calling syntax used in `plot_adapt_coefs.m` follows the standard needed for any listener. The first input argument is the S-function's block run-time object, and the second argument is a structure of event data, as shown below.

```
function plot_adapt_coefs(block, ei) %#ok<INUSD>
%
% Callback function for plotting the current adaptive filtering
% coefficients.

stemPlot = get_param(block.BlockHandle, 'UserData');

est = block.Dwork(2).Data;
set(stemPlot(2), 'YData', est);
drawnow('expose');
```

Synchronizing Run-Time Objects and Simulink Execution

You can use run-time objects to obtain the value of a block output and display in the MATLAB Command Window by entering the following commands.

```
rto = get_param(gcf, 'RuntimeObject')
rto.OutputPort(1).Data
```

However, the displayed data may not be the true block output if the run-time object is not synchronized with the Simulink execution. Simulink only ensures the run-time object and Simulink execution are synchronized when the run-time object is used either within a Level-2 MATLAB S-function or in an event listener callback. When called from the MATLAB Command Window, the run-time object can return incorrect output data if other blocks in the model are allowed to share memory.

To ensure the `Data` field contains the correct block output, open the Configuration Parameters dialog box, and then clear the **Signal storage reuse** check box (see “Signal storage reuse” (Simulink Coder)).

Set Block Parameter Values

Blocks have numeric parameters that determine how they calculate output values. To control the calculations that blocks perform, you can specify parameter values. For example, a Gain block has a **Gain** parameter, and a Transfer Fcn block has multiple parameters that represent the transfer function coefficients.

You can use numbers, variables, and expressions to set block parameter values. Choose a technique based on your modeling goals. For example, you can:

- Share parameter values between blocks and models by creating variables.
- Control parameter characteristics such as data type and dimensions by creating parameter objects.
- Model an algorithm as code by using mathematical expressions.

Set block parameters using the Model Data Editor (**View > Model Data Editor**) **Parameters** tab, the Property Inspector (**View > Property Inspector**), or the block dialog box. For more information, see “Setting Properties and Parameters” on page 1-52. To set block sample times, see “Specify Sample Time” on page 7-3.

Tip You can use the Model Explorer to make batch changes to many block parameter values at once. For more information, see “Search and Edit Using Model Explorer” on page 12-2.

Programmatically Access Parameter Values

To programmatically access block parameter values, use the `get_param` and `set_param` functions. You can use this technique to:

- Construct a model programmatically.
- Adjust parameter values during a simulation run when you simulate a model programmatically.

To sweep parameter values between simulation runs by using a script, use `Simulink.SimulationInput` objects instead of `get_param` and `set_param`. See “Optimize, Estimate, and Sweep Block Parameter Values” on page 37-52.

Suppose you create a model named `myModel` that contains a Constant block named `My Constant`. Next, you use the block dialog box to set the **Constant value** parameter to 15.

To programmatically return the parameter value, use the function `get_param`. You specify the block path and the equivalent programmatic parameter name, `Value`.

```
paramValue = get_param('myModel/My Constant', 'Value')

paramValue =

15
```

To programmatically change the value, for example to 25, use the function `set_param`. Use the character vector `'25'` as the input to the function.

```
set_param('myModel/My Constant', 'Value', '25')
```

For a list of programmatic names of block parameters, see “Block-Specific Parameters”.

For more information about programmatic simulation, see “Run Simulations Programmatically” on page 26-2.

To avoid using the `get_param` and `set_param` functions, use the name of a MATLAB variable or `Simulink.Parameter` object as the parameter value, and change the value of the variable or object at the command prompt. See “Share and Reuse Block Parameter Values by Creating Variables” on page 37-13.

Specify Parameter Values

Goal	Block Parameter Value	Description
Store the parameter value in the model file.	2.3 [1.2 2.3 4.5; 7.9 8.7 6.5] 2 + 3i	Literal numeric value. Specify a scalar, vector, matrix, or multidimensional array. Use <code>i</code> to specify complex values.

Goal	Block Parameter Value	Description
<ul style="list-style-type: none"> • Access the parameter value without having to locate or identify the block in the model. • Change the parameter value without having to modify the model file. • Share the parameter value between blocks or between models. • Identify the parameter by a specific name when sweeping or tuning the value. 	<code>myVar</code>	<p>MATLAB variable that exists in a workspace.</p> <p>For more information, see “Share and Reuse Block Parameter Values by Creating Variables” on page 37-13.</p>
<ul style="list-style-type: none"> • Avoid name clashes between workspace variables. • Organize parameter values using hierarchies and meaningful names. • Reduce the number of workspace variables that a model uses. 	<code>myParam.a.SpeedVect</code>	<p>Field of parameter structure.</p> <p>For more information, see “Organize Related Block Parameter Definitions in Structures” on page 37-26.</p>
<p>Use a portion of a matrix or array variable. For example, set the parameters of a n-D Lookup Table block.</p>	<code>myMatrixParam(:,2)</code>	<p>Index operation.</p>

Goal	Block Parameter Value	Description
<ul style="list-style-type: none">• Define parameter characteristics, such as data type, complexity, units, allowed value range, and dimensions, separately from the parameter value.• Define a system constant with custom documentation.• Create a tunable parameter in the generated code.• Set the value of a variable to a mathematical expression involving constants and other variables.	myParam	Parameter object. For more information, see “Use Parameter Objects” on page 37-6.

Goal	Block Parameter Value	Description
<ul style="list-style-type: none"> Express a parameter value as a mathematical relationship between known physical constants instead of as an unidentifiable literal number. Reduce block population in a model. Model an obscure or trivial calculation by using code instead of blocks. Use MATLAB operators and functions to perform calculations. Write a custom MATLAB function that calculates parameter values. 	$5^{3.2} - 1/3$ <code>myParam * myOtherparam + sin(0.78*pi)</code> <code>myFun(15.23)</code>	<p>Expression or custom function.</p> <p>For more information, see “Use Mathematical Expressions, MATLAB Functions, and Custom Functions” on page 37-7.</p>
<p>Specify a block parameter value by using a data type other than double.</p>	<code>15.23</code> <code>single(15.23)</code> <code>myParam</code>	<p>Typed or untyped expression, numeric MATLAB variable, or parameter object.</p> <p>For more information about controlling parameter data types, see “Control Block Parameter Data Types” on page 37-59.</p>

Use Parameter Objects

Parameter objects are `Simulink.Parameter` objects and objects of the subclasses that you create. The parameter object exists in a workspace such as the base workspace or a data dictionary.

You can use parameter objects to define system constants. For example, use a parameter object to represent the radius of the Earth. Use the properties of the object to specify the physical units and to document the purpose of the value.

Create parameter objects to prepare your model for code generation. You can configure parameter objects to appear as tunable global variables in the generated code. You can also control the parameter data type through the object.

To create and use parameter objects in models, see “Data Objects” on page 62-75. For information about using variables to set block parameter values, see “Share and Reuse Block Parameter Values by Creating Variables” on page 37-13.

Use Mathematical Expressions, MATLAB Functions, and Custom Functions

You can set a block parameter value to an expression that calls MATLAB functions and operators such as `sin` and `max`. You can also call your own custom functions that you write on the MATLAB path.

Suppose that a section of your block algorithm uses variables to calculate a single constant number used by the rest of the algorithm. You can perform the calculation by creating multiple blocks.

Instead, create a single Constant block that uses an expression written in MATLAB code. This technique reduces the size of the block algorithm and improves readability.

You can model a complicated portion of an algorithm by using an expression instead of many blocks. To operate on an existing signal, use a mathematical expression as the value of a parameter in an algorithmic block, such as the **Gain** parameter of a Gain block.

With expressions, you can also call your custom functions to set block parameter values. Suppose that you write a MATLAB function that calculates optimal P, I, and D parameters for a control algorithm by accepting a single input number.

```

paramFcn.m x +
1  function paramValue = paramFcn(performance,parameter)
2  %$PARAMVALUE = paramFcn(PERFORMANCE,PARAMETER) returns the P, I, or D
3  %value PARAMVALUE that you request using PARAMETER. Specify performance
4  %criteria using PERFORMANCE.
5
6  % Initialize output.
7  paramValue = [];
8
9  % Calculate parameter value.
10 switch parameter
11     case 'P'
12         paramValue = performance*3;
13     case 'I'
14         paramValue = sqrt(performance)/0.175;
15     case 'D'
16         paramValue = performance^0.25;
17
18 % Validation

```

You can parameterize a PID Controller block by using the function to set the parameter values.

Controller parameters

Source:	<input type="text" value="internal"/>
Proportional (P):	<input type="text" value="paramFcn(perf,'P')"/>
Integral (I):	<input type="text" value="paramFcn(perf,'I')"/>
Derivative (D):	<input type="text" value="paramFcn(perf,'D')"/>

To make the best use of expressions, consider these tips:

- If you use variables and parameter objects, you can explicitly model the algebraic relationships between the real-world quantities that the variables and objects represent. Use expressions in parameter objects as described in “Set Variable Value by Using a Mathematical Expression” on page 37-14.

- While you edit an expression in a block parameter value, to navigate to the documentation for a function, use the button  next to the parameter value. You can also navigate to the source code of a custom function.

Considerations for Other Modeling Goals

Choose a technique to set block parameter values based on your modeling goals.

Goal	Features or Products	Best Practice
Run multiple simulations quickly.	Simulink.SimulationInput objects and the sim function	Use variables or parameter objects to set block parameter values. This technique helps you to assign meaningful names to the parameters and to avoid having to identify or locate the blocks in the model. See “Optimize, Estimate, and Sweep Block Parameter Values” on page 37-52.
Sweep parameter values during testing.	Simulink Test™	Use variables or parameter objects to set block parameter values. Use iterations and parameter overrides to run multiple tests. See “Parameter Overrides” (Simulink Test) and “Test Iterations” (Simulink Test).
Estimate and optimize parameter values.	Simulink Design Optimization™	Use variables or parameter objects to set block parameter values. To estimate or optimize a parameter that uses a data type other than <code>double</code> , use a parameter object to separate the value from the data type. For parameter estimation, see “Parameter Estimation” (Simulink Design Optimization). For response optimization, see “Optimize Model Response” (Simulink Design Optimization).

Goal	Features or Products	Best Practice
Generate code from a model. Simulate an external program through SIL/PIL or External mode simulations.	Simulink Coder	<p>Use parameter objects to set block parameter values. This technique helps you to declare and identify tunable parameters in the generated code and to control parameter data types. See “Create Tunable Calibration Parameter in the Generated Code” (Simulink Coder).</p> <p>When you use expressions to set block parameter values, avoid using operators and functions that result in loss of tunability in the generated code. See “Tunable Expression Limitations” (Simulink Coder).</p>

Share and Reuse Block Parameter Values by Creating Variables

To set a block parameter value, such as the **Gain** parameter of a Gain block, you can use numeric variables that you create and store in workspaces such as the base workspace, a model workspace, or a Simulink data dictionary. You can use the variable to set multiple parameter values in multiple blocks, including blocks in different models. To change the values of the block parameters, you change the value of the variable in the workspace.

Using a variable to set a block parameter value also enables you to:

- Change the parameter value without having to modify the model file (if you store the variable outside the model workspace).
- Identify the parameter by a specific, meaningful name when sweeping or tuning the value.

For basic information about setting block parameter values, see “Set Block Parameter Values” on page 37-2.

Reuse Parameter Values in Multiple Blocks and Models

You can create a numeric MATLAB variable in a workspace, such as the base workspace or a data dictionary, and use it to specify one or more block parameter values.

The example model `sldemo_fuelsys` represents the fueling system of a gasoline engine. A subsystem in the model, `feedforward_fuel_rate`, calculates the fuel demand of the engine by using the constant number `14.6`, which represents the ideal (stoichiometric) ratio of air to fuel that the engine consumes. Two blocks in the subsystem use the number to set the values of parameters. In this example, to share the number between the blocks, you create a variable named `myParam`.

- 1 Open the model.
`sldemo_fuelsys`
- 2 In the model, select **View > Model Data Editor**. In the Model Data Editor, inspect the **Parameters** tab.
- 3 In the model, navigate into the subsystem.

```
open_system(...  
    'sldemo_fuelsys/fuel_rate_control/fuel_calc/feedforward_fuel_rate')
```

- 4 In the Model Data Editor, in the **Filter contents** box, enter 14.6.

The data table contains two rows, which correspond to the **Constant value** parameters of two of the Constant blocks in the subsystem.

- 5 Use the **Value** column to replace the literal number 14.6 with myParam. Perform the replacement for both parameters.
- 6 In the **Filter contents** box, enter myParam.
- 7 While editing the value of one of the parameters, click the action button  and select **Create**.
- 8 In the **Create New Data** dialog box, set **Value** to 14.6 and click **Create**.

The variable, myParam, appears in the base workspace.

Because the variable exists in the base workspace, you can use it in multiple models. However, when you end your MATLAB session, you lose the contents of the base workspace. Consider permanently storing the variable in a model workspace or data dictionary.

Define a System Constant

To define a system constant, such as a variable that represents the radius of the Earth, consider creating a `Simulink.Parameter` object instead of a numeric MATLAB variable. Parameter objects allow you to specify physical units and custom documentation as well as other characteristics.

- To create and use parameter objects in models, see “Data Objects” on page 62-75.
- Typically, the value of a system constant influences the values of other parameters and signals through mathematical relationships. To model these relationships explicitly, set the values of the dependent data by using expressions. See “Set Variable Value by Using a Mathematical Expression” on page 37-14.

Set Variable Value by Using a Mathematical Expression

You can set the value of a variable to an expression involving literal numbers and other variables. With expressions, you can:

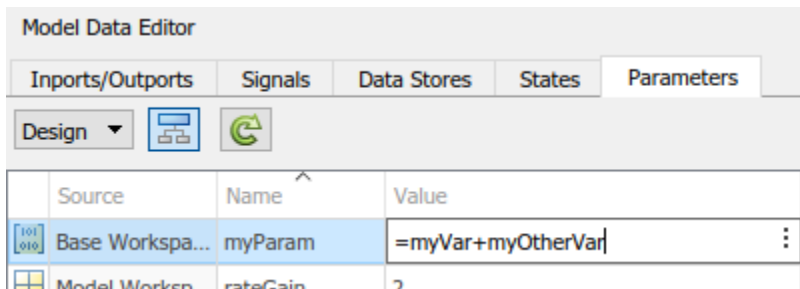

- Express the value as a relationship between known physical constants instead of as an unidentifiable literal number.

- Explicitly model algebraic dependencies between parameter data. When you change the values of independent data, you do not need to remember to adjust the values of dependent data.

General Technique

Convert the variable to a `Simulink.Parameter` object. Then, set the `Value` property of the object by using an expression:

- Interactively — For example, with the Model Data Editor or the Model Explorer, precede the expression with an equals sign, `=`. The figure shows how to specify the expression `myVar + myOtherVar`.

- Programmatically — Use the `slexpr` function, specifying the expression in a character vector or string. For example, to set the value of a parameter object named `myParam` to the expression `myVar + myOtherVar`:

```
myParam.Value = slexpr('myVar + myOtherVar')
```

Explicitly Model Algebraic Relationship Between Variables

The example `sldemo_metro` (see “Exploring the Solver Jacobian Structure of a Model”) models a system of three identical, pointlike metronomes suspended from a moving platform. Blocks in the model use these MATLAB variables from the base workspace:

- `m` — Mass of each metronome, initial value 0.1 kg
- `r` — Length of each metronome, initial value 1.0 m
- `J` — Moment of inertia of each metronome, initial value 0.1 kg/m²

These variables share an algebraic relationship: the moment of inertia of each metronome is equal to the mass times the length squared. In this example, you record this relationship in the value of `J`.

- 1 Open the model.

```
sldemo_metro
```

- 2 Update the block diagram. A model callback creates the variables in the base workspace.
- 3 To prevent the callback from overwriting changes that you make to the variables, for this example, remove the callback code.

```
set_param('sldemo_metro','InitFcn','')
```

- 4 In the model, select **View > Model Data Editor**.
- 5 On the Model Data Editor **Parameters** tab, activate the **Change scope** button.

The blocks that use the variables are in the subsystems, so you must configure the Model Data Editor to show data in subsystems.

- 6 Click the **Show/refresh additional information** button.

The data table contains rows that correspond to the variables in the base workspace.

- 7 In the **Filter contents** box, enter J.
- 8 In the data table, find the row that corresponds to J. In the **Value** column, set the value of the variable to `Simulink.Parameter(J)`.

Simulink converts J to a `Simulink.Parameter` object.

- 9 In the **Value** column, set the value of the parameter object to `m*r^2`.
- 10 Optionally, simulate the model with different metronome masses and lengths. As you change the values of m and r, you do not have to remember to correct the value of J.

Limitations and Considerations for Other Modeling Goals

- If the expression contains fixed-point data or data of an enumerated type, the expression can operate on only one variable or object.
- You cannot set the data type (`DataType` property) of the parameter object that uses the expression to `auto` (the default) and set the data types of parameter objects that appear in the expression to a value other than `auto`. For example, in the expression $J = m*r^2$, you cannot set the data type of J to `auto` and the data types of m and r to `single`.
 - To retain the benefits of `auto` (described in “Context-Sensitive Data Typing” on page 37-60) for the object that uses the expression, set the data types of the objects in the expression to `auto`. In other words, use `auto` for all of the involved objects. The objects in the expression acquire the same data type as the object that uses the expression.

- To use a value other than `auto` for an object that appears in the expression, set the data types of all dependent parameter objects to a value other than `auto`. In other words, do not use `auto` for any involved objects.

You must use the same data type for all objects used in the expression.

- If you have Simulink Coder and Embedded Coder licenses, you can generate code that initializes a global variable by using the expression. However, the code generator can preserve the expression only if it conforms to certain requirements. See “Expression Preservation” (Simulink Coder).

Control Scope of Parameter Values

The scope of a variable is the set of models and blocks that can use the variable. For example, variables that you create in the base workspace have global scope because all blocks in all open models can use the variables. Variables that you store in a model workspace have limited scope because only the blocks in the host model can use the variables.

You cannot create two variables that have the same name in the same scope. Controlling the scope of a variable helps you to avoid name conflicts and establish clear ownership of the variable.

The table describes the different ways that you can control the scope of a reusable parameter value.

Scope	Technique
All open models	Create a variable in the base workspace.
One or more targeted models	Create a variable in a data dictionary. To reuse the variable in multiple models, create a referenced dictionary. See “What Is a Data Dictionary?” on page 66-2
One model, including all subsystems in the model	Create a variable in the model workspace. See “Model Workspaces” on page 62-162.

Scope	Technique
Multiple blocks inside a subsystem, including blocks in nested subsystems	<p>Mask the subsystem and create a mask parameter instead of a workspace variable.</p> <p>To prevent blocks inside a subsystem from using workspace variables, in the subsystem block dialog box, set Permit Hierarchical Resolution to None. This technique allows you to use the same name to create both a variable in a workspace and a mask parameter in the subsystem mask. The blocks in the subsystem can use only the mask parameter.</p> <p>For information about subsystems, see <i>Subsystem</i>. For information about masking, see “Masking Fundamentals” on page 39-2.</p>

To avoid name conflicts when you have a large model with many variables in the same scope, consider packaging the variables into a single structure. For more information, see “Organize Related Block Parameter Definitions in Structures” on page 37-26.

For basic information about how blocks use the variable names that you specify, see “Symbol Resolution” on page 62-174.

Permanently Store Workspace Variables

Variables that you create in the base workspace do not persist between MATLAB sessions. However, you can store the variables in a MAT-file or script file, and load the file whenever you open the model using a model callback. A model callback is a set of commands that Simulink executes when you interact with a model in a particular way, such as opening the model. You can use a callback to load variables when you open the model. Use this technique to store variables while you learn about Simulink and experiment with models.

- 1 In a model that contains a Gain block, set the value of the **Gain** parameter to K.
- 2 At the command prompt, create a variable K in the base workspace.

```
K = 27;
```

- 3 In the Workspace browser, right-click the variable and select **Save As**.

To save multiple variables in one file, select all of the target variables in the Workspace browser, and then right-click any of the selected variables.

- 4 In the dialog box, set **Save as type** to MATLAB Script. Set **File name** to `loadvar` and click **Save**.

The script file `loadvar.m` appears in your current folder. You can open the file to view the command that creates the variable `K`.

- 5 In the model, select **File > Model Properties > Model Properties**.
- 6 In the **Callbacks** tab of the Model Properties dialog box, select `PreLoadFcn` as the callback that you want to define. In the **Model pre-load function** pane, enter `loadvar` and click **OK**.
- 7 Save the model.

The next time that you open the model, the `PreLoadFcn` callback loads the variable `K` into the base workspace. You can also save the variable to a MAT-file, for example `loadvar.mat`, and set the model callback to `load loadvar`.

To learn about callbacks, see “Callbacks for Customized Model Behavior” on page 4-50. To programmatically define a callback for loading variables, see “Programmatically Store Workspace Variables for a Model” on page 37-19.

When you save variables to a file, you must save the changes that you make to the variables during your MATLAB session. To permanently store variables for a model, consider using a model workspace or a data dictionary instead of a MAT-file or script file. For more information about permanently storing variables, see “Determine Where to Store Variables and Objects for Simulink Models” on page 62-134.

Programmatically Store Workspace Variables for a Model

In the example above, you define a model callback that creates variables when you open a model. You can programmatically save the variable and set the model callback.

- 1 At the command prompt, create the variable `K` in the base workspace.

```
K = 27;
```

- 2 Save the variable to a new script file named `loadvar.m`.

```
matlab.io.saveVariablesToScript('loadvar.m', 'K')
```

- 3 Set the model callback to load the script file.

```
set_param('myModel', 'PreloadFcn', 'loadvar')
```

- 4 Save the model.

```
save_system('myModel')
```

The function `matlab.io.saveVariablesToScript` saves variables to a script file. To save variables to a MAT-file, use the function `save`. To programmatically set model properties such as callbacks, use the function `set_param`.

Manage and Edit Workspace Variables

When you use variables to set block parameter values, you store the variables in a workspace or data dictionary. You can use the command prompt, the Model Explorer, and the Model Data Editor to create, move, copy, and edit variables. You can also determine where a variable is used in a model, list all of the variables that a model uses, and list all of the variables that a model does not use. For more information, see “Create, Edit, and Manage Workspace Variables” on page 62-143.

Package Shared Breakpoint and Table Data for Lookup Tables

To share breakpoint vectors or table data between multiple n-D Lookup Table, Prelookup, and Interpolation Using Prelookup blocks, consider storing the data in `Simulink.LookupTable` and `Simulink.Breakpoint` objects instead of MATLAB variables or `Simulink.Parameter` objects. This technique improves model readability by clearly identifying the data as parts of a lookup table and explicitly associating breakpoint data with table data.

Store Standalone Lookup Table in `Simulink.LookupTable` Object

A standalone lookup table consists of a set of table data and one or more breakpoint vectors. You do not share the table data or any of the breakpoint vectors with other lookup tables.

When you share a standalone lookup table, you use all of the table and breakpoint data together in multiple n-D Lookup Table blocks. To store this data in a `Simulink.LookupTable` object:

- 1 Create the object in a workspace or data dictionary. For example, at the command prompt, enter:

- ```
myLUTObj = Simulink.LookupTable;
```
- 2 Use the properties of the object to store the values of the table and breakpoint data.
  - 3 Use the properties of the object to configure a unique name for the structure type in the generated code. In the property dialog box, under **Struct Type definition**, specify **Name**.
  - 4 In the n-D Lookup Table blocks, set **Data specification** to Lookup table object.
  - 5 To the right of **Data specification**, set **Name** to the name of the Simulink.LookupTable object.

For ways to create and configure Simulink.LookupTable objects, see Simulink.LookupTable

### Store Shared Data in Simulink.LookupTable and Simulink.Breakpoint Objects

When you use Prelookup and Interpolation Using Prelookup blocks to more finely control the lookup algorithm, you can share breakpoint vectors and sets of table data. For example, you can share a breakpoint vector between two separate sets of table data. With this separation of the breakpoint data from the table data, you can share individual parts of a lookup table instead of sharing the entire lookup table.

To store breakpoint and table data:

- 1 Create a Simulink.LookupTable object for each unique set of table data. Create a Simulink.Breakpoint object for each unique breakpoint vector, including breakpoint vectors that you do not intend to share.
- 2 Use the properties of the objects to store the values of the table and breakpoint data.
- 3 Configure the Simulink.LookupTable objects to refer to the Simulink.Breakpoint objects for breakpoint data. In the Simulink.LookupTable objects, set **Specification** to Reference. Specify the names of the Simulink.Breakpoint objects.
- 4 In the Interpolation Using Prelookup blocks, set **Specification** to Lookup table object. Set **Name** to the name of a Simulink.LookupTable object.

In the Prelookup blocks, set **Specification** to Breakpoint object. Set **Name** to the name of a Simulink.Breakpoint object.

The example model fxdemo\_lookup\_shared\_param contains two Prelookup and two Interpolation Using Prelookup blocks. Configure the blocks so that each combination of a Prelookup and an Interpolation Using Prelookup block represents a unique lookup table.

Share the breakpoint vector between the two lookup tables. In this case, each lookup table has unique table data but shared breakpoint data.

- 1 Open the example model.
- 2 In the Prelookup block dialog box, set **Specification** to Breakpoint object. Set **Name** to sharedBkpts.
- 3 Click the button  next to the value of the **Name** parameter. Select **Create Variable**.
- 4 In the **Create New Data** dialog box, set **Value** to Simulink.Breakpoint and click **Create**.

A Simulink.Breakpoint object appears in the base workspace.

- 5 In the property dialog box for sharedBkpts, specify **Value** as a vector such as [1 2 3 4 5 6 7 8 9 10]. Click **OK**.
- 6 In the Prelookup block dialog box, click **OK**.
- 7 In the Prelookup1 block dialog box, set **Specification** to Breakpoint object. Set **Name** to sharedBkpts.
- 8 In the Interpolation Using Prelookup block dialog box, set **Specification** to Lookup table object. Set **Name** to dataForFirstTable.
- 9 Click the button  next to the value of the **Name** parameter. Select **Create Variable**.
- 10 In the **Create New Data** dialog box, set **Value** to Simulink.LookupTable and click **Create**.

A Simulink.LookupTable object appears in the base workspace.

- 11 In the property dialog box for dataForFirstTable, specify **Value** as a vector, such as [10 9 8 7 6 5 4 3 2 1].
- 12 Set **Specification** to Reference.
- 13 In the table under **Specification**, set **Name** to sharedBkpts and click **OK**.
- 14 In the Interpolation Using Prelookup block dialog box, click **OK**.
- 15 Configure the Interpolation Using Prelookup1 block to use a Simulink.LookupTable object named dataForSecondTable. In the object property dialog box, specify **Value** as a vector, such as [0 0.5 1 1.5 2 2.5 3 3.5 4 4.5]. Configure the object to refer to sharedBkpts for the breakpoint data.

The model now represents two unique lookup tables:

- A combination of `sharedBkpts` and `dataForFirstTable`.
- A combination of `sharedBkpts` and `dataForSecondTable`.

These lookup tables share the same breakpoint data through `sharedBkpts`.

## Parameter Interfaces for Reusable Components

You can use subsystems, referenced models, and custom library blocks as reusable components in other models. For guidelines to help you decide how to componentize a system, see “Capabilities of Model Components” on page 15-29.

Typically, a reusable algorithm requires that numeric block parameters, such as the **Gain** parameter of a Gain block, either:

- Use the same value in all instances of the component.
- Use a different value in each instance of the component. Each value is instance specific.

By default, if you use a literal number or expression to set the value of a block parameter, the parameter uses the same value in all instances of the component. If you set multiple block parameter values by using a MATLAB variable, `Simulink.Parameter` object, or other parameter object in a workspace or data dictionary, these parameters also use the same value in all instances of the component.

### Referenced Models

If you use model referencing to create a reusable component, to set parameter values that are specific to each instance, configure model arguments for the referenced model. When you instantiate the model by adding a Model block to a different model, you set the values of the arguments in the Model block. When you add another Model block to the same parent model or to a different model, you can set different values for the same arguments. Optionally, if you create more than two instances, you can set the same value for some of the instances and different values for the other instances.

If a model has many model arguments, consider packaging the arguments into a single structure. Instead of configuring many arguments, configure the structure as a single argument. Without changing the mathematical functionality of the component, this technique helps you to reduce the number of model argument values that you must set in each instance of the component.

For more information about model arguments, see “Parameterize Instances of a Reusable Referenced Model” on page 8-90.

## Subsystems

If you use subsystems or custom libraries to create reusable components, to set parameter values that are specific to each instance, use masks, mask parameters, and parameter promotion. When you instantiate the component in a model, you set the values of the mask parameters in the Subsystem block. When you instantiate the component again in the same model or a different model, you can set different values for the same mask parameters. Optionally, if you create more than two instances, you can set the same value for some of the instances and different values for the other instances.

If the subsystem has many mask parameters, consider packaging the parameters into a single structure. Instead of configuring many mask parameters, configure the structure as a single parameter. Without changing the mathematical functionality of the component, this technique helps you to reduce the number of mask parameter values that you must set in each instance of the component.

For more information about subsystems, see [Subsystem](#). For more information about custom block libraries, see [“Design and Create a Custom Block”](#) on page 40-18. For more information about masks, see [“Masking Fundamentals”](#) on page 39-2. For more information about structures, see [“Organize Related Block Parameter Definitions in Structures”](#) on page 37-26.

## Organize Related Block Parameter Definitions in Structures

When you use numeric MATLAB variables to set block parameter values in a model, large models can accumulate many variables, increasing the effort of maintenance and causing the variable names to grow in length.

Instead, you can organize these parameter values into structures. Each structure is a single variable and each field of the structure stores a numeric parameter value. You can assign meaningful names to the structures, substructures, and fields to indicate the purpose of each value.

Use structures to:

- Reduce the number of workspace variables that you must maintain.
- Avoid name conflicts between workspace variables.

You cannot create two variables that have the same name in the same scope, such as in the base workspace. When you create structures, you must provide each field a name, but multiple structures can each contain a field that uses the same name. Therefore, you can use each structure and substructure as a namespace that prevents the field names from conflicting with each other and with other variable names in the same scope.

- Logically group sets of block parameter values. For example, use nested structures to clearly identify the parameter values that each subsystem or referenced model uses.

If you use mask parameters or model arguments to pass parameter values to the components of a system, you can use structures to reduce the number of individual mask parameters or model arguments that you must maintain. Instead of passing multiple variables, you can pass a single structure variable.

For basic information about creating and manipulating MATLAB structures, see *Structures (MATLAB)*. For basic information about setting block parameter values in a model, see “Set Block Parameter Values” on page 37-2.

To use structures to initialize bus signals, see “Specify Initial Conditions for Bus Signals” on page 68-108.

## Create and Use Parameter Structure

This example shows how to create and use a parameter structure in a model.

The example model **f14** uses multiple variables from the base workspace to set block parameter values. For example, when you open the model, it creates the variables **Zw**, **Mw**, and **Mq** in the base workspace. To organize these variables into a single structure variable:

- 1 At the command prompt, open the example model.

```
f14
```

- 2 At the command prompt, create the parameter structure **myGains**. Set the field values by using the values of the target variables.

```
myGains.Zw = Zw;
myGains.Mw = Mw;
myGains.Mq = Mq;
```

- 3 In the Model Explorer, on the **Model Hierarchy** pane, click **Base Workspace**. In the **Contents** pane, right-click the variable **Mq** and select **Find Where Used**.
- 4 In the **Select a system** dialog box, click the node **f14** and click **OK**. Click **OK** when asked about updating the diagram.
- 5 In the **Contents** pane, right-click the row corresponding to the block labeled **Gain1** and select **Properties**. The **Gain1** block dialog box opens.
- 6 Change the value of the **Gain** parameter from **Mq** to **myGains.Mq** and click **OK**.
- 7 In the **Contents** pane, right-click the row corresponding to the **Transfer Fcn.1** block and select **Properties**.
- 8 Change the value of the **Denominator coefficients** parameter from **[1, -Mq]** to **[1, -myGains.Mq]** and click **OK**.
- 9 In the **Model Hierarchy** pane, click **Base Workspace**. Use **Find Where Used** to locate the blocks that use the variables **Mw** and **Zw**. In the block dialog boxes, replace the references to the variable names according to the table.

| Variable Name | Replacement Name |
|---------------|------------------|
| Mw            | myGains.Mw       |
| Zw            | myGains.Zw       |

- 10 Clear the old variables.

```
clear Zw Mw Mq
```

Each of the modified block parameters now uses a field of the `myGains` structure. The numeric value of each structure field is equal to the value of the corresponding variable that you cleared.

You can use the functions `Simulink.BlockDiagram.createVarStruct` and `Simulink.BlockDiagram.applyVarStruct` to migrate a model to use a single parameter structure instead of multiple workspace variables. For an example, see “Migration to Structure Parameters”.

## Store Data Type Information in Field Values

To use a structure or array of structures to organize parameter values that use a data type other than `double`, you can explicitly specify the type when you create the structure. When you create the structure, use typed expressions such as `single(15.23)` to specify the field values.

```
myParams.Gain = single(15.23);
```

If you want to change the field value later, you must remember to explicitly specify the type again. If you do not specify the type, the field value uses the data type `double` instead:

```
myParams.Gain = 15.23;
% The field 'Gain' now uses the data type 'double' instead of 'single'.
```

To preserve the type specification, you can use subscripted assignment to assign a new value to the field:

```
% Assign value of type 'single'.
myParams.Gain = single(15.23);

% Assign new value while retaining type 'single'.
myParams.Gain(:) = 11.79;
```

To match a fixed-point data type, set the field value by using an `fi` object.

## Control Field Data Types and Characteristics by Creating Parameter Object

A `Simulink.Parameter` object allows you to separate the value of a block parameter from its data type. If you use a parameter object to store a structure or array of

structures, you can create a `Simulink.Bus` object to use as the data type of the entire structure.

You can use the bus object and the parameter object to explicitly control:

- The data type of each field. When you use this technique, you do not have to remember to use typed expressions or subscripted assignment to set the field values.
- The complexity, dimensions, and units of each field.
- The minimum and maximum value of each field if the field represents a tunable parameter value.
- The shape of the entire structure. The shape of the structure is the number, names, and hierarchy of fields.
- The tunability of the structure in the code that you generate from the model.

- 1 Create a parameter structure `myParams`.

```
myParams = struct(...
 'SubsystemA', struct(...
 'Gain', 15.23, ...
 'Offset', 89, ...
 'Init', 0.59), ...
 'SubsystemB', struct(...
 'Coeffs', [5.32 7.99], ...
 'Offset', 57, ...
 'Init1', 1.76, ...
 'Init2', 2.76)...
);
```

- 2 Use the function `Simulink.Bus.createObject` to create `Simulink.Bus` objects that represent the structure and substructures.

```
Simulink.Bus.createObject(myParams)
```

Because `myParams` contains two unique substructures, the function creates three `Simulink.Bus` objects: one named `s1Bus1` to represent the parent structure `myParams`, one named `SubsystemA` for the substructure `SubsystemA`, and one named `SubsystemB` for the substructure `SubsystemB`.

- 3 Rename the bus object `s1Bus1` as `myParamsType`.

```
myParamsType = s1Bus1;
clear s1Bus1
```

- 4 Store the structure `myParams` in a `Simulink.Parameter` object.

```
myParams = Simulink.Parameter(myParams);
```

The `Value` property of the parameter object contains the structure.

- 5 Set the data type of the parameter object to the bus object `myParamsType`.

```
myParams.DataType = 'Bus: myParamsType';
```

- 6 Open the Bus Editor to view the bus objects.

```
buseditor
```

- 7 In the **Model Hierarchy** pane, click the node `SubsystemA`. In the **Contents** pane, set the field data types according to the figure.

| Name   | DataType | Complexity | Dimensions | DimensionsMode | SamplingMode |
|--------|----------|------------|------------|----------------|--------------|
| Gain   | single   | real       | [1 1]      | Fixed          | Sample based |
| Offset | int8     | real       | [1 1]      | Fixed          | Sample based |
| Init   | single   | real       | [1 1]      | Fixed          | Sample based |

- 8 Optionally, set the field data types for the substructure `SubsystemB`.

The parameter object `myParams` stores the parameter structure. The data type of the parameter object is the bus object `myParamsType`. Prior to simulation and code generation, the parameter object casts the field values to the data types that you specified in the bus object.

To use one of the fields to set a block parameter value, specify an expression such as `myParams.SubsystemB.Init1`.

To access the field values at the command prompt, use the `Value` property of the parameter object. Because the bus object controls the field data types, you do not need to use a typed expression to set the field value.

```
myParams.Value.SubsystemA.Gain = 12.79;
```

The bus object strictly controls the field characteristics and the shape of the structure. For example, if you set the value of the two-element field `myParams.SubsystemB.Coeffs` to a three-element array, the model generates an error when you set a block parameter value. To change the dimensions of the field, modify the element `Coeffs` in the bus object `SubsystemB`.

To manipulate bus objects after you create them, see “Modify Bus Objects” on page 68-84 and “Save and Import Bus Objects” on page 68-90.

## Match Field Data Type with Signal Data Type

Suppose that you use the field `myParams.SubsystemA.Gain` to set the value of the **Gain** parameter in a Gain block. If you want the data type of the field to match the data type of the output signal of the block, you cannot rely on context-sensitive data typing (see “Context-Sensitive Data Typing” on page 37-60). Consider using a `Simulink.AliasType` or a `Simulink.NumericType` object to set the data type of the field and the signal. If you do not use a data type object, you must remember to change the data type of the field whenever you change the data type of the signal.

- 1 At the command prompt, create a `Simulink.AliasType` object that represents the data type `single`.

```
myType = Simulink.AliasType;
myType.BaseType = 'single';
```

- 2 In the Gain block dialog box, on the **Signal Attributes** tab, set **Output data type** to `myType`.
- 3 At the command prompt, open the Bus Editor.

```
buseditor
```

- 4 In the **Model Hierarchy** pane, select the bus object `SubsystemA`. In the **Contents** pane, set the data type of the field `Gain` to `myType`.

Now, both the output signal of the Gain block and the structure field `myParams.SubsystemA.Gain` use the data type that you specify by using the `BaseType` property of `myType`.

For more information about data type objects, see `Simulink.AliasType` and `Simulink.NumericType`.

## Manage Structure Variables

To create, modify, and inspect a variable whose value is a structure, you can use the Variable Editor. For more information, see “Modify Structure and Array Variables Interactively” on page 62-144.

## Define Parameter Hierarchy by Creating Nested Structures

To further organize block parameter values, create a hierarchy of nested structures.

For example, suppose that you create subsystems named `SubsystemA` and `SubsystemB` in your model. You use variables such as `Offset_SubsystemA` and `Offset_SubsystemB` to set block parameter values in the subsystems.

```
Gain_SubsystemA = 15.23;
Offset_SubsystemA = 89;
Init_SubsystemA = 0.59;

Coeffs_SubsystemB = [5.32 7.99];
Offset_SubsystemB = 57;
Init1_SubsystemB = 1.76;
Init2_SubsystemB = 2.76;
```

Create a parameter structure that contains a substructure for each subsystem. Use the values of the existing variables to set the field values.

```
myParams = struct(...
 'SubsystemA', struct(...
 'Gain', Gain_SubsystemA, ...
 'Offset', Offset_SubsystemA, ...
 'Init', Init_SubsystemA), ...
 'SubsystemB', struct(...
 'Coeffs', Coeffs_SubsystemB, ...
 'Offset', Offset_SubsystemB, ...
 'Init1', Init1_SubsystemB, ...
 'Init2', Init2_SubsystemB)...
);
```

The single structure variable `myParams` contains all of the parameter information for the blocks in the subsystems. Because each substructure acts as a namespace, you can define the `Offset` field more than once.

To use the `Offset` field from the substructure `SubsystemB` as the value of a block parameter, specify the parameter value in the block dialog box as the expression `myParams.SubsystemB.Offset`.

## Group Multiple Parameter Structures into an Array

To organize parameter structures that have similar characteristics, you can create a single variable whose value is an array of structures. This technique helps you to parameterize a model that contains multiple instances of an algorithm, such as a library subsystem or a referenced model that uses model arguments.

Suppose that you create two identical subsystems in a model.

Suppose that the blocks in each subsystem require three numeric values to set parameter values. Create an array of two structures to store the values.

```
myParams(1).Gain = 15.23;
myParams(1).Offset = 89;
myParams(1).Init = 0.59;
```

```
myParams(2).Gain = 11.93;
myParams(2).Offset = 57;
myParams(2).Init = 2.76;
```

Each structure in the array stores the three parameter values for one of the subsystems.

To set the value of a block parameter in one of the subsystems, specify an expression that references a field of one of the structures in the array. For example, use the expression `myParams(2).Init`.

### Organize Parameter Values for Reusable Components and Iterative Algorithms

You can also partition an array of structures in a For Each Subsystem block. This technique helps you to organize workspace variables when a model executes an algorithm repeatedly, for example by iterating the algorithm over a vector signal. For an example, see “Repeat an Algorithm Using a For Each Subsystem” on page 68-143.

If you use model arguments to specify different parameter values across multiple instances of a referenced model, you can use arrays of structures to organize the model argument values. In the referenced model workspace, create a structure variable and configure the model to use the structure as a model argument. Use the fields of the structure to set block parameter values in the model. Then, create an array of structures in the base workspace or a data dictionary to which the parent model or models are linked. In the parent model or models, use each of the structures in the array as the value of the model argument in a Model block. Each structure in the array stores the parameter values for one instance of the referenced model.

The example model `sldemo_mdhref_datamngt` contains three instances (Model blocks) of the masked referenced model `sldemo_mdhref_counter_datamngt`. The base workspace variables `IC1`, `IC2`, `Param1`, and `Param2` are `Simulink.Parameter` objects whose values are structures. The parent model uses these variables to set the values of mask parameters on the Model blocks. Since `IC1` is structurally identical to `IC2`, and `Param1` to `Param2`, you can combine these four structures into two arrays of structures.

- 1 Open the example parent model.

```
sldemo_mdhref_datamngt
```

The model creates the four `Simulink.Parameter` objects in the base workspace.

- 2 Open the example referenced model.

```
sldemo_mdhref_counter_datamngt
```

The model workspace defines two model arguments, `CounterICs` and `CounterParams`, whose values are structures. The blocks in the model use the fields of these structures to set parameter values.

- 3 In the model `sldemo_mdhref_datamngt`, open the Model Data Editor (**View > Model Data Editor**). In the Model Data Editor, inspect the **Parameters** tab.
- 4 In the model, click one of the Model blocks.

The Model Data Editor highlights rows that correspond to two mask parameters on the selected Model block. The block uses the mask parameters to set the values of the two model arguments defined by the referenced model, `sldemo_mdhref_counter_datamngt`. Each Model block uses a different combination of the four parameter objects from the base workspace to set the argument values.

- 5 In the Model Data Editor **Value** column, click one of the cells to begin editing the value of the corresponding mask parameter (for example, `IC1`). Next to the

parameter value, click the action button  and select **Open**. The property dialog box for the parameter object opens.

- 6 In the property dialog box, next to the **Value** box, click the action button and select **Open Variable Editor**.

The Variable Editor shows that the parameter object stores a structure. The structures in Param2 and IC2 have the same fields as the structures in Param1 and IC1 but different field values.

- 7 At the command prompt, combine the four parameter objects into two parameter objects whose values are arrays of structures.

```
% Create a new parameter object by copying Param1.
Param = Param1.copy;
```

```
% Use the structure in Param2 as the second structure in the new object.
Param.Value(2) = Param2.Value;
% The value of Param is now an array of two structures.
```

```
% Delete the old objects Param1 and Param2.
clear Param1 Param2
```

```
% Create a new parameter object by copying IC1.
% Use the structure in IC2 as the second structure in the new object.
IC = IC1.copy;
IC.Value(2) = IC2.Value;
clear IC1 IC2
```

- 8 In the parent model, in the Model Data Editor, use the **Value** column to replace the values of the mask parameters according to the table

| Previous Value | New Value |
|----------------|-----------|
| Param1         | Param(1)  |
| IC1            | IC(1)     |
| Param2         | Param(2)  |
| IC2            | IC(2)     |

Each Model block sets the value of the model argument CounterICs by using one of the structures in the array IC. Similarly, each block sets the value of CounterParams by using one of the structures in Param.

## Enforce Uniformity in an Array of Structures

All of the structures in an array of structures must have the same hierarchy of fields. Each field in the hierarchy must have the same characteristics throughout the array. You can use a parameter object and a bus object to enforce this uniformity among the structures.

To use a parameter object to represent an array of parameter structures, set the value of the object to the array of structures:

```
% Create array of structures.
myParams(1).Gain = 15.23;
myParams(1).Offset = 89;
myParams(1).Init = 0.59;
myParams(2).Gain = 11.93;
myParams(2).Offset = 57;
myParams(2).Init = 2.76;

% Create bus object.
Simulink.Bus.createObject(myParams);
myParamsType = slBus1;
clear slBus1

% Create parameter object and set data type.
myParams = Simulink.Parameter(myParams);
myParams.DataType = 'Bus: myParamsType';
```

To use one of the fields to set a block parameter value, specify an expression such as `myParams(2).Offset`.

To access the field values at the command prompt, use the `Value` property of the parameter object.

```
myParams.Value(2).Offset = 129;
```

## Create a Structure of Constant-Valued Signals

You can use a structure in a Constant block to create a single bus signal that transmits multiple numeric constants. For more information, see `Constant`. For information about bus signals, see “Buses” on page 68-3.

## Considerations Before Migrating to Parameter Structures

- Before you migrate a model to use parameter structures, discover all of the blocks in the target model and in other models that use the variables that you intend to replace.

For example, suppose two blocks in a model use the workspace variable `myVar`. If you create a structure `myParams` with a field `myVar`, and set the parameter value in only one of the blocks to `myParams.myVar`, the other block continues to use the variable `myVar`. If you delete `myVar`, the model generates an error because the remaining block requires the deleted variable.

To discover all of the blocks that use a variable:

- 1 Open all models that might use the variable. If the models are in a model reference hierarchy, you can open only the top model.
- 2 In the Model Data Editor or in the Model Explorer **Contents** pane, right-click the variable and select **Find Where Used**. The Model Explorer displays all of the blocks that use the variable.

You can discover variable usage only in models that are open. Before you migrate to parameter structures, open all models that might use the target variables. For more information about determining variable usage in a model, see “Finding Blocks That Use a Specific Variable” on page 62-151.

Alternatively, you can refrain from deleting `myVar`. However, if you change the value of the `myParams.myVar` structure field, you must remember to change the value of `myVar` to match.

- You can combine multiple separate variables or parameter objects (such as `Simulink.Parameter`) into a structure that you store in a single variable or parameter object (to combine parameter objects, see “Combine Existing Parameter Objects Into a Structure” on page 37-37). However, the resulting variable or object acts as a single entity. As a result, you cannot apply different code generation settings, such as storage classes, to individual fields in the structure.

## Combine Existing Parameter Objects Into a Structure

When you use parameter objects to set block parameter values (for example, so you can apply storage classes), to combine the objects into a single structure:

- 1 Create a MATLAB structure and store it in a variable. To set the field values, use the parameter values that each existing parameter object stores.
- 2 Convert the variable to a parameter object. Create and use a `Simulink.Bus` object as the data type of the parameter object (see “Control Field Data Types and Characteristics by Creating Parameter Object” on page 37-28).
- 3 Choose a storage class to apply to the resulting parameter object. You can choose only one storage class, which applies to the entire structure.
- 4 Transfer parameter metadata, such as the `Min` and `Max` properties of the existing parameter objects, to the corresponding properties of the `Simulink.BusElement` objects in the bus object.

For example, suppose you have three individual parameter objects.

```
coeff = Simulink.Parameter(17.5);
coeff.Min = 14.33;
coeff.DataType = 'single';
coeff.StorageClass = 'ExportedGlobal';
```

```
init = Simulink.Parameter(0.00938);
init.Min = -0.005;
init.Max = 0.103;
init.DataType = 'single';
init.StorageClass = 'Model default';
```

```
offset = Simulink.Parameter(199);
offset.DataType = 'uint8';
offset.StorageClass = 'ExportedGlobal';
```

- 1 Create a structure variable.

```
myParams.coeff = coeff.Value;
myParams.init = init.Value;
myParams.offset = offset.Value;
```

- 2 Convert the variable to a parameter object.

```
myParams = Simulink.Parameter(myParams);
```

- 3 Create a bus object and use it as the data type of the parameter object.

```
Simulink.Bus.createObject(myParams.Value);
paramsDT = copy(slBus1);
```

```
myParams.DataType = 'Bus: paramsDT';
```

- 4 Transfer metadata from the old parameter objects to the bus elements in the bus object.

```
% coeff
paramsDT.Elements(1).Min = coeff.Min;
paramsDT.Elements(1).DataType = coeff.DataType;

% init
paramsDT.Elements(2).Min = init.Min;
paramsDT.Elements(2).Max = init.Max;
paramsDT.Elements(2).DataType = init.DataType;

% offset
paramsDT.Elements(3).DataType = offset.DataType;
```

To help you write a script that performs this transfer operation, you can use the `properties` function to find the properties that the bus elements and the old parameter objects have in common. To list the structure fields so that you can iterate over them, use the `fieldnames` function.

- 5 Apply a storage class to the parameter object.

```
myParams.StorageClass = 'ExportedGlobal';
```

Now, you can use the fields of `myParams`, instead of the old parameter objects, to set the block parameter values.

## Parameter Structures in the Generated Code

You can configure parameter structures to appear in the generated code as structures and arrays of structures. For information about generating code with parameter structures, see “Organize Data into Structures in Generated Code” (Simulink Coder).

## Parameter Structure Limitations

- The value of a field that you use to set a block parameter must be numeric or of an enumerated type. The value of a field can be a real or complex scalar, vector, or multidimensional array.
- If the value of any of the fields of a structure is a multidimensional array, you cannot tune any of the field values during simulation.
- All of the structures in an array of structures must have the same hierarchy of fields. Each field in the hierarchy must have the same characteristics throughout the array:

- Field name
- Numeric data type, such as `single` or `int32`
- Complexity
- Dimensions

Suppose that you define an array of two structures.

```
paramStructArray = ...
[struct('sensor1',int16(7),'sensor2',single(9.23)) ...
 struct('sensor1',int32(9),'sensor2',single(11.71))];
```

You cannot use any of the fields in a block parameter because the field `sensor1` uses a different data type in each structure.

- Parameter structures do not support context-sensitive data typing in the generated code. If the parameter structure is tunable in the code, the fields of the structure use the numeric data types that you specify by using either typed expressions or a `Simulink.Bus` object. If you do not use typed expressions or a `Simulink.Bus` object, the fields of the structure use the `double` data type.

## Package Shared Breakpoint and Table Data for Lookup Tables

When you share data between lookup table blocks, consider using `Simulink.LookupTable` and `Simulink.Breakpoint` objects instead of structures to store and group the data. This technique improves model readability by clearly identifying the data as parts of a lookup table and explicitly associating breakpoint data with table data. See “Package Shared Breakpoint and Table Data for Lookup Tables” on page 37-20.

## Create Parameter Structure According to Structure Type from Existing C Code

You can create a parameter structure that conforms to a `struct` type definition that your existing C code defines. Use this technique to:

- Replace existing C code with a Simulink model.
- Integrate existing C code for simulation in Simulink (for example, by using the Legacy Code Tool). For an example, see “Integrate C Function Whose Arguments Are Pointers to Structures”.

- Generate C code (Simulink Coder) that you can compile with existing C code into a single application. For an example, see “Exchange Structured and Enumerated Data Between Generated and External Code” (Embedded Coder).

In MATLAB, store the parameter structure in a parameter object and use a bus object as the data type (see “Control Field Data Types and Characteristics by Creating Parameter Object” on page 37-28). To create the bus object according to your C-code `struct` type, use the `Simulink.importExternalCTypes` function.

## Tune and Experiment with Block Parameter Values

As you construct a model you can experiment with block parameters, such as the coefficients of a Transfer Fcn block, to help you decide which blocks to use. You can simulate the model with different parameter values, and capture and observe the simulation output.

You can change the values of most numeric block parameters during a simulation. To observe the effects, you can visualize the simulation output in real time. This technique allows you to quickly test parameter values while you develop an algorithm. You can visually:

- Tune and optimize control parameters.
- Calibrate model parameters.
- Test control robustness under different conditions.

When you begin a simulation, Simulink first updates the model diagram. This operation can take time for larger models. To test parameter values without repeatedly updating the model diagram, you can tune the parameter values during a single simulation run.

Alternatively, to avoid updating the model diagram, use Fast Restart. For more information about Fast Restart, see “Get Started with Fast Restart” on page 73-5.

If you cannot visually analyze the simulation output in real time, or if you must run many simulations, consider using a programmatic approach to sweeping parameter values. You can capture the simulation output data and perform analysis later. For more information, see “Optimize, Estimate, and Sweep Block Parameter Values” on page 37-52.

For basic information about accessing and setting block parameter values, see “Set Block Parameter Values” on page 37-2.

### Iteratively Adjust Block Parameter Value Between Simulation Runs

This example shows how to prototype a model by changing block parameter values between simulation runs. You can experiment with parameter values and observe simulation results to help you decide which blocks to use and how to build your model.

The example model `sldemo_fuelsys` represents the fueling system of a gasoline engine. A subsystem in the model, `feedforward_fuel_rate`, calculates the fuel demand of the

engine by using the constant number 14.6, which represents the ideal (stoichiometric) ratio of air to fuel that the engine consumes. Two blocks in the subsystem use the number to set the values of parameters.

Suppose that you want to change the design value of the ideal air-to-fuel ratio from 14.6 to 17.5 to observe the effect on the fuel demand. To store the design value in the model, you can modify the value in the block dialog boxes. Alternatively, you can store the value in a variable with a meaningful name, which allows you to reuse the value in the two blocks.

To observe the change in simulation outputs by changing the value in the block dialog boxes:

- 1 Open the example model.  
`sldemo_fuelsys`
- 2 Set the model simulation time from 2000 to 50 for a faster simulation.
- 3 In the model, open the Scope block dialog box.

- 4 Simulate the model. Resize the window in the Scope dialog box to see all of the simulation results.

The scope display shows that throughout the simulation, the `fuel` signal oscillates between approximately 0.9 and 1.6. The `air_fuel_ratio` signal quickly climbs to 15 without overshoot.

- 5 In the model, open the Model Data Editor by selecting **View > Model Data Editor**. In the Model Data Editor, inspect the **Parameters** tab.
- 6 In the model or at the command prompt, navigate to the target subsystem.

```
open_system(...
 'sldemo_fuelsys/fuel_rate_control/fuel_calc/feedforward_fuel_rate')
```

- 7 In the Model Data Editor, use the **Value** column to change the **Constant value** (Value) parameter of the Constant block labeled `rich` from  $1/(14.6*0.8)$  to  $1/(17.5*0.8)$ .

- 8 Similarly, change the **Constant value** parameter of the block labeled `normal` from  $1/14.6$  to  $1/17.5$ .
- 9 Simulate the model.

The scope display shows that the signals now respond differently.

To replace the literal values in the block dialog boxes with a numeric variable:

- 1 Use the Model Data Editor to set the value of the `normal` Constant block to `1/mixture`.
- 2 Set the value of the `rich` block to `1/(mixture*0.8)`.
- 3 While editing the `rich` value, next to `1/(mixture*0.8)`, click the action button  and select **Create**.
- 4 In the **Create New Data** dialog box, set **Value** to `17.5` and click **Create**.

The numeric variable `mixture` appears in the base workspace with value `17.5`. Between simulation runs, you can change the value of `mixture` in the base workspace instead of changing the parameter values in the block dialog boxes.

## Tune Block Parameter Value During Simulation

This example shows how to observe the effect of changing a block parameter value during a simulation. This technique allows you to avoid updating the model diagram between simulation runs and to interactively test and debug your model.

The example model `sldemo_fuelsys` contains a Constant block, Throttle Command, that represents the throttle command. To observe the effect of increasing the magnitude of the command during simulation:

- 1 Open the example model.  
`sldemo_fuelsys`
- 2 In the model, open the Scope block dialog box.

**3** Begin a simulation.

The model is configured to simulate 2000 seconds. During the simulation, the values of the `fuel` and `air_fuel_ratio` signals appear on the scope graph in real time.

**4** In the model, when the status bar indicates approximately 1000 (1000 seconds), click the Pause button  to pause the simulation.**5** In the scope display, the **fuel** graph plots the simulation output prior to the pause time.**6** In the model, select **View > Model Data Editor**.**7** In the Model Data Editor, select the **Parameters** tab.**8** In the model, select the Throttle Command block.**9** In the Model Data Editor, select the `rep_seq_y` row. Make sure that you do not select the `rep_seq_t` row as well.**10** For the `rep_seq_y` row, change the value in the **Value** column from `[10 20 10]` to `[10 30 10]`.**11** Click the Step Forward button  to advance the simulation step by step. Click the button about 15 times or until you see a change in the **fuel** graph in the scope display.

The plot of the signal `fuel` indicates a sharp increase in fuel demand that corresponds to the increased throttle command.

**12** In the model, resume the simulation by clicking the Continue button .

The scope display shows the significant periodic increase in fuel demand, and the periodic reduction in the air-to-fuel ratio, throughout the rest of the simulation.

During the simulation, you must update the model diagram after you change the value of a workspace variable. For more information about updating the model diagram, see “Update Diagram and Run Simulation” on page 1-66.

## Prepare for Parameter Tuning and Experimentation

- Use workspace variables to set block parameter values.

To access the value of a block parameter, such as the **Constant value** parameter of a Constant block, you must navigate to the block in the model and open the block dialog box, search for the block by using the Model Explorer, or use the function `set_param` at the command prompt.

Alternatively, if you set the block parameter value by creating a workspace variable, you can change the value of the variable by using the command prompt, the MATLAB Workspace browser, or the Model Explorer. You can also create a variable to set the same value for multiple block parameters. When you change the variable value, all of the target block parameters use the new value. For more information about accessing and setting block parameter values, see “Set Block Parameter Values” on page 37-2.

- Visualize simulation output.

To observe simulation output in real time while you tune block parameter values, you can use blocks in a model such as the Scope block. You can also capture simulation output at the end of a simulation run, and view the data in the Simulation Data Inspector. For more information, see “Decide How to Visualize Simulation Data” on page 30-2.

- Specify value ranges for block parameters that you expect to tune during simulation.

If you expect another person to use your model and tune the parameter, you can control the allowed tuning values by specifying a range. Also, it is a best practice to specify value ranges for all fixed-point block parameters that you expect to tune. To specify block parameter value ranges, see “Specify Minimum and Maximum Values for Block Parameters” on page 37-69.

- Control simulation duration and pace.

A simulation run can execute so quickly that you cannot tune block parameter values. Also, if you want to change a parameter value at a specific simulation time, you must learn to control the simulation pace. You can configure the simulation to run for a specific duration or to run forever, and pause and advance the simulation when you want to. For more information, see “Simulate a Model Interactively” on page 25-2 and “Run Simulations Programmatically” on page 26-2.

## **Interactively Tune Using Dashboard Blocks**

You can tune block parameter values by adding blocks from the Dashboard library to your model. Dashboard blocks allow you to adjust the parameter values of other blocks, and to observe simulation output in real time, by interacting with knobs, switches, and readouts that mimic the appearance of industrial controls. You can interact with the Dashboard blocks without having to locate the target block parameters in the model. For more information, see “Tune and Visualize Your Model with Dashboard Blocks” on page 29-131.

## Which Block Parameters Are Tunable During Simulation?

Nontunable block parameters are parameters whose values you cannot change during simulation. For example, you cannot tune the **Sample time** block parameter. If a parameter is nontunable, you cannot change its value during simulation by changing the value in the block dialog box or by changing the value of a workspace variable.

Nontunable block parameters include:

- Sample times.
- Parameters that control the appearance or structure of a block such as the number of inputs of a Sum block.
- Priority, which allows you to control block execution order.
- Parameters that control the block algorithm, such as the **Integrator method** parameter of a Discrete-Time Integrator block.

To determine whether a block parameter is tunable during simulation, use one of these techniques:

- Begin a simulation and open the block dialog box. If the value of the target block parameter is gray during simulation, you cannot tune the parameter.
- At the command prompt, determine whether the flags `read-write` and `read-only-if-compiled` describe the parameter.

**1** Select the block in the model.

**2** At the command prompt, use the function `get_param` to return information about the block dialog box parameters. The function returns a structure that has a field for each parameter in the block dialog box.

```
paramInfo = get_param(gcf, 'DialogParameters');
```

Alternatively, rather than locating and selecting the block in the model, you can replace `gcb` with the block path, such as `'myModel/mySubsystem/myBlock'`.

**3** View the information about the target block parameter. For example, to view the information about the **Sample time** parameter of a block, view the value of the field `SampleTime`, which is also a structure.

```
paramInfo.SampleTime
```

```
ans =
```

```
Prompt: 'Sample time:'
Type: 'string'
Enum: {}
Attributes: {'read-write' 'read-only-if-compiled' 'dont-eval'}
```

- 4 Inspect the structure's `Attributes` field, whose value is a cell array of character vectors. If the flag `read-write` appears in the cell array, you can modify the parameter value. However, if the flag `read-only-if-compiled` also appears in the cell array, you cannot modify the parameter value during simulation.

If you use masks to create custom interfaces for blocks and subsystems, you can control the tunability of individual mask parameters. If you use model arguments to parameterize referenced models, you can tune the value of each model argument in each Model block.

## Why Did the Simulation Output Stay the Same?

If the output of your simulation does not change after you change a parameter value, use these troubleshooting techniques:

- Locate the definition of a workspace variable.

If you use a workspace variable to set block parameter values, determine where the variable definition resides. For example, if you define a variable `myVar` in a model workspace and use it to set a block parameter value in the model, you cannot change the parameter value by changing the value of a variable named `myVar` in the base workspace. You must access the variable definition in the model workspace.

To locate the definition of a variable, while editing the value of a block parameter that uses the variable, click the nearby action button  and select **Explore**. A dialog box opens, such as the Model Explorer, which displays the definition of the variable in the appropriate workspace. For more information about how models use variables, see “Symbol Resolution” on page 62-174.

- Specify value ranges for fixed-point parameters that you want to tune during simulation.

If the block parameter you want to tune uses a fixed-point data type with best-precision scaling, specify a minimum and maximum value for the parameter so that Simulink can calculate and apply an appropriate scaling. If you do not specify a value range, Simulink might apply a scaling that excludes the tuning values that you want to use. To specify value ranges, see “Specify Minimum and Maximum Values for Block Parameters” on page 37-69.

- Update the model diagram during a simulation run. If you use a workspace variable to set the value of one or more block parameters, after you change the value of the variable during a simulation, you must update the model diagram.

To learn how to update a model diagram, see “Update Diagram and Run Simulation” on page 1-66.

## **Tunability Considerations and Limitations for Other Modeling Goals**

### **Referenced Models**

When you use Model blocks, these parameter tunability limitations apply:

- If you set the simulation mode of a Model block to an accelerated mode or if you simulate the parent model in an accelerated mode, you cannot tune block parameters in the referenced model during simulation. However, if the referenced model uses variables in the base workspace or a data dictionary to set parameter values, you can tune the values of the variables.
- Suppose you use a MATLAB variable or `Simulink.Parameter` object in a model workspace to set the value of a block parameter in a model. If you use a Model block to refer to this model:
  - And you set the simulation mode of the Model block to an accelerated mode or simulate the parent model in an accelerated mode, you cannot change the value of the variable or object during the simulation.
  - When you simulate the parent model in an accelerated mode, changing the value of the variable or object between simulation runs causes Simulink to regenerate code.
  - And you use additional Model blocks to refer to the model multiple times in the parent model, you can choose a different simulation mode for each Model block. If at least one block uses normal simulation mode and any other block uses a different simulation mode, you cannot change the value of the variable or object during simulation. Also, when you simulate the parent model with fast restart on, you cannot change the value of the variable or object between fast-restart simulation runs.

As a workaround, move the variable or object to the base workspace or a data dictionary.

## Accelerator and SIL/PIL Simulations

These tunability limitations apply to accelerator, rapid accelerator, SIL, and PIL simulations:

- Suppose you use a MATLAB variable or `Simulink.Parameter` object in a model workspace to set the value of a block parameter in a model. If you use the `sim` function to simulate the model in rapid accelerator mode and set the `RapidAcceleratorUpToDateCheck` pair argument to `'off'`, you cannot use the `RapidAcceleratorParameterSets` pair argument to specify different values for the variable or object. The structure returned by `Simulink.BlockDiagram.buildRapidAcceleratorTarget` does not contain information about the variable or object.
- If a block parameter value references workspace variables, you cannot change the block parameter value during rapid accelerator simulation, such as by using the function `set_param`. Instead, you can tune the values of the referenced variables.

Alternatively, use parameter sets to tune runtime parameters in between rapid accelerator simulations. For more information, see “Tuning Runtime Parameters” on page 35-10.

For more information about parameter tunability during accelerated simulations, see “Tuning Runtime Parameters” on page 35-10 and “sim in parfor with Rapid Accelerator Mode” on page 26-16. For more information about parameter tunability during SIL and PIL simulations, see “Tunable Parameters and SIL/PIL” (Embedded Coder).

## Fast Restart

For more information about parameter tunability when you use fast restart, see “Get Started with Fast Restart” on page 73-5 .

## Code Generation and Simulation of External Programs

Parameters that are tunable during simulation can appear as nontunable inlined parameters in the generated code. If you simulate an external program by using SIL, PIL, or External mode simulation, parameter tunability during the simulation and between simulation runs can depend on your code generation settings.

To control parameter tunability in the generated code, you can adjust the code generation settings for a model by using the configuration parameter **Default parameter behavior**. You can also adjust settings for individual MATLAB variables, `Simulink.Parameter`

objects, and other parameter objects. For more information, see “Configure Data Accessibility for Rapid Prototyping” (Simulink Coder).

### **Stateflow Charts**

To debug a Stateflow chart by changing data during simulation, see “Change Data Values During Simulation” (Stateflow).

## Optimize, Estimate, and Sweep Block Parameter Values

When you sweep one or more parameters, you change their values between simulation runs, and compare and analyze the output signal data from each run. Use parameter sweeping to tune control parameters, estimate unknown model parameters, and test the robustness of a control algorithm by taking into consideration uncertainty in the real-world system.

You can sweep block parameter values or the values of workspace variables that you use to set the parameter values. Use the Model Data Editor (**View > Model Data Editor**) **Parameters** tab, the Property Inspector (**View > Property Inspector**), the command prompt, or scripts to change parameter values between simulation runs.

If you want to repeatedly change the value of a block parameter, consider creating a variable in a workspace. You can use the Model Explorer or programmatic commands to change the value of the variable instead of locating or identifying the block in the model. Also, several features and products that facilitate parameter optimization, estimation, and sweeping require that you set block parameter values by creating workspace variables.

To learn how to manipulate parameter values during the iterative process of creating a model, see “Tune and Experiment with Block Parameter Values” on page 37-42.

For basic information about accessing and setting block parameter values as you design a model, see “Set Block Parameter Values” on page 37-2. For basic information about programmatically simulating a model, such as by using a script, see “Run Simulations Programmatically” on page 26-2.

### Sweep Parameter Value and Inspect Simulation Results

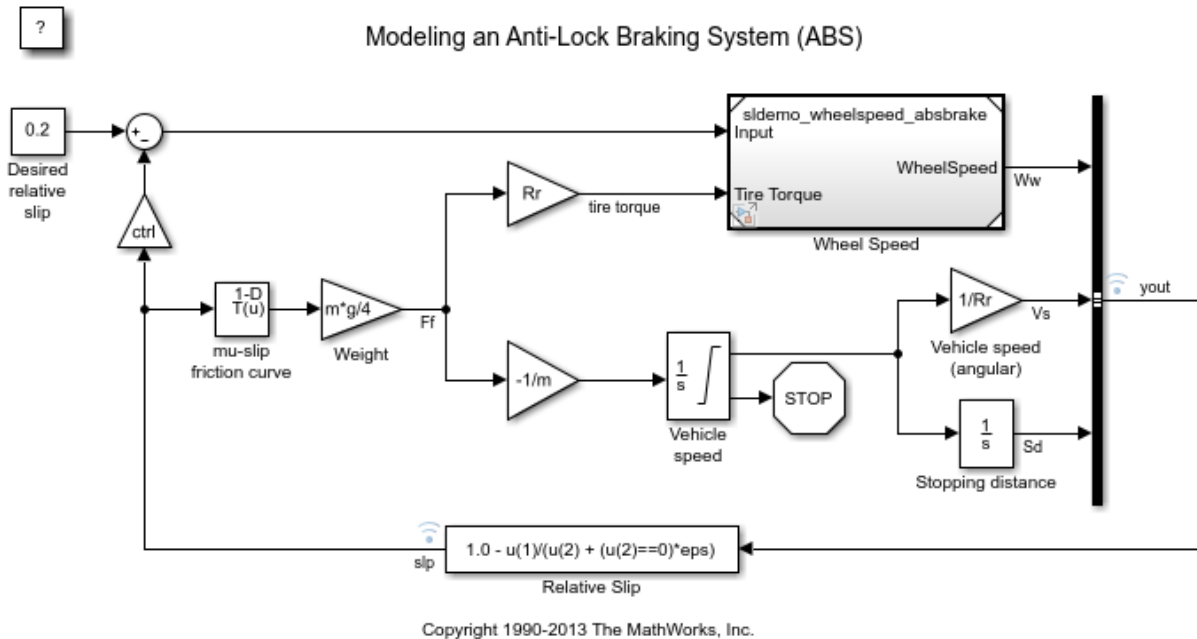

This example shows how to change a block parameter value between multiple programmatic simulation runs. Use this technique to determine an optimal parameter value by comparing the output signal data of each run.

The example model `sldemo_absbrake` uses a Constant block to specify a slip setpoint for an anti-lock braking system. Simulate the model with two different slip setpoint values, 0.24 and 0.25, and compare the output wheel speed of each simulation run.

To store the setpoint value, create a variable in the base workspace. This technique enables you to assign a meaningful name to the value.

Open the example model.

```
open_system('sldemo_absbrake');
```

In the model, select **View > Model Data Editor**.

In the Model Data Editor, select the **Signals** tab.

Set the **Change view** drop-down list to Instrumentation. The **Log Data** column shows that the signals `yout` (which is a virtual bus) and `slp` are configured for logging. When you simulate the model, you can collect and later inspect the values of these signals by using the Simulation Data Inspector.

In the Model Data Editor, select the **Parameters** tab. Set **Change view** to Design.

In the model, select the Constant block labeled `Desired relative slip`. The Model Data Editor highlights the row that corresponds to the **Constant value** parameter of the block.

Use the **Value** column to set the parameter value to `relSlip`.

While editing the value, next to `relSlip`, click the action button (with three vertical dots) and select **Create**.

In the Create New Data dialog box, set **Value** to `0.2` and click **Create**. A variable, whose value is `0.2`, appears in the base workspace. The model now acquires the relative slip setpoint from this variable.

Alternatively, you can use these commands at the command prompt to create the variable and configure the block:

```
relSlip = 0.2;
set_param('sldemo_absbrake/Desired relative slip', 'Value', 'relSlip')
```

At the command prompt, create an array to store the two experimentation values for the relative slip setpoint, `0.24` and `0.25`.

```
relSlip_vals = [0.24 0.25];
```

Create a `Simulink.SimulationInput` object for each simulation that you want to run (in this case, two). Store the objects in a single array variable, `simIn`. Use the `setVariable` method of each object to identify each of the two experimentation values.

```
for i = 1:length(relSlip_vals)
 simIn(i) = Simulink.SimulationInput('sldemo_absbrake');
 simIn(i) = setVariable(simIn(i), 'relSlip', relSlip_vals(i));
end
```

Use the `sim` function to simulate the model. Optionally, store the output in a variable named `simOutputs`.

```
simOutputs = sim(simIn);
```

```
[03-Mar-2019 16:35:49] Running simulations...
[03-Mar-2019 16:35:51] Completed 1 of 2 simulation runs
[03-Mar-2019 16:35:52] Completed 2 of 2 simulation runs
```

The model streams the logged signals, `yout` and `slp`, to the Simulation Data Inspector. You can view the signal data in the Simulation Data Inspector.

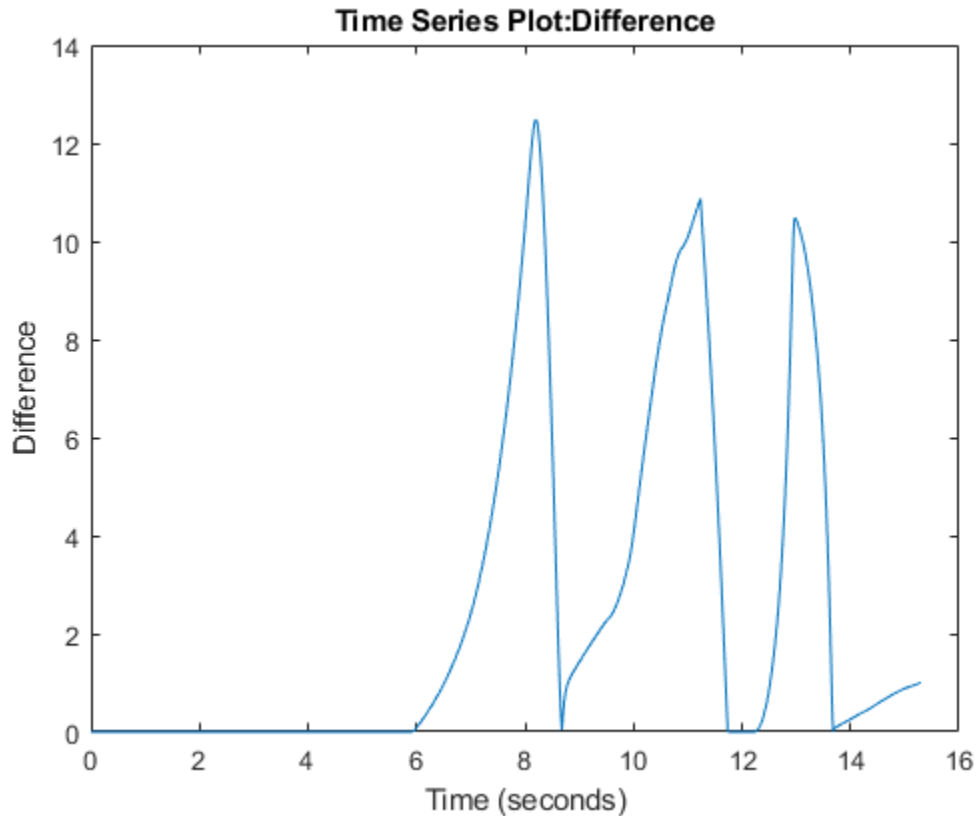

Compare the output data of the two latest simulation runs.

```
runIDs = Simulink.sdi.getAllRunIDs();
runResult = Simulink.sdi.compareRuns(runIDs(end-1), runIDs(end));
```

Plot the difference between the values of the Ww signal (which is an element of the virtual bus signal yout) by specifying the result index 1.

```
signalResult = getResultByIndex(runResult,1);
plot(signalResult.Diff);
```

## Store Sweep Values in Simulink.SimulationInput Objects

When you write a script to run many simulations, create an array of `Simulink.SimulationInput` objects (one object for each simulation that you want to run). Use the `setVariable` and `setBlockParameter` methods of each object to identify the parameter values to use for the corresponding simulation run. With this technique,

you avoid having to use the `set_param` function to modify block parameter values and assignment commands to modify workspace variable values between simulation runs.

For more information about using `Simulink.SimulationInput` objects to run multiple simulations, see `sim`.

### Sweep Nonscalars, Structures, and Parameter Objects

If you use nonscalar variables, structure variables, or `Simulink.Parameter` objects to set block parameter values, use the `setVariable` method of each `Simulink.SimulationInput` object. Refer to the examples in the table.

| Scenario                                                                                                                                               | Example                                                              |
|--------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------|
| MATLAB variable, <code>myArray</code> , whose value is an array. You want to set the third element in the array (assuming one-based indexing).         | <code>setVariable(simIn, 'myArray(3)', 15.23)</code>                 |
| MATLAB variable, <code>myStruct</code> , that has a field named <code>field1</code> .                                                                  | <code>setVariable(simIn, 'myStruct.field1', 15.23)</code>            |
| Parameter object, <code>myParam</code> , whose <code>Value</code> property is a scalar.                                                                | <code>setVariable(simIn, 'myParam.Value', 15.23)</code>              |
| Parameter object, <code>myArrayParam</code> , whose <code>Value</code> property is an array. You want to set the third element in the array.           | <code>setVariable(simIn, 'myArrayParam.Value(3)', 15.23)</code>      |
| Parameter object, <code>myStructParam</code> , whose <code>Value</code> property is a structure. The structure has a field named <code>field1</code> . | <code>setVariable(simIn, 'myStructParam.Value.field1', 15.23)</code> |

### Sweep Value of Variable in Model Workspace

If you use the model workspace to store variables, when you use the `setVariable` method of a `Simulink.SimulationInput` object to modify the variable value, use the `Workspace` pair argument to identify the containing model:

```
setVariable(simIn, 'myVar', 15.23, 'Workspace', 'myModel')
```

## Capture and Visualize Simulation Results

Each simulation run during a parameter sweep produces outputs, such as signal values from Outport blocks and from logged signals.

You can capture these outputs in variables and objects for later analysis. For more information, see “Export Simulation Data” on page 64-3.

To visualize simulation output data so you can compare the effect of each parameter value, see “Decide How to Visualize Simulation Data” on page 30-2.

## Improve Simulation Speed

To perform many simulations that each use different parameter values, you can use accelerated simulation modes. For larger models, accelerated simulations take less time to execute than normal simulations. If you also have Parallel Computing Toolbox, you can use the multiple cores of your processor to simultaneously execute simulations. Use arguments of the `sim` and `parsim` functions.

To improve the simulation speed of your model by using accelerated simulations and other techniques, see “Optimize Performance”. For examples and more information, see “Run Multiple Simulations” on page 27-2.

## Sweep Parameter Values to Test and Verify System

If you have Simulink Test, you can confirm that your model still meets requirements when you use different parameter values. Parameter overrides and test iterations enable you to set different parameter values for each test case. For more information, see “Parameter Overrides” (Simulink Test) and “Test Iterations” (Simulink Test).

## Estimate and Calibrate Model Parameters

If you have Simulink Design Optimization, you can estimate model parameter values so that simulation outputs closely fit the data that you measure in the real world. Use this technique to estimate the real-world values of parameters in a plant model, which represents the dynamics of a real-world system, when you cannot directly measure the values. This estimation improves the accuracy of the plant model. For more information, see “Estimate Parameters from Measured Data” (Simulink Design Optimization).

## **Tune and Optimize PID and Controller Parameters**

If you have Simulink Control Design, you can use PID Tuner to tune the parameters of a PID Controller block. For more information, see “PID Controller Tuning in Simulink” (Simulink Control Design).

If you have Simulink Design Optimization, you can optimize control parameter values so that simulation outputs meet response requirements that you specify. For more information, see “Design Optimization to Meet Step Response Requirements (GUI)” (Simulink Design Optimization).

## Control Block Parameter Data Types

A block parameter, such as the **Gain** parameter of a Gain block, has a data type in the same way that a signal has a data type (see “Control Signal Data Types” on page 62-8). MATLAB variables, `Simulink.Parameter` objects, and other parameter objects that you use to set block parameter values also have data types. Control block parameter data types to:

- Accurately simulate the execution of your control algorithm on hardware.
- Generate efficient code.
- Integrate the generated code with your custom code.
- Avoid using data types that your target hardware does not support.

### Reduce Maintenance Effort with Data Type Inheritance

By default, block parameters, numeric MATLAB variables that use the data type `double`, and `Simulink.Parameter` objects acquire a data type through inherited and context-sensitive data typing. For example, if the input and output signals of a Gain block use the data type `single`, the **Gain** parameter typically uses the same data type. If you use a `Simulink.Parameter` object to set the value of the block parameter, by default, the object uses the same data type as the parameter. You can take advantage of this inheritance to avoid explicitly specifying data types for parameters.

Some inheritance rules choose a parameter data type other than the data type that the corresponding signals use. For example, suppose that:

- The input and output signals of a Gain block use fixed-point data types with binary-point-only scaling.
- On the **Parameter Attributes** tab, **Parameter data type** is set to `Inherit: Inherit via internal rule` (the default).
- On the **Parameter Attributes** tab, you specify a minimum and maximum value for the parameter by using **Parameter minimum** and **Parameter maximum**.

The data type setting `Inherit: Inherit via internal rule` can cause the block to choose a different data type, with a different word length or scaling, than the data type that the signals use. The minimum and maximum values that you specified for the parameter influence the scaling that the block chooses.

When you select internal rules (Inherit: Inherit via internal rule) to enable Simulink to choose data types, before simulating or generating code, configure the characteristics of your target hardware. The internal rules can use these settings to choose data types that yield efficient generated code.

### Context-Sensitive Data Typing

When you use a MATLAB variable or `Simulink.Parameter` object to set the value of a block parameter, you can configure the variable or parameter object to use context-sensitive data typing. When you simulate or generate code, the variable or parameter object uses the same data type as the block parameter. With this technique, you can match the data type of the variable or parameter object with the data type of the block parameter. To control the data type of the block parameter and the variable or object, you specify only the data type of the block parameter.

To use context-sensitive data typing, set the value of a MATLAB variable to a double value. For a `Simulink.Parameter` object, set the `Value` property by using a double value and set the `DataType` property to `auto` (the default).

### Context-Sensitive Data Typing for Structure Fields

As described in “Organize Related Block Parameter Definitions in Structures” on page 37-26, you can organize multiple block parameter values into a structure.

The fields of parameter structures do not support context-sensitive data typing. However, to match the data type of a field with the data type of another data item in a model, you can use a bus object and a data type object.

- 1 Use a `Simulink.Bus` object as the data type of the structure.
- 2 Use a `Simulink.AliasType` or `Simulink.NumericType` object as the data type of the element in the bus object and as the data type of the target data item.

## Techniques to Explicitly Specify Parameter Data Types

Many blocks supported for discrete-time simulation and code generation (such as those in the built-in Discrete library) enable you to explicitly specify parameter data types. For example, in an **n-D Lookup Table** block dialog box, on the **Data Types** tab, you can specify a data type for the lookup table data by using the **Table data** parameter. In a Gain block dialog box, use the **Parameter Attributes** tab to set **Parameter data type**, which controls the data type of the **Gain** parameter.

Some blocks, such as those in the Continuous library, do not enable you to specify parameter data types. These block parameters use internal rules to choose a data type. To indirectly control the data type of such a parameter, apply the data type to a `Simulink.Parameter` object instead.

When you use a `Simulink.Parameter` object or other parameter object to set the value of a block parameter, you can use the `DataType` property of the object to specify a data type.

If you use model arguments, you can specify a data type:

- For the model argument that you store in the model workspace.
- With some blocks (such as those in the Discrete library), for the block parameter that uses the model argument.
- For the argument value that you specify in a Model block.

The default settings for these data types typically use inheritance and context-sensitive data typing. For example, the default value of the `DataType` property of a `Simulink.Parameter` object is `auto`, which causes the parameter object to acquire a data type from the block parameter or parameters that use the object.

To explicitly specify a data type, you can use the Data Type Assistant in block dialog boxes and property dialog boxes. For information about the Data Type Assistant, see “Specify Data Types Using Data Type Assistant” on page 62-38.

## Use the Model Data Editor for Batch Editing

Using the Model Data Editor (**View > Model Data Editor**), you can specify the same data type for multiple block parameters simultaneously. On the **Parameters** tab, set the **Change view** drop-down list to **Design** and specify data types by using the **Data Type** column.

For more information about the Model Data Editor, see “Configure Data Properties by Using the Model Data Editor” on page 62-179.

## Calculate Best-Precision Fixed-Point Scaling for Tunable Block Parameters

When you apply fixed-point data types to a model, you can use the Data Type Assistant and the Fixed-Point Tool to calculate best-precision scaling for tunable block parameters.

A block parameter, `Simulink.Parameter` object, or other parameter object is tunable if it appears in the generated code as a variable stored in memory.

The chosen scaling must accommodate the range of values that you expect to assign to the parameter. To enable the tools to calculate an appropriate scaling, specify the range information in the block or in a parameter object. Then, use one of these techniques to calculate the scaling:

- Use the Fixed-Point Tool to autoscale the entire model or subsystem. The tool can propose and apply fixed-point data types for data items including block parameters, `Simulink.Parameter` objects, signals, and states.
- Configure individual block parameters or parameter objects to calculate their own scaling.

When you later change value ranges for parameters, this technique enables you or the model to recalculate the scaling without having to autoscale the entire model.

However, if changing the value range of the parameter also changes the value range of an associated signal, you must manually calculate and apply a new scaling for the signal or use the Fixed-Point Tool to autoscale the model or subsystem.

For basic information about fixed-point data types, block parameters, and other tools and concepts, use the information in the table.

## Autoscale Entire Model by Using the Fixed-Point Tool

You can use the Fixed-Point Tool to autoscale data items in your model, including tunable parameters and signals whose values depend on those parameters. If you use this technique:

- To configure parameters as tunable, use parameter objects (for example, `Simulink.Parameter`) instead of the Model Parameter Configuration dialog box. The Fixed-Point Tool can autoscale parameter objects, but cannot autoscale numeric variables that you select through the Model Parameter Configuration dialog box.

If your model already uses the Model Parameter Configuration dialog box, use the `tunablevars2parameterobjects` function to create parameter objects instead.

- When you use `Simulink.Parameter` objects to set block parameter values, specify the value range information in the objects instead of the blocks. The Fixed-Point Tool uses the range information in each object to propose a data type for that object.
- To enable the tool to autoscale parameter values that you store as fields of a structure, use a `Simulink.Bus` object as the data type of the entire structure. Specify the range information for each field by using the `Min` and `Max` properties of the corresponding element in the bus object. The tool can then apply a data type to each element by using the `DataType` property.

To use a bus object as the data type of a parameter structure, see “Control Field Data Types and Characteristics by Creating Parameter Object” on page 37-28.

- Before you apply the data types that the Fixed-Point Tool proposes, clear the proposals for parameters and parameter objects whose data types you do not want the tool to change. For example, clear the proposals for these entities:
  - Parameter objects that you import into the generated code from your own handwritten code by applying a storage class such as `ImportedExtern`.
  - `Simulink.Parameter` model arguments in a model workspace.

Alternatively, before autoscaling the model, consider replacing these parameter objects with numeric MATLAB variables to prevent the Fixed-Point Tool from autoscaling them.

Allowing the tool to autoscale model arguments can increase the risk of unintentional data type mismatches between the model argument values (which you specify in Model blocks in a parent model), the model arguments in the model workspace, and the client block parameters in the model.

- Parameter objects whose `DataType` property is set to `auto` (context-sensitive). Clear the proposals if you want the parameter objects to continue to use context-sensitive data typing.

For more information about using the Fixed-Point Tool to autoscale Simulink.Parameter objects, see “Autoscaling Data Objects Using the Fixed-Point Tool” (Fixed-Point Designer).

### Calculate Best-Precision Scaling for Individual Parameters

You can configure a block parameter or Simulink.Parameter object to calculate its own best-precision scaling. First, specify value range information for the target parameter or parameter object. Then, use the Data Type Assistant or the function `fixdt` to apply a data type to the parameter or object. Use these techniques when you do not want to use the Fixed-Point Tool to autoscale the model.

#### Enable Block Parameter to Automatically Calculate Best-Precision Scaling

You can enable the parameters of some blocks (typically blocks in the Discrete library) to automatically calculate best-precision fixed-point scaling. Use this technique to store the range and data type information in the model instead of a parameter object. When you use this technique, if you later change the range information, the block parameter automatically recalculates best-precision scaling.

In the block dialog box, use the function `fixdt` to specify a fixed-point data type with unspecified scaling. For example, use best-precision scaling for lookup table data, and store the data in a 16-bit word:

- 1 On the **Data Types** tab of an n-D Lookup Table block, under the **Minimum** and **Maximum** columns, specify a value range for the elements of the table data.
- 2 Under the **Data Type** column, set the table data type to `fixdt(1,16)`.
- 3 If you use a tunable Simulink.Parameter object to set the value of the table data parameter, set the `DataType` property of the object to `auto`. In the generated code, the parameter object uses the same scaling as the block parameter.

When you simulate or generate code, the lookup table data uses a signed 16-bit fixed-point data type whose binary-point scaling depends on the range information that you specify. The calculated scaling allows the fixed-point type to represent values that lie within the range. If you later change the minimum or maximum values, the block recalculates the scaling when you simulate or generate code.

### Calculate Scaling for Parameter Object

If you use a `Simulink.Parameter` object to set the values of multiple block parameters, and if the block parameters use different data types (including different fixed-point scaling), you cannot set the `DataType` property of the object to `auto` (the default). Instead, you can calculate best-precision fixed-point scaling for the parameter object by specifying range and data type information in the object. You can also use this technique to store range and data type information in a parameter object instead of a block dialog box. When you use this technique, if you later change the range information, you must recalculate the best-precision scaling by using the Data Type Assistant.

Suppose that you create a parameter object to represent the value `15.25`, and that the design range of the value is between `0.00` and `32.00`. To calculate best-precision scaling, use the Data Type Assistant.

- 1 At the command prompt, create a parameter object in the base workspace whose value is `15.25`.  

```
myParam = Simulink.Parameter(15.25);
```
- 2 In the MATLAB Workspace browser, double-click the object `myParam`. The property dialog box opens.
- 3 Specify range information in the object. For example, set **Minimum** to `0.00` and **Maximum** to `32.00`.
- 4 Set **Data type** to `fixdt(0,16,0)`.
- 5 Expand the Data Type Assistant and click **Calculate Best-Precision Scaling**.

The data type changes from `fixdt(0,16,0)` to `fixdt(0,16,10)`.

The calculated scaling (a fraction length of 10 bits) enables the fixed-point data type to represent parameter values that lie within the range that you specified.

If you specify range and data type information in a parameter object, consider removing the range and data type information from the blocks that use the object. Some tools, such as the Fixed-Point Tool, ignore the range information that you specify in the block and use only the information in the parameter object. Removing the information from the block prevents confusion and user errors.

For example, on the **Parameter Attributes** tab of a Gain block dialog box, set **Parameter minimum** and **Parameter maximum** to `[]`. Set **Parameter data type** to an inherited data type such as `Inherit: Inherit from 'Gain'` so that the block parameter uses the same data type as the parameter object.

## Detect Numerical Accuracy Issues Due to Quantization and Overflow

When the data type of a block parameter, MATLAB variable, or parameter object cannot represent the value that you specify, the data type quantizes the value, compromising numerical accuracy. For example, the 32-bit floating-point data type `single` (`float` in C code) cannot exactly represent the parameter value `1.73`. When the real-world value of a data item lies outside the range of values that the data type can represent, overflow can cause loss of information.

To detect these issues, use the diagnostic configuration parameters under **Configuration Parameters > Diagnostics > Data Validity > Parameters**. Set the values of these diagnostic configuration parameters to `warning` or `error`:

- **Detect downcast**
- **Detect precision loss**
- **Detect underflow**
- **Detect overflow**

## Reuse Custom C Data Types for Parameter Data

In a model, you can create parameter data that conform to custom C data types, such as structures, that your existing C code defines. Use these data to:

- Replace existing C code with a Simulink model.
- Integrate C code for simulation in Simulink (for example, by using the Legacy Code Tool).
- Prepare to generate code (Simulink Coder) that you can integrate with existing code.

Use these techniques to match your custom data types:

- For a structure type, create a `Simulink.Bus` object. Use the object as the data type for a structure that you store in a `Simulink.Parameter` object. See “Organize Related Block Parameter Definitions in Structures” on page 37-26.
- For an enumeration, create an enumeration class and use it as the data type for block parameters. See “Use Enumerated Data in Simulink Models” on page 63-8.

- To match a typedef statement that represents an alias of a primitive, numeric data type, use a `Simulink.AliasType` object as the data type for block parameters. See `Simulink.AliasType`.

To create these classes and objects, you can use the function `Simulink.importExternalCTypes`.

If a MATLAB Function block or Stateflow chart in your model uses an imported enumeration or structure type, configure the model configuration parameters to include (`#include`) the type definition from your external header file. See “Control Imported Bus and Enumeration Type Definitions” on page 43-167 (for a MATLAB Function block) and “Access Custom Code Variables and Functions in Stateflow Charts” (Stateflow) and “Integrate Custom Structures in Stateflow Charts” (Stateflow) (for a chart).

## Data Types of Mathematical Expressions

If you specify a block parameter using a mathematical expression, the block determines the final parameter data type using a combination of MATLAB and Simulink data typing rules.

Suppose that you define two parameter objects `int8Param` and `doubleParam`, and use the objects to specify the **Constant value** parameter in a Constant block.

```
int8Param = Simulink.Parameter(3);
int8Param.DataType = 'int8';

doubleParam = Simulink.Parameter(9.36);
doubleParam.DataType = 'double';
```

The Constant block determines the data type of the **Constant value** parameter using these steps:

- 1 Each parameter object casts the specified numeric value to the specified data type.

| Parameter object | Data type | Numeric value | Result       |
|------------------|-----------|---------------|--------------|
| int8Param        | int8      | 3             | int8(3)      |
| doubleParam      | double    | 9.36          | double(9.36) |

- 2 The block evaluates the specified expression, `int8Param * doubleParam`, using MATLAB rules.

An expression that involves a `double` data type and a different type returns a result of the different type. Therefore, the result of the expression `int8(3) * double(9.36)` is `int8(28)`.

If you use an expression to set the value of a parameter object (such as `Simulink.Parameter`), parameter objects used in the expression follow different data typing rules. The `auto` setting of the `DataType` property has a slightly different meaning. See “Set Variable Value by Using a Mathematical Expression” on page 37-14.

## Block Parameter Data Types in the Generated Code

For more information about controlling parameter data types in the generated code, see “Parameter Data Types in the Generated Code” (Simulink Coder).

### Related Examples

- “Set Block Parameter Values” on page 37-2
- “Specify Minimum and Maximum Values for Block Parameters” on page 37-69
- “Tune and Experiment with Block Parameter Values” on page 37-42
- “Data Validity Diagnostics Overview”

## Specify Minimum and Maximum Values for Block Parameters

You can protect your model design by preventing block parameters from using values outside of a range. For example, if the value of a parameter that represents the angle of an aircraft aileron cannot feasibly exceed a known magnitude, you can specify a design maximum for the parameter in the model.

Fixed-Point Designer enables Simulink to use your range information to calculate best-precision fixed-point scaling for:

- Tunable parameters.
- Signals, by taking into consideration the range of values that you intend to assign to tunable parameters.

For basic information about block parameters, see “Set Block Parameter Values” on page 37-2.

### Specify Parameter Value Ranges

When you specify a value range for a block parameter, typically, you can choose to store the information in the block (the model file) or in an external variable or parameter object. Choose a technique based on your modeling goals.

- Use other parameters of the same block, if available. For example, you can control the value range of the **Gain** parameter of a Gain block by using the **Parameter minimum** and **Parameter maximum** parameters in the **Parameter Attributes** tab in the block dialog box. For other blocks, such as n-D Lookup Table and PID Controller, use the **Data Types** tab.

Use this technique to:

- Store the range information in the model file.
- Store the range information when you store fixed-point data type information in the block (for example, by setting the **Parameter data type** parameter of a Gain block to a fixed-point type, including best-precision scaling). This technique more clearly associates the range information with the data type information.

- Use parameter objects (for example, `Simulink.Parameter`) to set the parameter value. You can specify the range information in the object, instead of the block, by using the `Min` and `Max` properties of the object.

Use this technique to:

- Specify range information for blocks that cannot store minimum or maximum information, for example, many blocks in the Continuous library.
- Specify range information for a single value that you share between multiple block parameters (see “Share and Reuse Block Parameter Values by Creating Variables” on page 37-13). Instead of using a numeric MATLAB variable, use a parameter object so that you can specify the `Min` and `Max` properties.
- Store the range information when you store fixed-point data type information in a parameter object (by setting the `DataType` property to a fixed-point type instead of `auto`). This technique more clearly associates the range information with the data type information.

If you specify the range information in a parameter object, consider removing the range information from the block. For example, on the **Parameter Attributes** tab of a Gain block dialog box, set **Parameter minimum** and **Parameter maximum** to `[]`. Some tools, such as the Fixed-Point Tool, use the range information that you specify in the block only if you do not specify the range information in the parameter object. If you specify the range information in the parameter object, the tools ignore the range information that you specify in the block.

For basic information about creating and using data objects, see “Data Objects” on page 62-75.

### Specify Valid Range Information

Specify a minimum or maximum as an expression that evaluates to a scalar, real number with `double` data type. For example, you can specify a minimum value for the **Gain** parameter in a Gain block by setting **Parameter minimum**:

- A literal number such as `98.884`. Implicitly, the data type is `double`.
- A numeric workspace variable (see “Share and Reuse Block Parameter Values by Creating Variables” on page 37-13) whose data type is `double`. Use this technique to share a minimum or maximum value between multiple data items.

However, you cannot use variables to set the `Min` or `Max` properties of a parameter object.

To leave the minimum or maximum of a block parameter or parameter object unspecified, use an empty matrix `[]`, which is the default value.

### **Specify Range Information for Nonscalar Parameters**

If the value of a block parameter is a vector or matrix, the range information that you specify applies to each element of the vector or matrix. If the value of any of the elements is outside the specified range, the model generates an error.

If the value of a block parameter is a structure or a field of a structure, specify range information for the structure fields by creating a `Simulink.Parameter` object whose data type is a `Simulink.Bus` object. Specify the range information by using the properties of the signal elements in the bus object. For more information, see “Control Field Data Types and Characteristics by Creating Parameter Object” on page 37-28.

### **Specify Range Information for Complex-Valued Parameters**

If the value of a block parameter is complex (i), the range information that you specify applies separately to the real part and to the imaginary part of the complex number. If the value of either part of the number is outside the range, the model generates an error.

### **Specify Ranges for Multiple Parameters by Using the Model Data Editor**

Using the Model Data Editor (**View > Model Data Editor**), you can specify value ranges for multiple block parameters and variables with a searchable, sortable table. On the **Parameters** tab, set the **Change view** drop-down list to **Design** and specify values in the **Min** and **Max** columns.

For more information about the Model Data Editor, see “Configure Data Properties by Using the Model Data Editor” on page 62-179.

### **Restrict Allowed Values for Block Parameters**

To protect your design by preventing block parameters from using values outside of a range, you can specify the minimum and maximum information by using other parameters of the same block. If you or your users set the value of the target parameter outside the range that you specify, the model generates an error.

Whether a block allows you to specify a value range for a parameter, consider using a parameter object (for example, `Simulink.Parameter`) to set the value of the target parameter. Use the properties of the object to specify the range information. This

technique helps you to specify range information for a variable that you use to set multiple block parameter values.

## **Specify Range Information for Tunable Fixed-Point Parameters**

When you use fixed-point data types in your model, you can enable Simulink to choose a best-precision scaling for block parameters and `Simulink.Parameter` objects. If you intend to tune such a parameter by changing its value during simulation or during execution of the generated code, the fixed-point scaling chosen by Simulink must accommodate the range of values that you expect to assign to the parameter.

Also, if you expect to change the value of a parameter, signal data types in the model must accommodate the corresponding expanded range of possible signal values. If you use the Fixed-Point Tool to propose and apply fixed-point data types for a model, to allow the tool to accurately autoscale the signals, specify range information for tunable parameters.

To specify range information for tunable parameters, see “Calculate Best-Precision Fixed-Point Scaling for Tunable Block Parameters” on page 37-61. To learn how the Fixed-Point Tool autoscales signals by taking into account the value ranges of tunable parameters, see “Derive Ranges for Simulink.Parameter Objects” (Fixed-Point Designer).

## **Unexpected Errors or Warnings for Data with Greater Precision or Range than double**

When a data item (signal or parameter) uses a data type other than `double`, before comparison, Simulink casts the data item and each design limit (minimum or maximum value that you specify) to the nondouble data type. This technique helps prevent the generation of unnecessary, misleading errors and warnings.

However, Simulink stores design limits as `double` before comparison. If the data type of the data item has higher precision than `double` (for example, a fixed-point data type with a 128-bit word length and a 126-bit fraction length) or greater range than `double`, and `double` cannot exactly represent the value of a design limit, Simulink can generate unexpected warnings and errors.

If the nondouble type has higher precision, consider rounding the design limit to the next number furthest from zero that `double` can represent. For example, suppose that a signal generates an error after you set the maximum value to `98.8847692348509014`. At the

command prompt, calculate the next number furthest from zero that double can represent.

```
format long
98.8847692348509014 + eps(98.8847692348509014)

ans =

 98.884769234850921
```

Use the resulting number, 98.884769234850921, to replace the maximum value.

## Optimize Generated Code

If you have Embedded Coder, Simulink Coder can optimize the code that you generate from the model by taking into account the minimum and maximum values that you specify for signals and parameters. This optimization can remove algorithmic code and affect the results of some simulation modes such as SIL or external mode. For more information, see “Optimize using the specified minimum and maximum values” (Simulink Coder).

## Switch Between Sets of Parameter Values During Simulation and Code Execution

To store multiple independent sets of values for the same block parameters, you can use an array of structures. To switch between the parameter sets, create a variable that acts as an index into the array, and change the value of the variable. You can change the value of the variable during simulation and, if the variable is tunable, during execution of the generated code.

### Explore Example Model

Open the example model.

```
open_system('sldemo_fuelsys_dd_controller')
```

### Fuel Rate Controller

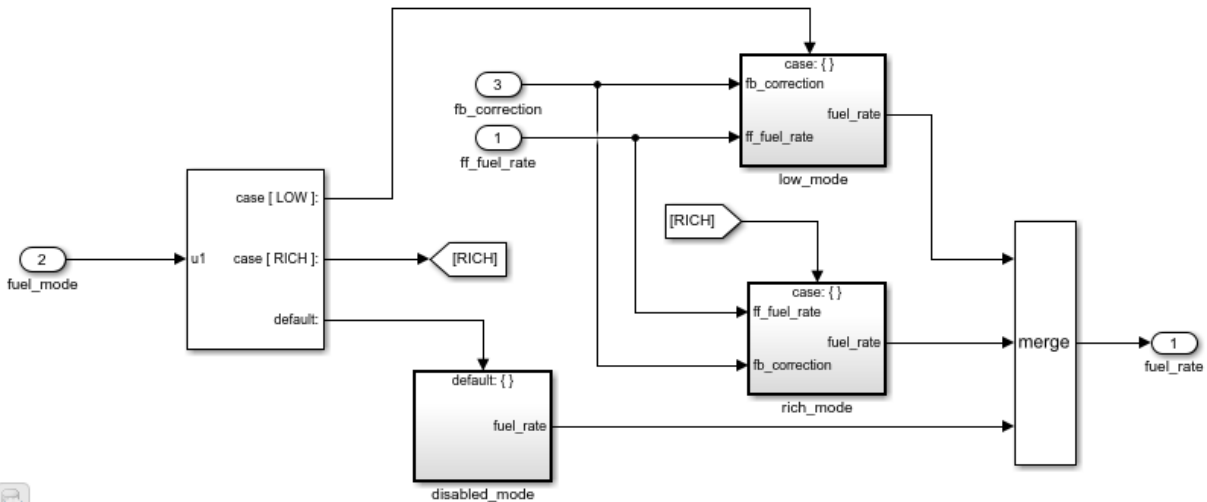

Copyright 1990-2017 The MathWorks, Inc.

This model represents the fueling system of a gasoline engine. The output of the model is the rate of fuel flow to the engine.

Navigate to the `switchable_compensation` nested subsystem.

```
open_system(['sldemo_fuelsys_dd_controller/fuel_calc/', ...
 'switchable_compensation'])
```

## Loop Compensation and Filtering

This subsystem corrects and filters noise out of the fuel rate signal. The subsystem uses different filter coefficients based on the fueling mode, which the control logic changes based on sensor failures in the engine. For example, the control algorithm activates the `low_mode` subsystem during normal operation. It activates the `rich_mode` subsystem in response to sensor failure.

Open the `low_mode` subsystem.

```
open_system(['sldemo_fuelsys_dd_controller/fuel_calc/',...
 'switchable_compensation/low_mode'])
```

The Discrete Filter block filters the fuel rate signal. In the block dialog box, the **Numerator** parameter sets the numerator coefficients of the filter.

The sibling subsystem `rich_mode` also contains a Discrete Filter block, which uses different coefficients.

Update the model diagram to display the signal data types. The input and output signals of the block use the single-precision, floating-point data type `single`.

In the lower-left corner of the model, click the data dictionary badge. The data dictionary for this model, `sldemo_fuelsys_dd_controller.sldd`, opens in the Model Explorer.

In the Model Explorer **Model Hierarchy** pane, select the **Design Data** node.

In the **Contents** pane, view the properties of the `Simulink.NumericType` objects, such as `s16En15`. All of these objects currently represent the single-precision, floating-point data type `single`. The model uses these objects to set signal data types, including the input and output signals of the Discrete Filter blocks.

Suppose that during simulation and execution of the generated code, you want each of these subsystems to switch between different numerator coefficients based on a variable whose value you control.

### Store Parameter Values in Array of Structures

Store the existing set of numerator coefficients in a `Simulink.Parameter` object whose value is a structure. Each field of the structure stores the coefficients for one of the Discrete Filter blocks.

```

lowBlock = ['sldemo_fuelsys_dd_controller/fuel_calc/'...
 'switchable_compensation/low_mode/Discrete Filter'];
richBlock = ['sldemo_fuelsys_dd_controller/fuel_calc/'...
 'switchable_compensation/rich_mode/Discrete Filter'];
params.lowNumerator = eval(get_param(lowBlock, 'Numerator'));
params.richNumerator = eval(get_param(richBlock, 'Numerator'));
params = Simulink.Parameter(params);

```

Copy the value of `params` into a temporary variable. Modify the field values in this temporary structure, and assign the modified structure as the second element of `params`.

```

temp = params.Value;
temp.lowNumerator = params.Value.lowNumerator * 2;
temp.richNumerator = params.Value.richNumerator * 2;
params.Value(2) = temp;
clear temp

```

The value of `params` is an array of two structures. Each structure stores one set of filter coefficients.

### Create Variable to Switch Between Parameter Sets

Create a `Simulink.Parameter` object named `Ctrl`.

```

Ctrl = Simulink.Parameter(2);
Ctrl.DataType = 'uint8';

```

In the `low_mode` subsystem, in the Discrete Filter block dialog box, set the **Numerator** parameter to the expression `params(Ctrl).lowNumerator`.

```

set_param(lowBlock, 'Numerator', 'params(Ctrl).lowNumerator');

```

In the Discrete Filter block in the `rich_mode` subsystem, set the value of the **Numerator** parameter to `params(Ctrl).richNumerator`.

```

set_param(richBlock, 'Numerator', 'params(Ctrl).richNumerator');

```

The expressions select one of the structures in `params` by using the variable `Ctrl`. The expressions then dereference one of the fields in the structure. The field value sets the values of the numerator coefficients.

To switch between the sets of coefficients, you change the value of `Ctrl` to the corresponding index in the array of structures.

### Use Bus Object as Data Type of Array of Structures

Optionally, create a `Simulink.Bus` object to use as the data type of the array of structures. You can:

- Control the shape of the structures.
- For each field, control characteristics such as data type and physical units.
- Control the name of the `struct` type in the generated code.

Use the function `Simulink.Bus.createObject` to create the object and rename the object as `paramsType`.

```
Simulink.Bus.createObject(params.Value)
paramsType = slBus1;
clear slBus1
```

You can use the `Simulink.NumericType` objects from the data dictionary to control the data types of the structure fields. In the bus object, use the name of a data type object to set the `DataType` property of each element.

```
paramsType.Elements(1).DataType = 's16En15';
paramsType.Elements(2).DataType = 's16En7';
```

Use the bus object as the data type of the array of structures.

```
params.DataType = 'Bus: paramsType';
```

### Use Enumerated Type for Switching Variable

Optionally, use an enumerated type as the data type of the switching variable. You can associate each of the parameter sets with a meaningful name and restrict the allowed values of the switching variable.

Create an enumerated type named `FilterCoeffs`. Create an enumeration member for each of the structures in `params`. Set the underlying integer value of each enumeration member to the corresponding index in `params`.

```
Simulink.defineIntEnumType('FilterCoeffs', {'Weak', 'Aggressive'}, [1 2])
```

Use the enumerated type as the data type of the switching variable. Set the value of the variable to `Aggressive`, which corresponds to the index 2.

```
Ctrl.Value = FilterCoeffs.Aggressive;
```

### Add New Objects to Data Dictionary

Add the objects that you created to the data dictionary  
`sldemo_fuelsys_dd_controller.slidd`.

```
dictObj = Simulink.data.dictionary.open('sldemo_fuelsys_dd_controller.slidd');
sectObj = getSection(dictObj, 'Design Data');
addEntry(sectObj, 'Ctrl', Ctrl)
addEntry(sectObj, 'params', params)
addEntry(sectObj, 'paramsType', paramsType)
```

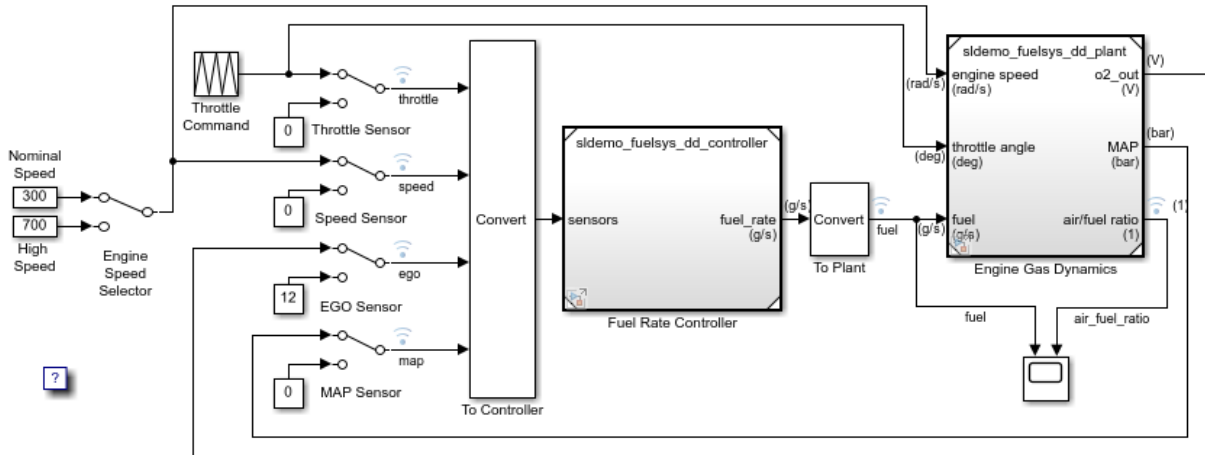

You can also store enumerated types in data dictionaries. However, you cannot import the enumerated type in this case because you cannot save changes to `sldemo_fuelsys_dd_controller.slidd`. For more information about storing enumerated types in data dictionaries, see “Enumerations in Data Dictionary” on page 66-15.

### Switch Between Parameter Sets During Simulation

Open the example model `sldemo_fuelsys_dd`, which references the controller model `sldemo_fuelsys_dd_controller`.

```
open_system('sldemo_fuelsys_dd')
```

## Fault-Tolerant Fuel Control System

The sensor switches simulate any combination of sensor failures.  
The Engine Speed Selector switch simulates different engine speeds (rad/s).

Copyright 1990-2017 The MathWorks, Inc.

Set the simulation stop time to  $\text{Inf}$  so that you can interact with the model during simulation.

Begin a simulation run and open the Scope block dialog box. The scope shows that the fuel flow rate (the fuel signal) oscillates with significant amplitude during normal operation of the engine.

In the Model Explorer, view the contents of the data dictionary `sldemo_fuelsys_dd_controller.slidd`. Set the value of `Ctrl` to `FilterCoeffs.Weak`.

Update the `sldemo_fuelsys_dd` model diagram. The scope shows that the amplitude of the fuel rate oscillations decreases due to the less aggressive filter coefficients.

Stop the simulation.

### Generate and Inspect Code

If you have Simulink Coder software, you can generate code that enables you to switch between the parameter sets during code execution.

In the Model Explorer, view the contents of the data dictionary `sldemo_fuelsys_dd_controller.sldd`. In the **Contents** pane, set **Column View** to **Storage Class**.

Use the **StorageClass** column to apply the storage class `ExportedGlobal` to `params` so that the array of structures appears as a tunable global variable in the generated code. Apply the same storage class to `Ctrl` so that you can change the value of the switching variable during code execution.

Alternatively, to configure the objects, use these commands:

```
tempEntryObj = getEntry(sectObj, 'params');
params = getValue(tempEntryObj);
params.StorageClass = 'ExportedGlobal';
setValue(tempEntryObj, params);
```

```
tempEntryObj = getEntry(sectObj, 'Ctrl');
Ctrl = getValue(tempEntryObj);
Ctrl.StorageClass = 'ExportedGlobal';
setValue(tempEntryObj, Ctrl);
```

Generate code from the controller model.

```
rtwbuild('sldemo_fuelsys_dd_controller')

Starting build procedure for model: sldemo_fuelsys_dd_controller
Successful completion of code generation for model: sldemo_fuelsys_dd_controller
```

In the code generation report, view the header file `sldemo_fuelsys_dd_controller_types.h`. The code defines the enumerated data type `FilterCoeffs`.

```
file = fullfile('sldemo_fuelsys_dd_controller_ert_rtw',...
 'sldemo_fuelsys_dd_controller_types.h');
rtwdemodbtype(file, '#ifndef DEFINED_TYPEDEF_FOR_FilterCoeffs_',...
 '/* Forward declaration for rtModel */', 1, 0)

#ifndef DEFINED_TYPEDEF_FOR_FilterCoeffs_
#define DEFINED_TYPEDEF_FOR_FilterCoeffs_

typedef enum {
 Weak = 1, /* Default value */
 Aggressive
```

```

} FilterCoeffs;

#endif

```

The code also defines the structure type `paramsType`, which corresponds to the `Simulink.Bus` object. The fields use the single-precision, floating-point data type from the model.

```

rtwdemodbtype(file, '#ifndef DEFINED_TYPEDEF_FOR_paramsType_', ...
 '#ifndef DEFINED_TYPEDEF_FOR_FilterCoeffs_', 1, 0)

#ifndef DEFINED_TYPEDEF_FOR_paramsType_
#define DEFINED_TYPEDEF_FOR_paramsType_

typedef struct {
 real32_T lowNumerator[2];
 real32_T richNumerator[2];
} paramsType;

#endif

```

View the source file `sldemo_fuelsys_dd_controller.c`. The code uses the enumerated type to define the switching variable `Ctrl`.

```

file = fullfile('sldemo_fuelsys_dd_controller_ert_rtw', ...
 'sldemo_fuelsys_dd_controller.c');
rtwdemodbtype(file, 'FilterCoeffs Ctrl = Aggressive;', ...
 '/* Block signals (default storage) */', 1, 0)

FilterCoeffs Ctrl = Aggressive; /* Variable: Ctrl
 * Referenced by:
 * '<S12>/Discrete Filter'
 * '<S13>/Discrete Filter'
 */

```

The code also defines the array of structures `params`.

```

rtwdemodbtype(file, '/* Exported block parameters */', ...
 '/* Variable: params', 1, 1)

/* Exported block parameters */
paramsType params[2] = { {

```

```
{ 8.7696F, -8.5104F },

{ 0.0F, 0.2592F }
, { { 17.5392F, -17.0208F },

{ 0.0F, 0.5184F }
} } ; /* Variable: params
```

The code algorithm in the model `step` function uses the switching variable to index into the array of structures.

To switch between the parameter sets stored in the array of structures, change the value of `Ctrl` during code execution.

Close the connections to the data dictionary. This example discards unsaved changes. To save the changes, use the `'-save'` option.

```
Simulink.data.dictionary.closeAll('sldemo_fuelsys_dd_controller.sldd', '-discard')
```

## About Lookup Table Blocks

A lookup table block uses an array of data to map input values to output values, approximating a mathematical function. Given input values, Simulink performs a “lookup” operation to retrieve the corresponding output values from the table. If the lookup table does not define the input values, the block estimates the output values based on nearby table values.

The following example illustrates a one-dimensional lookup table that approximates the function  $y = x^3$ . The lookup table defines its output ( $y$ ) data discretely over the input ( $x$ ) range  $[-3, 3]$ . The following table and graph illustrate the input/output relationship:

|   |     |    |    |   |   |   |    |
|---|-----|----|----|---|---|---|----|
| x | -3  | -2 | -1 | 0 | 1 | 2 | 3  |
| y | -27 | -8 | -1 | 0 | 1 | 8 | 27 |

An input of -2 enables the table to look up and retrieve the corresponding output value (-8). Likewise, the lookup table outputs 27 in response to an input of 3.

When the lookup table block encounters an input that does not match any of the table's  $x$  values, it can interpolate or extrapolate the answer. For instance, the lookup table does not define an input value of -1.5; however, the block can linearly interpolate the nearest adjacent data points  $(x_i, y_i)$  and  $(x_{i+1}, y_{i+1})$ . For example, given these two points:

- $(x_i, y_i)$  is (-2, -8)
- $(x_{i+1}, y_{i+1})$  is (-1, -1)

The lookup table estimates and returns a value of -4.5.

Similarly, although the lookup table does not include data for  $x$  values beyond the range of  $[-3, 3]$ , the block can extrapolate values using a pair of data points at either end of the table. Given an input value of 4, the lookup table block linearly extrapolates the nearest data points (2, 8) and (3, 27) to estimate an output value of 46.

Since table lookups and simple estimations can be faster than mathematical function evaluations, using lookup table blocks might result in speed gains when simulating a model. Consider using lookup tables in lieu of mathematical function evaluations when:

- An analytical expression is expensive to compute.
- No analytical expression exists, but the relationship has been determined empirically.

Simulink provides a broad assortment of lookup table blocks, each geared for a particular type of application. The sections that follow outline the different offerings, suggest how to choose the lookup table best suited to your application, and explain how to interact with the various lookup table blocks.

## Anatomy of a Lookup Table

The following figure illustrates the anatomy of a two-dimensional lookup table. Vectors or breakpoint data sets and an array, referred to as table data, constitute the lookup table.

Each breakpoint data set is an index of input values for a particular dimension of the lookup table. The array of table data serves as a sampled representation of a function evaluated at the breakpoint values. Lookup table blocks use breakpoint data sets to relate a table's input values to the output values that it returns.

## Lookup Tables Block Library

Several lookup table blocks appear in the Lookup Tables block library.

The following table summarizes the purpose of each block in the library.

| Block Name                    | Description                                                                                        |
|-------------------------------|----------------------------------------------------------------------------------------------------|
| 1-D Lookup Table              | Approximate a one-dimensional function.                                                            |
| 2-D Lookup Table              | Approximate a two-dimensional function.                                                            |
| n-D Lookup Table              | Approximate an N-dimensional function.                                                             |
| Prelookup                     | Compute index and fraction for Interpolation Using Prelookup block.                                |
| Interpolation Using Prelookup | Use precalculated index and fraction values to accelerate approximation of N-dimensional function. |
| Direct Lookup Table (n-D)     | Index into an N-dimensional table to retrieve the corresponding outputs.                           |

| <b>Block Name</b>    | <b>Description</b>                                                          |
|----------------------|-----------------------------------------------------------------------------|
| Lookup Table Dynamic | Approximate a one-dimensional function using a dynamically specified table. |
| Sine                 | Use a fixed-point lookup table to approximate the sine wave function.       |
| Cosine               | Use a fixed-point lookup table to approximate the cosine wave function.     |

## Guidelines for Choosing a Lookup Table

### In this section...

“Data Set Dimensionality” on page 38-9

“Data Set Numeric and Data Types” on page 38-9

“Data Accuracy and Smoothness” on page 38-9

“Dynamics of Table Inputs” on page 38-10

“Efficiency of Performance” on page 38-10

“Summary of Lookup Table Block Features” on page 38-11

### Data Set Dimensionality

In some cases, the dimensions of your data set dictate which of the lookup table blocks is right for your application. If you are approximating a one-dimensional function, consider using either the 1-D Lookup Table or Lookup Table Dynamic block. If you are approximating a two-dimensional function, consider the 2-D Lookup Table block. Blocks such as the n-D Lookup Table and Direct Lookup Table (n-D) allow you to approximate a function of  $N$  variables.

### Data Set Numeric and Data Types

The numeric and data types of your data set influence the decision of which lookup table block is most appropriate. Although all lookup table blocks support real numbers, the Direct Lookup Table (n-D), 1-D Lookup Table, 2-D Lookup Table, and n-D Lookup Table blocks also support complex table data. All lookup table blocks support integer and fixed-point data in addition to double and single data types.

---

**Note** For the Direct Lookup Table (n-D) block, fixed-point types are supported for the table data, output port, and optional table input port.

---

### Data Accuracy and Smoothness

The desired accuracy and smoothness of the data returned by a lookup table determine which of the blocks you should use. Most blocks provide options to perform interpolation and extrapolation, improving the accuracy of values that fall between or outside of the

table data, respectively. For instance, the Lookup Table Dynamic block performs linear interpolation and extrapolation, while the n-D Lookup Table block performs either linear or cubic spline interpolation and extrapolation. In contrast, the Direct Lookup Table (n-D) block performs table lookups without any interpolation or extrapolation. You can achieve a mix of interpolation and extrapolation methods by using the Prelookup block with the Interpolation Using Prelookup block.

## **Dynamics of Table Inputs**

The dynamics of the lookup table inputs impact which of the lookup table blocks is ideal for your application. The blocks use a variety of index search methods to relate the lookup table inputs to the table's breakpoint data sets. Most of the lookup table blocks offer a binary search algorithm, which performs well if the inputs change significantly from one time step to the next. The 1-D Lookup Table, 2-D Lookup Table, n-D Lookup Table, and Prelookup blocks offer a linear search algorithm. Using this algorithm with the option that resumes searching from the previous result performs well if the inputs change slowly. Some lookup table blocks also provide a search algorithm that works best for breakpoint data sets composed of evenly spaced breakpoints. You can achieve a mix of index search methods by using the Prelookup block with the Interpolation Using Prelookup block.

## **Efficiency of Performance**

When the efficiency with which lookup tables operate is important, consider using the Prelookup block with the Interpolation Using Prelookup block. These blocks separate the table lookup process into two components — an index search that relates inputs to the table data, followed by an interpolation and extrapolation stage that computes outputs. These blocks enable you to perform a single index search and then reuse the results to look up data in multiple tables. Also, the Interpolation Using Prelookup block can perform sub-table selection, where the block interpolates a portion of the table data instead of the entire table. For example, if your 3-D table data constitutes a stack of 2-D tables to be interpolated, you can specify a selection port input to select one or more of the 2-D tables from the stack for interpolation. A full 3-D interpolation has 7 sub-interpolations but a 2-D interpolation requires only 3 sub-interpolations. As a result, significant speed improvements are possible when some dimensions of a table are used for data stacking and not intended for interpolation. These features make table lookup operations more efficient, reducing computational effort and simulation time.

## Summary of Lookup Table Block Features

Use the following table to identify features that correspond to particular lookup table blocks, then select the block that best meets your requirements.

| Feature                                | 1-D Lookup Table | 2-D Lookup Table | Lookup Table Dynamic | n-D Lookup Table | Direct Lookup Table (n-D) | Prelookup | Interp. Using Prelookup |
|----------------------------------------|------------------|------------------|----------------------|------------------|---------------------------|-----------|-------------------------|
| <b>Interpolation Methods</b>           |                  |                  |                      |                  |                           |           |                         |
| Flat                                   | •                | •                | •                    | •                |                           |           | •                       |
| Nearest                                | •                | •                |                      | •                |                           |           | •                       |
| Linear                                 |                  |                  | •                    |                  |                           |           |                         |
| Linear point-slope                     | •                | •                |                      | •                |                           |           | •                       |
| Linear Lagrange                        | •                | •                |                      | •                |                           |           | •                       |
| Cubic spline                           | •                | •                |                      | •                |                           |           |                         |

## Enter Breakpoints and Table Data

### In this section...

“Entering Data in a Block Parameter Dialog Box” on page 38-13

“Entering Data in the Lookup Table Editor” on page 38-13

“Entering Data Using Inports of the Lookup Table Dynamic Block” on page 38-15

### Entering Data in a Block Parameter Dialog Box

This example shows how to populate a 1-D Lookup Table block using the parameter dialog box. The lookup table in this example approximates the function  $y = x^3$  over the range  $[-3, 3]$ .

- 1 Copy a 1-D Lookup Table block from the Lookup Tables block library to a Simulink model.
- 2 In the 1-D Lookup Table block dialog box, enter the table dimensions and table data in the specified fields of the dialog box:
  - Set **Number of table dimensions** to 1.
  - Set **Table data** to  $[-27 \ -8 \ -1 \ 0 \ 1 \ 8 \ 27]$ .

Alternatively, to use an existing lookup table (`Simulink.LookupTable`) object, select **Data specification > Lookup table object**.

- 3 Enter the breakpoint data set using either of two methods:
  - To specify evenly spaced data points, set **Breakpoint specification** to **Even spacing**. Set **First point** to -3 and **Spacing** to 1. The block calculates the number of evenly spaced breakpoints based on the table data.
  - To specify breakpoint data explicitly, set **Breakpoint specification** to **Explicit values** and set **Breakpoints 1** to  $[-3:3]$ .

### Entering Data in the Lookup Table Editor

Use the following procedure to populate a 2-D Lookup Table block using the Lookup Table Editor. In this example, the lookup table approximates the function  $z = x^2 + y^2$  over the input ranges  $x = [0, 2]$  and  $y = [0, 2]$ .

- 1** Copy a 2-D Lookup Table block from the Lookup Tables block library to a Simulink model.
- 2** Open the Lookup Table Editor by selecting **Lookup Table Editor** from the Simulink **Edit** menu or by clicking **Edit table and breakpoints** on the dialog box of the 2-D Lookup Table block.
- 3** Under **Viewing "n-D Lookup Table" block data**, enter the breakpoint data sets and table data in the appropriate cells. To change data, click a cell, enter the new value, and press **Enter**.
  - In the cells associated with the **Row Breakpoints**, enter each of the values [0 1 2].
  - In the cells associated with the **Column Breakpoints**, enter each of the values [0 1 2].
  - In the table data cells, enter the values in the array [0 1 4; 1 2 5; 4 5 8].

The Lookup Table Editor looks like this:

- 4 In the Lookup Table Editor, select **File > Update Block Data** to update the data in the 2-D Lookup Table block.
- 5 Close the Lookup Table Editor.

## Entering Data Using Inports of the Lookup Table Dynamic Block

Use the following procedure to populate a Lookup Table Dynamic block using that block's inports. In this example, the lookup table approximates the function  $y = 3x^2$  over the range  $[0, 10]$ .

- 1 Copy a Lookup Table Dynamic block from the Lookup Tables block library to a Simulink model.

- 2 Copy the blocks needed to implement the equation  $y = 3x^2$  to the Simulink model:
  - One Constant block to define the input range, from the Sources library
  - One Math Function block to square the input range, from the Math Operations library
  - One Gain block to multiply the signal by 3, also from the Math Operations library
- 3 Assign the following parameter values to the Constant, Math Function, and Gain blocks using their dialog boxes:

| Block         | Parameter      | Value  |
|---------------|----------------|--------|
| Constant      | Constant value | 0:10   |
| Math Function | Function       | square |
| Gain          | Gain           | 3      |

- 4 Input the breakpoint data set to the Lookup Table Dynamic block by connecting the output of the Constant block to the inport of the Lookup Table Dynamic block labeled **xdat**. This signal is the input breakpoint data set for  $x$ .
- 5 Input the table data to the Lookup Table Dynamic block by branching the output signal from the Constant block and connecting it to the Math Function block. Then connect the Math Function block to the Gain block. Finally, connect the Gain block to the inport of the Lookup Table Dynamic block labeled **ydat**. This signal is the table data for  $y$ .

## Characteristics of Lookup Table Data

### In this section...

“Sizes of Breakpoint Data Sets and Table Data” on page 38-18

“Monotonicity of Breakpoint Data Sets” on page 38-19

“Formulation of Evenly Spaced Breakpoints” on page 38-19

### Sizes of Breakpoint Data Sets and Table Data

The following constraints apply to the sizes of breakpoint data sets and table data associated with lookup table blocks:

- The memory limitations of your system constrain the overall size of a lookup table.
- Lookup tables must use consistent dimensions so that the overall size of the table data reflects the size of each breakpoint data set.

To illustrate the second constraint, consider the following vectors of input and output values that create the relationship in the plot.

Vector of input values: [-3 -2 -1 0 1 2 3]

Vector of output values: [-3 -1 0 -1 0 1 3]

In this example, the input and output data are the same size (1-by-7), making the data consistently dimensioned for a 1-D lookup table.

The following input and output values define the 2-D lookup table that is graphically shown.

Row index input values: [1 2 3]  
 Column index input values: [1 2 3 4]  
 Table data: [11 12 13 14; 21 22 23 24; 31 32 33 34]

|   |    |    |    |    |
|---|----|----|----|----|
|   | 1  | 2  | 3  | 4  |
| 1 | 11 | 12 | 13 | 14 |
| 2 | 21 | 22 | 23 | 24 |
| 3 | 31 | 32 | 33 | 34 |

In this example, the sizes of the vectors representing the row and column indices are 1-by-3 and 1-by-4, respectively. Consequently, the output table must be of size 3-by-4 for consistent dimensions.

## Monotonicity of Breakpoint Data Sets

The first stage of a table lookup operation involves relating inputs to the breakpoint data sets. The search algorithm requires that input breakpoint sets be strictly monotonically increasing, that is, each successive element is greater than its preceding element. For example, the vector

$$A = [0 \quad 0.5 \quad 1 \quad 1.9 \quad 2.1 \quad 3]$$

is a valid breakpoint data set as each element is larger than its predecessors.

---

**Note** Although a breakpoint data set is strictly monotonic in `double` format, it might not be so after conversion to a fixed-point data type.

---

## Formulation of Evenly Spaced Breakpoints

You can represent evenly spaced breakpoints in a data set by using one of these methods.

| Formulation                                                               | Example                           | When to Use This Formulation                           |
|---------------------------------------------------------------------------|-----------------------------------|--------------------------------------------------------|
| <code>[first_value:spacing:last_value]</code>                             | <code>[10:10:200]</code>          | The lookup table does <i>not</i> use double or single. |
| <code>first_value + spacing * [0:(last_value-first_value)/spacing]</code> | <code>1 + (0.02 * [0:450])</code> | The lookup table uses double or single.                |

Because floating-point data types cannot precisely represent some numbers, the second formulation works better for double and single. For example, use `1 + (0.02 * [0:450])` instead of `[1:0.02:10]`. For a list of lookup table blocks that support evenly spaced breakpoints, see “Summary of Lookup Table Block Features” on page 38-11.

Among other advantages, evenly spaced breakpoints can make the generated code division-free and reduce memory usage. For more information, see:

- `fixpt_evenspace_cleanup` in the Simulink documentation
- “Effects of Spacing on Speed, Error, and Memory Usage” (Fixed-Point Designer)
- “Identify questionable fixed-point operations” (Embedded Coder)

---

**Tip** Do not use the MATLAB `linspace` function to define evenly spaced breakpoints. Simulink uses a tighter tolerance to check whether a breakpoint set has even spacing. If you use `linspace` to define breakpoints for your lookup table, Simulink considers the breakpoints to be unevenly spaced.

## Methods for Approximating Function Values

### In this section...

“About Approximating Function Values” on page 38-21

“Interpolation Methods” on page 38-21

“Extrapolation Methods” on page 38-22

“Rounding Methods” on page 38-23

“Example Output for Lookup Methods” on page 38-24

### About Approximating Function Values

The second stage of a table lookup operation involves generating outputs that correspond to the supplied inputs. If the inputs match the values of indices specified in breakpoint data sets, the block outputs the corresponding values. However, if the inputs fail to match index values in the breakpoint data sets, Simulink estimates the output. In the block parameter dialog box, you can specify how to compute the output in this situation. The available lookup methods are described in the following sections.

### Interpolation Methods

When an input falls between breakpoint values, the block interpolates the output value using neighboring breakpoints. Most lookup table blocks have the following interpolation methods available:

- **Flat** — Disables interpolation and uses the rounding operation titled **Use Input Below**. For more information, see “Rounding Methods” on page 38-23.
- **Nearest** — Disables interpolation and returns the table value corresponding to the breakpoint closest to the input. If the input is equidistant from two adjacent breakpoints, the breakpoint with the higher index is chosen.
- **Linear point-slope** — Fits a line between the adjacent breakpoints, and returns the point on that line corresponding to the input. This is the equation for linear point-slope, where  $x$  is the input data,  $y$  is the output table data ( $x_i, y_i$  is the coordinate of the table data), and  $f$  is the fraction. For more information on  $x_i, y_i$ , see “About Lookup Table Blocks” on page 38-2.

$$f = \frac{x - x_i}{x_{i+1} - x_i}$$

$$y = y_i + f(y_{i+1} - y_i)$$

- **Cubic spline** — Fits a cubic spline to the adjacent breakpoints, and returns the point on that spline corresponding to the input.
- **Linear Lagrange** — Fits a line between the adjacent breakpoints using first-order Lagrange interpolation, and returns the point on that line corresponding to the input. This is the equation for linear Lagrange, where  $x$  is the input data,  $y$  is the output table data, and  $f$  is the fraction.  $f$  is constrained to range from 0 to less than 1 ( $[0, 1)$ ). For more information on  $x$  and  $y$ , see “About Lookup Table Blocks” on page 38-2.

$$f = \frac{x - x_i}{x_{i+1} - x_i}$$

$$y = (1 - f)y_i + fy_{i+1}$$

If the extrapolation method is **Linear**, the extrapolation value is calculated based on the selected linear interpolation method. For example, if the interpolation method is **Linear Lagrange**, the extrapolation method inherits the **Linear Lagrange** equation to compute the extrapolated value.

---

**Note** The **Lookup Table Dynamic** block does not let you select an interpolation method. The **Interpolation-Extrapolation** option in the **Lookup Method** field of the block parameter dialog box performs linear interpolation.

---

Each interpolation method includes a trade-off between computation time and the smoothness of the result. Although rounding is quickest, it is the least smooth. Linear interpolation is slower than rounding but generates smoother results, except at breakpoints where the slope changes. Cubic spline interpolation is the slowest method but produces the smoothest results.

## Extrapolation Methods

When an input falls outside the range of a breakpoint data set, the block extrapolates the output value from a pair of values at the end of the breakpoint data set. Most lookup table blocks have the following extrapolation methods available:

- **Clip** — Disables extrapolation and returns the table data corresponding to the end of the breakpoint data set range. This does not provide protection against out-of-range values.
- **Linear** — If the interpolation method is **Linear**, this extrapolation method fits a line between the first or last pair of breakpoints, depending on whether the input is less than the first or greater than the last breakpoint. If the interpolation method is **Cubic spline**, this extrapolation method fits a linear surface using the slope of the interpolant at the first or last break point, depending on whether the input is less than the first or greater than the last breakpoint. The extrapolation method returns the point on the generated linear surface corresponding to the input.

If the extrapolation method is **Linear**, the extrapolation value is calculated based on the selected linear interpolation method. For example, if the interpolation method is **Linear Lagrange**, the extrapolation method inherits the **Linear Lagrange** equation to compute the extrapolated value.

- **Cubic spline** — Fits a cubic spline to the first or last pair of breakpoints, depending if the input is less than the first or greater than the last breakpoint, respectively. This method returns the point on that spline corresponding to the input.

---

**Note** The **Lookup Table Dynamic** block does not let you select an extrapolation method. The **Interpolation-Extrapolation** option in the **Lookup Method** field of the block parameter dialog box performs linear extrapolation.

---

In addition to these methods, some lookup table blocks, such as the **n-D Lookup Table** block, allow you to select an action to perform when encountering situations that require extrapolation. For instance, you can specify that Simulink generate either a warning or an error when the lookup table inputs are outside the ranges of the breakpoint data sets. To specify such an action, select it from the **Diagnostic for out-of-range input** list on the block parameter dialog box.

## Rounding Methods

If an input falls between breakpoint values or outside the range of a breakpoint data set and you do not specify interpolation or extrapolation, the block rounds the value to an adjacent breakpoint and returns the corresponding output value. For example, the **Lookup Table Dynamic** block lets you select one of the following rounding methods:

- Use Input Nearest — Returns the output value corresponding to the nearest input value.
- Use Input Below — Returns the output value corresponding to the breakpoint value that is immediately less than the input value. If no breakpoint value exists below the input value, it returns the breakpoint value nearest the input value.
- Use Input Above — Returns the output value corresponding to the breakpoint value that is immediately greater than the input value. If no breakpoint value exists above the input value, it returns the breakpoint value nearest the input value.

## Example Output for Lookup Methods

In the following model, the Lookup Table Dynamic block accepts a vector of breakpoint data given by  $[-5:5]$  and a vector of table data given by  $\sinh([-5:5])$ .

The Lookup Table Dynamic block outputs the following values when using the specified lookup methods and inputs.

| Lookup Method                | Input | Output | Comment                                     |
|------------------------------|-------|--------|---------------------------------------------|
| Interpolation-Extrapolation  | 1.4   | 2.156  | N/A                                         |
|                              | 5.2   | 83.59  | N/A                                         |
| Interpolation-Use End Values | 1.4   | 2.156  | N/A                                         |
|                              | 5.2   | 74.2   | The block uses the value for $\sinh(5.0)$ . |
| Use Input Above              | 1.4   | 3.627  | The block uses the value for $\sinh(2.0)$ . |

| Lookup Method     | Input | Output | Comment                                      |
|-------------------|-------|--------|----------------------------------------------|
|                   | 5.2   | 74.2   | The block uses the value for $\sinh(5.0)$ .  |
| Use Input Below   | 1.4   | 1.175  | The block uses the value for $\sinh(1.0)$ .  |
|                   | -5.2  | -74.2  | The block uses the value for $\sinh(-5.0)$ . |
| Use Input Nearest | 1.4   | 1.175  | The block uses the value for $\sinh(1.0)$ .  |

## Edit Lookup Tables

| In this section...                               |
|--------------------------------------------------|
| “Edit N-Dimensional Lookup Tables” on page 38-26 |
| “Edit Custom Lookup Table Blocks” on page 38-28  |

You can edit a lookup table using:

- Lookup Table block dialog box
- Lookup Table Editor

To edit the lookup table in a block:

- 1 Open the subsystem that contains the lookup table block.
- 2 Open the lookup table block’s dialog box.
- 3 In the Table and Breakpoints tab, edit the **Table data** and relevant **Breakpoints** parameters as needed.

With the Lookup Table Editor, you can skip these steps and edit the desired lookup table without navigating to the block that uses it. However, you cannot use the Lookup Table Editor to change the dimensions of a lookup table. You must use the block parameter dialog box for this purpose.

### Edit N-Dimensional Lookup Tables

If the lookup table of the block currently selected in the Lookup Table Editor tree view has more than two dimensions, the table view displays a two-dimensional slice of the lookup table.

The **Dimension Selector** specifies which slice currently appears and lets you select another slice. The selector consists of a 2-by-N array of controls, where N is the number of dimensions in the lookup table. Each column corresponds to a dimension of the lookup table. The first column corresponds to the first dimension of the table, the second column to the second dimension of the table, and so on. The **Dimension size** row of the selector array displays the size of each dimension. The **Select 2-D slice** row specifies which dimensions of the table correspond to the row and column axes of the slice and the indices that select the slice from the remaining dimensions.

To select another slice of the table, specify the row and column axes of the slice in the first two columns of the **Select 2-D slice** row. Then select the indices of the slice from the pop-up index lists in the remaining columns.

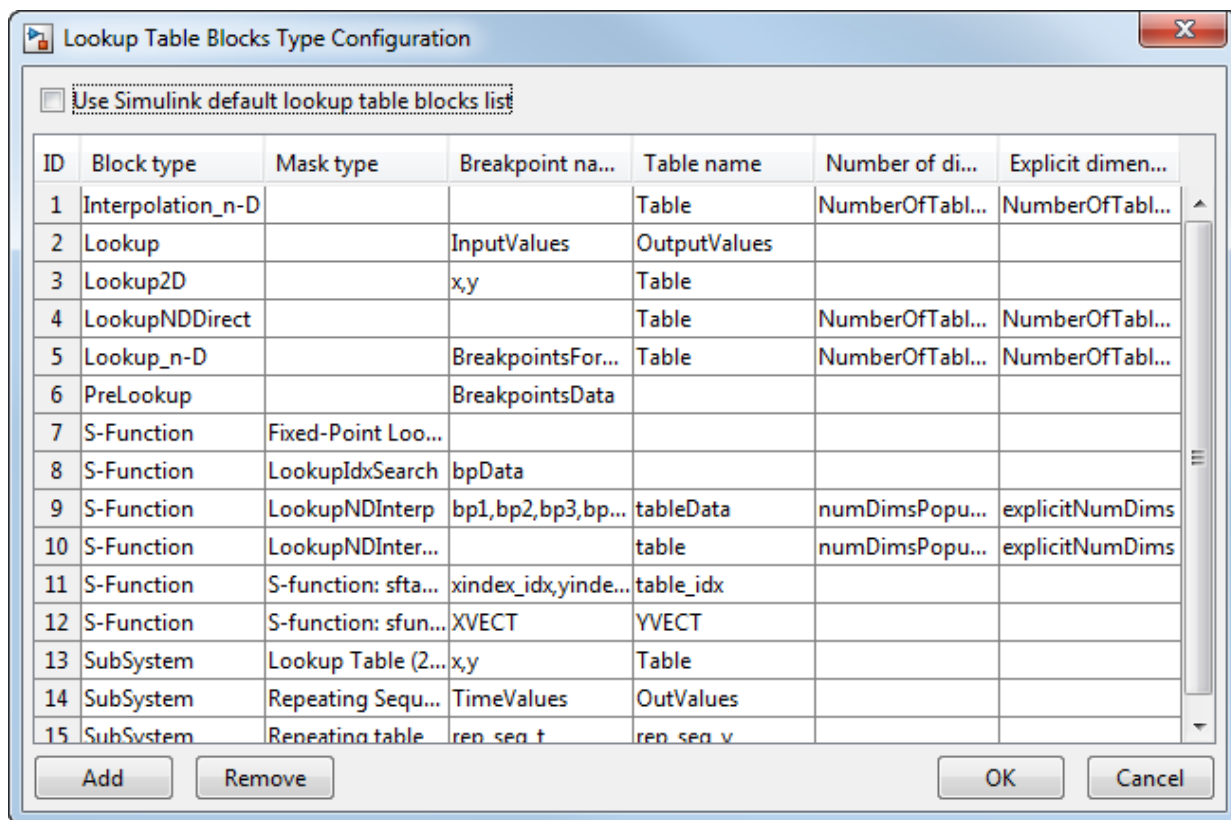

For example, the following selector displays slice (:,:,1) of a 3-D lookup table, as shown under Dimension Selector in the Lookup Table Editor.

To transpose the table display, select the **Transpose display** check box.

## Edit Custom Lookup Table Blocks

You can use the Lookup Table Editor to edit custom lookup table blocks that you have created. To do this, you must first configure the Lookup Table Editor to recognize the custom lookup table blocks in your model.

- 1 Select **File > Configure**. The Lookup Table Blocks Type Configuration dialog box appears.

The dialog box displays a table of the lookup table block types that the Lookup Table Editor currently recognizes. This table includes the standard blocks. Each row of the table displays key attributes of a lookup table block type.

- 2 Click **Add** on the dialog box. A new row appears at the bottom of the block type table.
- 3 Enter information for the custom block in the new row under these headings.

| Field Name           | Description                                                                                                  |
|----------------------|--------------------------------------------------------------------------------------------------------------|
| Block type           | Block type of the custom block. The block type is the value of the block's <code>BlockType</code> parameter. |
| Mask type            | Mask type of the custom block. The mask type is the value of the block's <code>MaskType</code> parameter.    |
| Breakpoint name      | Names of the block parameters that store the breakpoints.                                                    |
| Table name           | Name of the block parameter that stores the table data.                                                      |
| Number of dimensions | Leave empty.                                                                                                 |
| Explicit dimensions  | Leave empty.                                                                                                 |

- 4 Click **OK**.

To remove a custom lookup table block type from the list that the Lookup Table Editor recognizes, select the custom entry in the table of the Lookup Table Blocks Type Configuration dialog box and click **Remove**. To remove all custom lookup table block types, select the **Use Simulink default lookup table blocks list** check box at the top of the dialog box.

## Import Lookup Table Data from MATLAB

### In this section...

“Import Standard Format Lookup Table Data” on page 38-30

“Propagate Standard Format Lookup Table Data” on page 38-31

“Import Nonstandard Format Lookup Table Data” on page 38-32

“Propagate Nonstandard Format Lookup Table Data” on page 38-34

You can import table and breakpoint data from variables in the MATLAB workspace by referencing them in the **Table and Breakpoints** tab of the dialog box. The following examples show how to import and export standard format and non-standard format data from the MATLAB workspace.

### Import Standard Format Lookup Table Data

Suppose you specify a 3-D lookup table in your n-D Lookup Table block.

Create workspace variables to use as breakpoint and table data for the lookup table.

```
table3d_map = zeros(2,4,3);
table3d_map(:,:,1) = [1 2 3 4; 5 6 7 8];
table3d_map(:,:,2) = [11 12 13 14; 15 16 17 18];
table3d_map(:,:,3) = [111 112 113 114; 115 116 117 118];
bp3d_z = [0 10 20];
bp3d_x = [0 10 20 30];
bp3d_y = [400 6400];
```

Open the n-D Lookup Table block dialog box, and enter the following parameters in the Table and Breakpoints tab:

- Table data: table3d\_map
- Breakpoints 1: bp3d\_y
- Breakpoints 2: bp3d\_x
- Breakpoints 3: bp3d\_z

Click **Edit table and breakpoints** to open the Lookup Table Editor and show the data from the workspace variables.

## Propagate Standard Format Lookup Table Data

When you make changes to your lookup table data, consider propagating the changes back to the MATLAB workspace variables the data was imported from using **File > Update Block Data**.

You can also use the Lookup Table Editor to edit the table data and breakpoint data set of `Simulink.LookupTable` and the breakpoint data set of `Simulink.Breakpoint` objects and propagate the changes back to the object.

Suppose you make a change to the lookup table variables imported from the MATLAB workspace variables in “Import Standard Format Lookup Table Data” on page 38-30. For example, change the value of the data in (1,1,1) from 1 to 33. To propagate this change

back to `table3d_map` in the workspace, select **File > Update Block Data**. Click **Yes** to confirm that you want to overwrite `table3d_map`.

## Import Nonstandard Format Lookup Table Data

Suppose you specify a 3-D lookup table in your n-D Lookup Table block. Create workspace variables to use as breakpoint and table data for the lookup table. The variable for table data, `table3d_map_custom`, is a two-dimensional matrix.

```
table3d_map_custom = zeros(6,4);
table3d_map_custom = [1 2 3 4; 5 6 7 8;
11 12 13 14; 15 16 17 18;
111 112 113 114; 115 116 117 118];
bp3d_z =[0 10 20];
bp3d_x =[0 10 20 30];
bp3d_y =[400 6400];
```

Open the n-D Lookup Table block dialog box, and enter the following parameters in the Table and Breakpoints tab. Transform `table3d_map_custom` into a three-dimensional matrix for the table data input using the `reshape` command.

- Table data: `reshape(table3d_map_custom, [2,4,3])`
- Breakpoints 1: `bp3d_y`
- Breakpoints 2: `bp3d_x`
- Breakpoints 3: `bp3d_z`

Click **Edit table and breakpoints** to open the Lookup Table Editor and show the data from the workspace variables.

Change 1 to 33 in the Lookup Table Editor. The Lookup Table Editor records your changes by maintaining a copy of the table. To restore the variable values from the MATLAB workspace, select **File > Reload Block Data**. To update the MATLAB workspace variables with the edited data, select **File > Update Block Data** in the Lookup Table Editor. You cannot propagate the change to `table3d_map_custom`, the workspace variable that contains the nonstandard table data for the n-D Lookup Table block. To propagate the change, you must register a customization function that resides on the MATLAB search path. For details, see "Propagate Nonstandard Format Lookup Table Data" on page 38-34.

## Propagate Nonstandard Format Lookup Table Data

This example shows how to propagate changes from the Lookup Table Editor to workspace variables of nonstandard format. Suppose your Simulink model from “Import Nonstandard Format Lookup Table Data” on page 38-32 has a three-dimensional lookup table that gets its table data from the two-dimensional workspace variable `table3d_map_custom`. Update the lookup table in the Lookup Table Editor and propagate these changes back to `table3d_map_custom` using a customization function.

- 1 Create a file named `sl_customization.m` with these contents.

```
function sl_customization(cm)
cm.LookupTableEditorCustomizer.getTableConvertToCustomInfoFcnHandle{end+1} = ...
@myGetTableConvertInfoFcn;
end
```

In this function:

- The argument `cm` is the handle to a customization manager object.
  - The handle `@myGetTableConvertInfoFcn` is added to the list of function handles in the cell array for `cm.LookupTableEditorCustomizer.getTableConvertToCustomInfoFcnHandle`. You can use any alphanumeric name for the function whose handle you add to the cell array.
- 2 In the same file, define the `myGetTableConvertInfoFcn` function.

```
function blkInfo = myGetTableConvertInfoFcn(blk, tableStr)
 blkInfo.allowTableConvertLocal = true;
 blkInfo.tableWorkspaceVarName = 'table3d_map_custom';
 blkInfo.tableConvertFcnHandle = @myConvertTableFcn;
end
```

The `myGetTableConvertInfoFcn` function returns the `blkInfo` object containing three fields.

- `allowTableConvertLocal` — Allows table data conversion for a block.
- `tableWorkspaceVarName` — Specifies the name of the workspace variable that has a nonstandard table format.
- `tableConvertFcnHandle` — Specifies the handle for the conversion function.

When `allowTableConvertLocal` is set to `true`, the table data for that block is converted to the nonstandard format of the workspace variable whose name matches `tableWorkspaceVarName`. The conversion function corresponds to the handle that

`tableConvertFcnHandle` specifies. You can use any alphanumeric name for the conversion function.

- 3 In the same file, define the `myConvertTableFcn` function. This function converts a three-dimensional lookup table of size *Rows* \* *Columns* \* *Height* to a two-dimensional variable of size  $(Rows * Height) * Columns$ .

```
% Converts 3-dimensional lookup table from Simulink format to
% nonstandard format used in workspace variable
function cMap = myConvertTableFcn(data)
```

```
% Determine the row and column number of the 3D table data
 mapDim = size(data);
 numCol = mapDim(2);
 numRows = mapDim(1)*mapDim(3);
 cMap = zeros(numRow, numCol);
 % Transform data back to a 2-dimensional matrix
 cMap = reshape(data,[numRow,numCol]);
end
```

- 4 Put `sl_customization.m` on the MATLAB search path. You can have multiple files named `sl_customization.m` on the search path. For more details, see “Behavior with Multiple Customization Functions” on page 38-36.
- 5 Refresh Simulink customizations at the MATLAB command prompt.

```
sl_refresh_customizations
```

- 6 Open the Lookup Table Editor for your lookup table block and select **File > Update Block Data**. Click **Yes** to overwrite the workspace variable `table3d_map_custom`.
- 7 Check the value of `table3d_map_custom` in the base workspace.

```
table3d_map_custom =
```

```
 33 2 3 4
 5 6 7 8
 11 12 13 14
 15 16 17 18
 111 112 113 114
 115 116 117 118
```

The change in the Lookup Table Editor has propagated to the workspace variable.

---

**Note** If you do not overwrite the workspace variable `table3d_map_custom`, you are prompted to replace it with numeric data. Click **Yes** to replace the expression in the **Table data** field with numeric data. Click **No** if you do not want your Lookup Table Editor changes for the table data to appear in the block dialog box.

---

## Behavior with Multiple Customization Functions

At the start of a MATLAB session, Simulink loads each `sl_customization.m` customization file on the path and executes the `sl_customization` function. Executing each function establishes the customizations for that session.

When you select **File > Update Block Data** in the Lookup Table Editor, the editor checks the list of function handles in the cell array for `cm.LookupTableEditorCustomizer.getTableConvertToCustomInfoFcnHandle`. If the cell array contains one or more function handles, the `allowTableConvertLocal` property determines whether changes in the Lookup Table Editor can be propagated.

- If the value is set to `true`, then the table data is converted to the nonstandard format in the workspace variable.
- If the value is set to `false`, then table data is not converted to the nonstandard format in the workspace variable.
- If the value is set to `true` and another customization function specifies it to be `false`, the Lookup Table Editor reports an error.

- “Guidelines for Choosing a Lookup Table” on page 38-9
- “Import Lookup Table Data from Excel” on page 38-37

## Import Lookup Table Data from Excel

This example shows how to use the MATLAB `xlsread` function in a Simulink model to import data into a lookup table.

- 1 Save the Excel file in a folder on the MATLAB path.
- 2 Open the model containing the lookup table block and select **File > Model Properties > Model Properties**.
- 3 In the Model Properties dialog box, in the **Callbacks** tab, click **PostLoadFcn** callback in the model callbacks list.
- 4 Enter the code to import the Excel Spreadsheet data in the text box. Use the MATLAB `xlsread` function, as shown in this example for a 2-D lookup table.

```
% Import the data from Excel for a lookup table
data = xlsread('MySpreadsheet','Sheet1');
% Row indices for lookup table
breakpoints1 = data(2:end,1)';
% Column indices for lookup table
breakpoints2 = data(1,2:end);
% Output values for lookup table
table_data = data(2:end,2:end);
```

- 5 Click **OK**.

After you save your changes, the next time you open the model, Simulink invokes the callback and imports the data.

- “Import Lookup Table Data from MATLAB” on page 38-30

## Create a Logarithm Lookup Table

Suppose you want to approximate the common logarithm (base 10) over the input range [1, 10] without performing an expensive computation. You can perform this approximation using a lookup table block as described in the following procedure.

- 1** Copy the following blocks to a Simulink model:
  - One Constant block to input the signal, from the Sources library
  - One n-D Lookup Table block to approximate the common logarithm, from the Lookup Tables library
  - One Display block to display the output, from the Sinks library
- 2** Assign the table data and breakpoint data set to the n-D Lookup Table block:
  - a** In the **Number of table dimensions** field, enter 1.
  - b** In the **Table data** field, enter  
[0 .301 .477 .602 .699 .778 .845 .903 .954 1].
  - c** In the **Breakpoints 1** field, enter [1:10].
  - d** Click **Apply**.

The dialog box looks something like this:

- 3 Double-click the Constant block to open the parameter dialog box, and change the **Constant value** parameter to 5. Click **OK** to apply the changes and close the dialog box.
- 4 Connect the blocks as follows.

- 5 Start simulation.

The following behavior applies to the n-D Lookup Table block.

| Value of the Constant Block                        | Action by the n-D Lookup Table Block                                                               | Example of Block Behavior |              |
|----------------------------------------------------|----------------------------------------------------------------------------------------------------|---------------------------|--------------|
|                                                    |                                                                                                    | Input Value               | Output Value |
| Equals a breakpoint                                | Returns the corresponding output value                                                             | 5                         | 0.699        |
| Falls between breakpoints                          | Linearly interpolates the output value using neighboring breakpoints                               | 7.5                       | 0.874        |
| Falls outside the range of the breakpoint data set | Linearly extrapolates the output value from a pair of values at the end of the breakpoint data set | 10.5                      | 1.023        |

For the n-D Lookup Table block, the default settings for **Interpolation method** and **Extrapolation method** are both Linear.

### Remove Code That Checks for Out-of-Range Inputs

By default, generated code for the following lookup table blocks include conditional statements that check for out-of-range breakpoint or index inputs:

- 1-D Lookup Table
- 2-D Lookup Table
- n-D Lookup Table
- Prelookup
- Interpolation Using Prelookup

To generate code that is more efficient, you can remove the conditional statements that protect against out-of-range input values.

| Block                         | Check Box to Select                                                   |
|-------------------------------|-----------------------------------------------------------------------|
| 1-D Lookup Table              | <b>Remove protection against out-of-range input in generated code</b> |
| 2-D Lookup Table              |                                                                       |
| n-D Lookup Table              |                                                                       |
| Prelookup                     |                                                                       |
| Interpolation Using Prelookup | <b>Remove protection against out-of-range index in generated code</b> |

Selecting the check box on the block dialog box improves code efficiency because there are fewer statements to execute. However, if you are generating code for safety-critical applications, you should not remove the range-checking code.

To verify the usage of the check box, run the following Model Advisor checks and perform the recommended actions.

| <b>Model Advisor Check</b>                                                                                                       | <b>When to Run the Check</b>     |
|----------------------------------------------------------------------------------------------------------------------------------|----------------------------------|
| <b>By Product &gt; Embedded Coder &gt; Identify lookup table blocks that generate expensive out-of-range checking code</b>       | For code efficiency              |
| <b>By Product &gt; Simulink Check &gt; Modeling Standards &gt; DO-178C/DO-331 Checks &gt; Check usage of lookup table blocks</b> | For safety-critical applications |

For more information about the Model Advisor, see “Select and Run Model Advisor Checks” on page 5-2 in the Simulink documentation.

## Optimize Breakpoint Spacing in Lookup Tables

When breakpoints in a lookup table are tunable, the spacing does not affect efficiency or memory usage of the generated code. When breakpoints are *not* tunable, the type of spacing can affect the following factors.

| <b>Factor</b>   | <b>Even Power of 2 Spaced Data</b>                                                                                                                                                                                                                                  | <b>Evenly Spaced Data</b>                                                                                                                            | <b>Unevenly Spaced Data</b>                                                                                                                         |
|-----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| Execution speed | The execution speed is the fastest. The position search and interpolation are the same as for evenly-spaced data. However, to increase speed a bit more for fixed-point types, a bit shift replaces the position search, and a bit mask replaces the interpolation. | The execution speed is faster than that for unevenly-spaced data because the position search is faster and the interpolation uses a simple division. | The execution speed is the slowest of the different spacings because the position search is slower, and the interpolation requires more operations. |

| Factor    | Even Power of 2 Spaced Data                                                                                                                                              | Evenly Spaced Data                                                                                                                                                       | Unevenly Spaced Data                                                                                                                    |
|-----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| Error     | The error can be larger than that for unevenly-spaced data because approximating a function with nonuniform curvature requires more points to achieve the same accuracy. | The error can be larger than that for unevenly-spaced data because approximating a function with nonuniform curvature requires more points to achieve the same accuracy. | The error can be smaller because approximating a function with nonuniform curvature requires fewer points to achieve the same accuracy. |
| ROM usage | Uses less command ROM, but more data ROM.                                                                                                                                | Uses less command ROM, but more data ROM.                                                                                                                                | Uses more command ROM, but less data ROM.                                                                                               |
| RAM usage | Not significant.                                                                                                                                                         | Not significant.                                                                                                                                                         | Not significant.                                                                                                                        |

Follow these guidelines:

- For fixed-point data types, use breakpoints with even, power-of-2 spacing.
- For non-fixed-point data types, use breakpoints with even spacing.

To identify opportunities for improving code efficiency in lookup table blocks, run the following Model Advisor checks and perform the recommended actions:

- **By Product > Embedded Coder > Identify questionable fixed-point operations**
- **By Product > Embedded Coder > Identify blocks that generate expensive saturation and rounding code**

For more information about the Model Advisor, see “Select and Run Model Advisor Checks” on page 5-2 in the Simulink documentation.

## Reduce Data Copies for Lookup Table Blocks

When you use workspace variables to store table and breakpoint data for Lookup Table blocks, and then configure these variables for tunability, you can avoid data copies by using the same data type for the block parameter and variable. Workspace variables include numeric MATLAB variables and `Simulink.Parameter` objects that you store in a workspace, such as the base workspace, or in a data dictionary. If the data type of the variable is smaller than the data type of the block parameter, the generated code

implicitly casts the data type of the variable to the data type of the block parameter. This implicit cast requires a data copy which can potentially significantly increase RAM consumption and slow down code execution speed for large vectors or matrices.

For more information, see “Parameter Data Types in the Generated Code” (Embedded Coder) and “Create Tunable Calibration Parameter in the Generated Code” (Simulink Coder).

## Efficient Code for Row-Major Array Layout

To generate efficient code for row-major array layout, select the model configuration parameter **Math and Data Types > Use algorithms optimized for row-major array layout**. The row-major algorithms perform with the best speed and memory usage when operating on table data with row-major array layout. Similarly, the default column-major algorithms perform best with column-major array layout. Consider using the algorithm that is optimized for the specified array layout to achieve best performance. For example, use row-major algorithms when array layout is set as row-major during code generation.

| Array Layout | Algorithm    | Cache-Friendly Algorithm |
|--------------|--------------|--------------------------|
| Column-major | Column-major | Recommended              |
| Row-major    | Row-major    | Recommended              |
| Row-major    | Column-major | Not recommended          |
| Column-major | Row-major    | Not recommended          |

For more information, see “Column-Major Layout to Row-Major Layout Conversion of Models with Lookup Table Blocks” (Simulink Coder).

## Row-Major Algorithm in Existing Models Containing Lookup Table Blocks

The Direct Lookup Table (n-D), Interpolation Using Prelookup, and n-D Lookup Table blocks have algorithms that work with row-major array layouts or column-major array layouts. This capability requires a Simulink Coder license. For more information on row-major support, see “Code Generation of Matrices and Arrays” (Simulink Coder).

Prior to R2018b, lookup table blocks supported only column-major array layouts. When selecting algorithms optimized for row-major array layout for a model previously configured for algorithms optimized for column-major array layout, you may need to preserve lookup table block semantics. For example, if a model contains lookup table blocks configured like these:

- An Interpolation Using Prelookup block configured with a subtable selection before interpolation.
- A Direct Lookup Table (n-D) configured for a vector or 2-D matrix output

Use the `permute` function to rearrange the dimensions of the array and preserve the semantics.

For an example of preserving semantics by using table permutations, see “Direct Lookup Table Algorithm for Row-Major Array Layout” (Simulink Coder) .

For an example of converting column-major arrays to row-major arrays see “Column-Major Layout to Row-Major Layout Conversion of Models with Lookup Table Blocks” (Simulink Coder).

| Lookup Table (n-D) | <ul style="list-style-type: none"> <li>• Block renamed as n-D Lookup Table</li> <li>• Icon changed</li> </ul> | <ul style="list-style-type: none"> <li>• Default integer rounding mode changed from Floor to Simplest</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

## Compatibility of Models with Older Versions of Lookup Table Blocks

When you load existing models that contain the Lookup Table, Lookup Table (2-D), and Lookup Table (n-D) blocks, those versions of the blocks appear. The current versions of the lookup table blocks appear only when you drag the blocks from the Simulink Library Browser into new models.

If you use the `add_block` function to add the Lookup Table, Lookup Table (2-D), or Lookup Table (n-D) blocks to a model, those versions of the blocks appear. If you want to

add the *current* versions of the blocks to your model, change the source block path for `add_block`:

| Block              | Old Block Path                            | New Block Path                          |
|--------------------|-------------------------------------------|-----------------------------------------|
| Lookup Table       | simulink/Lookup Tables/Lookup Table       | simulink/Lookup Tables/1-D Lookup Table |
| Lookup Table (2-D) | simulink/Lookup Tables/Lookup Table (2-D) | simulink/Lookup Tables/2-D Lookup Table |
| Lookup Table (n-D) | simulink/Lookup Tables/Lookup Table (n-D) | simulink/Lookup Tables/n-D Lookup Table |

## How to Update Your Model

To update your model to use current versions of the lookup table blocks, follow these steps:

| Step | Action                                                                                                                                                                                   | Reason                                                                                                      |
|------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------|
| 1    | Run the Upgrade Advisor.                                                                                                                                                                 | Identify blocks that do not have compatible settings with the 1-D Lookup Table and 2-D Lookup Table blocks. |
| 2    | For each block that does not have compatible settings: <ul style="list-style-type: none"> <li>Decide how to address each warning.</li> <li>Adjust block parameters as needed.</li> </ul> | Modify each Lookup Table or Lookup Table (2-D) block to ensure compatibility with the current versions.     |
| 3    | Repeat steps 1 and 2 until you are satisfied with the results of the Upgrade Advisor check.                                                                                              | Ensure that block replacement works for the entire model.                                                   |

After block replacement, the block names that appear in the model remain the same. However, the block icons match the ones for the 1-D Lookup Table and 2-D Lookup Table blocks. For more information about the Upgrade Advisor, see “Model Upgrades”.

## What to Expect from the Model Advisor Check

The Model Advisor check groups all Lookup Table and Lookup Table (2-D) blocks into three categories:

- Blocks that have compatible settings with the 1-D Lookup Table and 2-D Lookup Table blocks
- Blocks that have incompatible settings with the 1-D Lookup Table and 2-D Lookup Table blocks
- Blocks that have repeated breakpoints

### Blocks with Compatible Settings

When a block has compatible parameter settings, automatic block replacement can occur without backward incompatibilities.

| Lookup Method in the Lookup Table or Lookup Table (2-D) Block | Parameter Settings After Automatic Block Replacement |                |
|---------------------------------------------------------------|------------------------------------------------------|----------------|
|                                                               | Interpolation                                        | Extrapolation  |
| Interpolation-Extrapolation                                   | Linear                                               | Linear         |
| Interpolation-Use End Values                                  | Linear                                               | Clip           |
| Use Input Below                                               | Flat                                                 | Not applicable |

Depending on breakpoint spacing, one of two index search methods can apply.

| Breakpoint Spacing in the Lookup Table or Lookup Table (2-D) Block | Index Search Method After Automatic Block Replacement                         |
|--------------------------------------------------------------------|-------------------------------------------------------------------------------|
| Not evenly spaced                                                  | Binary search                                                                 |
| Evenly spaced and tunable                                          | A prompt appears, asking you to select Binary search or Evenly spaced points. |
| Evenly spaced and not tunable                                      |                                                                               |

### Blocks with Incompatible Settings

When a block has incompatible parameter settings, the Model Advisor shows a warning and a recommended action, if applicable.

- If you perform the recommended action, you can avoid incompatibility during block replacement.
- If you use automatic block replacement without performing the recommended action, you might see numerical differences in your results.

| Incompatibility Warning                                                                                                                                                                                                                                 | Recommended Action                                                                                                                                                                                                      | What Happens for Automatic Block Replacement                                                                                                                                                                                                                                |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <p>The <b>Lookup Method</b> is Use Input Nearest or Use Input Above. The replacement block does not support these lookup methods.</p>                                                                                                                   | <p>Change the lookup method to one of the following options:</p> <ul style="list-style-type: none"> <li>• Interpolation - Extrapolation</li> <li>• Interpolation - Use End Values</li> <li>• Use Input Below</li> </ul> | <p>The <b>Lookup Method</b> changes to Interpolation - Use End Values.</p> <p>In the replacement block, this setting corresponds to:</p> <ul style="list-style-type: none"> <li>• <b>Interpolation</b> set to Linear</li> <li>• <b>Extrapolation</b> set to Clip</li> </ul> |
| <p>The <b>Lookup Method</b> is Interpolation - Extrapolation, but the input and output are not the same floating-point type. The replacement block supports linear extrapolation only when all inputs and outputs are the same floating-point type.</p> | <p>Change the extrapolation method or the port data types of the block.</p>                                                                                                                                             | <p>You also see a message that explains possible numerical differences.</p>                                                                                                                                                                                                 |
| <p>The block uses small fixed-point word lengths, so that interpolation uses only one rounding operation. The replacement block uses two rounding operations for interpolation.</p>                                                                     | <p>None</p>                                                                                                                                                                                                             | <p>You see a message that explains possible numerical differences.</p>                                                                                                                                                                                                      |

### Blocks with Repeated Breakpoints

When a block has repeated breakpoints, the Model Advisor recommends that you change the breakpoint data and rerun the check. You cannot perform automatic block replacement for blocks with repeated breakpoints.

## Lookup Table Glossary

The following table summarizes the terminology used to describe lookup tables in the Simulink user interface and documentation.

| Term                     | Meaning                                                                                                                                                                                                                                                                                                                                                                      |
|--------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| breakpoint               | A single element of a breakpoint data set. A breakpoint represents a particular input value to which a corresponding output value in the table data is mapped.                                                                                                                                                                                                               |
| breakpoint data set      | A vector of input values that indexes a particular dimension of a lookup table. A lookup table uses breakpoint data sets to relate its input values to the output values that it returns.                                                                                                                                                                                    |
| extrapolation            | A process for estimating values that lie beyond the range of known data points.                                                                                                                                                                                                                                                                                              |
| interpolation            | A process for estimating values that lie between known data points.                                                                                                                                                                                                                                                                                                          |
| lookup table             | An array of data that maps input values to output values, thereby approximating a mathematical function. Given a set of input values, a “lookup” operation retrieves the corresponding output values from the table. If the lookup table does not explicitly define the input values, Simulink can estimate an output value using interpolation, extrapolation, or rounding. |
| monotonically increasing | The elements of a set are ordered such that each successive element is greater than or equal to its preceding element.                                                                                                                                                                                                                                                       |
| rounding                 | A process for approximating a value by altering its digits according to a known rule.                                                                                                                                                                                                                                                                                        |

| Term                              | Meaning                                                                                                                                                                                                                 |
|-----------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| strictly monotonically increasing | The elements of a set are ordered such that each successive element is greater than its preceding element.                                                                                                              |
| table data                        | An array that serves as a sampled representation of a function evaluated at a lookup table's breakpoint values. A lookup table uses breakpoint data sets to index the table data, ultimately returning an output value. |

## Masking Fundamentals

A mask is a custom interface for a block that hides the block content, making it appear as an atomic block with its own icon and parameter dialog box. It encapsulates the block logic, provides controlled access to the block data, and simplifies the graphical appearance of a model.

When you mask a block, a mask definition is created and saved along with the block. A mask changes only the block interface, and not the underlying block characteristics. You can provide access to one or more underlying block parameters by defining corresponding mask parameters on the mask.

Mask a Simulink block to:

- Display a meaningful icon on a block
- Provide a customized dialog box for the block
- Provide a dialog box that enables you to access only select parameters of the underlying blocks
- Provide users customized description that is specific to the masked block
- Initialize parameters using MATLAB code

Consider the model `masking_example` that represents the equation of line  $y = mx + b$ .

Each block has its own dialog box, making it complicated to specify the values for the line equation variables. To simplify the user interface, a mask is applied on the top-level subsystem block.

Here the variable  $m$  represents slope and the variable  $b$  represents the intercept for the line equation  $y = mx + b$ .

The mask dialog box displays the fields for **Slope** and **Intercept** that are internally mapped to variables  $m$  and  $b$ .

Masked blocks do not support content preview. To preview the contents of a subsystem, see “Preview Content of Model Components” on page 1-60.

---

**Tip** For masking examples, see Simulink Masking Examples. The examples are grouped by type. In an example model:

- To view the mask definition, double-click the View Mask block.
  - To view the mask dialog box, double-click the block.
- 

Examples of few blocks that cannot be masked are:

- Scope blocks
- Simulink Function block
- Initialize, Terminate and Reset Function blocks
- Gauge blocks

## Masking Terminology

| Term                      | Description                                                                                                                                                                                                                                                         |
|---------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Mask icon                 | The masked block icon generated using drawing commands. Mask icon can be static or change dynamically with underlying block parameter values.                                                                                                                       |
| Mask parameters           | The parameters that are defined in the Mask Editor and appear on the mask dialog box. Setting the value of a mask parameter on the mask dialog box sets the corresponding block parameter value.                                                                    |
| Mask initialization code  | MATLAB Code that initializes a masked block or reflects current parameter values. Add mask initialization code in the <b>Initialization</b> pane of the Mask Editor dialog box. For example, add initialization code to set a parameter value automatically.        |
| Mask dialog callback code | MATLAB Code that runs in the base workspace when the value of a mask parameter changes. Use callback code to change the appearance of a mask dialog box dynamically and reflect current parameter values. For example, enable visible parameters on the dialog box. |
| Mask documentation        | Description and usage information for a masked block defined in the Mask Editor.                                                                                                                                                                                    |
| Mask dialog box           | A dialog box that contains fields for setting mask parameter values and provides mask description.                                                                                                                                                                  |
| Mask workspace            | Masks that define mask parameters or contain initialization code have a mask workspace. This workspace stores the evaluated values of the mask parameters and temporary values used by the mask.                                                                    |

### More About

- “Create Block Masks”
- “Create a Simple Mask” on page 39-7
- “Mask Editor Overview”
- Set mask parameters
- Creating a Mask: Masking Fundamentals (3 min, 46 sec)

## Create a Simple Mask

You can mask a block interactively by using the Mask Editor or mask it programmatically. This example describes how to mask a block by using the **Mask Editor**. To mask a block programmatically, see “Control Masks Programmatically” on page 39-37.

For masking examples, see Simulink Masking Examples.

### Step 1: Open Mask Editor

- 1 Open the model in which you want to mask a block. For example, open `subsystem_example`.

This model contains a Subsystem block that models the equation for a line:  $y = mx + b$ .

- 2 Right-click the Subsystem block and select **Mask > Create Mask**.

## Step 2: Define the Mask

The **Mask Editor** contains four tabs that enable you to define the block mask and customize the dialog box for the mask.

For detailed information on each pane, see “Mask Editor Overview”.

### Icon & Ports Tab

Use this tab to create an icon for the block mask. You can use the **Options** pane on the left to specify icon properties and icon visibility.

Add an image to the block mask.

- 1 In the **Block frame** drop-down box, select **Visible**.
- 2 In the **Icon transparency** drop-down box, select **Opaque**.
- 3 In the **Icon units** drop-down box, select **Autoscale**.
- 4 To restrict the icon rotation, select **Fixed** from the **Icon rotation** list.
- 5 In the **Icon drawing commands** text box, type,

```
x = [0 0.5 1 1.5];y = [0 0.5 1 1.5];
% An example to defines the variables x and y
plot(y,x) % Command to plot the graph
```

For more information on drawing command syntax, see “Icon drawing commands”.

- 6 To save the changes, click **Apply**. To preview the block mask icon without exiting the **Mask Editor**, click **Preview**

---

**Note** For detailed information, see “Icon & Ports Pane”.

---

You can create static or dynamic block mask icons. For more information, see “Draw Mask Icon” on page 39-22 and `slexMaskDisplayAndInitializationExample`.

### Parameters & Dialog Tab

Use this tab to add controls like parameters, displays, and action items to the mask dialog box.

To add **Edit** boxes to the block mask.

- 1 In the left pane, under **Parameter**, click **Edit** twice to add two new rows in the **Dialog box** pane.
- 2 Type **Slope** and **Intercept** in the **Prompt** and **Name** columns, respectively. The value that you enter in **Prompt** column appears on the mask dialog box. The value you enter in **Name** column is the mask parameter name. The mask parameter name must be a valid MATLAB name.
- 3 In the right pane, under **Property editor**, provide values in the **Properties**, **Dialog**, and **Layout** sections.
- 4 Click **Apply**.

- 5 To preview the mask dialog box without exiting the Mask Editor, click **Preview**.

---

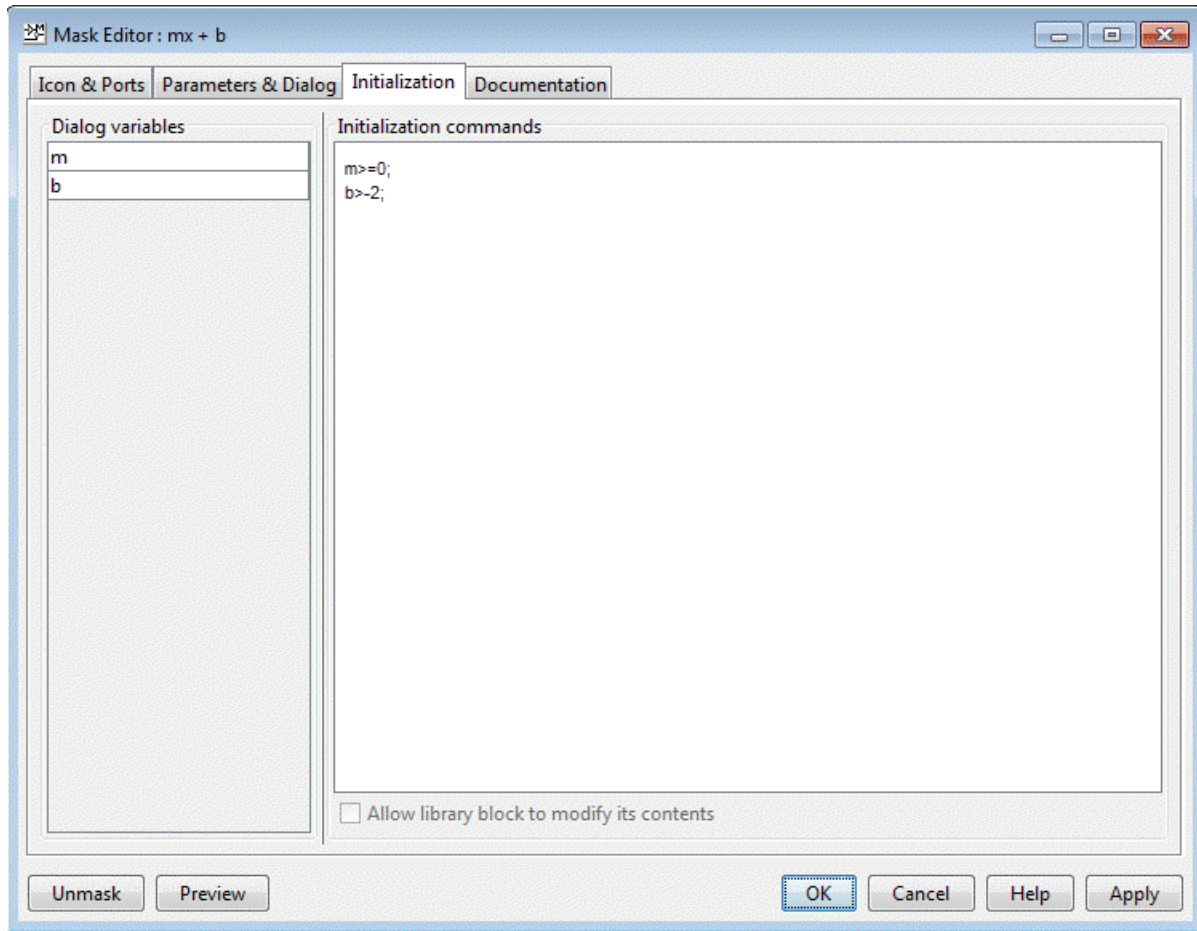

**Note** For detailed information, see “Parameters & Dialog Pane”.

---

### **Initialization Tab**

Use this pane to specify MATLAB code to control the mask parameters. You can add conditions for the user specified values, provide a predefined value for a mask parameter, and so on.

Consider the equation  $y = mx + b$ . To allow positive value for  $m$ , you can add MATLAB code in the initialization pane to specify the acceptable range for  $m$  as greater than zero.

---

**Note** For detailed information, see “Initialization Pane”.

---

### Documentation Tab

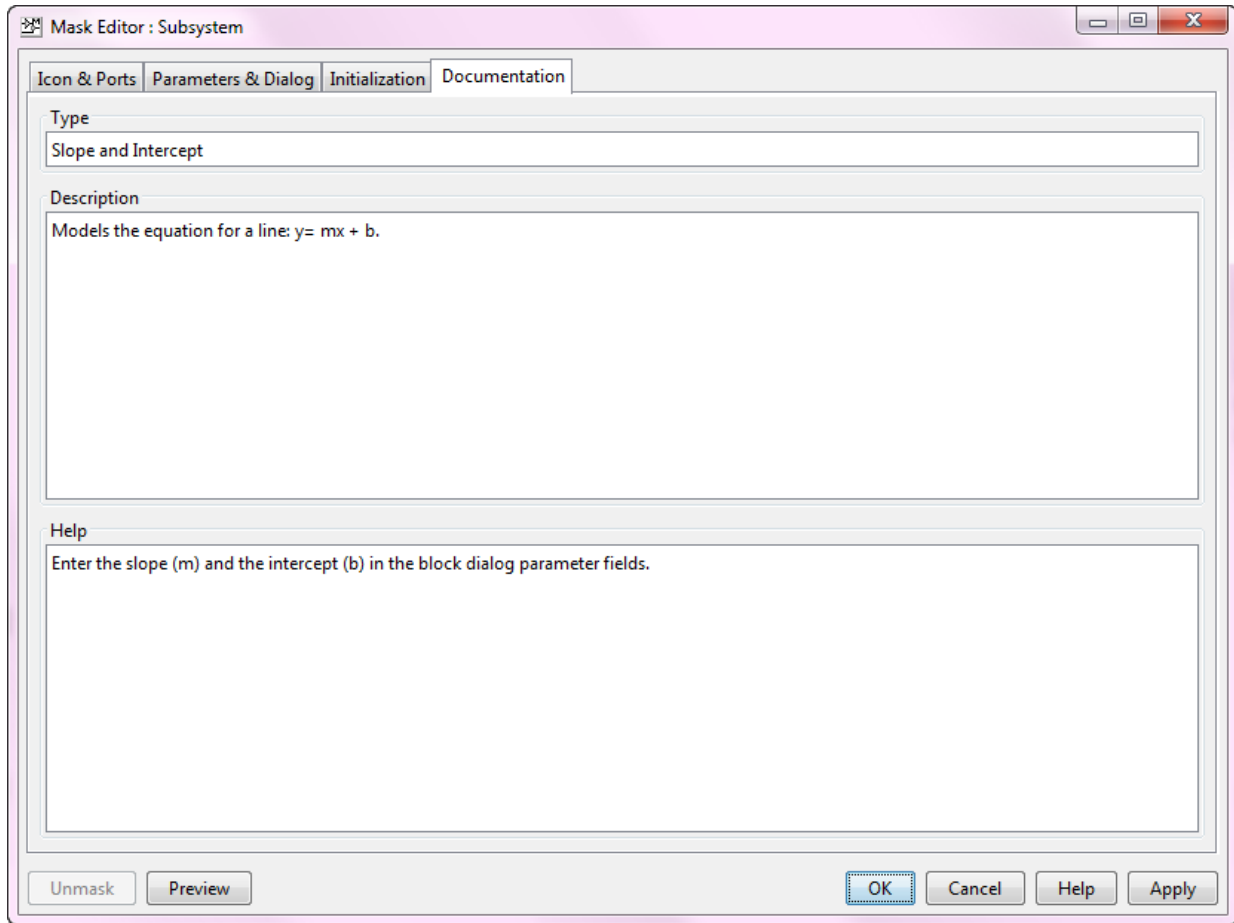

Use this tab to add a name, description, and additional information for the mask.

The **Documentation** tab contains these fields:

- 1 Type:** You can add a name for the block mask in this box. The mask name appears on top of the mask dialog box. You cannot add new lines.
- 2 Description:** You can add a description for the block mask in this box. By default, the description is displayed below the mask name, and it can contain new lines and spaces.
- 3 Help.** You can add additional information for the block mask in this box. You click **Help** on the mask dialog box, this information is displayed. You can use plain text, HTML and graphics, URLs, and web or eval commands to add information in the **Help** field.

After you have added information in the **Mask Editor**, click **Apply** or **OK**.

The block is now masked.

---

**Note** For detailed information, see “Documentation Pane”.

---

### Step 3: Operate on Mask

- 1 You can preview the mask and choose to unmask the block or edit the block mask.
- 2 Double-click the masked block.

The mask dialog box appears.

- 3 Type values in the **Slope** and **Intercept** boxes of the mask dialog box. To view the output, simulate the model.
- 4 Click **OK**.
- 5 To edit the mask definition, right-click the block and select **Mask > Edit Mask**. For more information, see “Manage Existing Masks” on page 39-16.
- 6 Right-click the masked block and select **Mask > Look Under Mask** to view:
  - The blocks inside the masked subsystem
  - The built-in block dialog box of a masked block
  - The base mask dialog box of a linked masked block

## See Also

“Create Block Masks” | “Mask Editor Overview” | “Masking Fundamentals” on page 39-2 | Creating a Mask: Masking Fundamentals (3 min, 46 sec)

## Manage Existing Masks

### Change a Block Mask

You can change an existing mask by reopening the Mask Editor and using the same techniques that you used to create the mask:

- 1 Select the masked block.
- 2 Select **Mask > Edit Mask**.

The Mask Editor reopens, showing the existing mask definition. Change the mask as needed. After you change a mask, click **Apply** to preserve the changes.

### View Mask Parameters

To display a mask dialog box, double-click the block. Alternatively, right-click the block and select **Mask > Mask Parameters** or click **Diagram > Mask > Mask Parameters**.

---

**Tip** Each block has a block parameter dialog box. To view the block parameters dialog box of a masked block, right-click the masked block and select **Block Parameters (BlockType)**.

---

### Look Under Block Mask

To see the block diagram under a masked Subsystem block, built-in block, or the model referenced by a masked model block, right-click the block and select **Mask > Look Under Mask**.

### Remove Mask

To remove a mask from a block,

- 1 Right-click the block.
- 2 Select **Mask > Edit Mask**.

The Mask Editor opens and displays the existing mask, for example:

- 3 Click **Unmask** in the lower left corner of the Mask Editor.

The Mask Editor removes the mask from the block.

## Mask Callback Code

### In this section...

“Add Mask Code” on page 39-18  
 “Execute Drawing Command” on page 39-18  
 “Execute Initialization Command” on page 39-19  
 “Execute Callback Code” on page 39-20

### Add Mask Code

You can use MATLAB code to initialize a mask and to draw mask icons. Since the location of code affects model performance, add your code to reflect the functionality you need.

| Purpose                           | Add in Mask Editor                  | Programmatic Specification   |
|-----------------------------------|-------------------------------------|------------------------------|
| Initialize the mask               | <b>Initialization</b> pane          | MaskInitialization parameter |
| Draw mask icon                    | <b>Icon &amp; Ports</b> pane        | MaskDisplay parameter        |
| Callback code for mask parameters | <b>Parameters &amp; Dialog</b> pane | MaskCallbacks parameter      |

### Execute Drawing Command

Place MATLAB code for drawing mask icons in the **Icon Drawing Commands** section of the **Icon & Ports** pane. Simulink executes these commands sequentially to redraw the mask icon when:

- Block is rendered first on the Mask Editor canvas.
- Mask parameters and values that depend on drawing commands change.
- Block appearance is altered due to rotation or other changes.

---

**Note** Placing MATLAB code for drawing mask icons in the **Initialization** pane affects model performance. This behavior is because Simulink redraws the icon each time the masked block is evaluated in the model.

---

## Execute Initialization Command

Initialization commands for all masked blocks in a model run when you:

- Update the diagram
- Start simulation
- Start code generation
- Apply mask changes
- Change any of the parameters that define the mask, such as `MaskDisplay` and `MaskInitialization`, using the Mask Editor or `set_param`.
- Rotate or flip the masked block, if the icon depends on initialization commands.
- Cause the icon to be drawn or redrawn, and the icon drawing depends on initialization code.
- Change the value of a mask parameter by using the block dialog box or `set_param`.
- Copy the masked block within the same model or between different models.

When you open a model, Simulink locates visible masked blocks that reside at the top level of the model or in an open subsystem.

Simulink only executes the initialization commands for these visible masked blocks if they meet either of the following conditions:

- The masked block has icon drawing commands.

---

**Note** Simulink does not initialize masked blocks that do not have icon drawing commands, even if they have initialization commands during model load.

---

- The masked subsystem belongs to a library and has the **Allow library block to modify its contents** parameter enabled.

When you load a model into memory without displaying it graphically, no initialization commands initially run for any masked blocks. See “Load a Model” on page 1-13 and `load_system` for information about loading a model without displaying it.

---

**Note** The non-tunable parameters of a masked block are not evaluated if the model is already compiled (initialized).

---

## Execute Callback Code

Mask parameter callback codes are executed in a temporary workspace and not in the base workspace. If you need a variable created in the callback to be available later (not during callback processing), you must explicitly assign those variables to the base workspace.

Simulink executes the callback commands when:

- You open the mask dialog box. Callback commands execute sequentially, starting with the top mask dialog box.
- You modify a parameter value in the mask dialog box and then change the cursor location. For example, you press the **Tab** key or click into another field in the dialog box after changing the parameter value.
- You modify the parameter value by using the `set_param` command, the callback commands execute.
- You modify the parameter value, either in the mask dialog box or using `set_param`, and then apply the change by clicking **Apply** or **OK**. Mask initialization commands execute after callback commands. For more information, see “Initialization Pane”.
- You hover over a masked block to see the tool tip for the block, when the tool tip contains parameter names and values.

---

**Note** Callback commands do not execute if the mask dialog box is open when the block tool tip appears.

---

- You update a diagram (for example, by pressing **Ctrl+D** or by selecting **Simulation > Update diagram** in the Simulink Editor).
- If you close a mask dialog box without saving the changes, the Callback command for parameters is executed sequentially.

---

**Note** Buttons on mask dialog box are unavailable when the callback code associated with the button is being executed.

---

For related Simulink example models, see:

- Sequence mask callbacks
- Unsafe mask callbacks

- Unsafe nested mask callbacks

## **See Also**

“Create Block Masks” | “Initialize Mask” on page 39-26

## Draw Mask Icon

You can create icons that update when you change the mask parameters to reflect the purpose of the block. This example shows how to use drawing commands to create a mask icon.

### In this section...

“Draw Static Icon” on page 39-22

“Draw Dynamic Icon” on page 39-23

## Draw Static Icon

A static mask icon remains unchanged, independent of the value of the mask parameters.

- 1 Right-click the masked block that requires the icon and select **Mask > Edit Mask**.

- 2 In the **Icons & Ports** tab, enter this command in the **Icon Drawing commands** pane:

```
% Use specified image as mask icon
image('engine.jpg')
```

The image file must be on the MATLAB path.

For more examples of drawing command syntax, see “Icon drawing commands”.

Images in formats `.cur`, `.hdf4`, `.ico`, `.pcx`, `.ras`, `.xwd`, `.svg` cannot be used as block mask images. However, you can use images in these formats if you wrap the file name in the `imread()` function and use the RGB triplet. Using the `imread()` function is not efficient. However, it is still supported for backward compatibility.

## Draw Dynamic Icon

A dynamic icon changes with the values of the mask parameters. Use it to represent the purpose of the masked block.

- 1 Right-click the masked block that requires the icon and select **Mask > Edit Mask**.

The Mask Editor opens.

- 2 In the **Icons & Ports** tab, enter this command in the **Icon Drawing commands** pane:

```
pos = get_param(gcf, 'Position');
width = pos(3) - pos(1);
x = [0, width];
y = m*x + b;
% Parameters 'm' and 'b' must be defined in 'Parameters & Dialog' pane.
plot(x,y)
```

- 3 Under **Options**, set **Icon Units** to **Pixels**.

The drop-down lists under **Options** allow you to specify icon frame visibility, icon transparency, drawing context, icon rotation, and port rotation.

- 4 Click **Apply**. To view the icon generated, see `model_masking_example`.

---

**Note** If Simulink cannot evaluate all commands in the **Icon Drawing commands** pane to generate an icon, three question marks (? ? ?) appear on the mask.

---

See `slexMaskDisplayAndInitializationExample` for more examples of icon drawing commands. This model shows how to draw:

- Static mask
- Dynamic shape mask
- Dynamic text mask
- Image mask

## See Also

“Create Block Masks”

## Initialize Mask

You can add MATLAB code in the Initialization pane of the Mask Editor to initialize a masked block. Simulink executes these initialization commands to initialize a masked subsystem at critical times, such as model loading and start of a simulation run. For more information, see “Execute Initialization Command” on page 39-19.

You can add mask initialization code for these cases:

- To specify the initial values of mask parameters. For example to specify an initial value of parameter `a`, type `a = 5` in the Initialization pane.
- To specify an acceptable range of inputs for mask parameter. For example, to specify the range between 0 and 10 as the acceptable values for parameter `a`, type `assert(0<=a && a<=10)`.
- To specify the value of a child block. For example,  

```
set_param('Child block Name','Parameter name','Parameter Value')
```
- To create a self-modifiable mask. For more information, see Self-Modifying Mask.

The initialization code of a masked subsystem can refer only to the variables in its local workspace.

When you reference a block with, or copy a block into, a model, the mask dialog box displays the specified default values. You cannot use mask initialization code to change mask parameter default values in a library block or any other block.

Ensure that the mask parameters used in the mask initialization code are defined. During edit-time, errors in the mask initialization code are not reported if Simulink fails to evaluate the mask parameters used in the mask initialization code. However, such errors are reported during edit-time and during model compilation if there are no errors in evaluating the mask parameters.

---

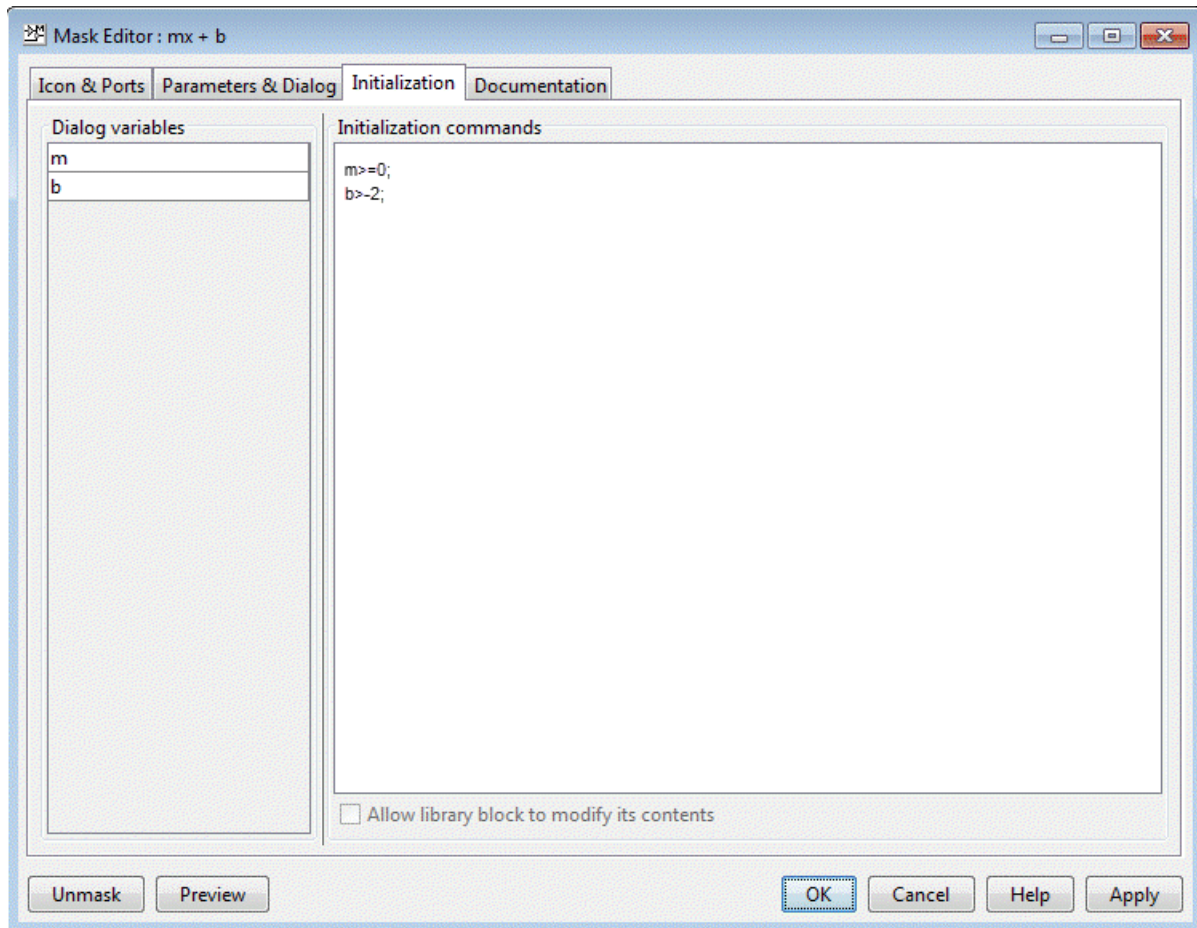

### Note

- Blocks that contain initialization code do not work as expected when using model reference.
  - When you use `set_param` in the mask initialization code of a Subsystem block, the child blocks are also evaluated.
-

Use the Mask Editor **Initialization** pane to add MATLAB commands that initialize a masked block.

The **Initialization** pane contains these sections:

- **Dialog variables**
- **Initialization commands**

## Dialog Variables

The **Dialog variables** section displays the names of the variables associated with the mask parameters of the masked block that are defined in the **Parameters** pane.

You can copy the name of a parameter from this list and paste it into the **Initialization commands** section.

You can change the name of the mask parameter variable in the list by double-clicking and editing the name.

## Initialization Commands

You can add the initialization commands in this section. The initialization code must be a valid MATLAB expression, consisting of MATLAB functions and scripts, operators, and variables defined in the mask workspace. Initialization commands cannot access base workspace variables.

To avoid echoing results to the MATLAB Command Window, terminate initialization commands with a semicolon.

To view related examples, see

- Define mask display and initialization
- Use MATLAB graphics in masking

## Mask Initialization Best Practices

Mask initialization commands must observe the following rules:

- Do not use initialization code to create dynamic mask dialog boxes (Dialog boxes whose appearance or control settings change depending on changes made to other control settings). Instead, use the mask callbacks that are intended for this purpose. For more information, see “Dynamic Mask Dialog Box” on page 39-49.
- For nested masked subsystem, do not use `set_param` on a block located in the lower-level masked subsystem from the higher-level masked subsystem. The lower-level mask and the higher-level mask both could be initializing the same parameter of the block leading to unexpected behavior. For more information, see Unsafe Mask Callback Error.

- Do not use `set_param` commands on blocks that reside in another masked subsystem that you are initializing. Trying to set parameters of blocks in lower-level masked subsystems can trigger unresolved symbol errors if lower-level masked subsystems reference symbols defined by higher-level masked subsystems.

Suppose, for example, a masked subsystem A contains a masked subsystem B which contains Gain block C, whose `Gain` parameter references a variable defined by B. Suppose also that subsystem A has initialization code that contains this command:

```
set_param([gcb '/B/C'], 'SampleTime', '-1');
```

Simulating or updating a model containing A causes an unresolved symbol error.

- You cannot use mask initialization code to create data objects. Data objects are objects of these classes:
  - `Simulink.Parameter` and subclasses
  - `Simulink.Signal` and subclasses
- Do not add initialization code to delete the same masked block.
- Use mask initialization code to control direct child blocks only.

---

**Note** Do not use mask initialization code to comment or uncomment a block.

---

“Create Block Masks” | “Masking Fundamentals” on page 39-2 | “Mask Callback Code” on page 39-18 | Self-Modifying Interface Connector

## Promote Parameter to Mask

| In this section...                                              |
|-----------------------------------------------------------------|
| “Promote Underlying Parameters to Block Mask” on page 39-32     |
| “Promote Underlying Parameters to Subsystem Mask” on page 39-34 |
| “Unresolved Promoted Parameter” on page 39-36                   |
| “Best Practices” on page 39-36                                  |

Blocks and subsystems can have multiple parameters associated with them. Block masks allow you to expose one or more of these parameters while hiding others from view. Promoting specific parameters to the mask block simplifies the interface and enables you to specify the parameters the user of the block can view and set.

You can use the **Promote** button on the Mask Editor to promote any underlying parameter of a block either to a block mask or to a subsystem mask. The promoted block parameter gets associated with a parameter in the mask, enabling you to edit the parameter value from the mask dialog box.

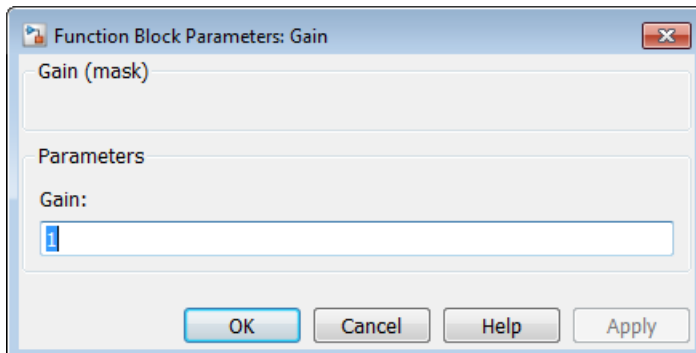

Promote parameters from the block dialog box to the mask:

- To customize the mask dialog box by moving the required parameters from the block dialog box to the mask dialog box.
- To reuse a library block at different instances of a model. For each instance of the library block, you can create individual mask dialog box by promoting parameters for each block.

Consider the block dialog box of the Gain block, which has parameters such as **Gain**, **Multiplication**.

To expose only the **Gain** parameter, mask the Gain block and promote the **Gain** parameter to the mask dialog box.

Similarly, you can mask a subsystem block and promote parameters to the mask from child blocks of the subsystem block. If the data type of subsystem child block parameters is same, you can associate a single mask parameter with multiple promoted parameters. For example, you can promote multiple **Gain** parameters in a subsystem to a single dialog box on your mask.

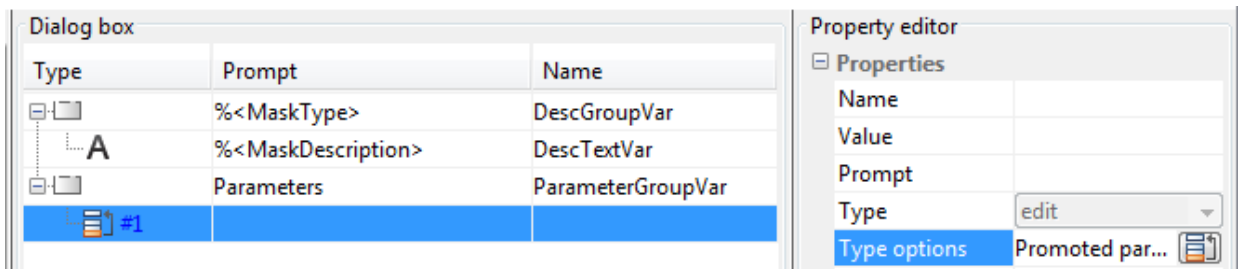

If the parameter is of data type popup or `DataType`, the options must also be the same for the parameters to be promoted together. The **Evaluate** attribute for all the parameters to be promoted must be similar.

For a related example, see Promote mask parameters

You can also change the attributes of a promoted parameter. For example, you can make a promoted parameter read only or hidden. For more information on attributes, see “Property editor”.

## Promote Underlying Parameters to Block Mask

- 1 Right-click the block whose parameter you want to promote and select **Mask > Create Mask**.
- 2 In the **Mask Editor** dialog box, click the **Parameters & Dialog** tab.
- 3 In the **Controls** pane, click **Promote**.
- 4 In the **Property editor** pane, next to **Type options**, click .

Use the **Promoted Parameter Selector** dialog box to select the parameters that you want to promote.

- To add a parameter to the **Promoted parameters** list, select a parameter from the **Promotable parameters** table and click the **Add to promoted parameter list** button .

To view the parameter properties such as **Type**, hover over the parameter name in the **Promotable parameter** pane.

---

### Tip

- You can use the **Child blocks** list or the **Search** box to find underlying block parameters to promote.
  - To prevent tuning of a property during simulation, you can disable the **Tunable** attribute while promoting a tunable parameter.
- 

- Click **OK**.
- In the **Mask Editor** dialog box, edit the prompt names for the promoted parameters and click **OK**. You cannot edit the variable names. You can change the attributes of the promoted parameter in the Property editor section. For example, you can mark

the promoted parameter as read-only, evaluate, hidden, and tunable. For more information, see “Property editor”.

- 8 Click **OK**. Look at the block mask. Only the parameters you promoted are available to set.

---

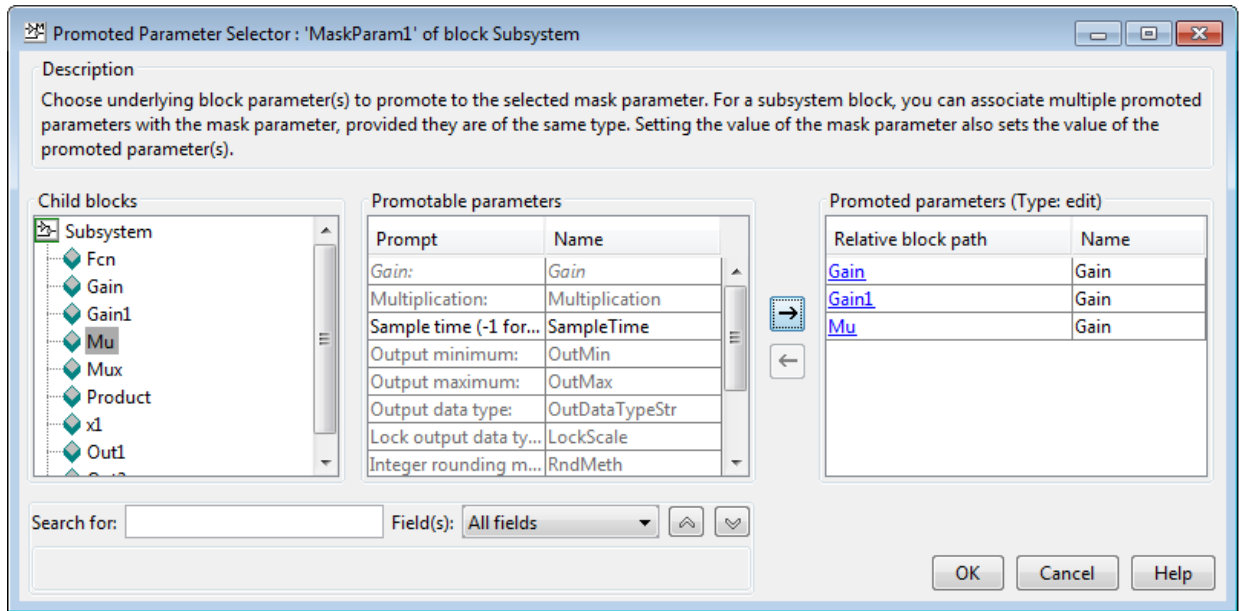

**Note**

- You can use **Promote all**  to promote all parameters. **Promote all** is available for all block masks except for subsystem masks.
  - To remove a promoted parameter, select the parameter and press **Delete** key.
  - You cannot view or promote parameters of a nested masked or linked child block.
- 

## Promote Underlying Parameters to Subsystem Mask

- 1 Right-click the subsystem and select **Mask > Create Mask**.
- 2 In the **Mask Editor** dialog box, click the **Parameters & Dialog** tab.
- 3 In the **Controls** pane, click **Promote**.
- 4 In the **Property editor** pane, next to **Type options**, click .
- 5 In the **Promoted Parameter Selector** dialog box, select the parameters that you want to promote.
- 6 To add a parameter to the **Promoted parameters** list, select a parameter from the **Promotable parameters** table and click the **Add to promoted parameter list** button .

You can add parameters of the same data type from different child blocks to the **Promoted parameters** list. For example, the Gain parameter from a different child block can be added to the **Promoted parameters** list to promote to the single Gain parameter on the mask.

- 7 Click **OK**.
- 8 In the **Mask Editor** dialog box, edit the prompt names for the promoted parameters and click **OK**. You cannot edit the variable names.
- 9 Click **OK**. Look at the block mask. Only the parameters you promoted are available to set.

## Unresolved Promoted Parameter

When a promoted parameter is disconnected from the underlying block parameter, the promoted parameter is unresolved. Unresolved promoted parameters can cause the model to be erroneous as the promoted parameter cannot find the corresponding block parameter. Promoted parameters can become unresolved for any of these reasons:

- The underlying block is deleted.
- The underlying block is replaced with another block of same name but does not have the specified parameter.
- The underlying block is moved within another mask.

## Best Practices

- Set the value of a promoted parameter only in the mask dialog box and not in the underlying block dialog box or from the command line.
- Parameters once promoted cannot be promoted again to any other mask.
- Do not edit the **Evaluate** attribute of the promoted parameter. This property is inherited from the block parameter.
- If you are promoting a nontunable parameter, do not edit the **Tunable** attribute.
- Parameters of a masked or linked child block cannot be viewed or promoted.
- Callbacks associated with a block parameter are promoted to the block mask and not to the subsystem mask. User-defined callbacks are sequentially executed after the dynamic dialog callback execute.

## Control Masks Programmatically

### In this section...

“Use Simulink.Mask and Simulink.MaskParameter” on page 39-37

“Use get\_param and set\_param” on page 39-38

“Programmatically Create Mask Parameters and Dialogs” on page 39-39

Simulink defines a set of parameters that help in setting and editing masks. To set and edit a mask from the MATLAB command line, you can use `Simulink.Mask` and `Simulink.MaskParameter` class methods. You can also use the `get_param` and `set_param` functions to set and edit masks. However, since these functions use delimiters that do not support Unicode (Non-English) characters it is recommended that you use methods of the `Simulink.Mask` and `Simulink.MaskParameter` class methods to control masks.

### Use Simulink.Mask and Simulink.MaskParameter

Use methods of `Simulink.Mask` and `Simulink.MaskParameter` classes to perform the following mask operations:

- Create, copy, and delete masks
  - Create, edit, and delete mask parameters
  - Determine the block that owns the mask
  - Get workspace variables defined for a mask
- 1** In this example the `Simulink.Mask.create` method is used to create a block mask:

```
maskObj = Simulink.Mask.create(gcb);
```

```
maskObj =
 Simulink.Mask handle
 Package: Simulink
 Properties:
 Type: ''
 Description: ''
 Help: ''
 Initialization: ''
 SelfModifiable: 'off'
 Display: ''
```

```

 IconFrame: 'on'
 IconOpaque: 'on'
 RunInitForIconRedraw: 'off'
 IconRotate: 'none'
 PortRotate: 'default'
 IconUnits: 'autoscale'
 Parameters: []
 Methods, Events, Superclasses

```

- 2 In this example the mask object is assigned to variable `maskObj` using the `Simulink.Mask.get` method:

```

maskObj = Simulink.Mask.get(gcb)

maskObj =
 Simulink.Mask handle
 Package: Simulink
 Properties:
 Type: ''
 Description: ''
 Help: ''
 Initialization: ''
 SelfModifiable: 'off'
 Display: ''
 IconFrame: 'on'
 IconOpaque: 'on'
 RunInitForIconRedraw: 'off'
 IconRotate: 'none'
 PortRotate: 'default'
 IconUnits: 'autoscale'
 Parameters: [1x1 Simulink.MaskParameter]
 Methods, Events, Superclasses

```

For examples of other mask operations, like creating and editing mask parameters and copying and deleting masks see `Simulink.Mask` and `Simulink.MaskParameter`.

## Use `get_param` and `set_param`

The `set_param` and `get_param` functions have parameters for setting and controlling the mask. You can use these functions to set the mask of any block in the model or library based on a value passed from the MATLAB command line:

```

set_param(gcb, 'MaskStyleString', 'edit,edit', ...
'MaskVariables', 'maskparameter1=@1;maskparameter2=&2;', ...

```

```

'MaskPromptString','Mask Parameter 1:|Mask Parameter 2:',...
'MaskValues',{ '1','2'});

get_param(gcb,'MaskStyleString');

set_param(gcb,'MaskStyles',{'edit','edit'},'MaskVariables',...
'maskparameter1=@1;maskparameter2=&2;', 'MaskPrompts',...
{'Mask Parameter 1:', 'Mask Parameter 2:'},...
'MaskValueString','1|2');

get_param(gcb,'MaskStyles');

```

where

- | separates individual character vector values for the mask parameters.
- @ indicates that the parameter field is evaluated.
- & indicates that the parameter field is not evaluated but assigned as a character vector.

---

### Note

- When you use `get_param` to get the Value of a mask parameter, Simulink returns the value that was last applied using the mask dialog. Values that you have entered into the mask dialog box but not applied are not reflected when you use the `get_param` command.
  - To specify the value of a mask parameter programmatically, it is recommended to use **set\_param** command on the **mask parameter** instead of using **set\_param** on **MaskValues**.
- 

To control the mask properties programmatically for a release before R2014a, see Mask Parameters.

## Programmatically Create Mask Parameters and Dialogs

This example shows how to create this simple mask dialog, add controls to the dialog, and change the properties of the controls.

- 1 Create the mask for a block you selected in the model.

```
maskobj = Simulink.Mask.create(gcf);
```

- 2 To customize the dialog and to use tabs instead of the default group, remove the **Parameters** group box.

```
maskobj.removeDialogControl('ParameterGroupVar');
```

Simulink preserves the child dialog controls- the two check boxes in this example- even when you delete the `ParametersGroupVar` group surrounding them. These controls are parameters, that cannot be deleted using dialog control methods.

You can delete parameters using methods such as `Simulink.Mask.removeAllParameters`, which belongs to the `Simulink.Mask` class.

- 3 Create a tab container and get its handle.

```
tabgroup = maskobj.addDialogControl('tabcontainer','tabgroup');
```

**4** Create tabs within this tab container.

```
tab1 = tabgroup.addDialogControl('tab','tab1');
tab1.Prompt = 'First';
maskobj.addParameter('Type','checkbox','Prompt','Option 1',...
 'Name','option1','Container','tab1');
maskobj.addParameter('Type','checkbox','Prompt','Option 2',...
 'Name','option2','Container','tab1');

tab2 = tabgroup.addDialogControl('tab','tab2');
tab2.Prompt = 'Second';
tab3 = tabgroup.addDialogControl('tab','tab3');
tab3.Prompt = 'Third (invisible)';
```

Make the third tab invisible.

```
tab3.Visible = 'off'
```

```
tab3 =
```

```
 Tab with properties:
```

```
 Name: 'tab3'
 Prompt: 'Third (invisible)'
 Enabled: 'on'
 Visible: 'on'
 DialogControls: []
```

You can change the location and other properties of the parameters on the dialog by using the `Simulink.dialog.Control` commands. For more information on dialog controls and their properties, see `Simulink.dialog.Control`.

## See Also

“Create Block Masks” | “Masking Fundamentals” on page 39-2 | “Initialize Mask” on page 39-26

## Pass Values to Blocks Under the Mask

A masked block can pass values to the block parameters under the mask. The underlying blocks use the passed values during simulation to execute the block logic.

A masked block has variables associated with mask parameters. These variables are stored in the mask workspace for a model and can correspond to a block parameter under the mask. When such a block is evaluated, the block variables look for matching values in the mask workspace to get a value.

The mapping of variables from the mask workspace to the base workspace must be correct. A correct mapping ensures that the right block variable is assigned the value that is passed from the mask.

Use any of these options to pass values to blocks under the mask:

- Parameter promotion (recommended)
- Mask initialization
- Referencing block parameters using variable names (For the Edit Parameter only)

### Parameter Promotion

When you promote a block parameter to its mask, the block parameter becomes accessible from the mask dialog box, allowing you to pass a value for the block parameter. Parameter promotion ensures correct mapping of parameter values and is a recommended way to pass values to the block from the mask dialog box. For more information on promoting a parameter, see “Promote Parameter to Mask” on page 39-30.

### Mask Initialization

You can use MATLAB code in the Initialization pane of the Mask Editor to assign or pass values to the block parameters under the mask. You can assign a fixed value to a block parameter, specify an acceptable range for the input values, or specify a value for the child block. For more information, see “Initialize Mask” on page 39-26.

### Referencing Block Parameters Using Variable Names

You can add an Edit parameter to the mask dialog box and pass values to the block parameters through it. The values that you provide for the Edit parameter in the mask

dialog box automatically becomes associated with the block parameter, by using the techniques described in “Symbol Resolution” on page 62-174.

Consider the model `masking_example`, which contains a masked Subsystem block and governs the equation  $y = mx + b$ . Here,  $m$  and  $b$  are variables controlling the slope and intercept of the equation and are associated with the Gain and the Constant block, respectively.

The variables  $m$  and  $b$  are assigned to the mask parameters **Slope** and **Intercept**, respectively, as parameter names in the Mask Editor.

When you type values for **Slope** and **Intercept** in the mask dialog box, these values are internally assigned to the variables  $m$  and  $b$ . When the model is simulated, the Gain block and the Constant block search for numeric values of  $m$  and  $b$  and apply them to resolve the equation  $y = mx + b$ .

## Mask Linked Blocks

|                                                         |
|---------------------------------------------------------|
| <b>In this section...</b>                               |
| “Guidelines for Mask Parameters” on page 39-47          |
| “Mask Behavior for Masked, Linked Blocks” on page 39-47 |
| “Mask a Linked Block” on page 39-48                     |

Simulink libraries can contain blocks that have masks. An example of this type of block is the Ramp block. These blocks become library links when copied to a model or another library. You can add a mask on this linked block. If this linked block is in a library and copied again, you can add another mask to this new linked block thus creating a stack of masks. Masking linked blocks allows you to add a custom interface to the link blocks similar to other Simulink blocks.

You can also apply a mask to a block, then include the block in a library. Masking a block that is later included in a library requires no special provisions. For more information, see “Create a Custom Library” on page 41-4.

The block mask that is present as part of the library is the base mask. A derived mask is the one created on top of the base mask.

For example, in the figure, Library A contains Block A, which has a Mask A. Block A is copied to Library B, and Mask B is added to it. When Block A is copied to Library B, a library link from Library B to Library A is created.

Block B is then copied to a model, and Mask C is added to it. This creates a library link from Block C to Library B. Block C now has Mask A, Mask B, and Mask C. Mask C is the derived mask and Mask B is the base mask.

For Block C:

- Mask parameter names are unique in the stack.
- You can set mask parameters for Mask B and Mask C.
- Mask B and Mask C inherit `MaskType` and `MaskSelfModifiable` parameters from Mask A.
- Mask initialization code for Mask C executes first, followed by Mask B and Mask A.
- Variables are resolved starting from the mask immediately above the current mask in the stack. If the current mask is the top mask, it follows the regular variable resolution rules.

Creating or changing a library block mask changes the block interface in all models that access the block using a library reference, but has no effect on instances of the block that exist as separate copies.

To view related example, see Use self-modifying library masks.

## Guidelines for Mask Parameters

- You cannot use same names for the mask parameters. The exception is the **Promote** type mask parameter, for which the name is inherited and is the same as that of the parameter promoted to it.
- You cannot set mask parameters for masks below the base mask. Mask parameters for masks below the base mask are inherited from the library.

## Mask Behavior for Masked, Linked Blocks

The following are some of the behaviors that are important to understand about masked, linked blocks.

- The `MaskType` and the `MaskSelfModifiable` parameters are inherited from the base mask.
- The mask display code for the derived mask executes first, followed by the display code for the masks below it until we come across a mask whose `MaskIconFrame` parameter is set to `opaque`.
- The mask initialization code for the derived mask executes first, followed by the initialization code for the masks below it.
- Variables are resolved starting from the mask immediately above the current mask in the stack. If the current mask is the top mask, the regular variable resolution rules apply.
- When you save a Simulink model or library containing a block with multiple masks, using **File > Export Model to > Previous Version**, the `SourceBlock` parameter is modified to point to the library block having the bottom-most mask.
- The following occurs when you disable, break, or reestablish links to libraries:
  - If you disable the link to the library block, the entire mask hierarchy is saved to the model file so that the block can act as a standalone block.
  - If you break the link to the library block, the block becomes a standalone block.
  - If you reestablish the link after disabling by doing a restore, all changes to the mask are discarded. If you mask subsystems, you must reestablish the link after disabling by doing a push. When you do a push, subsystem changes are pushed to the library block and top mask changes are pushed to the immediate library.

## Mask a Linked Block

### Step 1: Create Custom Library with Masked Linked Block

- 1 In the **Simulink Library Browser**, click the arrow next to  and select **New Library**.
- 2 Open the Ramp block in the Library editor window.
- 3 Right-click the Ramp block and select **Mask > Create Mask**.  
The **Mask Editor** opens.
- 4 In the **Icon drawing commands** section of the **Icons & Ports** pane, type:  

```
plot ([0:10],[0,1:10])
```
- 5 In the **Parameter & Dialog** pane, select  **Promote** to promote the Slope and Initial Output parameters.
- 6 Click **OK**.
- 7 Rename the block to Derived Ramp block.

### Step 2: Add a Mask to the Masked, Link Block

- 1 In the **Simulink Library Browser**, click the arrow next to  and select **New Model**. The Model editor window opens.
- 2 Drag the Derived Ramp block from the Library editor to the Model editor.

The Derived Ramp block in the model has multiple masks on it. You can set parameters of the derived mask.

### Step 3: View Masks Below the Top Mask

- Right-click the Derived Ramp block in the model and select **Mask > View Base Mask**. This opens the **Mask Editor** displaying the base mask definition.

“Create Block Masks” | “Linked Blocks” on page 41-15

## Dynamic Mask Dialog Box

| In this section...                                    |
|-------------------------------------------------------|
| “Show Parameter” on page 39-50                        |
| “Enable Parameter” on page 39-50                      |
| “Create Dynamic Mask Dialog Box” on page 39-50        |
| “Set Up Nested Masked Block Parameters” on page 39-51 |

You can create dialogs for masked blocks whose appearance changes in response to user input. Features of masked dialog boxes that can change in this way include:

- Visibility of parameter controls — Changing a parameter can cause the control for another parameter to appear or disappear. The dialog expands or shrinks when a control appears or disappears, respectively.
- Enabled state of parameter controls — Changing a parameter can cause the control for another parameter to be enabled or disabled for input. A disabled control is grayed to indicate visually that it is disabled.
- Parameter values — Changing a mask dialog box parameter can cause related mask dialog box parameters to be set to appropriate values.

---

**Note** Mask parameter addition, deletion, or modification is restricted from mask callback.

---

Creating a dynamic masked dialog box entails using the Mask Editor with the `set_param` command. Specifically, you use the Mask Editor to define parameters of the dialog box, both static and dynamic. For each dynamic parameter, you enter a callback function that defines how the dialog box responds to changes to that parameter (see “Execute Callback Code” on page 39-20). The callback function can in turn use the `set_param` command to set mask parameters that affect the appearance and settings of other controls on the dialog box (see “Create Dynamic Mask Dialog Box” on page 39-50). Finally, you save the model or library containing the masked subsystem to complete the creation of the dynamic masked dialog box.

To view related example, see Create dynamic mask dialog boxes.

## Show Parameter

The selected parameter appears on the mask dialog box only if this option is checked (the default).

## Enable Parameter

Clearing this option grays the prompt of the selected parameter and disables the edit control of the prompt.

## Create Dynamic Mask Dialog Box

This example shows how to create a mask dialog blocks whose appearance changes in response to your input.

You can set two parameters using this mask dialog box. The first parameter is a popup menu through which you select one of three gain values: 2, 5, or *User-defined*. Depending on the value that you select in this popup menu, an edit field for specifying the gain appears or disappears.

- 1 Mask a subsystem by right-clicking the block and selecting **Mask > Create Mask**.
- 2 Select the **Parameters & Dialog** pane on the Mask Editor.
- 3 Drag and drop a **Popup** parameter and select it in the **Dialog box** pane.
  - a In the **Prompt** field, enter Gain.
  - b In the **Name** field, enter gainpopup.
  - c In the Property editor pane, clear **Evaluate** so that Simulink uses the literal values you specify for the popup.
  - d In the **Type options** field, click the **Edit** button to enter these three values in the Popup Options dialog box:  
  
2  
5  
User-defined
- 4 Enter this code in the **Dialog callback** field:

```
% Get the mask parameter values. This is a cell
% array of character vectors.
maskStr = get_param(gcb, 'gainpopup');
```

```

% The pop-up menu is the first mask parameter.
% Check the value selected in the pop-up
if strcmp(maskStr(1),'U'),

 % Set the visibility of both parameters on when
 % User-defined is selected in the pop-up.

 set_param(gcf,'MaskVisibilities',{'on';'on'}),

else

 % Turn off the visibility of the Value field
 % when User-defined is not selected.

 set_param(gcf,'MaskVisibilities',{'on';'off'}),

 % Set the character vector in the Values field equal to the
 % character vector selected in the Gain pop-up menu.

 %maskStr{2}=maskStr{1};
 set_param(gcf,'editvalue',maskStr);
end

```

- 5 Drag and drop an **Edit** parameter and select it in the **Dialog box** pane.
  - a In the **Prompt** field, enter Value.
  - b In the **Name** field, enter editvalue.
  - c In the Property editor pane, clear **Visible** so that Simulink turns off the visibility of this property by default.
- 6 Click **Apply**.
- 7 To open the mask dialog box, double-click the masked subsystem.

If you select 2 or 5 as the **Gain**, Simulink hides the **Value**. If you select User-defined as the **Gain** the **Value** is visible.

## Set Up Nested Masked Block Parameters

If lower-level masked subsystems reference symbols defined by higher-level masked subsystems and you try to set parameters of blocks in lower-level masked subsystems, unresolved symbol errors can occur. Therefore, avoid using `set_param` commands to set parameters of blocks residing in masked subsystems that reside in the masked subsystem

being initialized. Trying if lower-level masked subsystems reference symbols defined by higher-level masked subsystems.

Suppose, for example, a masked subsystem A contains masked subsystem B, which contains Gain block C, whose Gain parameter references a variable defined by B. Suppose also that subsystem A's initialization code contains this command:

```
set_param([gcb '/B/C'], 'SampleTime', '-1');
```

Simulating or updating a model containing A causes an unresolved symbol error.

## **See Also**

“Create Block Masks” | “Dynamic Masked Subsystem” on page 39-53

## Dynamic Masked Subsystem

### In this section...

“Allow Library Block to Modify Its Contents” on page 39-53

“Create Self-Modifying Masks for Library Blocks” on page 39-53

“Evaluate Blocks Under Self-Modifying Mask” on page 39-57

### Allow Library Block to Modify Its Contents

This check box is enabled only if the masked subsystem resides in a library. Checking this option allows the block initialization code to modify the contents of the masked subsystem (that is, it lets the code add or delete blocks and set the parameters of those blocks). Otherwise, an error is generated when a masked library block tries to modify its contents in any way. To set this option at the MATLAB prompt, select the self-modifying block and enter the following command.

```
set_param(gcb, 'MaskSelfModifiable', 'on');
```

Then save the block.

### Create Self-Modifying Masks for Library Blocks

You can create masked library blocks that can modify their structural contents. These self-modifying masks allow you to:

- Modify the contents of a masked subsystem based on parameters in the mask dialog box or when the subsystem is initially dragged from the library into a new model.
- Vary the number of ports on a multiport S-Function block that resides in a library.

#### Creating Self-Modifying Masks Using the Mask Editor

To create a self-modifying mask using the Mask Editor:

- 1 Unlock the library (see “Lock and Unlock Libraries” on page 41-9).
- 2 Right-click the block in the library.
- 3 Select **Mask > Edit Mask**. The Mask Editor opens.
- 4 In the Mask Editor **Initialization** pane, select the **Allow library block to modify its contents** option.

- 5 Enter the code that modifies the masked subsystem in the mask **Initialization** pane.

Do not enter code that structurally modifies the masked subsystem in a dialog parameter callback (see “Add Mask Code” on page 39-18). Doing so triggers an error when you edit the parameter.

- 6 Click **Apply** to apply the change or **OK** to apply the change and close the Mask Editor.
- 7 Lock the library.

### Creating Self-Modifying Masks from the Command Line

To create a self-modifying mask from the command line:

- 1 Unlock the library using the following command:  

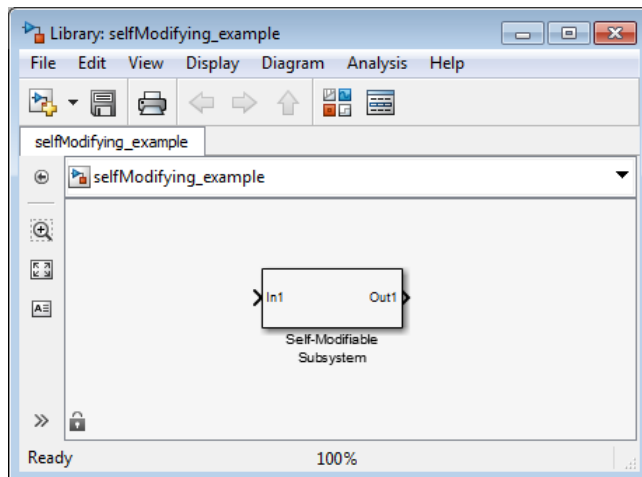

```
set_param(gcs, 'Lock', 'off')
```
- 2 Specify that the block is self-modifying by using the following command:

```
set_param(block_name, 'MaskSelfModifiable', 'on')
```

where `block_name` is the full path to the block in the library.

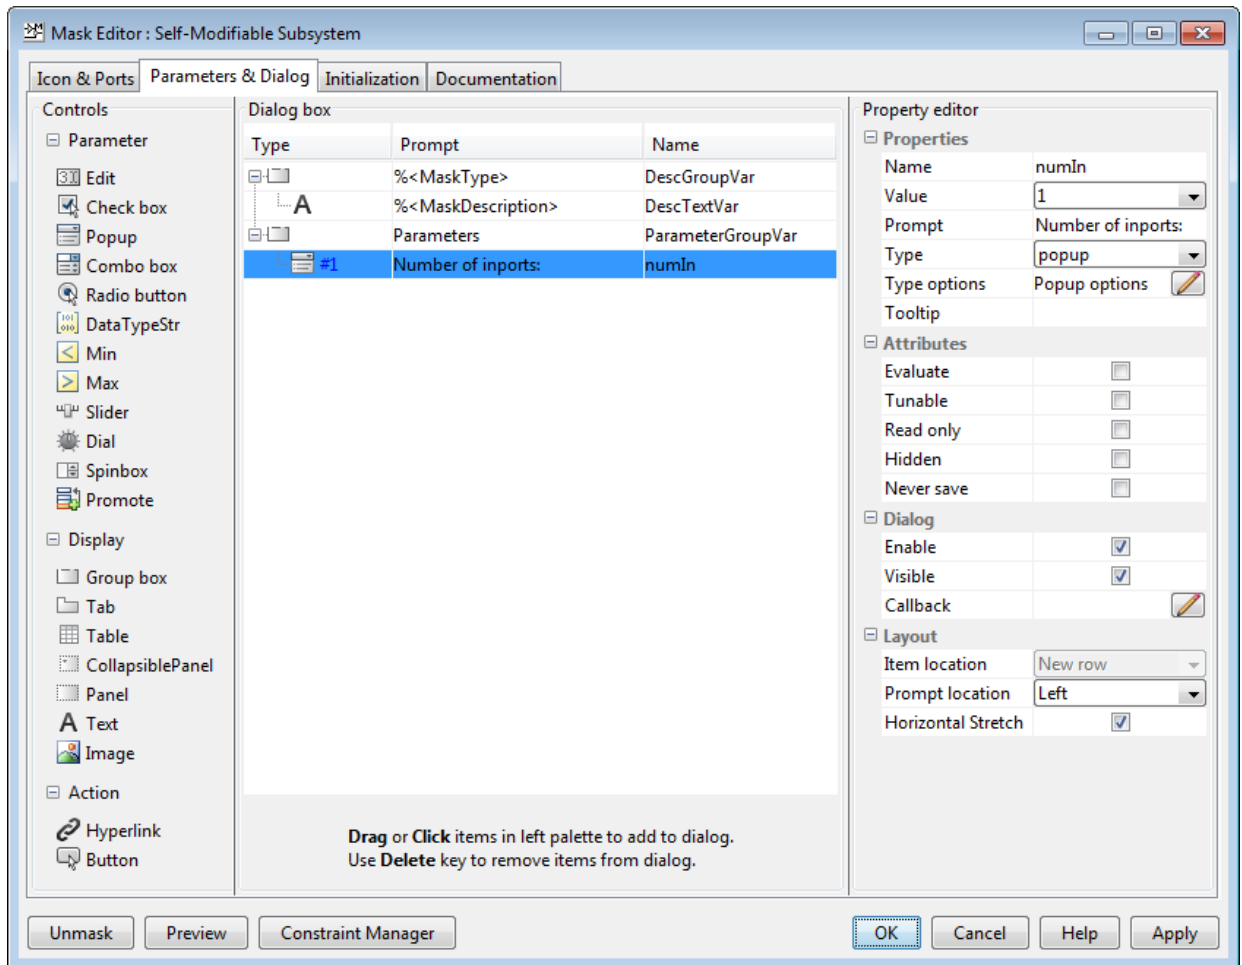

### Create Self-Modifying Mask

The library `selfModifying_example` contains a masked subsystem that modifies its number of input ports based on a selection made in the subsystem mask dialog box.

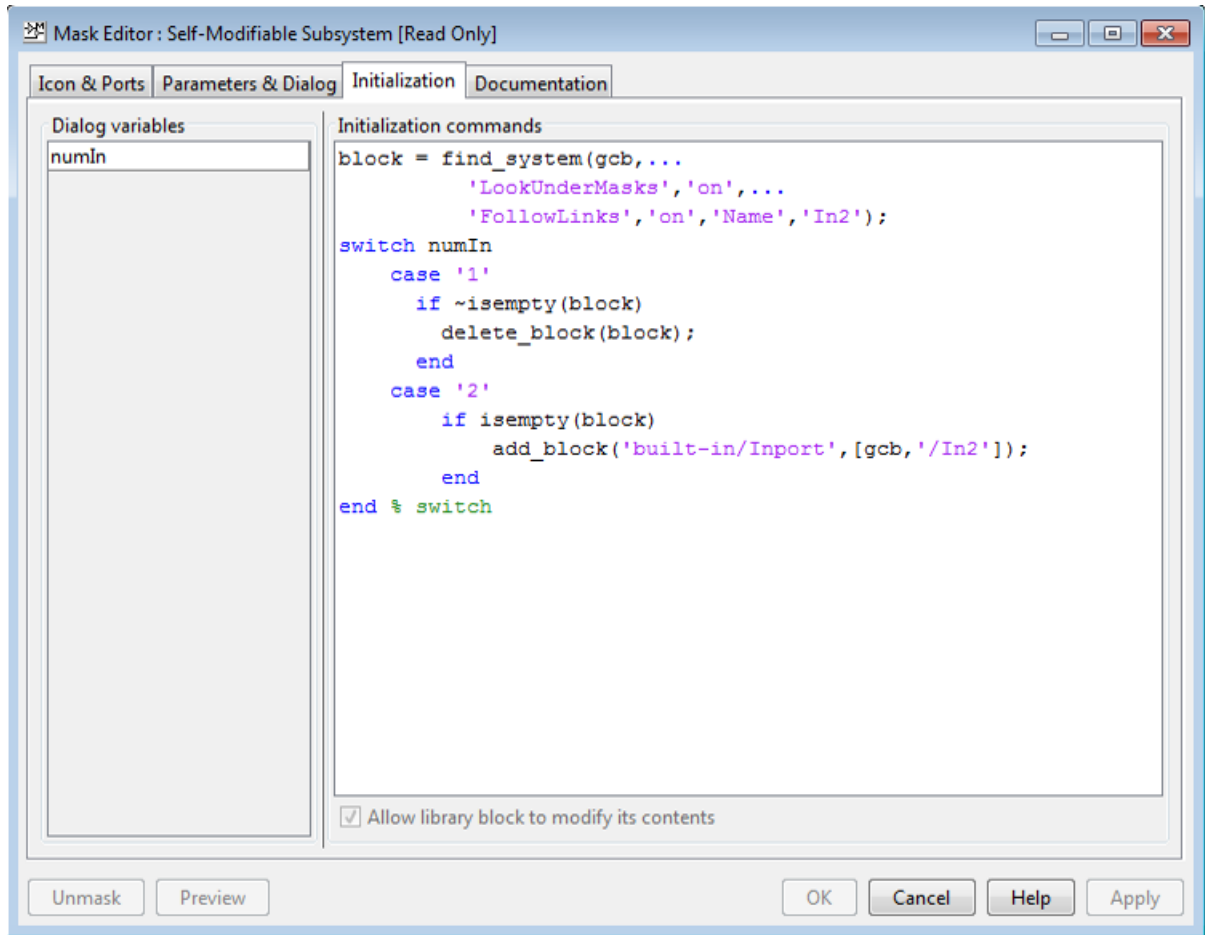

- 1 Click **Diagram > Unlock Library**.
- 2 Right-click the subsystem and select **Mask > Edit Mask**. The Mask Editor opens.
- 3 The Mask Editor **Parameters & Dialog** pane defines a parameter numIn that stores the value for the **Number of inports** option. This mask dialog box callback adds or removes Input ports inside the masked subsystem based on the selection made in the **Number of inports** list.

- To allow the dialog box callback to function properly, the **Allow library block to modify its contents** option on the Mask Editor **Initialization** pane is selected. If this option is not selected, copy of the library block could not modify their structural contents. Also, changing the selection in the **Number of inports** list would produce an error.

## Evaluate Blocks Under Self-Modifying Mask

This example shows how to force Simulink to evaluate blocks inside self-modifying masks.

Simulink evaluates elements of models containing masks in the following order:

- 1 Mask dialog box
- 2 Mask initialization code
- 3 Blocks or masked subsystems under the mask

Suppose a block named `myBlock` inside subsystem `mySubsys` masked by a self-modifying mask depends on mask parameter `myParam` to update itself.

`myParam` is exposed to the user through the **Mask Parameters** dialog box. `mySubsys` is updated through MATLAB code written in the **Mask Initialization** pane.

In this model, the sequence of updates is as follows:

- 1 You modify `myParam` through the mask dialog box.
- 2 The mask initialization code receives this change and modifies `mySubsys` under the mask.
- 3 `myBlock`, which lies under `mySubsys`, modifies itself based on the change to `myParam`.

In this sequence, Simulink does not evaluate `myBlock`, which lies under `mySubsys`, when the mask initialization code executes. Instead, Simulink only evaluates and updates the masked subsystem `mySubsys`. Meanwhile, `myBlock` remains unmodified.

You can force Simulink to evaluate such blocks earlier by using the `Simulink.Block.eval` method in the initialization code of the masked subsystem.

```
Simulink.Block.eval('mySubsys/myBlock');
```

## Debug Masks That Use MATLAB Code

|                                                           |
|-----------------------------------------------------------|
| <b>In this section...</b>                                 |
| “Code Written in Mask Editor” on page 39-59               |
| “Code Written Using MATLAB Editor/Debugger” on page 39-59 |

### Code Written in Mask Editor

Debug initialization commands and parameter callbacks entered directly into the Mask Editor by:

- Removing the terminating semicolon from a command to echo its results to the MATLAB Command Window.
- Placing a keyboard command in the code to stop execution and give control to the keyboard.

---

**Tip** To stop debugging the mask initialization callback code when an error is encountered, use the command `dbstop if caught error`.

---

### Code Written Using MATLAB Editor/Debugger

---

**Note** You cannot debug icon drawing commands using the MATLAB Editor/Debugger. For information on icon drawing commands syntax, see “Icon drawing commands”.

---

Debug initialization commands and parameter callbacks written in files using the MATLAB Editor/Debugger in the same way that you would with any other MATLAB program file.

When debugging initialization commands, you can view the contents of the mask workspace. However, when debugging parameter callbacks, you can only access the base workspace of the block. If you need the value of a mask parameter, use `get_param`.

## **See Also**

### **More About**

- “Initialize Mask” on page 39-26
- “Mask Callback Code” on page 39-18

## Introduction to Model Mask

A model consists of multiple blocks, with each block containing its own parameter and block dialog box. Simulink enables you to mask a model. By masking a model you encapsulate the model to have its own mask parameter dialog box. You can customize the mask parameter dialog box. When you mask a model, the model arguments become the model mask parameters. Referencing a masked model helps in having a better user interface for a model with ease of controlling the model parameters through the mask.

When you reference a masked model from a Model block, a mask is generated automatically on the Model block. The generated mask on the Model block is a copy of the model mask that it is referencing. You can reference a masked model from multiple Model block instances.

Consider a model that represents the DC motor equation. `Plant` in this model is a Model block that references a masked model, simplifying the user interface.

Components of 'Plant' Model block (Masked Model)

The `Plant` block contains the same mask as that of the masked model and the mask is uneditable. The mask can only be edited from the Mask Editor dialog box of the masked model.

## See Also

"Create and Reference a Masked Model" on page 39-62 | "Control Model Mask Programmatically" on page 39-69 | "Masking Fundamentals" on page 39-2

## Create and Reference a Masked Model

This example shows how to mask a model and reference the masked model from the Model block.

### Step 1: Define Mask Arguments

- 1 Open the model in Simulink. For example, consider a simple model containing two Gain blocks, a Constant block, and a Display block.

- 2 Click **View > Model Explorer > Model Workspace**. The Model Explorer dialog box opens.
- 3 Click **Add > MATLAB Variable**. A variable of data type `double` is created in the Model Workspace.
- 4 Select the **Argument** check box corresponding to the MATLAB variables to make it a model argument, for example, `k` and `l`.

## Step 2: Create Model Mask

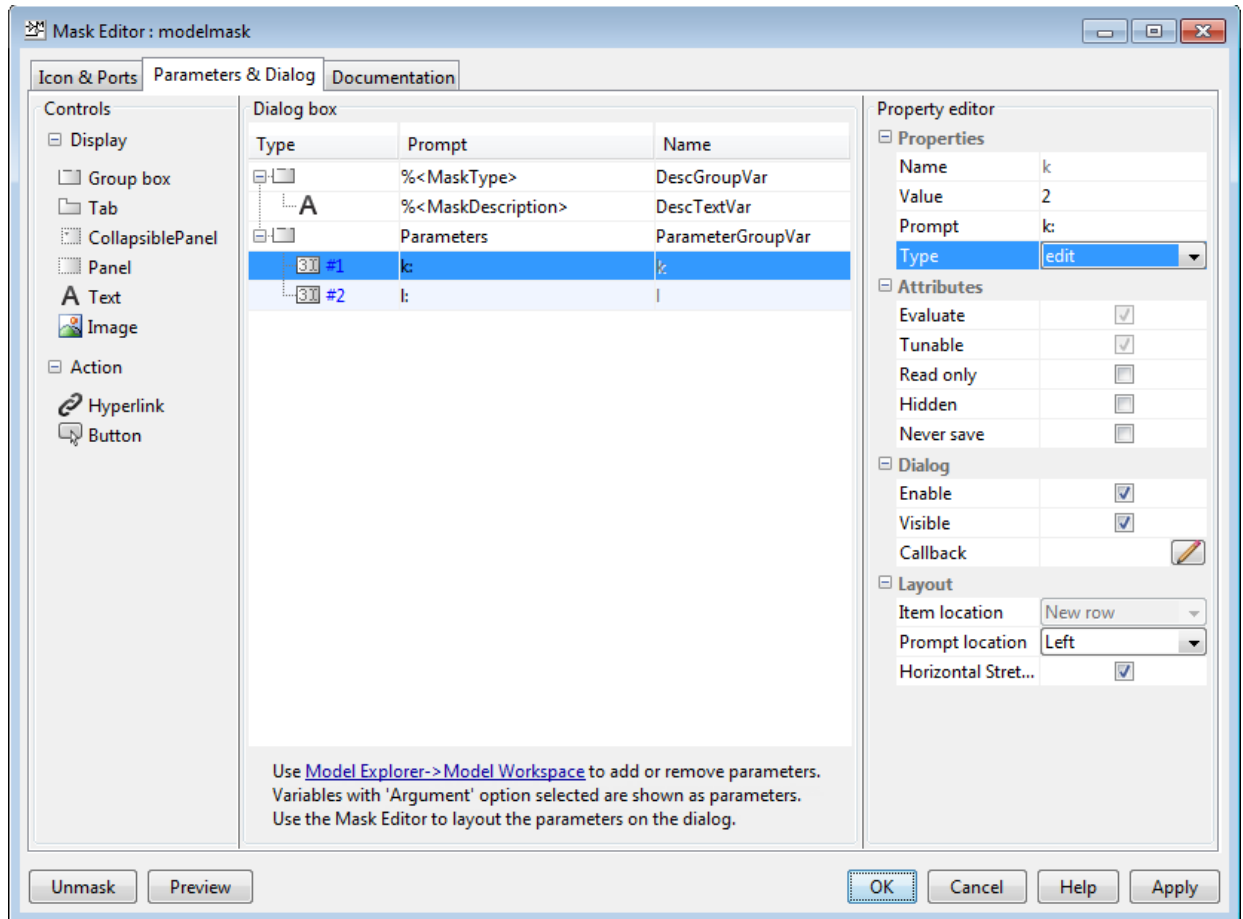

- 1 In the **Model Workspace** pane, click **Create Model Mask**.

Alternatively, in Simulink click **Diagram > Mask > Create Model Mask** or right-click the model, and in the context menu, click **Mask > Create Model Mask**.

The Mask Editor dialog box opens.

- 2 Click the **Parameters & Dialog** tab. The model arguments that you select in Model Explorer appear in the Mask Editor dialog box as mask parameters.

**Tip** Ensure that the model arguments you have selected in the Model Explorer dialog box are added as block parameters in the model. For example, the arguments *k* and *l* are passed to Gain A and Gain B blocks, respectively.

**Note** The Mask Editor dialog box for model mask does not contain the **Initialization** tab. Initialization code can alter the model and other model reference blocks, and thus affect the simulation results.

- 3 Select a mask parameter (k or l) on the **Dialog box** pane and edit its properties in the Property editor, as required. For example, you can change the prompt name, parameter type, value, or orientation.

By default, the **Edit** parameter type is assigned to a model mask parameter. You can change the parameter type by editing the **Type** property in the **Property editor** section.

---

**Note**

- Simulink supports only the **Edit**, **Slider**, **Dial**, and **Spinbox** parameter types for model mask.
  - Model mask supports all types of display and action controls.
- 
- 4 Click **OK**. The Simulink model is now masked and contains the model arguments as the mask parameter.
  - 5 Save the model.

### Step 3: View Model Mask Parameters

- 1 To view the mask parameter dialog box, click **Diagram > Mask > Model Mask Parameters**.

---

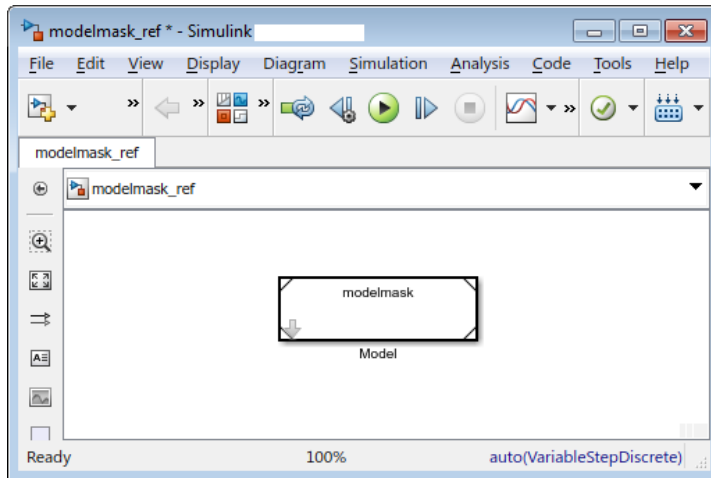

**Tip** To edit the model mask parameters, click **Diagram > Mask > Edit Model Mask**.

---

- 2 Save the masked model.

## Step 4: Reference Masked Model

- 1 Open a blank model in Simulink and add the Model block from the library.
- 2 To reference the masked model from the Model block, specify the name of the masked model as the **Model name** in the **Block parameter** dialog box.

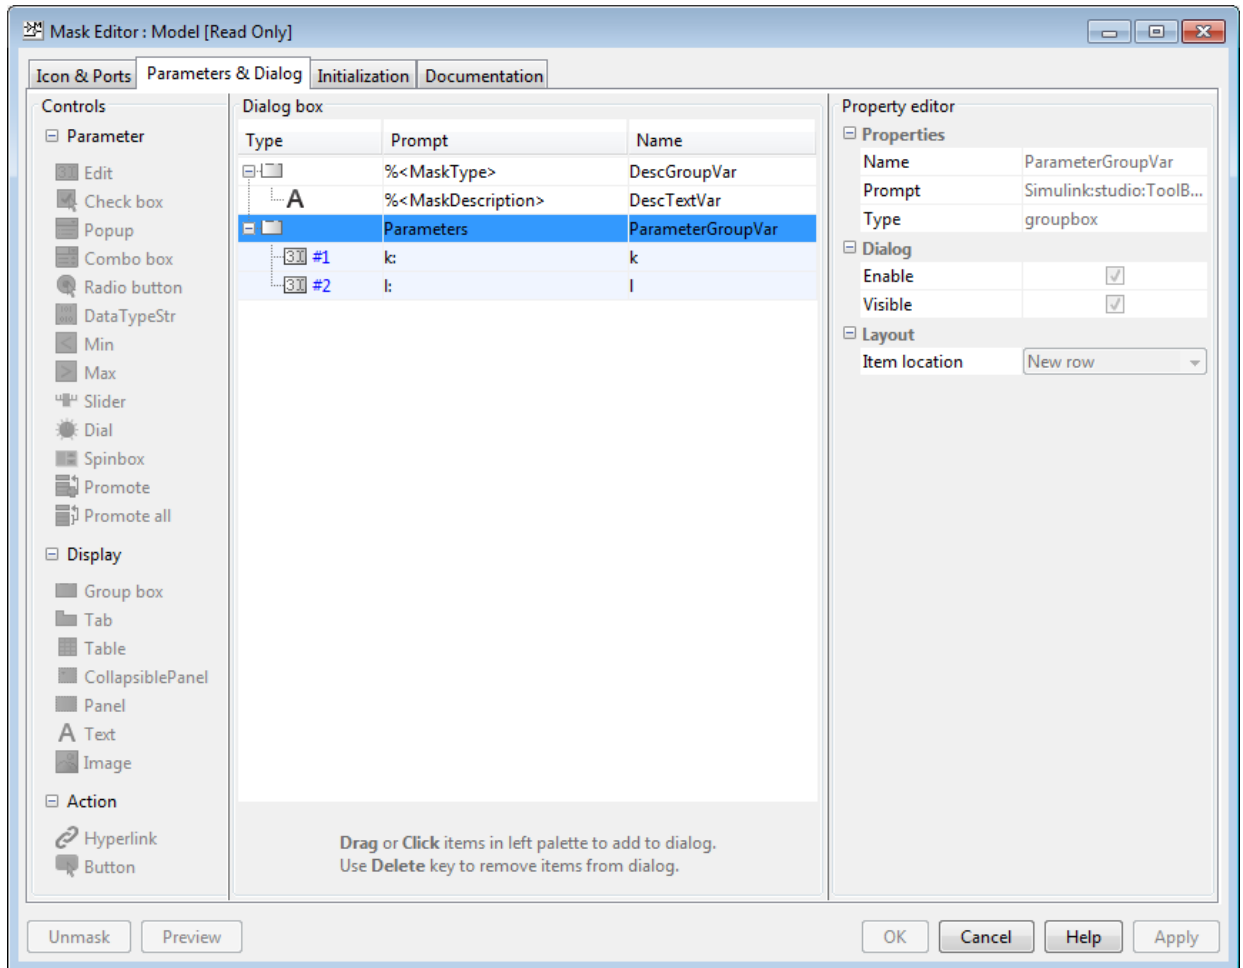

Masked model referenced by the Model block

- 3 To view the parameter dialog box of the referenced model, right-click the Model block, and in the context menu, click **Mask > Mask Parameters**. Alternatively, double-click the Model block.
- 4 Type 2 and 3 as the parameter values for k and l respectively.

- 5 Click **OK**.
- 6 Simulate the model and view the result on the display block.
- 7 To view the referenced model from the Model block, click **Mask > Look Under Mask**.
- 8 To view the mask, right-click the Model block and click **Mask > View Mask**. The **Mask Editor** dialog box opens. The Mask Editor dialog box displays the uneditable mask parameters of the referenced model.

## See Also

## Control Model Mask Programmatically

Simulink defines a set of parameters to configure and edit a model mask.

---

**Note** Adding, removing, and renaming parameters on a model mask using these methods is not supported:

- `addParameter`
  - `removeParameter`
  - `removeAllParameters`
  - `MaskParameter.Name`
- 

### Simulink.Mask.create

Use the `Simulink.Mask.create` method to create mask on a model. The syntax to mask a model is,

- Using the model name:

```
Simulink.Mask.create(ModelName)
```

- Using the model handle

```
ModelHandle = get_param(gcs, 'Handle') %To get the model handle
Simulink.Mask.create(ModelHandle) %To create mask using model handle
```

An example follows,

```
maskObj = Simulink.Mask.create('vdp');

 Type: 'vdp'
 Description: 'The van der Pol Equation...'
 Help: ''
 Initialization: ''
 SelfModifiable: 'off'
 Display: ''
 IconFrame: 'on'
 IconOpaque: 'opaque'
 RunInitForIconRedraw: 'off'
 IconRotate: 'none'
```

```
PortRotate: 'default'
IconUnits: 'autoscale'
Parameters: [0x0 Simulink.MaskParameter]
BaseMask: [0x0 Simulink.Mask]
```

## Simulink.Mask.get

Use the `Simulink.Mask.get` method to get the mask on a model as a mask object. The syntax to get the existing mask of a model is,

- Using the model name:

```
Simulink.Mask.get(ModelName)
```

- Using the model handle

```
ModelHandle = get_param(gcs, 'Handle') %To get the model handle
Simulink.Mask.get(ModelHandle) %To create mask using model handle
```

An example follows:

```
maskObj = Simulink.Mask.get('vdp');
```

```
 Type: 'vdp'
Description: 'The van der Pol Equation...'
 Help: ''
Initialization: ''
SelfModifiable: 'off'
 Display: ''
 IconFrame: 'on'
 IconOpaque: 'opaque'
RunInitForIconRedraw: 'off'
 IconRotate: 'none'
 PortRotate: 'default'
 IconUnits: 'autoscale'
Parameters: [0x0 Simulink.MaskParameter]
 BaseMask: [0x0 Simulink.Mask]
```

---

**Note** To get the model mask as a mask object in the mask callback, you can use `Simulink.Mask.get()` without passing a system name or system handle. Simulink does not require the system name (`gcb`) or the system handle (`gcs`) to query the mask object for the model mask.

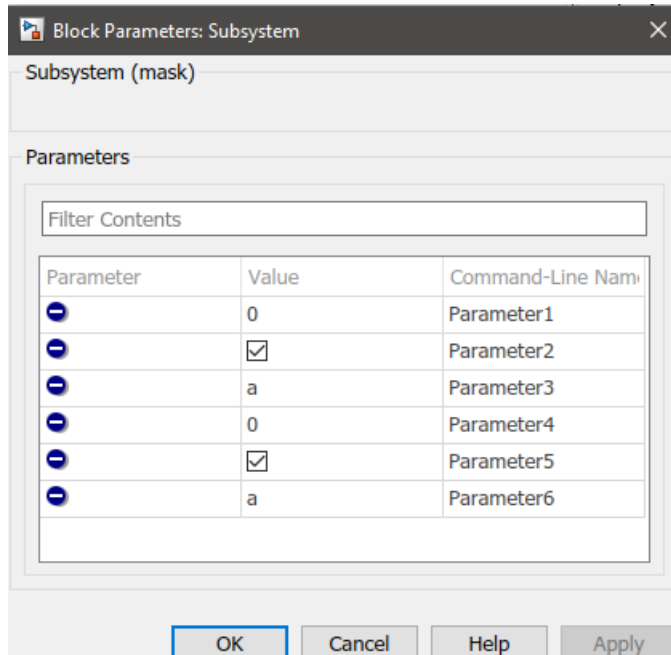

---

## Handling Large Number of Mask Parameters

The **Table** control in Mask Editor dialog box allows you to organize large number of mask parameters. The **Table** control can handle large (500+) number of mask parameters. You can include **Edit**, **Checkbox**, and **Popup** parameters within a **Table**.

You can also add large number of mask parameters in a **Table** programmatically. An example follows,

```
% Get mask object.
aMaskObj = Simulink.Mask.get(gcbh);

% Add Table controls to the mask.
aMaskObj.addDialogControl('Table', 'MyTable');

% Add parameters to table container.
for i = 1:length(Parameters) % To import values from an array called 'Parameters'
 aMaskObj.addParameter('Name', Parameters(i).Name, 'Type', Parameters(i).Type, 'Cont
end
```

### More About

- “Create Block Masks”
- “Create a Simple Mask” on page 39-7
- “Mask Editor Overview”

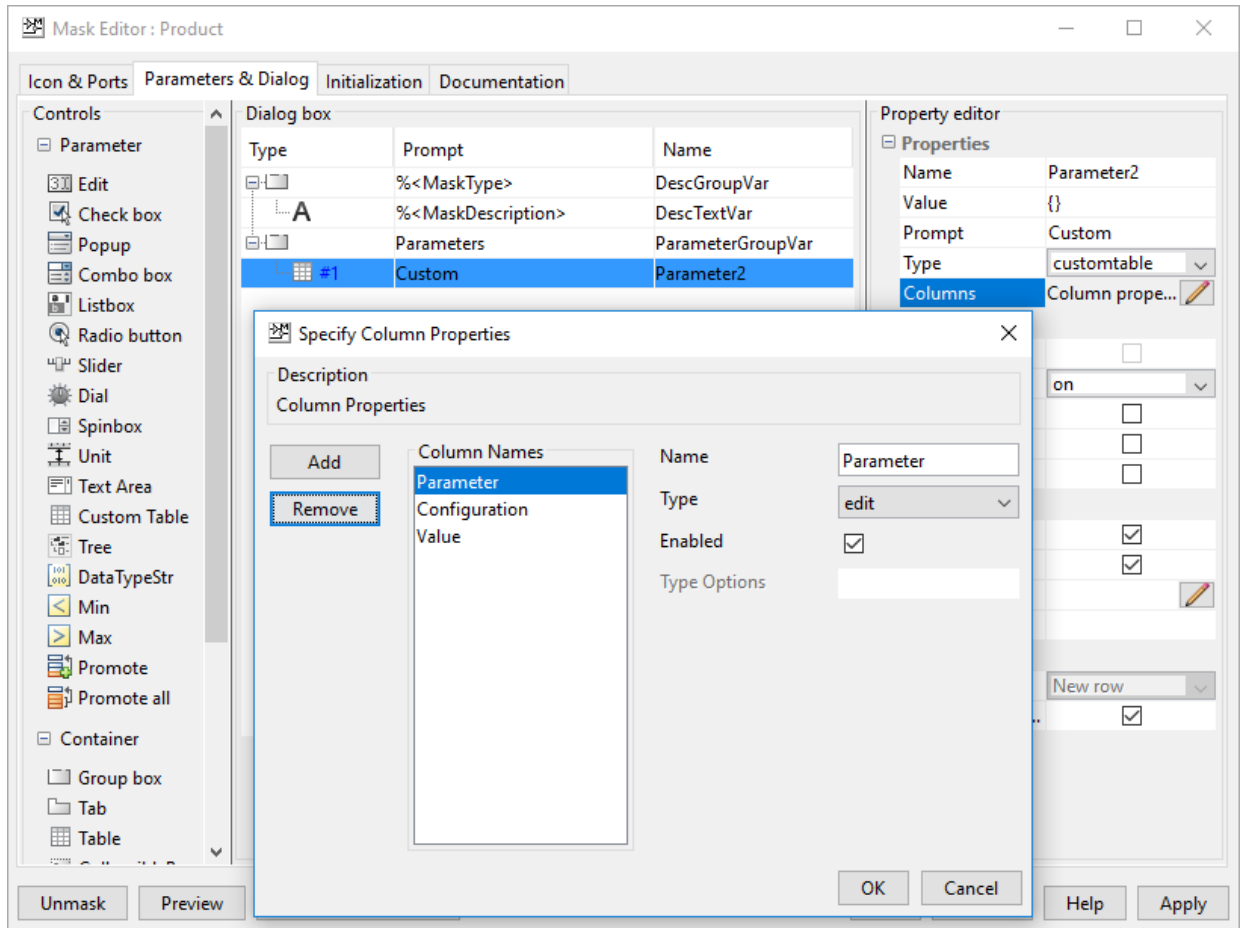

## Customize Tables for Masked Blocks

The **Custom Table** parameter allows you to add customized table with structured data on a mask dialog box without writing custom codes. As a mask parameter, the custom table widget supports parameter promotion unlike the tables created using custom block dialog code.

You can provide input to the **Custom Table** parameter as a string in the cell array format.

### Adding a Custom Table Parameter

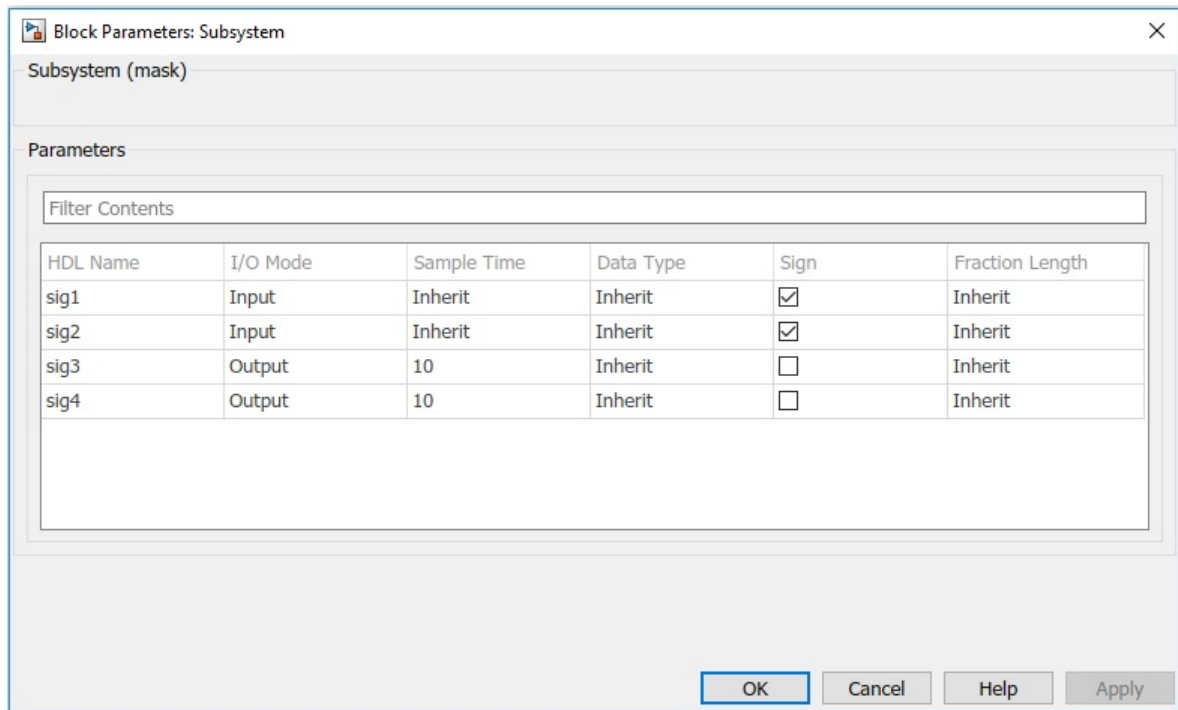

- 1 Open a Simulink model.
- 2 Right-click any block and select **Mask > Create Mask**.
- 3 In the **Parameters & Dialog** tab, click **Custom Table** to add it to the mask as a parameter. Specify a name and prompt for the parameter, as required.
- 4 In the **Property Editor** pane, click the edit icon in the Columns field to specify the column properties like the number of columns, name of each column, and type of column. The available column types are **edit**, **checkbox**, and **popup**. Use the **Add** button to add a column and **Remove** button to remove an existing column.

- 5 Enter the values for the table in the **Value** field of **Property Editor** as a string in the cell array format. For example, if the value is given as:

```
{ 'sig1', 'Input', 'Inherit', 'Inherit', 'on', 'Inherit';...
 'sig2', 'Input', 'Inherit', 'Inherit', 'on', 'Inherit';...
 'sig3', 'Output', '10', 'Inherit', 'off', 'Inherit';...
 'sig4', 'Output', '10', 'Inherit', 'off', 'Inherit' }
```

The table created is:

- 6 Click **Apply** to save the changes to the mask. If you want to edit the table, right click and select **Mask > Edit Mask**.

## See Also

“Control Custom Tables Programmatically” on page 39-77

## Control Custom Tables Programmatically

You can add a custom table on the mask dialog box programmatically and control its properties using command line interface. For information on creating a custom table from the Mask Editor, see “Customize Tables for Masked Blocks” on page 39-74.

### Add a Custom Table Parameter

You can add a custom table parameter to a mask dialog box using these commands:

```
% Mask Object
maskObj = Simulink.Mask.create(gcb);

% Add custom table parameter
tableParam = maskObj.addParameter('Name', 'myTable', 'Type', 'customtable', 'Evaluate', 'off');

% Add values to the table
tableParam.Value = "{ 'sig1', 'Input', 'Inherit', 'Inherit', 'on', 'Inherit'; 'sig2', ...
'Input', 'Inherit', 'Inherit', 'on', 'Inherit'; 'sig3', 'Output', '10', 'Inherit', 'off',...
'Inherit'; 'sig4', 'Output', '10', 'Inherit', 'off', 'Inherit' }";
```

### Add Columns to a Table

You can add columns to a custom table using the addColumn command:

```
tableControl = maskObj.getDialogControl('myTable');
tableControl.addColumn('Name', 'HDL Name', 'Type', 'edit');
tableControl.addColumn('Name', 'I/O Mode', 'Type', 'popup', 'TypeOptions', {'Input',
```

### Get and Set Table Properties

You can fetch the value of a cell if it had a change and set a new value for a cell in the table using these commands:

```
% get values of the changed cell
changedCells = tableControl.getChangedCells();

% get value of a particular cell
tableControl.getValue([rowIdx colIdx]);

% Set value for a particular cell
tableControl.setValue([rowIdx colIdx], 'Value');
```

## Edit Rows in a Custom Table

You can insert, remove, swap, and get the value of a specific row in a custom table. The commands used are:

```
% add a row to the table
tableControl.addRow('sig5', 'Input', 'Inherit', 'Inherit', 'on', 'Inherit')

% Insert a row at a specific location in the table
tableControl.insertRow(rowIndex, 'insertSig4', 'Input', 'Inherit', 'Inherit', 'on', 'Inherit')

% Remove a particular row
tableControl.removeRow(rowIndex)

% Swap two rows
tableControl.swapRows(rowIndex1, rowIndex2)

tableControl.getSelectedRows()

ans =
 3 4
```

## Edit Columns in a Custom Table

You can insert, remove, swap, and get the value of a specific column in a custom table. The commands used are:

```
% add a column to the table
tableControl.addColumn('Name', 'HDL Name', 'Type', 'edit');

% Insert a column at a particular location in the table
tableControl.insertColumn(columnIndex, 'Name', 'HDL Name', 'Type', 'edit');

% Remove a column from the table
tableControl.removeColumn(columnIndex);

tableControl.getColumn(columnIndex);

For example,

tableControl.getColumn(4)
```

```
ans =
 TableParamColumnInfo with properties:
 Name: 'Data Type'
 Type: 'popup'
 Enabled: 'on'
 TypeOptions: {4x1 cell}
```

## Get and Set Table Parameter

You can use the `set_param` and `get_param` commands to set or get the values of the custom table parameter you created in a mask dialog box.

```
get_param(gcb, 'myTable')
```

```
ans =
 '{ 'sig1', 'Input', 'Inherit', 'Inherit',...
 'on', 'Inherit'; 'sig2', 'Input', 'Inherit', 'Inherit',...
 'on', 'Inherit'; 'sig3', 'Output', '10', 'Inherit', 'off',...
 'Inherit'; 'sig4', 'Output', '10', 'Inherit', 'off', 'Inherit' }'
```

```
set_param(gcb, 'myTable', "{ 'Hello', 'Input', 'Inherit', 'Inherit',...
 'on', 'Inherit'; 'sig2', 'Input', 'Inherit', 'Inherit', 'on', 'Inherit'; ...
 'sig3', 'Output', '10', 'Inherit', 'off', 'Inherit'; 'sig4', 'Output', '10',...
 'Inherit', 'off', 'Inherit' }")
```

## Add Constraints to Mask Parameters

A mask can contain parameters that accept user-input value. You can provide the input values for these mask parameters from the mask dialog box. You can add constraints to the mask parameters to ensure that the input value for the mask parameter is within a desired specification. If the input value is not within the desired specification, the simulation can generate error.

. To add mask constraints without having to write validation code (“Initialize Mask” on page 39-26, “Mask Callback Code” on page 39-18), use the **Constraint Manager** option available in the Mask Editor.

Constraints are of type:

- **Parameter Constraint** — Associated with one or more **Edit** type mask parameters. You can create these constraints in the mask or save them as a MAT file. Multiple block masks can share a parameter constraint saved as a MAT file.
- **Cross Parameter Constraint** — Applied among two or more **Edit** type mask parameters.

### Create Parameter Constraints

Consider the model `masking_example`. This model contains two **Edit** type mask parameters, `Slope` and `Intercept`.

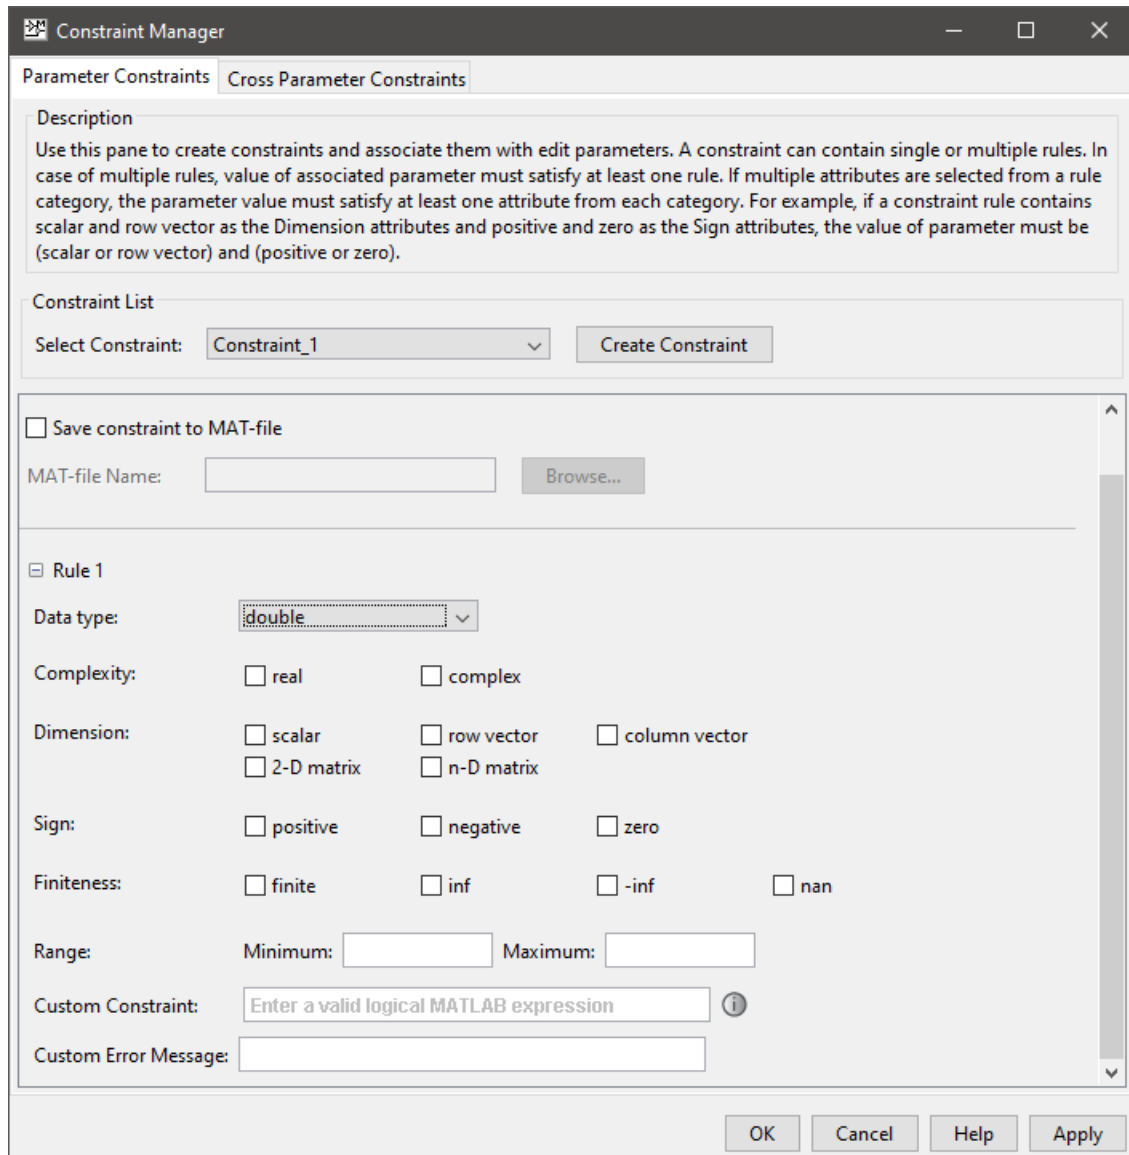

You can specify values for the `Slope` and `Intercept` in the mask dialog box. To restrict the input value (for example, data type) for the `Slope` and `Intercept` parameters, create a parameter constraint with the required rule and associate it with the `Slope` and `Intercept` parameters. To restrict the input value such that the value of `Slope` is greater than the input value of the `Intercept` parameter, you can create a cross-parameter constraint between these two parameters.

- 1 Open the model `masking_example`. This model contains a masked Subsystem block with two **Edit** type mask parameters, Slope (m) and Intercept (b).
- 2 Right-click the masked Subsystem block (mx + b) and select **Mask > Edit Mask**.
- 3 In the Mask Editor dialog box, click the **Parameters & Dialog** tab.
- 4 Click **Constraint Manager** at the bottom left of the Mask Editor. Alternatively, select any edit parameter and then in the Property editor, from the **Constraint** drop-down menu, select **Add New Constraint**. The **Constraint Manager** window appears.

**Constraint Manager** has two panes, **Parameter Constraints** and **Cross Parameter Constraints**. By default, the **Parameter Constraints** pane opens. The constraints that you create using the **Parameter Constraints** pane can be associated with **Edit** type mask parameters.

- 5 Click **Create Constraint**. A constraint with a default name (`Constraint_1`) is created and properties related to this constraint are displayed. To change the constraint name, edit the **Name** field. The constraint name must be a valid MATLAB name. By default, a rule (`Rule_1`) with **Data type** as `double` is added when a new constraint is created. You can modify the attributes of the rule. You can also add more rules to a constraint by clicking **Add Rule**.

- To save the new constraint to a MAT file, select the **Save constraint to MAT file** check box. This enables the **Mat-file Name** field and the **Browse** button.

---

**Note** Saving a constraint to a MAT file makes it independent of the mask so that multiple masks can share that constraint. You can skip this action if you want the constraint to be tagged to the specific mask that you are editing.

---

- 7 Enter the MAT file name in the **Mat-file Name** field or click **Browse** to create a new MAT file or select one from the local directory.
- 8 Specify attributes for the rule. This table shows the rule attributes and acceptable values.

| Rule Attribute    | Attribute Value                                                                                           | Description                                                                                                                                                                    |
|-------------------|-----------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Data type</b>  | double, single, numeric, integer, int8, uint8, int16, uint16, int32, uint32, boolean, enum, fixdt, string | Specify the acceptable data type of the mask parameter value. For example, if the data type specified is uint8, the acceptable value is in the range of uint8, that is, 0–255. |
| <b>Complexity</b> | real, complex                                                                                             | Specify if the mask parameter value can be a real or complex number.                                                                                                           |
| <b>Dimensions</b> | scalar, row vector, column vector, 2-D matrix, n-D matrix                                                 | Specify the acceptable dimensions for the mask parameter.                                                                                                                      |
| <b>Sign</b>       | positive, negative, zero                                                                                  | Specify if the input value can be positive, negative, or zero.                                                                                                                 |
| <b>Finiteness</b> | finite, inf, -inf, NaN                                                                                    | Specify the acceptable finiteness of mask parameter value.                                                                                                                     |
| <b>Range</b>      | Minimum, Maximum                                                                                          | Specify the acceptable range of mask parameter value.                                                                                                                          |

| Rule Attribute              | Attribute Value         | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-----------------------------|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Custom Constraint</b>    | Valid MATLAB expression | Specify custom constraint for the mask parameter using a valid MATLAB expression. You can use the value token to parameterize the expression. During validation, the evaluated value of the parameter replaces the value token. For example, if the MATLAB expression for a constraint is <code>value &gt; 100</code> and is associated with the <b>Edit</b> type mask parameter, <code>Parameter1</code> , the MATLAB expression evaluates as <code>Parameter1 &gt; 100</code> . |
| <b>Custom Error Message</b> | Character vector        | Specify a custom error message for the custom constraint. You can specify the error message as character vector or as a message catalog ID.                                                                                                                                                                                                                                                                                                                                       |

A constraint can contain single or multiple rules. In case of multiple rules, value of associated parameter must satisfy at least one rule. If multiple attributes are selected from a rule category, the parameter value must satisfy at least one attribute from each category. For example, if a constraint rule contains `scalar` and `row vector` as the **Dimension** attributes and `positive` and `zero` as the **Sign** attributes, the value of parameter must be (scalar or row vector) and (positive or zero).

- 9 Optionally, to add more rules to the constraints, click **Add Rule**. A new rule section with rule attribute opens.
- 10 Click **Apply**. A parameter constraint with specified rules is now created. You can associate this constraint with one or many **Edit** type mask parameters.

- 11 Optionally, to delete a constraint, select the constraint in the **Constraint Name** field available in the **Parameter Constraints** pane and click **Delete Constraint**.

Consider the `Parameter Constraint` model in `slexMaskConstraints`. This model contains a masked UDP Send block that has parameter constraints, `constraint_1` and `constraint_2`. The `constraint_1` is associated with `Remote IP Port` parameter while the `constraint_2` is associated with the `SampleTime` parameter.

## Shared Parameter Constraints

You can create and save parameter constraints in a MAT file. You can save a constraint in a MAT file either from the Mask Editor or programmatically. Multiple block masks can share a parameter constraint if the constraint is saved in a MAT file. A shared constraint is listed in the Property editor section in the format `<MATFileName>:<ConstraintName>`. You can select any available constraint as required and associate it with an Edit parameter. For more information, see “Associate Constraint to a Parameter” on page 39-86.

While creating shared constraints it is recommended that you:

- Save constraints to MAT files that are in the MATLAB path.
- Provide meaningful names to constraints so that other users can understand the nature of the constraint easily.

Constraints associated to an Edit parameter from a MAT file (shared constraints) are validated during edit-time and simulation.

To create a shared constraint, select the **Save constraint to MAT file** check box available in the Constraint Manager and specify the MAT file name. For more information, see “Create Parameter Constraints” on page 39-80.

---

**Note** If you clear the **Save constraint to MAT file** check box of a shared constraint that is associated with an Edit parameter, a copy of the constraint is created within the context of that particular mask. You can now make changes to the attributes of that constraint without affecting the original shared constraint saved in the MAT file. Note that the original shared constraint is still in the MAT file and is available for other users.

---

## Save and Load Constraints Programmatically

You can save constraints in a MAT file and load constraints from a MAT file programmatically.

To save a constraint in a MAT file:

```
uint16Constraint = Simulink.Mask.Constraints;
uint16Constraint.Name = 'uint16Constraint';
uint16Constraint.AddParameterConstraintRule('DataType', 'uint16');
save('constraintList.mat', 'uint16Constraint', '-append'); %this will append the
constraint uint16Constraint in the mat file
save('constraintList.mat', 'uint16Constraint') % this will clear all the
content of
the mat file and write just 'uint16Constraint' into the mat file.
```

---

**Note** It is recommended that the constraint name (for example, `uint16Constraint.Name = 'uint16Constraint'`) and the variable used for storing the constraint (for example, `uint16Constraint = Simulink.Mask.Constraints`) have the same name.

---

To load a constraint from a MAT file:

```
myConstraints = load('constraintList') //this will load the constraint into
the variable 'myConstraints'
```

For more information on working with constraints programmatically, see `Simulink.Mask` and `Simulink.Mask.Constraints`.

## Associate Constraint to a Parameter

You can associate constraints to any **Edit** mask parameters. Associating a constraint to an **Edit** parameter ensures that the input value for the mask parameter is within a desired specification.

- 1 Open the model `masking_example`. This model contains a masked Subsystem block with two **Edit** type mask parameters, Slope (m) and Intercept (b).
- 2 Right-click the masked Subsystem block (mx + b) and select **Mask > Edit Mask**.
- 3 Click the **Parameters & Dialog** tab and select any Edit parameter.

- 4 In the **Property editor** pane, from the **Constraint** drop-down menu, select an available constraint. Here, the constraints available in a MAT file are shown as <MATFileName>:<Constraint name>. The constraints available within the mask are shown as <Constraint Name>. If no constraints are shown in the drop-down menu, click **Add New Constraint** to add a new one from Constraint Manager or click **Browse and Add New Constraint** to add constraints saved in MAT files. You can also type the constraint name to associate them to a parameter.
- 5 Click **Apply**. The selected constraint is now associated to the **Edit** parameter.

## Create Cross-Parameter Constraint

The cross-parameter constraints allow you to create constraints among **Edit** type mask parameters of a block. You can use the **Cross Parameter Constraints** pane to create this type of constraints. As a best practice, create the cross-parameter constraints between related mask parameters. For example, between slope and intercept, or upper bound and lower bound of the Integrator block.

- 1 Open the model `masking_example`. This model contains a masked Subsystem block with two **Edit** type mask parameters, Slope (m) and Intercept (b).
- 2 Right-click the masked Subsystem block ( $mx + b$ ) and select **Mask > Edit Mask**.
- 3 In the Mask Editor dialog box, click the **Parameters & Dialog** tab.
- 4 Click **Constraint Manager** at the bottom left of the Mask Editor. The Constraint Manager opens.
- 5 Click the **Cross Parameter Constraints** tab.
- 6 Click **Create Constraint**. A new cross-parameter constraint is created with a default name (`Constraint_1`). You can change the constraint name.
- 7 Specify these values for the constraints:
  - a **Name** - Specify the name of the cross-parameter constraint.
  - b **MATLAB Expression** - Specify a valid MATLAB expression. This expression is evaluated during edit-time and simulation. For example, `Slope < Intercept`.
  - c **ErrorMessage** - Specify the error message to be displayed when the constraint rule is not met. If no error message is specified, a default error message is displayed.
- 8 Click **OK**. Cross-parameter constraint with specified rules is now created.

Consider the Cross-Parameter Constraint model in `slexMaskConstraints`. This model contains a masked Integrator block that has a cross-parameter constraint

(LimitConstraint). This cross-parameter constraint is applied among mask parameters using the MATLAB expression:

```
(UpperSaturationLimit > LowerSaturationLimit) && isequal(class
(UpperSaturationLimit), class(LowerSaturationLimit),
class(InitialCondition)).
```

## Define Measurement Units for Masked Blocks

Measurement units translate the amount of entities supplied to your computations. They are also crucial when diverse users using different systems of measurement are using the same equation. You can add measuring units to a Simulink model to enhance the usability and to avoid confusion while analyzing equations.

To specify measuring units for masked blocks, you can:

- Promote a **Unit** parameter from the underlying block to the mask. For more information, see “Promote Parameter to Mask” on page 39-30.
- Add a **Unit** parameter to the mask dialog box as shown in the following steps:
  - 1 Open a Simulink Model.
  - 2 Select the block to be masked and press **Ctrl+M**. The Mask Editor opens.
  - 3 In the Mask Editor, click the **Parameters & Dialog** tab.
  - 4 In the Parameters section, click **Unit**.
  - 5 Click the **Initialization** tab in the Mask Editor dialog box.
  - 6 To define the measurement unit for the **Unit** parameter, specify the initialization command by using the following syntax:

```
set_param([gcb '<blockname>'], '<unit parameter name>', get_param(gcb, '<unit p
```

For example, to associate the **Unit** parameter with the measuring unit of the Inport block, use:

```
set_param([gcb '/In1'], 'Unit', get_param(gcb, 'Unit'));
```

- 7 Click **Apply**, and then click **OK**. For more information, see `slexMaskingUnit`.

## Masking Example Models

The Simulink Masking example models help you to understand and configure mask parameters, properties, and features. The examples are grouped by type. In an example model:

- To view the mask definition, double-click the View Mask block.
- To view the mask dialog box, double-click the block.

| Goals                                                                                                                                                                                                                                                                                                                                                        | Example Models        | Related Topics         |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------|------------------------|
| Add Parameters control type to mask dialog box. For example, Evaluate, Tune, Add Image, Pop-up, Combo-box, Slider and Dial, Slider Range                                                                                                                                                                                                                     | Mask Parameters       | "Mask Editor Overview" |
| <ul style="list-style-type: none"> <li>• Add an opaque mask with visible port labels (<b>Icon Transparency</b>).</li> <li>• Specify Run Initialization instructions</li> </ul>                                                                                                                                                                               | Mask Icon Drawing     | "Mask Editor Overview" |

## Mask a Variant Subsystem

This example shows how to use a masked Variant Subsystem block in a Simulink model. Click the **Open Model** button located on the top right corner to view the related example model. This example model references masked library blocks. The **Allow library block to modify its contents** check box in the initialization pane of the library mask must be selected.

### Masking a Variants Subsystem

This model contains masked Subsystem block as a linked block. The masked Subsystem block contains a masked Variant Subsystem block within. Initialization code in the Variant Subsystem block mask sets the variant choice that is passed from the Subsystem block (MaskedSubsystem). Parameter promotion is used to record the variant choice (V1 & V2) on the masked Subsystem block.

This model contains a masked Variant Subsystem as a linked block. Initialization code in the mask sets the variant choice that is passed from the mask. Popup mask parameter is used to record variant choice V1 and V2.

This model contains a Subsystem block as a linked block. The linked Subsystem block (masked) contains a linked Variant Subsystem block. Initialization code in the Subsystem block sets the variant choice that is passed from the mask. Popup mask parameter is used to record variant choice V1 and V2.

Copyright 2015 - 2017 The MathWorks, Inc.

When you mask a Variant Subsystem block, you can specify the variant choice from the mask dialog box. The variant choice that you specify on the mask dialog box is applied on the underneath Variant Subsystem block.

To pass the variant choice from the mask to the Variant Subsystem block, you can either use the `set_param` command or the parameter promotion option.

Let's consider the cases described in the example model.

- Case 1: The mask parameter promotion option is used to promote the Variant Subsystem block parameter to the mask. The Variant Subsystem block is wrapped within a masked Subsystem block. Initialization code (`set_param`) is used in the Variant Subsystem block to define the variant choice which is further passed on to the mask on the Subsystem block using parameter promotion. This promoted parameter records the variant choice specified from the masked Subsystem block.
- Case 2: The Popup mask parameter is used to create the choice option on the top level masked Subsystem block. This masked Subsystem block contains a Variant Subsystem block. Initialization code (`set_param`) is used in the Variant Subsystem block to define the variant choice. The value that you specify as a variant choice from the mask dialog box (**Popup** parameter) is transferred to the underneath Variant Subsystem block to set its choices.
- Case 3: This case is similar to Case 2 with an additional layer of Subsystem in the model. Here, the Variant Subsystem block is wrapped in a double layer of masked Subsystem block.

## Types of Custom Blocks

| In this section...                    |
|---------------------------------------|
| “MATLAB Function Blocks” on page 40-2 |
| “MATLAB System Blocks” on page 40-3   |
| “Subsystem Blocks” on page 40-3       |
| “C Caller Block” on page 40-3         |
| “S-Function Blocks” on page 40-4      |
| “Masked Blocks” on page 40-5          |

### MATLAB Function Blocks

A MATLAB Function block allows you to use the MATLAB language to define custom functionality. These blocks are a good starting point for creating a custom block if:

- You have an existing MATLAB function that models the custom functionality.
- You find it easier to model custom functionality using a MATLAB function than using a Simulink block diagram.
- The custom functionality does not include continuous or discrete dynamic states.

You can create a custom block from a MATLAB function using one of the following types of MATLAB function blocks.

- The Fcn block allows you to use a MATLAB expression to define a single-input, single-output (SISO) block.
- The Interpreted MATLAB Function block allows you to use a MATLAB function to define a SISO block.
- The MATLAB Function block allows you to define a custom block with multiple inputs and outputs that you can deploy to an embedded processor.

Each of these blocks has advantages in particular modeling applications. For example, you can generate code from models containing MATLAB Function blocks, whereas you cannot generate code for models containing an Fcn block.

## MATLAB System Blocks

A MATLAB System block allows you to use System objects written with the MATLAB language to define custom functionality. These blocks are a good starting point for creating a custom block if:

- You have an existing System object™ that models the custom functionality.
- You find it easier to model custom functionality using the MATLAB language than using a Simulink block diagram.
- The custom functionality includes discrete dynamic states.

## Subsystem Blocks

Subsystem blocks allow you to build a Simulink diagram to define custom functionality. These blocks serve as a good starting point for creating a custom block if:

- You have an existing Simulink diagram that models custom functionality.
- You find it easier to model custom functionality using a graphical representation rather than using handwritten code.
- The custom functionality is a function of continuous or discrete system states.
- You can model the custom functionality using existing Simulink blocks.

Once you have a Simulink subsystem that models the required behavior, you can convert it into a custom block by:

- 1 Masking the block to hide the block contents and provide a custom block dialog box.
- 2 Placing the block in a library to prohibit modifications and allow for easily updating copies of the block.

For more information, see “Libraries” and “Create Block Masks”.

## C Caller Block

The C Caller block allows you to integrate C code into Simulink blocks. These blocks serve as a good starting point for creating a custom block if:

- You have existing C code that models custom functionality.
- Your C functions do not read or write global/static variables.

- You want blocks to easily integrate with other Simulink features, such as Simulink Coverage, Simulink Test, and Simulink Coder.
- You are not modeling dynamic systems.

## **S-Function Blocks**

S-function blocks allow you to write MATLAB, C, or C++ code to define custom functionality. These blocks serve as a good starting point for creating a custom block if:

- You have existing MATLAB, C, or C++ code that models custom functionality.
- You use continuous or discrete dynamic states or other system behaviors that require access to the S-function API.
- You cannot model the custom functionality using existing Simulink blocks.

You can create a custom block from an S-function using one of the following types of S-function blocks.

- The Level-2 MATLAB S-Function block allows you to write your S-function using the MATLAB language. (See “Write Level-2 MATLAB S-Functions”). You can debug a MATLAB S-function during a simulation using the MATLAB debugger.
- The S-Function block allows you to write your S-function in C or C++, or to incorporate existing code into your model using a C MEX wrapper. (See “Implement C/C++ S-Functions”.)
- The S-Function Builder block assists you in creating a C MEX S-function or a wrapper function to incorporate legacy C or C++ code. (See “Implement C/C++ S-Functions”.)
- The Legacy Code Tool transforms existing C or C++ functions into C MEX S-functions. (See “Integrate C Functions Using Legacy Code Tool”.)

The S-function target in the Simulink Coder product automatically generates a C MEX S-function from a graphical subsystem. If you want to build your custom block in a Simulink subsystem, but implement the final version of the block in an S-function, you can use the S-function target to convert the subsystem to an S-function. See “Accelerate Simulation, Reuse Code, or Protect Intellectual Property by Using S-Function Target” (Simulink Coder) in the Simulink Coder User's Guide for details and limitations on using the S-function target.

## Masked Blocks

You can customize any block by adding a mask to it. A mask is a custom interface to the block. You can customize a block using a mask in many ways, such as:

- Change the block appearance.
- Hide some or all of the parameters from the user of the block.
- Customize block parameters.

To learn more about masked blocks, see “Create Block Masks”.

## Comparison of Custom Block Functionality

| In this section...                                                                   |
|--------------------------------------------------------------------------------------|
| "Block Type Flowchart" on page 40-7                                                  |
| "Model State Behavior" on page 40-9                                                  |
| "Simulation Performance" on page 40-10                                               |
| "Code Generation" on page 40-12                                                      |
| "Multiple Input and Output Ports" on page 40-13                                      |
| "Speed of Updating the Simulink Diagram" on page 40-14                               |
| "Callback Methods" on page 40-15                                                     |
| "Comparing MATLAB S-Functions to MATLAB Functions for Code Generation" on page 40-16 |
| "Expanding Custom Block Functionality" on page 40-17                                 |

When creating a custom block, consider:

- Does the block model continuous or discrete state behavior on page 40-9?
- Is the simulation performance on page 40-10 important?
- Do you need to generate code on page 40-12 for a model containing the custom block?

This table shows how each custom block type addresses the three concerns.

## Modelling Considerations

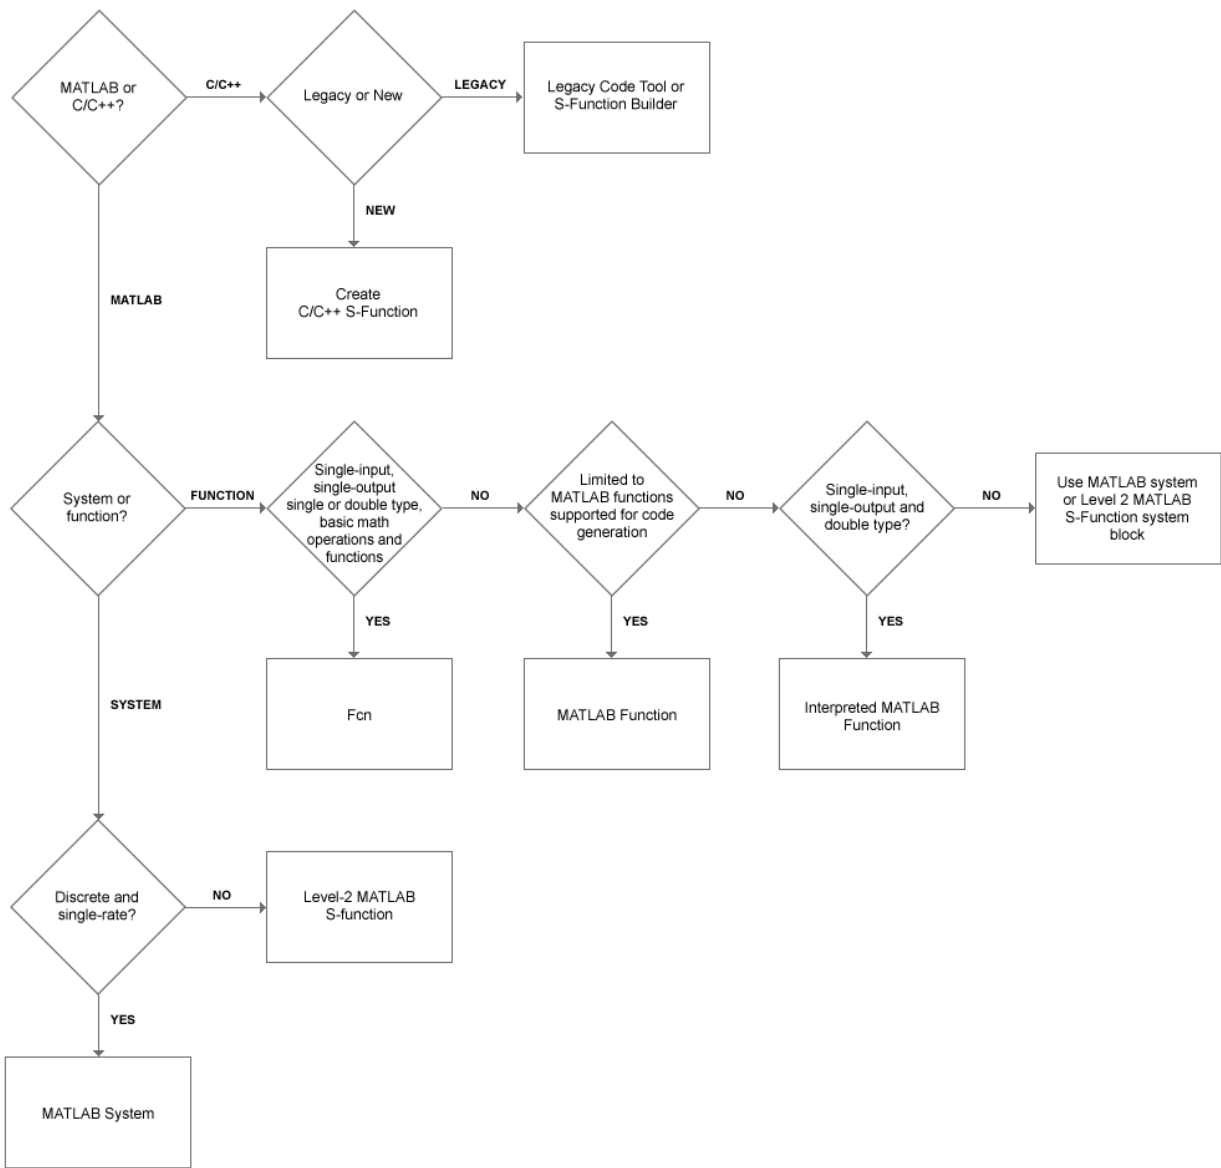

| Custom Block Type           | Model State Dynamics on page 40-9 | Simulation Performance on page 40-10 | Code Generation on page 40-12                        |
|-----------------------------|-----------------------------------|--------------------------------------|------------------------------------------------------|
| Fcn                         | No                                | Very fast                            | Supported                                            |
| Interpreted MATLAB Function | No                                | Less fast                            | Not supported                                        |
| Level-2 MATLAB S-function   | Yes                               | Less fast                            | Requires a TLC file                                  |
| MATLAB Function             | No                                | Fast                                 | Supported with exceptions                            |
| MATLAB System               | Yes                               | Fast                                 | Supported with exceptions                            |
| S-Function                  | Yes                               | Fast                                 | Requires a TLC file or non-inline S-Function support |
| S-Function Builder          | Yes                               | Fast                                 | Supported                                            |
| Simulink Function           | Yes                               | Fast                                 | Supported                                            |
| Subsystem                   | Yes                               | Fast                                 | Supported                                            |

For detailed design of custom blocks, consider:

- Does the custom block need multiple input and output ports on page 40-13?
- What are the callback methods on page 40-15 to communicate with the Simulink engine and which custom blocks let you implement all or a subset of these callback methods?
- How important is the effect of the custom block on the speed of updating the Simulink diagram on page 40-14?

## Block Type Flowchart

This diagram helps to decide which block to use. First, determine whether you need the block for a function or a system. A function defines the relationship between a set of inputs and outputs. A system defines the relationship between a set of states as well as a set of inputs and outputs, parameters, System object processing methods for initialization, output, update, termination, and so forth.

**Note** In the flowchart, Legacy stands for the existing code or models.

## Model State Behavior

You need to model the state behavior for a block that requires some or all of its previous outputs to compute its current outputs. See “Modeling Dynamic Systems” on page 3-3 for more information.

| Custom Block Type                    | Notes                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Fcn, Interpreted MATLAB Function     | Does not allow you to model state behavior.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| MATLAB Function                      | Allows you to model a discrete state using <code>persistent</code> variables.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| Level-2 MATLAB S-Function            | Allows you to model both continuous and discrete state behavior using the <code>ContStates</code> or <code>Dwork</code> run-time object methods in combination with block callback methods. For a list of supported methods, see “Level-2 MATLAB S-Function Callback Methods” in “Write Level-2 MATLAB S-Functions”.                                                                                                                                                                                                                                                                                                      |
| MATLAB System                        | Allows you to model discrete state behavior using <code>DiscreteState</code> properties of the <code>System</code> object, in combination with block callback methods. This block uses <code>System</code> object methods for callback methods: <code>mdlOutputs</code> ( <code>stepImpl</code> , <code>outputImpl</code> ), <code>mdlUpdate</code> ( <code>updateImpl</code> ), <code>mdlInitializeConditions</code> ( <code>resetImpl</code> ), <code>mdlStart</code> ( <code>setupImpl</code> ), <code>mdlTerminate</code> ( <code>releaseImpl</code> ). For more information see “What Are System Objects?” (MATLAB). |
| C MEX S-Function, S-Function Builder | Allows you to model both continuous and discrete state behavior in combination with block callback methods. For more information, see “Callback Methods for C MEX S-Functions”                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| Simulink Function                    | Communicates directly with the engine. You can model the state behavior using appropriate blocks from the continuous and discrete Simulink block libraries. When multiple calls to this function originate from different callers, the state values are also persistent between these calls. For more information, see “Call a Simulink Function Block from Multiple Sites” on page 10-166.                                                                                                                                                                                                                               |
| Subsystem                            | Communicates directly with the engine. You can model the state behavior using appropriate blocks from the continuous and discrete Simulink block libraries.                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

## Simulation Performance

For most applications, all custom block types provide satisfactory simulation performance. Use the Simulink profiler to get the actual performance indication. See “How Profiler Captures Performance Data” on page 31-5 for more information.

The two categories of performance indication are the interface cost and the algorithm cost. The interface cost is the time it takes to move data from the Simulink engine into the block. The algorithm cost is the time it takes to perform the algorithm that the block implements.

| Custom Block Type           | Notes                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|-----------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Fcn                         | Has the highest simulation performance. The block is tightly integrated with the Simulink engine and optimized for simulation and code generation.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Interpreted MATLAB Function | Has a slower performance due to the interface, but has the same algorithm cost as a MATLAB function. When block data (such as inputs and outputs) is accessed or returned from an Interpreted MATLAB Function block, the Simulink engine packages this data into MATLAB arrays. This packaging takes additional time and causes a temporary increase in memory during communication. If you pass large amounts of data across this interface, such as frames or arrays, the performance can be substantially slow. Once the data has been converted, the MATLAB execution engine executes the algorithm. As a result, the algorithm cost is the same as for MATLAB function. |
| Level-2 MATLAB S-Function   | Incurs the same algorithm costs as the Interpreted MATLAB Function block, but with a slightly higher interface cost. Since MATLAB S-Functions can handle multiple inputs and outputs, the packaging is more complicated than for the Interpreted MATLAB Function block. In addition, the Simulink engine calls the MATLAB execution engine for each block method you implement, whereas the Interpreted MATLAB Function block calls the MATLAB execution engine only for the <code>Outputs</code> method.                                                                                                                                                                    |

| Custom Block Type  | Notes                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| MATLAB Function    | <p>Performs simulation through code generation and incurs the same interface cost as other Simulink built-in blocks.</p> <p>The algorithm cost of this block is harder to analyze because of the block's implementation. On average, a function for this block and the MATLAB function run at about the same speed.</p> <p>If the MATLAB Function block has code that uses <code>coder.extrinsic</code> to call out to the MATLAB execution engine, it incurs all the costs that the MATLAB S-Function or Interpreted MATLAB Function block incur. Calling out to the MATLAB execution engine from a MATLAB Function block produces a warning to prevent you from doing so unintentionally.</p> <p>To reduce the algorithm cost, you can disable debugging for all MATLAB Function blocks.</p> |
| MATLAB System      | <p>In the interpreted execution mode, performance is similar to that of the Level-2 MATLAB S-Function because the model simulates the block using the MATLAB execution engine. In the code generation mode, performance is similar to that of the MATLAB Function because the model simulates the block using the generated code. For more information, see the MATLAB Function entry in this table.</p>                                                                                                                                                                                                                                                                                                                                                                                       |
| C MEX S-Function   | <p>Simulates via the compiled code and incurs the same interface cost as Simulink built-in blocks. The algorithm cost depends on the complexity of the S-Function.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| S-Function Builder | <p>This block only builds an S-Function from the specifications and C code you supply. You can also use this block as a wrapper for the generated S-Function in models. The algorithm cost of this block compared to C MEX S-Function is incurred only from the wrapper.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| Custom Block Type            | Notes                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Simulink Function, Subsystem | If included in a library, introduces no interface or algorithm costs beyond what would normally be incurred if the block existed as a regular subsystem in the model.<br>Performance is proportional to the complexity of the algorithm implemented in the subsystem. If the subsystem is contained in a library, some cost is incurred when Simulink loads any unloaded libraries the first time the diagram is updated or readied for simulation. If all referenced library blocks remain unchanged, Simulink does not subsequently reload the library. Compiling the model becomes faster than if the model did not use libraries. |

## Code Generation

You need code generation if your model is part of a bigger system. Not all custom block types support code generation with Simulink Coder.

| Custom Block Type              | Notes                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|--------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Fcn                            | Supports code generation.                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| Interpreted MATLAB Function    | Does not support code generation.                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Level-2 MATLAB S-Function      | Generates code only if you implement the algorithm using a Target Language Compiler (TLC) function. In accelerated and external mode simulations, you can choose to execute the S-Function in the interpretive mode by calling back to the MATLAB execution engine without implementing the algorithm in TLC. If the MATLAB S-Function is <code>SimViewingDevice</code> , the Simulink Coder product automatically omits the block during code generation. |
| MATLAB Function, MATLAB System | Supports code generation. However, if your block calls out to the MATLAB execution engine, it will build with the Simulink Coder product only if the calls to the MATLAB execution engine do not affect the block outputs. Under this condition, the Simulink Coder product omits these calls from the generated C code. This feature allows you to leave visualization code in place, even when generating embedded code.                                 |

| Custom Block Type                    | Notes                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|--------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| C MEX S-Function, S-Function Builder | <p>Both supports code generation.</p> <ul style="list-style-type: none"> <li>For non-inlined S-Functions, the Simulink Coder product uses the C MEX function during code generation.</li> <li>In the case of C MEX S-Functions, if you need to either inline the S-Function or create a wrapper for handwritten code, you must write a TLC file for the S-Function.</li> <li>In the case of S-Function Builder, you can choose the Generate wrapper TLC option to automatically generate a TLC file.</li> </ul> <p>See “S-Functions and Code Generation” (Simulink Coder) for more information.</p> |
| Simulink Function                    | Supports code generation.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| Subsystem                            | Supports code generation as long as the blocks contained within the subsystem support code generation. For more information, see “Control Generation of Functions for Subsystems” (Embedded Coder)                                                                                                                                                                                                                                                                                                                                                                                                  |

## Multiple Input and Output Ports

These types of custom blocks support multiple input and output ports.

| Custom Block Type                | Notes                                                                                                                                                                                                                                           |
|----------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Fcn, Interpreted MATLAB Function | Supports only a single input and a single output port.                                                                                                                                                                                          |
| MATLAB Function                  | Supports multiple input and output ports, including bus signals. See “How Structure Inputs and Outputs Interface with Bus Signals” on page 43-80 for more information.                                                                          |
| MATLAB System                    | Supports multiple input and output ports, including bus signals. In addition, you can modify the number of input and output ports based on system object properties using the <code>getNumInputs</code> and <code>getNumOutputs</code> methods. |

| Custom Block Type                                               | Notes                                                                                                                                                                                                                                           |
|-----------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Level-2 MATLAB S-Function, C MEX S-Function, S-Function Builder | Supports multiple input and output ports. In addition, you can modify the number of input and output ports based on user-defined parameters. The C MEX S-Function and S-Function Builder support bus signals.                                   |
| Simulink Function                                               | Supports multiple input and output ports, including bus signals.                                                                                                                                                                                |
| Subsystem                                                       | Supports multiple input and output ports, including bus signals. In addition, you can modify the number of input and output ports based on user-defined parameters. See “Self-Modifiable Linked Subsystems” on page 41-24 for more information. |

## Speed of Updating the Simulink Diagram

Simulink updates the diagram before every simulation and when requested by the user. Every block introduces some overhead into the diagram update process.

| Custom Block Type                | Notes                                                                                                                                                                                                                                                                                   |
|----------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Fcn, Interpreted MATLAB Function | Low diagram update cost.                                                                                                                                                                                                                                                                |
| MATLAB Function                  | Simulation is performed through code generation, so this blocks can take a significant amount of time when first updated. However, because code generation is incremental, Simulink does not repeatedly update the block if the block and the signals connected to it have not changed. |
| MATLAB System                    | Faster than MATLAB Function because code is not generated to update the diagram. Since, code generation is incremental, Simulink does not repeatedly update the block if the block and the signals connected to it have not changed.                                                    |

| Custom Block Type                           | Notes                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|---------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| C MEX S-Function, Level-2 MATLAB S-Function | Incurs greater costs than other Simulink blocks only if it overrides methods executed when updating the diagram. If these methods become complex, they can contribute significantly to the time it takes to update the diagram. For a list of methods executed when updating the diagram, see the process view in “Simulink Engine Interaction with C S-Functions”. When updating the diagram, Simulink invokes all relevant methods in the model initialization phase up to, but not including, <code>mdlStart</code> . |
| Simulink Function, Subsystem                | The speed is proportional to the complexity of the algorithm implemented in the subsystem. If the subsystem is contained in a library, some cost is incurred when Simulink loads any unloaded libraries the first time the diagram is updated or readied for simulation. If all referenced library blocks remain unchanged, Simulink does not subsequently reload the library. Compiling the model becomes faster than if the model does not use libraries.                                                              |

## Callback Methods

Simulink blocks communicate with the Simulink engine through block callback methods, which fully specify the behavior of blocks (except the Simulink Function block). Each custom block type allows you to implement a different set of callback methods. To learn how blocks interact with Simulink engine, see “Simulink Engine Interaction with C S-Functions”. This table uses “S-Function Callback Methods” names as equivalents.

| Custom Block Type                                 | Notes                                                                                                                                                                                                                                                         |
|---------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Fcn, Interpreted MATLAB Function, MATLAB Function | All create a <code>mdlOutputs</code> method to calculate the value of outputs given the value of inputs. You cannot implement any other callback methods using one of these blocks and, therefore, cannot model state behavior.                               |
| Level-2 MATLAB S-Function                         | Allows implementation of a larger subset of callback methods, including methods you can use to model continuous and discrete states. For a list of supported methods, see “Level-2 MATLAB S-Function Callback Methods” in “Write Level-2 MATLAB S-Functions”. |

| Custom Block Type  | Notes                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| MATLAB System      | Uses System object methods for callback methods: <code>mdlOutputs</code> ( <code>stepImpl</code> , <code>outputImpl</code> ), <code>mdlUpdate</code> ( <code>updateImpl</code> ), <code>mdlInitializeConditions</code> ( <code>resetImpl</code> ), <code>mdlStart</code> ( <code>setupImpl</code> ), <code>mdlTerminate</code> ( <code>releaseImpl</code> ). For more information, see “Simulink Engine Interaction with System Object Methods” on page 45-35 |
| C MEX S-Function   | Allows implementation of a complete set of callback methods.                                                                                                                                                                                                                                                                                                                                                                                                  |
| S-Function Builder | Allows implementation of <code>mdlOutputs</code> , <code>mdlDerivatives</code> and <code>mdlUpdate</code> .                                                                                                                                                                                                                                                                                                                                                   |
| Simulink Function  | Packaged as a standalone function. Any caller to this function becomes part of one of the callback methods based on the caller’s location.                                                                                                                                                                                                                                                                                                                    |
| Subsystem          | Communicates directly with the engine. You can model state behaviors using appropriate blocks from the continuous and discrete Simulink block libraries.                                                                                                                                                                                                                                                                                                      |

## Comparing MATLAB S-Functions to MATLAB Functions for Code Generation

MATLAB S-functions and MATLAB functions for code generation have some fundamental differences.

- The Simulink Coder product can generate code for both MATLAB S-functions and MATLAB functions for code generation. However, MATLAB S-functions require a Target Language Compiler (TLC) file for code generation. MATLAB functions for code generation do not require a TLC file.
- MATLAB S-functions can use any MATLAB function whereas MATLAB functions for code generation are a subset of the MATLAB language. For a list of supported functions for code generation, see “Functions and Objects Supported for C/C++ Code Generation — Alphabetical List” on page 48-2.
- MATLAB S-functions can model discrete and continuous state dynamics whereas MATLAB functions for code generation cannot model state dynamics.

## Expanding Custom Block Functionality

You can expand the functionality of any custom block using callbacks and MATLAB graphics.

Block callbacks perform user-defined actions at specific points in the simulation. For example, the callback can load data into the MATLAB workspace before the simulation or generate a graph of simulation data at the end of the simulation. You can assign block callbacks to any of the custom block types. For a list of available callbacks and more information on how to use them, see “Specify Block Callbacks” on page 4-57.

GUIDE, the MATLAB graphical user interface development environment, provides tools for easily creating custom user interfaces. See “App Building” (MATLAB) for more information on using GUIDE.

### How to Design a Custom Block

In general, use the following process to design a custom block:

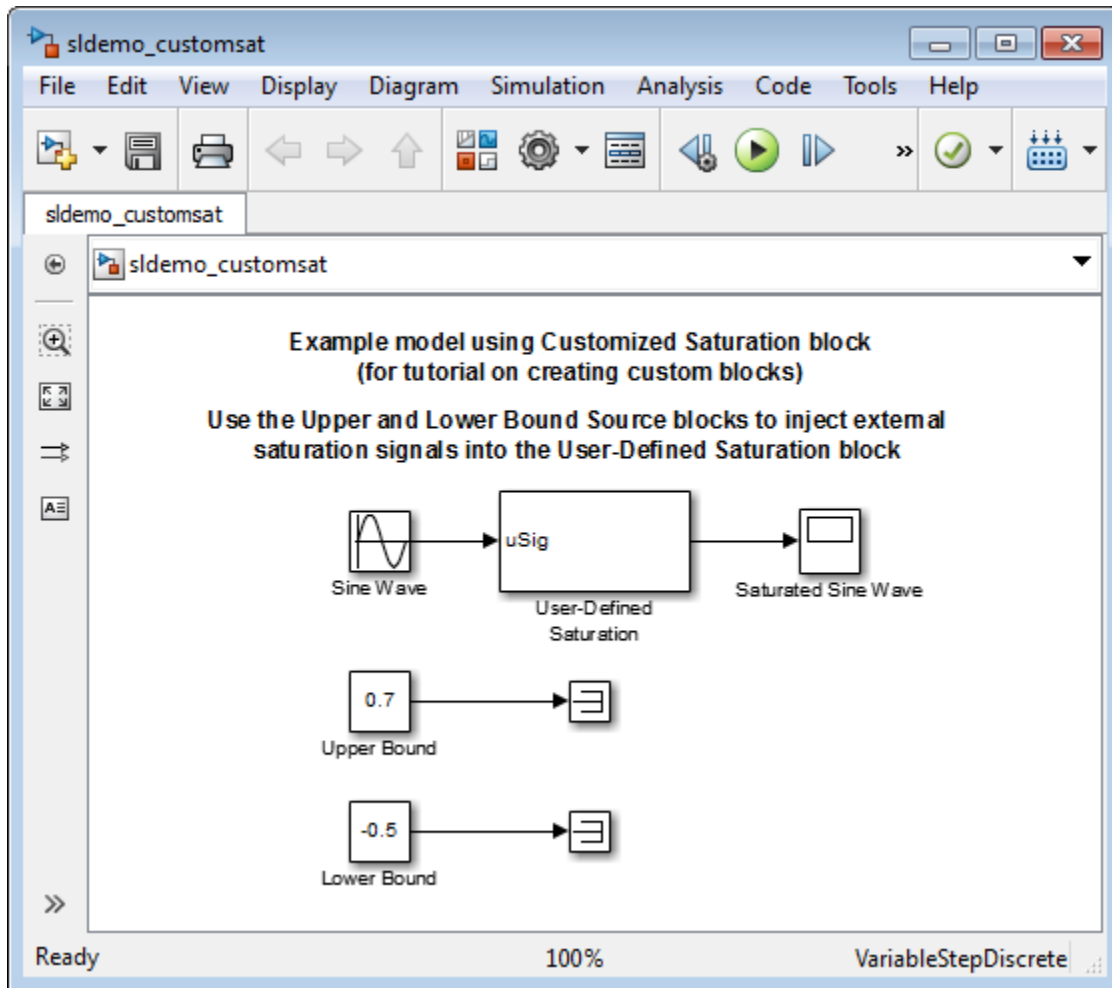

- 1 “Defining Custom Block Behavior” on page 40-20
- 2 “Deciding on a Custom Block Type” on page 40-21
- 3 “Placing Custom Blocks in a Library” on page 40-25
- 4 “Adding a User Interface to a Custom Block” on page 40-28

Suppose you want to create a customized saturation block that limits the upper and lower bounds of a signal based on either a block parameter or the value of an input signal. In a second version of the block, you want the option to plot the saturation limits after the simulation is finished. The following tutorial steps you through designing these blocks. The library `ex_customsat_lib` contains the two versions of the customized saturation block.

The example model `sldemo_customsat` uses the basic version of the block.

## Defining Custom Block Behavior

Begin by defining the features and limitations of your custom block. In this example, the block supports the following features:

- Turning on and off the upper or lower saturation limit.
- Setting the upper and/or lower limits via a block parameters.

- Setting the upper and/or lower limits using an input signal.

It also has the following restrictions:

- The input signal under saturation must be a scalar.
- The input signal and saturation limits must all have a data type of double.
- Code generation is not required.

## Deciding on a Custom Block Type

Based on the custom block features, the implementation needs to support the following:

- Multiple input ports
- A relatively simple algorithm
- No continuous or discrete system states

Therefore, this tutorial implements the custom block using a Level-2 MATLAB S-function. MATLAB S-functions support multiple inputs and, because the algorithm is simple, do not have significant overhead when updating the diagram or simulating the model. See “Comparison of Custom Block Functionality” on page 40-6 for a description of the different functionality provided by MATLAB S-functions as compared to other types of custom blocks.

## Parameterizing the MATLAB S-Function

Begin by defining the S-function parameters. This example requires four parameters:

- The first parameter indicates how the upper saturation limit is set. The limit can be off, set via a block parameter, or set via an input signal.
- The second parameter is the value of the upper saturation limit. This value is used only if the upper saturation limit is set via a block parameter. In the event this parameter is used, you should be able to change the parameter value during the simulation, i.e., the parameter is tunable.
- The third parameter indicates how the lower saturation limit is set. The limit can be off, set via a block parameter, or set via an input signal.
- The fourth parameter is the value of the lower saturation limit. This value is used only if the lower saturation limit is set via a block parameter. As with the upper saturation limit, this parameter is tunable when in use.

The first and third S-function parameters represent modes that must be translated into values the S-function can recognize. Therefore, define the following values for the upper and lower saturation limit modes:

- 1 indicates that the saturation limit is off.
- 2 indicates that the saturation limit is set via a block parameter.
- 3 indicates that the saturation limit is set via an input signal.

### Writing the MATLAB S-Function

After you define the S-function parameters and functionality, write the S-function. The template `msfuntmpl.m` provides a starting point for writing a Level-2 MATLAB S-function. You can find a completed version of the custom saturation block in the file `custom_sat.m`. Save this file to your working folder before continuing with this tutorial.

This S-function modifies the S-function template as follows:

- The `setup` function initializes the number of input ports based on the values entered for the upper and lower saturation limit modes. If the limits are set via input signals, the method adds input ports to the block. The `setup` method then indicates there are four S-function parameters and sets the parameter tunability. Finally, the method registers the S-function methods used during simulation.

```
function setup(block)

% The Simulink engine passes an instance of the Simulink.MSFcnRunTimeBlock
% class to the setup method in the input argument "block". This is known as
% the S-function block's run-time object.

% Register original number of input ports based on the S-function
% parameter values

try % Wrap in a try/catch, in case no S-function parameters are entered
 lowMode = block.DialogPrm(1).Data;
 upMode = block.DialogPrm(3).Data;
 numInPorts = 1 + isequal(lowMode,3) + isequal(upMode,3);
catch
 numInPorts=1;
end % try/catch
block.NumInputPorts = numInPorts;
block.NumOutputPorts = 1;

% Setup port properties to be inherited or dynamic
block.SetPreCompInpPortInfoToDynamic;
block.SetPreCompOutPortInfoToDynamic;

% Override input port properties
block.InputPort(1).DatatypeID = 0; % double
```

```

block.InputPort(1).Complexity = 'Real';

% Override output port properties
block.OutputPort(1).DatatypeID = 0; % double
block.OutputPort(1).Complexity = 'Real';

% Register parameters. In order:
% -- If the upper bound is off (1) or on and set via a block parameter (2)
% or input signal (3)
% -- The upper limit value. Should be empty if the upper limit is off or
% set via an input signal
% -- If the lower bound is off (1) or on and set via a block parameter (2)
% or input signal (3)
% -- The lower limit value. Should be empty if the lower limit is off or
% set via an input signal
block.NumDialogPrms = 4;
block.DialogPrmsTunable = {'Nontunable','Tunable','Nontunable', ...
 'Tunable'};

% Register continuous sample times [0 offset]
block.SampleTimes = [0 0];

%% -----
%% Options
%% -----
% Specify if Accelerator should use TLC or call back into
% MATLAB script
block.SetAccelRunOnTLC(false);

%% -----
%% Register methods called during update diagram/compilation
%% -----

block.RegBlockMethod('CheckParameters', @CheckPrms);
block.RegBlockMethod('ProcessParameters', @ProcessPrms);
block.RegBlockMethod('PostPropagationSetup', @DoPostPropSetup);
block.RegBlockMethod('Outputs', @Outputs);
block.RegBlockMethod('Terminate', @Terminate);
%end setup function

```

- The `CheckParameters` method verifies the values entered into the Level-2 MATLAB S-Function block.

```

function CheckPrms(block)

lowMode = block.DialogPrm(1).Data;
lowVal = block.DialogPrm(2).Data;
upMode = block.DialogPrm(3).Data;
upVal = block.DialogPrm(4).Data;

% The first and third dialog parameters must have values of 1-3
if ~any(upMode == [1 2 3]);
 error('The first dialog parameter must be a value of 1, 2, or 3');
end

if ~any(lowMode == [1 2 3]);

```

```

 error('The first dialog parameter must be a value of 1, 2, or 3');
 end

 % If the upper or lower bound is specified via a dialog, make sure there
 % is a specified bound. Also, check that the value is of type double
 if isequal(upMode,2),
 if isempty(upVal),
 error('Enter a value for the upper saturation limit.');
```

```

 end
 if ~strcmp(class(upVal), 'double')
 error('The upper saturation limit must be of type double.');
```

```

 end
 end

 if isequal(lowMode,2),
 if isempty(lowVal),
 error('Enter a value for the lower saturation limit.');
```

```

 end
 if ~strcmp(class(lowVal), 'double')
 error('The lower saturation limit must be of type double.');
```

```

 end
 end

 % If a lower and upper limit are specified, make sure the specified
 % limits are compatible.
 if isequal(upMode,2) && isequal(lowMode,2),
 if lowVal >= upVal,
 error('The lower bound must be less than the upper bound.');
```

```

 end
 end

 %end CheckPrms function

```

- The `ProcessParameters` and `PostPropagationSetup` methods handle the S-function parameter tuning.

```

function ProcessPrms(block)

%% Update run time parameters
block.AutoUpdateRuntimePrms;

%end ProcessPrms function

function DoPostPropSetup(block)

%% Register all tunable parameters as runtime parameters.
block.AutoRegRuntimePrms;

%end DoPostPropSetup function

```

- The `Outputs` method calculates the block's output based on the S-function parameter settings and any input signals.

```

function Outputs(block)

```

```

lowMode = block.DialogPrm(1).Data;
upMode = block.DialogPrm(3).Data;
sigVal = block.InputPort(1).Data;
lowPortNum = 2; % Initialize potential input number for lower saturation limit

% Check upper saturation limit
if isequal(upMode,2), % Set via a block parameter
 upVal = block.RuntimePrm(2).Data;
elseif isequal(upMode,3), % Set via an input port
 upVal = block.InputPort(2).Data;
 lowPortNum = 3; % Move lower boundary down one port number
else
 upVal = inf;
end

% Check lower saturation limit
if isequal(lowMode,2), % Set via a block parameter
 lowVal = block.RuntimePrm(1).Data;
elseif isequal(lowMode,3), % Set via an input port
 lowVal = block.InputPort(lowPortNum).Data;
else
 lowVal = -inf;
end

% Assign new value to signal
if sigVal > upVal,
 sigVal = upVal;
elseif sigVal < lowVal,
 sigVal=lowVal;
end

block.OutputPort(1).Data = sigVal;

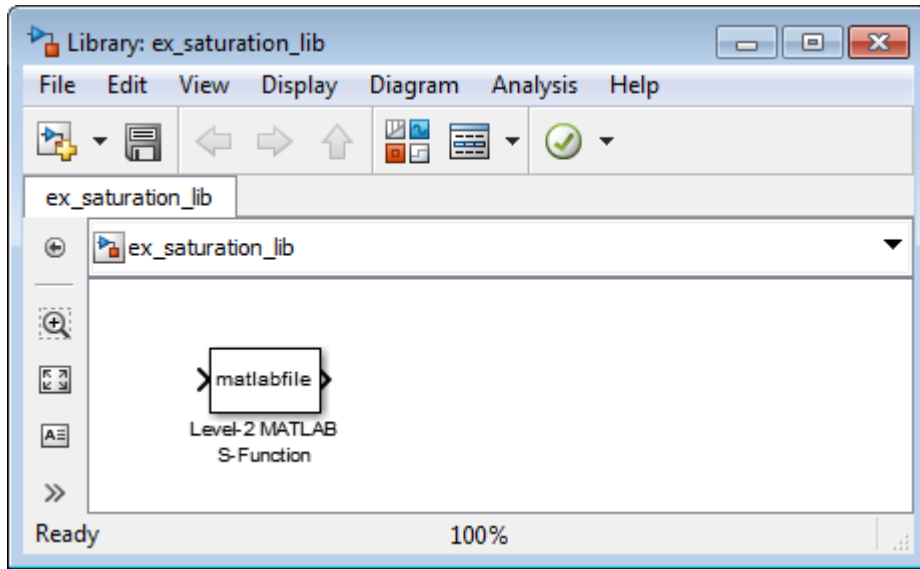

%end Outputs function

```

## Placing Custom Blocks in a Library

Libraries allow you to share your custom blocks with other users, easily update the functionality of copies of the custom block, and collect blocks for a particular project into a single location. This example places the custom saturation block into a library.

- 1 In the Simulink Library Browser, select **File > New > Library**.
- 2 From the User-Defined Functions library, drag a Level-2 MATLAB S-Function block into your new library.

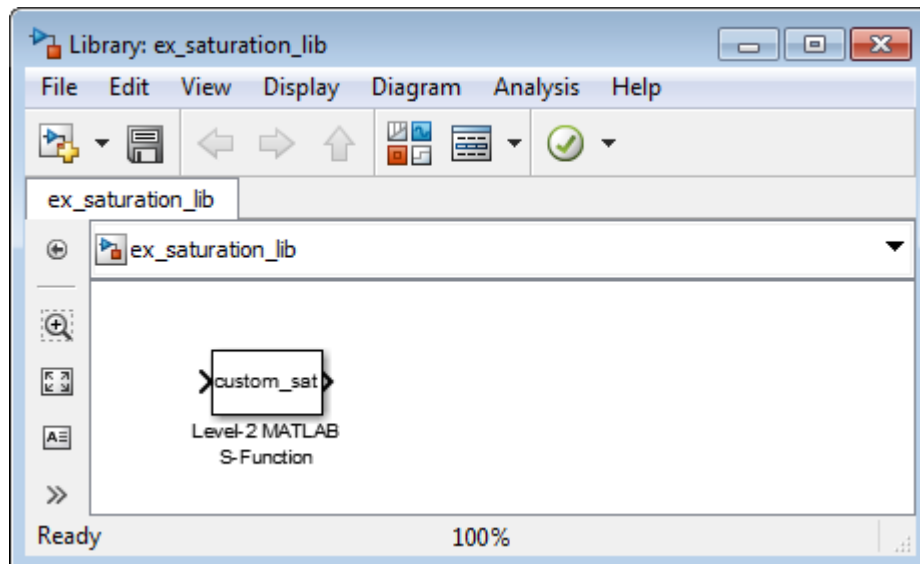

- 3 Save your library with the filename `saturation_lib`.
- 4 Double-click the block to open its Function Block Parameters dialog box.
- 5 In the **S-function name** field, enter the name of the S-function. For example, enter `custom_sat`. In the **Parameters** field enter `2, -1, 2, 1`.

- 6 Click **OK**.

You have created a custom saturation block that you can share with other users.

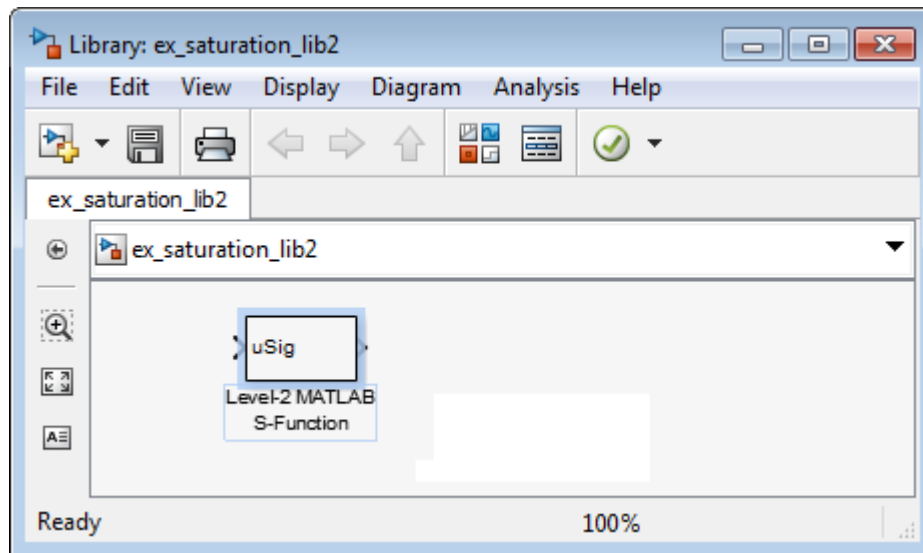

You can make the block easier to use by adding a customized user interface.

## Adding a User Interface to a Custom Block

You can create a block dialog box for a custom block using the masking features of Simulink. Masking the block also allows you to add port labels to indicate which ports corresponds to the input signal and the saturation limits.

- 1 Open the library `saturation_lib` that contains the custom block you created,
- 2 Right-click the Level-2 MATLAB S-Function block and select **Mask > Create Mask**.
- 3 On the **Icon & Ports** pane in the **Icons drawing commands** box, enter `port_label('input',1,'uSig')`, and then click **Apply**.

This command labels the default port as the input signal under saturation.

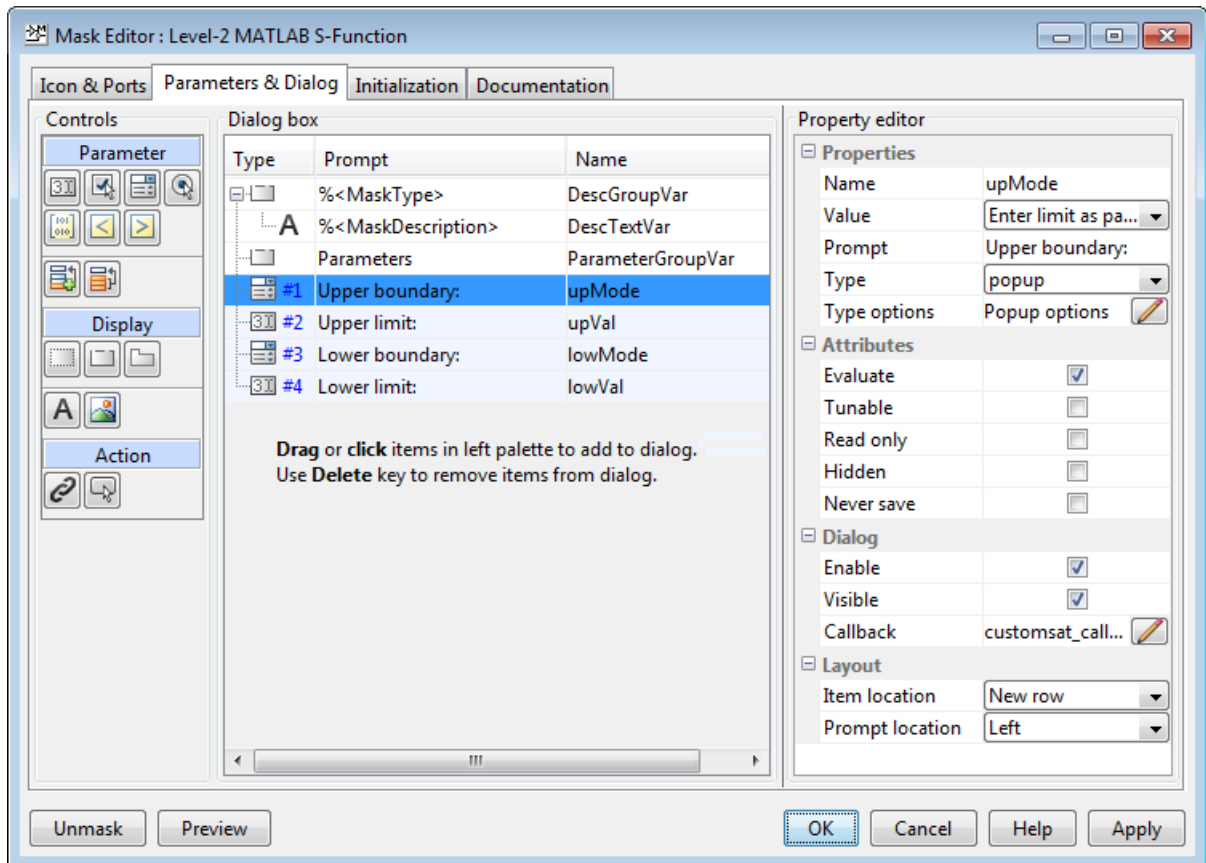

- 4 In the **Parameters & Dialog** pane, add four parameters corresponding to the four S-Function parameters. For each new parameter, drag a popup or edit control to the **Dialog box** section, as shown in the table. Drag each parameter into the Parameters group.

| Type  | Prompt          | Name  | Evaluate | Tunable | Popup options                                                    | Callback                                        |
|-------|-----------------|-------|----------|---------|------------------------------------------------------------------|-------------------------------------------------|
| popup | Upper boundary: | upMod | ✓        |         | No limit<br>Enter limit as parameter<br>Limit using input signal | customsat_callback('upper_bound_callback', gcb) |
| edit  | Upper limit:    | upVal | ✓        | ✓       | N/A                                                              | customsat_callback('upper_param_callback', gcb) |

| Type  | Prompt          | Name   | Evaluate | Tunable | Popup options                                                    | Callback                                        |
|-------|-----------------|--------|----------|---------|------------------------------------------------------------------|-------------------------------------------------|
| popup | Lower boundary: | lowMod | ✓        |         | No limit<br>Enter limit as parameter<br>Limit using input signal | customsat_callback('lower_bound_callback', gcb) |
| edit  | Lower limit:    | lowVal | ✓        | ✓       | N/A                                                              | customsat_callback('lower_param_callback', gcb) |

The MATLAB S-Function script `custom_sat_final.m` contains the mask parameter callbacks. Save `custom_sat_final.m` to your working folder to define the callbacks in this example. This MATLAB script has two input arguments. The first input argument is a character vector indicating which mask parameter invoked the callback. The second input argument is the handle to the associated Level-2 MATLAB S-Function block.

The figure shows the completed **Parameters & Dialog** pane in the Mask Editor.

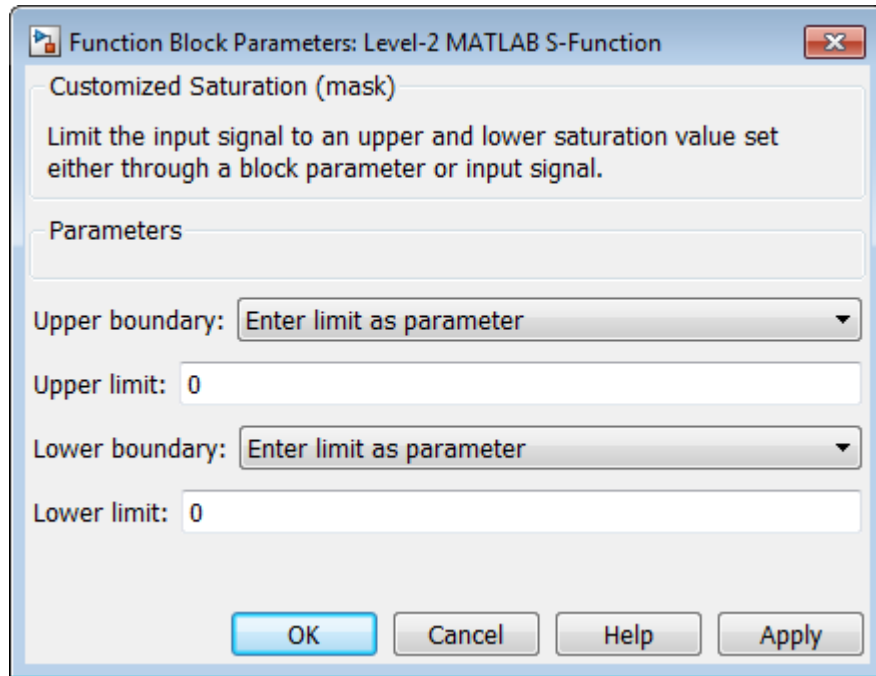

- 5 In the **Initialization** pane, select the **Allow library block to modify its contents** check box. This setting allows the S-function to change the number of ports on the block.
- 6 In the **Documentation** pane:
  - In the **Mask type** field, enter  
Customized Saturation
  - In the **Mask description** field, enter  
Limit the input signal to an upper and lower saturation value set either through a block parameter or input signal.

- 7 Click **OK**.
- 8 To map the S-function parameters to the mask parameters, right-click the Level-2 MATLAB S-Function block and select **Mask > Look Under Mask**.
- 9 Change the **S-function name** field to `custom_sat_final` and the **Parameters** field to `lowMode,lowVal,upMode,upVal`.

The figure shows the Function Block Parameters dialog box after the changes.

- 10 Click **OK**. Save and close the library to exit the edit mode.
- 11 Reopen the library and double-click the customized saturation block to open the masked parameter dialog box.

To create a more complicated user interface, place a MATLAB graphics user interface on top of the masked block. The block `OpenFcn` invokes the MATLAB graphics user interface, which uses calls to `set_param` to modify the S-function block parameters based on settings in the user interface.

### Writing the Mask Callback

The function `customsat_callback.m` contains the mask callback code for the custom saturation block mask parameter dialog box. This function invokes local functions corresponding to each mask parameter through a call to `feval`.

The following local function controls the visibility of the upper saturation limit's field based on the selection for the upper saturation limit's mode. The callback begins by obtaining values for all mask parameters using a call to `get_param` with the property name `MaskValues`. If the callback needed the value of only one mask parameter, it could call `get_param` with the specific mask parameter name, for example, `get_param(block, 'upMode')`. Because this example needs two of the mask parameter values, it uses the `MaskValues` property to reduce the calls to `get_param`.

The callback then obtains the visibilities of the mask parameters using a call to `get_param` with the property name `MaskVisibilities`. This call returns a cell array of character vectors indicating the visibility of each mask parameter. The callback alters the values for the mask visibilities based on the selection for the upper saturation limit's mode and then updates the port label text.

The callback finally uses the `set_param` command to update the block's `MaskDisplay` property to label the block's input ports.

```
function customsat_callback(action,block)
% CUSTOMSAT_CALLBACK contains callbacks for custom saturation block

% Copyright 2003-2007 The MathWorks, Inc.

%% Use function handle to call appropriate callback
feval(action,block)

%% Upper bound callback
function upperbound_callback(block)

vals = get_param(block,'MaskValues');
vis = get_param(block,'MaskVisibilities');
portStr = {'port_label('input',1,'uSig')'};
switch vals{1}
 case 'No limit'
 set_param(block,'MaskVisibilities',[vis(1);{'off'};vis(3:4)]);
 case 'Enter limit as parameter'
 set_param(block,'MaskVisibilities',[vis(1);{'on'};vis(3:4)]);
 case 'Limit using input signal'
 set_param(block,'MaskVisibilities',[vis(1);{'off'};vis(3:4)]);
 portStr = [portStr;{'port_label('input',2,'up')'}];
end
if strcmp(vals{3},'Limit using input signal'),
 portStr = [portStr;{'port_label('input','',num2str(length(portStr)+1), ...
 '','low')'}]];
end
set_param(block,'MaskDisplay',char(portStr));
```

The final call to `set_param` invokes the `setup` function in the MATLAB S-function `custom_sat.m`. Therefore, the `setup` function can be modified to set the number of input ports based on the mask parameter values instead of on the S-function parameter values. This change to the `setup` function keeps the number of ports on the Level-2 MATLAB S-Function block consistent with the values shown in the mask parameter dialog box.

The modified MATLAB S-function `custom_sat_final.m` contains the following new `setup` function. If you are stepping through this tutorial, open the file and save it to your working folder.

```
%% Function: setup =====
function setup(block)

% Register original number of ports based on settings in Mask Dialog
ud = getPortVisibility(block);
numInPorts = 1 + isequal(ud(1),3) + isequal(ud(2),3);

block.NumInputPorts = numInPorts;
block.NumOutputPorts = 1;

% Setup port properties to be inherited or dynamic
block.SetPreCompInpPortInfoToDynamic;
block.SetPreCompOutPortInfoToDynamic;

% Override input port properties
block.InputPort(1).DatatypeID = 0; % double
block.InputPort(1).Complexity = 'Real';

% Override output port properties
block.OutputPort(1).DatatypeID = 0; % double
block.OutputPort(1).Complexity = 'Real';

% Register parameters. In order:
% -- If the upper bound is off (1) or on and set via a block parameter (2)
% or input signal (3)
% -- The upper limit value. Should be empty if the upper limit is off or
% set via an input signal
% -- If the lower bound is off (1) or on and set via a block parameter (2)
% or input signal (3)
% -- The lower limit value. Should be empty if the lower limit is off or
% set via an input signal
block.NumDialogPrms = 4;
block.DialogPrmsTunable = {'Nontunable','Tunable','Nontunable','Tunable'};

% Register continuous sample times [0 offset]
block.SampleTimes = [0 0];

%% -----
%% Options
%% -----
% Specify if Accelerator should use TLC or call back into
% MATLAB script
block.SetAccelRunOnTLC(false);

%% -----
%% Register methods called during update diagram/compilation
%% -----

block.RegBlockMethod('CheckParameters', @CheckPrms);
block.RegBlockMethod('ProcessParameters', @ProcessPrms);
block.RegBlockMethod('PostPropagationSetup', @DoPostPropSetup);
block.RegBlockMethod('Outputs', @Outputs);
block.RegBlockMethod('Terminate', @Terminate);
%endfunction
```

The `getPortVisibility` local function in `custom_sat_final.m` uses the saturation limit modes to construct a flag that is passed back to the `setup` function. The `setup` function uses this flag to determine the necessary number of input ports.

```
%% Function: Get Port Visibilities =====
function ud = getPortVisibility(block)

ud = [0 0];

vals = get_param(block.BlockHandle,'MaskValues');
switch vals{1}
 case 'No limit'
 ud(2) = 1;
 case 'Enter limit as parameter'
 ud(2) = 2;
 case 'Limit using input signal'
 ud(2) = 3;
end

switch vals{3}
 case 'No limit'
 ud(1) = 1;
 case 'Enter limit as parameter'
 ud(1) = 2;
 case 'Limit using input signal'
 ud(1) = 3;
end
```

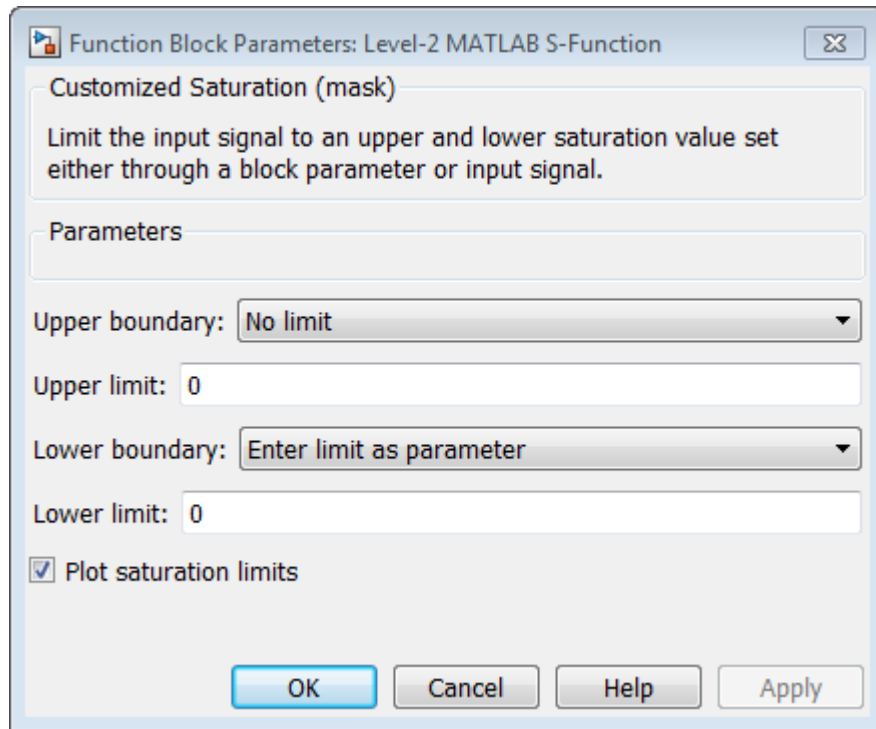

## Adding Block Functionality Using Block Callbacks

The User-Defined Saturation with Plotting block in `customsat_lib` uses block callbacks to add functionality to the original custom saturation block. This block provides an option to plot the saturation limits when the simulation ends. The following steps show how to modify the original custom saturation block to create this new block.

- 1 Add a check box to the mask parameter dialog box to toggle the plotting option on and off.
  - a Right-click the Level-2 MATLAB S-Function block in `saturation_lib` and select **Mask + Create Mask**.
  - b On the Mask Editor **Parameters** pane, add a fifth mask parameter with the following properties.

| Prompt                 | Name      | Type     | Tunable | Type options | Callback                                |
|------------------------|-----------|----------|---------|--------------|-----------------------------------------|
| Plot saturation limits | plotcheck | checkbox | No      | NA           | customsat_callback('lotsaturation',gcb) |

- c Click **OK**.

- 2 Write a callback for the new check box. The callback initializes a structure to store the saturation limit values during simulation in the Level-2 MATLAB S-Function block `UserData`. The MATLAB script `customsat_plotcallback.m` contains this new callback, as well as modified versions of the previous callbacks to handle the new mask parameter. If you are following through this example, open `customsat_plotcallback.m` and copy its local functions over the previous local functions in `customsat_callback.m`.

```

%% Plotting checkbox callback
function plotsaturation(block)

% Reinitialize the block's userdata
vals = get_param(block, 'MaskValues');
ud = struct('time', [], 'upBound', [], 'upVal', [], 'lowBound', [], 'lowVal', []);

if strcmp(vals{1}, 'No limit'),
 ud.upBound = 'off';
else
 ud.upBound = 'on';
end

if strcmp(vals{3}, 'No limit'),
 ud.lowBound = 'off';
else
 ud.lowBound = 'on';
end

set_param(gcb, 'UserData', ud);

```

- 3** Update the MATLAB S-function Outputs method to store the saturation limits, if applicable, as done in the new MATLAB S-function `custom_sat_plot.m`. If you are following through this example, copy the Outputs method in `custom_sat_plot.m` over the original Outputs method in `custom_sat_final.m`

```

%% Function: Outputs =====
function Outputs(block)

lowMode = block.DialogPrm(1).Data;
upMode = block.DialogPrm(3).Data;
sigVal = block.InputPort(1).Data;
vals = get_param(block.BlockHandle, 'MaskValues');
plotFlag = vals{5};
lowPortNum = 2;

% Check upper saturation limit
if isequal(upMode, 2)
 upVal = block.RuntimePrm(2).Data;
elseif isequal(upMode, 3)
 upVal = block.InputPort(2).Data;
 lowPortNum = 3; % Move lower boundary down one port number
else
 upVal = inf;
end

% Check lower saturation limit
if isequal(lowMode, 2),
 lowVal = block.RuntimePrm(1).Data;
elseif isequal(lowMode, 3)
 lowVal = block.InputPort(lowPortNum).Data;
else
 lowVal = -inf;
end

```

```
% Use userdata to store limits, if plotFlag is on
if strcmp(plotFlag,'on');
 ud = get_param(block.BlockHandle,'UserData');
 ud.lowVal = [ud.lowVal;lowVal];
 ud.upVal = [ud.upVal;upVal];
 ud.time = [ud.time;block.CurrentTime];
 set_param(block.BlockHandle,'UserData',ud)
end

% Assign new value to signal
if sigVal > upVal,
 sigVal = upVal;
elseif sigVal < lowVal,
 sigVal=lowVal;
end

block.OutputPort(1).Data = sigVal;

%endfunction
```

- 4 Write the function `plotsat.m` to plot the saturation limits. This function takes the handle to the Level-2 MATLAB S-Function block and uses this handle to retrieve the block's `UserData`. If you are following through this tutorial, save `plotsat.m` to your working folder.

```
function plotSat(block)

% PLOTSAT contains the plotting routine for custom_sat_plot
% This routine is called by the S-function block's StopFcn.

ud = get_param(block,'UserData');
fig=[];
if ~isempty(ud.time)
 if strcmp(ud.upBound,'on')
 fig = figure;
 plot(ud.time,ud.upVal,'r');
 hold on
 end
 if strcmp(ud.lowBound,'on')
 if isempty(fig),
 fig = figure;
 end
 plot(ud.time,ud.lowVal,'b');
 end
 if ~isempty(fig)
 title('Upper bound in red. Lower bound in blue.')
 end

 % Reinitialize userdata
 ud.upVal=[];
 ud.lowVal=[];
 ud.time = [];
 set_param(block,'UserData',ud);
end
```

- 5 Right-click the Level-2 MATLAB S-Function block and select **Properties**. The Block Properties dialog box opens. On the **Callbacks** pane, modify the StopFcn to call the plotting callback as shown in the following figure, then click **OK**.

## Custom Libraries and Linked Blocks

### Why Create Custom Libraries?

A *block library* is a collection of blocks that you can use to create instances of those blocks in a Simulink model. You can create instances of blocks from installed Simulink libraries, and you can create custom libraries to create and maintain instances of your own blocks in models.

You can access the installed libraries from the Simulink Library Browser. You cannot modify the installed libraries. Instead, if you want others to be able to create customized blocks, you can create your own library of your blocks and add it to the Library Browser. Otherwise, you can make your library accessible to the models that use it.

Creating your own libraries is a useful componentization technique for:

- Providing frequently used, and seldom changed, modeling utilities
- Reusing components in a model or in multiple models

To learn how using custom libraries compares to other Simulink componentization techniques, see “Manage Components Using Libraries” on page 22-12 and “Capabilities of Model Components” on page 15-29.

### How Block Instances Connect to Libraries

When you add masked blocks, subsystems, or charts from a custom library to a model, the block you add becomes a linked block. A linked block connects to the library block by way of a *library link*. The library block is the *prototype block*, and the linked block in the model is an *instance* of the library block.

The linked block looks and acts like the library block. However, if you change the library block, you need to update the link on the instances. Making changes to an instance can also require additional steps. To learn about how linked blocks work, see “Linked Blocks” on page 41-15.

## Create a Custom Library

### In this section...

- “Create a Library” on page 41-4
- “Blocks for Custom Libraries” on page 41-5
- “Annotations in Custom Libraries” on page 41-8
- “Lock and Unlock Libraries” on page 41-9
- “Prevent Disabling of Library Links” on page 41-9

### Create a Library

You can create your own library and, optionally, add it to the Simulink Library Browser. You save a library as a .SLX file as you do a model. However, you cannot simulate in a library, and a library becomes locked for editing each time you close it. You must unlock a library before you make changes to it. See “Lock and Unlock Libraries” on page 41-9.

- 1 From the Simulink start page, select **Blank Library** and click **Create Library**.
- 2 Add blocks from models or libraries to the new library. Make the changes you want to the blocks, such as changing block parameters, adding masks, or adding blocks to subsystems.

Subsystem names in a library hierarchy must be unique. For example, do not create a hierarchy such as Subsystem\_Name1/Subsystem\_Name2/Subsystem\_Name1.

- 3 Add annotations or images. Right-click the ones you want to appear in the library in the Library Browser and select **Show in Library Browser**.
- 4 If you plan to add the library to the Library Browser, you can order the blocks and annotations in your library model. By default, they appear alphabetically in the Library Browser, with subsystems first, then blocks, and then annotations. The user of your library can use the Library Browser context menu to choose between viewing them in alphabetical order or the order you specified. When the user selects this option, the order in which they appear in your library model determines the order they appear on the grid in the library in the Library Browser.
- 5 If you want the library to appear in the Library Browser, enable the model property `EnableLBRepository` before you save the library.

```
set_param(gcs, 'EnableLBRepository', 'on');
```

## 6 Save the library.

Where you save the library depends on how you plan to use it. If you want to add it to the Library Browser, save it to a folder on the MATLAB path or add the location to the MATLAB path. Otherwise, save it to a location where the models that use the blocks can access it.

If you want the library to appear in the Library Browser, you must also create a function `slblocks` on your MATLAB path that adds the library to the browser. For an example that shows complete steps for adding a library to the browser, see “Add Libraries to the Library Browser” on page 41-11.

---

**Note** To update the Library Browser with your custom libraries, right-click anywhere in the Library Browser library list and select **Refresh Library Browser**. Refreshing the Library Browser also updates the quick insert list to include the blocks in custom libraries currently in effect. The quick insert list lets you add blocks to a model without leaving the canvas. Click the canvas and start typing to add blocks from the quick insert list.

---

## Blocks for Custom Libraries

Your library can contain the blocks you need, configured for your purposes. Subsystems, masked blocks, and charts in your library become linked blocks as instances in the model and stay updated if you change them in your library. Knowing about custom blocks is also useful when you create a library. See “Design and Create a Custom Block” on page 40-18.

You can create blocks in custom libraries with settings for specific purposes.

### Create a Sublibrary

If your library contains many blocks, you can group the blocks into subsystems or separate sublibraries. To create a sublibrary, you create a library of the sublibrary blocks and reference the library from a Subsystem block in the parent library.

- 1 In the library you want to add a sublibrary to, add a Subsystem block.
- 2 Inside the Subsystem block, delete the default input and output ports.
- 3 If you want, create a mask for the subsystem that displays text or an image that conveys the sublibrary’s purpose.
- 4 In the subsystem’s block properties, set the `OpenFcn` callback to the name of the library you want to reference.

To learn more about masks, see “Create a Simple Mask” on page 39-7.

### **Prevent Library Block from Linking to Instance**

You can configure a library block so the instances created from it are not linked blocks and are instead copies. Set the block’s CopyFcn callback.

```
set_param(gcbh, 'LinkStatus', 'none');
```

### **Include Block Description in Linked Block**

To add a description that appears in the linked block, mask the library block and add the description in the **Documentation** pane of the mask. Descriptions added to the library block through the block’s properties do not appear on the linked block.

### **Configure Block with Keywords for Quick Insert**

You can add one or more keywords to a block in your library. The keyword lets you add the block to your model from the quick insert prompt by entering the keyword or the block name.

For example, suppose you have a custom Gain block in your library. You can add the keyword **My Gain** to the block. Then, you can add the block to your model by entering **My Gain** at the quick insert prompt.

---

**Note** You cannot add keywords to the blocks from **Commonly Used Blocks**. While adding a keyword to a block, make sure that you are setting it on the parent library of the block.

---

To add the keyword to the block in your library, use `set_param` with the 'BlockKeywords' parameter. You can use a character vector, string scalar, or string array as the value. For example:

```
set_param(gcb, 'BlockKeywords', {'My Gain', 'Your Gain'})
set_param(gcb, 'BlockKeywords', 'My Integrator')
```

---

**Note** The supported special characters in keywords are '&', '(', ')', '+', '@', '!'.  

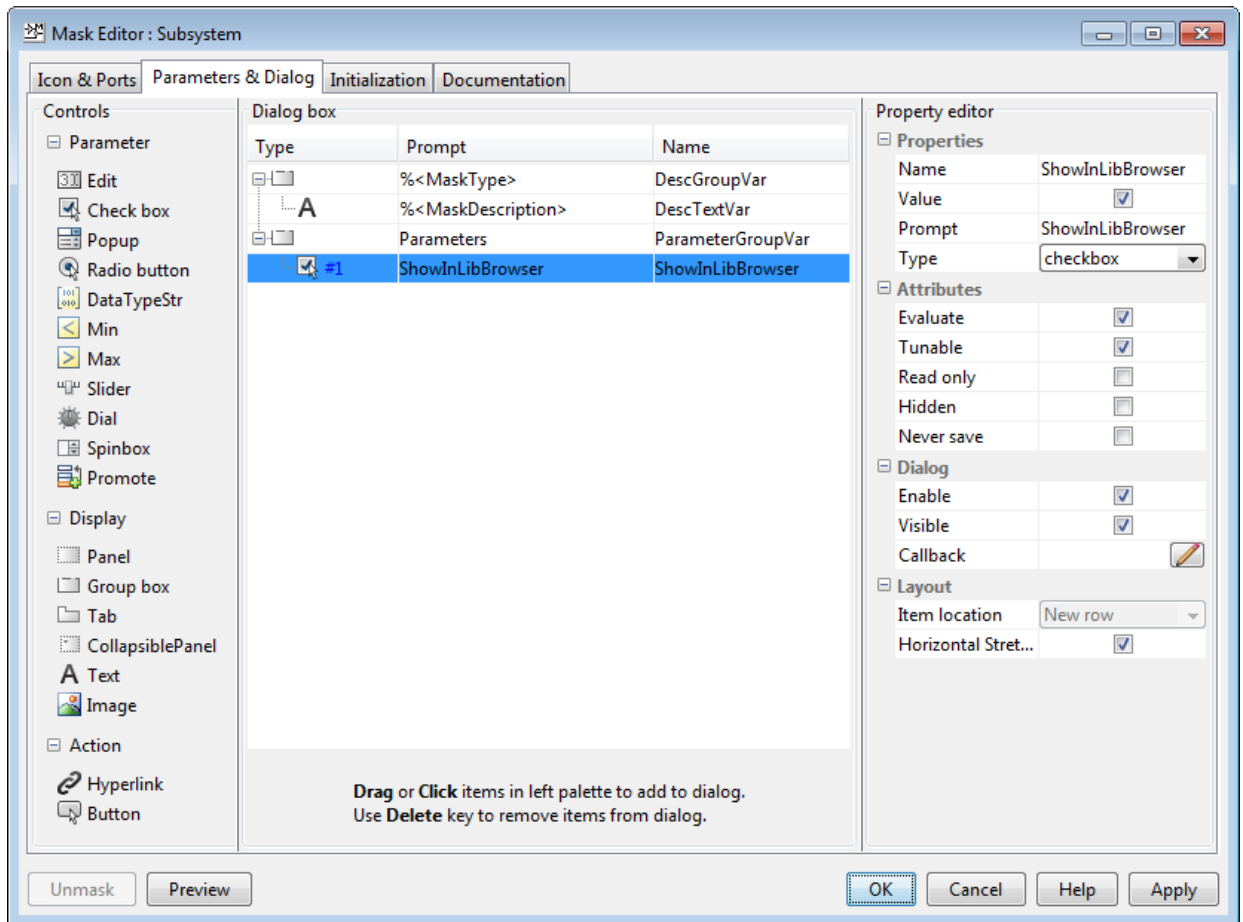

---

### Configure Subsystems with OpenFcn Callback for Library Browser

A common use of a Subsystem block in a custom library is to set the `OpenFcn` callback property to open a library, creating a library hierarchy. However, you can use the `OpenFcn` callback property of a Subsystem block for other purposes, for example to run MATLAB code or to open a link.

If your subsystem block in a library is empty and its `OpenFcn` callback contains code that performs an action other than point to a library or model, then you need to add a `ShowInLibBrowser` mask parameter to the subsystem to have it appear in the Library Browser.

- 1 Right-click the subsystem and select **Mask > Create Mask**. If the block already has a mask, select **Edit Mask** instead.
- 2 In the Mask Editor **Parameters & Dialog** tab, on the **Controls** pane, click **Check box**.
- 3 In the **Dialog box** pane, set the prompt and name for the new check box to `ShowInLibBrowser` and click **OK**.

## Annotations in Custom Libraries

You can add annotations in your custom library and optionally have them appear in the Library Browser. For example, you can add an annotation that documents the library. You can also add annotations that the user of your library can add to their model from the Library Browser. Annotations can contain text and images or display an equation. Annotations can also perform an action when clicked. Learn more about annotations in “Describe Models Using Annotations” on page 4-5.

You can add callout lines from annotations to blocks in your library. However, the callouts do not appear in the Library Browser.

If you want the annotation to appear in the Library Browser, after you add it to your library, right-click it and select **Show in Library Browser**. If you want a description to appear in a tooltip when the user hovers over the annotation in the Library Browser, add the description to the annotation programmatically. At the MATLAB command prompt, enter:

```
set_param(annotationHandle,'Description','descriptionText')
```

To get the annotation handle, use `find_system`. This example gets all the annotations in the library `mylib`:

```
ann = find_system('mylib','FindAll','on','Type','annotation');
```

To get a specific annotation, turn on regular expression search and specify part of the annotation text with the `'Name'` argument:

```
ann = find_system('mylib2','FindAll','on','RegExp',...
'on','Type','annotation','Name','matchingText');
```

“Add Libraries to the Library Browser” on page 41-11 includes instructions for adding an annotation that appears in the Library Browser.

## Lock and Unlock Libraries

When you close a library, it becomes locked for editing. When you next open it, unlock it if you want to make changes to it. Click the lock badge in the lower-left corner of the library to unlock it. Additionally, if you try to modify a locked library, a message prompts you to unlock it.

You can unlock a library programmatically. At the MATLAB command prompt, enter:

```
set_param('library_name','Lock','off');
```

To lock the library programmatically, enter:

```
set_param('library_name','Lock','on');
```

## Prevent Disabling of Library Links

By default, a user of the blocks in your library can disable the link to library blocks. If you want to control editing of linked blocks and prevent the block user from disabling links,

you can lock links to your library. Locking library links prevents the user from making any changes to the block instances.

- In your library, select **Diagram > Lock Links To Library**.

To understand how the block user interacts with blocks from locked libraries, see “Lock Links to Blocks in a Library” on page 41-29.

- “Customize Library Browser Appearance” on page 70-24

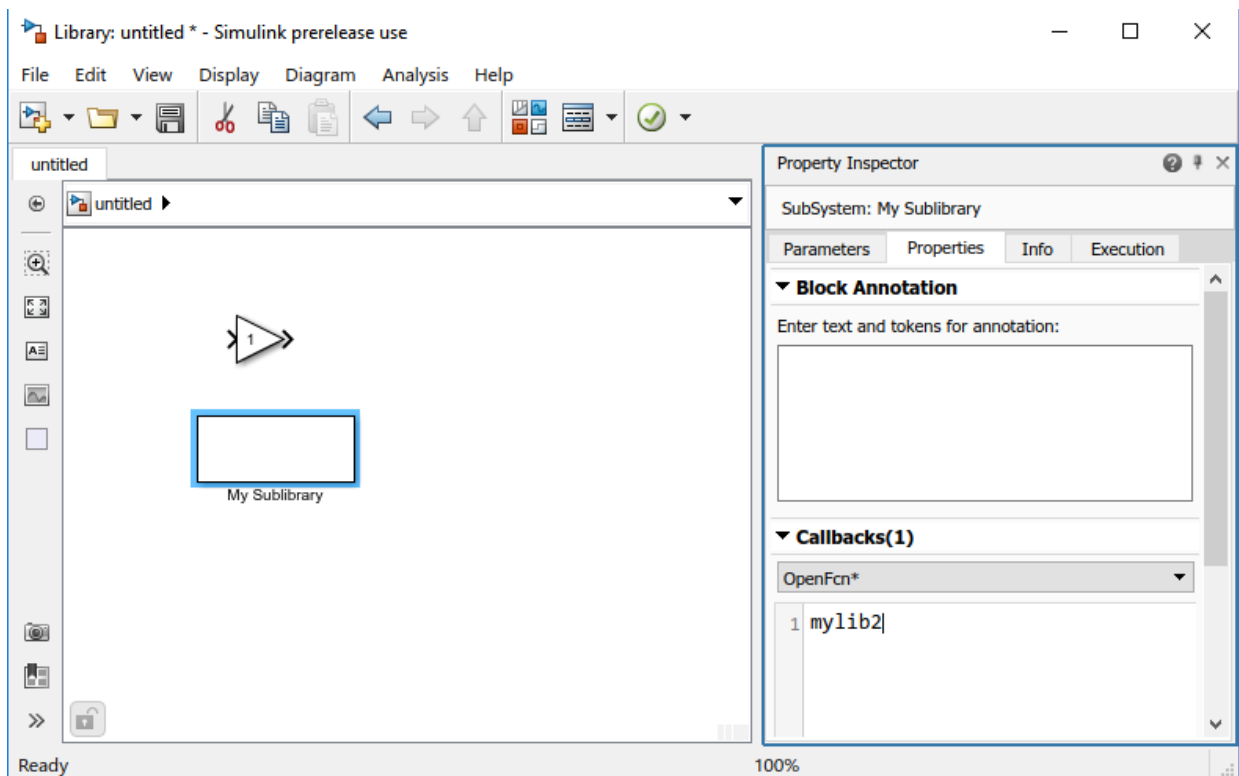

## Add Libraries to the Library Browser

This example shows how to create a block library and add it to the Simulink Library Browser. This example also shows how to add a sublibrary.

You create a function `sliblocks` to specify information about your library. You can save the function as a `.m` or `.mlx` file. You cannot save it as a P-code file.

- 1 From the Simulink start page, select **Blank Library** and click **Create Library**.
- 2 Add a Gain block and a Subsystem block to the library. Remove the inport and output from the subsystem.
- 3 Name the Subsystem block My Sublibrary. To link it to a sublibrary, in the My Sublibrary properties, set the `OpenFcn` callback to `mylib2`.

- 4 At the MATLAB command prompt, enter this command to enable the model property `EnableLBRepository`. Your library can appear in the browser only if this property is on when you save your library.

```
set_param(gcs, 'EnableLBRepository', 'on');
```

- 5 Save the library in a folder on the MATLAB path. For this example, name the library `mylib`.
- 6 Create another library `mylib2` and add some blocks to it.
- 7 At the MATLAB command prompt, enable the model property `EnableLBRepository` for the new library.

```
set_param(gcs, 'EnableLBRepository', 'on');
```

- 8 Save `mylib2` to the same folder you saved `mylib` to.

You can close both libraries if you want.

- 9 In MATLAB, right-click the folder you saved the library to and select **New File > Script**. Name the file `slblocks.m`.
- 10 Open `slblocks.m`. Add this function to it and save.

```
function blkStruct = slblocks
 % This function specifies that the library should appear
 % in the Library Browser
 % and be cached in the browser repository

 Browser.Library = 'mylib';
 % 'mylib' is the name of the library

 Browser.Name = 'My Library';
 % 'My Library' is the library name that appears
 % in the Library Browser

 blkStruct.Browser = Browser;
```

- 11 In the Library Browser, refresh to see the new library and sublibrary. Right-click the library list and select **Refresh Library Browser**.

The figure shows the example library `mylib` with the Library Browser name **My Library**.

Because of the callback you created, clicking My Sublibrary displays the contents of the mylib2 library.

**Note** If you saved your library without setting 'EnableLBRepository' to 'on', a message appears at the top of the Library Browser.

Click **Fix** and respond to the prompt as appropriate.

## Specify Library Order in the Library List

You can specify the order of your library relative to the other libraries in the list by adding a `sl_customization.m` file to the MATLAB path and setting the sort priority of your library. For example, to see your library at the top of the list, you can set the sort priority to `-2`. By default, the sort priority of the Simulink library is `-1`. The other libraries have a sort priority of `0` by default, and these libraries appear below the Simulink library. Libraries with the same sort priority appear in alphabetical order.

This sample content of the `sl_customization.m` file places the new library at the top of the list of libraries.

```
function sl_customization(cm)
% Change the order of libraries in the Simulink Library Browser.
cm.LibraryBrowserCustomizer.applyOrder({'My Library',-2});
end
```

To make the customization take effect immediately, at the command prompt, enter:

```
sl_refresh_customizations
```

## Linked Blocks

### In this section...

“Rules for Linked Blocks” on page 41-16

“Linked Block Terminology” on page 41-16

When you add a masked library block or a Subsystem block from a Library to a Simulink model, a referenced instance of the library block is created. Such referenced instance of a library block is called a linked block and contains link or path to the parent library block. The link or path allows the linked block to update when the library block is updated.

To optimize the performance, the child blocks (and the parameters) of a linked block are not saved with the Simulink model. When such a model is loaded and viewed, the child blocks are referenced from the parent library. If you change the parameter value of a child block of such a linked block, the changed information is saved as linked data in the model.

To locate the parent library block of a linked block, right-click the block and select **Library Link > Go To Library Link** (Ctrl + L). This option is available only for the blocks that are linked and not for the Simulink built-in blocks. To prevent unintentional disabling of library links, use the locked links option on the library. For more information, see “Lock Links to Blocks in a Library” on page 41-29.

**Note** The tooltip for a linked block shows the name of the referenced masked library block.

When you edit a library block (either in Simulink Editor or at the command line), Simulink updates the changes in the linked blocks. The outdated links are updated when you:

- Simulate or update the model.
- Use the `find_system` command.
- **Diagram > Refresh Blocks (or press Ctrl+K)**
- Load the model or library (only the visible links are updated).
- Use `get_param` to query the link status of the block (see “Control Linked Block Programmatically” on page 41-37).

You can use the `LinkStatus` parameter or the `StaticLinkStatus` parameter to query the link status.

- `LinkStatus`: First updates the linked block and then returns the link status.
- `StaticLinkStatus`: Returns the link status without updating the linked block.

Selective usage of `StaticLinkStatus` over `LinkStatus` can result in better Simulink performance. For more information on `StaticLinkStatus` and `LinkStatus`, see “Control Linked Block Programmatically” on page 41-37.

## Rules for Linked Blocks

- You can change the values of a linked block parameter (including the existing mask) in the mask dialog box.
- To allow the library block initialization code to change the values of a linked block parameter, select the **Allow library block to modify its contents** check box in the **Initialization** pane of the library block.
- It is not recommended to set callback parameters for a linked block.
- If the reference library block of a linked block is a subsystem, you can make nonstructural changes such as changing the parameter value of the linked subsystem. To make structural changes to a linked block, disable the link of the linked block from its library block (See “Disable or Break Links to Library Blocks” on page 41-27).

## Linked Block Terminology

| Terminology          | Definition                                                 |
|----------------------|------------------------------------------------------------|
| Parent library block | Library block from which the linked blocks are referenced. |

| Terminology           | Definition                                                                                                                                                                                             |
|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Linked block          | Reference instance of a library block that contains links or path to its parent library block.                                                                                                         |
| Locked links          | Prevents unintentional modification of a linked block. For more information, see “Lock Links to Blocks in a Library” on page 41-29.                                                                    |
| Disabled links        | Library links that are temporarily disconnected from their parent library block. For more information, see “Disable or Break Links to Library Blocks” on page 41-27.                                   |
| Restore links         | Restores the disabled link of a linked block to their parent library block. For more information, see “Restore Disabled or Parameterized Links” on page 41-31.                                         |
| Break links           | Permanently breaks the link of a linked block from its parent library block. For more information, see “Disable or Break Links to Library Blocks” on page 41-27.                                       |
| Self-modifiable links | Linked block with the ability to have structural changes in a linked Subsystem block. For more information, see “Self-Modifiable Linked Subsystems” on page 41-24.                                     |
| Parameterized links   | Created when the parameter values of a linked block are modified using the MATLAB command prompt. For more information, see “Parameterized Links and Self-Modifiable Linked Subsystems” on page 41-19. |
| Forwarding Tables     | Maps the old library block path to new library block path. For more information, see “Forwarding Tables” on page 41-41.                                                                                |

| <b>Terminology</b>      | <b>Definition</b>                                                                                                                                                                                                            |
|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Transformation function | Corrects the mismatch of parameters in the <code>InstanceData</code> of the new and old library links to ensure that the library links continue to work. For more information, see “Transformation Functions” on page 41-45. |

## Parameterized Links and Self-Modifiable Linked Subsystems

You can use the MATLAB command prompt to change the value of a parameter in a linked block. Such parameter changes on the linked block result in parameterized links.

Similarly, you can also modify the structure of a linked Subsystem block without changing the parent library block. Such changes can be applied using the mask initialization code and as called self-modifiable linked subsystem.

### Parameterized Links

A parameterized link is created when you change the parameter values of the child blocks of a masked subsystem linked block.

A parameterized link allows you to have a different parameter value for the linked block and the parent library block. For such library blocks, the link to the parent block is still retained.

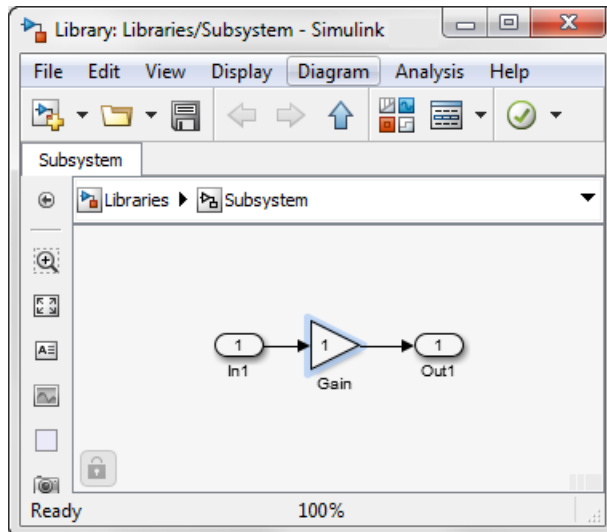

---

**Note** Changing the mask value of a parent library block does not create a parameterized link.

---

For example, you can use the `set_param` command to set a parameter value in the child blocks of a linked subsystem block. The `set_param` command overrides the parameter values of the child blocks of the subsystem linked block. Thus, differentiating the child block value from its parent library block and creating a parameterized link.

Consider a Subsystem library block (see “Subsystem Library Block” on page 41-20) that contains a Gain block within with its parameter value as 1.

### Subsystem Library Block

Use this Subsystem block as a linked block in a model.

You can modify the parameter values of the child blocks of the linked block without changing the value of the parent library block. For example, you can change the parameter value of the Gain block within the Subsystem linked block.

To change the Gain parameter value of the Gain block within the Subsystem linked block to 100, sequentially type these commands at MATLAB command prompt:

```
pathName = [modelName, '/Gain_Subsystem1/Gain'];
set_param(pathName, 'Gain', '100')
```

A parameterized link is now created, overriding the parameter value (see, “Parameterized Linked Block” on page 41-22). Similarly, change the Gain parameter value of the Subsystem1 linked block.

### Parameterized Linked Block

When you save a model containing a parameterized link, Simulink saves the changes to a local copy of the Subsystem with the path to the parent library. When you reopen the model, Simulink copies the library block into the loaded model and applies the saved changes.

**Note** To view the parameterized changes on a block, right-click the block, and on the context menu, select **View Changes**. The **Link changes** dialog box opens displaying the list of modified blocks. You can also use this dialog box to remove parameterized changes from a block.

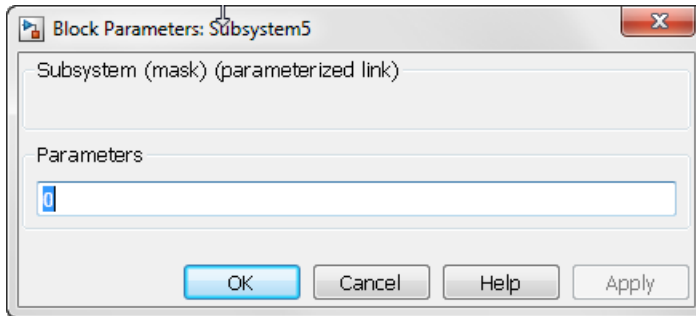

## Identifying Parameterized Links

A parameterized link displays these identifications:

- The link badge of a parameterized link contains a black link with a red star icon, .
- The tooltip of a parameterized linked block displays **Modified parameter in link**.

- Block dialog box of a linked Subsystem block contains **parametrized link**.

### Self-Modifiable Linked Subsystems

---

**Tip** We recommend using variant blocks over self-modifiable linked subsystems.

---

A self-modifiable linked subsystem is a linked block with the ability to have structural changes in the subsystem without disabling the link. A self-modifiable linked subsystem is created when you use a library block containing a self-modifiable mask as a linked block. You can use the mask initialization code to change the structural contents.

For more information, see “Dynamic Masked Subsystem” on page 39-53 and Self-Modifiable Mask.

## Display Library Links

Each linked block has a link badge associated with it. The badge makes it easier to identify the linked block in a model and also displays its link status.

To control the display of library link badges in a Simulink model, click **Display > Library Links** and use these options:

- **None** — displays no links.
- **Disabled** — displays only disabled links (the default for new models).
- **User Defined** — displays only links to user libraries.
- **All** — displays all links.

If activated, link badges are displayed at the bottom left corner of a linked block. You can right-click the link badge to access link menu options.

The color and icon of the link badge indicates the status of the link.

| Link Badge                                                                                                  | Status        |
|-------------------------------------------------------------------------------------------------------------|---------------|
| Black links<br>          | Active link   |
| Gray separated links<br> | Inactive link |

| Link Badge                                                                                                            | Status                                   |
|-----------------------------------------------------------------------------------------------------------------------|------------------------------------------|
| Black links with a red star icon<br> | Active and modified (parameterized link) |
| White links, black background<br>    | Locked link                              |

## Disable or Break Links to Library Blocks

Structural changes in a model include addition or deletion of blocks or adding ports while non-structural changes include changes in parameter value.

A linked block does not allow structural changes to it. You can disable the link of a linked block from its parent library block and perform required modifications. A disabled linked block behaves like a local instance of a block and allows you to make structural and nonstructural changes.

To disable a link, right-click the linked block and, on the context menu, click **Library Link > Disable Link**. Alternatively, select the linked block and click **Diagram > Library Link > Disable Link**.

To prevent unintentional disabling of a linked block, you can lock its links to the library. To lock a link, on the library window, click **Diagram > Lock Links To Library**. You can later choose to unlock the locked link by selecting **Diagram > Unlock Links To Library** on the library window.

---

**Note** Simulink offers to disable the library links (unless the link is locked) when you try to make structural changes to a block that contains active library links.

Do not use `set_param` to make structural changes to an active link. The result of this type of change is undefined.

---

A disabled link of a linked block can be restored. For more information, see “Restore Disabled or Parameterized Links” on page 41-31.

### Break Links

You can permanently break links to the parent library. Before you break a library link, the link must first be disabled. When you break a link, the linked block is converted to a standalone block.

To break a link, use any of these options:

- For disabled links, right-click the linked block and, in the context menu, select **Library Link > Break Link**.

- To copy and break links to multiple blocks simultaneously, select multiple blocks and then drag. The locked links are ignored and not broken.
- When you save the model, you can break links by supplying arguments to the `save_system` command. For more information, see `save_system`.

---

### Note

- Some models can contain blocks from third-party libraries or optional Simulink block sets. Breaking the link for such models does not guarantee that you can run the model standalone. It is possible that a library block invokes functions supplied with the library and hence can run only if the library is installed on the system running the model.
  - Breaking a link can cause a model to fail when you install a new version of the library on a system. For example, if a model block invokes a function that is supplied from a library. If you break the link for such a block, the function can no longer be invoked from the model, causing simulation to fail. To avoid such problems, avoid breaking links to libraries.
-

## Lock Links to Blocks in a Library

You can lock links to a library. Lockable library links prevent unintentional disabling of these links. Lockable libraries ensure robust usage of mature stable libraries.

To lock links to a library, in the library window, click **Diagram > Lock Links To Library**. The linked block's links to its parent library is now locked. When you refresh the model, you see a change in the link badge. The locked link badges have a black background.

Locked linked block links cannot be disabled from the parent library block. Such links can only be disabled from the command line by changing the `LinkStatus` to `inactive`. For more information, see “Control Linked Block Programmatically” on page 41-37.

The context menu of a locked linked block displays **Locked Library Link** and not **Library Link**. Also notice that the only enabled option on this menu is **Go To Library Block**.

If you open a locked linked block, the window title displays **Locked Link: *b*lockname**. The bottom left corner shows a lock icon and a link badge. You can also hover over the link badge to view lock information.

To unlock links from the library window, select **Diagram > Unlock Links To Library**. If the library is locked, the **Unlock Links To Library** option is disabled. You must unlock the library to enable the option.

### Rules for Locked Links

- Locked links cannot be edited. If you try to make a structural change to a locked link (such as editing the diagram), you see a message that you cannot modify the link because it is either locked or inside another locked link.
- The mask and block parameter dialogs are disabled for blocks inside locked links. For a resolved linked block with a mask, its parameter dialog is always disabled.
- You cannot parameterize locked links in the Model Editor.
- When you copy a block, the library status determines the status of a link (locked or not). If you copy a block from a library with locked links, the link is locked. If you later unlock the library links, any existing linked blocks do not change to unlocked links until you refresh the links.
- If you use sublibraries, when you lock links to a library, lock links to the sublibraries.

“Linked Blocks” on page 41-15 | “Restore Disabled or Parameterized Links” on page 41-31

## Restore Disabled or Parameterized Links

You can restore disabled library links and resolve any differences between the linked block and its parent library block.

- 1 In the Model Editor window, right-click a disabled linked block, and on the context menu, select **Library Link > Resolve Link**.

The Links Tool window opens.

- 2 To view disabled links and the parameterized links, select **Show all disabled links** in the **Options** section.
- 3 To restore the links for an individual block or the whole hierarchy, select **Individual** or **Hierarchy** in the **Push/Restore Mode** section. For more information, see “Pushing or Restoring Link Hierarchies” on page 41-33.

4 The **Edited links** table has these columns:

- **Linked block** — Displays the list of linked blocks that have disabled or parameterized links. Select a block to restore its links.
- **Action** — Allows you to either push the linked block changes to the library or restore the linked block from the library.

| Action Choice      | Links Tool Action                                                                                                                                                                       |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Push               | Replaces the version of the block in the library with the version in the model (linked block).                                                                                          |
| Restore            | Replaces the version of the linked block in the model with the version in the library.                                                                                                  |
| Push Individual    | In the <b>Individual</b> mode, the disabled or edited block is pushed to the library, preserving the changes inside it without acting on the hierarchy. All other links are unaffected. |
| Restore Individual | In the <b>Individual</b> mode, the disabled or edited block is restored from the library, and all other links are unaffected.                                                           |

To select the same action for all linked blocks, click **Push all**, **Restore all**, or **Clear all**.

- **Library** — Displays the library name and version number.
- 5 Click **OK** or **Apply** to complete the push or restore action. The version in the library and the linked block now match.

---

**Note** Changes that you push to the library are not saved until you actively save the library.

---

If a linked block name has a cautionary icon , the model has other instances of this block linked from the same library block, and they have different changes. Choose one of the instances to push changes to the library block and restore links to the other blocks, or choose to restore all them with the library version.

---

## Pushing or Restoring Link Hierarchies

---

**Caution** If you are using Push or Restore in the Hierarchy mode and you have a large hierarchy of edited and disabled links, ensure that you want to push or restore the whole hierarchy of links.

---

Pushing a hierarchy of disabled links affects the disabled links inside and outside the hierarchy for a given link. If you push changes from a disabled link in the middle of a hierarchy, the inside links are pushed and the outside links are restored if unchanged. This operation does not affect outer (parent) links with changes unless you also explicitly selected them for push. The Links Tool starts to push from the lowest inside links and then moves up in the hierarchy.

For examples:

- 1 Link A contains link B and both have changes.
  - Push A. The Links Tool pushes both A and B.
  - Push B. The Links Tool pushes B and not A.
- 2 Link A contains link B. A has no changes, and B has changes.
  - Push B. The Links Tool pushes B and restores A. When parent links are unmodified, they are restored.

If you have a hierarchy of parameterized links, the Links Tool can manipulate only the top level.

---

**Tip** To compare files and view structural changes, use **Analysis > Compare Simulink XML Files**.

---

## Fix Unresolved Library Links

If Simulink is unable to find either the library block or the source library on your MATLAB path during linked block update, the link becomes unresolved. Simulink changes the appearance of these blocks.

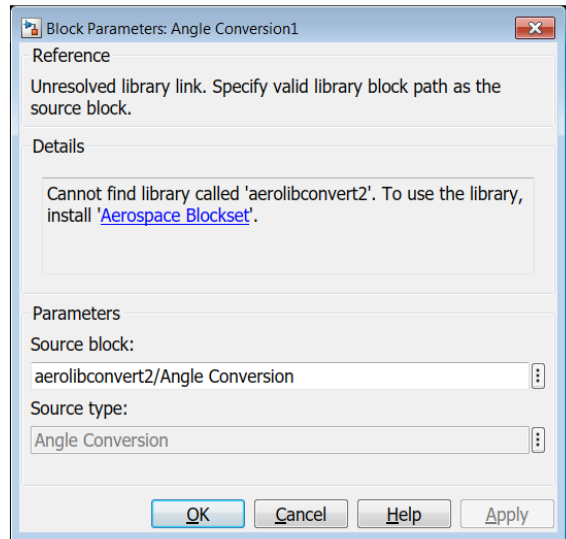

Simulink tries to help you find and install missing products that a model needs to run. If you open a model that contains built-in blocks or library links from missing products, you see labels and links to help you fix the problem.

- Blocks are labeled with missing products (for example, **SimEvents not installed**)
- Tooltips include the name of the missing product
- Messages provide links to open Add-On Explorer and install the missing products

For unresolved library links, double-click the block to view details. Click the link to open Add-On Explorer and install the product.

To fix an unresolved link, you can:

- Double-click the unresolved block to open its dialog box (see the Unresolved Link block reference page). If a product is missing, click the link to open Add-On Explorer

and install the product. Alternatively, correct the path name in the **Source block** field and click **OK**.

- Delete the unresolved block and copy the library block back into your model.
- Add the folder that contains the required library to the MATLAB path and select either **Simulation > Update Diagram** or **Diagram > Refresh Blocks**.

## Control Linked Block Programmatically

### Linked Block Information

Use the `libinfo` command to get information about the linked blocks in the model. `libinfo` also provides information about the parent library blocks of a linked block.

For example, here is a model with linked blocks:

Masking variant blocks

When you execute the `libinfo(gcb)` command on this block:

```
Block: 'slexMaskVariantExample/VariantSubsystem2' %Linked block
 Library: 'slexMaskingVariants_libraryblock' %Parent library block
 ReferenceBlock: 'slexMaskingVariants_libraryblock/VariantSubsystem2'
 LinkStatus: 'resolved' %Link status
```

The `ReferenceBlock` property gives the path of the library block to which a block links. You can change this path programmatically by using the `set_param` command. For example:

```
set_param('slexMaskVariantExample/VariantSubsystem2', 'ReferenceBlock', 'slexMaskVariantExample2/VariantSubsystem')
```

Here, `slexMaskVariantExample/VariantSubsystem2` is the original library block path and `slexMaskVariantExample2/VariantSubsystem` is the new library block path.

---

**Note** It is not recommended to change the properties of a referenced block by using the `set_param` command in the mask initialization code or callback code of the same block. For such modeling patterns, you can use Variant blocks (Masking variant blocks) or use the `referenceblock` command on the callback code or the mask initialization code of the parent block of the reference block.

---

### Lock Linked Blocks

Use the `LockLinksToLibrary` command to lock or unlock a linked block in a library from the command line. When you set the value of `LockLinksToLibrary` to `on`, the linked block links to the library are locked.

```
set_param('MyLibraryName', 'LockLinksToLibrary', 'on') %Lock links
set_param('MyLibraryName', 'LockLinksToLibrary', 'off') %Unlock links
```

## Link Status

All blocks have a `LinkStatus` parameter and a `StaticLinkStatus` parameter to indicate whether the block is a linked block.

Use `get_param(gcb, 'StaticLinkStatus')` to query the link status without updating the linked blocks. You can use `StaticLinkStatus` to query the status of a linked block that is either active or outdated.

Use `get_param` to send a query to get the value of the `LinkStatus`.

| Get LinkStatus Value | Description                                                                                                                                                                                                                                                                       |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| none                 | Block is not a linked block.                                                                                                                                                                                                                                                      |
| resolved             | Resolved link.                                                                                                                                                                                                                                                                    |
| unresolved           | Unresolved link.                                                                                                                                                                                                                                                                  |
| implicit             | Block resides in library block and is itself not a link to a library block. Suppose that A is a link to a subsystem in a library that contains the Gain block. If you open A and select the Gain block, <code>get_param(gcb, 'LinkStatus')</code> returns <code>implicit</code> . |
| inactive             | Disabled link.                                                                                                                                                                                                                                                                    |

Use `set_param` to set the `LinkStatus`.

| Set LinkStatus Value  | Description                                                                                                                                                   |
|-----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|
| none                  | Breaks link. Use <code>none</code> to break a link, for example, <code>set_param(gcb, 'LinkStatus', 'none')</code> .                                          |
| breakWithoutHierarchy | Breaks links in place without breaking the nested parent hierarchy of link. For example, <code>set_param(gcb, 'LinkStatus', 'breakWithoutHierarchy')</code> . |
| inactive              | Disables link. Use <code>inactive</code> to disable a link, for example, <code>set_param(gcb, 'LinkStatus', 'inactive')</code> .                              |

| Set LinkStatus Value | Description                                                                                                                                                                                                                                                                                                                                                                                                                      |
|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| restore              | Restores an inactive or disabled link to a library block and discards any changes made to the local copy of the library block. For example, <code>set_param(gcb, 'LinkStatus', 'restore')</code> replaces the selected block with a link to a library block of the same type. It discards any changes in the local copy of the library block.<br><br>restore is equivalent to <code>Restore Individual</code> in the Links Tool. |
| propagate            | Pushes any changes made to the disabled link to the library block and re-establishes its link. <code>propagate</code> is equivalent to <code>Push Individual</code> in the Links Tool.                                                                                                                                                                                                                                           |
| restoreHierarchy     | Restores all disabled links in the hierarchy with their corresponding library blocks. <code>restoreHierarchy</code> is equivalent to <code>Restore</code> in hierarchy mode in the Links Tool.                                                                                                                                                                                                                                   |
| propagateHierarchy   | Pushes all links with changes in the hierarchy to their libraries. <code>propagateHierarchy</code> is equivalent to <code>Push</code> in the <b>Hierarchy</b> mode of the Links Tool. See “Restore Disabled or Parameterized Links” on page 41-31.                                                                                                                                                                               |

---

### Note

- When you use `get_param` to query the link status of a block, the outdated block links also resolve.
  - Using the `StaticLinkStatus` command to query the link status when `get_param` is being used in the callback code of a child block is recommended. `StaticLinkStatus` command does not resolve any outdated links.
- 

If you call `get_param` on a block inside a library link, Simulink resolves the link wherever necessary. Executing `get_param` can involve loading part of the library and executing callbacks.

## Forwarding Tables

If you edit an existing library block, you would want to ensure that the changes do not break the model when the model is saved with an older version of the library block. The type of edits in the library block can include, library path change, library block name change, or addition, removal, or renaming of parameters.

The Forwarding Table helps you to maintain compatibility of library blocks and ensures that the models continue to work. You can use the Forwarding Table to create a map between the old and the new library blocks without any loss of data or functionality. After specifying the mapping of old library blocks to new library blocks in the forwarding table, links to the old library blocks update automatically during model load. For example, if you rename or move a block in a library, you can use a forwarding table to update the models that have links to the old library block.

### Create Forwarding Table

---

**Note** Models that have broken or disabled links cannot be updated using the forwarding tables.

---

- 1 Open a locked library model.
- 2 Click **Diagram > Unlock Library**. The library is now unlocked for editing.
- 3 Click **File > Library Properties > Library Properties**. The **Library Properties** dialog box opens.
- 4 Click the **Forwarding Table** tab.
- 5 Click  (Add New Entry) button. A new row is added in the Forwarding Table.

- 6 Specify values in the **Old Block Path** and **New Block Path** columns. To get the path of a block, select the block in the model and click .
- 7 In the **Version** column, you can choose to specify a version number for the library block.

If the old block name and the new block name are the same, the forwarding table populates the version number automatically. The initial value of the library version (`LibraryVersion`) is derived from the model version (`ModelVersion`) of the library at the time the library link is created. Any subsequent updated to the library block would update the library version to match the model version of the library.

**Note**

- Version number must be a numeric value.
- When the old and the new block paths are the same, the version number must be of the format <major\_version>.<minor\_version>. For example, while renaming a library block.
- The version number cannot have more than one dot notation. For example, a version number of 1.3 is acceptable whereas, version number 1.3.1 is not acceptable.
- When you use forwarding table to move a library block from one library to another, the version number format is not critical.

- 
- 8** In the **Transformation Function** column, you can specify a MATLAB file that corrects the mismatch of parameter data between the old and the new link. Transforming old link parameter data for the new library block enables you to load old links and preserve parameter data. For more information, see “Transformation Functions” on page 41-45.

If no transformation function is specified, the Transformation Function column displays **No Transformation** when you save the library.

- 9** To apply the changes and close the dialog box, click **OK**. The mapping of old path to new path is created in the Forwarding Table. The links to the old library blocks are updated automatically when you open a model containing links to the library.

An example of user-defined forwarding table is as shown:

When you specify identical library block name and path for the older and the newer blocks, the Forwarding Table populates the version number automatically. For the first entry with identical names and path, the version number of the old block starts with 0, and the new version of the block is set as the model version of the library. You can view the model version of the library under the **History** tab of the Forwarding Table.

A transformation function must be specified when the instance-specific parameters (InstanceData) have changed in the old and the new library block.

In this example,

- Block path for Block A changes from LibA to LibB.
- Block name for Block X changes to Block Y while the library path remains the same.
- Block name for Block M changed to Block N. A transformation function is specified to take care of the instance-specific changes.
- Block version and instance-specific parameter changed for Block L.

### Create Forwarding Table Programmatically

At the command line, you can create a simple forwarding table specifying the old locations and new locations of blocks that have moved within the library or to another library. You associate a forwarding table with a library by setting its `ForwardingTable` parameter to a cell array of two-element cell arrays, each of which specifies the old and new path of a block that has moved. For example, the syntax to create a forwarding table and assign it to a library named `Lib1` is:

```
set_param('Lib1', 'ForwardingTable', {'Lib1/A', 'Lib2/A'}
{'Lib1/B', 'Lib1/C'});
```

where:

- `Lib1` is the library associated to the forwarding table.
- Block A is transferred from `Lib1` to `Lib2`.
- Block B is renamed to C in the same library.

### Transformation Functions

A linked block instance is associated with instance-specific parameters called `InstanceData`. When you create versions of a library block, parameter sets can get added or removed from the `InstanceData`.

A transformation function corrects the mismatch of parameters in the `InstanceData` of the new and old library links thus ensuring that the library links continue to work.

You can define a transformation function using a MATLAB file on the path, then specify the function in the **Transformation Function** column of the **Forwarding Table**.

The new block path defined in the forwarding table overrides the values defined in the transformation function. If the new block path is a dynamic value that changes based on certain conditions, then the new block path must be only defined using the transformation function.

The syntax for transformation function must be:

```
function outData = TransformationFcn(inData)
```

where:

- `inData` is a structure with fields `ForwardingTableEntry` and `InstanceData`, and `ForwardingTableEntry` is also a structure.
- `outData` is a structure with fields `NewInstanceData` and `NewBlockPath`.

A general transformation function can have many local functions defined in it. The function calls the appropriate local functions based on old block names and versions. You can use this to combine multiple local functions into a single transformation function, to avoid having many transformation functions on the MATLAB path.

Consider the Compare to Constant block in Simulink Library. You must create versions of this block without changing the name and the block path but add the parameters to the newer library block.

The table displays the parameter difference in two versions of the Compare to Constant block.

| Old Version | New Version    |
|-------------|----------------|
| Block {     | Block {        |
| BlockType   | BlockType      |
| Name        | Name           |
| Ports       | Ports          |
| Position    | Position       |
| SourceBlock | SourceBlock    |
| SourceType  | SourceType     |
| relop       | relop          |
| const       | const          |
| }           | }              |
|             | LibraryVersion |
|             | SourceBlock    |
|             | SourceType     |
|             | relop          |
|             | const          |
|             | OutDataTypeStr |
|             | ZeroCross      |
|             | }              |

The new version of the Compare to Constant block has additional parameters (`OutDataTypeStr` and `ZeroCross`) associated with it. For such cases, the

transformation function must ensure that the additional parameters in the InstanceData are set so that the old library links work.

This example shows a transformation function for the Compare to Constant block to add the OutDataTypeStr parameter with a value of uint8.

```
function [outData] = TransformationCompConstBlk(inData)
outData.NewBlockPath = ''; % No change in the library block path
outData.NewInstanceData = [];
instanceData = inData.InstanceData;
% Get the field type 'Name' from instanceData
[ParameterNames{1:length(instanceData)}] = instanceData.Name;

if (~ismember('OutDataTypeStr',ParameterNames))
 % OutDataTypeStr parameter is not present in old link. Add it and set value uint8
 instanceData(end+1).Name = 'OutDataTypeStr';
 instanceData(end).Value = 'uint8';
end

outData.NewInstanceData = instanceData;
```

## Create Mask Parameter Aliases

If you rename a mask parameter, you must ensure that the existing MATLAB scripts that use the old parameter names, continues to work. To ensure the compatibility, you can create alias (alternate names) for a mask parameter name. Alias allows you to change the name of a mask parameter in a library block without having to recreate links to the block in existing models.

Consider a masked block that contains an **Edit** parameter. The mask parameter name for this **Edit** parameter is p1.

```
MaskObj=
% MaskParameter with properties:
```

```
 Type: 'edit'
TypeOptions: {0x1 cell}
 Name: 'p1'
 Prompt: 'p1'
 Value: '0'
 Evaluate: 'on'
 Tunable: 'on'
 NeverSave: 'off'
 Hidden: 'off'
 Enabled: 'on'
 Visible: 'on'
 ToolTip: 'on'
```

```
Callback: ''
Alias: ''
```

Notice that the **Edit** mask parameter does not have any alias name. To add an alias name for the mask parameter, you can set a value for the **Alias** mask parameter property.

```
MaskObj.Alias = 'pa'
```

You can either use the mask parameter name or the alias to do a function call on the mask parameter. For example, in this case you can either use `set_param(gcb, 'p1, '10)` (mask parameter name) `set_param(gcb, 'pa, '10)` (mask parameter alias) to set a value for the **Edit** mask parameter.

# **Integrate C Code in Simulink Models**

## Integrate C Code Using C Caller Blocks

### In this section...

- “Specify Source Code and Dependencies” on page 42-2
- “Call C Caller Block and Specify Ports” on page 42-4
- “Map C Function Arguments to Simulink Ports” on page 42-5
- “Create a Custom C Caller Library” on page 42-10
- “Limitations” on page 42-10

You can integrate new or existing C code into Simulink using the C Caller block. To create custom blocks in your Simulink models, the C Caller block allows you to call external C functions specified in external source code and libraries. The advantages of the C Caller block are:

- Automated integration of simple C functions
- Integration with Simulink Coverage, Simulink Test, and Simulink Design Verifier
- Integration with Simulink Coder

The C Caller block allows you to bring C algorithms into Simulink. To model dynamic systems, use the S-Function Builder instead. Next steps describe the workflow to integrate C code into Simulink using the C Caller block.

### Specify Source Code and Dependencies

Specify your external source code file that contains your C functions.

- 1 From Simulink toolstrip, open the **Configuration Parameters**.
- 2 In the left pane, select **Simulation Target**.
- 3 To enable code parsing by the C Caller block, ensure that the **Import custom code** box is selected.

The directories and file paths can be absolute and relative file paths to model directories or to the current working directory. See “Specify Relative Paths to Your Custom Code” (Stateflow).

- 4 Select **Header file** and enter the name of your header file with the `#include` tag.

Insert custom C code in generated:

|                     |                      |
|---------------------|----------------------|
| Source file         | Header file:         |
| Header file         | #include "my_func.h" |
| Initialize function |                      |
| Terminate function  |                      |

- 5 Under **Additional build information**, select **Include directories**, and enter the folders where additional build information, such as header files, are stored.

Additional build information:

|                     |                      |
|---------------------|----------------------|
| Include directories | Include directories: |
| Source files        | include              |
| Libraries           |                      |
| Defines             |                      |

- 6 Select **Source files** and enter the path and the name of the source file. If the model and the source files are in different directories, enter the directory that contains the source file before the file name.

Additional build information:

|                     |               |
|---------------------|---------------|
| Include directories | Source files: |
| Source files        | src/my_func.c |
| Libraries           |               |
| Defines             |               |

**Note** If a function is declared in the header file but not implemented in the source code, an empty stub function is automatically generated to simulate and compile the model.

## Define Default Function Array Layout

You can specify the order of how your matrix data is stored in Simulink. Matrix data passed to and from your C functions is converted to the default function array layout you specify. If the function array layout is not specified, the matrix data is passed through the C Caller in the same order of your Simulink data, and computational errors may occur due to row-column major disarrangement. Ensure that you follow the same default function array layout for all Simulink data.

- **Column-Major** — The C Caller block handles Simulink data in column-major order. Suppose that you have a 3-by-3 matrix. In the C Caller block, this matrix is stored in this sequence: first column, second column, and third column.
- **Row-Major** — The C Caller block handles Simulink data in row-major order. Suppose that you have a 3-by-3 matrix. In the C Caller block, this matrix is stored in this sequence: first row, second row, and third row.
- **Any** — Array data can be stored both in column-major and row-major order in the C Caller block. As a result, you can generate code both in column-major and row-major settings.
- **Not specified** — Array data can be stored in both column-major and row-major order. Compared to **Any** setting, you can only generate code in column-major setting.

To learn more about the row-major and column-major array layouts in Simulink, see “Default function array layout”.

- 1 Select an array layout option under **Default Array Function Layout**.
- 2 If you need to apply a specific array layout to some of the functions in your code, click **Specify by Function** to select these functions.
- 3 Click **Apply** to accept your changes.
- 4 Click **OK** to close the **Configuration Parameters**.

## Call C Caller Block and Specify Ports

You can start your custom C code integration into Simulink by typing C Caller in the Simulink canvas. Alternatively, drag a C Caller block from the **Library Browser > User-**

**Defined Functions.** Double-click the block to open the **Block Parameters** dialog box to see the names of your functions and port specifications.

- 1 Click on the **Refresh custom code**  to import your source code and its dependencies.
- 2 Your C functions are displayed under **Function Name**. If you can't see your full list of functions, click on the  to reimport your source code.
- 3 To view function declarations or input/output variables to your functions in the header file, click the **Go to function declaration**  to navigate the source files.
- 4 To change source files and their dependencies, or to define and select function array layouts, click the **Custom code settings**  to open the **Simulation Target** tab in Configuration Parameters.

## Map C Function Arguments to Simulink Ports

You can map C function arguments from your source code to Simulink ports using the **Port specification** in the C Caller block. In your source code, the header file includes the C function arguments to be connected to Simulink ports.

```
extern void mean_filter(const unsigned char* src,
 unsigned char* dst,
 unsigned int width, unsigned int height,
 unsigned int filterSize);
```

**Port specification** shows the details of your arguments and how they connect to your C Caller block in Simulink.

▼ Port specification:

| Arg name   | Scope     | Label       | Type   | Size      |
|------------|-----------|-------------|--------|-----------|
| src        | Input     | src         | uint8  | -1        |
| dst        | Output    | dst         | uint8  | size(src) |
| width      | Constant  | size(src,1) | uint32 | 1         |
| height     | Constant  | size(src,2) | uint32 | 1         |
| filterSize | Parameter | filterSize  | uint32 | 1         |

**Arg name** — Specifies the name of input and output arguments. **Arg name** is the function argument or parameter name as defined in your C functions from source code. This column is for reference purposes only.

**Scope** — Specifies how C function arguments map to the Simulink scope. Your arguments have default scopes depending on the function definition and you can change the scopes depending your function definition in the source code.

| Simulink Scope | Scope to Block Mapping      |
|----------------|-----------------------------|
| input          | Block input port            |
| output         | Block output port           |
| inputoutput    | Block input and output port |
| parameter      | Block tunable parameter     |
| constant       | Constant value              |

When you have a constant qualifier definition such as `const double *u`, the argument can only be an input or a parameter. When there is no constant qualifier, the argument is an output by default, and you can change it to an `input`, `inputoutput` or to a `parameter` scope. In this case, ensure that the C function does not modify the memory pointed by the pointer. If the argument is of an `output` type, every element pointed by this pointer should be reassigned in every call for this function.

| <b>C Argument</b>                                                                  | <b>Simulink Scope</b>                           |
|------------------------------------------------------------------------------------|-------------------------------------------------|
| Function return                                                                    | output                                          |
| double u                                                                           | input, parameter, constant                      |
| double u[]<br>double u[][2]<br>double u[2][3]                                      | output (default), input, parameter              |
| double *u                                                                          | output (default), inputoutput, input, parameter |
| const double *u<br>const double u[]<br>const double u[][2]<br>const double u[2][3] | input (default), parameter                      |

To map C function arguments to an inputoutput port, define the variable as a pointer in your function definitions.

```
extern void mean_filter(unsigned char* src,
 unsigned int width, unsigned int height,
 unsigned int filterSize);
```

Then, select the port specification to the inputoutput scope in the **Port Specification** table, and assign the resulting function output to the input variable in the custom function.

▼ Port specification:

| Arg name   | Scope       | Label       | Type   | Size |
|------------|-------------|-------------|--------|------|
| src        | InputOutput | src         | uint8  | -1   |
| width      | Constant    | size(src,2) | uint32 | 1    |
| height     | Constant    | size(src,1) | uint32 | 1    |
| filterSize | Parameter   | filterSize  | uint32 | 1    |

**Label** — Indicates the label for the corresponding argument in a Simulink block. By default, your argument label is the same as the argument name, unless you change it.

| Simulink Scope | Simulink Port Label                                                                                                         |
|----------------|-----------------------------------------------------------------------------------------------------------------------------|
| input, output  | Port name                                                                                                                   |
| inputoutput    | Port name in both input and output port                                                                                     |
| parameter      | Parameter name                                                                                                              |
| constant       | Expression for the constant value.<br><br>size expressions using input argument names, for example <code>size(in1,1)</code> |

**Type** — Demonstrates the match between the Simulink data type and the C function argument data type.

| C Argument Data Type | Simulink Data Type                       |
|----------------------|------------------------------------------|
| signed char          | int8                                     |
| unsigned char        | uint8                                    |
| char                 | int8 or uint8, depending on the compiler |
| int*                 | int32                                    |

| <b>C Argument Data Type</b>                                                                                                                                     | <b>Simulink Data Type</b>                                 |

| uint32_t*                                                                                                                                                       | uint32                                                    |
| typedef struct {...} AStruct**                                                                                                                                  | Bus: AStruct                                              |
| typedef enum {...} AnEnum**                                                                                                                                     | Enum: AnEnum                                              |
| * If the C Caller takes an integer type, for example, int16_t, you can modify it to a fixed-point type with matching base type, for example to fixdt(1, 16, 3). |                                                           |
| ** The C Caller sync button prompts you to import struct or enum types used by a C function as Simulink bus and enumeration types.                              |                                                           |

**Size** — Specifies the data dimensions in the argument.

| <b>C Argument Dimensions</b> | <b>Simulink Port Dimensions</b>                                                                                      |
|------------------------------|----------------------------------------------------------------------------------------------------------------------|
| double u                     | scalar (1)                                                                                                           |
| double u[]                   | inherited (-1) (default)                                                                                             |
| double u[][2]                | If the argument is for an output port, the size should be specified. The size of an output port cannot be inherited. |

| C Argument Dimensions | Simulink Port Dimensions                                                                                                                                           |
|-----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| double *u             | inherited (-1) (default)<br><br>If the argument is for an inputoutput port, the size cannot be inherited even though the size in the output port can be inherited. |
| double u[2][3]        | Size is [2, 3].                                                                                                                                                    |

## Create a Custom C Caller Library

You can create a library model to group your C Caller blocks and keep your models organized.

- 1 Open a new library model from **File > New > Library** and click **Blank Library**.
- 2 Open **Simulation Target** from **View > Library Custom Code Settings > Simulation Target**
- 3 Select C or C++ in the **Language** option, depending on your code, and ensure the **Import custom code** box is selected.
- 4 Follow the instructions in “Specify Source Code and Dependencies” on page 42-2 to add your source files and their dependencies.
- 5 Create C Caller blocks to call C functions.
- 6 To insert a block from your library model to a Simulink model, simply drag the block into your model.

## Limitations

- **Global Initialization of C States** — If your C functions read or write global or static variables, observe the order. For example, if multiple C functions are accessing the same set of global variables, the execution order of the blocks may lead to unexpected results.
- **Initialization/Termination of Custom Code Settings** — If you need to allocate and deallocate memory for your custom code, insert allocate and deallocate in the **Initialize function** and **Terminate function** fields of custom code settings.
- **Complex Data Support** — The C Caller block does not support complex data types in Simulink.

- **Continuous Sample Time** — The C Caller block does not support continuous sample time.
- **Variable Arguments** — Variable arguments in C are not supported, for example, `int sprintf(char *str, const char *format, ...)`.
- **C++ Syntax** — The C Caller block does not support native C++ syntax directly. You need to write a C function wrapper to interface with C++ code.

To test your models that includes C Caller blocks, see “Test Integrated C Code” (Simulink Test).

## Integrate MATLAB Algorithm in Model

Here is an example of a Simulink model that contains a MATLAB Function block:

The MATLAB Function block contains the following algorithm:

```
function [mean,stdev] = stats(vals)

% calculates a statistical mean and a standard
% deviation for the values in vals.

len = length(vals);
mean = avg(vals,len);
stdev = sqrt(sum(((vals-avg(vals,len)).^2))/len);
plot(vals,'-+');

function mean = avg(array,size)
mean = sum(array)/size;
```

You build this model in “Create Custom Functionality Using MATLAB Function Block” on page 43-9.

## Implementing MATLAB Functions Using Blocks

The MATLAB Function block is the easiest way to implement custom MATLAB functions into Simulink. To model the functionality that is not captured by the Simulink graphical language, or for algorithms that are easily represented in the MATLAB textual language, you can use MATLAB Function blocks. Use MATLAB Function blocks to generate readable, efficient, and compact C/C++ code for deployment to desktop and embedded applications.

In other words, MATLAB Function blocks enable you to define custom functionality using the MATLAB language. These blocks are a good starting point to create custom functionality if:

- You have an existing MATLAB function that models the custom functionality.
- You find it easier to model custom functionality using a MATLAB function than by using a Simulink block diagram.
- The custom functionality does not include continuous or discrete dynamic states. To model dynamic states, use S-functions.

### Decide When to Use MATLAB Function Blocks

MATLAB Function blocks provide the following capabilities:

- Allow you to build MATLAB functions into embeddable applications — MATLAB Function blocks support a subset of MATLAB toolbox functions that generate efficient C/C++ code. For more information, see “Functions and Objects Supported for C/C++ Code Generation — Alphabetical List” on page 48-2. With this support, you can use Simulink Coder to generate embeddable C code from MATLAB Function blocks that implement a variety of sophisticated mathematical applications. In this way, you can build executables that harness MATLAB functionality but run outside the MATLAB environment.
- Inherit properties from Simulink input and output signals — By default, both the size and type of input and output signals to a MATLAB Function block are inherited from Simulink signals. You can also choose to specify the size and type of inputs and outputs explicitly in the Ports and Data Manager (see “Ports and Data Manager” on page 43-40) or in the Model Explorer (see “Search and Edit Using Model Explorer” on page 12-2).

## Call Functions from MATLAB Function Blocks

To integrate MATLAB code into Simulink models, you can call any of these functions from a MATLAB Function block.

- Local functions — You can call local functions defined in the body of the MATLAB Function block.
- MATLAB toolbox functions that support code generation — You can call toolbox functions that support code generation from MATLAB Function blocks. When you build your model with Simulink Coder, these functions generate C code that is optimized to meet the memory and performance requirements of desktop and embedded environments. For a list of supported functions, see “Functions and Objects Supported for C/C++ Code Generation — Alphabetical List” on page 48-2.
- MATLAB functions that do not support code generation — You can also call *extrinsic* functions from MATLAB Function blocks. These are functions on the MATLAB path that the compiler dispatches to MATLAB for execution because the target language does not support them. They do not generate code but execute only in the MATLAB workspace during model simulation. The Simulink Coder software attempts to compile all MATLAB functions unless you explicitly declare them to be extrinsic by using `coder.extrinsic`. See “Declaring MATLAB Functions as Extrinsic Functions” on page 59-10.

The code generation software detects calls to many common visualization functions, such as `plot`, `disp`, and `figure`. For MEX code generation, it automatically calls out to MATLAB for these functions. For standalone code generation, it does not generate code for these visualization functions. Therefore, you do not have to declare these functions extrinsic using the `coder.extrinsic` function. See “Resolution of Function Calls for Code Generation” on page 59-2.

- Functions from **Simulink Function** blocks and Stateflow blocks — From MATLAB Function blocks, you can also call functions defined in a Simulink Function block. You can call Stateflow functions when you select the **Export Chart Level Functions (Make Global)** and **Allow exported functions to be called by Simulink** check boxes in the chart Properties dialog box. To learn more about how to call functions defined in Simulink Function and Stateflow blocks, see “Using Simulink Function Blocks and Exported Stateflow Functions” on page 10-152.

---

## Use Nondirect Feedthrough in a MATLAB Function Block

In Simulink blocks, *direct feedthrough* means that the output of a block is controlled directly by the value of an input port signal. In nondirect feedthrough, the value of the output signal does not depend on the value of the input signal in at least one function during the simulation.

By default, MATLAB Function blocks have direct feedthrough enabled. If you disable direct feedthrough, the Simulink semantics ensures that outputs rely only on current state. Using nondirect feedthrough enables you to use MATLAB Function blocks in a feedback loop and prevent algebraic loops.

To use nondirect feedthrough, in the Ports and Data Manager, in the **MATLAB Function Block Editor**, select **Edit Data** on the **Editor** tab and clear the **Allow direct feedthrough** check box. For more information, see “Ports and Data Manager” on page 43-40.

---

**Tip** Do not program outputs to rely on inputs or updated persistent variables. For example, do not use this code in a nondirect feedthrough block:

```
counter = counter + 1; % update state
output = counter; % compute output based on updated state
```

Instead, use this code:

```
output = counter; % compute output based on current state
counter = counter + 1; % update state
```

---

**Note** To use nondirect feedthrough, you need to enable the function inlining using `coder.inline`.

# Create Custom Functionality Using MATLAB Function Block

## In this section...

“Create Model” on page 43-9

“Program the MATLAB Function Block” on page 43-10

“Build the Function and Check for Errors” on page 43-11

“Define Inputs and Outputs” on page 43-13

“Define Local Variables for Code Generation” on page 43-14

“Generate Code for the MATLAB Function Block” on page 43-14

“Add Code to a MATLAB Function Block Programmatically” on page 43-14

This example shows how to create a model that uses the MATLAB Function block to calculate the mean and standard deviation for a vector of values.

## Create Model

- 1 Create a new Simulink model and insert a MATLAB Function block to the from the User-Defined Functions library.

- 2 Add a Constant block and set its value to vector [2 3 4 5]. Add two Display blocks to the model. Connect these blocks as shown in the diagram.

- 3 Save the model as `call_stats_block1`.

## Program the MATLAB Function Block

Program the block to calculate the mean and standard deviation for a vector of values:

- 1 Double-click the MATLAB Function block. A default function signature appears in the MATLAB Function Block Editor. Write any code inside the defined function signatures.
- 2 Edit the function header line:

```
function [mean,stdev] = stats(vals)
```

From this code, you define a function called `stats`, which calculates a statistical mean and standard deviation for the values in the vector `vals`. The function header declares `vals` as an argument to the `stats` function, with `mean` and `stdev` as return values.

- 3 In the MATLAB Function Block Editor, enter a line space after the function header and add the following code:

```
% Calculates a statistical mean and a standard
% deviation for the values in vals.

len = length(vals);
mean = avg(vals,len);
stdev = sqrt(sum(((vals-avg(vals,len)).^2))/len);
plot(vals,'-+');

function mean = avg(array,size)
mean = sum(array)/size;
```

### More about length

The function `length` is an example of a toolbox function that supports code generation. When you simulate this model, C code is generated for this function in the simulation application.

### More about len

The class, size, and complexity of local variable `len` matches the output of the toolbox function `length`, which returns a real scalar of type `double`.

By default, implicitly declared local variables like `len` are temporary. They come into existence only when the function is called and cease to exist when the function is exited. To make implicitly declared variables persist between function calls, see `persistent`.

### More about plot

The function `plot` is not supported for code generation. The code generation software detects calls to many common visualization functions, such as `plot`, `disp`, and `figure`. For MEX code generation, it automatically calls out to MATLAB for these functions. For standalone code generation, it does not generate code for these visualization functions.

- 4 Save the model as `call_stats_block2`.

## Build the Function and Check for Errors

After programming the block in a Simulink model, you can build the function and test for errors. Building your MATLAB Function block requires a supported compiler. MATLAB automatically selects one as the default compiler. If you have multiple MATLAB-supported compilers installed on your system, you can change the default compiler using the `mex -setup` command. See “Change Default Compiler” (MATLAB).

### Supported Compilers for Simulation and Code Generation Builds

View a list of compilers for building models containing MATLAB Function blocks simulation and code generation.

- 1 Navigate to the Supported and Compatible Compilers Web page and select your platform.

- 2 Scroll to the table under Simulink Product Family.
- 3 To check the table for models that contain MATLAB Function blocks for simulation, find the compilers checked in the column titled **Simulink For Model Referencing, Accelerator mode, Rapid Accelerator mode, and MATLAB Function blocks**.

To check the table for models that contain MATLAB Function blocks and generate code, find the compilers checked in the column titled **Simulink Coder** .

### **Supported Compilers for Code Generation**

To generate code for models that contain MATLAB Function blocks, you can use any of the C compilers supported by Simulink software for code generation with Simulink Coder. For a list of these compilers:

- 1 Navigate to the **Supported and Compatible Compilers Web page**.
- 2 Select your platform.
- 3 In the table for Simulink and related products, find the compilers checked in the column titled **Simulink Coder**.

### **Locate and Fix Errors**

If errors occur during the build process, the **Diagnostics Viewer** window lists the errors with links to the offending code.

The following exercise shows the way to locate and fix an error in a MATLAB Function block.

- 1 In the **stats** function, change the local function **avg** to a fictitious local function **aug** and then compile again to see the following messages in window. The **Diagnostics Viewer** window displays each detected error with a shaded red line.
- 2 Investigate the error titled **Undefined function or variable 'aug'**. In the diagnostic message for the selected error, click the blue link after the function name to display the offending code. The offending line appears highlighted in the **MATLAB Function Block Editor**.
- 3 The message also links to a report about compile-time type information for variables and expressions in your MATLAB functions. This information helps you diagnose error messages and understand type propagation rules. For more information about the report, see “MATLAB Function Reports” on page 43-56. To see the report, click the highlighted blue link in the line called **Launch diagnostic report**

- 4 Correct the error by changing `aug` back to `avg` and recompile.

## Define Inputs and Outputs

By default, function inputs and outputs inherit their data type and size from the signals attached to their ports. Examine input and output data for the MATLAB Function block to verify that it inherits the correct type and size.

- 1 Double-click the MATLAB Function block `stats`.
- 2 In the MATLAB Function Block Editor, select **Edit Data**. The Ports and Data Manager opens to help you define arguments for MATLAB Function blocks.

The left pane displays the argument `vals` and the return values `mean` and `stdev` that you have already created for the MATLAB Function block. Observe that `vals` is assigned a **Scope** of **Input**, which is short for **Input from Simulink**. `mean` and `stdev` are assigned the **Scope** of **Output**, which is short for **Output to Simulink**.

- 3 In the left pane of the Ports and Data Manager, click anywhere in the row for `vals` to highlight it.

The right pane displays the **Data** properties dialog box for `vals`. By default, the class, size, units, and complexity of input and output arguments are inherited from the signals attached to each input or output port. Inheritance is specified by setting **Size** to `-1`, **Complexity** to **Inherited**, and **Type** to **Inherit: Same as Simulink**.

The actual inherited values for size and type are set during compilation of the model, and are reported in the **Compiled Type** and **Compiled Size** columns of the left pane.

You can specify the type of an input or output argument by selecting a type in the **Type** field of the **Data** properties dialog box, for example, `double`. You can also specify the size of an input or output argument by entering an expression in the **Size** field. For example, you can enter `[2 3]` in the **Size** field to specify `vals` as a 2-by-3 matrix. See “Type Function Arguments” on page 43-61 and “Size Function Arguments” on page 43-68 for more information on the expressions that you can enter for type and size.

---

**Note** The default first index for any arrays that you add to a MATLAB Function block function is `1`, just as it would be in MATLAB.

---

## Define Local Variables for Code Generation

To generate code from the MATLAB algorithm in a MATLAB Function block, you must explicitly assign the class, size, and complexity of local variables before using them in operations or returning them as outputs (see “Data Definition for Code Generation” on page 51-2). In the example function `stats`, the local variable `len` is defined before being used to calculate mean and standard deviation:

```
len = length(vals);
```

Once you assign properties to a variable, you cannot redefine its class, size, or complexity elsewhere in the function body with some exceptions (see “Reassignment of Variable Properties” on page 50-9).

## Generate Code for the MATLAB Function Block

- 1 Open the `call_stats_block2` model that you saved at the end of “Program the MATLAB Function Block” on page 43-10.
- 2 Double-click `stats` block.
- 3 Select **Build Model > Build** to compile and build the example model.

If you get an error related to the **Variable-step** solver, from **Configuration Parameters > Solver**, change the solver type to a **Fixed-step** solver and rerun the build. To learn more about the differences between fixed-step and variable-step solvers, see “Fixed-Step Solvers Versus Variable-Step Solvers” on page 3-21.

If no errors occur, the **Diagnostics Viewer** window displays a message indicating success. Otherwise, this window helps you locate errors, as described in “Locate and Fix Errors” on page 43-12.

## Add Code to a MATLAB Function Block Programmatically

This example shows how to programmatically add a MATLAB Function block to a model and populate the block with MATLAB code. If you already have MATLAB code and do not want to add it to a MATLAB Function block manually, this workflow can be convenient.

- 1 Create and save a model called `myModel1`.
- 2 Create a MATLAB function with the following code and save it in `myAdd.m`.

```
function c = myAdd(a, b)
c = a + b;
```

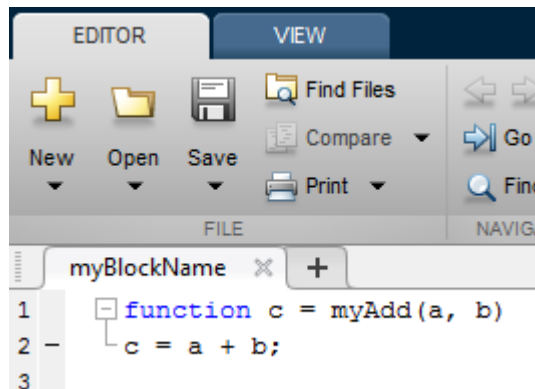

- 3 Write a MATLAB script that adds a MATLAB Function block to myModel and populates it with the contents of myAdd.m.

```
% Add a MATLAB Function block to a model and populate the block with MATLAB
% code.
```

```
%
% Copyright 2018 The Mathworks, Inc.
```

```
open_system('myModel.slx');
libraryBlockPath = 'simulink/User-Defined Functions/MATLAB Function';
newBlockPath = 'myModel/myBlockName';
% Add a MATLAB Function to the model
add_block(libraryBlockPath, newBlockPath);
% In memory, open models and their parts are represented by a hierarchy of
% objects. The root object is slroot. This line of the script returns the
% object that represents the new MATLAB Function block:
blockHandle = find(slroot, '-isa', 'Stateflow.EMChart', 'Path', newBlockPath);
% The Script property of the object contains the contents of the block,
% represented as a character vector. This line of the script loads the
% contents of the file myAdd.m into the Script property:
blockHandle.Script = fileread('myAdd.m');
% Alternatively, you can specify the code directly in a character vector.
% For example:
% blockHandle.Script = 'function c = fcn (a, b)';
```

- 4 Run the script and observe the new MATLAB Function block in myModel.  
5 To see the code that you added to the block, double-click the block myBlockName.

## Code Generation Readiness Tool

The code generation readiness tool screens MATLAB code for features and functions that code generation does not support. The tool provides a report that lists the source files that contain unsupported features and functions. The report also indicates the amount of work required to make the MATLAB code suitable for code generation. It is possible that the tool does not detect all code generation issues. Under certain circumstances, it is possible that the tool can report false errors. Therefore, before you generate C code, verify that your code is suitable for code generation by generating a MEX function.

## Summary Tab

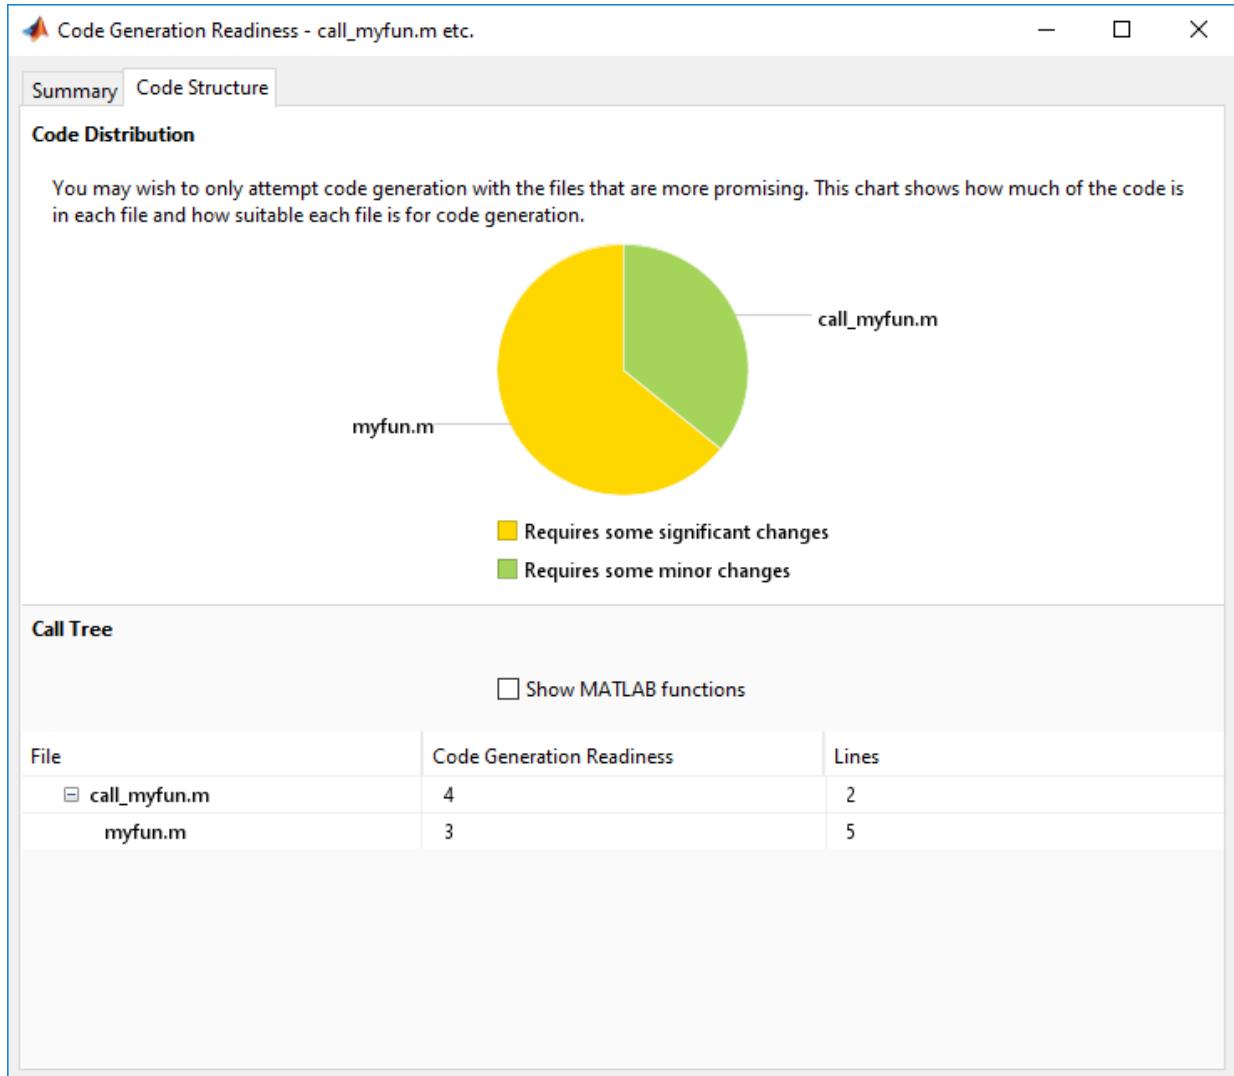

The **Summary** tab provides a **Code Generation Readiness Score**, which ranges from 1 to 5. A score of 1 indicates that the tool detects issues that require extensive changes to the MATLAB code to make it suitable for code generation. A score of 5 indicates that the

tool does not detect code generation issues; the code is ready to use with minimal or no changes.

On this tab, the tool also displays information about:

- MATLAB syntax issues. These issues are reported in the MATLAB editor. To learn more about the issues and how to fix them, use the Code Analyzer.
- Unsupported MATLAB function calls.
- Unsupported MATLAB language features.
- Unsupported data types.

## Code Structure Tab

If the code that you are checking calls other MATLAB functions, or you are checking multiple entry-point functions, the tool displays the **Code Structure Tab**.

This tab displays information about the relative size of each file and how suitable each file is for code generation.

### **Code Distribution**

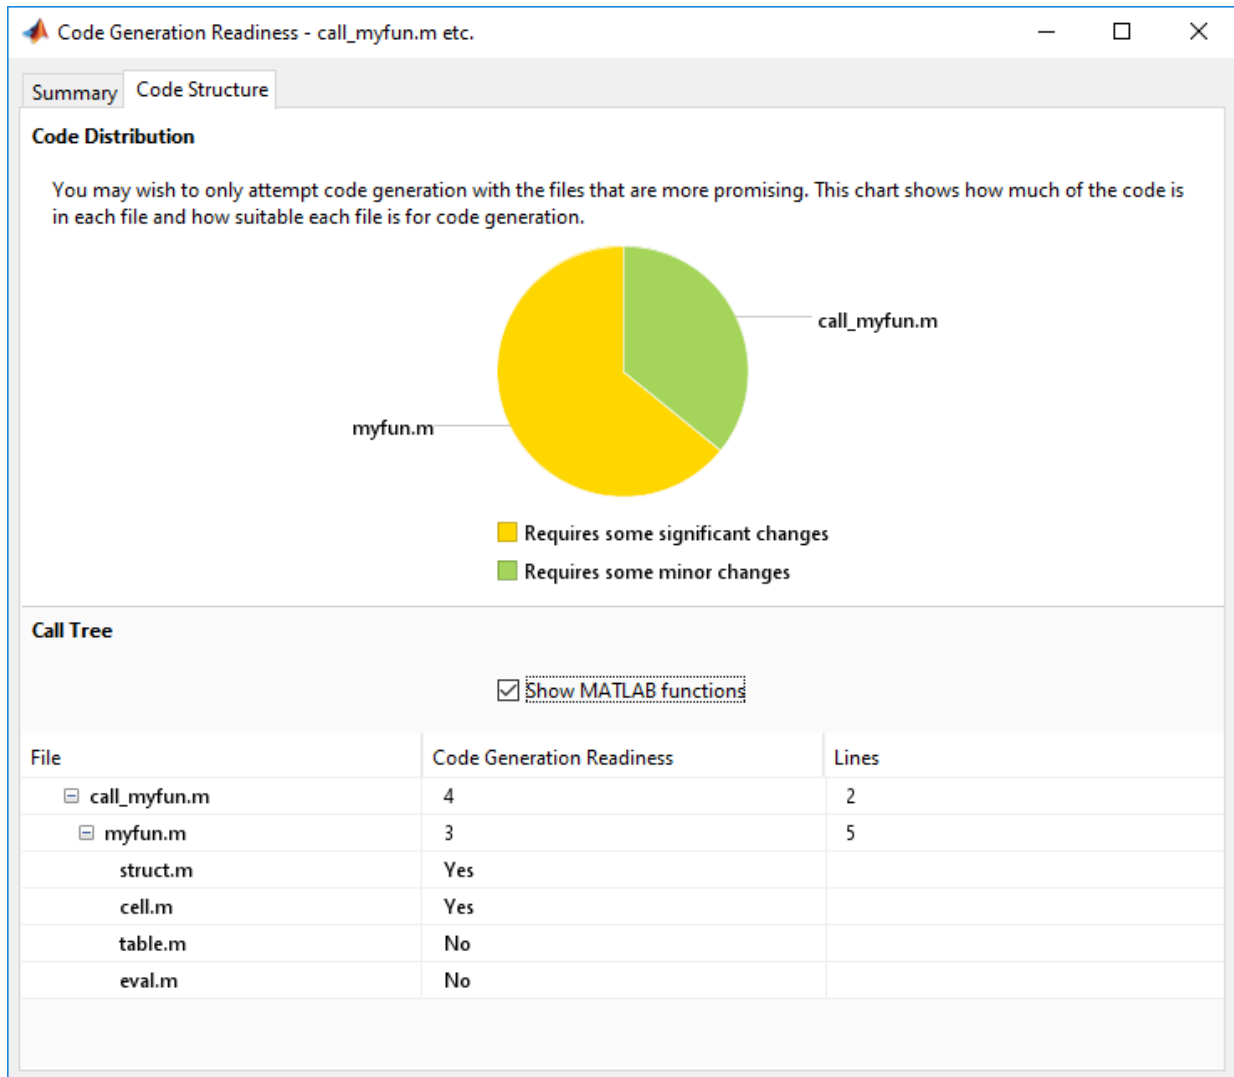

The **Code Distribution** pane displays a pie chart that shows the relative sizes of the files and how suitable each file is for code generation. During the planning phase of a project, you can use this information for estimation and scheduling. If the report indicates that multiple files are not suitable for code generation, consider fixing files that require minor changes before addressing files with significant issues.

### **Call Tree**

The **Call Tree** pane displays information about the nesting of function calls. For each called function, the report provides a **Code Generation Readiness** score, which ranges from 1 to 5. A score of 1 indicates that the tool detects issues that require extensive changes to the MATLAB code to make it suitable for code generation. A score of 5 indicates that the tool does not detect code generation issues. The code is ready to use with minimal or no changes. The report also lists the number of lines of code in each file.

### **Show MATLAB Functions**

If you select **Show MATLAB Functions**, the report also lists the MATLAB functions that your function calls. For each of these MATLAB functions, if code generation supports the function, the report sets **Code Generation Readiness** to Yes.

## Check Code Using the Code Generation Readiness Tool

| In this section...                                                                     |
|----------------------------------------------------------------------------------------|
| “Run Code Generation Readiness Tool at the Command Line” on page 43-24                 |
| “Run the Code Generation Readiness Tool From the Current Folder Browser” on page 43-24 |

### Run Code Generation Readiness Tool at the Command Line

- 1 Navigate to the folder that contains the file that you want to check for code generation readiness.
- 2 At the MATLAB command prompt, enter:

```
coder.screener('filename')
```

The **Code Generation Readiness** tool opens for the file named `filename`, provides a code generation readiness score, and lists issues that must be fixed prior to code generation.

### Run the Code Generation Readiness Tool From the Current Folder Browser

- 1 In the current folder browser, right-click the file that you want to check for code generation readiness.
- 2 From the context menu, select **Check Code Generation Readiness**.

The **Code Generation Readiness** tool opens for the selected file and provides a code generation readiness score and lists issues that must be fixed prior to code generation.

## Debugging a MATLAB Function Block

### In this section...

“Debugging the Function in Simulation” on page 43-25

“Set Conditions on Breakpoints” on page 43-28

“Watching Function Variables During Simulation” on page 43-28

“Checking for Data Range Violations” on page 43-30

“Debugging Tools” on page 43-31

### Debugging the Function in Simulation

In “Create Custom Functionality Using MATLAB Function Block” on page 43-9, you created an example model with a MATLAB Function block that calculates the mean and standard deviation for a set of input values. The software enables debugging for a MATLAB Function when you set a breakpoint.

To debug the MATLAB Function in this model:

- 1 Open the `call_stats_block2` model and double-click the MATLAB Function block `stats` to open the editor.
- 2 In the MATLAB Function Block Editor, click the dash (-) in the left margin of the line:

```
len = length(vals);
```

A red dot appears in the line margin, indicating the breakpoint.

```

1 function [mean, stdev] = stats(vals)
2 %#codegen
3
4 % Calculates a statistical mean and a standard deviation
5 % for the values in vals
6
7 - coder.extrinsic('plot');
8
9 ● len = length(vals);
10 - mean = avg(vals,len);
11 - stdev = sqrt(sum((vals-avg(vals,len)).^2)/len);
12 - plot(vals,'-+');
13
14 function mean = avg(array,size)
15 - mean = sum(array)/size;

```

- 3 Simulate the model.

Simulation pauses when execution reaches the breakpoint. This is indicated by a green arrow in the margin.

```

1 function [mean, stdev] = stats(vals)
2 %#codegen
3
4 % Calculates a statistical mean and a standard deviation
5 % for the values in vals
6
7 - coder.extrinsic('plot');
8
9 ● → len = length(vals);
10 - mean = avg(vals,len);
11 - stdev = sqrt(sum((vals-avg(vals,len)).^2)/len);
12 - plot(vals,'-+');
13
14 function mean = avg(array,size)
15 - mean = sum(array)/size;

```

- 4 In the toolbar, click **Step** to advance execution.

The execution arrow advances to the next line of `stats`, which calls the local function `avg`.

- 5 In the toolbar, click **Step In**.

Execution advances to enter the local function `avg`. Once you are in a local function, you can use the Step or Step In commands to advance execution. If the local function calls another local function, use Step In to enter it. If you want to execute the remaining lines of the local function, use Step Out.

- 6 Click **Step** to execute the only line in the local function `avg`. When the local function `avg` finishes executing, a green arrow, pointing down, appears under the last line of the function.
- 7 Click **Step** to return to the function `stats`.

Execution advances to the line after the call to the local function `avg`.

- 8 Click **Step** twice to calculate the `stdev` and to execute the `plot` function.

The plot function executes in MATLAB:

In the MATLAB Function Block Editor, a green arrow points down under the last line of code, indicating the completion of the function `stats`.

- 9 Click **Continue** to continue execution of the model.

The computed values of `mean` and `stdev` appear in the Display blocks.

- 10 In the MATLAB Function Block Editor, click **Quit Debugging** to stop simulation.

## Set Conditions on Breakpoints

To help you debug code, you can enter a MATLAB expression as a condition on a breakpoint inside a MATLAB Function block. Simulation then pauses on that breakpoint only when the condition is true. To set a conditional breakpoint, in the MATLAB Function block editor, right-click beside the line of code and select **Set Conditional Breakpoint**. Type the condition in the pop-up window. You can use any valid MATLAB expression as a condition. This condition expression can include numerical values and any data that is in scope at the breakpoint.

To add or modify a condition on an existing breakpoint, right-click the breakpoint and select **Set/Modify Condition**. You can also perform these actions from the **Breakpoints** menu.

## Watching Function Variables During Simulation

While you simulate a MATLAB Function block, you can use several tools to keep track of variable values in the function.

### Watching with the Interactive Display

To display the value of a variable in the function of a MATLAB Function block during simulation:

- 1 In the MATLAB Function Block Editor, place the mouse cursor over the variable text and observe the pop-up display.

For example, to watch the variable `len` during simulation, place the mouse cursor over the text `len` in the code. The value of `len` appears adjacent to the cursor, as shown:

```

8
9 ● len = length(vals);
10 - → mean(len = (vals, len);
11 - std 4
12 - plot rt(sum(((vals-avg(vals, len)).^2))/len);
13 '-+');

```

## Watching with the Command Line Debugger

You can report the values for a function variable with the Command Line Debugger utility in the MATLAB window during simulation. When you reach a breakpoint, the Command Line Debugger prompt, `debug>>`, appears. At this prompt, you can see the value of a variable defined for the MATLAB Function block by entering its name:

```
debug>> stdev
```

```
1.1180
```

```
debug>>
```

The Command Line Debugger also provides the following commands during simulation:

| Command                        | Description                                                                                                                                                                                                                                    |
|--------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>ctrl-c</code>            | Quit debugging and terminate simulation.                                                                                                                                                                                                       |
| <code>dbcont</code>            | Continue execution to next breakpoint.                                                                                                                                                                                                         |
| <code>dbquit</code>            | Quit debugging and terminate simulation.                                                                                                                                                                                                       |
| <code>dbstep [in out]</code>   | Advance to next program step after a breakpoint is encountered. Step over or step into/out of a MATLAB local function.                                                                                                                         |
| <code>help</code>              | Display help for command line debugging.                                                                                                                                                                                                       |
| <code>print &lt;var&gt;</code> | Display the value of the variable <code>var</code> in the current scope. If <code>var</code> is a vector or matrix, you can also index into <code>var</code> . For example, <code>var(1,2)</code> .                                            |
| <code>save</code>              | Saves all variables in the current scope to the specified file. Follows the syntax of the MATLAB <code>save</code> command. To retrieve variables to the MATLAB base workspace, use <code>load</code> command after simulation has been ended. |
| <code>&lt;var&gt;</code>       | Equivalent to "print <var>" if variable is in the current scope.                                                                                                                                                                               |
| <code>who</code>               | Display the variables in the current scope.                                                                                                                                                                                                    |

| Command           | Description                                                              |
|-------------------|--------------------------------------------------------------------------|
| <code>whos</code> | Display the size and class (type) of all variables in the current scope. |

You can issue any other MATLAB command at the `debug>>` prompt, but the results are executed in the workspace of the MATLAB Function block. To issue a command in the MATLAB base workspace at the `debug>>` prompt, use the `evalin` command with the first argument `'base'` followed by the second argument command, for example, `evalin('base', 'whos')`. To return to the MATLAB base workspace, use the `dbquit` command.

### Watching with MATLAB

You can display the execution result of a MATLAB Function block line by omitting the terminating semicolon. If you do, execution results for the line are echoed to the MATLAB window during simulation.

### Display Size Limits

The MATLAB Function Block Editor does not display the contents of matrices that have more than two dimensions or more than 200 elements. For matrices that exceed these limits, the MATLAB Function Block Editor displays the shape and base type only.

## Checking for Data Range Violations

MATLAB Function blocks check inputs and outputs for data range violations when the input or output values enter or leave the blocks. To enable data range violation checking, set **Simulation range checking** in the **Diagnostics: Data Validity** pane of the Configuration Parameters dialog box to error.

### Specifying a Range

To specify a range for input and output data, follow these steps:

- 1 In the Ports and Data Manager, select the input or output of interest.

The data properties dialog box opens.

- 2 In the data properties dialog box, select the General tab and enter a limit range, as described in “Setting General Properties” on page 43-47.

## Debugging Tools

Use the following tools during a MATLAB Function block debugging session:

| Tool Button                                                                                                | Description                                                                                                                                                                                                                                                                           | Shortcut Key        |
|------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------|
| <br><b>Build</b>          | <p>Access this tool from the <b>Editor</b> tab by selecting <b>Build Model &gt; Build</b>.</p> <p>Check for errors and build a simulation application (if no errors are found) for the model containing this MATLAB Function block.</p>                                               | <b>Ctrl+B</b>       |
| <br><b>Update Diagram</b> | <p>Access this tool from the <b>Editor</b> tab by selecting <b>Build Model &gt; Update Diagram</b>.</p> <p>Check for errors based on the latest changes you make to the MATLAB Function block.</p>                                                                                    | <b>Ctrl+D</b>       |
| <br><b>Update Ports</b>   | <p>Access this tool from the <b>Editor</b> tab by selecting <b>Build Model &gt; Update Ports</b>.</p> <p>Updates the ports of the MATLAB Function block with the latest changes made to the function argument and return values without closing the MATLAB Function Block Editor.</p> | <b>Ctrl+Shift+A</b> |
| <br><b>Run Model</b>    | <p>Start simulation of the model containing the MATLAB Function block. If execution is paused at a breakpoint, continues debugging.</p>                                                                                                                                               | <b>F5</b>           |
| <br><b>Stop Model</b>   | <p>Stop simulation of the model containing the MATLAB Function block. Alternatively, from the <b>Editor</b> tab, select <b>Quit Debugging</b> if execution is paused at a breakpoint.</p>                                                                                             | <b>Shift+F5</b>     |

| Tool Button                                                                                                    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               | Shortcut Key       |
|----------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------|
|  <p><b>Set/Clear</b></p>      | <p>Access this tool by selecting <b>Breakpoints &gt; Set/Clear</b>.</p> <p>Set a new breakpoint or clear an existing breakpoint for the selected line of code in the MATLAB Function block. The presence of the text cursor or highlighted text selects the line. A breakpoint indicator  appears on the selected line.</p> <p>Alternatively, click the hyphen character (-) next to the line number. A breakpoint indicator appears in place of the hyphen. Click the breakpoint indicator to clear the breakpoint.</p> | <p><b>F12</b></p>  |
|  <p><b>Enable/Disable</b></p> | <p>Access this tool by selecting <b>Breakpoints &gt; Enable/Disable</b>.</p> <p>Enable or disable an existing breakpoint for the selected line of code in the MATLAB Function block. If the breakpoint is disabled, an indicator  appears on the selected line.</p>                                                                                                                                                                                                                                                      | <p><b>None</b></p> |
|  <p><b>Set Condition</b></p> | <p>Access this tool by selecting <b>Breakpoints &gt; Set Condition</b>.</p> <p>Set a condition on the breakpoint for the selected line of code in the MATLAB Function block. If the breakpoint has a condition associated with it, an indicator  appears on the selected line.</p>                                                                                                                                                                                                                                     |                    |
|  <p><b>Clear All</b></p>    | <p>Access this tool by selecting <b>Breakpoints &gt; Clear All</b>.</p> <p>Clear all existing breakpoints in the MATLAB Function block code.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                          | <p><b>None</b></p> |

| Tool Button                                                                                                 | Description                                                                                                                                                                                                                                                   | Shortcut Key     |
|-------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------|
| <br><b>Step</b>            | Step through the execution of the next line of code in the MATLAB Function block. This tool steps past function calls and does not enter called functions for line-by-line execution. You can use this tool only after execution has stopped at a breakpoint. | <b>F10</b>       |
| <br><b>Step In</b>         | Step through the execution of the next line of code in the MATLAB Function block. If the line calls a local function, step into the first line of the local function. You can use this tool only after execution has stopped at a breakpoint.                 | <b>F11</b>       |
| <br><b>Step Out</b>        | Step out of line-by-line execution of the current function or local function. If in a local function, the debugger continues to the line following the call to this local function. You can use this tool only after execution has stopped at a breakpoint.   | <b>Shift+F11</b> |
| <br><b>Continue</b>        | Continue debugging after a pause, such as stopping at a breakpoint. You can use this tool only after execution has stopped at a breakpoint.                                                                                                                   | <b>F5</b>        |
| <br><b>Quit Debugging</b> | Exit debug mode. You can use this tool only after execution has stopped at a breakpoint.                                                                                                                                                                      | <b>Shift+F5</b>  |

## Prevent Algebraic Loop Errors in MATLAB Function and Stateflow Blocks

You can use Stateflow charts, MATLAB Function blocks, and Stateflow Truth Tables in feedback loops in your model. You can also use these blocks with synchronous subsystems enabled by the State Control block. To prevent algebraic loop or synchronous semantic errors, apply these restrictions.

| Simulink Block        | Restrictions                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Stateflow Chart       | Use Moore charts to prevent an algebraic loop. In the Property Inspector, set the <b>State Machine Type</b> to <b>Moore</b> . Moore charts prevent algebraic loops by ensuring that outputs depend only on current state.                                                                                                                                                                                                                                                                                                                                         |
| MATLAB Function block | <p>Nondirect feedthrough semantics prevent algebraic loop errors by ensuring that outputs depend only on current state. To enable these semantics, clear the <b>Allow direct feedthrough</b> property check box.</p> <p>If your block uses direct feedthrough, do not:</p> <ul style="list-style-type: none"> <li>• Call imported functions.</li> <li>• Define output function-call events.</li> <li>• Define or use persistent variables.</li> </ul> <p>When you apply these restrictions, you allow the Simulink solver to try to solve the algebraic loop.</p> |

| Simulink Block | Restrictions                                                                                                                                                                                                                                                                                                                                                                                                |
|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Truth Table    | <p>Do not:</p> <ul style="list-style-type: none"><li>• Call imported functions.</li><li>• Define local or output function-call events.</li><li>• Define local or data store memory data.</li><li>• Define or use persistent variables.</li><li>• Use machine-parented data or events.</li></ul> <p>When you apply these restrictions, you allow the Simulink solver to try to solve the algebraic loop.</p> |

## MATLAB Function Block Editor

### In this section...

“Customizing the MATLAB Function Block Editor” on page 43-36

“MATLAB Function Block Editor Tools” on page 43-36

“Editing and Debugging MATLAB Function Block Code” on page 43-37

### Customizing the MATLAB Function Block Editor

Use the toolbar icons to customize the appearance of the MATLAB Function Block Editor in the same manner as the MATLAB editor. See “Basic Settings” (MATLAB).

### MATLAB Function Block Editor Tools

Use the following tools to work with the MATLAB Function block:

| Tool Button                                                                                                     | Description                                                                                                                                                           |
|-----------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <br><b>Edit Data</b>           | Opens the Ports and Data Manager dialog to add or modify arguments for the current MATLAB Function block. To learn more, see “Ports and Data Manager” on page 43-40). |
| <br><b>View Report</b>       | Opens the MATLAB Function report for the MATLAB Function block. For more information, see “MATLAB Function Reports” on page 43-56.                                    |
| <br><b>Simulation Target</b> | Opens the <b>Simulation Target</b> pane in the <b>Configuration Parameters</b> dialog to include custom code.                                                         |
| <br><b>Go To Diagram</b>     | Displays the MATLAB function in its native diagram without closing the editor.                                                                                        |

See “Define Inputs and Outputs” on page 43-13 for an example of defining an input argument for a MATLAB Function block.

## Editing and Debugging MATLAB Function Block Code

### Manual Indenting

To indent a block of code manually:

- 1 Highlight the text that you would like to indent.
- 2 Select one of the Indent tools on the Editor tab:

| Tool                                                                              | Description                                |
|-----------------------------------------------------------------------------------|--------------------------------------------|
|  | Applies smart indenting to selected text.  |
|  | Move selected text right one indent level. |
|  | Move selected text left one indent level.  |

### Opening a Selection

You can open a local function, function, file, or variable from within a file in the MATLAB Function Block Editor.

To open a selection:

- 1 Position the cursor in the name of the item you would like to open.
- 2 Right-click and select **Open <selection>** from the context menu.

The Editor chooses the appropriate tool to open the selection. For more information, refer to “Manage Files and Folders” (MATLAB).

---

**Note** If you open a MATLAB Function block input or output parameter, the Ports and Data Manager opens with the selected parameter highlighted. You can use the Ports and Data Manager to modify parameter attributes. For more information, refer to “Ports and Data Manager” on page 43-40.

---

### Evaluating a Selection

You can use the **Evaluate a Selection** menu option to report the value for a MATLAB function variable or equation in the MATLAB window during simulation.

To evaluate a selection:

- 1 Highlight the variable or equation that you would like to evaluate.
- 2 Hold the mouse over the highlighted text and then right-click and select **Evaluate Selection** from the context menu. (Alternatively, select **Evaluate Selection** from the **Text** menu).

When you reach a breakpoint, the MATLAB command Window displays the value of the variable or equation at the Command Line Debugger prompt.

```
debug>> stdev
```

```
1.1180
```

```
debug>>
```

---

**Note** You cannot evaluate a selection while MATLAB is busy, for example, running a MATLAB file.

---

### Setting Data Scope

To set the data scope of a MATLAB Function block input parameter:

- 1 Highlight the input parameter that you would like to modify.
- 2 Hold the mouse over the highlighted text and then right-click and select **Data Scope for <selection>** from the context menu.
- 3 Select:
  - **Input** if your input data is provided by the Simulink model via an input port to the MATLAB Function block.
  - **Parameter** if your input is a variable of the same name in the MATLAB or model workspace or in the workspace of a masked subsystem containing this block.

For more information, refer to “Setting General Properties” on page 43-47.

## Ports and Data Manager

The Ports and Data Manager provides a convenient method for defining objects and modifying their properties in a MATLAB Function block.

The Ports and Data Manager provides the same data definition capabilities for individual MATLAB Function blocks as the Model Explorer provides across the model hierarchy (see “Search and Edit Using Model Explorer” on page 12-2).

### Ports and Data Manager Dialog Box

The Ports and Data Manager dialog box allows you to add and define data arguments, input triggers, and function call outputs for MATLAB Function blocks. Using this dialog, you can also modify properties for the MATLAB Function block and the objects it contains.

The dialog box consists of two panes:

- The **Contents** (left) pane lists the objects that have been defined for the MATLAB Function block.
- The **Dialog** (right) pane displays fields for modifying the properties of the selected object.

Properties vary according to the scope and type of the object. Therefore, the Ports and Data Manager properties dialogs are dynamic, displaying only the property fields that are relevant for the object you add or modify.

When you first open the dialog box, it displays the properties of the MATLAB Function block.

### Opening the Ports and Data Manager

To open the Ports and Data Manager from the MATLAB Function Block Editor, select **Edit Data** on the Editor tab. The Ports and Data Manager appears for the MATLAB Function block that is open and has focus.

### Ports and Data Manager Tools

The following tools are specific to the Ports and Data Manager:

| Tool Button                                                                                                    | Description                                                                                                                                                                                                                               |
|----------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <br><b>Go to Block Editor</b> | Displays the MATLAB function in the MATLAB Function Block Editor.                                                                                                                                                                         |
| <br><b>Show Block Dialog</b>  | Displays the default MATLAB function properties. To learn more, see “MATLAB Function Block Properties” on page 43-52. Use this button to return to the settings used by the block after viewing data associated with the block arguments. |

## Adding Function Call Outputs to a MATLAB Function Block

A function call output is an event on the output port of a MATLAB Function block that causes a Function-Call Subsystem block in the Simulink model to execute. Another block can invoke a function-call subsystem directly during a simulation. See “Using Function-Call Subsystems” on page 10-44.

Use the Ports and Data Manager to add and modify function call outputs to a MATLAB Function block that is open and has focus. To add a function call output and modify its properties, follow these steps:

- 1 In the Ports and Data Manager, select **Add > Function Call Output**.

The Ports and Data Manager adds a default definition of the new function call output to the MATLAB Function block and displays the Function Call properties dialog.

- 2 Modify function call output properties.
- 3 Return to the MATLAB Function block properties at any time by selecting **Tools > Block Dialog**.

### Considerations when Supplying Output to the Function-Call Subsystem

If a MATLAB Function block triggers a function-call subsystem, and supplies an output signal to the same function-call subsystem, the signal to the function-call subsystem can effectively be delayed by one time step compared to the function call. At the moment of the function call, the function-call subsystem sees the previous MATLAB Function block output value even if the output data has been updated within the block MATLAB code.

### The Function Call Properties Dialog

The Function Call properties dialog in the Ports and Data Manager allows you to edit the properties of function call outputs in MATLAB Function blocks.

To open the Function Call properties dialog, select a function call output in the Contents pane.

## Setting Function Call Output Properties

You can set the following properties in the Function Call properties dialog:

| Property             | Description                                                                                                                                                                                                                                                                                                                                                                                                  |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Name</b>          | Name of the function call output, following the same naming conventions used in MATLAB.                                                                                                                                                                                                                                                                                                                      |
| <b>Port</b>          | Index of the port associated with the function call output. Function call output ports are numbered sequentially after input and output ports.                                                                                                                                                                                                                                                               |
| <b>Description</b>   | Description of the function call output.                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Document link</b> | Link to documentation for the function call output. You can enter a Web URL address or a MATLAB command that displays documentation in a suitable format, such as an HTML file or text in the MATLAB Command Window. When you click <b>Document link</b> displayed at the bottom of the <b>Function Call</b> properties dialog, the MATLAB Function block evaluates the link and displays the documentation. |

## Adding Input Triggers to a MATLAB Function Block

An input trigger is an event on the input port that causes the MATLAB Function block to execute. See “Using Triggered Subsystems” on page 10-21.

You can define the following types of triggers in MATLAB Function blocks:

- Rising
- Falling
- Either (rising or falling)
- Function call

For a description of each trigger type, see “Setting Input Trigger Properties” on page 43-44.

Use the Ports and Data Manager to add input triggers to a MATLAB Function block that is open and has focus. To add an input trigger and modify its properties, follow these steps:

- 1 In the Ports and Data Manager, select **Add > Input Trigger**.

The Ports and Data Manager adds a default definition of the new input trigger to the MATLAB Function block and displays the Trigger properties dialog.

- 2 Modify trigger properties.
- 3 Return to the MATLAB Function block properties at any time by selecting **Tools > Block Dialog**.

### The Trigger Properties Dialog

The Trigger properties dialog in the Ports and Data Manager allows you to set and modify the properties of input triggers in MATLAB Function blocks.

To open the Trigger properties dialog, select an input trigger in the Contents pane.

### Setting Input Trigger Properties

You can set the following properties in the Trigger properties dialog:

| Property             | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|----------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Name</b>          | Name of the input trigger, following the same naming conventions used in MATLAB.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Port</b>          | Index of the port associated with the input trigger. The default value is 1.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Trigger</b>       | Type of event that triggers execution of the MATLAB Function block. You can select one of the following types of triggers: <ul style="list-style-type: none"> <li>• <b>Rising</b> (default) — Triggers execution of the MATLAB Function block when the control signal rises from a negative or zero value to a positive value (or zero if the initial value is negative).</li> <li>• <b>Falling</b>— Triggers execution of the MATLAB Function block when the control signal falls from a positive or zero value to a negative value (or zero if the initial value is positive).</li> <li>• <b>Either</b>— Triggers execution of the MATLAB Function block when the control signal is either rising or falling.</li> <li>• <b>Function call</b>— Triggers execution of the MATLAB Function block from a block that outputs function-call events, or from an S-function</li> </ul> |
| <b>Description</b>   | Description of the input trigger.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Document link</b> | Link to documentation for the input trigger. You can enter a Web URL address or a MATLAB command that displays documentation in a suitable format, such as an HTML file or text in the MATLAB Command Window. When you click the blue text that reads <b>Document link</b> displayed at the bottom of the <b>Trigger</b> properties dialog, the MATLAB Function block evaluates the link and displays the documentation.                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

## Adding Data to a MATLAB Function Block

You can define data arguments for MATLAB Function blocks using the following methods:

| Method                                                 | For Defining                                                                                     | Reference                                                        |
|--------------------------------------------------------|--------------------------------------------------------------------------------------------------|------------------------------------------------------------------|
| Define data directly in the MATLAB Function block code | Input and output data                                                                            | See “Define Inputs and Outputs” on page 43-13.                   |
| Use the Ports and Data Manager                         | Input, output, and parameter data in the MATLAB Function block that is open and has focus        | See “Defining Data in the Ports and Data Manager” on page 43-47. |
| Use the Model Explorer                                 | Input, output, and parameter data in MATLAB Function blocks at all levels of the model hierarchy | See “Search and Edit Using Model Explorer” on page 12-2          |

### Defining Data in the Ports and Data Manager

To add a data argument, in the Ports and Data Manager, select **Add > Data** and modify the data properties.

### Setting General Properties

You can set the following properties in the General tab:

| Property    | Description                                                                      |
|-------------|----------------------------------------------------------------------------------|
| <b>Name</b> | Name of the data argument, following the same naming conventions used in MATLAB. |

| Property                                           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|----------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Scope</b>                                       | <p>Where data resides in memory, relative to its parent. Scope determines the range of functionality of the data argument. You can set scope to one of the following values:</p> <ul style="list-style-type: none"> <li>• <b>Parameter</b>— Specifies that the source for this data is a variable of the same name in the MATLAB or model workspace or in the workspace of a masked subsystem containing this block. If a variable of the same name exists in more than one of the workspaces visible to the block, the variable closest to the block in the workspace hierarchy is used (see “Model Workspaces” on page 62-162).</li> <li>• <b>Input</b>— Data provided by the model via an input port to the MATLAB Function block.</li> <li>• <b>Output</b>— Data provided by the MATLAB Function block via an output port to the model.</li> <li>• <b>Data Store Memory</b>— Data provided by a Data Store Memory block in the model.</li> </ul> <p>For more information, see “Define Inputs and Outputs” on page 43-13 and “Add Parameter Arguments” on page 43-73.</p> |
| <b>Port</b>                                        | <p>Index of the port associated with the data argument. This property applies only to input and output data.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Tunable</b>                                     | <p>Indicates whether the parameter used as the source of this data item is tunable (see “Tunable Parameters” on page 3-8). This property applies only to parameter data. Clear this option if the parameter must be a constant expression, such as for MATLAB toolbox functions supported for code generation (see “Functions and Objects Supported for C/C++ Code Generation — Alphabetical List” on page 48-2).</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Data must resolve to Simulink signal object</b> | <p>Specifies that the data argument must resolve to a Simulink signal object. This property applies only to output data. This property appears only if you set the model configuration parameter <b>Signal resolution</b> to a value other than None. See “Symbol Resolution” on page 62-174 for more information.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Size</b>                                        | <p>Size of the data argument. Size can be a scalar value or a MATLAB vector of values. Size defaults to -1, which means that it is inherited, as described in “Inheriting Argument Sizes from Simulink” on page 43-68. This property does not apply to Data Store Memory data. For more details, see “Size Function Arguments” on page 43-68.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| Property                                    | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|---------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Variable Size</b>                        | Indicates whether the size of this data item is variable. This property does not apply to Data Store Memory data.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Complexity</b>                           | <p>Indicates real or complex data arguments. You can set complexity to one of the following values:</p> <ul style="list-style-type: none"> <li>• <b>Off</b>— Data argument is a real number</li> <li>• <b>On</b>— Data argument is a complex number</li> <li>• <b>Inherited</b>— Data argument inherits complexity based on its scope. Input and output data inherit complexity from the Simulink signals connected to them; parameter data inherits complexity from the parameter to which it is bound.</li> </ul>                                                                                                                                                                                 |
| <b>Type</b>                                 | <ul style="list-style-type: none"> <li>• Selecting a built-in type from the <b>Type</b> drop down list.</li> <li>• Entering an expression in the <b>Type</b> field that evaluates to a data type (see “About Data Types in Simulink” on page 62-3).</li> <li>• Using the Data Type Assistant to specify a data <b>Mode</b>, then specifying the data type based on that mode.</li> </ul> <p><b>Note</b> To display the Data Type Assistant, click the Show data type assistant button:</p> <div style="text-align: center;">  </div> <p>For more information, see “Specifying Argument Types” on page 43-61.</p> |
| <b>Unit (e.g., m, m/s<sup>2</sup>, N*m)</b> | Specify physical units for input and output data. By default, the property is set to inherit the unit from the Simulink signal on the corresponding input or output port. See “Units in MATLAB Function Blocks” on page 43-71.                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| Property           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Limit range</b> | <p>Specify the range of acceptable values for input or output data. The MATLAB Function block uses this range to validate the input or output as it enters or leaves the block. You can enter an expression or parameter that evaluates to a numeric scalar value.</p> <ul style="list-style-type: none"> <li>• <b>Minimum</b> — The smallest value allowed for the data item during simulation. The default value is <code>-inf</code>.</li> <li>• <b>Maximum</b> — The largest value allowed for the data item during simulation. The default value is <code>inf</code>.</li> </ul> |

## Setting Description Properties

You can set the following properties on the Description tab:

| Property                                  | Description                                                                                                                                                                                                                                                                                                                                                                                                   |
|-------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Save final value to base workspace</b> | The MATLAB Function block assigns the value of the data argument to a variable of the same name in the MATLAB base workspace at the end of simulation.                                                                                                                                                                                                                                                        |
| <b>Description</b>                        | Description of the data argument.                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Document link</b>                      | Link to documentation for the data argument. You can enter a Web URL address or a MATLAB command that displays documentation in a suitable format, such as an HTML file or text in the MATLAB Command Window. When you click the blue text, <b>Document link</b> , displayed at the bottom of the <b>Data</b> properties dialog, the MATLAB Function block evaluates the link and displays the documentation. |

## MATLAB Function Block Properties

This section describes each property of a MATLAB Function block.

### Name

Name of the MATLAB Function block.

### Update method

Method for activating the MATLAB Function block. You can choose from the following update methods:

| Update Method       | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|---------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Inherited (default) | Input from the Simulink model activates the MATLAB Function block. If you define an input trigger, the MATLAB Function block executes in response to a Simulink signal or function-call event on the trigger port. If you do not define an input trigger, the MATLAB Function block implicitly inherits triggers from the model. These implicit events are the sample times (discrete or continuous) of the signals that provide inputs to the chart.<br>If you define data inputs, the MATLAB Function block samples at the rate of the fastest data input. If you do not define data inputs, the MATLAB Function block samples as defined by its parent subsystem's execution behavior. |
| Discrete            | The MATLAB Function block is sampled at the rate you specify as the block's <b>Sample Time</b> property. An implicit event is generated at regular time intervals corresponding to the specified rate. The sample time is in the same units as the Simulink simulation time. Note that other blocks in the model can have different sample times.                                                                                                                                                                                                                                                                                                                                         |
| Continuous          | The Simulink software wakes up (samples) the MATLAB Function block at each step in the simulation, as well as at intermediate time points that can be requested by the solver. This method is consistent with the continuous method.                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

## Saturate on integer overflow

Option that determines how the MATLAB Function block handles overflow conditions during integer operations:

| Setting           | Action When Overflow Occurs                                                                                                           |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| Enabled (default) | Saturates an integer by setting it to the maximum positive or negative value allowed by the word size. Matches MATLAB behavior.       |
| Disabled          | In simulation mode, generates a run-time error. For Simulink Coder code generation, the behavior depends on your C language compiler. |

**Note** The **Saturate on integer overflow** option is relevant only for integer arithmetic. It has no effect on fixed-point or double-precision arithmetic.

When you enable **Saturate on integer overflow**, MATLAB adds additional checks during simulation to detect integer overflow or underflow. Therefore, it is more efficient to disable this option if you are sure that integer overflow and underflow will not occur in your MATLAB Function block code.

Note that the code generated by Simulink Coder does *not* check for integer overflow or underflow and, therefore, may produce unpredictable results when **Saturate on integer overflow** is disabled. In this situation, it is recommended that you simulate first to test for overflow and underflow before generating code.

## Lock Editor

Option for locking the MATLAB Function Block Editor. When enabled, this option prevents users from making changes to the MATLAB Function block.

## Treat these inherited Simulink signal types as fi objects

Setting that determines whether to treat inherited fixed-point and integer signals as Fixed-Point Designer `fi` objects (“Ways to Construct `fi` Objects” (Fixed-Point Designer)).

- When you select **Fixed-point**, the MATLAB Function block treats all fixed-point inputs as Fixed-Point Designer `fi` objects.

- When you select **Fixed-point & Integer**, the MATLAB Function block treats all fixed-point and integer inputs as Fixed-Point Designer `fi` objects.

## MATLAB Function block `fimath`

Setting that defines `fimath` properties for the MATLAB Function block. The block associates the `fimath` properties you specify with the following objects:

- All fixed-point and integer input signals to the MATLAB Function block that you choose to treat as `fi` objects.
- All `fi` and `fimath` objects constructed in the MATLAB Function block.

You can select one of the following options for the **MATLAB Function block `fimath`**.

| Setting               | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Same as MATLAB</b> | When you select this option, the block uses the same <code>fimath</code> properties as the current default <code>fimath</code> . The edit box appears dimmed and displays the current global <code>fimath</code> in read-only form.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Specify other</b>  | <p>When you select this option, you can specify your own <code>fimath</code> object in the edit box. You can do so in one of two ways:</p> <ul style="list-style-type: none"> <li>• Constructing the <code>fimath</code> object inside the edit box.</li> <li>• Constructing the <code>fimath</code> object in the MATLAB or model workspace and then entering its variable name in the edit box. If you use this option and plan to share your model with others, make sure you define the variable in the model workspace. See “Sharing Models with Fixed-Point MATLAB Function Blocks” (Fixed-Point Designer).</li> </ul> <p>For more information on <code>fimath</code> objects, see “<code>fimath</code> Object Construction” (Fixed-Point Designer).</p> |

## Description

Description of the MATLAB Function block.

## Document link

Link to documentation for the MATLAB Function block. To document a MATLAB Function block, set the **Document link** property to a Web URL address or MATLAB expression

that displays documentation in a suitable format (for example, an HTML file or text in the MATLAB Command Window). The MATLAB Function block evaluates the expression when you click the blue **Document link** text.

## MATLAB Function Reports

### In this section...

“Opening a MATLAB Function Report” on page 43-56

“Error and Warning Messages” on page 43-56

“Functions List” on page 43-57

“MATLAB Source” on page 43-57

“MATLAB Variables” on page 43-58

“Report Limitations” on page 43-60

When you simulate or build a Simulink model that contains MATLAB Function blocks, Simulink generates a report for each MATLAB Function block in your model. Use the report to debug your MATLAB functions and verify that they are suitable for code generation. The report provides type information for the variables and expressions in your functions. This information helps you to find sources of error messages and to understand type propagation rules.

Stateflow produces one report for each Stateflow chart, regardless of the number of MATLAB functions it contains.

If you have identical MATLAB Function blocks in your model, for example, one in a library and one in the model, a single report is generated for the identical blocks.

### Opening a MATLAB Function Report

Use one of these methods:

- In the MATLAB Function Block Editor, select **View Report**.
- If compilation errors occur, in the **Diagnostic Viewer** window, select the report link.

### Error and Warning Messages

View errors and warnings on the **All Messages** tab. To highlight the source code for an error or warning, click the message. It is best practice to address the first message in the list, because often subsequent errors and warnings are related to the first message.

## Functions List

In the **MATLAB Source** pane, the **Function List** view organizes functions according to the containing file. To visualize functions according to the call structure, use the **Call Tree** view.

To view a function in the code pane of the report, click the function. To edit the function, click **Edit in MATLAB**. A function that is in the MATLAB Function block opens in the MATLAB Function Block Editor. Other functions open in the MATLAB Editor.

## MATLAB Source

To view a MATLAB function in the code pane, click the function in the **MATLAB Source** pane. To see information about the type of a variable or expression, pause over the variable or expression.

In the code pane, syntax highlighting of MATLAB source code helps you to identify MATLAB syntax elements. Syntax highlighting also helps you to identify certain code generation attributes such as whether a function is extrinsic or whether an argument is constant.

## Extrinsic Functions

In the MATLAB code, the report identifies an extrinsic function with purple text. The information window indicates that the function is extrinsic.

The screenshot shows a MATLAB code editor window titled "Function: callMyExtrinsic". The code is as follows:

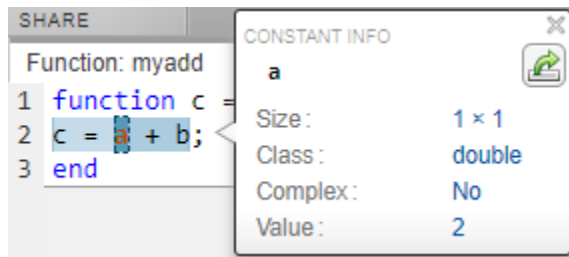

```
1 function z = callMyExtrinsic(a,b)
2 %#codegen
3 coder.extrinsic('myExtrinsic');
4 z = 0;
5 z = myExtrinsic(a,b);
6 disp(z);
7 end
8
```

The expression `myExtrinsic(a,b)` on line 5 is highlighted with a blue dashed border. A tooltip titled "EXPRESSION INFO" is displayed over it, showing the following information:

| EXPRESSION INFO                         |         |
|-----------------------------------------|---------|
| myExtrinsic(a,b)                        |         |
| Size:                                   | 1 × 1   |
| Class:                                  | mxArray |
| i myExtrinsic is an extrinsic function. |         |

## Constant Arguments

In the MATLAB code, orange text indicates a compile-time constant argument to an entry-point function or a specialized function. The information window includes the constant value.

Knowing the value of the constant arguments helps you to understand generated function signatures. It also helps you to see when code generation created function specializations for different constant argument values.

To export the value to a variable in the workspace, click .

## MATLAB Variables

The **Variables** tab provides information about the variables for the selected MATLAB function. To select a function, click the function in the **MATLAB Source** pane.

The variables table shows:

- Class, size, and complexity
- Properties of fixed-point types

This information helps you to debug errors, such as type mismatch errors, and to understand type propagation.

### Visual Indicators on the Variables Tab

This table describes symbols, badges, and other indicators in the variables table.

| Column in the Variables Table | Indicator      | Description                                                                                                                                                                                                                                                                                                                                                         |
|-------------------------------|----------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Name                          | expander       | Variable has elements or properties that you can see by clicking the expander.                                                                                                                                                                                                                                                                                      |
| Name                          | { : }          | Heterogeneous cell array (all elements have the same properties)                                                                                                                                                                                                                                                                                                    |
| Name                          | {n}            | nth element of a heterogeneous cell array                                                                                                                                                                                                                                                                                                                           |
| Class                         | v > n          | v is reused with a different class, size, and complexity. The number n identifies each unique reuse (a reuse with a unique set of properties). When you pause over a renamed variable, the report highlights only the instances of this variable that share the class, size, and complexity. See “Reuse the Same Variable with Different Properties” on page 50-10. |
| Size                          | : n            | Variable-size dimension with an upper bound of n                                                                                                                                                                                                                                                                                                                    |
| Size                          | : ?            | Variable-size with no upper bound                                                                                                                                                                                                                                                                                                                                   |
| Size                          | <i>italics</i> | Variable-size array whose dimensions do not change size during execution                                                                                                                                                                                                                                                                                            |
| Class                         | sparse prefix  | Sparse array                                                                                                                                                                                                                                                                                                                                                        |
| Class                         | complex prefix | Complex number                                                                                                                                                                                                                                                                                                                                                      |

| Column in the Variables Table | Indicator                                                                         | Description                                                                 |
|-------------------------------|-----------------------------------------------------------------------------------|-----------------------------------------------------------------------------|
| Class                         |  | Fixed-point type<br><br>To see the fixed-point properties, click the badge. |

## Report Limitations

- The variables table does not show individual elements of `varargin` and `varargout`.
- The report does not show full information for unrolled loops. It displays data types of one arbitrary iteration.
- The report does not show information about dead code.

## About Function Arguments

You create function arguments for a MATLAB Function block by entering them in its function header in the MATLAB Function Block Editor. When you define arguments, the Simulink software creates corresponding ports on the MATLAB Function block that you can attach to signals. You can select a data type mode for each argument that you define for a MATLAB Function block. Each data type mode presents its own set of options for selecting a data type.

By default, the data type mode for MATLAB Function block function arguments is **Inherited**. This means that the function argument inherits its data type from the incoming or outgoing signal. To override the default type, you first choose a data type mode and then select a data type based on the mode.

## Specifying Argument Types

To specify the type of a MATLAB Function block function argument:

- 1 From the MATLAB Function Block Editor, select **Edit Data** to open the Ports and Data Manager.
- 2 In the left pane, select the argument of interest.
- 3 In the **Data** properties dialog box (right pane), click the Show data type assistant button  to display the Data Type Assistant. Then, choose an option from the **Mode** drop-down menu.

The **Data** properties dialog box changes dynamically to display additional fields for specifying the data type associated with the mode.

- 4 Based on the mode you select, specify a desired data type:

| Mode              | What to Specify                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Inherit (default) | <p>You cannot specify a value. The data type is inherited from previously-defined data, based on the scope you selected for the MATLAB Function block function argument:</p> <ul style="list-style-type: none"> <li>• If scope is <b>Input</b>, data type is inherited from the input signal on the designated port.</li> <li>• If scope is <b>Output</b>, data type is inherited from the output signal on the designated port.</li> <li>• If scope is <b>Parameter</b>, data type is inherited from the associated parameter, which can be defined in the Simulink masked subsystem or the MATLAB workspace.</li> </ul> <p>See “Inheriting Argument Data Types” on page 43-63.</p> |
| Built in          | <p>Select from the drop-down list of supported data types, as described in “Built-In Data Types for Arguments” on page 43-63.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Fixed point       | <p>Specify the fixed-point data properties as described in “Specifying Fixed-Point Designer Data Properties” on page 43-64.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| Expression        | <p>Enter an expression that evaluates to a data type, as described in “Specifying Argument Types with Expressions” on page 43-64.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| Bus Object        | <p>In the <b>Bus object</b> field, enter the name of a <code>Simulink.Bus</code> object to define the properties of a MATLAB structure. You must define the bus object in the base workspace. See “How Structure Inputs and Outputs Interface with Bus Signals” on page 43-80.</p> <hr/> <p><b>Note</b> You can click the <b>Edit</b> button to create or modify <code>Simulink.Bus</code> objects using the Simulink Bus Editor (see “Attach Bus Signals to MATLAB Function Blocks” on page 43-78).</p>                                                                                                                                                                             |
| Enumerated        | <p>In the Enumerated field, enter the name of a <code>Simulink.IntEnumType</code> object that you define in the base workspace. See “Code Generation for Enumerations” on page 43-112.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

## Inheriting Argument Data Types

MATLAB Function block function arguments can inherit their data types, including fixed point types, from the signals to which they are connected.

- 1 Select the argument of interest in the Ports and Data Manager
- 2 In the **Data** properties dialog, select **Inherit: Same as Simulink** from the **Type** drop-down menu.

See “Built-In Data Types for Arguments” on page 43-63 for a list of supported data types.

---

**Note** An argument can also inherit its complexity (whether its value is a real or complex number) from the signal that is connected to it. To inherit complexity, set the **Complexity** field on the **Data** properties dialog to **Inherited**.

---

After you build the model, the **Compiled Type** column of the Ports and Data Manager gives the actual type inherited from Simulink in the compiled simulation application.

The inherited type of output data is inferred from diagram actions that store values in the specified output. In the preceding example, the variables `mean` and `stdev` are computed from operations with double operands, which yield results of type `double`. If the expected type matches the inferred type, inheritance is successful. In all other cases, a mismatch occurs during build time.

---

**Note** Library MATLAB Function blocks can have inherited data types, sizes, and complexities like ordinary MATLAB Function blocks. However, all instances of the library block in a given model must have inputs with the same properties.

---

## Built-In Data Types for Arguments

When you select **Built-in** for **Data type mode**, the **Data** properties dialog displays a **Data type** field that provides a drop-down list of supported data types. You can also choose a data type from the **Data Type** column in the Ports and Data Manager. The supported data types are:

| Data Type | Description                            |
|-----------|----------------------------------------|
| double    | 64-bit double-precision floating point |
| single    | 32-bit single-precision floating point |
| int32     | 32-bit signed integer                  |
| int16     | 16-bit signed integer                  |
| int8      | 8-bit signed integer                   |
| uint32    | 32-bit unsigned integer                |
| uint16    | 16-bit unsigned integer                |
| uint8     | 8-bit unsigned integer                 |
| boolean   | Boolean (1 = true; 0 = false)          |

## Specifying Argument Types with Expressions

You can specify the types of MATLAB Function block function arguments as expressions in the Ports and Data Manager.

- 1 Select `<data type expression>` from the **Type** drop-down menu of the Data properties dialog.
- 2 In the **Type** field, replace "`<data type expression>`" with an expression that evaluates to a data type. The following expressions are allowed:
  - Alias type from the MATLAB workspace, as described in `Simulink.AliasType`.
  - `fixdt` function to create a `Simulink.NumericType` object describing a fixed-point or floating-point data type
  - `type` (Stateflow) operator, to base the type on previously defined data

## Specifying Fixed-Point Designer Data Properties

MATLAB Function blocks can represent signals and parameter values as fixed-point numbers. To simulate models that use fixed-point data in MATLAB Function blocks, you must install the Fixed-Point Designer product on your system.

You can set the following fixed-point properties:

**Signedness.** Select whether you want the fixed-point data to be Signed or Unsigned. Signed data can represent positive and negative quantities. Unsigned data represents positive values only. The default is Signed.

**Word length.** Specify the size (in bits) of the word that will hold the quantized integer. Large word sizes represent large quantities with greater precision than small word sizes. Word length can be any integer between 0 and 128 bits. The default is 16.

**Scaling.** Specify the method for scaling your fixed point data to avoid overflow conditions and minimize quantization errors. You can select the following scaling modes:

| Scaling Mode           | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Binary point (default) | <p>If you select this mode, the Data Type Assistant displays the <b>Fraction Length</b> field, specifying the binary point location.</p> <p>Binary points can be positive or negative integers. A positive integer moves the binary point left of the rightmost bit by that amount. For example, an entry of 2 sets the binary point in front of the second bit from the right. A negative integer moves the binary point further right of the rightmost bit by that amount, as in this example:</p>  <p>The diagram shows a horizontal row of 16 small squares representing bits. Above the squares, a double-headed arrow spans the entire row and is labeled "16 bit binary word". Below the squares, two arrows point to specific positions. The first arrow points to the second square from the right and is labeled "binary point (fraction length = 2)". The second arrow points to the right edge of the row and is labeled "binary point (fraction length = -2)".</p> <p>The default is 0.</p> |
| Slope and bias         | <p>If you select this mode, the Data Type Assistant displays fields for entering the <b>Slope</b> and <b>Bias</b>.</p> <ul style="list-style-type: none"> <li>• Slope can be any <i>positive</i> real number. The default is 1.0.</li> <li>• Bias can be any real number. The default value is 0.0.</li> </ul> <p>You can enter slope and bias as expressions that contain parameters defined in the MATLAB workspace.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

---

**Note** You should use binary-point scaling whenever possible to simplify the implementation of fixed-point data in generated code. Operations with fixed-point data using binary-point scaling are performed with simple bit shifts and eliminate the expensive code implementations required for separate slope and bias values.

---

**Data type override.** Specify whether the data type override setting is `Inherit` (default) or `Off`.

**Calculate Best-Precision Scaling.** The Simulink software can automatically calculate “best-precision” values for both `Binary point` and `Slope and bias` scaling, based on the Limit range properties you specify.

To automatically calculate best precision scaling values:

- 1 Specify **Minimum**, **Maximum**, or both Limit range properties.
- 2 Click **Calculate Best-Precision Scaling**.

The Simulink software calculates the scaling values, then displays them in either the **Fraction Length**, or **Slope** and **Bias** fields.

---

**Note** The Limit range properties do not apply to `Constant` or `Parameter` scopes. Therefore, Simulink cannot calculate best-precision scaling for these scopes.

---

**Fixed-point Details.** You can view the following Fixed-point details:

| Fixed-point Detail    | Description                                                                                                                                     |
|-----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| Representable maximum | The maximum number that can be represented by the chosen data type, sign, word length and fraction length (or data type, sign, slope and bias). |
| Maximum               | The maximum value specified.                                                                                                                    |
| Minimum               | The minimum value specified.                                                                                                                    |
| Representable minimum | The minimum number that can be represented by the chosen data type, sign, word length and fraction length (or data type, sign, slope and bias). |

| Fixed-point Detail | Description                                                                      |
|--------------------|----------------------------------------------------------------------------------|
| Precision          | The precision for the given word length and fraction length (or slope and bias). |

### Using Data Type Override with the MATLAB Function Block

If you set the Data Type Override mode to `Double` or `Single` in Simulink, the MATLAB Function block sets the type of all inherited input signals and parameters to `fi_double` or `fi_single` objects respectively (see “MATLAB Function Block with Data Type Override” (Fixed-Point Designer) for more information). You must check the data types of your inherited input signals and parameters and use the Ports and Data Manager (see “Ports and Data Manager” on page 43-40) to set explicit types for any inputs that should not be fixed-point. Some operations, such as `sin`, are not applicable to fixed-point objects.

---

**Note** If you do not set the correct input types explicitly, you may encounter compilation problems after setting Data Type Override.

---

### How Do I Set Data Type Override?

To set Data Type Override, follow these steps:

- 1 From the Simulink **Analysis** menu, select **Fixed-Point Tool**.
- 2 Set the value of the **Data type override** parameter to `Double` or `Single`.

## Size Function Arguments

### In this section...

“Specifying Argument Size” on page 43-68

“Inheriting Argument Sizes from Simulink” on page 43-68

“Specifying Argument Sizes with Expressions” on page 43-69

### Specifying Argument Size

To examine or specify the size of an argument, follow these steps:

- 1 From the MATLAB Function Block Editor, select **Edit Data**.
- 2 Enter the size of the argument in the **Size** field of the Data properties dialog, located in the **General** pane.

---

**Note** The default value is -1, indicating that size is inherited, as described in “Inheriting Argument Sizes from Simulink” on page 43-68.

---

### Inheriting Argument Sizes from Simulink

Size defaults to -1, which means that the data argument inherits its size from Simulink based on its scope:

| For Scope | Inherits Size                                                                                            |
|-----------|----------------------------------------------------------------------------------------------------------|
| Input     | From the Simulink input signal connected to the argument.                                                |
| Output    | From the Simulink output signal connected to the argument.                                               |
| Parameter | From the Simulink or MATLAB parameter to which it is bound. See “Add Parameter Arguments” on page 43-73. |

After you compile the model, the **Compiled Size** column in the **Contents** pane displays the actual size used in the compiled simulation application.

The size of an output argument is the size of the value that is assigned to it. If the expected size in the Simulink model does not match, a mismatch error occurs during compilation of the model.

---

**Note** No arguments with inherited sizes are allowed for MATLAB Function blocks in a library.

---

## Specifying Argument Sizes with Expressions

The size of a data argument can be a scalar value or a MATLAB vector of values.

To specify size as a scalar, set the **Size** field to 1 or leave it blank. To specify **Size** as a vector, enter an array of up to two dimensions in [row column] format where

- Number of dimensions equals the length of the vector.
- Size of each dimension corresponds to the value of each element of the vector.

For example, a value of [2 4] defines a 2-by-4 matrix. To define a row vector of size 5, set the **Size** field to [1 5]. To define a column vector of size 6, set the **Size** field to [6 1] or just 6. You can enter a MATLAB expression for each [row column] element in the **Size** field. Each expression can use one or more of the following elements:

- Numeric constants
- Arithmetic operators, restricted to +, -, \*, and /
- Parameters
- Calls to the MATLAB functions min, max, and size

The following examples are valid expressions for **Size**:

```
k+1
size(x)
min(size(y),k)
```

In these examples, k, x, and y are variables of scope Parameter.

Once you build the model, the **Compiled Size** column displays the actual size used in the compiled simulation application.

## Units in MATLAB Function Blocks

### In this section...

“Units for Input and Output Data” on page 43-71

“Consistency Checking” on page 43-71

“Units for Stateflow Limitations” on page 43-71

### Units for Input and Output Data

MATLAB Function blocks support the specification of physical units as properties for data inputs and outputs. Specify units by using the **Unit (e.g., m, m/s<sup>2</sup>, N\*m)** parameter. When you start typing in the unit field, this parameter provides matching suggestions for units that Simulink supports. By default, the property is set to inherit the unit from the Simulink signal on the corresponding input or output port. If you select the **Data must resolve to Simulink signal object** property for output data, you cannot specify units. In this case, output data is assigned the same unit type as the Simulink signal connected to the output port.

To display the units on the Simulink lines in the model, select **Display > Signals and Ports > Port Units**.

### Consistency Checking

MATLAB Function blocks check the consistency of the signal line unit from Simulink with the unit setting for the corresponding input or output data in the block. If the units do not match, Simulink displays a warning during model update.

### Units for Stateflow Limitations

The unit property settings do not affect the execution of the MATLAB Function block. Simulink checks only consistency with the corresponding Simulink signal line connected to the input or output. It does not check consistency of assignments inside the MATLAB Function blocks. For example, Simulink does not warn against an assignment of an input with unit set to ft to an output with unit set to m. A MATLAB Function block does not perform unit conversions.

## Add Parameter Arguments

Parameter arguments for MATLAB Function blocks do not take their values from signals in the Simulink model. Instead, Simulink searches up the workspace hierarchy. Simulink first looks in a masked workspace if the MATLAB Function block or a parent subsystem is masked. If the value is not found, it next looks in the model workspace and then the MATLAB base workspace.

You can provide a custom interface for parameters by masking the MATLAB Function block. Creating a mask for a block allows you to define the access for each parameter.

- 1 In the MATLAB Function Block Editor, add an argument to the function header of the MATLAB Function block. The name of the argument must match the name of the masked parameter or MATLAB variable that you want to pass to the MATLAB Function block.

The new argument appears as an input port on the MATLAB Function block in the model.

- 2 In the MATLAB Function Block Editor, click **Edit Data**.
- 3 Select the new argument.
- 4 Set **Scope** to Parameter and click **Apply**.

The input port for the parameter argument no longer appears in the MATLAB Function block.

---

**Note** Parameter arguments appear as arguments in the function header of the MATLAB Function block to maintain MATLAB consistency. As a result, you can test functions in a MATLAB Function block by copying and pasting them to MATLAB.

## Resolve Signal Objects for Output Data

| In this section...                                                               |
|----------------------------------------------------------------------------------|
| “Implicit Signal Resolution” on page 43-74                                       |
| “Eliminating Warnings for Implicit Signal Resolution in the Model” on page 43-74 |
| “Disabling Implicit Signal Resolution for a MATLAB Function Block” on page 43-75 |
| “Forcing Explicit Signal Resolution for an Output Data Signal” on page 43-75     |

### Implicit Signal Resolution

MATLAB Function blocks participate in signal resolution with Simulink signal objects. By default, output data from MATLAB Function blocks become associated with Simulink signal objects of the same name during a process called *implicit signal resolution*.

By default, implicit signal resolution generates a warning when you update the chart in the Simulink model. The following sections show you how to manage implicit signal resolution at various levels of the model hierarchy. See “Symbol Resolution” on page 62-174 and “Explicit and Implicit Symbol Resolution” on page 62-177 for more information.

### Eliminating Warnings for Implicit Signal Resolution in the Model

To enable implicit signal resolution for all signals in a model, but eliminate the attendant warnings, follow these steps:

- 1 In the Simulink Editor, select **Simulation > Model Configuration Parameters**.

The Configuration Parameters dialog appears.

- 2 In the left pane of the Configuration Parameters dialog, under Diagnostics, select **Data Validity**.

Data Validity configuration parameters appear in the right pane.

- 3 In the Signal resolution field, select **Explicit and implicit**.

## Disabling Implicit Signal Resolution for a MATLAB Function Block

To disable implicit signal resolution for a MATLAB Function block in your model, follow these steps:

- 1 Right-click the MATLAB Function block and select **Block Parameters (Subsystem)** in the context menu.

The Block Parameters dialog opens.

- 2 In the Permit hierarchical resolution field, select **ExplicitOnly** or **None**, and click **OK**.

## Forcing Explicit Signal Resolution for an Output Data Signal

To force signal resolution for an output signal in a MATLAB Function block, follow these steps:

- 1 In the Simulink model, right-click the signal line connected to the output that you want to resolve and select **Properties** from the context menu.
- 2 In the Signal Properties dialog, enter a name for the signal that corresponds to the signal object.
- 3 Select the **Signal name must resolve to Simulink signal object** check box and click **OK**.

## Types of Structures in MATLAB Function Blocks

In MATLAB Function blocks, you can define structure data as inputs or outputs that interact with bus signals. MATLAB Function blocks also support arrays of buses. You can also define structures inside MATLAB functions that are not part of MATLAB Function blocks.

The following table summarizes how to create different types of structures in MATLAB Function blocks:

| Scope      | How to Create                                             | Details                                                                                                                                                                                     |
|------------|-----------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Input      | Create structure data with scope of <b>Input</b> .        | You can create structure data as inputs or outputs in the top-level MATLAB function for interfacing to other environments. See “Create Structures in MATLAB Function Blocks” on page 43-85. |
| Output     | Create structure data with scope of <b>Output</b> .       |                                                                                                                                                                                             |
| Local      | Create a local variable implicitly in a MATLAB function.  | See “Define Scalar Structures for Code Generation” on page 53-4.                                                                                                                            |
| Persistent | Declare a variable to be persistent in a MATLAB function. | See <i>persistent</i> .                                                                                                                                                                     |
| Parameter  | Create structure data with scope of <b>Parameter</b> .    | See “Define and Use Structure Parameters” on page 43-92.                                                                                                                                    |

Structures in MATLAB Function blocks can contain fields of any type and size, including muxed signals, buses, and arrays of structures.

## Attach Bus Signals to MATLAB Function Blocks

For an example of how to use structures in a MATLAB Function block, open the model `emldemo_bus_struct`.

In this model, a MATLAB Function block receives a bus signal using the structure `inbus` at input port 1 and outputs two bus signals from the structures `outbus` at output port 1 and `outbus1` at output port 2. The input signal comes from the Bus Creator block `MainBusCreator`, which bundles signals `ele1`, `ele2`, and `ele3`. The signal `ele3` is the output of another Bus Creator block `SubBusCreator`, which bundles the signals `a1` and `a2`. The structure `outbus` connects to a Bus Selector block `BusSelector1`; the structure `outbus1` connects to another Bus Selector block `BusSelector3`.

To explore the MATLAB function `fcn`, double-click the MATLAB Function block. Notice that the code implicitly defines a local structure variable `mystruct` using the `struct` function, and uses this local structure variable to initialize the value of the first output `outbus`. It initializes the second output `outbus1` to the value of field `ele3` of structure `inbus`.

### Structure Definitions in Example

Here are the definitions of the structures in the MATLAB Function block in the example, as they appear in the Ports and Data Manager:

|                                                                                     | Name                 | Scope  | Port | Resolve Signal           | DataType                  | Size |
|-------------------------------------------------------------------------------------|----------------------|--------|------|--------------------------|---------------------------|------|
|  | <code>inbus</code>   | Input  | 1    | <input type="checkbox"/> | Inherit: Same as Simulink | -1   |
|  | <code>outbus</code>  | Output | 1    | <input type="checkbox"/> | Bus: MainBus              | 1    |
|  | <code>outbus1</code> | Output | 2    | <input type="checkbox"/> | Bus: SubBus               | 1    |

### Bus Objects Define Structure Inputs and Outputs

Each structure input and output must be defined by a `Simulink.Bus` object in the base workspace (see “Create Structures in MATLAB Function Blocks” on page 43-85). This means that the structure shares the same properties as the bus object, including number, name, type, and sequence of fields. In this example, the following bus objects define the structure inputs and outputs:

The screenshot shows a Simulink workspace with a tree view on the left and a table on the right. The tree view shows a hierarchy: Base Workspace > MainBus (with fields ele1, ele2) > ele3(SubBus) > SubBus (with fields a1, a2). The table on the right lists the field definitions for these objects.

| Name       | Data Type | Complexity | Dimensions | Dimension |
|------------|-----------|------------|------------|-----------|
| ele1       | double    | real       | 1          | Fixed     |
| ele2       | single    | real       | 1          | Fixed     |
| ele3(Su... | SubBus    | real       | 1          | Fixed     |

The `Simulink.Bus` object `MainBus` defines structure input `inbus` and structure output `outbus`. The `Simulink.Bus` object `SubBus` defines structure output `outbus1`. Based on these definitions, `inbus` and `outbus` have the same properties as `MainBus` and, therefore, reference their fields by the same names as the fields in `MainBus`, using dot notation (see “Index Substructures and Fields” on page 43-83). Similarly, `outbus1` references its fields by the same names as the fields in `SubBus`. Here are the field references for each structure in this example:

| Structure            | First Field              | Second Field             | Third Field              |
|----------------------|--------------------------|--------------------------|--------------------------|
| <code>inbus</code>   | <code>inbus.ele1</code>  | <code>inbus.ele2</code>  | <code>inbus.ele3</code>  |
| <code>outbus</code>  | <code>outbus.ele1</code> | <code>outbus.ele2</code> | <code>outbus.ele3</code> |
| <code>outbus1</code> | <code>outbus1.a1</code>  | <code>outbus1.a2</code>  | —                        |

## How Structure Inputs and Outputs Interface with Bus Signals

Buses in a Simulink model appear inside the MATLAB Function block as structures; structure outputs from the MATLAB Function block appear as buses in Simulink models. When you create structure inputs, the MATLAB Function block determines the type, size, and complexity of the structure from the input signal. When you create structure outputs, you must define their type, size, and complexity in the MATLAB function.

You connect structure inputs and outputs from MATLAB Function blocks to any bus signal, including:

- Blocks that output bus signals — such as Bus Creator blocks
- Blocks that accept bus signals as input — such as Bus Selector and Gain blocks
- S-Function blocks
- Other MATLAB Function blocks

You can use global bus type data in Data Store Memory blocks with MATLAB Function blocks. For more information on using buses and Data Store Memory, see “Data Stores with Buses and Arrays of Buses” on page 65-31.

### Working with Virtual and Nonvirtual Buses

MATLAB Function blocks supports nonvirtual buses only (see “Virtual and Nonvirtual Buses” on page 68-4). For MATLAB Function block bus inputs, incoming virtual bus signals are converted to nonvirtual buses.

## Rules for Defining Structures in MATLAB Function Blocks

Follow these rules when defining structures in MATLAB Function blocks:

- For each structure input or output in a MATLAB Function block, you must define a `Simulink.Bus` object in the base workspace to specify its type.
- MATLAB Function blocks support nonvirtual buses only.

## Index Substructures and Fields

As in MATLAB, you index substructures and fields structures in MATLAB Function blocks by using dot notation. However, for code generation from MATLAB, you must reference field values individually (see “Structure Definition for Code Generation” on page 53-2).

For example, in the `emldemo_bus_struct` model described in “Attach Bus Signals to MATLAB Function Blocks” on page 43-78, the MATLAB function uses dot notation to index fields and substructures:

```
function [outbus, outbus1] = fcn(inbus)
%#codegen
substruct.a1 = inbus.ele3.a1;
substruct.a2 = int8([1 2;3 4]);

mystruct = struct('ele1',20.5,'ele2',single(100),
 'ele3',substruct);

outbus = mystruct;
outbus.ele3.a2 = 2*(substruct.a2);

outbus1 = inbus.ele3;
```

The following table shows how the code generation software resolves symbols in dot notation for indexing elements of the structures in this example:

| Dot Notation                    | Symbol Resolution                                                                                                                   |
|---------------------------------|-------------------------------------------------------------------------------------------------------------------------------------|
| <code>substruct.a1</code>       | Field <code>a1</code> of local structure <code>substruct</code>                                                                     |
| <code>inbus.ele3.a1</code>      | Value of field <code>a1</code> of field <code>ele3</code> , a substructure of structure <code>inputinbus</code>                     |
| <code>inbus.ele3.a2(1,1)</code> | Value in row 1, column 1 of field <code>a2</code> of field <code>ele3</code> , a substructure of structure <code>input inbus</code> |

## Create Structures in MATLAB Function Blocks

Here is the workflow for creating a structure in a MATLAB Function block:

- 1 Decide on the type (or scope) of the structure (see “Types of Structures in MATLAB Function Blocks” on page 43-76).
- 2 Based on the scope, follow these guidelines for creating the structure:

| For Structure Scope: | Follow These Steps:                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Input                | <p><b>a</b> Create a <code>Simulink.Bus</code> object in the base workspace to define the structure input.</p> <p><b>b</b> Add data to the MATLAB Function block, as described in “Adding Data to a MATLAB Function Block” on page 43-47. The data should have the following properties</p> <ul style="list-style-type: none"> <li>• <b>Scope</b> = Input</li> <li>• <b>Type</b> = Bus: &lt;object name&gt;</li> </ul> <p>For &lt;object name&gt;, enter the name of the <code>Simulink.Bus</code> object that defines the structure input</p> <p>See “Rules for Defining Structures in MATLAB Function Blocks” on page 43-82.</p> |

| <b>For Structure Scope:</b> | <b>Follow These Steps:</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Output                      | <p><b>a</b> Create a <code>Simulink.Bus</code> object in the base workspace to define the structure output.</p> <p><b>b</b> Add data to the MATLAB Function block with the following properties:</p> <ul style="list-style-type: none"> <li>• <b>Scope</b> = Output</li> <li>• <b>Type</b> = Bus: &lt;object name&gt;</li> </ul> <p>For &lt;object name&gt;, enter the name of the <code>Simulink.Bus</code> object that defines the structure output</p> <p><b>c</b> Define and initialize the output structure implicitly as a variable in the MATLAB function, as described in “Structure Definition for Code Generation” on page 53-2.</p> <p><b>d</b> Make sure the number, type, and size of fields in the output structure variable definition match the properties of the <code>Simulink . Bus</code> object.</p> |
| Local                       | Define the structure implicitly as a local variable in the MATLAB function, as described in “Structure Definition for Code Generation” on page 53-2. By default, local variables in MATLAB Function blocks are temporary.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| Persistent                  | Define the structure implicitly as a persistent variable in the MATLAB function.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| Parameter                   | <p><b>a</b> Create a structure variable in the base workspace.</p> <p><b>b</b> Add data to the MATLAB Function block with the following properties:</p> <ul style="list-style-type: none"> <li>• <b>Name</b> = same name as the structure variable you created in step 1.</li> <li>• <b>Scope</b> = Parameter</li> </ul> <p>See “Define and Use Structure Parameters” on page 43-92.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                  |

## Assign Values to Structures and Fields

You can assign values to any structure, substructure, or field in a MATLAB Function block. Here are the guidelines:

| Operation                                                                      | Conditions                                                                                                                                                                                                                                                        |
|--------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Assign one structure to another structure                                      | You must define each structure with the same number, type, and size of fields, either as <code>Simulink.Bus</code> objects in the base workspace or locally as implicit structure declarations (see “Create Structures in MATLAB Function Blocks” on page 43-85). |
| Assign one structure to a substructure of a different structure and vice versa | You must define the structure with the same number, type, and size of fields as the substructure, either as <code>Simulink.Bus</code> objects in the base workspace or locally as implicit structure declarations.                                                |
| Assign an element of one structure to an element of another structure          | The elements must have the same type and size.                                                                                                                                                                                                                    |

For example, the following table presents valid and invalid structure assignments based on the specifications for the model described in “Attach Bus Signals to MATLAB Function Blocks” on page 43-78:

| Assignment                         | Valid or Invalid? | Rationale                                                                                                                                                                                                                                                                                                         |
|------------------------------------|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>outbus = mystruct;</code>    | Valid             | Both <code>outbus</code> and <code>mystruct</code> have the same number, type, and size of fields. The structure <code>outbus</code> is defined by the <code>Simulink.Bus</code> object <code>MainBus</code> and <code>mystruct</code> is defined locally to match the field properties of <code>MainBus</code> . |
| <code>outbus = inbus;</code>       | Valid             | Both <code>outbus</code> and <code>inbus</code> are defined by the same <code>Simulink.Bus</code> object, <code>MainBus</code> .                                                                                                                                                                                  |
| <code>outbus1 = inbus.ele3;</code> | Valid             | Both <code>outbus1</code> and <code>inbus.ele3</code> have the same type and size because each is defined by the <code>Simulink.Bus</code> object <code>SubBus</code> .                                                                                                                                           |

| <b>Assignment</b> | <b>Valid or Invalid?</b> | <b>Rationale</b>                                                                              |
|-------------------|--------------------------|-----------------------------------------------------------------------------------------------|
| outbus1 = inbus;  | Invalid                  | The structure outbus1 is defined by a different Simulink.Bus object than the structure inbus. |

## Initialize a Matrix Using a Nontunable Structure Parameter

The following simple example uses a nontunable structure parameter input to initialize a matrix output. The model looks like this:

This model defines a structure variable `p` in its pre-load callback function, as follows:

The structure `p` has two fields, `rows` and `cols`, which specify the dimensions of a matrix. The MATLAB Function block uses a constant input `u` to initialize the matrix output `y`. Here is the code:

```
function y = fcn(u, p)
y = zeros(p.rows,p.cols) + u;
```

Running the model initializes each element of the 2-by-3 matrix `y` to 99, the value of `u`:

“FIMATH Properties of Nontunable Structure Parameters” on page 43-92

### Defining Structure Parameters

To define structure parameters in MATLAB Function blocks, follow these steps:

- 1 Define and initialize a structure variable

A common method is to create a structure in the base workspace.

- 2 In the Ports and Data Manager, add data in the MATLAB Function block with the following properties:

| Property | What to Specify                                                                                                                                                                             |
|----------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Name     | Enter same name as the structure variable you defined in the base workspace                                                                                                                 |
| Scope    | Select Parameter                                                                                                                                                                            |
| Tunable  | Leave checked if you want to change (tune) the value of the parameter during simulation; otherwise, clear to make the parameter nontunable and preserve the initial value during simulation |
| Type     | Select Inherit: Same as Simulink                                                                                                                                                            |

- 3 Click **Apply**.

### FIMATH Properties of Nontunable Structure Parameters

FIMATH properties for nontunable structure parameters containing fixed-point values are based on the initial values of the structure. They do *not* come from the FIMATH properties specified for fixed-point input signals to the parent MATLAB Function block. (These FIMATH properties appear in the properties dialog box for MATLAB Function blocks.)

## Limitations of Structures and Buses in MATLAB Function Blocks

- Structures in MATLAB Function blocks support a subset of the operations available for MATLAB structures (see “Structures”).
- You cannot use structures that contain cell arrays or classes for Simulink signals, parameters, or data store memory.
- You cannot use variable-size data with arrays of buses (see “Array of Buses Requirements and Limitations” on page 68-126).

## Control Support for Variable-Size Arrays in a MATLAB Function Block

By default, support for variable-size arrays is enabled for a MATLAB Function block. To disable this support:

- 1 In the MATLAB Function Block Editor, select **Edit Data**.
- 2 Clear the **Support variable-size arrays** check box.

## Declare Variable-Size Inputs and Outputs

By default, a MATLAB Function block input signal or output signal is not variable-size. To make the signal variable-size:

- 1 In the MATLAB Function Block Editor, select **Edit Data**.
- 2 Select the input or output signal.
- 3 Select the **Variable size** check box.
- 4 Enter the size according to this table.

| For:   | Specify                                                                                                                                                         |
|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Input  | To inherit the size from Simulink, enter -1.<br><br>Otherwise, specify the explicit size and upper bound. For example, to specify a 2-by-4 matrix, enter [2 4]. |
| Output | Specify the explicit size and upper bound.                                                                                                                      |

“Source Signal” on page 43-98

“MATLAB Function Block: uniquify” on page 43-98

“MATLAB Function Block: avg” on page 43-100

“Variable-Size Results” on page 43-101

### About the Example

This example uses a variable-size vector to store the values of a white noise signal. The size of the vector can vary at run time because the signal values get pruned by functions that:

- Filter out signal values that are not unique within a specified tolerance of each other.
- Average every two signal values and output only the resulting means.

### Simulink Model

Open the example model by typing `emldemo_process_signal` at the MATLAB command prompt. The model contains the following blocks:

| Simulink Block                        | Description                                                                                    |
|---------------------------------------|------------------------------------------------------------------------------------------------|
| Band-Limited White Noise              | Generates a set of normally distributed random values as the source of the white noise signal. |
| MATLAB Function <code>uniquify</code> | Filters out signal values that are not unique to within a specified tolerance of each other.   |
| MATLAB Function <code>avg</code>      | Outputs the average of a specified number of unique signal values.                             |

| Simulink Block | Description                                                                                  |
|----------------|----------------------------------------------------------------------------------------------|
| Unique values  | Scope that displays the unique signal values output from the <code>uniquify</code> function. |
| Average values | Scope that displays the average signal values output from the <code>avg</code> function.     |

## Source Signal

The band-limited white noise signal has these properties:

Parameters

Noise power:  
[0.1 0.2 0.3 0.4 0.5 0.6 0.1 0.2 0.3]

Sample time:  
0.1

Seed:  
[2223334]

Interpret vector parameters as 1-D

The size of the noise power value defines the size of the array that holds the signal values. This array is a 1-by-9 vector of double values.

## MATLAB Function Block: `uniquify`

This block filters out signal values that are not within a tolerance of 0.2 of each other. Here is the code:

```
function y = uniquify(u) %#codegen
y = emldemo_uniquetol(u,0.2);
```

The `uniquify` function calls an external MATLAB function `emldemo_uniquetol` to filter the signal values. `uniquify` passes the 1-by-9 vector of white noise signal values as the first argument and the tolerance value as the second argument. Here is the code for `emldemo_uniquetol`:

```
function B = emldemo_uniquetol(A,tol) %#codegen

A = sort(A);
coder.varsize('B',[1 100]);
B = A(1);
k = 1;
for i = 2:length(A)
 if abs(A(k) - A(i)) > tol
 B = [B A(i)];
 k = i;
 end
end
```

`emldemo_uniquetol` returns the filtered values of `A` in an output vector `B` so that  $\text{abs}(B(i) - B(j)) > \text{tol}$  for all `i` and `j`. Every time Simulink samples the Band-Limited White Noise block, it generates a different set of random values for `A`. As a result, `emldemo_uniquetol` may produce a different number of output signals in `B` each time it is called. To allow `B` to accommodate a variable number of elements, `emldemo_uniquetol` declares it as variable-size data with an explicit upper bound:

```
coder.varsize('B',[1 100]);
```

In this statement, `coder.varsize` declares `B` as a vector whose first dimension is fixed at 1 and whose second dimension can grow to a maximum size of 100. Accordingly, output `y` of the `uniquify` block must also be variable-size so that it can pass the values returned from `emldemo_uniquetol` to the **Unique values** scope. Here are the properties of `y`:

**Data y**

General Description

Name:

Scope:  Port:

Data must resolve to Simulink signal object

Size:   Variable size

Complexity:

Sampling mode:

Type:

For variable-size outputs, you must specify an explicit size and upper bound, shown here as [1 9].

## MATLAB Function Block: avg

This block averages signal values filtered by the `uniquify` block as follows:

| If number of signal values is     | The MATLAB Function block                                                    |
|-----------------------------------|------------------------------------------------------------------------------|
| > 1 and divisible by 2            | Averages every consecutive pair of values                                    |
| > 1 but <i>not</i> divisible by 2 | Drops the first (smallest) value and average the remaining consecutive pairs |
| = 1                               | Returns the value unchanged                                                  |

The `avg` function outputs the results to the **Average values** scope. Here is the code:

```
function y = avg(u) %#codegen

if numel(u) == 1
 y = u;
else
 k = numel(u)/2;
 if k ~= floor(k)
 u = u(2:numel(u));
 end
 y = emldemo_navg(u,2);
end
```

Both input `u` and output `y` of `avg` are declared as variable-size vectors because the number of elements varies depending on how the `uniquify` function block filters the signal values. Input `u` inherits its size from the output of `uniquify`.

**Data u**

General Description

Name: u

Scope: Input Port: 1

Size: -1  Variable size

Complexity: Inherited

Type: Inherit: Same as Simulink >>

The avg function calls an external MATLAB function `emldemo_navg` to calculate the average of every two consecutive signal values. Here is the code for `emldemo_navg`:

```
function B = emldemo_navg(A,n) %#codegen

assert(n>=1 && n<=numel(A));

B = zeros(1,numel(A)/n);
k = 1;
for i = 1 : numel(A)/n
 B(i) = mean(A(k + (0:n-1)));
 k = k + n;
end
```

## Variable-Size Results

Simulating the model produces the following results:

- The `uniquify` block outputs a variable number of signal values each time it executes:

- The avg block outputs a variable number of signal values each time it executes — approximately half the number of the unique values:

## Control Memory Allocation for Variable-Size Arrays in a MATLAB Function Block

Dynamic memory allocation allocates memory on the heap as needed at run time, instead of allocating memory statically on the stack. You can use dynamic memory allocation for arrays inside a MATLAB Function block.

You cannot use dynamic memory allocation for:

- Input and output signals. Variable-size input and output signals must have an upper bound.
- Parameters or global variables. Parameters and global variables must be fixed-size.
- Fields of bus arrays. Bus arrays cannot have variable-size fields.
- Discrete state properties of System objects associated with a MATLAB System block.

Dynamic memory allocation is beneficial when:

- You do not know the upper bound of an array.
- You do not want to allocate memory on the stack for large arrays.

Dynamic memory allocation and the freeing of this memory can result in slower execution of the generated code. To control the use of dynamic memory allocation for variable-size arrays in a MATLAB Function block, you can:

- Provide upper bounds for variable-size arrays on page 43-105.
- Disable dynamic memory allocation for MATLAB Function blocks on page 43-106.
- Modify the dynamic memory allocation threshold on page 43-106.

### Provide Upper Bounds for Variable-Size Arrays

For an unbounded variable-size array, the code generator allocates memory dynamically on the heap. For a bounded variable-size array, if the size, in bytes, is less than the dynamic memory allocation threshold, the code generator allocates memory statically on the stack. To avoid dynamic memory allocation, provide upper bounds for the array dimensions so that the size of the array, in bytes, is less than the dynamic memory allocation threshold. See “Specify Upper Bounds for Variable-Size Arrays” on page 52-5.

## Disable Dynamic Memory Allocation for MATLAB Function Blocks

By default, dynamic memory allocation for MATLAB Function blocks is enabled for GRT-based targets and disabled for ERT-based targets. To change the setting, in the Configuration Parameters dialog box, clear or select **Dynamic memory allocation in MATLAB functions**.

If you disable dynamic memory allocation, you must provide upper bounds for variable-size arrays.

## Modify the Dynamic Memory Allocation Threshold

Instead of disabling dynamic memory allocation for all variable-size arrays, you can use the dynamic memory allocation threshold to specify when the code generator uses dynamic memory allocation.

Use the dynamic memory allocation threshold to:

- Disable dynamic memory allocation for smaller arrays. For smaller arrays, static memory allocation can speed up generated code. However, static memory allocation can lead to unused storage space. You can decide that the unused storage space is not a significant consideration for smaller arrays.
- Enable dynamic memory allocation for larger arrays. For larger arrays, when you use dynamic memory allocation, you can significantly reduce storage requirements.

The default value of the dynamic memory allocation threshold is 64 kilobytes. To change the threshold, in the Configuration Parameters dialog box, set the **Dynamic memory allocation threshold in MATLAB functions** parameter.

To use dynamic memory allocation for all variable-size arrays, set the threshold to 0.

## Use Dynamic Memory Allocation for Variable-Size Arrays in a MATLAB Function Block

This example shows how to use dynamic memory allocation for variable-size arrays in a MATLAB Function block. Dynamic memory allocation allocates memory on the heap as needed at run time, instead of allocating memory statically on the stack. Dynamic memory allocation is beneficial when:

- You do not know the upper bound of an array.
- You do not want to allocate memory on the stack for large arrays.

You can use dynamic memory allocation only for arrays that are local to the MATLAB Function block.

You cannot use dynamic memory allocation for:

- Input and output signals. Variable-size input and output signals must have an upper bound.
- Parameters or global variables. Parameters and global variables must be fixed-size.
- Fields of bus arrays. Bus arrays cannot have variable-size fields.
- Discrete state properties of System objects associated with a MATLAB System block.

### Create Model

Create this Simulink model that has a MATLAB Function block with an unbounded variable-size array.

- 1 Create a Simulink model `mymodel`.
- 2 Add a MATLAB Function block to the model.
- 3 In the MATLAB Function block, add this code:

```
function s = myfcn(n)
Z = rand(1,n);
s = sum(Z);
end
```

- 4 Add a Constant block to the left of the MATLAB Function block.
- 5 Add an Outport block to the right of the MATLAB Function block.
- 6 Connect the blocks.

## Configure Model for Dynamic Memory Allocation

Make sure that you configure the model to use dynamic memory allocation for variable-size arrays in MATLAB Function blocks. In the Configuration Parameters dialog box, in the **Simulation Target > Advanced parameters** category, make sure that:

- The **Dynamic memory allocation in MATLAB functions** check box is selected.
- The **Dynamic memory allocation threshold in MATLAB functions** parameter has the default value 65536.

## Simulate Model Using Dynamic Memory Allocation

- 1 Simulate the model.
- 2 In the MATLAB Function Editor, to open the MATLAB Function report, click **View Report**.

The variables tab shows that Z is a 1-by-?: array. The colon (:) indicates that the second dimension is variable-size. The question mark (?) indicates that the second dimension is unbounded.

Simulation must use dynamic memory allocation for Z because the second dimension of Z does not have an upper bound.

## Use Dynamic Memory Allocation for Bounded Arrays

When an array is unbounded, the code generator must use dynamic memory allocation. If an array is bounded, the code generator uses dynamic memory allocation only if the array size, in bytes, is greater than or equal to the dynamic memory allocation threshold. The default value for this threshold is 65536.

Dynamic memory has a run-time performance cost. By controlling its use, you can improve execution speed.

If you make Z a bounded variable-size array with a size that is greater than the threshold, the code generator uses dynamic memory allocation for Z. For example:

- 1 In `mymodel`, modify `myfcn` so that Z has an upper bound of 500.

```
function s = myfcn(n)
assert(n < 500);
Z = rand(1,n);
s = sum(Z);
end
```

- 2 Simulate the model.

In the MATLAB Function report, you see that Z is a 1-by-500 array. It is variable-size with an upper bound of 500.

- 3 Lower the dynamic memory allocation to a value less than or equal to 4000, which is the size, in bytes, of Z. In the Configuration Parameters dialog box, in the **Simulation Target > Advanced parameters** category, set the **Dynamic memory allocation threshold in MATLAB functions** parameter to 4000.
- 4 Simulate the model.

The code generator uses dynamic memory allocation because the size of Z is equal to the dynamic memory allocation threshold, 4000.

## Generate C Code That Uses Dynamic Memory Allocation

If you have Simulink Coder, you can generate C code for this model. Then, you can see how the code generator represents dynamically allocated arrays.

- 1 Configure the model to use a fixed-step solver. In the Configuration Parameters dialog box, in the **Solver** pane, under **Solver selection**:
  - For **Type**, select **Fixed-step**.
  - For **Solver**, select **discrete (no continuous states)**.
- 2 Configure the model to create and use a code generation report. In the Configuration Parameters dialog box, in the **Code Generation > Report** pane, select **Create code generation report** and **Open report automatically**.

- 3 Edit the code in the MATLAB Function block so that it looks like this code:

```
function s = myfcn(n)
Z = rand(1,n);
s = sum(Z);
end
```

Z is an unbounded variable-size array.

- 4 Make sure that the model is configured for dynamic memory allocation:
  - The **Dynamic memory allocation in MATLAB functions** check box is selected.
  - The **Dynamic memory allocation threshold in MATLAB functions** parameter has the default value 65536.
- 5 Build the model.
- 6 In the code generation report, open `mymodel.c`. You can tell that the code generator used dynamic memory allocation for Z because you see the `emxArray` type `emxArray_real_T_mymodel_T` and `emxArray` utility functions, such as `mymodel_emxInit_real_T`. The code generator uses an `emxArray` type for variables whose memory is dynamically allocated. The generated code uses the `emxArray` utility functions to manage the `emxArrays`.

If you have Embedded Coder, you can customize the identifiers for `emxArray` types and the utility functions. See “Identifier Format Control” (Embedded Coder).

## Code Generation for Enumerations

Enumerations represent a fixed set of named values. Enumerations help make your MATLAB code and generated C/C++ code more readable. For example, the generated code can test equality with code such as `if (x == Red)` instead of using `strcmp`. To generate C/C++ code, you must have Simulink Coder.

When you use enumerations in a MATLAB Function block, adhere to these restrictions:

- Calls to methods of enumeration classes are not supported.
- For a MATLAB Function block, you can import an externally defined type by using `Simulink.defineIntEnumType` or you can define an enumeration class. The enumeration class must derive from one of these base types: `Simulink.IntEnumType`, `int8`, `uint8`, `int16`, `uint16`, or `int32`. See “Define Enumerations for MATLAB Function Blocks” on page 43-112.
- You can use only a limited set of operations on enumerations. See “Allowed Operations on Enumerations” on page 43-114.
- Use enumerations with functions that support enumerated types for code generation. See “MATLAB Toolbox Functions That Support Enumerations” on page 43-115.

### Define Enumerations for MATLAB Function Blocks

You can define enumerations for MATLAB Function blocks in two ways:

- To import an externally defined enumeration, use the `Simulink.defineIntEnumType` function. See “Import Enumerations Defined Externally to MATLAB” on page 63-13.
- In a class definition file, define an enumerated type. For example:

```
classdef PrimaryColors < Simulink.IntEnumType
 enumeration
 Red(1),
 Blue(2),
 Yellow(4)
 end
end
```

If you define an enumerated type in a class definition file, the class must derive from one of these base types: `Simulink.IntEnumType`, `int8`, `uint8`, `int16`, `uint16`, or `int32`.

Then, you can exchange enumerated data between MATLAB Function blocks and other Simulink blocks in a model.

If you use Simulink Coder to generate C/C++ code, you can use the enumeration class base type to control the size of an enumerated type in generated C/C++ code. You can:

- Represent an enumerated type as a fixed-size integer that is portable to different targets.
- Reduce memory usage.
- Interface with legacy code.
- Match company standards.

The base type determines the representation of the enumerated type in generated C/C++ code.

If the base type is `Simulink.IntEnumType`, the code generator produces a C enumeration type. Consider the following MATLAB enumerated type definition:

```
classdef LEDcolor < Simulink.IntEnumType
 enumeration
 GREEN(1),
 RED(2)
 end
end
```

This enumerated type definition results in the following C code:

```
typedef enum {
 GREEN = 1,
 RED
} LEDcolor;
```

For built-in integer base types, the code generator produces a `typedef` statement for the enumerated type and `#define` statements for the enumerated values. Consider the following MATLAB enumerated type definition:

```
classdef LEDcolor < int16
 enumeration
 GREEN(1),
 RED(2)
 end
end
```

This enumerated type definition results in the following C code:

```
typedef int16_T LEDcolor;

#define GREEN ((LEDcolor)1)
#define RED ((LEDcolor)2)
```

To customize the code generated for an enumerated type, see “Customize Simulink Enumeration” on page 63-10.

### Allowed Operations on Enumerations

For code generation, you are restricted to the operations on enumerations listed in this table.

| Operation                                | Example              | Notes                                                                                                                                                                      |
|------------------------------------------|----------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| assignment operator: =                   |                      | —                                                                                                                                                                          |
| relational operators: < ><br><= >= == ~= | xon == xoff          | Code generation does not support using == or ~= to test equality between an enumeration member and a string array, a character array, or a cell array of character arrays. |
| cast operation                           | double(LEDcolor.RED) | —                                                                                                                                                                          |

## MATLAB Toolbox Functions That Support Enumerations

For code generation, you can use enumerations with these MATLAB toolbox functions:

- cast
- cat
- char
- circshift
- enumeration
- fliplr
- flipud
- histc
- intersect
- ipermute
- isequal
- isequaln
- isfinite
- isinf
- ismember
- isnan
- issorted
- length
- permute
- repmat
- reshape
- rot90
- setdiff
- setxor
- shiftdim
- sort
- sortrows
- squeeze
- string
- union

- `unique`

## Add Enumerated Inputs, Outputs, and Parameters to a MATLAB Function Block

When you add enumerated inputs, outputs, or parameters to a MATLAB Function block, follow these guidelines:

- For inputs, inherit the type from the enumerated type of the connected Simulink signal or specify the enumeration explicitly.
- For outputs, specify the enumerated type explicitly.
- For tunable parameters, specify the enumerated type explicitly. For nontunable parameters, derive properties from an enumerated parameter in a parent Simulink masked subsystem or enumerated variable defined in the MATLAB base workspace.

To add enumerated data to a MATLAB Function block:

- 1 In the MATLAB Function Block Editor, select **Edit Data**.
- 2 In the Ports and Data Manager, select **Add > Data**.
- 3 In the **Name** field, enter a name for the enumerated data.

For parameters, the name must match the enumerated masked parameter or workspace variable name.

- 4 In the **Type** field, specify an enumerated type.
  - For an explicit enumerated type, set **Type** to Enum:<class name>. Replace <class name> with the name of an enumerated data type that you defined in a MATLAB file on the MATLAB path.

The **Complexity** field is not visible because enumerated data types do not support complex values.

- To inherit the enumerated type from a connected Simulink signal (for inputs only), set **Type** to Inherit:Same as Simulink.

## Use Enumerations to Control an LED Display

### In this section...

“Simulink Model” on page 43-120

“Enumeration Class Definitions” on page 43-121

“MATLAB Function Block Function” on page 43-122

“Simulation” on page 43-122

This example shows how to use enumerations in a MATLAB Function block. The example shows how MATLAB Function blocks exchange enumerated data with other Simulink blocks.

The `emldemo_led_switch` model uses enumerations to represent the modes of a device that controls the colors of an LED display. The MATLAB Function block receives an enumerated input signal that represents the mode. The enumerated output signal represents the color that the LED displays.

### Simulink Model

To open the model, at the command prompt, enter:

```
emldemo_led_switch
```

The model contains the blocks listed in this table.

| Simulink Block                            | Description                                                                                                                |
|-------------------------------------------|----------------------------------------------------------------------------------------------------------------------------|
| Step                                      | Provides source of the on/off signal. Outputs an initial value of 0 (off) and at 10 seconds steps up to a value of 1 (on). |
| Data Type Conversion from double to int32 | Converts the Step signal of type double to type int32.                                                                     |

| Simulink Block                                                | Description                                                                                                                                                                                                                                                                                          |
|---------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Data Type Conversion from int32 to enumerated type switchmode | <p>Converts the value of type int32 to the enumerated type switchmode.</p> <p>The Data Type Conversion block parameters have these settings:</p> <ul style="list-style-type: none"> <li>• Output minimum: [ ]</li> <li>• Output maximum: [ ]</li> <li>• Output data type: Enum:switchmode</li> </ul> |
| MATLAB Function block checkState                              | Evaluates the enumerated input state to determine the value of the enumerated output ledval. state inherits its enumerated type switchmode from the Simulink step signal. ledval has the type Enum:led.                                                                                              |
| Display                                                       | Displays the value of ledval.                                                                                                                                                                                                                                                                        |

## Enumeration Class Definitions

The switchmode enumeration represents the allowed modes for the input to the checkstate block.

```
classdef switchmode < Simulink.IntEnumType
 enumeration
 OFF(0)
 ON(1)
 end
end
```

The led enumeration represents the colors that the checkstate block can output.

```
classdef led < Simulink.IntEnumType
 enumeration
 GREEN(1),
 RED(8)
 end
end
```

Both enumeration classes inherit from the built-in type Simulink.IntEnumType and reside on the MATLAB path.

## MATLAB Function Block Function

The function `checkState` uses enumerations to activate an LED display, based on the state of a device. It lights a green LED display to indicate the ON state. It lights a red LED display to indicate the OFF state.

```
function ledval = checkState(state)
%#codegen

if state == switchmode.ON
 ledval = led.GREEN;
else
 ledval = led.RED;
end
```

## Simulation

When you simulate the model, the Display block displays the state of the LED display. If you simulate the model for less than 10 seconds, the state is off. The Display block displays RED. If you simulate the model for more than 10 seconds, the state is on. The Display block displays GREEN.

“Limitations of Using Shared Data in MATLAB Function Blocks” on page 43-129

## When Do You Need to Use Global Data?

You might need to use global data with a MATLAB Function block if:

- You have multiple MATLAB functions that use global variables and you want to call these functions from MATLAB Function blocks.
- You have an existing model that uses a large amount of global data and you are adding a MATLAB Function block to this model, and you want to avoid cluttering your model with additional inputs and outputs.
- You want to scope the visibility of data to parts of the model.

## Using Global Data with the MATLAB Function Block

In Simulink, you store global data using data store memory. You implement data store memory using either Data Store Memory blocks or `Simulink.Signal` objects. How you store global data depends on the number and scope of your global variables. For more information, see “Local and Global Data Stores” on page 65-3 and “Choosing How to Store Global Data” on page 43-124.

### How MATLAB Globals Relate to Data Store Memory

In MATLAB functions in Simulink, global declarations are not mapped to the MATLAB global workspace. Instead, you register global data with the MATLAB Function block to map the data to data store memory. This difference allows global data in MATLAB

functions to inter-operate with the Simulink solver and to provide diagnostics if they are misused.

A global variable resolves hierarchically to the closest data store memory with the same name in the model. The same global variable occurring in two different MATLAB Function blocks might resolve to different data store memory depending on the hierarchy of your model. You can use this ability to scope the visibility of data to a subsystem.

**How to Use Globals with the MATLAB Function Block**

To use global data in your MATLAB Function block, or in any code that this block calls, you must:

- 1** Declare a global variable in your MATLAB Function block, or in any code that is called by the MATLAB Function block.
- 2** Register a Data Store Memory block or Simulink.Signal object that has the same name as the global variable with the MATLAB Function block.

For more information, see “Storing Data Using Data Store Memory Blocks” on page 43-125 and “Storing Data Using Simulink.Signal Objects” on page 43-127.

**Choosing How to Store Global Data**

The following table summarizes whether to use Data Store Memory blocks or Simulink.Signal objects.

| If you want to:                                                                             | Use:                                                                                                      | For more information:                                        |
|---------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------|--------------------------------------------------------------|

## Storing Data Using Data Store Memory Blocks

This model demonstrates how a MATLAB Function block uses the global data stored in a Data Store Memory block A.

- 1 Open the `dsm_demo` model. At the MATLAB command line, enter:

```
run(docpath(fullfile(docroot, 'toolbox', 'simulink', 'examples', 'dsm_demo.mdl')))
```

- 2 Double-click the MATLAB Function block to open the MATLAB Function Block Editor.

The MATLAB Function block code declares a global variable A. The block modifies the value of A during each execution.

```
function y = fcn
%#codegen
global A;
A = A+1;
y = A;
```

- 3 Make sure the global variable is registered to the MATLAB Function block.
  - a In the MATLAB Function Block Editor, select **Edit Data** to open the Ports and Data Manager dialog box.
  - b In the Ports and Data Manager, select the data **A** in the left pane. This data uses the same name as the global variable.
  - c The **Scope** of the data is set to **Data Store Memory**.

See also “Ports and Data Manager” on page 43-40.

- 4 Double-click the Data Store Memory block A. In the Block Parameters dialog box, you see that the **Data store name A** matches the global variable name. The block has an initial value of 25.

When you add a Data Store Memory to your model:

- a Set the **Data store name** to match the name of the global variable in your MATLAB Function block code.
  - b Set **Data type** to an explicit data type. The data type cannot be auto.
  - c Set the **Signal type** and specify an **Initial value**.
- 5 Simulate the model.

The MATLAB Function block reads the initial value of global data stored in A and updates the value of A each time it executes.

## Storing Data Using Simulink.Signal Objects

This model demonstrates how a MATLAB Function block uses the global data stored in a Simulink.Signal object A.

- 1 Open the `simulink_signal_local` model.

Open the `simulink_signal_local` model. At the MATLAB command line, enter:

```
run(docpath(fullfile(docroot, 'toolbox', 'simulink', ...
 'examples', 'simulink_signal_local.mdl')))
```

The model uses a Simulink.Signal object in the model workspace.

---

**Note** To use the global data with multiple models, create a Simulink.Signal object in the base workspace .

---

- 2 Make sure that the Simulink.Signal object is added to the Model Explorer.

- a From the model menu, select **View > Model Explorer**.
- b In the left pane of the Model Explorer, select the model workspace for the `simulink_signal_local` model.

The **Contents** pane displays the data in the model workspace.

- c Click the Simulink.Signal object A.

In the right pane, make sure that the Model Explorer displays these attributes for A.

| Attribute  | Value  |
|------------|--------|
| Data type  | double |
| Complexity | real   |
| Dimensions | 1      |

| Attribute     | Value |
|---------------|-------|
| Initial value | 5     |

See also “Search and Edit Using Model Explorer” on page 12-2.

- 3** Double-click the MATLAB Function block to open its editor.

The MATLAB Function block modifies the value of global data A each time it executes.

```
function y = fcn
%#codegen
global A;
A = A+1;
y = A;
```

- 4** Make sure the `Simulink.Signal` object is registered to the MATLAB Function block.
  - a** In the MATLAB Function Block Editor, select **Edit Data** to open the Ports and Data Manager dialog box.
  - b** In the Ports and Data Manager, select the data **A** in the left pane. This data uses the same name as the global variable.
  - c** Set the **Scope** of the data to **Data Store Memory**.

See also “Ports and Data Manager” on page 43-40.

- 5** Simulate the model.

The MATLAB Function block reads the initial value of global data stored in A and updates the value of A each time it executes.

## Using Data Store Diagnostics to Detect Memory Access Issues

You can configure your model to provide run-time and compile-time diagnostics for avoiding problems with data stores. Diagnostics are available in the Configuration Parameters dialog box and the parameters dialog box for the Data Store Memory block. These diagnostics are available for Data Store Memory blocks only, not for `Simulink.Signal` objects. For more information on using data store diagnostics, see “Data Store Diagnostics” on page 65-3.

**Note** If you pass data store memory arrays to functions, optimizations such as `A=foo(A)` might result in the code generation software marking the entire contents of the array as read or written even though only some elements were accessed.

---

## Limitations of Using Shared Data in MATLAB Function Blocks

There is no Data Store Memory support for:

- MATLAB structures
- Variable-sized data

## Initialize Persistent Variables in MATLAB Functions

A persistent variable is a local variable in a MATLAB function that retains its value in memory between calls to the function. For code generation, functions must initialize a persistent variable if it is empty. For more information, see `persistent`.

When programming MATLAB functions in these situations:

- MATLAB Function blocks with no direct feedthrough
- MATLAB Function blocks in models that contain State Control blocks in Synchronous mode
- MATLAB functions in Stateflow charts that implement Moore machine semantics

the specialized semantics impact how a function initializes its persistent data. Because the initialization must be independent of the input to the function, follow these guidelines:

- The function initializes its persistent variables only by accessing constants.
- The control flow of the function does not depend on whether the initialization occurs.

For example, this function has a persistent variable `n`.

```
function y = fcn(u)
 persistent n

 if isempty(n)
 n = u;
 y = 1;
 return
 end

 y = n;
 n = n + u;
end
```

This type of initialization results in an error because the initial value of `n` depends on the input `u` and the `return` statement interrupts the normal control flow of the function.

To correct the error, initialize the persistent variable by setting it to a constant value and remove the `return` statement. For example, this function initializes the persistent variable without producing an error.

```
function y = fcn(u)
 persistent n
```

```

if isempty(n)
 n = 1;
end

y = n;
n = n + u;
end

```

## MATLAB Function Block With No Direct Feedthrough

This model contains a MATLAB function block that defines the function `fcn`, described previously. The input `u` is a square wave with values of 1 and -1.

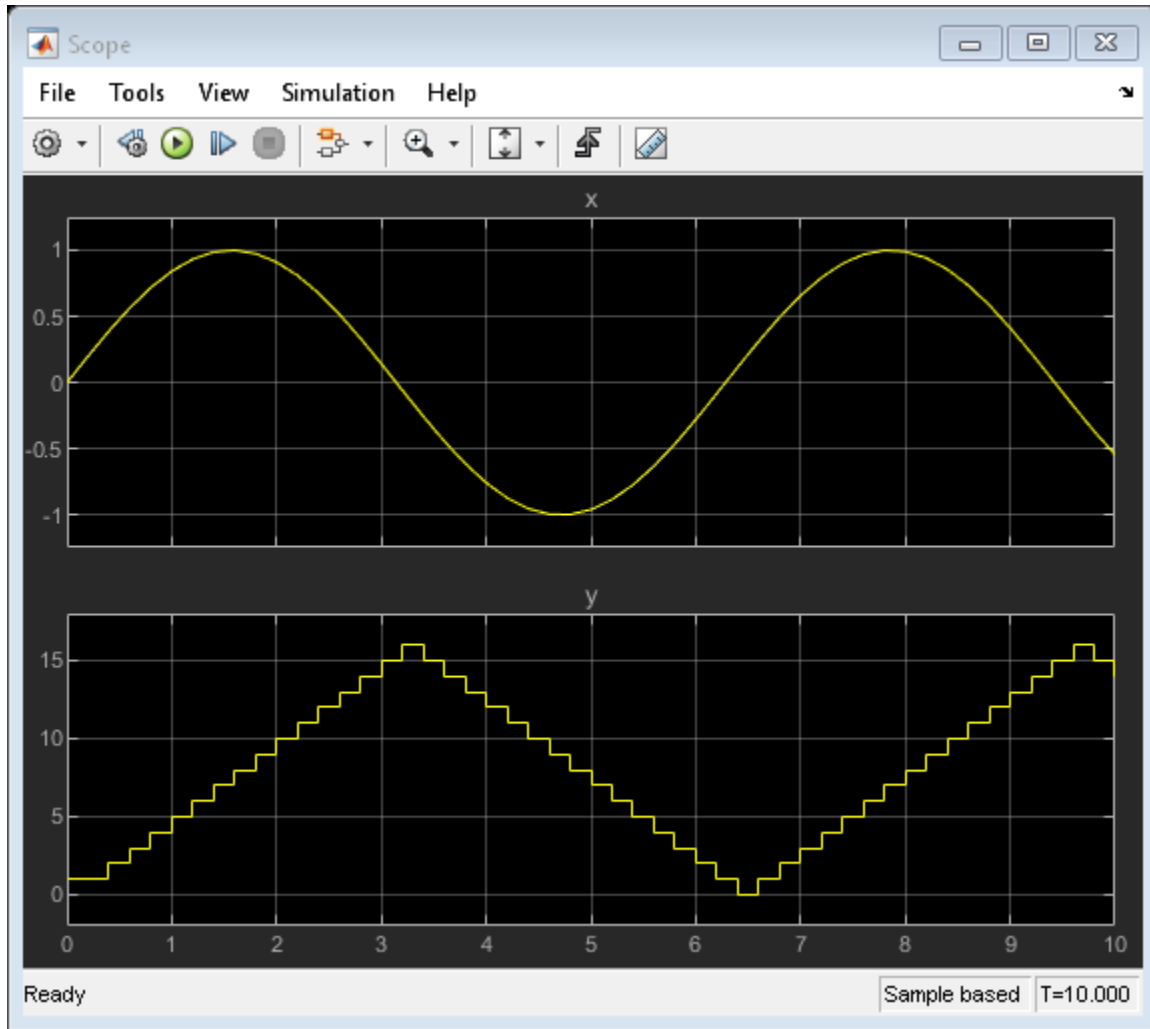

In the MATLAB function block:

- The initial value of the persistent variable `n` depends on the input `u`.
- The `return` statement interrupts the normal control flow of the function.

Because the `Allow direct feedthrough` check box is cleared, the initialization results in an error.

If you modify the function so it initializes `n` independently of the input, then you can simulate an error-free model.

### State Control Block in Synchronous Mode

This model contains a MATLAB function block that defines the function `fcn`, described previously. The input `u` is a square wave with values of 1 and -1.

In the MATLAB function block:

- The initial value of the persistent variable  $n$  depends on the input  $u$ .
- The `return` statement interrupts the normal control flow of the function.

Because the model contains a State Control block in Synchronous mode, the initialization results in an error.

If you modify the function so it initializes  $n$  independently of the input, then you can simulate an error-free model.

## Stateflow Chart Implementing Moore Semantics

This model contains a Stateflow chart that implements Moore machine semantics. The chart contains a MATLAB function that defines the function `fcn`, described previously. The input `u` has values of 1 and -1 that depend on the state of the chart.

In the MATLAB function:

- The initial value of the persistent variable `n` depends on the input `u`.
- The `return` statement interrupts the normal control flow of the function.

Because the chart implements Moore semantics, the initialization results in an error.

If you modify the function so it initializes `n` independently of the input, then you can simulate an error-free model.

## Create Custom Block Libraries

### In this section...

“When to Use MATLAB Function Block Libraries” on page 43-138

“How to Create Custom MATLAB Function Block Libraries” on page 43-138

“Example: Creating a Custom Signal Processing Filter Block Library” on page 43-139

“Code Reuse with Library Blocks” on page 43-150

“Debugging MATLAB Function Library Blocks” on page 43-155

“Properties You Can Specialize Across Instances of Library Blocks” on page 43-155

### When to Use MATLAB Function Block Libraries

In Simulink, you can create your own block libraries as a way to reuse the functionality of blocks or subsystems in one or more models. If you want to reuse a set of MATLAB algorithms in Simulink models, you can encapsulate your MATLAB code in a MATLAB Function block library.

As with other Simulink block libraries, you can specialize each instance of MATLAB Function library blocks in your model to use different data types, sample times, and other properties. Library instances that inherit the same properties can reuse generated code

### How to Create Custom MATLAB Function Block Libraries

Here is a basic workflow for creating custom block libraries with MATLAB Function blocks. To work through these steps with an example, see “Example: Creating a Custom Signal Processing Filter Block Library” on page 43-139.

- 1 Add polymorphic MATLAB code to MATLAB Function blocks in a Simulink model.

Polymorphic code is code that can process data with different properties, such as type, size, and complexity.

- 2 Configure the blocks to inherit the properties you want to specialize.

For a list of properties you can specialize, see “Properties You Can Specialize Across Instances of Library Blocks” on page 43-155.

- 3 Optionally, customize your library code using masking.

- 4 Add instances of MATLAB Function library blocks to a Simulink model.

---

**Note** If your MATLAB Function block library is masked, you cannot modify contents of the block with mask initialization code. The **Allow library block to modify its contents** option in the Mask dialog box is not supported for MATLAB Function block libraries.

---

## Example: Creating a Custom Signal Processing Filter Block Library

- “What You Will Learn” on page 43-139
- “About the Filter Algorithms” on page 43-139
- “Step 1: Add the Filter Algorithms to MATLAB Function Library Blocks” on page 43-140
- “Step 2: Configure Blocks to Inherit Properties You Want to Specialize” on page 43-141
- “Step 3: Customize Your Library Using Masking” on page 43-142
- “Step 4: Add Instances of MATLAB Library Blocks to a Simulink Model” on page 43-145

### What You Will Learn

This simple example takes you through the workflow described in “How to Create Custom MATLAB Function Block Libraries” on page 43-138 to show you how to:

- Create a library of signal processing filter algorithms using MATLAB Function blocks
- Customize one of the library blocks using mask parameters
- Convert one of the filter algorithms to source-protected P-code that you can call from a MATLAB Function library block

### About the Filter Algorithms

The MATLAB filter algorithms are:

#### **my\_fft**

Performs a discrete Fourier transform on an input signal. The input can be a vector, matrix, or multidimensional array whose length is a power of 2.

**my\_conv**

Convolve two input vector signals. Outputs a subsection of the convolution with a size specified by a mask parameter, Shape.

**my\_sobel**

Convolve a 2D input matrix with a Sobel edge detection filter.

**Step 1: Add the Filter Algorithms to MATLAB Function Library Blocks**

- 1 In Simulink, create a library model by selecting **File > New > Library**
- 2 Drag three MATLAB Function blocks into the model from the User-Defined Functions section of the Simulink Library Browser and name them:

- my\_fft\_filter
- my\_conv\_filter
- my\_sobel\_filter

- 3 Save the library model as my\_filter\_lib.

- 4 Open the MATLAB Function block named my\_fft\_filter, replace the template code with the following code, and save the block:

```
function y = my_fft(x)
```

```
y = fft(x);
```

- 5 Replace the template code in my\_conv\_filter block with the following code and save the block:

```
function c = my_conv(a, b)
```

```
c = conv(a, b);
```

- 6 Replace the template code in my\_sobel\_filter block with the following code and save the block:

```
function y = my_sobel(u)
```

```
%% "my_sobel_filter" is a MATLAB function
```

```
%% on the MATLAB path.
```

```
y = my_sobel_filter(u);
```

The my\_sobel function acts as a wrapper that calls a MATLAB function, my\_sobel\_filter, on the code generation path. my\_sobel\_filter implements

the algorithm that convolves a 2D input matrix with a Sobel edge detection filter. By calling the function rather than inlining the code directly in the MATLAB Function block, you can reuse the algorithm both as MATLAB code and in a Simulink model. You will create `my_sobel_filter` next.

- 7 In the same folder where you created `my_filter_lib`, create a new MATLAB function `my_sobel_filter` with the following code:

```
function y = my_sobel_filter(u)

% Sobel edge detection filter
h = [1 2 1;...
 0 0 0;...
 -1 -2 -1];

y = abs(conv2(u, h));
```

Save the file as `my_sobel_filter.m`.

## Step 2: Configure Blocks to Inherit Properties You Want to Specialize

In this example, the data in the signal processing filter algorithms must inherit size, type, and complexity from the Simulink model. By default, data in MATLAB Function blocks inherit these properties. To explicitly configure data to inherit properties:

- 1 Open a MATLAB Function block and select **Edit Data**.
- 2 In the left pane of the Ports and Data Manager, select the data of interest.
- 3 In the right pane, configure the data to inherit properties from Simulink:

| To Inherit | What to Specify                                            |
|------------|------------------------------------------------------------|
| Size       | Enter -1 in Size field                                     |
| Complexity | Select <b>Inherited</b> from the Complexity menu           |
| Type       | Select <b>Inherit: Same as Simulink</b> from the Type menu |

For example, if you open the MATLAB Function block `my_fft_filter` and look at the properties of input `x` in the Ports and Data Manager, you see that size, type, and complexity are inherited by default.

---

**Note** If your design has specific requirements or constraints, you can enter values for any of these properties, rather than inherit them from Simulink. For example, if your algorithm is not supposed to work with complex inputs, set **Complexity** to **Off**.

---

### Step 3: Customize Your Library Using Masking

In this exercise you will modify the convolution filter `my_conv` to use a custom parameter shape that specifies what subsection of the convolution to output. To customize this algorithm for your library, place the `my_conv_filter` block under a masked subsystem and define `shape` as a mask parameter.

- 1 Convert the block to a masked subsystem:
  - a Right-click the `my_conv_filter` block and select **Subsystem & Model Reference > Create Subsystem from Selection**.

The `my_conv_filter` block changes to a subsystem block.

- b Change the name of the subsystem to `my_conv_filter`.
  - c Right-click the `my_conv_filter` subsystem and select **Mask > Create Mask** from the context menu.

The Mask Editor appears with the **Icon & Ports** tab open.

- d Enter in the **Icon drawing commands** text box:

```
disp('my_conv');
port_label('output', 1, 'c');
port_label('input', 1, 'a');
port_label('input', 2, 'b');
```

- e Select the **Parameters & Dialog** tab.
  - f Highlight the **Parameters** line item in the Dialog box pane.
  - g Add a popup-type parameter by clicking **Popup** under the **Parameter** list in the **Controls** pane.

A new parameter will appear in the Dialog box pane.

- h In the **Property editor** pane, set the **Properties**:

| Property | Value |
|----------|-------|
| Name     | shape |

| Property     | Value                                                                |
|--------------|----------------------------------------------------------------------|
| Value        | full                                                                 |
| Prompt       | shape                                                                |
| Type         | popup                                                                |
| Type options | Open the Type Options Editor and enter:<br><br>full<br>same<br>valid |

- i Set the **Attributes**, **Dialog**, and **Layout** properties in the **Property editor** pane:

| Attributes, Dialog, and Layout Items | Value                                                                                                                                                                                     |
|--------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Attributes</b>                    | <ul style="list-style-type: none"> <li>• Evaluate: Checked</li> <li>• Tunable: Cleared</li> <li>• Read only: Cleared</li> <li>• Hidden: Cleared</li> <li>• Never save: Cleared</li> </ul> |
| <b>Dialog</b>                        | <ul style="list-style-type: none"> <li>• Enable: Checked</li> <li>• Visible: Checked</li> <li>• Callback: no entry</li> </ul>                                                             |
| <b>Layout</b>                        | <ul style="list-style-type: none"> <li>• Item location: Grayed out</li> <li>• Prompt location: Left</li> </ul>                                                                            |

- j Click **OK**.

Your subsystem should now look like this:

2 Set subsystem properties for code reuse:

- a Right-click the `my_conv_filter` subsystem and select **Block Parameters (Subsystem)** from the context menu.
- b In the subsystem parameters dialog box, select the **Treat as atomic unit** check box.

The dialog box expands to display new fields.

- c To generate a reusable function, select the Code Generation tab and in the **Function packaging** field, select `Reusable` function from the drop-down menu.

---

**Note** This is an optional step, required for this example. If you leave the default setting of **Auto**, the code generation software uses an internal rule to determine whether to inline the function or not.

---

- d Click **OK**.

3 Define the shape parameter in the MATLAB Function `my_conv`:

- a Right-click the `my_conv_filter` subsystem and select **Mask > Look Under Mask** from the context menu.

The block diagram under the masked subsystem opens, containing the `my_conv` block:

- b Change the names of the port blocks to match the data names as follows:

| Change: | To: |
|---------|-----|
| In1     | a   |
| In2     | b   |

| Change: | To: |
|---------|-----|
| Out1    | c   |

- c Double-click the my\_conv\_filter block to open the MATLAB Function Block Editor.
- d In the MATLAB Function Block Editor, select **Edit Data**.
- e In the Ports and Data Manager, select **Add > Data**.

A new data element appears selected, along with its properties dialog.

- f Enter the following properties:

| Property | What To Specify           |
|----------|---------------------------|
| Name     | Enter shape.              |
| Scope    | Select <b>Parameter</b> . |
| Tunable  | Clear the box.            |

- g Leave **Size**, **Complexity**, and **Type** as inherited (the defaults), as described in “Step 2: Configure Blocks to Inherit Properties You Want to Specialize” on page 43-141.
  - h Click **Apply**, close the Ports and Data Manager, and return to the MATLAB Function Block Editor.
- 4 Use the shape parameter to determine the size of the convolution to output:
- a In the MATLAB Function Block Editor, modify the my\_conv function to call conv with the right shape:

```
function c = my_conv(a, b, shape)
if shape == 1
 c = conv(a, b, 'full');
elseif shape == 2
 c = conv(a, b, 'same');
else
 c = conv(a, b, 'valid');
end
```
  - b Save your changes and close the MATLAB Function Block Editor.

#### Step 4: Add Instances of MATLAB Library Blocks to a Simulink Model

In this exercise, you will add specialized instances of the my\_conv\_filter library block to a simple test model.

- 1 Open a new Simulink model.

For purposes of this exercise, set the following configuration parameters for simulation:

| Pane                      | Section                 | What to Specify                                                                                                                                                                                                              |
|---------------------------|-------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Solver</b>             | <b>Solver selection</b> | <ul style="list-style-type: none"> <li>• Select <b>Fixed-Step</b> for <b>Type</b></li> <li>• Select <b>discrete (no continuous states)</b> for <b>Solver</b></li> <li>• Enter <b>1</b> for <b>Fixed-step size</b></li> </ul> |
| <b>Data Import/Export</b> | <b>Save options</b>     | <b>Structure for Format</b>                                                                                                                                                                                                  |

- 2 Drag two instances of the my\_conv\_filter block from the my\_filter\_lib library into the model.
- 3 Add Constant, Output, and Display blocks. Your model should look something like this:

Both library instances share the same size, type, and complexity for inputs a and b respectively.

- 4 Double-click each library instance.

The shape parameter defaults to **full** for both instances.

- 5 Simulate the model.

Each library instance outputs the same result, the full 2D convolution:

- 6 Specialize the second instance, my\_conv\_filter1 by setting the value of its shape parameter to **same**.
- 7 Now simulate the model again.

This time, the outputs have different sizes: my\_conv\_filter3 outputs the full 2D convolution, while my\_conv\_filter1 displays the central part of the convolution as a 1-by-2 vector, the same size as a:

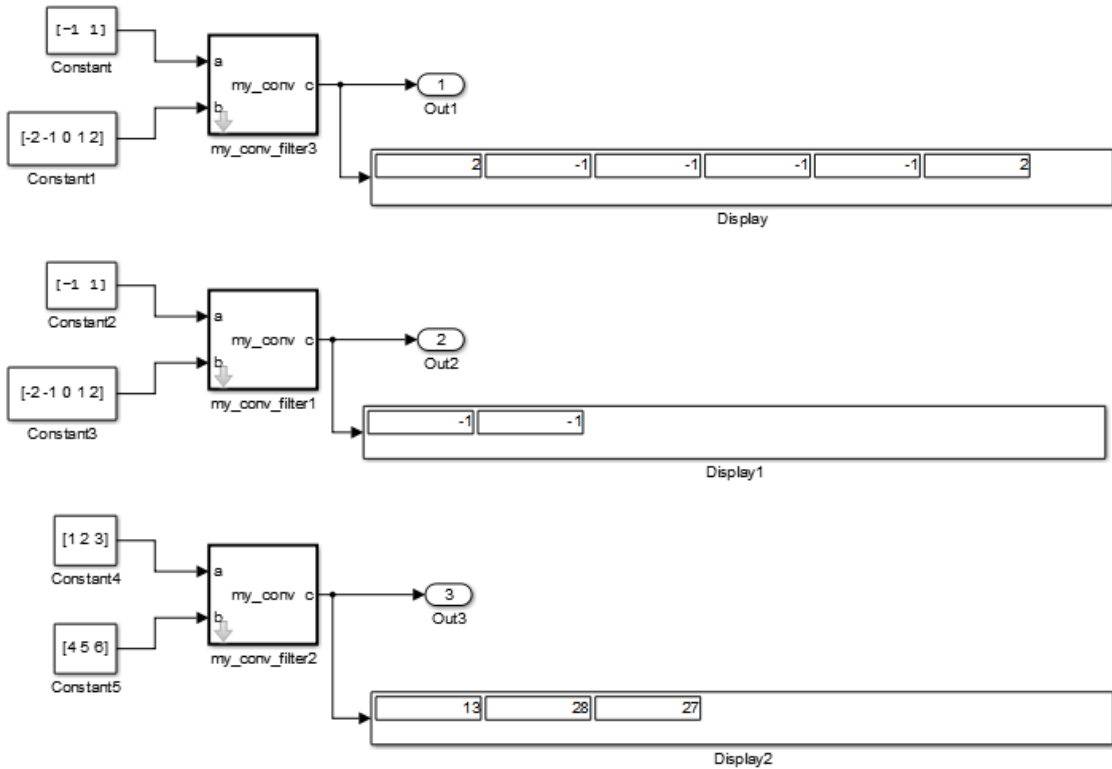

- 8 Now, add a third instance by copying my\_conv\_filter1. Specialize the new instance, my\_conv\_filter2, so that it does not inherit the same size inputs as the first two instances:

9 Simulate the model again.

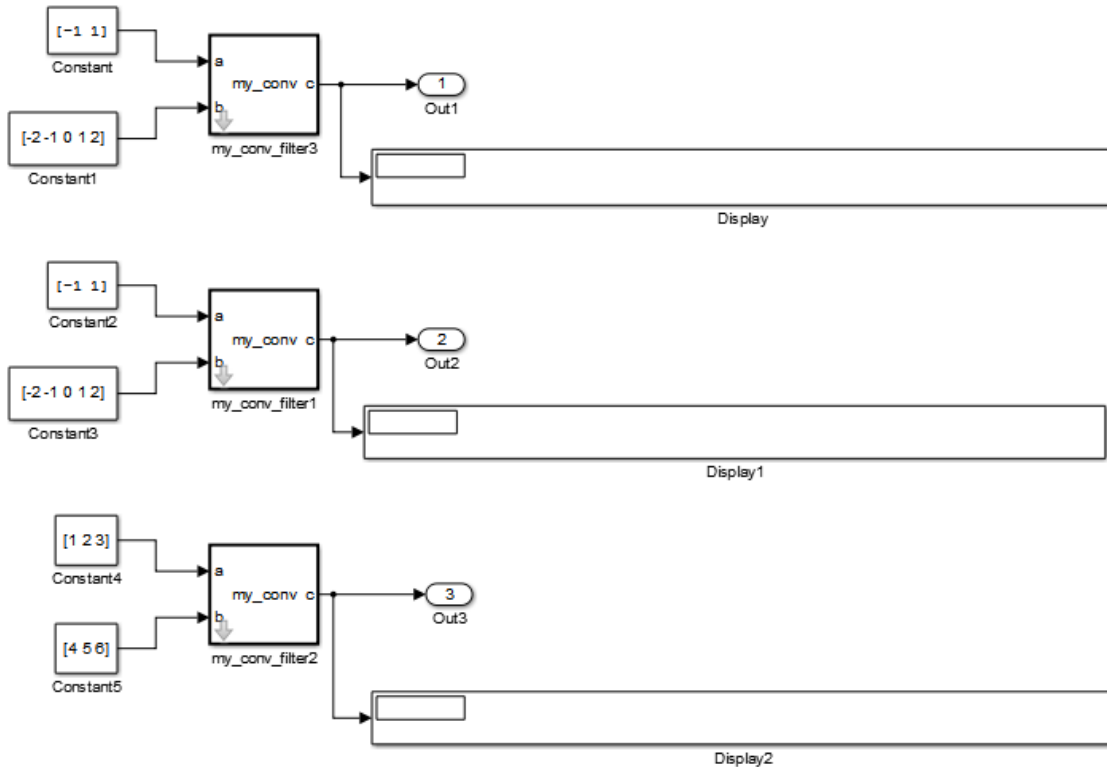

This time, `my_conv_filter1` and `my_conv_filter2` each display the central part of the convolution, but the output sizes are different because each matches a different sized input  $a$ .

## Code Reuse with Library Blocks

When instances of MATLAB Function library blocks inherit the same properties, they can reuse generated code, as illustrated by an example based on “Step 4: Add Instances of MATLAB Library Blocks to a Simulink Model” on page 43-145:

In this model, the library instances `my_conv_filter` and `my_conv_filter1` inherit the same size, type, and complexity for each respective input. For each instance, input `a` is a 1-by-2 vector and input `b` is a 1-by-5 vector. By comparison, the inputs of `my_conv_filter2` inherit different respective sizes; both are 1-by-3 vectors.

In addition, each library instance has a mask parameter called `shape` that determines what subsection of the convolution to output. Assume that the value of `shape` is the same for each instance.

To generate code for this example, follow these steps:

- 1 Enable code reuse for the library block:

- a In the library, right-click the MATLAB Function block `my_conv_filter` and select **Block Parameters (Subsystem)** from the context menu.
  - b In the Function Block Parameters dialog box, set these parameters:
    - Select the **Treat as atomic unit** check box.
    - In the **Function packaging** field, select `Reusable` function from the drop-down menu.
- 2 Configure the model for code generation.

For purposes of this exercise, set the following configuration parameters:

| Pane                               | Section                 | What to Specify                                        |
|------------------------------------|-------------------------|--------------------------------------------------------|
| <b>Code Generation</b>             | <b>Target selection</b> | Enter <code>ert.tlc</code> for System target file      |
| <b>Code Generation &gt; Report</b> |                         | Select <b>Create code generation report</b> check box. |

- 3 Build the model.

If you build this model, the generated C code reuses logic for the `my_conv_filter` and `my_conv_filter1` library instances because they inherit the same input properties:

```

/*
 * Output and update for atomic system:
 * '<Root>/my_conv_filter'
 * '<Root>/my_conv_filter1'
 */
void sp_algorithm_tes_my_conv_filter(const real32_T rtu_a[2], const real32_T
 rtu_b[5], rtB_my_conv_filter_sp_algorithm *localB)
{
 int32_T jA;
 int32_T jA_0;
 real32_T s;
 int32_T jC;

 /* MATLAB Function Block: '<S1>/my_conv_filter' */
 /* MATLAB Function 'my_conv_filter/my_conv_filter': '<S4>:1' */
 /* '<S4>:1:4' */
 for (jC = 0; jC < 6; jC++) {
 if (5 < jC + 2) {
 jA = jC - 4;
 } else {
 jA = 0;
 }

 if (2 < jC + 1) {
 jA_0 = 2;
 } else {
 jA_0 = jC + 1;
 }

 s = 0.0F;
 while (jA + 1 <= jA_0) {
 s += rtu_b[jC - jA] * rtu_a[jA];
 jA++;
 }

 localB->c[jC] = s;
 }

 /* end of MATLAB Function Block: '<S1>/my_conv_filter' */
}

```

However, a separate function is generated for my\_conv\_filter2:

```

/* Output and update for atomic system: '<Root>/my_conv_filter2' */
void sp_algorithm_te_my_conv_filter2(const real_T rtu_a[3], const real_T rtu_b[3],
 rtB_my_conv_filter_sp_algorit_h *localB)
{
 int32_T jA;
 int32_T jA_0;
 real_T s;
 int32_T jC;

 /* MATLAB Function Block: '<S3>/my_conv_filter' */
 /* MATLAB Function 'my_conv_filter/my_conv_filter': '<S6>:1' */
 /* '<S6>:1:4' */
 for (jC = 0; jC < 5; jC++) {
 if (3 < jC + 2) {
 jA = jC - 2;
 } else {
 jA = 0;
 }

 if (3 < jC + 1) {
 jA_0 = 3;
 } else {
 jA_0 = jC + 1;
 }

 s = 0.0;
 while (jA + 1 <= jA_0) {
 s += rtu_b[jC - jA] * rtu_a[jA];
 jA++;
 }

 localB->c[jC] = s;
 }

 /* end of MATLAB Function Block: '<S3>/my_conv_filter' */
}

```

---

**Note** Generating C code for this model requires a Simulink Coder or Embedded Coder license.

---

## Debugging MATLAB Function Library Blocks

You debug MATLAB Function library blocks the same way you debug any MATLAB Function block. However, when you add a breakpoint in a library block, the breakpoint is shared by all instances. As you continue execution, the debugger stops at the breakpoint in each instance.

## Properties You Can Specialize Across Instances of Library Blocks

You can specialize instances of MATLAB Function library blocks by allowing them to inherit any of the following properties from Simulink:

| Property                                     | Inherits by Default? | How to Specify Inheritance                                                                                                                                                                                                                                                                                              |
|----------------------------------------------|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Type                                         | Yes                  | Set data type property to <b>Inherit: Same as Simulink</b> .                                                                                                                                                                                                                                                            |
| Size                                         | Yes                  | Set data size property to <b>-1</b> .                                                                                                                                                                                                                                                                                   |
| Complexity                                   | Yes                  | Set data complexity property to <b>Inherited</b> .                                                                                                                                                                                                                                                                      |
| Limit range                                  | No                   | Specify minimum and maximum values as Simulink parameters.<br>For example, if minimum value = <code>aParam</code> and maximum value = <code>aParam + 3</code> , different instances of a MATLAB Function library block can resolve to different <code>aParam</code> parameters defined in their parent mask subsystems. |
| Sampling mode (input)                        | Yes                  | MATLAB Function block input ports always inherit sampling mode                                                                                                                                                                                                                                                          |
| Data type override mode for fixed-point data | Yes                  | Set data type override property to <b>Inherit</b> .                                                                                                                                                                                                                                                                     |
| Sample time (block)                          | Yes                  | Set block sample time property to <b>-1</b> .                                                                                                                                                                                                                                                                           |

## Use Traceability in MATLAB Function Blocks

### In this section...

“Extent of Traceability in MATLAB Function Blocks” on page 43-157

“Traceability Requirements” on page 43-157

“Tutorial: Using Traceability in a MATLAB Function Block” on page 43-157

### Extent of Traceability in MATLAB Function Blocks

Like other Simulink blocks, MATLAB Function blocks support bidirectional traceability, but extend navigation to lines of source code. That is, you can navigate between a line of generated code and its corresponding line of source code. In other Simulink blocks, you can navigate between a line of generated code and its corresponding object.

In addition, you can select to include the source code as comments in the generated code. When you select **MATLAB source code as comments** parameter, the MATLAB source code appears immediately after the associated traceability tag. For more information, see “How to Include MATLAB Code as Comments in the Generated Code” on page 43-160.

For information about how traceability works in Simulink blocks, see “Verify Generated Code by Using Code Tracing” (Embedded Coder).

### Traceability Requirements

To enable traceability comments in your code, you must have a license for Embedded Coder software. These comments appear only in code that you generate for an Embedded Real-Time (ERT) target.

---

**Note** Traceability is not supported for MATLAB files that you call from a MATLAB Function block.

---

### Tutorial: Using Traceability in a MATLAB Function Block

This example shows how to trace between source code and generated code in a MATLAB Function block in the `eml_fire` model. Follow these steps:

- 1 Type `eml_fire` at the MATLAB prompt.
- 2 In the Simulink model window, select **Simulation > Model Configuration Parameters**.
- 3 In the **Code Generation** pane, go to the **Target selection** section and enter `ert.tlc` for the system target file. Then click **Apply**. Traceability comments appear hyperlinked in generated code only for embedded real-time (ert) targets.
- 4 In the **Code Generation > Report** pane, select the **Create code generation report** (Simulink Coder) parameter, if not already selected.

This action automatically selects the “Open report automatically” (Simulink Coder), “Code-to-model” (Simulink Coder), and “Model-to-code” (Simulink Coder) parameters.

- 5 Verify that **Code-to-model** and **Model-to-code** parameters are enabled.
- 6 In the **Code Generation > Comments** pane, select the “MATLAB source code as comments” (Simulink Coder) and “Stateflow object comments” (Simulink Coder) parameters. These parameters control different parts of the traceability comment. See “Location of Comments in Generated Code” on page 43-161 for more information.
- 7 Go to the **Code Generation > Interface** pane. In the **Software environment** section, select the **continuous time** parameter. Then click **Apply**. Because this example model contains a block with a continuous sample time, you must perform this step before generating code.
- 8 In the model window, press **Ctrl+B**.

This action generates source code and header files for the `eml_fire` model that contains the `flame` block. After the code generation process is complete, the code generation report appears automatically.

- 9 Click the `eml_fire.c` hyperlink in the report.
- 10 Scroll down through the code to see the traceability comments, which appear as links inside `/* . . . */` brackets, as in this example.

```

/* '<S2>:1:19' for x = 1 : WIDTH */
for (x = 0; x < 256; x++) {
 /* '<S2>:1:21' yb = y+2; */
 yb = iU;

 /* '<S2>:1:22' xb1 = x-1; */
 xb1 = x;

```

- 11** Click the [<S2>:1:19](#) hyperlink in this traceability comment:

```
/* '<S2>:1:19' */
```

Line 19 of the function in the source code appears highlighted in the MATLAB Function Block Editor.

- 12** You can trace a line in a MATLAB function to lines of generated code. For example, right-click on line 21 of your function and select **Code Generation > Navigate to Code** from the context menu.

The code location for line 21 appears highlighted in `eml_fire.c`.

- 13** You can trace a line of generated code to a line of source code in a MATLAB function using the line number hyperlinks in the generated code.

### More About

- “Implementing MATLAB Functions Using Blocks” on page 43-5
- “Verify Generated Code by Using Code Tracing” (Embedded Coder)

## Include MATLAB Code as Comments in Generated Code

If you have a Simulink Coder license, you can include MATLAB source code as comments in the code generated for a MATLAB Function block. Including this information in the generated code enables you to:

- Correlate the generated code with your source code.
- Understand how the generated code implements your algorithm.
- Evaluate the quality of the generated code.

When you select **MATLAB source code as comments** parameter, the generated code includes:

- The source code as a comment immediately after the traceability tag. When you enable traceability and generate code for ERT targets (requires an Embedded Coder license), the traceability tags are hyperlinks to the source code. For more information on traceability for the MATLAB Function block, see “Use Traceability in MATLAB Function Blocks” on page 43-157.

For examples and information on the location of the comments in the generated code, see “Location of Comments in Generated Code” on page 43-161.

- The function help text in the function body in the generated code. The function help text is the first comment after the MATLAB function signature. It provides information about the capabilities of the function and how to use it.

---

**Note** With an Embedded Coder license, you can also include the function help text in the function banner of the generated code. For more information, see “Including MATLAB user comments in Generated Code” on page 43-163.

---

## How to Include MATLAB Code as Comments in the Generated Code

To include MATLAB source code as comments in the code generated for a MATLAB Function block:

- 1 In the model, select **Simulation > Model Configuration Parameters**.
- 2 In the **Code Generation > Comments** pane, select **MATLAB source code as comments** and click **Apply**.

## Location of Comments in Generated Code

The automatically generated comments containing the source code appear after the traceability tag in the generated code as follows.

```
/* '<S2>:1:18' for y = 1 : 2 : (HEIGHT-4) */
```

Selecting the **Stateflow object comments** parameter generates the traceability comment '<S2>:1:18'. Selecting the **MATLAB source code as comments** parameter generates the for y = 1 : 2 : (HEIGHT-4) comment.

### Straight-Line Source Code

The comment containing the source code precedes the generated code that implements the source code statement. This comment appears after any comments that you add that precede the generated code. The comments are separated from the generated code because the statements are assigned to function outputs.

#### MATLAB Code

```
function [x y] = straightline(r,theta)
%#codegen
% Convert polar to Cartesian
x = r * cos(theta);
y = r * sin(theta);
```

#### Commented C Code

```
/* MATLAB Function 'straightline': '<S1>:1' */
/* Convert polar to Cartesian */
/* '<S1>:1:4' x = r * cos(theta); */
/* '<S1>:1:5' y = r * sin(theta); */
straightline0_Y.x = straightline0_U.r * cos(straightline0_U.theta);

/* Output: '<Root>/y' incorporates:
 * Inport: '<Root>/r'
 * Inport: '<Root>/theta'
 * MATLAB Function Block: '<Root>/straightline'
 */
straightline0_Y.y = straightline0_U.r * sin(straightline0_U.theta);
```

### If Statements

The comment for the if statement immediately precedes the code that implements the statement. This comment appears after any comments that you add that precede the

generated code. The comments for the `elseif` and `else` clauses appear immediately after the code that implements the clause, and before the code generated for statements in the clause.

#### **MATLAB Code**

```
function y = ifstmt(u,v)
%#codegen
if u > v
 y = v + 10;
elseif u == v
 y = u * 2;
else
 y = v - 10;
end
```

#### **Commented C Code**

```
/* MATLAB Function 'MLFcn': '<S1>:1' */
/* '<S1>:1:3' if u > v */
if (MLFcn_U.u > MLCfn_U.v) {
 /* Outport: '<Root>/y' */
 /* '<S1>:1:4' y = v + 10; */
 MLCfn_Y.y = MLCfn_U.v + 10.0;
} else if (MLFcn_U.u == MLCfn_U.v) {
 /* Outport: '<Root>/y' */
 /* '<S1>:1:5' elseif u == v */
 /* '<S1>:1:6' y = u * 2; */
 MLCfn_Y.y = MLCfn_U.u * 2.0;
} else {
 /* Outport: '<Root>/y' */
 /* '<S1>:1:7' else */
 /* '<S1>:1:8' y = v - 10; */
 MLCfn_Y.y = MLCfn_U.v - 10.0;
}
```

#### **For Statements**

The comment for the `for` statement header immediately precedes the generated code that implements the header. This comment appears after any comments that you add that precede the generated code.

#### **MATLAB Code**

```
function y = forstmt(u)
%#codegen
```

```

y = 0;
for i=1:u
 y = y + 1;
end

```

### Commented C Code

```

/* MATLAB Function 'MLFcn': '<S1>:1' */
/* '<S1>:1:3' y = 0; */
rtb_y = 0.0;

/* '<S1>:1:5' for i=1:u */
for (i = 1.0; i <= MLFcn_U.u; i++) {
/* '<S1>:1:6' y = y + 1; */
 rtb_y++;
}

```

### While Statements

The comment for the `while` statement header immediately precedes the generated code that implements the statement header. This comment appears after any comments that you add that precede the generated code.

### Switch Statements

The comment for the `switch` statement header immediately precedes the generated code that implements the statement header. This comment appears after any comments that you add that precede the generated code. The comments for the `case` and `otherwise` clauses appear immediately after the generated code that implements the clause, and before the code generated for statements in the clause.

## Including MATLAB user comments in Generated Code

MATLAB user comments include the function help text and other comments. The function help text is the first comment after the MATLAB function signature. It provides information about the capabilities of the function and how to use it. You can include the MATLAB user comments in the code generated for a MATLAB Function block.

- 1 In the model, select **Simulation > Model Configuration Parameters**.
- 2 In the **Code Generation > Comments** pane, select “MATLAB user comments” (Simulink Coder) and click **Apply**.

## Limitations of MATLAB Source Code as Comments

The MATLAB Function block has the following limitations for including MATLAB source code as comments.

- You cannot include MATLAB source code as comments for:
  - MathWorks toolbox functions
  - P-code
  - Simulation targets
  - Stateflow Truth Table blocks
- The appearance or location of comments can vary depending on the following conditions:
  - Comments might still appear in the generated code even if the implementation code is eliminated, for example, due to constant folding.
  - Comments might be eliminated from the generated code if a complete function or code block is eliminated.
  - For certain optimizations, the comments might be separated from the generated code.
  - The generated code always includes legally required comments from the MATLAB source code, even if you do not choose to include source code comments in the generated code.

# Integrate C Code Using the MATLAB Function Block

## In this section...

“Call C Code from a Simulink Model” on page 43-165

“Use `coder.ceval` in a MATLAB Function Block” on page 43-166

“Control Imported Bus and Enumeration Type Definitions” on page 43-167

## Call C Code from a Simulink Model

You can call external C code from a Simulink model using a MATLAB Function block. Follow these high-level steps:

- 1 Start with existing C code consisting of the source (.c) and header (.h) files.
- 2 In the MATLAB Function block, enter the MATLAB code that calls the C code. Use the `coder.ceval` function. To pass data by reference, use `coder.ref`, `coder.rref`, or `coder.wref`.
- 3 Specify the C source and header files for simulation in the **Simulation Target** pane of the **Model Configuration Parameters** dialog box. Include the header file using double quotations, for example, `#include "program.h"`. If you need to access C source and header files outside your working folder, list the path in the **Simulation Target** pane, in the **Include Directories** text box.

Alternatively, use the `coder.cinclude` and `coder.updateBuildInfo` functions to specify source and header files within your MATLAB code. To develop an interface to external code, you can use the `coder.ExternalDependency` class. To see which workflow is supported, see “Import custom code”.

- 4 Test your Simulink model and ensure it functions correctly.
- 5 If you have a Simulink Coder license, you can generate code for targets using this method. To use the same source and header files for code generation, click **Use the same custom code settings as Simulation Target** in the **Code Generation > Custom Code** pane. You can also specify different source and header files.

To conditionalize your code to execute different commands for simulation and code generation, you can use the `coder.target` function.

## Use coder.ceval in a MATLAB Function Block

This example shows how to call the simple C program `doubleIt` from a MATLAB Function block.

- 1 Create the source file `doubleIt.c` in your current working folder.

```
#include "doubleIt.h"

double doubleIt(double u)
{
 return(u*2.0);
}
```

- 2 Create the header file `doubleIt.h` in your current working folder.

```
#ifndef MYFN
#define MYFN

double doubleIt(double u);

#endif
```

- 3 Create a new Simulink model. Save it as `myModel.slx`.
- 4 In the **Library Browser**, from **User-Defined Functions**, add a MATLAB Function block to the model and double-click the block to open the editor.
- 5 Enter code that calls the `doubleIt` program:

```
function y = callingDoubleIt(u)

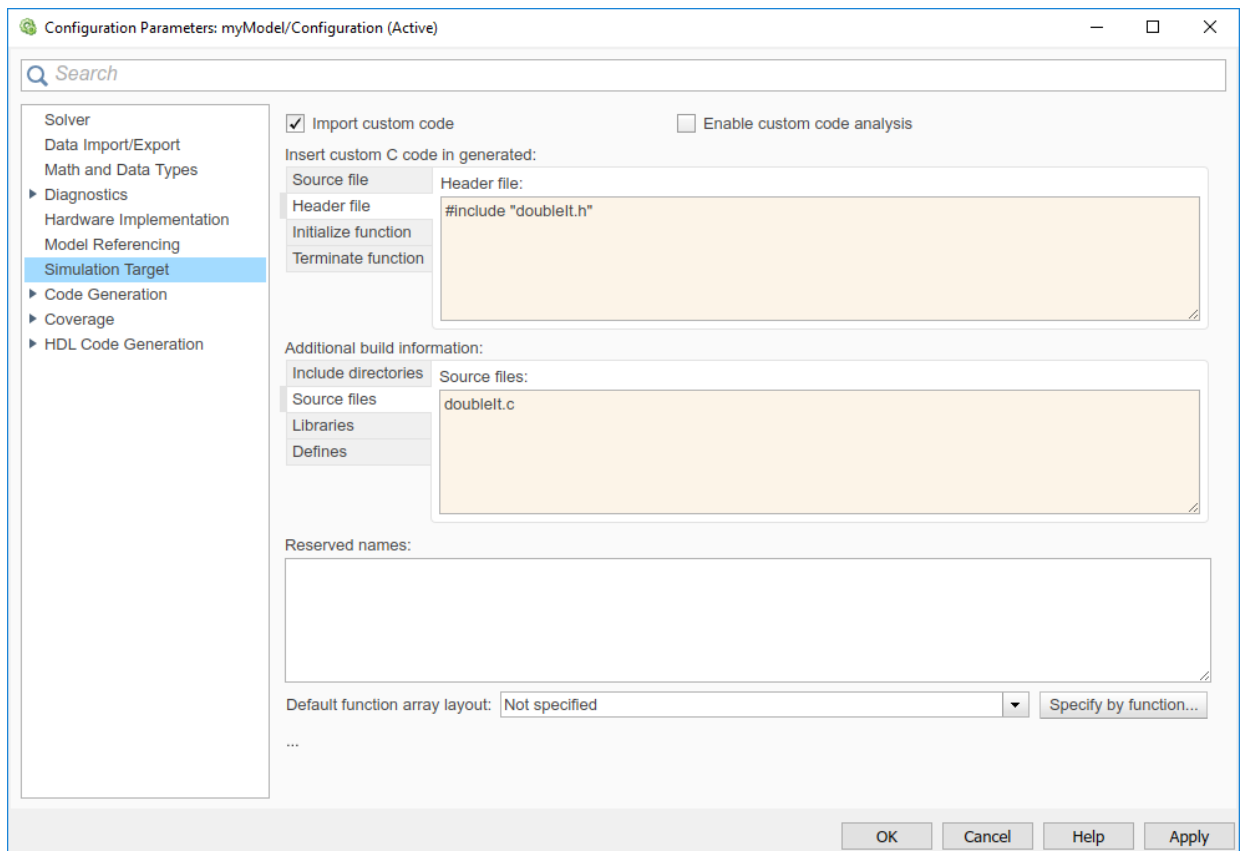

y = 0.0;
y = coder.ceval('doubleIt',u);
```

- 6 Connect a Constant block having a value of 3.5 to the input port of the MATLAB Function block.
- 7 Connect a Display block to the output port.

- 8 In the **Model Configuration Parameters** dialog box, open the **Simulation Target** pane.
- 9 In the **Insert custom C code in generated** section, select **Header file** from the list, and enter `#include "doubleIt.h"` in the **Header file** text box.
- 10 In the **Additional build information** section, select **Source files** from the list, enter `doubleIt.c` in the **Source files** text box, and click **OK**.

- 11 Run the simulation. The value 7 appears in the Display block.

## Control Imported Bus and Enumeration Type Definitions

This procedure applies to simulation only.

Simulink generates code for MATLAB Function blocks and Stateflow to simulate the model. When you call external C code using MATLAB Function blocks or Stateflow, you can control the type definitions for imported buses and enumerations in model simulation.

Simulink can generate type definitions, or you can supply a header file containing the type definitions. You control this behavior using the **Generate typedefs for imported bus and enumeration types** check box in the **Model Configuration Parameters** dialog box.

To include a custom header file defining the enumeration and bus types:

- 1 Clear the **Generate typedefs for imported bus and enumeration types** check box.
- 2 List the header file in the **Simulation Target** pane, in the **Header file** text box.

To configure Simulink to automatically generate type definitions:

- 1 Select the **Generate typedefs for imported bus and enumeration types** check box.
- 2 Do not list a header file that corresponds to the buses or enumerations.

# Enhance Code Readability for MATLAB Function Blocks

## In this section...

“Requirements for Using Readability Optimizations” on page 43-169

“Converting If-Elseif-Else Code to Switch-Case Statements” on page 43-169

“Example of Converting Code for If-Elseif-Else Decision Logic to Switch-Case Statements” on page 43-171

## Requirements for Using Readability Optimizations

To use readability optimizations in your code, you must have an Embedded Coder license. These optimizations appear only in code that you generate for an embedded real-time (ert) target.

---

**Note** These optimizations do not apply to MATLAB files that you call from the MATLAB Function block.

---

For more information, see “Configure a System Target File” (Embedded Coder) and “Control Code Style” (Embedded Coder).

## Converting If-Elseif-Else Code to Switch-Case Statements

When you generate code for embedded real-time targets, you can choose to convert `if-elseif-else` decision logic to `switch-case` statements. This conversion can enhance readability of the code.

For example, when a MATLAB Function block contains a long list of conditions, the `switch-case` structure:

- Reduces the use of parentheses and braces
- Minimizes repetition in the generated code

### How to Convert If-Elseif-Else Code to Switch-Case Statements

The following procedure describes how to convert generated code for the MATLAB Function block from `if-elseif-else` to `switch-case` statements.

| Step | Task                                                     | Reference                                            |
|------|----------------------------------------------------------|------------------------------------------------------|
| 1    | Verify that your block follows the rules for conversion. | “Verifying the Contents of the Block” on page 43-173 |
| 2    | Enable the conversion.                                   | “Enabling the Conversion” on page 43-174             |
| 3    | Generate code for your model.                            | “Generating Code for Your Model” on page 43-175      |

### Rules for Conversion

For the conversion to occur, the following rules must hold. LHS and RHS refer to the left-hand side and right-hand side of a condition, respectively.

| Construct             | Rules to Follow                                                                                                                                                                     |
|-----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| MATLAB Function block | <p>Must have two or more <i>unique</i> conditions, in addition to a default.</p> <p>For more information, see “How the Conversion Handles Duplicate Conditions” on page 43-171.</p> |

|                       | <p>Must have an integer or enumerated data type.</p>                                                                                                                                |

## How the Conversion Handles Duplicate Conditions

If a MATLAB Function block has duplicate conditions, the conversion preserves only the first condition. The generated code discards all other instances of duplicate conditions.

After removal of duplicates, two or more unique conditions must exist. Otherwise, no conversion occurs and the generated code contains all instances of duplicate conditions.

The following examples show how the conversion handles duplicate conditions.

| Example of Generated Code                                                                                                                                                                                           | Code After Conversion                                                                                                                                                  |
|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <pre>if (x == 1) {     block1 } else if (x == 2) {     block2 } else if (x == 1) { // duplicate     block3 } else if (x == 3) {     block4 } else if (x == 1) { // duplicate     block5 } else {     block6 }</pre> | <pre>switch (x) {     case 1:         block1; break;     case 2:         block2; break;     case 3:         block4; break;     default:         block6; break; }</pre> |
| <pre>if (x == 1) {     block1 } else if (x == 1) { // duplicate     block2 } else {     block3 }</pre>                                                                                                              | <p>No change, because only one unique condition exists</p>                                                                                                             |

## Example of Converting Code for If-Elseif-Else Decision Logic to Switch-Case Statements

Suppose that you have the following model with a MATLAB Function block. Assume that the output data type is `double` and the input data type is `Controller`, an enumerated type that you define. (For more information, see “Code Generation for Enumerations” on page 43-112.)

The block contains the following code:

```
function system = fcn(type)
%#codegen

if (type == Controller.P)
 system = 0;
elseif (type == Controller.I)
 system = 1;
elseif (type == Controller.PD)
 system = 2;
elseif (type == Controller.PI)
 system = 3;
elseif (type == Controller.PID)
 system = 4;
else
 system = 10;
end
```

The enumerated type definition in `Controller.m` is:

```
classdef Controller < Simulink.IntEnumType
 enumeration
 P(0)
 I(1)
 PD(2)
 PI(3)
 PID(4)
 UNKNOWN(10)
 end
end
```

If you generate code for an embedded real-time target using default settings, you see something like this:

```

if (if_to_switch_eml_blocks_U.In1 == P) {
 /* '<S1>:1:4' */
 /* '<S1>:1:5' */
 if_to_switch_eml_blocks_Y.Out1 = 0.0;
} else if (if_to_switch_eml_blocks_U.In1 == I) {
 /* '<S1>:1:6' */
 /* '<S1>:1:7' */
 if_to_switch_eml_blocks_Y.Out1 = 1.0;
} else if (if_to_switch_eml_blocks_U.In1 == PD) {
 /* '<S1>:1:8' */
 /* '<S1>:1:9' */
 if_to_switch_eml_blocks_Y.Out1 = 2.0;
} else if (if_to_switch_eml_blocks_U.In1 == PI) {
 /* '<S1>:1:10' */
 /* '<S1>:1:11' */
 if_to_switch_eml_blocks_Y.Out1 = 3.0;
} else if (if_to_switch_eml_blocks_U.In1 == PID) {
 /* '<S1>:1:12' */
 /* '<S1>:1:13' */
 if_to_switch_eml_blocks_Y.Out1 = 4.0;
} else {
 /* '<S1>:1:15' */
 if_to_switch_eml_blocks_Y.Out1 = 10.0;
}

```

The LHS variable `if_to_switch_eml_blocks_U.In1` appears multiple times in the generated code.

---

**Note** By default, variables that appear in the block do not retain their names in the generated code. Modified identifiers guarantee that no naming conflicts occur.

---

Traceability comments appear between each set of `/*` and `*/` markers. To learn more about traceability, see “Use Traceability in MATLAB Function Blocks” on page 43-157.

### Verifying the Contents of the Block

Check that the block follows all the rules in “Rules for Conversion” on page 43-170.

| Construct             | How the Construct Follows the Rules                                                                                                                                                                                                                                                                                                |
|-----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| MATLAB Function block | Five unique conditions exist, in addition to the default: <ul style="list-style-type: none"> <li>• (type == Controller.P)</li> <li>• (type == Controller.I)</li> <li>• (type == Controller.PD)</li> <li>• (type == Controller.PI)</li> <li>• (type == Controller.PID)</li> </ul>                                                   |
| Each condition        | Each condition: <ul style="list-style-type: none"> <li>• Tests equality</li> <li>• Uses the same input for the LHS</li> </ul>                                                                                                                                                                                                      |
| Each LHS              | Each LHS: <ul style="list-style-type: none"> <li>• Contains a single variable</li> <li>• Is the input to the block and therefore not a constant</li> <li>• Is of enumerated type <code>Controller</code>, which you define in <code>Controller.m</code> on the MATLAB path</li> <li>• Has no side effects on simulation</li> </ul> |
| Each RHS              | Each RHS: <ul style="list-style-type: none"> <li>• Is an enumerated value and therefore a constant</li> <li>• Is of enumerated type <code>Controller</code></li> </ul>                                                                                                                                                             |

### Enabling the Conversion

- 1 Open the Configuration Parameters dialog box.
- 2 In the **Code Generation** pane, select `ert.tlc` for the **System target file**.

This step specifies an embedded real-time target for your model.

- 3 In the **Code Generation > Code Style** pane, select the **Convert if-elseif-else patterns to switch-case statements** check box.

---

**Tip** This conversion works on a per-model basis. If you select this check box, the conversion applies to:

- All MATLAB Function blocks in a model
- MATLAB functions in all Stateflow charts of that model
- Flow charts in all Stateflow charts of that model

For more information, see “Enhance Readability of Code for Flow Charts” (Embedded Coder).

---

## Generating Code for Your Model

In the model window, press **Ctrl+B**.

The code for the MATLAB Function block uses `switch-case` statements instead of `if-elseif-else` code:

```
switch (if_to_switch_eml_blocks_U.In1) {
 case P:
 /* '<S1>:1:4' */
 /* '<S1>:1:5' */
 if_to_switch_eml_blocks_Y.Out1 = 0.0;
 break;

 case I:
 /* '<S1>:1:6' */
 /* '<S1>:1:7' */
 if_to_switch_eml_blocks_Y.Out1 = 1.0;
 break;

 case PD:
 /* '<S1>:1:8' */
 /* '<S1>:1:9' */
 if_to_switch_eml_blocks_Y.Out1 = 2.0;
 break;

 case PI:
 /* '<S1>:1:10' */
 /* '<S1>:1:11' */
 if_to_switch_eml_blocks_Y.Out1 = 3.0;
 break;

 case PID:
 /* '<S1>:1:12' */
 /* '<S1>:1:13' */
 if_to_switch_eml_blocks_Y.Out1 = 4.0;
```

```
 break;

default:
 /* '<S1>:1:15' */
 if_to_switch_eml_blocks_Y.Out1 = 10.0;
 break;
}
```

The switch-case statements provide the following benefits to enhance readability:

- The code reduces the use of parentheses and braces.
- The LHS variable `if_to_switch_eml_blocks_U.In1` appears only once, minimizing repetition in the code.

# Control Run-Time Checks

**In this section...**

“Types of Run-Time Checks” on page 43-177

“When to Disable Run-Time Checks” on page 43-177

“How to Disable Run-Time Checks” on page 43-178

## Types of Run-Time Checks

In simulation, the code generated for your MATLAB Function block includes the following run-time checks:

- Memory integrity checks

These checks detect violations of memory integrity in code generated for MATLAB Function blocks and stop execution with a diagnostic message.

---

**Caution** For safety, these checks are enabled by default. Without memory integrity checks, violations result in unpredictable behavior.

---

- Responsiveness checks in code generated for MATLAB Function blocks

These checks enable periodic checks for Ctrl+C breaks in the generated code. Enabling responsiveness checks also enables graphics refreshing.

---

**Caution** For safety, these checks are enabled by default. Without these checks, the only way to end a long-running execution might be to terminate MATLAB.

---

## When to Disable Run-Time Checks

Generally, generating code with run-time checks enabled results in more lines of generated code and slower simulation than generating code with the checks disabled. Disabling run-time checks usually results in streamlined generated code and faster simulation, with these caveats:

| <b>Consider disabling:</b> | <b>Only if:</b>                                                                                      |
|----------------------------|------------------------------------------------------------------------------------------------------|
| Memory integrity checks    | You are sure that your code is safe and that all array bounds and dimension checking is unnecessary. |
| Responsiveness checks      | You are sure that you will not need to stop execution of your application using Ctrl+C.              |

## How to Disable Run-Time Checks

MATLAB Function blocks enable run-time checks by default, but you can disable them explicitly for all MATLAB Function blocks in your Simulink model. Follow these steps:

- 1 Open your MATLAB Function block.
- 2 In the MATLAB Function Block Editor, select **Simulation Target**.
- 3 In the Configuration Parameters dialog box, clear the **Ensure memory integrity** or **Ensure responsiveness** check boxes, as applicable, and click **Apply**.

“Key Points to Remember” on page 43-201

### Learning Objectives

In this tutorial, you will learn how to:

- Use the MATLAB Function block to add MATLAB functions to Simulink models for modeling, simulation, and deployment to embedded processors.

This capability is useful for coding algorithms that are better stated in the textual language of MATLAB than in the graphical language of Simulink.

- Use `coder.extrinsic` to call MATLAB code from a MATLAB Function block.

This capability allows you to do rapid prototyping. You can call existing MATLAB code from Simulink without having to make this code suitable for code generation.

- Check that existing MATLAB code is suitable for code generation before generating code.

You must prepare your code before generating code.

- Specify variable-size inputs when generating code.

### Tutorial Prerequisites

- “What You Need to Know” on page 43-180
- “Required Products” on page 43-180

## What You Need to Know

To complete this tutorial, you should have basic familiarity with MATLAB software. You should also understand how to create and simulate a basic Simulink model.

## Required Products

To complete this tutorial, you must install the following products:

- MATLAB
- MATLAB Coder
- Simulink
- Simulink Coder
- C compiler

For a list of supported compilers, see [https://www.mathworks.com/support/compilers/current\\_release/](https://www.mathworks.com/support/compilers/current_release/).

You must set up the C compiler before generating C code. See “Setting Up Your C Compiler” on page 43-185.

For instructions on installing MathWorks products, see the MATLAB installation documentation for your platform. If you have installed MATLAB and want to check which other MathWorks products are installed, enter `ver` in the MATLAB Command Window.

## Example: The Kalman Filter

- “Description” on page 43-180
- “Algorithm” on page 43-181
- “Filtering Process” on page 43-182
- “Reference” on page 43-182

### Description

This section describes the example used by the tutorial. You do not have to be familiar with the algorithm to complete the tutorial.

The example for this tutorial uses a Kalman filter to estimate the position of an object moving in a two-dimensional space from a series of noisy inputs based on past positions.

The position vector has two components,  $x$  and  $y$ , indicating its horizontal and vertical coordinates.

Kalman filters have a wide range of applications, including control, signal and image processing; radar and sonar; and financial modeling. They are recursive filters that estimate the state of a linear dynamic system from a series of incomplete or noisy measurements. The Kalman filter algorithm relies on the state-space representation of filters and uses a set of variables stored in the state vector to characterize completely the behavior of the system. It updates the state vector linearly and recursively using a state transition matrix and a process noise estimate.

### Algorithm

This section describes the algorithm of the Kalman filter and is implemented in the MATLAB version of the filter supplied with this tutorial.

The algorithm predicts the position of a moving object based on its past positions using a Kalman filter estimator. It estimates the present position by updating the Kalman state vector, which includes the position ( $x$  and  $y$ ), velocity ( $V_x$  and  $V_y$ ), and acceleration ( $A_x$  and  $A_y$ ) of the moving object. The Kalman state vector, `x_est`, is a persistent variable.

```
% Initial conditions
persistent x_est p_est
if isempty(x_est)
 x_est = zeros(6, 1);
 p_est = zeros(6, 6);
end
```

`x_est` is initialized to an empty 6x1 column vector and updated each time the filter is used.

The Kalman filter uses the laws of motion to estimate the new state:

$$X = X_0 + V_x \cdot dt$$

$$Y = Y_0 + V_y \cdot dt$$

$$V_x = V_{x0} + A_x \cdot dt$$

$$V_y = V_{y0} + A_y \cdot dt$$

These laws of motion are captured in the state transition matrix  $A$ , which is a matrix that contains the coefficient values of  $x$ ,  $y$ ,  $V_x$ ,  $V_y$ ,  $A_x$ , and  $A_y$ .

```
% Initialize state transition matrix
dt=1;
```

```
A=[1 0 dt 0 0 0;...
 0 1 0 dt 0 0;...
 0 0 1 0 dt 0;...
 0 0 0 1 0 dt;...
 0 0 0 0 1 0 ;...
 0 0 0 0 0 1];
```

### Filtering Process

The filtering process has two phases:

- Predicted state and covariance

The Kalman filter uses the previously estimated state,  $x_{est}$ , to predict the current state,  $x_{prd}$ . The predicted state and covariance are calculated in:

```
% Predicted state and covariance
x_prd = A * x_est;
p_prd = A * p_est * A' + Q;
```

- Estimation

The filter also uses the current measurement,  $z$ , and the predicted state,  $x_{prd}$ , to estimate a more accurate approximation of the current state. The estimated state and covariance are calculated in:

```
% Measurement matrix
H = [1 0 0 0 0 0; 0 1 0 0 0 0];
Q = eye(6);
R = 1000 * eye(2);

% Estimation
S = H * p_prd' * H' + R;
B = H * p_prd';
klm_gain = (S \ B)';

% Estimated state and covariance
x_est = x_prd + klm_gain * (z - H * x_prd);
p_est = p_prd - klm_gain * H * p_prd;

% Compute the estimated measurements
y = H * x_est;
```

## Files for the Tutorial

- “About the Tutorial Files” on page 43-183
- “Location of Files” on page 43-183
- “Names and Descriptions of Files” on page 43-183

### About the Tutorial Files

The tutorial uses the following files:

- Simulink model files for each step of the tutorial.
- Example MATLAB code files for each step of the tutorial.

Throughout this tutorial, you work with Simulink models that call MATLAB files containing a Kalman filter algorithm.

- A MAT-file that contains example input data.
- A MATLAB file for plotting.

### Location of Files

The tutorial files are available in the following folder: `docroot\toolbox\simulink\examples\kalman`. To run the tutorial, you must copy these files to a local folder. For instructions, see “Copying Files Locally” on page 43-184.

### Names and Descriptions of Files

## Tutorial Steps

- “Copying Files Locally” on page 43-184
- “Setting Up Your C Compiler” on page 43-185
- “About the ex\_kalman00 Model” on page 43-185
- “Adding a MATLAB Function Block to Your Model” on page 43-187
- “Simulating the ex\_kalman11 Model” on page 43-189
- “Modifying the Filter to Accept a Fixed-Size Input” on page 43-191
- “Using the Filter to Accept a Variable-Size Input” on page 43-195
- “Debugging the MATLAB Function Block” on page 43-197
- “Generating C Code” on page 43-198

### Copying Files Locally

Copy the tutorial files to a local working folder:

- 1 Create a local *solutions* folder, for example, `c:\simulink\kalman\solutions`.
- 2 Change to the `docroot\toolbox\simulink\examples` folder. At the MATLAB command line, enter:

```
cd(fullfile(docroot, 'toolbox', 'simulink', 'examples'))
```

- 3 Copy the contents of the `kalman` subfolder to your local *solutions* folder, specifying the full path name of the *solutions* folder:

```
copyfile('kalman', 'solutions')
```

For example:

```
copyfile('kalman', 'c:\simulink\kalman\solutions')
```

Your *solutions* folder now contains a complete set of solutions for the tutorial. If you do not want to perform the steps for each task in the tutorial, you can view the solutions to see how the code should look.

- 4 Create a local *work* folder, for example, `c:\simulink\kalman\work`.
- 5 Copy the following files from your *solutions* folder to your *work* folder.

- `ex_kalman01`
- `ex_kalman00`
- `position`
- `plot_trajectory`

Your *work* folder now contains all the files that you need to get started with the tutorial.

## Setting Up Your C Compiler

Building your MATLAB Function block requires a supported compiler. MATLAB automatically selects one as the default compiler. If you have multiple MATLAB-supported compilers installed on your system, you can change the default using the `mex -setup` command. See “Change Default Compiler” (MATLAB).

## About the `ex_kalman00` Model

First, examine the `ex_kalman00` model supplied with the tutorial to understand the problem that you are trying to solve using the Kalman filter.

- 1 Open the `ex_kalman00` model in Simulink:
  - a Set your MATLAB current folder to the folder that contains your working files for this tutorial. At the MATLAB command line, enter:

```
cd work
```

where *work* is the full path name of the folder containing your files.

- b** At the MATLAB command line, enter:

```
ex_kalman00
```

This model is an incomplete model to demonstrate how to integrate MATLAB code with Simulink. The complete model is `ex_kalman11`, which is also supplied with this tutorial.

### **InitFcn Model Callback Function**

The model uses this callback function to:

- Load position data from a MAT-file.
- Set up data used by the Index generator block, which provides the second input to the Selector block.

To view this callback:

- 1** Select **File > Model Properties > Model Properties**.
- 2** Select the **Callbacks** tab.
- 3** Select `InitFcn` in the **Model callbacks** pane.

The callback appears.

```
load position.mat;
[R,C]=size(position);
idx=(1:C)';
t=idx-1;
```

### **Source Blocks**

The model uses two Source blocks to provide position data and a scalar index to a Selector block.

### **Selector Block**

The model uses a Selector block that selects elements of its input signal and generates an output signal based on its index input and its **Index Option** settings. By changing the configuration of this block, you can generate different size signals.

To view the Selector block settings, double-click the Selector block to view the function block parameters.

In this model, the **Index Option** for the first port is `Select all` and for the second port is `Index vector (port)`. Because the input is a  $2 \times 310$  position matrix, and the index data increments from 1 to 310, the Selector block simply outputs one  $2 \times 1$  output at each sample time.

### **MATLAB Function Block**

The model uses a MATLAB Function block to plot the trajectory of the object and the Kalman filter estimated position. This function:

- First declares the `figure`, `hold`, and `plot_trajectory` functions as extrinsic because these MATLAB visualization functions are not supported for code generation. When you call an unsupported MATLAB function, you must declare it to be extrinsic so MATLAB can execute it, but does not try to generate code for it.
- Creates a figure window and holds it for the duration of the simulation. Otherwise a new figure window appears for each sample time.
- Calls the `plot_trajectory` function, which plots the trajectory of the object and the Kalman filter estimated position.

### **Simulation Stop Time**

The simulation stop time is 309, because the input to the filter is a vector containing 310 elements and Simulink uses zero-based indexing.

### **Adding a MATLAB Function Block to Your Model**

To modify the model and code yourself, work through the exercises in this section. Otherwise, open the supplied model `ex_kalman11` in your *solutions* subfolder to see the modified model.

For the purposes of this tutorial, you add the MATLAB Function block to the `ex_kalman00.mdl` model supplied with the tutorial. You would have to develop your own test bench starting with an empty Simulink model.

### **Adding the MATLAB Function Block**

To add a MATLAB Function block to the `ex_kalman00` model:

- 1 Open `ex_kalman00` in Simulink.  
`ex_kalman00`
- 2 Add a MATLAB Function block to the model:

- a At the MATLAB command line, type `slLibraryBrowser` to open the Simulink Library Browser.
- b From the list of Simulink libraries, select the User-Defined Functions library.
- c Click the MATLAB Function block and drag it into the `ex_kalman00` model. Place the block just above the red text annotation that reads Place MATLAB Function Block here.
- d Delete the red text annotations from the model.
- e Save the model in the current folder as `ex_kalman11`.

**Calling Your MATLAB Code from the MATLAB Function Block**

To call your MATLAB code from the MATLAB Function block:

- 1 Double-click the MATLAB Function block to open the MATLAB Function Block Editor.
- 2 Delete the default code displayed in the editor.
- 3 Copy the following code to the MATLAB Function block.

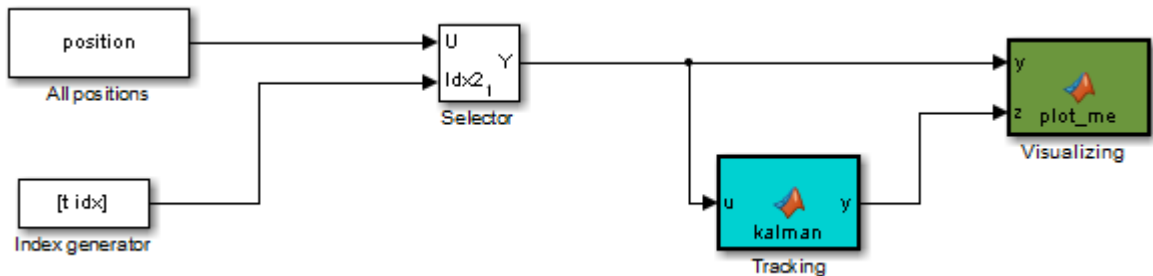

```
function y = kalman(u)
%#codegen

y = ex_kalman01(u);
```

- 4 Save the model.

**Connecting the MATLAB Function Block Input and Output**

- 1 Connect the MATLAB Function block input and output so that your model looks like this.

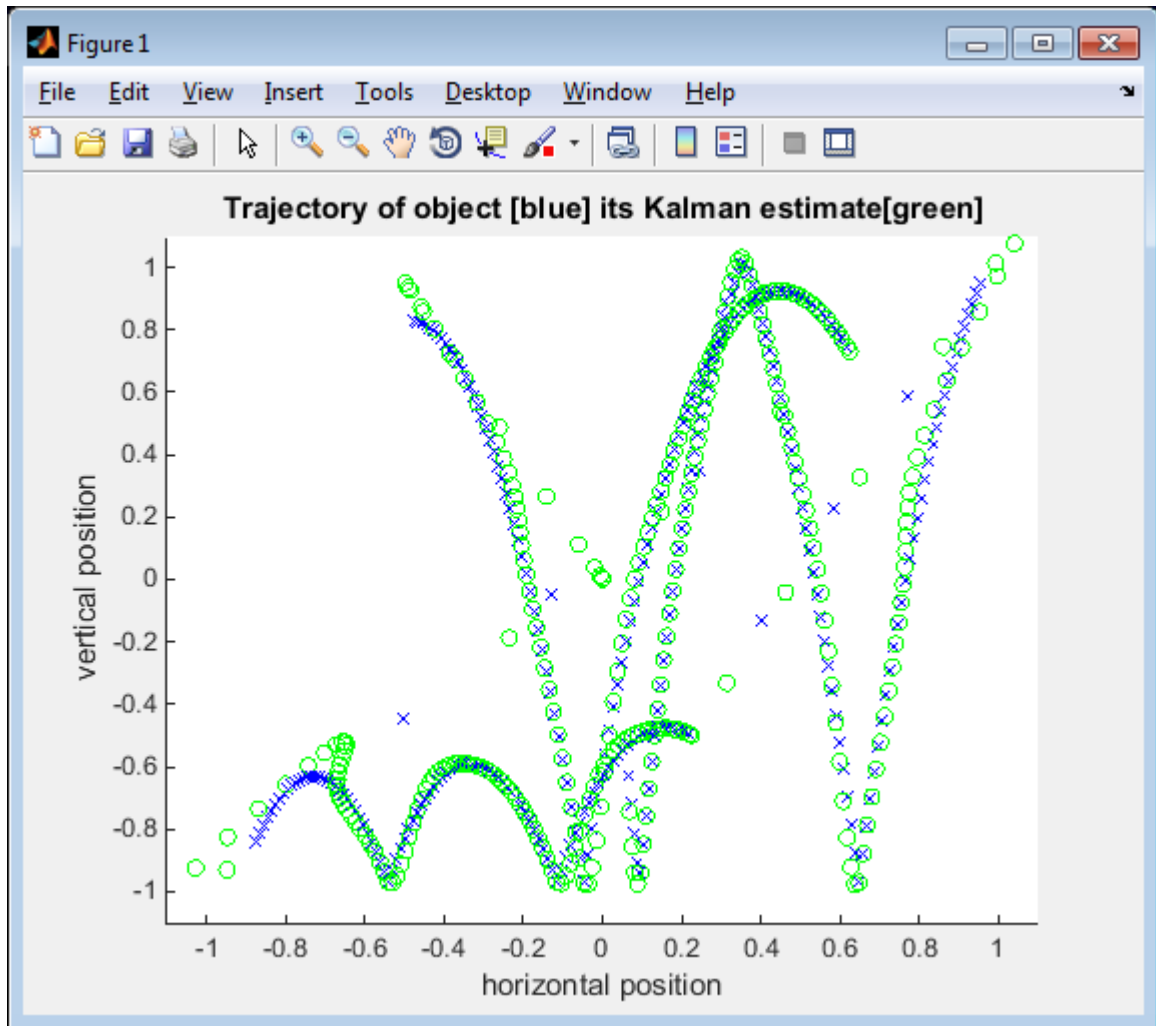

- 2 Save the model.

### **Simulating the ex\_kalman11 Model**

To simulate the model:

- 1 In the Simulink model window, select **Simulation > Run**.

As Simulink runs the model, it plots the trajectory of the object in blue and the Kalman filter estimated position in green. Initially, you see that it takes a short time for the estimated position to converge with the actual position of the object. Then three sudden shifts in position occur—each time the Kalman filter readjusts and tracks the object after a few iterations.

2 The simulation stops.

You have proved that your MATLAB algorithm works in Simulink. You are now ready to modify the filter to accept a fixed-size input, as described in “Modifying the Filter to Accept a Fixed-Size Input” on page 43-191.

## Modifying the Filter to Accept a Fixed-Size Input

The filter you have worked on so far in this tutorial uses a simple batch process that accepts one input at a time, so you must call the function repeatedly for each input. In this part of the tutorial, you learn how to modify the algorithm to accept a fixed-sized input, which makes the algorithm suitable for frame-based processing. You then modify the model to provide the input as fixed-size frames of data and call the filter passing in the data one frame at a time.

### Modifying Your MATLAB Code

To modify the code yourself, work through the exercises in this section. Otherwise, open the supplied file `ex_kalman03.m` in your *solutions* subfolder to see the modified algorithm.

You can now modify the algorithm to process a vector containing more than one input. You need to find the length of the vector and call the filter code for each element in the vector in turn. You do this by calling the filter algorithm in a `for` loop.

- 1 Open `ex_kalman02.m` in the MATLAB Editor. At the MATLAB command line, enter:

```
edit ex_kalman02.m
```

- 2 Add a `for` loop around the filter code.

- a Before the comment:

```
% Predicted state and covariance
```

```
insert:
```

```
for i=1:size(z,2)
```

- b After:

```
% Compute the estimated measurements
```

```
y = H * x_est;
```

```
insert:
```

```
end
```

- c Select the code between the `for` statement and the end statement, right-click to open the context menu and select **Smart Indent** to indent the code.

Your filter code should now look like this:

```
for i=1:size(z,2)
 % Predicted state and covariance
 x_prd = A * x_est;
 p_prd = A * p_est * A' + Q;

 % Estimation
 S = H * p_prd' * H' + R;
 B = H * p_prd';
 klm_gain = (S \ B)';

 % Estimated state and covariance
 x_est = x_prd + klm_gain * (z - H * x_prd);
 p_est = p_prd - klm_gain * H * p_prd;

 % Compute the estimated measurements
 y = H * x_est;
end
```

- 3 Modify the line that calculates the estimated state and covariance to use the  $i^{\text{th}}$  element of input  $z$ .

Change:

```
x_est = x_prd + klm_gain * (z - H * x_prd);
```

to:

```
x_est = x_prd + klm_gain * (z(1:2,i) - H * x_prd);
```

- 4 Modify the line that computes the estimated measurements to append the result to the  $i^{\text{th}}$  element of the output  $y$ .

Change:

```
y = H * x_est;
```

to:

```
y(:,i) = H * x_est;
```

The code analyzer message indicator in the top right turns orange to indicate that the code analyzer has detected warnings. The code analyzer underlines the offending code in orange and places a orange marker to the right.

- 5 Move your pointer over the orange marker to view the error information.

The code analyzer detects that `y` must be fully defined before sub-scripting it and that you cannot grow variables through indexing in generated code.

- 6 To address this warning, preallocate memory for the output `y`, which is the same size as the input `z`. Add this code before the `for` loop.

```
% Pre-allocate output signal:
y=zeros(size(z));
```

The orange marker disappears and the code analyzer message indicator in the top right edge of the code turns green, which indicates that you have fixed all the errors and warnings detected by the code analyzer.

### Why Preallocate the Outputs?

You must preallocate outputs because code generation does not support increasing the size of an array over time.

- 7 Change the function name to `ex_kalman03` and save the file as `ex_kalman03.m` in the current folder.

You are ready to begin the next task in the tutorial, “Modifying Your Model to Call the Updated Algorithm” on page 43-193.

### Modifying Your Model to Call the Updated Algorithm

To modify the model yourself, work through the exercises in this section. Otherwise, open the supplied model `ex_kalman22.mdl` in your *solutions* subfolder to see the modified model.

Next, update your model to provide the input as fixed-size frames of data and call `ex_kalman03` passing in the data one frame at a time.

- 1 Open `ex_kalman11` model in Simulink.

```
ex_kalman11
```

- 2 Double-click the MATLAB Function block to open the MATLAB Function Block Editor.
- 3 Replace the code that calls `ex_kalman02` with a call to `ex_kalman03`.

```
function y = kalman(u)
%#codegen
```

```
y = ex_kalman03(u);
```

- 4 Close the editor.
- 5 Modify the InitFcn callback:
  - a Select **File > Model Properties > Model Properties**.

The Model Properties dialog box opens.

- b In this dialog box, select the **Callbacks** tab.
- c Select InitFcn in the **Model callbacks** pane.
- d Replace the existing callback with:

```
load position.mat;
[R,C]=size(position);
FRAME_SIZE=5;
idx=(1:FRAME_SIZE:C)';
LEN=length(idx);
t=(1:LEN)'-1;
```

This callback sets the frame size to 5, and the index to increment by 5.

- e Click **Apply** and close the Model Properties dialog box.
- 6 Update the Selector block to use the correct indices.
  - a Double-click the Selector block to view the function block parameters.

The Function Block Parameters dialog box opens.
  - b Set the second **Index Option** to `Starting index (port)`.
  - c Set the **Output Size** for the second input to `FRAME_SIZE`, click **Apply** and close the dialog box.

Now, the **Index Option** for the first port is `Select all` and for the second port is `Starting index (port)`. Because the index increments by 5 each sample time, and the output size is 5, the Selector block outputs a 2x5 output at each sample time.

- 7 Change the model simulation stop time to 61. Now the frame size is 5, so the simulation completes in a fifth of the sample times.
  - a In the Simulink model window, select **Simulation > Model Configuration Parameters**.
  - b In the left pane of the Configuration Parameters dialog box, select **Solver**.
  - c In the right pane, set **Stop time** to 61.

- d Click **Apply** and close the dialog box.
- 8 Save the model as `ex_kalman22.mdl`.

### Testing Your Modified Algorithm

To simulate the model:

- 1 In the Simulink model window, select **Simulation > Run**.

As Simulink runs the model, it plots the trajectory of the object in blue and the Kalman filter estimated position in green as before when you used the batch filter.

- 2 The simulation stops.

You have proved that your algorithm accepts a fixed-size signal. You are now ready for the next task, “Using the Filter to Accept a Variable-Size Input” on page 43-195.

### Using the Filter to Accept a Variable-Size Input

In this part of the tutorial, you learn how to specify variable-size data in your Simulink model. Then you test your Kalman filter algorithm with variable-size inputs and see that the algorithm is suitable for processing packets of data of varying size. For more information on using variable-size data in Simulink, see “Variable-Size Signal Basics” on page 69-2.

### Updating the Model to Use Variable-Size Inputs

To modify the model yourself, work through the exercises in this section. Otherwise, open the supplied model `ex_kalman33.mdl` in your *solutions* subfolder to see the modified model.

- 1 Open `ex_kalman22.mdl` in Simulink.
- `ex_kalman22`
- 2 Modify the `InitFcn` callback:
- a Select **File > Model Properties > Model Properties**.

The Model Properties dialog box opens.

- b Select the **Callbacks** tab.
- c Select `InitFcn` in the **Model callbacks** pane.
- d Replace the existing callback with:

```
load position.mat;
idx=[1 1 ;2 3 ;4 6 ;7 10 ;11 15 ;16 30 ;
 31 70 ;71 100 ;101 200 ;201 250 ;251 310];
LEN=length(idx);
t=(0:1:LEN-1)';
```

This callback sets up indexing to generate eleven different size inputs. It specifies the start and end indices for each sample time. The first sample time uses only the first element, the second sample time uses the second and third elements, and so on. The largest sample, 101 to 200, contains 100 elements.

- e Click **Apply** and close the **Model Properties** dialog box.
- 3 Update the Selector block to use the correct indices.
  - a Double-click the Selector block to view the function block parameters.

The Function Block Parameters dialog box opens.
  - b Set the second **Index Option** to **Starting and ending indices (port)**, then click **Apply** and close the dialog box.

This setting means that the input to the index port specifies the start and end indices for the input at each sample time. Because the index input specifies different starting and ending indices at each sample time, the Selector block outputs a variable-size signal as the simulation progresses.
- 4 Use the Ports and Data Manager to set the MATLAB Function input  $x$  and output  $y$  as variable-size data.
  - a Double-click the MATLAB Function block to open the MATLAB Function Block Editor.
  - b From the editor menu, select **Edit Data**.
  - c In the Ports and Data Manager left pane, select the input  $u$ .

The Ports and Data Manager displays information about  $u$  in the right pane.
  - d On the **General** tab, select the **Variable size** check box and click **Apply**.
  - e In the left pane, select the output  $y$ .
  - f On the **General** tab:
    - i Set the **Size** of  $y$  to  $[2 \ 100]$  to specify a 2-D matrix where the upper bounds are 2 for the first dimension and 100 for the second, which is the maximum size input specified in the `InitFcn` callback.

- ii Select the **Variable size** check box.
  - iii Click **Apply**.
- g Close the Ports and Data Manager.
- 5 Now do the same for the other MATLAB Function block. Use the Ports and Data Manager to set the Visualizing block inputs y and z as variable-size data.
  - a Double-click the Visualizing block to open the MATLAB Function Block Editor.
  - b From the editor menu, select **Edit Data**.
  - c In the Ports and Data Manager left pane, select the input y.
  - d On the **General** tab, select the **Variable size** check box and click **Apply**.
  - e In the left pane, select the input z.
  - f On the **General** tab, select the **Variable size** check box and click **Apply**.
  - g Close the Ports and Data Manager.
- 6 Change the model simulation stop time to 10. This time, the filter processes one of the eleven different size inputs each sample time.
- 7 Save the model as `ex_kalman33.mdl`.

### Testing Your Modified Model

To simulate the model:

- 1 In the Simulink model window, select **Simulation > Run**.

As Simulink runs the model, it plots the trajectory of the object in blue and the Kalman filter estimated position in green as before.

Note that the signal lines between the Selector block and the Tracking and Visualization blocks change to show that these signals are variable-size.

- 2 The simulation stops.

You have successfully created an algorithm that accepts variable-size inputs. Next, you learn how to debug your MATLAB Function block, as described in “Debugging the MATLAB Function Block” on page 43-197.

### Debugging the MATLAB Function Block

You can debug your MATLAB Function block just like you can debug a function in MATLAB.

**1** Double-click the MATLAB Function block that calls the Kalman filter to open the MATLAB Function Block Editor.

**2** In the editor, click the dash (-) character in the left margin of the line:

```
y = kalman03(u);
```

A small red ball appears in the margin of this line, indicating that you have set a breakpoint.

**3** In the Simulink model window, select **Simulation > Run**.

The simulation pauses when execution reaches the breakpoint and a small green arrow appears in the left margin.

**4** Place the pointer over the variable `u`.

The value of `u` appears adjacent to the pointer.

**5** From the MATLAB Function Block Editor menu, select **Step In**.

The `kalman03.m` file opens in the editor and you can now step through this code using **Step**, **Step In**, and **Step Out**.

**6** Select **Step Out**.

The `kalman03.m` file closes and the MATLAB Function block code reappears in the editor.

**7** Place the pointer over the output variable `y`.

You can now see the value of `y`.

**8** Click the red ball to remove the breakpoint.

**9** From the MATLAB Function Block Editor menu, select **Quit Debugging**.

**10** Close the editor.

**11** Close the figure window.

Now you are ready for the next task, “Generating C Code” on page 43-198.

### **Generating C Code**

You have proved that your algorithm works in Simulink. Next you generate code for your model.

---

**Note** Before generating code, you must check that your MATLAB code is suitable for code generation. If you call your MATLAB code as an extrinsic function, you must remove extrinsic calls before generating code.

---

- 1 Rename the MATLAB Function block to **Tracking**. To rename the block, double-click the annotation **MATLAB Function** below the MATLAB Function block and replace the text with **Tracking**.

When you generate code for the MATLAB Function block, Simulink Coder uses the name of the block in the generated code. It is good practice to use a meaningful name.

- 2 Before generating code, ensure that Simulink Coder creates a code generation report. This HTML report provides easy access to the list of generated files with a summary of the configuration settings used to generate the code.

- a In the Simulink model window, select **Simulation > Model Configuration Parameters**.

The Configuration Parameters dialog box opens.

- b In the left pane of the Configuration Parameters dialog box, select **Report** under **Code Generation**.
    - c In the right pane, select **Create code generation report**.

The **Open report automatically** option is also selected.

- d Click **Apply** and close the Configuration Parameters dialog box.
      - e Save your model.

- 3 To generate code for the Tracking block:

- a In your model, select the Tracking block.
  - b In the Simulink model window, select **Code > C/C++ Code > Build Selected Subsystem**.

- 4 The Simulink software generates an error informing you that it cannot log variable-size signals as arrays. You need to change the format of data saved to the MATLAB workspace. To change this format:

- In the Simulink model window, select **Simulation > Model Configuration Parameters**.

The Configuration Parameters dialog box opens.

- In the left pane of the Configuration Parameters dialog box, select **Data Import/Export** and set the **Format** to Structure with time.

The logged data is now a structure that has two fields: a time field and a signals field, enabling Simulink to log variable-size signals.

- Click **Apply** and close the Configuration Parameters dialog box.
- Save your model.

**5** Repeat step 3 to generate code for the Tracking block.

The Simulink Coder software generates C code for the block and launches the code generation report.

For more information on using the code generation report, see “Reports for Code Generation” (Simulink Coder).

- 6** In the left pane of the code generation report, click the `Tracking.c` link to view the generated C code. Note that in the code generated for the MATLAB Function block, `Tracking`, there is no code for the `ex_kalman03` function because inlining is enabled by default.
- 7** Modify your filter algorithm to disable inlining:

- a** In `ex_kalman03.m`, after the function declaration, add:

```
coder.inline('never');
```

- b** Change the function name to `ex_kalman04` and save the file as `ex_kalman04.m` in the current folder.

- c** In your `ex_kalman33` model, double-click the Tracking block.

The MATLAB Function Block Editor opens.

- d** Modify the call to the filter algorithm to call `ex_kalman04`.

```
function y = kalman(u)
 %#codegen
```

```
 y = ex_kalman04(u);
```

- e** Save the model as `ex_kalman44.mdl`.

**8** Generate code for the updated model.

- a** Select the Tracking block.

- b** In the model window, select **Code > C/C++Code > Build Selected Subsystem**.

The **Build code for Subsystem** dialog box appears.

- c** Click the **Build** button.

The Simulink Coder software generates C code for the block and launches the code generation report.

- d** In the left pane of the code generation report, click the `Tracking.c` link to view the generated C code.

This time the `ex_kalman04` function has code because you disabled inlining.

```
/* Forward declaration for local functions */
static void Tracking_ex_kalman04(const real_T z_data[620], const int32_T
 z_sizes[2], real_T y_data[620], int32_T y_sizes[2]);

/* Function for MATLAB Function Block: '<Root>/Tracking' */
static void Tracking_ex_kalman04(const real_T z_data[620], const int32_T 48
 z_sizes[2], real_T y_data[620], int32_T y_sizes[2])
```

## Best Practices Used in This Tutorial

### Best Practice — Saving Incremental Code Updates

Save your code before making modifications. This practice provides a fallback in case of error and a baseline for testing and validation. Use a consistent file naming convention. For example, add a two-digit suffix to the file name for each file in a sequence.

### Key Points to Remember

- Back up your MATLAB code before you modify it.
- Decide on a naming convention for your files and save interim versions frequently. For example, this tutorial uses a two-digit suffix to differentiate the various versions of the filter algorithm.
- For simulation purposes, before generating code, call your MATLAB code using `coder.extrinsic` to check that your algorithm is suitable for use in Simulink. This practice provides these benefits:
  - You do not have to make the MATLAB code suitable for code generation.

- You can debug your MATLAB code in MATLAB while calling it from Simulink.
- Create a Simulink Coder code generation report. This HTML report provides easy access to the list of generated files with a summary of the configuration settings used to generate the code.

# Filter Audio Signal Using MATLAB Code

## In this section...

- “Learning Objectives” on page 43-203
- “Tutorial Prerequisites” on page 43-203
- “Example: The LMS Filter” on page 43-204
- “Files for the Tutorial” on page 43-207
- “Tutorial Steps” on page 43-208

## Learning Objectives

In this tutorial, you will learn how to:

- Use the MATLAB Function block to add MATLAB functions to Simulink models for modeling, simulation, and deployment to embedded processors.

This capability is useful for coding algorithms that are better stated in the textual language of MATLAB than in the graphical language of Simulink.

- Use `coder.extrinsic` to call MATLAB code from a MATLAB Function block.

This capability allows you to call existing MATLAB code from Simulink without first having to make this code suitable for code generation, allowing for rapid prototyping.

- Check that existing MATLAB code is suitable for code generation.
- Convert a MATLAB algorithm from batch processing to streaming.
- Use persistent variables in code that is suitable for code generation.

You need to make the filter weights persistent so that the filter algorithm does not reset their values each time it runs.

## Tutorial Prerequisites

- “What You Need to Know” on page 43-204
- “Required Products” on page 43-204

## What You Need to Know

To work through this tutorial, you should have basic familiarity with MATLAB software. You should also understand how to create a basic Simulink model and how to simulate that model. For more information, see “Create a Simple Model”.

## Required Products

To complete this tutorial, you must install the following products:

- MATLAB
- MATLAB Coder
- Simulink
- Simulink Coder
- DSP System Toolbox
- C compiler

For a list of supported compilers, see [https://www.mathworks.com/support/compilers/current\\_release/](https://www.mathworks.com/support/compilers/current_release/).

For instructions on installing MathWorks products, refer to the installation documentation. If you have installed MATLAB and want to check which other MathWorks products are installed, enter `ver` in the MATLAB Command Window. For instructions on installing and setting up a C compiler, see “Setting Up the C or C++ Compiler” (MATLAB Coder).

## Example: The LMS Filter

- “Description” on page 43-204
- “Algorithm” on page 43-205
- “Filtering Process” on page 43-206
- “Reference” on page 43-206

## Description

A least mean squares (LMS) filter is an adaptive filter that adjusts its transfer function according to an optimizing algorithm. You provide the filter with an example of the desired signal together with the input signal. The filter then calculates the filter weights,

or coefficients, that produce the least mean squares of the error between the output signal and the desired signal.

This example uses an LMS filter to remove the noise in a music recording. There are two inputs. The first input is the distorted signal: the music recording plus the filtered noise. The second input is the desired signal: the unfiltered noise. The filter works to eliminate the difference between the output signal and the desired signal and outputs the difference, which, in this case, is the clean music recording. When you start the simulation, you hear both the noise and the music. Over time, the adaptive filter removes the noise so you hear only the music.

### Algorithm

This example uses the least mean squares (LMS) algorithm to remove noise from an input signal. The LMS algorithm computes the filtered output, filter error, and filter weights given the distorted and desired signals.

At the start of the tutorial, the LMS algorithm uses a batch process to filter the audio input. This algorithm is suitable for MATLAB, where you are likely to load in the entire signal and process it all at once. However, a batch process is not suitable for processing a signal in real time. As you work through the tutorial, you refine the design of the filter to convert the algorithm from batch-based to stream-based processing.

The baseline function signature for the algorithm is:

```
function [signal_out, err, weights] = ...
 lms_01(signal_in, desired)
```

The filtering is performed in the following loop:

```
for n = 1:SignalLength
 % Compute the output sample using convolution:
 signal_out(n,ch) = weights' * signal_in(n:n+FilterLength-1,ch);
 % Update the filter coefficients:
 err(n,ch) = desired(n,ch) - signal_out(n,ch) ;
 weights = weights + mu*err(n,ch)*signal_in(n:n+FilterLength-1,ch);
end
```

where `SignalLength` is the length of the input signal, `FilterLength` is the filter length, and `mu` is the adaptation step size.

### What Is the Adaptation Step Size?

LMS algorithms have a step size that determines the amount of correction to apply as the filter adapts from one iteration to the next. Choosing the appropriate step size requires experience in adaptive filter design. A step size that is too small increases the time for the filter to converge. Filter convergence is the process where the error signal (the difference between the output signal and the desired signal) approaches an equilibrium state over time. A step size that is too large might cause the adapting filter to overshoot the equilibrium and become unstable. Generally, smaller step sizes improve the stability of the filter at the expense of the time it takes to adapt.

### Filtering Process

The filtering process has three phases:

- Convolution

The convolution for the filter is performed in:

```
signal_out(n,ch) = weights' * signal_in(n:n+FilterLength-1,ch);
```

### What Is Convolution?

Convolution is the mathematical foundation of filtering. In signal processing, convolving two vectors or matrices is equivalent to filtering one of the inputs by the other. In this implementation of the LMS filter, the convolution operation is the vector dot product between the filter weights and a subset of the distorted input signal.

- Calculation of error

The error is the difference between the desired signal and the output signal:

```
err(n,ch) = desired(n,ch) - signal_out(n,ch);
```

- Adaptation

The new value of the filter weights is the old value of the filter weights plus a correction factor that is based on the error signal, the distorted signal, and the adaptation step size:

```
weights = weights + mu*err(n,ch)*signal_in(n:n+FilterLength-1,ch);
```

## Files for the Tutorial

- “About the Tutorial Files” on page 43-207
- “Location of Files” on page 43-207
- “Names and Descriptions of Files” on page 43-207

### About the Tutorial Files

The tutorial uses the following files:

- Simulink model files for each step of the tutorial.
- MATLAB code files for each step of the example.

Throughout this tutorial, you work with Simulink models that call MATLAB files that contain a simple least mean squares (LMS) filter algorithm.

### Location of Files

The tutorial files are available in the following folder: `docroot\toolbox\simulink\examples\lms`. To run the tutorial, you must copy these files to a local folder. For instructions, see “Copying Files Locally” on page 43-208.

### Names and Descriptions of Files

| Type                 | Name                              | Description                                                                               |
|----------------------|-----------------------------------|-------------------------------------------------------------------------------------------|
| MATLAB files         | <code>lms_01</code>               | Baseline MATLAB implementation of batch filter. Not suitable for code generation.         |
|                      | <code>lms_02</code>               | Filter modified from batch to streaming.                                                  |
|                      | <code>lms_03</code>               | Frame-based streaming filter with Reset and Adapt controls.                               |
|                      | <code>lms_04</code>               | Frame-based streaming filter with Reset and Adapt controls. Suitable for code generation. |
|                      | <code>lms_05</code>               | Disabled inlining for code generation.                                                    |
|                      | <code>lms_06</code>               | Demonstrates use of <code>coder.nullcopy</code> .                                         |
| Simulink model files | <code>acoustic_environment</code> | Simulink model that provides an overview of the acoustic environment.                     |

| Type | Name             | Description                                                       |
|------|------------------|-------------------------------------------------------------------|
|      | noise_cancel_00  | Simulink model without a MATLAB Function block.                   |
|      | noise_cancel_01  | Complete noise_cancel_00 model including a MATLAB Function block. |
|      | noise_cancel_02  | Simulink model for use with lms_02.m.                             |
|      | noise_cancel_03  | Simulink model for use with lms_03.m.                             |
|      | noise_cancel_04  | Simulink model for use with lms_04.m.                             |
|      | noise_cancel_05  | Simulink model for use with lms_05.m.                             |
|      | noise_cancel_06  | Simulink model for use with lms_06.m.                             |
|      | design_templates | Simulink model containing Adapt and Reset controls.               |

## Tutorial Steps

- “Copying Files Locally” on page 43-208
- “Setting Up Your C Compiler” on page 43-209
- “Running the acoustic\_environment Model” on page 43-209
- “Adding a MATLAB Function Block to Your Model” on page 43-210
- “Calling Your MATLAB Code As an Extrinsic Function for Rapid Prototyping” on page 43-211
- “Simulating the noise\_cancel\_01 Model” on page 43-214
- “Modifying the Filter to Use Streaming” on page 43-216
- “Adding Adapt and Reset Controls” on page 43-222
- “Generating Code” on page 43-226
- “Optimizing the LMS Filter Algorithm” on page 43-230

### Copying Files Locally

Copy the tutorial files to a local folder:

- 1 Create a local *solutions* folder, for example, `c:\test\lms\solutions`.
- 2 Change to the `docroot\toolbox\simulink\examples` folder. At the MATLAB command line, enter:

```
cd(fullfile(docroot, 'toolbox', 'simulink', 'examples'))
```

- 3 Copy the contents of the `lms` subfolder to your *solutions* folder, specifying the full path name of the *solutions* folder:

```
copyfile('lms', 'solutions')
```

Your *solutions* folder now contains a complete set of solutions for the tutorial. If you do not want to perform the steps for each task, you can view the supplied solution to see how the code should look.

- 4 Create a local *work* folder, for example, `c:\test\lms\work`.
- 5 Copy the following files from your *solutions* folder to your *work* folder.

- `lms_01`
- `lms_02`
- `noise_cancel_00`
- `acoustic_environment`
- `design_templates`

Your *work* folder now contains all the files that you need to get started.

You are now ready to set up your C compiler.

### Setting Up Your C Compiler

Building your MATLAB Function block requires a supported compiler. MATLAB automatically selects one as the default compiler. If you have multiple MATLAB-supported compilers installed on your system, you can change the default using the `mex -setup` command. See “Change Default Compiler” (MATLAB) and the list of .

### Running the acoustic\_environment Model

Run the `acoustic_environment` model supplied with the tutorial to understand the problem that you are trying to solve using the LMS filter. This model adds band-limited white noise to an audio signal and outputs the resulting signal to a speaker.

To simulate the model:

- 1 Open the `acoustic_environment` model in Simulink:
  - a Set your MATLAB current folder to the folder that contains your working files for this tutorial. At the MATLAB command line, enter:

```
cd work
```

where *work* is the full path name of the folder containing your files. See “Find Files and Folders” (MATLAB) for more information.

- b** At the MATLAB command line, enter:

```
acoustic_environment
```

- 2** Ensure that your speakers are on.
- 3** To simulate the model, from the Simulink model window, select **Simulation > Run**.

As Simulink runs the model, you hear the audio signal distorted by noise.

- 4** While the simulation is running, double-click the Manual Switch to select the audio source.

Now you hear the desired audio input without any noise.

The goal of this tutorial is to use a MATLAB LMS filter algorithm to remove the noise from the noisy audio signal. You do this by adding a MATLAB Function block to the model and calling the MATLAB code from this block.

### **Adding a MATLAB Function Block to Your Model**

To modify the model and code yourself, work through the exercises in this section. Otherwise, open the supplied model `noise_cancel_01` in your *solutions* subfolder to see the modified model.

For the purposes of this tutorial, you add the MATLAB Function block to the `noise_cancel_00` model supplied with the tutorial. In practice, you would have to develop your own test bench starting with an empty Simulink model.

To add a MATLAB Function block to the `noise_cancel_00` model:

- 1** Open `noise_cancel_00` in Simulink.  

```
noise_cancel_00
```
- 2** Add a MATLAB Function block to the model:
  - a** At the MATLAB command line, type `sLibraryBrowser` to open the Simulink Library Browser.
  - b** From the list of Simulink libraries, select the **User-Defined Functions** library.

- c Click the MATLAB Function block and drag it into the `noise_cancel_00` model. Place the block just above the red text annotation Place MATLAB Function Block here.
- d Delete the red text annotations from the model.
- e Save the model in the current folder as `noise_cancel_01`.

### Calling Your MATLAB Code As an Extrinsic Function for Rapid Prototyping

In this part of the tutorial, you use the `coder.extrinsic` function to call your MATLAB code from the MATLAB Function block for rapid prototyping.

#### Why Call MATLAB Code As an Extrinsic Function?

Calling MATLAB code as an extrinsic function provides these benefits:

- For rapid prototyping, you do not have to make the MATLAB code suitable for code generation.
- Using `coder.extrinsic` enables you to debug your MATLAB code in MATLAB. You can add one or more breakpoints in the `lms_01.m` file, and then start the simulation in Simulink. When the MATLAB execution engine encounters a breakpoint, it temporarily halts execution so that you can inspect the MATLAB workspace and view the current values of all variables in memory. For more information about debugging MATLAB code, see “Debug a MATLAB Program” (MATLAB).

#### How to Call MATLAB Code As an Extrinsic Function

To call your MATLAB code from the MATLAB Function block:

- 1 Double-click the MATLAB Function block to open the MATLAB Function Block Editor.
- 2 Delete the default code displayed in the MATLAB Function Block Editor.
- 3 Copy the following code to the MATLAB Function block.

```
function [Signal_Out, Weights] = LMS(Noise_In, Signal_In) %#codegen
 % Extrinsic:
 coder.extrinsic('lms_01');

 % Compute LMS:
 [~, Signal_Out, Weights] = lms_01(Noise_In, Signal_In);
end
```

**Why Use the Tilde (~) Operator?**

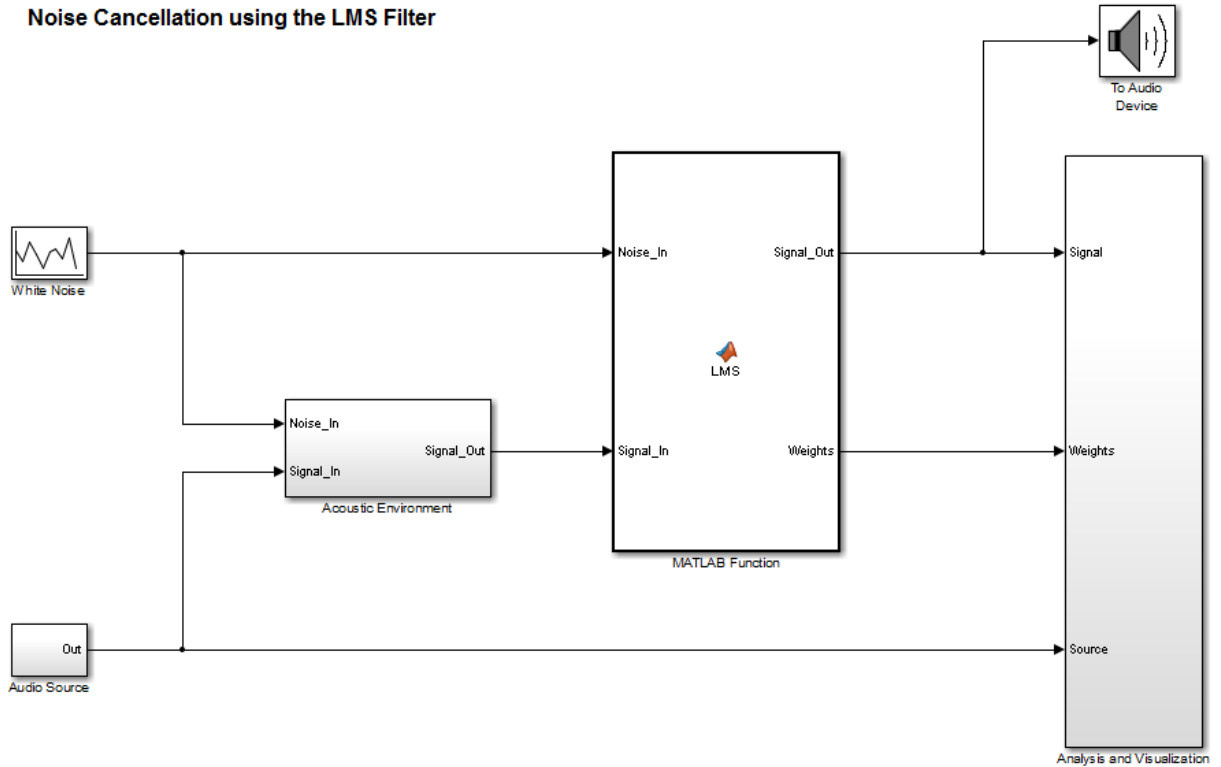

Because the LMS function does not use the first output from `lms_01`, replace this output with the MATLAB `~` operator. MATLAB ignores inputs and outputs specified by `~`. This syntax helps avoid confusion in your program code and unnecessary clutter in your workspace, and allows you to reuse existing algorithms without modification.

- 4 Save the model.

The `lms_01` function inputs `Noise_In` and `Signal_In` now appear as input ports to the block and the function outputs `Signal_Out` and `Weights` appear as output ports.

**Connecting the MATLAB Function Block Inputs and Outputs**

- 1 Connect the MATLAB Function block inputs and outputs so that your model looks like this.

See “Block and Signal Line Shortcuts and Actions” on page 1-93 for more information.

- 2 In the MATLAB Function block code, preallocate the outputs by adding the following code after the extrinsic call:

```
% Outputs:
Signal_Out = zeros(size(Signal_In));
Weights = zeros(32,1);
```

The size of **Weights** is set to match the Numerator coefficients of the Digital Filter in the Acoustic Environment subsystem.

### Why Preallocate the Outputs?

For code generation, you must assign variables explicitly to have a specific class, size, and complexity before using them in operations or returning them as outputs in MATLAB functions. For more information, see “Differences Between Generated Code and MATLAB Code” on page 47-9.

- 3 Save the model.

You are now ready to check your model for errors.

### Simulating the noise\_cancel\_01 Model

To simulate the model:

- 1 Ensure that you can see the **Time Domain** plots.

To view the plots, in the noise\_cancel\_01 model, open the Analysis and Visualization block and then open the Time Domain block.

- 2 In the Simulink model window, select **Simulation > Run** .

As Simulink runs the model, you see and hear outputs. Initially, you hear the audio signal distorted by noise. Then the filter attenuates the noise gradually, until you hear only the music playing with very little noise remaining. After two seconds, you hear the distorted noisy signal again and the filter attenuates the noise again. This cycle repeats continuously.

MATLAB displays the following plot showing this cycle.

**3** Stop the simulation.

### Why Does the Filter Reset Every 2 Seconds?

The filter resets every 2 seconds because the model uses 16384 samples per frame and a sampling rate of 8192, so the 16384 samples represent 2 seconds of audio.

To see the model configuration:

- 1 Double-click the White Noise subsystem and note that it uses a **Sample time** of  $1/F_s$  and **Samples per frame** of `FrameSize`. The music in the Audio Source subsystem also uses these values.
- 2 `FrameSize` is set in the model `InitFcn` callback. To view this callback:
  - a Right-click inside the model window and select **Model Properties** from the context menu.
  - b Select the **Callbacks** tab.
  - c Select `InitFcn` in the **Model callbacks** pane.

Note that `FrameSize = 16*1024`, which is 16384.

- 3 `Fs` is set in the model `PostLoadFcn` callback. To view this callback, select `PostLoadFcn` in the **Model callbacks** pane:

The following MATLAB commands set up `Fs`:

```
data = load('handel.mat');
music = data.y;
Fs = data.Fs;
```

### Modifying the Filter to Use Streaming

- “What Is Streaming?” on page 43-216
- “Why Use Streaming?” on page 43-217
- “Viewing the Modified MATLAB Code” on page 43-217
- “Summary of Changes to the Filter Algorithm” on page 43-218
- “Modifying Your Model to Call the Updated Algorithm” on page 43-219
- “Simulating the Streaming Algorithm” on page 43-220

### What Is Streaming?

A streaming filter is called repeatedly to process fixed-size chunks of input data, or *frames*, until it has processed the entire input signal. The frame size can be as small as a

single sample, in which case the filter would be operating in a sample-based mode, or up to a few thousand samples, for frame-based processing.

### **Why Use Streaming?**

The design of the filter algorithm in `lms_01` has the following disadvantages:

- The algorithm does not use memory efficiently.

Preallocating a fixed amount of memory for each input signal for the lifetime of the program means more memory is allocated than is in use.

- You must know the size of the input signal at the time you call the function.

If the input signal is arriving in real time or as a stream of samples, you would have to wait to accumulate the entire signal before you could pass it, as a batch, to the filter.

- The signal size is limited to a maximum size.

In an embedded application, the filter is likely to be processing a continuous input stream. As a result, the input signal can be substantially longer than the maximum length that a filter working in batch mode could possibly handle. To make the filter work for any signal length, it must run in real time. One solution is to convert the filter from batch-based processing to stream-based processing.

### **Viewing the Modified MATLAB Code**

The conversion to streaming involves:

- Introducing a first-in, first-out (FIFO) queue

The FIFO queue acts as a temporary storage buffer, which holds a small number of samples from the input data stream. The number of samples held by the FIFO queue must be exactly the same as the number of samples in the filter's impulse response, so that the function can perform the convolution operation between the filter coefficients and the input signal.

- Making the FIFO queue and the filter weights persistent

The filter is called repeatedly until it has processed the entire input signal. Therefore, the FIFO queue and filter weights need to persist so that the adaptation process does not have to start over again after each subsequent call to the function.

Open the supplied file `lms_02.m` in your *work* subfolder to see the modified algorithm.

### Summary of Changes to the Filter Algorithm

Note the following important changes to the filter algorithm:

- The filter weights and the FIFO queue are declared as persistent:

```
persistent weights;
persistent fifo;
```

- The FIFO queue is initialized:

```
fifo = zeros(FilterLength,ChannelCount);
```

- The FIFO queue is used in the filter update loop:

```
% For each channel:
for ch = 1:ChannelCount

 % For each sample time:
 for n = 1:FrameSize

 % Update the FIFO shift register:
 fifo(1:FilterLength-1,ch) = fifo(2:FilterLength,ch);
 fifo(FilterLength,ch) = signal_in(n,ch);

 % Compute the output sample using convolution:
 signal_out(n,ch) = weights' * fifo(:,ch);

 % Update the filter coefficients:
 err(n,ch) = desired(n,ch) - signal_out(n,ch) ;
 weights = weights + mu*err(n,ch)*fifo(:,ch);

 end
end
```

- You cannot output a persistent variable. Therefore, a new variable, `weights_out`, is used to output the filter weights:

```
function [signal_out, err, weights_out] = ...
 lms_02(distorted, desired)

weights_out = weights;
```

### Modifying Your Model to Call the Updated Algorithm

To modify the model yourself, work through the exercises in this section. Otherwise, open the supplied model `noise_cancel_02` in your *solutions* subfolder to see the modified model.

- 1 In the `noise_cancel_01` model, double-click the MATLAB Function block to open the MATLAB Function Block Editor.
- 2 Modify the MATLAB Function block code to call `lms_02`.

- a Modify the extrinsic call.

```
% Extrinsic:
coder.extrinsic('lms_02');
```

- b Modify the call to the filter algorithm.

```
% Compute LMS:
[~, Signal_Out, Weights] = lms_02(Noise_In, Signal_In);
```

#### Modified MATLAB Function Block Code

Your MATLAB Function block code should now look like this:

```
function [Signal_Out, Weights] = LMS(Noise_In, Signal_In)
% Extrinsic:
coder.extrinsic('lms_02');
% Outputs:
Signal_Out = zeros(size(Signal_In));
Weights = zeros(32,1);
% Compute LMS:
[~, Signal_Out, Weights] = lms_02(Noise_In, Signal_In);
end
```

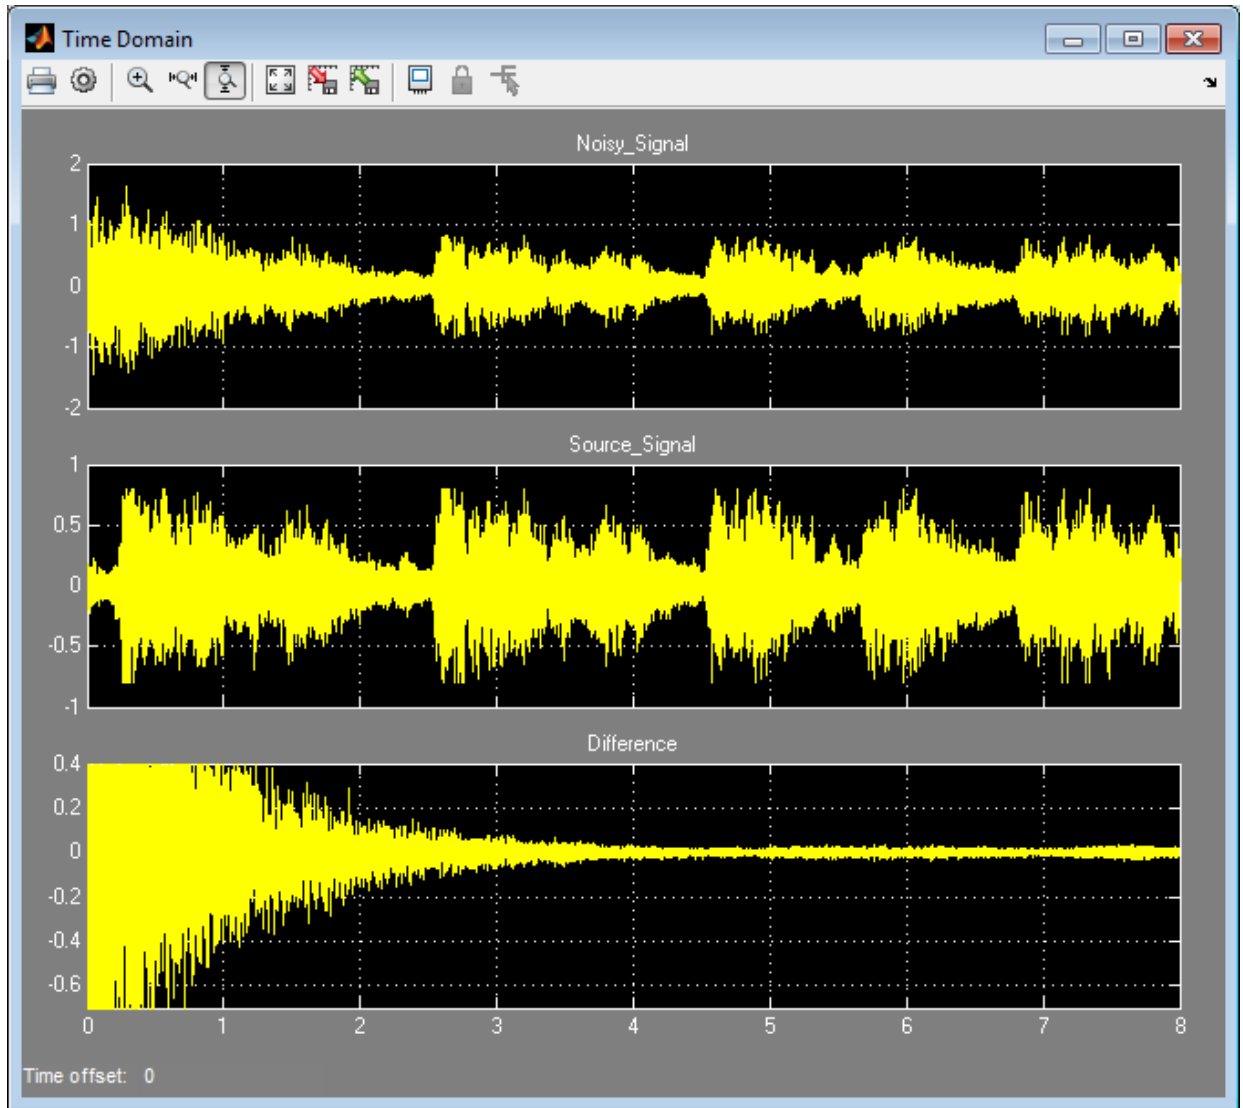

- 3 Change the frame size from 16384 to 64, which represents a more realistic value.
  - a Right-click inside the model window and select **Model Properties** from the context menu.
  - b Select the **Callbacks** tab.
  - c In the **Model callbacks** list, select `InitFcn`.
  - d Change the value of `FrameSize` to 64.
  - e Click **Apply** and close the dialog box.
- 4 Save your model as `noise_cancel_02`.

**Simulating the Streaming Algorithm**

To simulate the model:

- 1** Ensure that you can see the **Time Domain** plots.
- 2** Start the simulation.

As Simulink runs the model, you see and hear outputs. Initially, you hear the audio signal distorted by noise. Then, during the first few seconds, the filter attenuates the noise gradually, until you hear only the music playing with very little noise remaining. MATLAB displays the following plot showing filter convergence after only a few seconds.

**3** Stop the simulation.

The filter algorithm is now suitable for Simulink. You are ready to elaborate your model to use Adapt and Reset controls.

### Adding Adapt and Reset Controls

- “Why Add Adapt and Reset Controls?” on page 43-222
- “Modifying Your MATLAB Code” on page 43-222
- “Modifying Your Model to Use Reset and Adapt Controls” on page 43-223
- “Simulating the Model with Adapt and Reset Controls” on page 43-225

### Why Add Adapt and Reset Controls?

In this part of the tutorial, you add Adapt and Reset controls to your filter. Using these controls, you can turn the filtering on and off. When `Adapt` is enabled, the filter continuously updates the filter weights. When `Adapt` is disabled, the filter weights remain at their current values. If `Reset` is set, the filter resets the filter weights.

### Modifying Your MATLAB Code

To modify the code yourself, work through the exercises in this section. Otherwise, open the supplied file `lms_03.m` in your *solutions* subfolder to see the modified algorithm.

To modify your filter code:

- 1 Open `lms_02.m`.
- 2 In the `Set up` section, replace  

```
if (isempty(weights))
```

with  

```
if (reset || isempty(weights))
```
- 3 In the filter loop, update the filter coefficients only if `Adapt` is ON.  

```
if adapt
 weights = weights + mu*err(n,ch)*fifo(:,ch);
end
```
- 4 Change the function signature to use the `Adapt` and `Reset` inputs and change the function name to `lms_03`.  

```
function [signal_out, err, weights_out] = ...
 lms_03(signal_in, desired, reset, adapt)
```
- 5 Save the file in the current folder as `lms_03.m`:

## Summary of Changes to the Filter Algorithm

Note the following important changes to the filter algorithm:

- The new input parameter `reset` is used to determine if it is necessary to reset the filter coefficients:

```
if (reset || isempty(weights))
 % Filter coefficients:
 weights = zeros(L,1);
 % FIFO Shift Register:
 fifo = zeros(L,1);
end
```

- The new parameter `adapt` is used to control whether the filter coefficients are updated or not.

```
if adapt
 weights = weights + mu*err(n)*fifo;
end
```

## Modifying Your Model to Use Reset and Adapt Controls

To modify the model yourself, work through the exercises in this section. Otherwise, open the supplied model `noise_cancel_03` in your *solutions* subfolder to see the modified model.

- 1 Open the `noise_cancel_02` model.
- 2 Double-click the MATLAB Function block to open the MATLAB Function Block Editor.
- 3 Modify the MATLAB Function block code:

- a Update the function declaration.

```
function [Signal_Out, Weights] = ...
 LMS(Adapt, Reset, Noise_In, Signal_In)
```

- b Update the extrinsic call.

```
coder.extrinsic('lms_03');
```

- c Update the call to the LMS algorithm.

```
% Compute LMS:
[~, Signal_Out, Weights] = ...
 lms_03(Noise_In, Signal_In, Reset, Adapt);
```

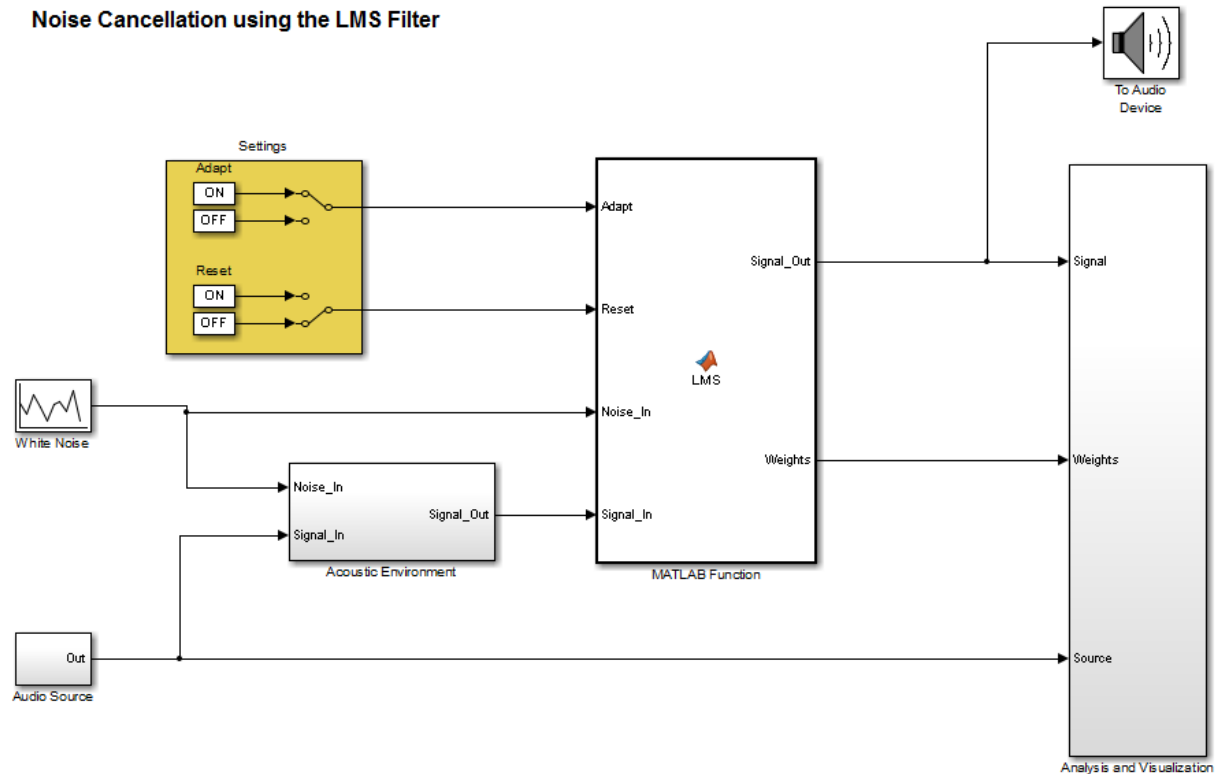

- d Close the MATLAB Function Block Editor.

The `lms_03` function inputs `Reset` and `Adapt` now appear as input ports to the MATLAB Function block.

- 4 Open the `design_templates` model.

- 5 Copy the Settings block from this model to your `noise_cancel_02` model:
- From the `design_templates` model menu, select **Edit > Select All**.
  - Select **Edit > Copy**.
  - From the `noise_cancel_02` model menu, select **Edit > Paste**.
- 6 Connect the Adapt and Reset outputs of the Settings subsystem to the corresponding inputs on the MATLAB Function block. Your model should now appear as follows.

7 Save the model as `noise_cancel_03`.

### Simulating the Model with Adapt and Reset Controls

To simulate the model and see the effect of the Adapt and Reset controls:

- 1 In the `noise_cancel_03` model, view the Convergence scope:
  - a Double-click the Analysis and Visualization subsystem.
  - b Double-click the Convergence scope.
- 2 In the Simulink model window, select **Simulation > Run**.

Simulink runs the model as before. While the model is running, toggle the Adapt and Reset controls and view the Convergence scope to see their effect on the filter.

The filter converges when Adapt is ON and Reset is OFF, then resets when you toggleReset. The results might look something like this:

- 3 Stop the simulation.

### Generating Code

You have proved that your algorithm works in Simulink. Next you generate code for your model. Before generating code, you must ensure that your MATLAB code is suitable for code generation. For code generation, you must remove the extrinsic call to your code.

### Making Your Code Suitable for Code Generation

To modify the model and code yourself, work through the exercises in this section. Otherwise, open the supplied model `noise_cancel_04` and file `lms_04.m` in your `solutions` subfolder to see the modifications.

- 1 Rename the MATLAB Function block to `LMS_Filter`. Select the annotation MATLAB Function below the MATLAB Function block and replace the text with `LMS_Filter`.

When you generate code for the MATLAB Function block, Simulink Coder uses the name of the block in the generated code. It is good practice to use a meaningful name.

- 2 In your `noise_cancel_03` model, double-click the MATLAB Function block.

The MATLAB Function Block Editor opens.

- 3 Delete the extrinsic declaration.

```
% Extrinsic:
coder.extrinsic('lms_03');
```

- 4 Delete the preallocation of outputs.

```
% Outputs:
Signal_Out = zeros(size(Signal_In));
Weights = zeros(32,1);
```

- 5 Modify the call to the filter algorithm.

```
% Compute LMS:
[~, Signal_Out, Weights] = ...
 lms_04(Noise_In, Signal_In, Reset, Adapt);
```

- 6 Save the model as `noise_cancel_04`.

- 7 Open `lms_03.m`

- a Modify the function name to `lms_04`.
- b Turn on error checking specific to code generation by adding the  `%#codegen` compilation directive after the function declaration.

```
function [signal_out, err, weights_out] = ...
 lms_04(signal_in, desired, reset, adapt) %#codegen
```

The code analyzer message indicator in the top right turns red to indicate that the code analyzer has detected code generation issues. The code analyzer underlines the offending code in red and places a red marker to the right of it.

- 8 Move your pointer over the first red marker to view the error information.

The code analyzer detects that code generation requires `signal_out` to be fully defined before subscripting it and does not support growth of variable size data through indexing.

- 9 Move your pointer over the second red marker and note that the code analyzer detects the same errors for `err`.

- 10** To address these errors, preallocate the outputs `signal_out` and `err`. Add this code after the filter setup.

```
% Output Arguments:

% Pre-allocate output and error signals:
signal_out = zeros(FrameSize,ChannelCount);
err = zeros(FrameSize,ChannelCount);
```

### Why Preallocate the Outputs?

You must preallocate outputs because code generation does not support increasing the size of an array over time.

The red error markers for the two lines of code disappear. The code analyzer message indicator in the top right edge of the code turns green, which indicates that you have fixed all the errors and warnings detected by the code analyzer.

- 11** Save the file as `lms_04.m`.

### Generating Code for `noise_cancel_04`

- 1** Before generating code, ensure that Simulink Coder creates a code generation report. This HTML report provides easy access to the list of generated files with a summary of the configuration settings used to generate the code.
  - a** In the Simulink model window, select **Simulation > Model Configuration Parameters**.
  - b** In the left pane of the Configuration Parameters dialog box, select **Code Generation > Report**.
  - c** In the right pane, select **Create code generation report**.  
  
The **Open report automatically** option is also selected.
  - d** Click **Apply** and close the Configuration Parameters dialog box.
  - e** Save your model.
- 2** To generate code for the LMS Filter subsystem:
  - a** In your model, select the LMS Filter subsystem.
  - b** From the Build Model tool menu, select **Build Selected Subsystem**.

The **Build code for subsystem** dialog box appears. Click the **Build** button.

The Simulink Coder software generates C code for the subsystem and opens the code generation report.

For more information on using the code generation report, see “Generate a Code Generation Report” (Simulink Coder).

- c In the left pane of the code generation report, click the `LMS_Filter.c` link to view the generated C code. Note that the `lms_04` function has no code because inlining is enabled by default.
- 3** Modify your filter algorithm to disable inlining:
- a In `lms_04.m`, after the function declaration, add:
 

```
coder.inline('never')
```
  - b Change the function name to `lms_05` and save the file as `lms_05.m` in the current folder.
  - c In your `noise_cancel_04` model, double-click the MATLAB Function block.
 

The MATLAB Function Block Editor opens.
  - d Modify the call to the filter algorithm to call `lms_05`.
 

```
% Compute LMS:
[~, Signal_Out, Weights] = ...
 lms_05(Noise_In, Signal_In, Reset, Adapt);
```
  - e Save the model as `noise_cancel_05`.
- 4** Generate code for the updated model.
- a In the model, select the LMS Filter subsystem.
  - b From the Build Model tool menu, select **Build Selected Subsystem**.

The **Build code for subsystem** dialog box appears.

- c Click the **Build** button.

The Simulink Coder software generates C code for the subsystem and opens the code generation report.

- d In the left pane of the code generation report, click the `LMS_Filter.c` link to view the generated C code.

This time the `lms_05` function has code because you disabled inlining.

```
/* Forward declaration for local functions */
static void LMS_Filter_lms_05 ...
 (const real_T signal_in[64],const real_T ...
 desired[64], real_T reset, real_T adapt, ...
 real_T signal_out[64], ...
 real_T err[64], real_T weights_out[32]);

/* Function for MATLAB Function Block: 'root/LMS_Filter' */
static void LMS_Filter_lms_05 ...
 (const real_T signal_in[64], const real_T ...
 desired[64], real_T reset, real_T adapt, ...
 real_T signal_out[64], ...
 real_T err[64], real_T weights_out[32])
```

### Optimizing the LMS Filter Algorithm

This part of the tutorial demonstrates when and how to preallocate memory for a variable without incurring the overhead of initializing memory in the generated code.

In `lms_05.m`, the MATLAB code not only declares `signal_out` and `err` to be a `FrameSize-by-ChannelCount` vector of real doubles, but also initializes each element of `signal_out` and `err` to zero. These signals are initialized to zero in the generated C code.

| MATLAB Code                                                                                                                          | Generated C Code                                                                                                                       |
|--------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------|
| <pre>% Pre-allocate output and error signals: signal_out = zeros(FrameSize,ChannelCount); err = zeros(FrameSize,ChannelCount);</pre> | <pre>/* Pre-allocate output and error signals: */ 79 for (i = 0; i &lt; 64; i++) { 80 signal_out[i] = 0.0; 81 err[i] = 0.0; 82 }</pre> |

This forced initialization is unnecessary because both `signal_out` and `err` are explicitly initialized in the MATLAB code before they are read.

---

**Note** You should not use `coder.nullcopy` when declaring the variables `weights` and `fifo` because these variables need to be initialized in the generated code. Neither variable is explicitly initialized in the MATLAB code before they are read.

---

Use `coder.nullcopy` in the declaration of `signal_out` and `err` to eliminate the unnecessary initialization of memory in the generated code:

- 1 In `lms_05.m`, preallocate `signal_out` and `err` using `coder.nullcopy`:

```
% Pre-allocate output and error signals:
signal_out = coder.nullcopy(zeros(FrameSize, ChannelCount));
err = coder.nullcopy(zeros(FrameSize, ChannelCount));
```

---

**Caution** After declaring a variable with `coder.nullcopy`, you must explicitly initialize the variable in your MATLAB code before reading it. Otherwise, you might get unpredictable results.

---

- 2 Change the function name to `lms_06` and save the file as `lms_06.m` in the current folder.
- 3 In your `noise_cancel_05` model, double-click the MATLAB Function block.

The MATLAB Function Block Editor opens.

- 4 Modify the call to the filter algorithm.

```
% Compute LMS:
[~, Signal_Out, Weights] = ...
 lms_06(Noise_In, Signal_In, Reset, Adapt);
```

- 5 Save the model as `noise_cancel_06`.

Generate code for the updated model.

- 1 Select the LMS Filter subsystem.
- 2 From the Build Model tool menu, select **Build Selected Subsystem**.

The **Build code for subsystem** dialog box appears. Click the **Build** button.

The Simulink Coder software generates C code for the subsystem and opens the code generation report.

- 3 In the left pane of the code generation report, click the `LMS_Filter.c` link to view the generated C code.

In the generated C code, this time there is no initialization to zero of `signal_out` and `err`.

## Customize System Block Appearance

### In this section...

“Specify Input and Output Names” on page 44-2

“Add Text to Block Icon” on page 44-3

“Add Image to Block Icon” on page 44-5

### Specify Input and Output Names

Specify the names of the input and output ports of a System object-based block implemented using a MATLAB System block.

Use `getInputNamesImpl` and `getOutputNamesImpl` to specify the names of the input port as “source data” and the output port as “count.”

If you do not specify the `getInputNamesImpl` and `getOutputNamesImpl` methods, the object uses the `stepImpl` method input and output variable names for the input and output port names, respectively. If the `stepImpl` method uses *varargin* and *varargout* instead of variable names, the port names default to empty character vectors.

```
methods (Access = protected)
 function inputName = getInputNamesImpl(~)
 inputName = 'source data';
 end

 function outputName = getOutputNamesImpl(~)
 outputName = 'count';
 end
end
```

### Complete Class Definition with Named Inputs and Outputs

```
classdef MyCounter < matlab.System

 % MyCounter Count values above a threshold

 properties
 Threshold = 1
 end
 properties (DiscreteState)
 Count
 end
end
```

```

end

methods
 function obj = MyCounter(varargin)
 setProperties (obj,nargin,varargin{:});
 end
end

methods (Access = protected)
 function setupImpl(obj)
 obj.Count = 0;
 end
 function resetImpl(obj)
 obj.Count = 0;
 end
 function y = stepImpl(obj,u)
 if (u > obj.Threshold)
 obj.Count = obj.Count + 1;
 end
 y = obj.Count;
 end
 function inputName = getInputNamesImpl(~)
 inputName = 'source data';
 end
 function outputName = getOutputNamesImpl(~)
 outputName = 'count';
 end
end
end

```

## Add Text to Block Icon

Add text to the block icon of a System object-based block implemented using a MATLAB System block.

- 1 Subclass from custom icon class.

```
classdef MyCounter < matlab.System & matlab.system.mixin.CustomIcon
```

- 2 Use `getIconImpl` to specify the block icon as New Counter with a line break between the two words.

```

methods (Access = protected)
 function icon = getIconImpl(~)

```

```
 icon = {'New', 'Counter'};
 end
end
```

### Complete Class Definition File with Defined Icon

```
classdef MyCounter < matlab.System & ...
 matlab.system.mixin.CustomIcon

 % MyCounter Count values above a threshold

 properties
 Threshold = 1
 end
 properties (DiscreteState)
 Count
 end

 methods
 function obj = MyCounter(varargin)
 setProperties(obj, nargin, varargin{:});
 end
 end

 methods (Access = protected)
 function setupImpl(obj)
 obj.Count = 0;
 end
 function resetImpl(obj)
 obj.Count = 0;
 end
 function y = stepImpl(obj, u)
 if (u > obj.Threshold)
 obj.Count = obj.Count + 1;
 end
 y = obj.Count;
 end
 function icon = getIconImpl(~)
 icon = {'New', 'Counter'};
 end
 end
end
```

## Add Image to Block Icon

Define an image on the block icon of a System object-based block implemented using a MATLAB System block.

- 1 Subclass from custom icon class.

```
classdef MyCounter < matlab.System & matlab.system.mixin.CustomIcon
```

- 2 Use `getIconImpl` method to call the `matlab.system.display.Icon` class and specify the image.

```
methods (Access = protected)
 function icon = getIconImpl(~)
 icon = matlab.system.display.Icon('counter.png');
 end
end
```

### Complete Class Definition File with Icon Image

```
classdef MyCounter < matlab.System & ...
 matlab.system.mixin.CustomIcon

 % MyCounter Count values above a threshold

 properties
 Threshold = 1
 end
 properties (DiscreteState)
 Count
 end

 methods
 function obj = MyCounter(varargin)
 setProperties(obj,nargin,varargin{:});
 end
 end

 methods (Access = protected)
 function setupImpl(obj)
 obj.Count = 0;
 end
 function resetImpl(obj)
 obj.Count = 0;
 end
 end
```

```
function y = stepImpl(obj,u)
 if (u > obj.Threshold)
 obj.Count = obj.Count + 1;
 end
 y = obj.Count;
end
function icon = getIconImpl(~)
 icon = matlab.system.display.Icon('counter.png');
end
end
end
```

## Customize System Block Dialog Box

### In this section...

“Add Header to MATLAB System Block” on page 44-7

“Add Data Types Tab to MATLAB System Block” on page 44-8

“Add Property Groups to System Object and MATLAB System Block” on page 44-10

“Control Simulation Type in MATLAB System Block” on page 44-15

“Add Button to MATLAB System Block” on page 44-17

### Add Header to MATLAB System Block

Add a header panel to a System object-based block implemented using a MATLAB System block.

#### Define Header Title and Text

Use `getHeaderImpl` to specify a panel title and text for the `MyCounter` System object.

If you do not specify the `getHeaderImpl`, the block does not display any title or text for the panel.

You always set the `getHeaderImpl` method access to `protected` because it is an internal method that end users do not directly call or run.

```
methods (Static, Access = protected)
 function header = getHeaderImpl
 header = matlab.system.display.Header('MyCounter', ...
 'Title', 'My Enhanced Counter');
 end
end
```

#### Complete Class Definition File with Defined Header

```
classdef MyCounter < matlab.System

 % MyCounter Count values

 properties
 Threshold = 1
 end
```

```
properties (DiscreteState)
 Count
end

methods (Static, Access = protected)
 function header = getHeaderImpl
 header = matlab.system.display.Header('MyCounter',...
 'Title', 'My Enhanced Counter',...
 'Text', 'This counter is an enhanced version.');
```

```
 end
end

methods (Access = protected)
 function setupImpl(obj,u)
 obj.Count = 0;
 end
 function y = stepImpl(obj,u)
 if (u > obj.Threshold)
 obj.Count = obj.Count + 1;
 end
 y = obj.Count;
 end
 function resetImpl(obj)
 obj.Count = 0;
 end
end
end
```

## Add Data Types Tab to MATLAB System Block

Add a **Data Types** tab to the MATLAB System block dialog box. This tab includes fixed-point data type settings.

### Display Data Types Tab

Use `matlab.system.showFiSettingsImpl` to display the **Data Types** tab in the MATLAB System block dialog box.

```
methods (Static, Access = protected)
 function showTab = showFiSettingsImpl
 showTab = true;
 end
end
```

## Complete Class Definition File with Data Types Tab

Use `showFiSettingsImpl` to display the **Data Types** tab for a System object that adds an offset to a fixed-point input.

```
classdef FiTabAddOffset < matlab.System
% FiTabAddOffset Add an offset to input

 properties
 Offset = 1;
 end

 methods
 function obj = FiTabAddOffset(varargin)
 setProperties(obj,nargin,varargin{:});
 end
 end

 methods (Access = protected)
 function y = stepImpl(~,u)
 y = u + obj.Offset;
 end
 end

 methods(Static, Access=protected)
 function header = getHeaderImpl
 header = matlab.system.display.Header('Title',...
 'Add Offset','Text','Add an offset to the input');
 end

 function isVisible = showFiSettingsImpl
 isVisible = true;
 end
 end
end
```

### Dialog Box with the Data Types Tab

### Add Property Groups to System Object and MATLAB System Block

Define property sections and section groups for System object display. The sections and section groups display as panels and tabs, respectively, in the MATLAB System block

dialog box.

### Define Section of Properties

Use `matlab.system.display.Section` and `getPropertyGroupsImpl` to define two property group sections by specifying their titles and property lists.

If you do not specify a property in `getPropertyGroupsImpl`, the block does not display that property.

```
methods (Static, Access = protected)
 function groups = getPropertyGroupsImpl
 valueGroup = matlab.system.display.Section(...
 'Title','Value parameters',...
 'PropertyList',{'StartValue','EndValue'});

 thresholdGroup = matlab.system.display.Section(...
 'Title','Threshold parameters',...
 'PropertyList',{'Threshold','UseThreshold'});
 groups = [valueGroup,thresholdGroup];
 end
end
```

### Define Group of Sections

Use `matlab.system.display.SectionGroup`, `matlab.system.display.Section`, and `getPropertyGroupsImpl` to define two tabs, each containing specific properties.

```
methods (Static, Access = protected)
 function groups = getPropertyGroupsImpl
 upperGroup = matlab.system.display.Section(...
 'Title','Upper threshold', ...
 'PropertyList',{'UpperThreshold'});
 lowerGroup = matlab.system.display.Section(...
 'Title','Lower threshold', ...
 'PropertyList',{'UseLowerThreshold','LowerThreshold'});

 thresholdGroup = matlab.system.display.SectionGroup(...
 'Title','Parameters', ...
 'Sections', [upperGroup,lowerGroup]);

 valuesGroup = matlab.system.display.SectionGroup(...
 'Title','Initial conditions', ...
 'PropertyList', {'StartValue'});
 end
end
```

```
 groups = [thresholdGroup, valuesGroup];
 end
end
```

### Complete Class Definition File with Property Group and Separate Tab

```
classdef EnhancedCounter < matlab.System
 % EnhancedCounter Count values considering thresholds

 properties
 UpperThreshold = 1;
 LowerThreshold = 0;
 end

 properties (Nontunable)
 StartValue = 0;
 end

 properties(Logical,Nontunable)
 % Count values less than lower threshold
 UseLowerThreshold = true;
 end

 properties (DiscreteState)
 Count;
 end

 methods (Static, Access = protected)
 function groups = getPropertyGroupsImpl
 upperGroup = matlab.system.display.Section(...
 'Title', 'Upper threshold', ...
 'PropertyList',{'UpperThreshold'});
 lowerGroup = matlab.system.display.Section(...
 'Title','Lower threshold', ...
 'PropertyList',{'UseLowerThreshold','LowerThreshold'});

 thresholdGroup = matlab.system.display.SectionGroup(...
 'Title', 'Parameters', ...
 'Sections', [upperGroup,lowerGroup]);

 valuesGroup = matlab.system.display.SectionGroup(...
 'Title', 'Initial conditions', ...
 'PropertyList', {'StartValue'});

 groups = [thresholdGroup, valuesGroup];
 end
 end
end
```

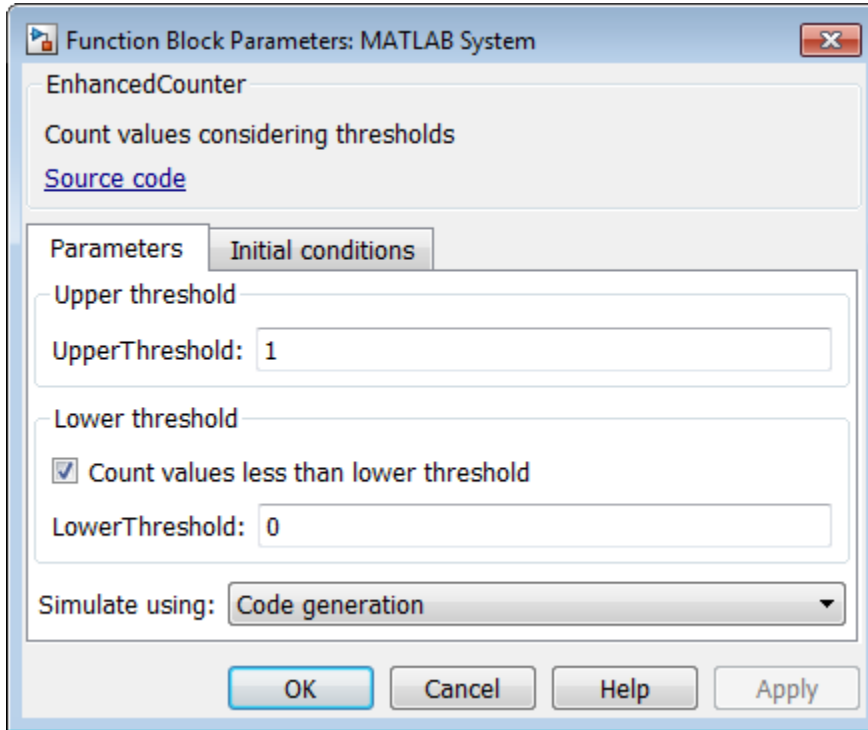

```
 end
 end

 methods (Access = protected)
 function setupImpl(obj)
 obj.Count = obj.StartValue;
 end

 function y = stepImpl(obj,u)
 if obj.UseLowerThreshold
 if (u > obj.UpperThreshold) || ...
 (u < obj.LowerThreshold)
 obj.Count = obj.Count + 1;
 end
 else
 if (u > obj.UpperThreshold)
 obj.Count = obj.Count + 1;
 end
 end
 y = obj.Count;
 end
 function resetImpl(obj)
 obj.Count = obj.StartValue;
 end

 function flag = isInactivePropertyImpl(obj, prop)
 flag = false;
 switch prop
 case 'LowerThreshold'
 flag = ~obj.UseLowerThreshold;
 end
 end
 end
 end
end
```

### Customized Dialog Box

## Control Simulation Type in MATLAB System Block

Specify a simulation type and whether the **Simulate using** parameter appears on the Simulink MATLAB System block dialog box. The simulation options are 'Code generation' and 'Interpreted mode'.

If you do not include the `getSimulateUsingImpl` method in your class definition file, the System object allows both simulation modes and defaults to 'Code generation'. If you do not include the `showSimulateUsingImpl` method, the **Simulate using** parameter appears on the block dialog box.

You must set the `getSimulateUsingImpl` and `showSimulateUsingImpl` methods to `static` and the access for these methods to `protected`.

Use `getSimulateUsingImpl` to specify that only interpreted execution is allowed for the System object.

```
methods(Static,Access = protected)
 function simMode = getSimulateUsingImpl
 simMode = 'Interpreted execution';
 end
end
```

View the method in the complete class definition file.

```
classdef PlotRamp < matlab.System
 % Display a button to launch a plot figure.

 properties (Nontunable)
 RampLimit = 10;
 end

 methods(Static, Access=protected)
 function group = getPropertyGroupsImpl
 group = matlab.system.display.Section(mfilename('class'));
 group.Actions = matlab.system.display.Action(@(~,obj)...
 visualize(obj),'Label','Visualize');
 end

 function simMode = getSimulateUsingImpl
 simMode = 'Interpreted execution';
 end
 end

 methods
 function obj = ActionDemo(varargin)
 setProperties(obj,nargin,varargin{:});
 end

 function visualize(obj)
 figure;
 d = 1:obj.RampLimit;
 plot(d);
 end
 end
end
end
```

## Dialog Box with Simulation Type Parameter

## Add Button to MATLAB System Block

Add a button to the MATLAB System block dialog box. This button opens a figure that plots a ramp function.

### Define Action for Dialog Button

Use `matlab.system.display.Action` to define the MATLAB function or code associated with a button in the MATLAB System block dialog box. The example also shows how to set button options and use an `actionData` object input to store a figure handle. This part of the code example uses the same figure when the button is clicked multiple times, rather than opening a new figure for each button click.

```
methods(Static, Access = protected)
 function group = getPropertyGroupsImpl
 group = matlab.system.display.Section(mfilename('class'));
 group.Actions = matlab.system.display.Action(@(actionData,obj)...
 visualize(obj,actionData),'Label','Visualize');
 end
end
```

```
methods
function obj = ActionDemo(varargin)
 setProperties(obj,nargin,varargin{:});
end

function visualize(obj,actionData)
 f = actionData.UserData;
 if isempty(f) || ~ishandle(f)
 f = figure;
 actionData.UserData = f;
 else
 figure(f); % Make figure current
 end

 d = 1:obj.RampLimit;
 plot(d);
end
end
```

### Complete Class Definition File for Dialog Button

Define a property group and a second tab in the class definition file.

```
classdef PlotRamp < matlab.System
 % Display a button to launch a plot figure.

 properties (Nontunable)
 RampLimit = 10;
 end

 methods(Static,Access = protected)
 function group = getPropertyGroupsImpl
 group = matlab.system.display.Section(mfilename('class'));
 group.Actions = matlab.system.display.Action(@(actionData,obj)...
 visualize(obj,actionData),'Label','Visualize');
 end
 end

 methods
 function obj = ActionDemo(varargin)
 setProperties(obj,nargin,varargin{:});
 end

 function visualize(obj,actionData)
 f = actionData.UserData;
```

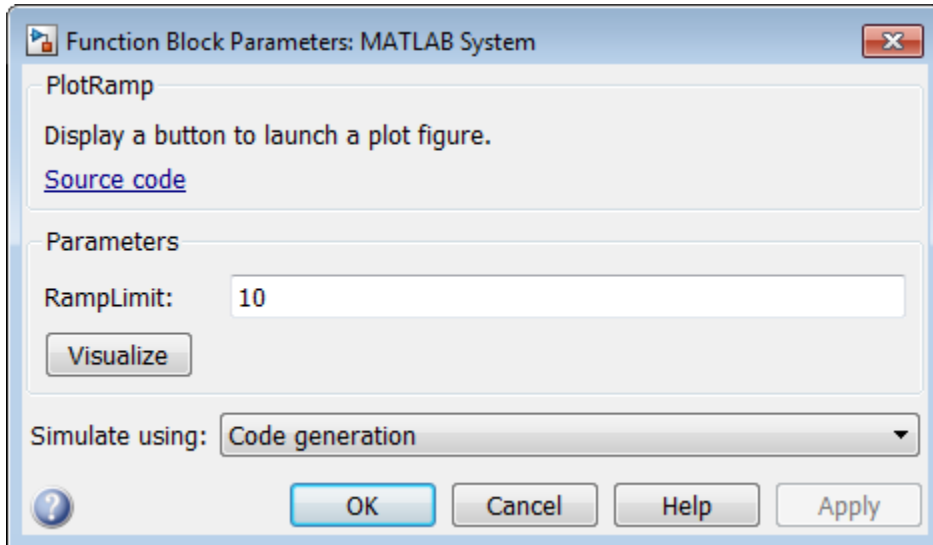

```

if isempty(f) || ~ishandle(f)
 f = figure;
 actionData.UserData = f;
else
 figure(f); % Make figure current
end

d = 1:obj.RampLimit;
plot(d);
end
end
end

```

### Dialog Box with Visualize Button

## **More About**

- “Using ~ as an Input Argument in Method Definitions” (MATLAB)

## Specify Output

### In this section...

“Set Output Size” on page 44-21  
 “Set Fixed- or Variable-Size Output” on page 44-23  
 “Set Output Data Type” on page 44-25  
 “Set Output Complexity” on page 44-29  
 “Set Discrete State Output Specification” on page 44-31

Sometimes, Simulink cannot infer the output characteristics of your System object during model compilation. To give Simulink more information about the System object output, use these methods.

### Set Output Size

Specify the size of a System object output using the `getOutputSizeImpl` method. Use this method when Simulink cannot infer the output size from the inputs during model compilation. For instance, when the System object has multiple inputs or outputs or has variable-sized output.

For variable-size inputs, the propagated input size from `propagatedInputSizeImpl` differs depending on the environment.

- MATLAB — When you first run an object, it uses the actual sizes of the inputs.
- Simulink — The maximum of all the input sizes is set before the model runs and does not change during the run.

Subclass from both the `matlab.System` base class and the `Propagates` mixin class.

```
classdef CounterReset < matlab.System & ...
 matlab.system.mixin.Propagates
```

Use the `getOutputSizeImpl` method to specify the output size.

```
methods (Access = protected)
 function sizeout = getOutputSizeImpl(~)
 sizeout = [1 1];
 end
end
```

View the method in the complete class definition file.

```
classdef CounterReset < matlab.System & matlab.system.mixin.Propagates
 % CounterReset Count values above a threshold

 properties
 Threshold = 1
 end

 properties (DiscreteState)
 Count
 end

 methods (Access = protected)
 function setupImpl(obj)
 obj.Count = 0;
 end

 function y = stepImpl(obj,u1,u2)
 % Add to count if u1 is above threshold
 % Reset if u2 is true
 if (u2)
 obj.Count = 0;
 elseif (any(u1 > obj.Threshold))
 obj.Count = obj.Count + 1;
 end
 y = obj.Count;
 end

 function resetImpl(obj)
 obj.Count = 0;
 end

 function [sz,dt,cp] = getDiscreteStateSpecificationImpl(~,name)
 if strcmp(name,'Count')
 sz = [1 1];
 dt = 'double';
 cp = false;
 else
 error(['Error: Incorrect State Name: ', name.]);
 end
 end

 function dataout = getOutputDataTypeImpl(~)
 dataout = 'double';
 end
 end
end
```

```

end
function sizeout = getOutputSizeImpl(~)
 sizeout = [1 1];
end
function cplxout = isOutputComplexImpl(~)
 cplxout = false;
end
function fixedout = isOutputFixedSizeImpl(~)
 fixedout = true;
end
function flag = isInputSizeMutableImpl(~,idx)
 if idx == 1
 flag = true;
 else
 flag = false;
 end
end
end
end
end

```

## Set Fixed- or Variable-Size Output

Specify the System object output is fixed-size. Fixed-size output is always the same size, while variable-size output can be different size vectors.

Simulink cannot infer the output size for variable-size output. To avoid errors, implement `isOutputFixedSizeImpl` and `getOutputSizeImpl`.

`isOutputFixedSizeImpl` accepts the port index and returns:

- `true` — the input size is fixed (variable sized vectors are disallowed)
- `false` — the input size is not variable (variable sized vectors are allowed)

Subclass from both the `matlab.System` base class and the `matlab.system.mixin.Propagates` mixin class.

```

classdef CounterReset < matlab.System & ...
 matlab.system.mixin.Propagates

```

Use the `isOutputFixedSizeImpl` method to specify that the output is fixed size.

```

methods (Access = protected)
 function fixedout = isOutputFixedSizeImpl(~)

```

```
 fixedout = true;
 end
end
```

View the method in the complete class definition file.

```
classdef CounterReset < matlab.System & matlab.system.mixin.Propagates
 % CounterReset Count values above a threshold

 properties
 Threshold = 1
 end

 properties (DiscreteState)
 Count
 end

 methods (Access = protected)
 function setupImpl(obj)
 obj.Count = 0;
 end

 function y = stepImpl(obj,u1,u2)
 % Add to count if u1 is above threshold
 % Reset if u2 is true
 if (u2)
 obj.Count = 0;
 elseif (any(u1 > obj.Threshold))
 obj.Count = obj.Count + 1;
 end
 y = obj.Count;
 end

 function resetImpl(obj)
 obj.Count = 0;
 end

 function [sz,dt,cp] = getDiscreteStateSpecificationImpl(~,name)
 if strcmp(name,'Count')
 sz = [1 1];
 dt = 'double';
 cp = false;
 else
 error(['Error: Incorrect State Name: ', name.']);
 end
 end
 end
end
```

```

end
function dataout = getOutputDataTypeImpl(~)
 dataout = 'double';
end
function sizeout = getOutputSizeImpl(~)
 sizeout = [1 1];
end
function cplxout = isOutputComplexImpl(~)
 cplxout = false;
end
function fixedout = isOutputFixedSizeImpl(~)
 fixedout = true;
end
function flag = isInputSizeMutableImpl(~,idx)
 if idx == 1
 flag = true;
 else
 flag = false;
 end
end
end
end
end

```

## Set Output Data Type

Specify the data type of a System object output using the `getOutputDataTypeImpl` method. A second example shows how to specify a gain object with bus output. Use this method when Simulink cannot infer the data type from the inputs during model compilation or when you want different input and output data types. If you want bus output, also use the `getOutputDataTypeImpl` method. To use bus output, you must define the bus data type in the base workspace and you must include the `getOutputDataTypeImpl` method in your class definition file.

For both examples, subclass from both the `matlab.System` base class and the `matlab.system.mixin.Propagates` mixin class.

```

classdef DataTypeChange < matlab.System & ...
 matlab.system.mixin.Propagates

```

Specify, in your class definition file, how to control the output data type from a MATLAB System block. Use the `getOutputDataTypeImpl` method to change the output data type from double to single, or propagate the input as a double. It also shows how to cast the data type to change the output data type in the `stepImpl` method, if necessary.

```
methods (Access = protected)
 function out = getOutputDataTypeImpl(obj)
 if obj.Quantize == true
 out = 'single';
 else
 out = propagatedInputDataType(obj,1);
 end
 end
end

classdef DataTypeChange < matlab.System & ...
 matlab.system.mixin.Propagates

 properties(Nontunable)
 Quantize = false;
 end

 methods(Access = protected)
 function y = stepImpl(obj,u)
 if obj.Quantize == true
 % Cast for output data type to differ from input.
 y = single(u);
 else
 % Propagate output data type.
 y = u;
 end
 end

 function out = getOutputDataTypeImpl(obj)
 if obj.Quantize == true
 out = 'single';
 else
 out = propagatedInputDataType(obj,1);
 end
 end
 end
end
```

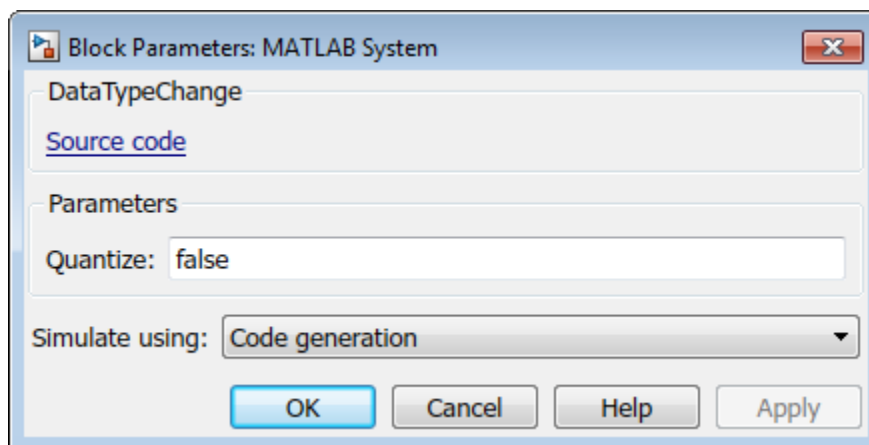

This model shows propagated double data type.

This model shows the result of changing the data type from double to single. The Display block shows the effect of quantizing the data.

The block mask for the MATLAB System block includes an edit field to switch between using propagation (**Quantize** = false) and switching from double to single (**Quantize** = true).

Use the `getOutputDataTypeImpl` method to specify the output data type as a bus. Specify the bus name in a property.

```
properties(Nontunable)
 OutputBusName = 'bus_name';
end

methods (Access = protected)
 function out = getOutputDataTypeImpl(obj)
 out = obj.OutputBusName;
 end
end
```

View the method in the complete class definition file. This class definition file also includes code to implement a custom icon for this object in the MATLAB System block

```
classdef busGain < matlab.System & matlab.system.mixin.Propagates
% busGain Apply a gain of two to bus input.
```

```
 properties
 GainK = 2;
 end

 properties(Nontunable)
 OutputBusName = 'bus_name';
 end

 methods (Access=protected)
 function out = stepImpl(obj,in)
 out.a = obj.GainK * in.a;
 out.b = obj.GainK * in.b;
 end

 function out = getOutputSizeImpl(obj)
 out = propagatedInputSize(obj, 1);
 end

 function out = isOutputComplexImpl(obj)
 out = propagatedInputComplexity(obj, 1);
 end

 function out = getOutputDataTypeImpl(obj)
 out = obj.OutputBusName;
 end
 end
end
```

```

 function out = isOutputFixedSizeImpl(obj)
 out = propagatedInputFixedSize(obj,1);
 end
 end
end

```

## Set Output Complexity

Specify whether a System object output is complex or real using the `isOutputComplexImpl` method. Use this method when Simulink cannot infer the output complexity from the inputs during model compilation.

Subclass from both the `matlab.System` base class and the `Propagates` mixin class.

```

classdef CounterReset < matlab.System & ...
 matlab.system.mixin.Propagates

```

Use the `isOutputComplexImpl` method to specify that the output is real.

```

methods (Access = protected)
 function cplxout = isOutputComplexImpl(~)
 cplxout = false;
 end
end

```

View the method in the complete class definition file.

```

classdef CounterReset < matlab.System & matlab.system.mixin.Propagates
 % CounterReset Count values above a threshold

 properties
 Threshold = 1
 end

 properties (DiscreteState)
 Count
 end

 methods (Access = protected)
 function setupImpl(obj)
 obj.Count = 0;
 end

 function y = stepImpl(obj,u1,u2)

```

```
% Add to count if u1 is above threshold
% Reset if u2 is true
if (u2)
 obj.Count = 0;
elseif (any(u1 > obj.Threshold))
 obj.Count = obj.Count + 1;
end
y = obj.Count;
end

function resetImpl(obj)
 obj.Count = 0;
end

function [sz,dt,cp] = getDiscreteStateSpecificationImpl(~,name)
 if strcmp(name,'Count')
 sz = [1 1];
 dt = 'double';
 cp = false;
 else
 error(['Error: Incorrect State Name: ', name.]);
 end
end

function dataout = getOutputDataTypeImpl(~)
 dataout = 'double';
end

function sizeout = getOutputSizeImpl(~)
 sizeout = [1 1];
end

function cplxout = isOutputComplexImpl(~)
 cplxout = false;
end

function fixedout = isOutputFixedSizeImpl(~)
 fixedout = true;
end

function flag = isInputSizeMutableImpl(~,idx)
 if idx == 1
 flag = true;
 else
 flag = false;
 end
end
```

```
end
end
```

## Set Discrete State Output Specification

Specify the size, data type, and complexity of a discrete state property using the `getDiscreteStateSpecificationImpl` method. Use this method when your System object has a property with the `DiscreteState` attribute and Simulink cannot infer the output specifications during model compilation.

Subclass from both the `matlab.System` base class and from the `Propagates` mixin class.

```
classdef CounterReset < matlab.System & ...
 matlab.system.mixin.Propagates
```

Use the `getDiscreteStateSpecificationImpl` method to specify the size and data type. Also specify the complexity of a discrete state property `Count`, which is used in the counter reset example.

```
function [sz,dt,cp] = getDiscreteStateSpecificationImpl(~,name)
 if strcmp(name,'Count')
 sz = [1 1];
 dt = 'double';
 cp = false;
 else
 error(['Error: Incorrect State Name: ', name.]);
 end
end
```

View the method in the complete class definition file.

```
classdef CounterReset < matlab.System & matlab.system.mixin.Propagates
 % CounterReset Count values above a threshold

 properties
 Threshold = 1
 end

 properties (DiscreteState)
 Count
 end
```

```
methods (Access = protected)
function setupImpl(obj)
 obj.Count = 0;
end

function y = stepImpl(obj,u1,u2)
 % Add to count if u1 is above threshold
 % Reset if u2 is true
 if (u2)
 obj.Count = 0;
 elseif (any(u1 > obj.Threshold))
 obj.Count = obj.Count + 1;
 end
 y = obj.Count;
end

function resetImpl(obj)
 obj.Count = 0;
end

function [sz,dt,cp] = getDiscreteStateSpecificationImpl(~,name)
 if strcmp(name,'Count')
 sz = [1 1];
 dt = 'double';
 cp = false;
 else
 error(['Error: Incorrect State Name: ', name.]);
 end
end

function dataout = getOutputDataTypeImpl(~)
 dataout = 'double';
end

function sizeout = getOutputSizeImpl(~)
 sizeout = [1 1];
end

function cplxout = isOutputComplexImpl(~)
 cplxout = false;
end

function fixedout = isOutputFixedSizeImpl(~)
 fixedout = true;
end

function flag = isInputSizeMutableImpl(~,idx)
 if idx == 1
 flag = true;
 end
end
```

```
 else
 flag = false;
 end
 end
end
end
```

## Set Model Reference Discrete Sample Time Inheritance

Disallow model reference discrete sample time inheritance for a System object. The System object defined in this example has one input, so by default, it allows sample time inheritance. To override the default and disallow inheritance, the class definition file for this example includes the `allowModelReferenceDiscreteSampleTimeInheritanceImpl` method, with its output set to `false`.

```
methods (Access = protected)
 function flag = ...
 allowModelReferenceDiscreteSampleTimeInheritanceImpl(obj)
 flag = false;
 end
end
```

View the method in the complete class definition file.

```
classdef MyCounter < matlab.System

 % MyCounter Count values

 properties
 Threshold = 1;
 end

 properties (DiscreteState)
 Count
 end

 methods (Static, Access = protected)
 function header = getHeaderImpl
 header = matlab.system.display.Header('MyCounter',...
 'Title', 'My Enhanced Counter',...
 'Text', 'This counter is an enhanced version.');
 end
 end

 methods (Access = protected)
 function flag = ...
 allowModelReferenceDiscreteSampleTimeInheritanceImpl(obj)
 flag = false
 end
 function setupImpl(obj,u)
```

```
 obj.Count = 0;
 end
 function y = stepImpl(obj,u)
 if (u > obj.Threshold)
 obj.Count = obj.Count + 1;
 end
 y = obj.Count;
 end
 function resetImpl(obj)
 obj.Count = 0;
 end
end
end
```

## Use Update and Output for Nondirect Feedthrough

Implement nondirect feedthrough for a System object by using the `updateImpl`, `outputImpl`, and `isInputDirectFeedthroughImpl` methods. In nondirect feedthrough, the outputs depend only on the internal states and properties of the object, rather than the input at that instant in time. You use these methods to separate the output calculation from the state updates of a System object. Implementing these two methods overrides the `stepImpl` method. These methods enable you to use the object in a feedback loop and prevent algebraic loops.

### Subclass from the Nondirect Mixin Class

To use the `updateImpl`, `outputImpl`, and `isInputDirectFeedthroughImpl` methods, you must subclass from both the `matlab.System` base class and the `Nondirect` mixin class.

```
classdef IntegerDelaySysObj < matlab.System & ...
 matlab.system.mixin.Nondirect
```

### Implement Updates to the Object

Implement an `updateImpl` method to update the object with previous inputs.

```
methods (Access = protected)
 function updateImpl(obj,u)
 obj.PreviousInput = [u obj.PreviousInput(1:end-1)];
 end
end
```

### Implement Outputs from Object

Implement an `outputImpl` method to output the previous, not the current input.

```
methods (Access = protected)
 function [y] = outputImpl(obj,~)
 y = obj.PreviousInput(end);
 end
end
```

### Implement Whether Input Is Direct Feedthrough

Implement an `isInputDirectFeedthroughImpl` method to indicate that the input is nondirect feedthrough.

```

methods (Access = protected)
 function flag = isInputDirectFeedthroughImpl(~,~)
 flag = false;
 end
end

```

### Complete Class Definition File with Update and Output

```

classdef intDelaySysObj < matlab.System &...
 matlab.system.mixin.Nondirect
 % intDelaySysObj Delay input by specified number of samples.

 properties
 InitialOutput = 0;
 end
 properties (Nontunable)
 NumDelays = 1;
 end
 properties (DiscreteState)
 PreviousInput;
 end

 methods (Access = protected)
 function validatePropertiesImpl(obj)
 if ((numel(obj.NumDelays)>1) || (obj.NumDelays <= 0))
 error('Number of delays must be > 0 scalar value.');
 end
 if (numel(obj.InitialOutput)>1)
 error('Initial Output must be scalar value.');
 end
 end

 function setupImpl(obj)
 obj.PreviousInput = ones(1,obj.NumDelays)*obj.InitialOutput;
 end

 function resetImpl(obj)
 obj.PreviousInput = ones(1,obj.NumDelays)*obj.InitialOutput;
 end

 function [y] = outputImpl(obj,~)
 y = obj.PreviousInput(end);
 end
 function updateImpl(obj, u)
 obj.PreviousInput = [u obj.PreviousInput(1:end-1)];
 end
 end
end

```

```
end
function flag = isInputDirectFeedthroughImpl(~,~)
 flag = false;
end
end
end
```

## Enable For Each Subsystem Support

Enable For Each subsystem support by using a System object in a Simulink For Each subsystem. Include the `supportsMultipleInstanceImpl` method in your class definition file. This method applies only when the System object is used in Simulink via the MATLAB System block.

Use the `supportsMultipleInstanceImpl` method and have it return `true` to indicate that the System object supports multiple calls in a Simulink For Each subsystem.

```
methods (Access = protected)
 function flag = supportsMultipleInstanceImpl(obj)
 flag = true;
 end
end
```

View the method in the complete class definition file.

```
classdef RandSeed < matlab.System
% RANDSEED Random noise with seed for use in For Each subsystem

 properties (DiscreteState)
 count;
 end

 properties (Nontunable)
 seed = 20;
 end

 properties (Nontunable,Logical)
 useSeed = false;
 end

 methods (Access = protected)
 function y = stepImpl(obj,u1)
 % Initial use after reset/setup
 % and use the seed
 if (obj.useSeed && ~obj.count)
 rng(obj.seed);
 end
 obj.count = obj.count + 1;
 [m,n] = size(u1);
 % Uses default rng seed
 y = rand(m,n) + u1;
 end
 end
end
```

```
 end

 function setupImpl(obj)
 obj.count = 0;
 end
 function resetImpl(obj)
 obj.count = 0;
 end

 function flag = supportsMultipleInstanceImpl(obj)
 flag = obj.useSeed;
 end
end
end
```

## Define System Object for Use in Simulink

| In this section...                                                   |
|----------------------------------------------------------------------|
| “Develop System Object for Use in MATLAB System Block” on page 44-41 |
| “Define Block Dialog Box for Plot Ramp” on page 44-42                |

### Develop System Object for Use in MATLAB System Block

You can develop a System object for use in a System block and interactively preview the block dialog box. This feature requires Simulink.

With the **System Block** editing options, the MATLAB Editor inserts predefined code into the System object. This coding technique helps you create and modify your System object faster and increases accuracy by reducing typing errors.

Using these options, you can also:

- View and interact with the block dialog box design as you define the System object.
- Add dialog box customization methods. If the block dialog box is open when you make changes, the block dialog design preview updates the display on saving the file.
- Add icon methods. However, these elements display only on the MATLAB System Block in Simulink, not in the **Preview Block Dialog**.

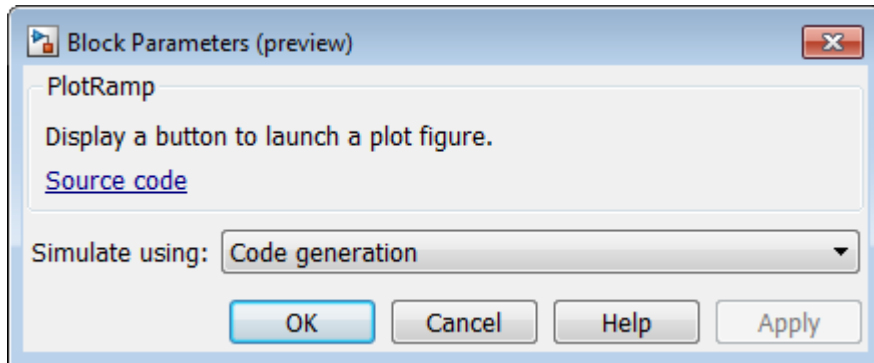

## Define Block Dialog Box for Plot Ramp

- 1 Create a System object using the menu option **New > System Object > Simulink Extension**.
- 2 Name the System object `PlotRamp` and save the file. This name becomes the block dialog box title.
- 3 Delete the comment at the beginning of the file and replace it with the block description.

```
% Display a button to launch a plot figure.
```

This comment becomes the block parameters dialog box description, under the block title.

- 4 Select **System Block > Preview Block Dialog**. The block dialog box displays as you develop the System object.

- 5 Add a ramp limit by selecting **Insert Property > Numeric**. Then change the property name and set the value to 10.

```
properties (Nontunable)
 RampLimit = 10;
end
```

- 6 Locate the `getPropertyGroupsImpl` method using the **Analyze** button.

```
function group = getPropertyGroupsImpl
 % Define property section(s) for System block dialog
 group = matlab.system.display.Section(mfilename('class'));
end
```

- 7 Create the group for the **Visualize** action.

```
function group = getPropertyGroupsImpl
 % Define property section(s) for System block dialog
 group = matlab.system.display.Section(mfilename('class'));
 group.Actions = matlab.system.display.Action(@(~,obj)...
 visualize(obj), 'Label', 'Visualize');
end
```

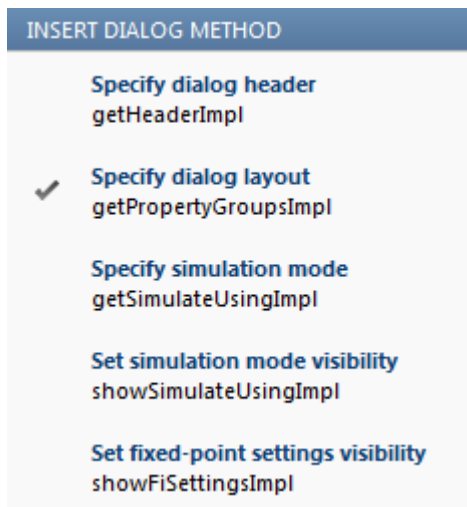

- 8 Add a function that adds code to display the **Visualize** button on the dialog box.

```
methods
 function visualize(obj)
 figure;
 d = 1:obj.RampLimit;
 plot(d);
 end
end
```

- As you add elements to the System block definition, save your file. Observe the effects of your code additions to the System block definition.

The **System Block** menu also displays checks next to the methods included in your file.

- 10 Delete any unused methods in the template or modify the methods to further customize the System object and System block. The class definition file now has all the code necessary for the PlotRamp System object.

```
classdef PlotRamp < matlab.System
 % Display a button to launch a plot figure.

 properties (Nontunable)
 RampLimit = 10;
 end

 methods(Static, Access=protected)
 function group = getPropertyGroupsImpl
 group = matlab.system.display.Section(mfilename('class'));
 group.Actions = matlab.system.display.Action(@(~, obj)...
 visualize(obj), 'Label', 'Visualize');
 end
 end

 methods
 function visualize(obj)
 figure;
 d = 1:obj.RampLimit;
 plot(d);
 end
 end
end
```

After you complete your System block definition, save it, and then load it into a MATLAB System block in Simulink.

## Use Global Variables in System Objects

Global variables are variables that you can access in other MATLAB functions or Simulink blocks.

### System Object Global Variables in MATLAB

For System objects that are used only in MATLAB, you define global variables in the System object class definition files in the same way that you define global variables in other MATLAB code (see “Global Variables” (MATLAB)).

### System Object Global Variables in Simulink

For System objects that are used in the MATLAB System block in Simulink, you also define global variables as you do in MATLAB. However, to use global variables in Simulink, if you have declared global variables in methods called by `stepImpl`, `updateImpl`, or `outputImpl`, you must declare global variables in the `stepImpl`, `updateImpl`, or `outputImpl` method, respectively.

You set up and use global variables for the MATLAB System block in the same way as you do for the MATLAB Function block (see “Data Stores” and “Share Data Globally” on page 43-123). Like the MATLAB Function block, you must also use variable name matching with a Data Store Memory block to use global variables in Simulink.

For example, this class definition file defines a System object that increments the first row of a matrix by 1 at each time step. If the file is P-coded, you must include `getGlobalNamesImpl`.

```
classdef GlobalSysObjMatrix < matlab.System
 methods (Access = protected)
 function y = stepImpl(obj)
 global B;
 B(1,:) = B(1, :)+1;
 y = B;
 end

 % Include getGlobalNamesImpl only if the class file is P-coded.
 function globalNames = getGlobalNamesImpl(~)
 globalNames = {'B'};
 end
end
```

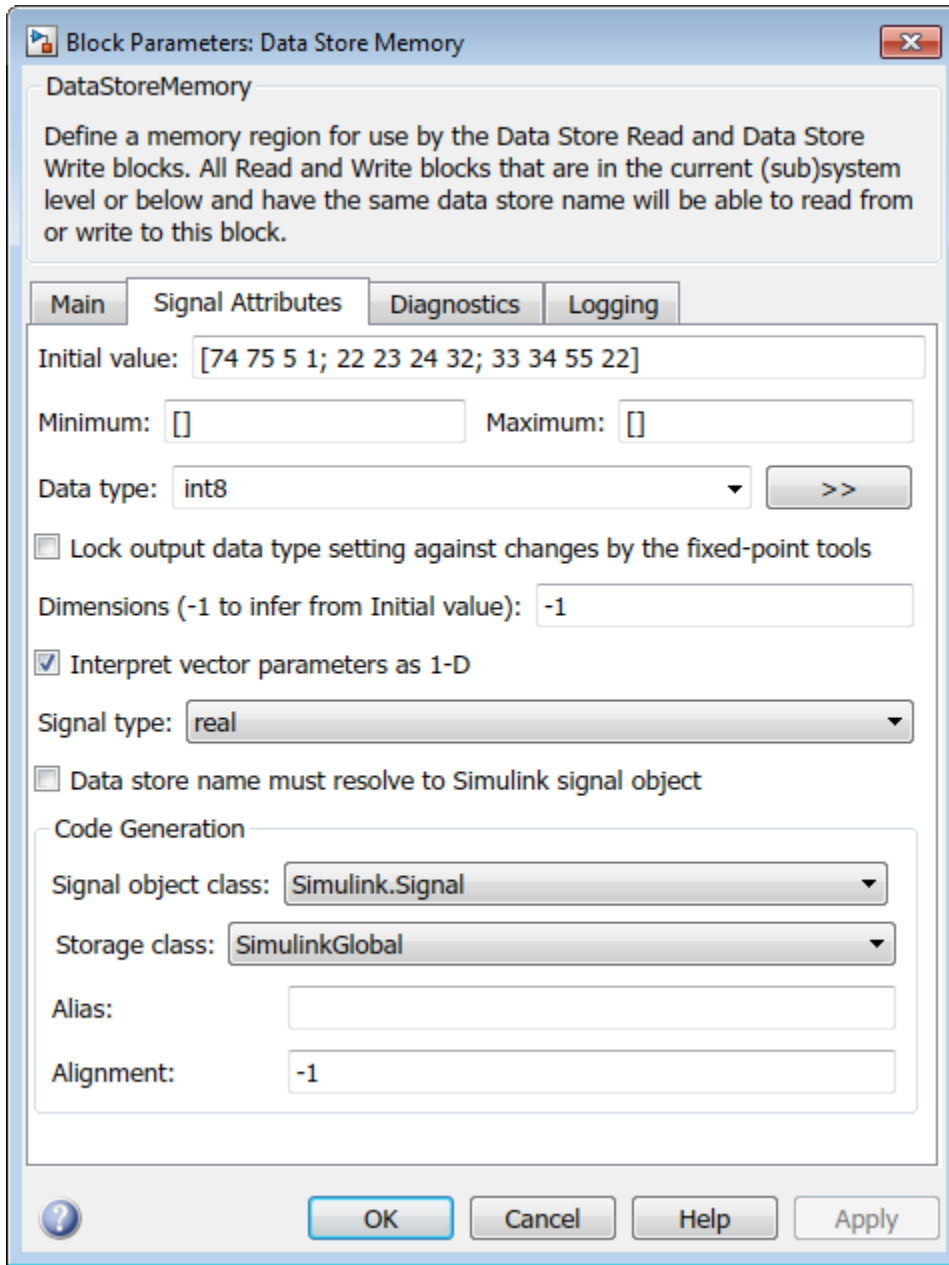

```
end
end
```

This model includes the `GlobalSysObjMatrix` object in a MATLAB System block and the associated Data Store Memory block.

## Use System Objects in Simulink

| “System Objects in the MATLAB Function Block” on page 44-50 |
| “System Objects in the MATLAB System Block” on page 44-50   |

### System Objects in the MATLAB Function Block

You can include System object code in Simulink models with the MATLAB Function block. Your function can include one or more System objects. Portions of your system may be easier to implement in the MATLAB environment than directly in Simulink. Many System objects have Simulink block counterparts with equivalent functionality. Before writing MATLAB code to include in a Simulink model, check for existing blocks that perform the desired operation.

### System Objects in the MATLAB System Block

You can include individual System objects that you create with a class definition file into Simulink with the MATLAB System block. This option is one way to add your own algorithm blocks into your Simulink models. For information, see “Integrate System Objects Using MATLAB System Block”.

## System Design and Simulation in Simulink

You can use System objects in your model to simulate in Simulink.

- 1 Create a System object to be used in your model. See “Define New System Objects for Use in Simulink” on page 44-51 for information.
- 2 Test your new System object in MATLAB. See “Test New System Objects in MATLAB” on page 44-57
- 3 Add the System object to your model by using the MATLAB System block. See “Add System Objects to Your Simulink Model” on page 44-57 for information.
- 4 Add other Simulink blocks as needed and connect the blocks to construct your system.
- 5 Run the system

## Define New System Objects for Use in Simulink

- “Define System Object with Block Customizations” on page 44-51
- “Define System Object with Nondirect Feedthrough” on page 44-54

A System object is a component you can use to create your system in MATLAB. You can write the code in MATLAB and use that code to create a block in Simulink. To define your own System object, you write a class definition file, which is a text-based MATLAB file that contains the code defining your object. See “Integrate System Objects Using MATLAB System Block”.

### Define System Object with Block Customizations

Create a System object for use in Simulink. The example performs system identification using a least mean squares (LMS) adaptive filter.

Create a class definition text file to define your System object. The code in this example creates a least mean squares (LMS) filter and includes customizations to the block icon and dialog box appearance. It is similar to the System Identification Using MATLAB System Blocks Simulink example.

---

**Note** Instead of manually creating your class definition file, you can use the **New > System Object > Simulink Extension** menu option to open a template. This template includes customizations of the System object for use in the Simulink MATLAB System block. You edit the template file, using it as guideline, to create your own System object.

---

On the first line of the class definition file, specify the name of your System object and subclass from both `matlab.System` and `matlab.system.mixin.CustomIcon`. The `matlab.System` base class enables you to use all the basic System object methods and specify the block input and output names, title, and property groups. The `CustomIcon` mixin class enables the method that lets you specify the block icon.

Add the appropriate basic System object methods to set up, reset, set the number of inputs and outputs, and run your algorithm. See the reference pages for each method and the full class definition file below for the implementation of each of these methods.

- Use the `setUpImpl` method to perform one-time calculations and initialize variables.
- Use the `stepImpl` method to implement the block's algorithm.
- Use the `resetImpl` method to reset the state properties or `DiscreteState` properties.
- Use the `getNumInputsImpl` and `getNumOutputsImpl` methods to specify the number of inputs and outputs, respectively.

Add the appropriate `CustomIcon` methods to define the appearance of the MATLAB System block in Simulink. See the reference pages for each method and the full class definition file below for the implementation of each of these methods.

- Use the `getHeaderImpl` method to specify the title and description to display on the block dialog box.
- Use the `getPropertyGroupsImpl` method to specify groups of properties to display on the block dialog box.
- Use the `getIconImpl` method to specify the text to display on the block icon.
- Use the `getInputNamesImpl` and `getOutputNamesImpl` methods to specify the labels to display for the block input and output ports.

The full class definition file for the least mean squares filter is:

```

classdef lmsSysObj < matlab.System &...
 matlab.system.mixin.CustomIcon
 % lmsSysObj Least mean squares (LMS) adaptive filtering.
 % #codegen

 properties
 % Mu Step size
 Mu = 0.005;
 end

 properties (Nontunable)
 % Weights Filter weights
 Weights = 0;
 % N Number of filter weights
 N = 32;
 end

 properties (DiscreteState)
 X;
 H;
 end

 methods (Access = protected)
 function setupImpl(obj)
 obj.X = zeros(obj.N,1);
 obj.H = zeros(obj.N,1);
 end

 function [y, e_norm] = stepImpl(obj,d,u)
 tmp = obj.X(1:obj.N-1);
 obj.X(2:obj.N,1) = tmp;
 obj.X(1,1) = u;
 y = obj.X'*obj.H;
 e = d-y;
 obj.H = obj.H + obj.Mu*e*obj.X;
 e_norm = norm(obj.Weights'-obj.H);
 end

 function resetImpl(obj)
 obj.X = zeros(obj.N,1);
 obj.H = zeros(obj.N,1);
 end
 end
end

```

```
end

% Block icon and dialog customizations
methods (Static, Access = protected)
 function header = getHeaderImpl
 header = matlab.system.display.Header(...
 'lmsSysObj', ...
 'Title', 'LMS Adaptive Filter');
 end

 function groups = getPropertyGroupsImpl
 upperGroup = matlab.system.display.SectionGroup(...
 'Title', 'General', ...
 'PropertyList', {'Mu'});

 lowerGroup = matlab.system.display.SectionGroup(...
 'Title', 'Coefficients', ...
 'PropertyList', {'Weights', 'N'});

 groups = [upperGroup, lowerGroup];
 end
end

methods (Access = protected)
 function icon = getIconImpl(~)
 icon = sprintf('LMS Adaptive\nFilter');
 end
 function [in1name, in2name] = getInputNamesImpl(~)
 in1name = 'Desired';
 in2name = 'Actual';
 end
 function [out1name, out2name] = getOutputNamesImpl(~)
 out1name = 'Output';
 out2name = 'EstError';
 end
end
end
```

### Define System Object with Nondirect Feedthrough

Create a System object for use in Simulink. The example performs system identification using a least mean squares (LMS) adaptive filter and uses feedback loops.

Create a class definition text file to define your System object. The code in this example creates an integer delay and includes feedback loops, and customizations to the block icon. For information on feedback loops, see “Use System Objects in Feedback Loops” on page 45-22. This example implements a System object that you can use for nondirect feedthrough. It is similar to the System Identification Using MATLAB System Blocks Simulink example.

On the first line of the class definition file, subclass from `matlab.System` and `matlab.system.mixin.CustomIcon`. The `matlab.System` base class enables you to use all the basic System object methods and specify the block input and output names, title, and property groups. The `CustomIcon` mixin class enables the method that lets you specify the block icon. The `Nondirect` mixin enables the methods that let you specify how the block is updated and what it outputs.

Add the appropriate basic System object methods to set up and reset the object and set and validate the properties. Since this object supports nondirect feedthrough, you do not implement the `stepImpl` method. You implement the `updateImpl` and `outputImpl` methods instead. See the reference pages for each method and the full class definition file below for the implementation of each of these methods.

- Use the `setupImpl` method to initialize some of the object’s properties.
- Use the `resetImpl` method to reset the property states.
- Use the `validatePropertiesImpl` method to check that the property values are valid.

Add the following `Nondirect` mixin class methods instead of the `stepImpl` method to specify how the block updates its state and its output. See the reference pages and the full class definition file below for the implementation of each of these methods.

- Use the `outputImpl` method to implement code to calculate the block output.
- Use the `updateImpl` method to implement code to update the block’s internal states.
- Use the `isInputDirectFeedthroughImpl` method to specify that the block is not direct feedthrough. Its inputs do not directly affect its outputs.

Add the `getIconImpl` method to define the block icon when it is used in Simulink via the MATLAB System block. See the reference page and the full class definition file below for the implementation of this method.

The full class definition file for the delay is:

```
classdef intDelaySysObj < matlab.System &...
 matlab.system.mixin.Nondirect &...
 matlab.system.mixin.CustomIcon
 % intDelaySysObj Delay input by specified number of samples.
 % #codegen

 properties
 % InitialOutput Initial output
 InitialOutput = 0;
 end

 properties (Nontunable)
 % NumDelays Number of delays
 NumDelays = 1;
 end

 properties (DiscreteState)
 PreviousInput;
 end

 methods (Access = protected)
 function setupImpl(obj, ~)
 obj.PreviousInput = ones(1,obj.NumDelays)*obj.InitialOutput;
 end

 function [y] = outputImpl(obj, ~)
 % Output does not directly depend on input
 y = obj.PreviousInput(end);
 end

 function updateImpl(obj, u)
 obj.PreviousInput = [u obj.PreviousInput(1:end-1)];
 end

 function flag = isInputDirectFeedthroughImpl(~,~)
 flag = false;
 end

 function validatePropertiesImpl(obj)
 if ((numel(obj.NumDelays)>1) || (obj.NumDelays <= 0))
 error('Number of delays must be positive non-zero ...
 scalar value.');
```

```
 error('Initial output must be scalar value.');
```

```
 end
```

```
end
```

```
function resetImpl(obj)
```

```
 obj.PreviousInput = ones(1,obj.NumDelays)*obj.InitialOutput;
```

```
end
```

```
function icon = getIconImpl(~)
```

```
 icon = sprintf('Integer\nDelay');
```

```
end
```

```
end
```

```
end
```

## Test New System Objects in MATLAB

- 1 Create an instance of your new System object. For example, create an instance of the `lmsSysObj`.

```
s = lmsSysObj;
```

- 2 Run the object multiple times with different inputs. Doing this step tests for syntax errors and other possible issues before you add it to Simulink. For example,

```
desired = 0;
```

```
actual = 0.2;
```

```
s(desired,actual);
```

## Add System Objects to Your Simulink Model

- 1 Add your System objects to your Simulink model by using the MATLAB System block as described in “Mapping System Objects to Block Dialog Box” on page 45-27.
- 2 Add other Simulink blocks, connect them, and configure any needed parameters to complete your model as described in the Simulink documentation. See the System Identification for an FIR System Using MATLAB System Blocks Simulink example.
- 3 Run your model in the same way you run any Simulink model.

## Specify Sample Time for MATLAB System Block System Objects

This example shows how to control the sample time of the MATLAB System block using System object™ methods.

Inside the class definition, use the `matlab.system.mixin.SampleTime` methods to configure the sample time and modify the System object behavior based on the current simulation time.

### Specify Sample Time

To specify the sample time, implement the `getSampleTimeImpl` method. In this example, a property `SampleTimeTypeProp` is created to assign the sample time based on different property values. The `getSampleTimeImpl` method creates a sample time specification based on the `SampleTimeTypeProp` property. The `getSampleTimeImpl` method returns a sample time specification object `sts` to set the sample time specifications.

```
16 function sts = getSampleTimeImpl(obj)
17 switch char(obj.SampleTimeTypeProp)
18 case 'Inherited'
19 sts = createSampleTime(obj,'Type','Inherited');
20 case 'InheritedNotControllable'
21 sts = createSampleTime(obj,'Type','Inherited',...
22 'Disallow','Controllable');
23 case 'FixedInMinorStep'
24 sts = createSampleTime(obj,'Type','Fixed In Minor Step');
25 case 'Discrete'
26 sts = createSampleTime(obj,'Type','Discrete',...
27 'SampleTime',obj.SampleTime, ...
28 'OffsetTime',obj.OffsetTime);
29 case 'Controllable'
30 sts = createSampleTime(obj,'Type','Controllable',...
31 'TickTime',obj.TickTime);
32 end
33 end
```

### Query Simulation Time and Sample Time

Use the `getSampleTime` and `getCurrentTime` methods to query the MATLAB System block for the current sample time and simulation time, respectively. `getSampleTime`

returns a sample time specification object with properties describing the sample time settings.

```

35 function [Count, Time, SampleTime] = stepImpl(obj,u)
36 Count = obj.Count + u;
37 obj.Count = Count;
38 Time = getCurrentTime(obj);
39 sts = getSampleTime(obj);
40 if strcmp(sts.Type,'Controllable')
41 setNumTicksUntilNextHit(obj,obj.Count);
42 end
43 SampleTime = sts.SampleTime;
44 end

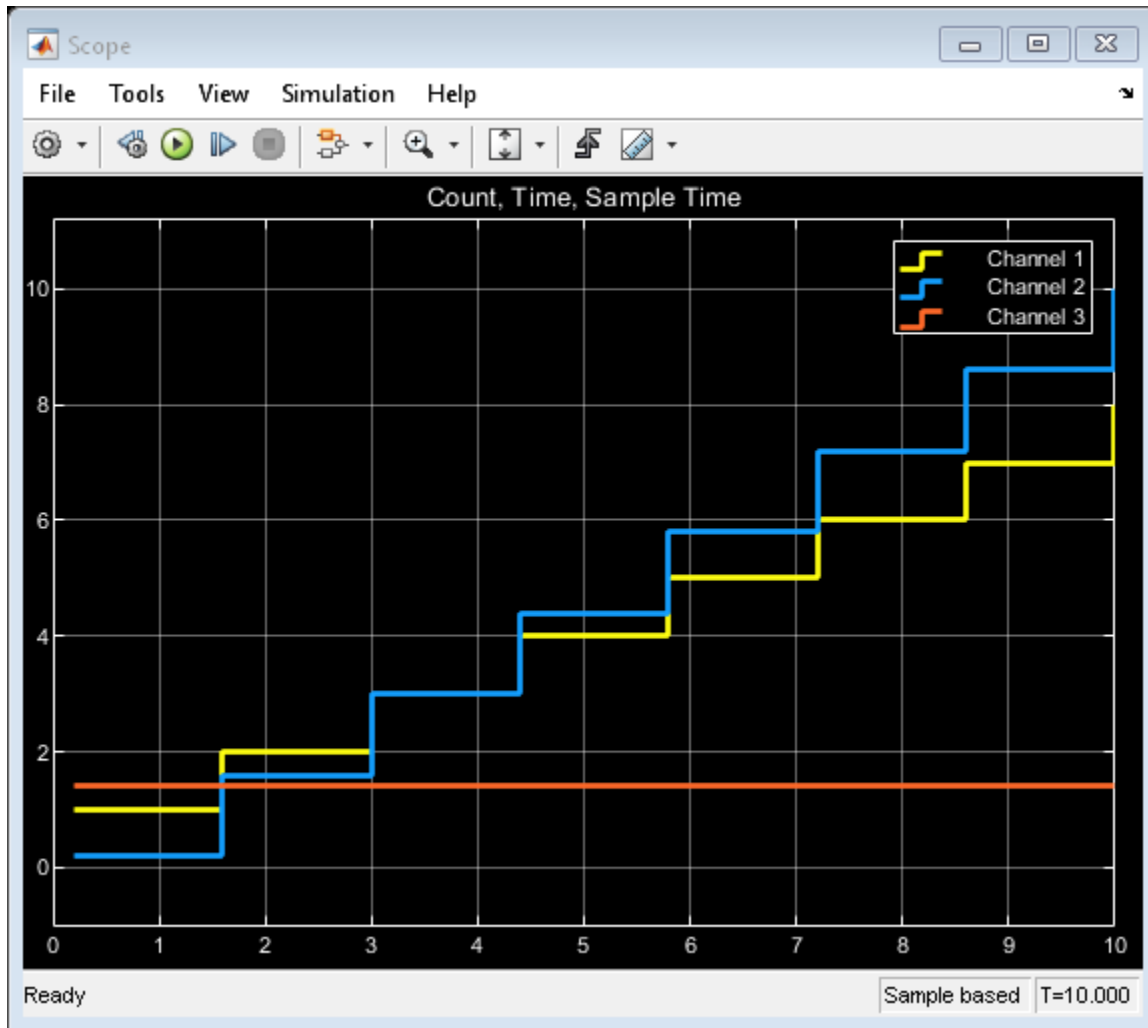

```

### Behavior in Simulink

Include this System object in a MATLAB System block.

In the scope, you can see the effects of the sample time changes to the block.

### Full Class Definition

Full class definition of the CountTime System object and its associated enumeration class SampleTimeTypePropValues.

```
classdef CountTime < matlab.System & matlab.system.mixin.SampleTime
 % Counts Hits and Time
```

```

properties(Nontunable)
 SampleTime = 1.4; % Sample Time
 OffsetTime = 0.2; % Offset Time
 TickTime = 0.1;
 SampleTimeTypeProp (1, 1) SampleTimeTypePropValues = SampleTimeTypePropValues.L
end

properties(DiscreteState)
 Count
end

methods(Access = protected)
 function sts = getSampleTimeImpl(obj)
 switch char(obj.SampleTimeTypeProp)
 case 'Inherited'
 sts = createSampleTime(obj,'Type','Inherited');
 case 'InheritedNotControllable'
 sts = createSampleTime(obj,'Type','Inherited',...
 'Disallow','Controllable');
 case 'FixedInMinorStep'
 sts = createSampleTime(obj,'Type','Fixed In Minor Step');
 case 'Discrete'
 sts = createSampleTime(obj,'Type','Discrete',...
 'SampleTime',obj.SampleTime, ...
 'OffsetTime',obj.OffsetTime);
 case 'Controllable'
 sts = createSampleTime(obj,'Type','Controllable',...
 'TickTime',obj.TickTime);
 end
 end
end

function [Count, Time, SampleTime] = stepImpl(obj,u)
 Count = obj.Count + u;
 obj.Count = Count;
 Time = getCurrentTime(obj);
 sts = getSampleTime(obj);
 if strcmp(sts.Type,'Controllable')
 setNumTicksUntilNextHit(obj,obj.Count);
 end
 SampleTime = sts.SampleTime;
end

function setupImpl(obj)

```

```
 obj.Count = 0;
 end

 function resetImpl(obj)
 % Initialize / reset discrete-state properties
 obj.Count = 0;
 end

 function flag = isInactivePropertyImpl(obj,prop)
 flag = false;
 switch char(obj.SampleTimeTypeProp)
 case {'Inherited', ...
 'InheritedNotControllable', ...
 'FixedInMinorStep'}
 if any(strcmp(prop,{'SampleTime','OffsetTime','TickTime'}))
 flag = true;
 end
 case 'Discrete'
 if any(strcmp(prop,{'TickTime'}))
 flag = true;
 end
 case 'Controllable'
 if any(strcmp(prop,{'SampleTime','OffsetTime'}))
 flag = true;
 end
 end
 end
 end
end
end
end

classdef SampleTimeTypePropValues < int32
 enumeration
 Discrete (0)
 Inherited (1)
 InheritedNotControllable (2)
 FixedInMinorStep (3)
 Controllable (4)
 end
end
```

end

| “MATLAB System and System Objects Examples” on page 45-5 |

### Why Use the MATLAB System Block?

System objects let you implement algorithms using the MATLAB language. The MATLAB System block enables you to use System objects in Simulink.

The MATLAB System block lets you:

- Share the same System object in MATLAB and Simulink
- Dedicate integration of System objects with Simulink
- Unit test your algorithm in MATLAB before using it in Simulink
- Customize dialog box customization
- Simulate efficiently with better initialization
- Handle states
- Customize block icons with port labels
- Access two simulation modes

### Choosing the Right Block Type

There are several mechanisms for including MATLAB algorithms in Simulink, such as:

- MATLAB System block
- MATLAB Function block

- Interpreted MATLAB Function block
- Level-2 MATLAB S-Function block
- Fcn block

For help on choosing the right block, see “Comparison of Custom Block Functionality” on page 40-6.

## System Objects

Before you use a MATLAB System block, you must have a System object to associate with the block. A System object is a specialized kind of MATLAB class. System objects are designed specifically for implementing and simulating dynamic systems with inputs that change over time.

For more information on creating System objects, see “Customize System Objects for Simulink”.

---

**Note** To use your System object in the Simulink environment, it must have a constructor that you can call with no arguments. By default, the System object constructor has this capability and you do not need to define your own constructor. However, if you create your own System object constructor, you must be able to call it with no arguments.

---

System objects exist in other MATLAB products. MATLAB System block supports only the System objects written in the MATLAB language. In addition, if a System object has a corresponding Simulink block, you cannot implement a MATLAB System block for it.

## Interpreted Execution or Code Generation

You can use MATLAB System blocks in Simulink models for simulation via interpreted execution or code generation.

- With interpreted execution, the model simulates the block using the MATLAB execution engine.
- With code generation, the model simulates the block using code generation (requires the use of the subset of MATLAB code supported for code generation). For a list of supported functions, see “Functions and Objects Supported for C/C++ Code Generation — Alphabetical List” on page 48-2.

## Default Input Signal Attributes

If a MATLAB System block has one or more inputs that are unconnected to another block's output port or connected to a port that has underspecified attributes, the default input signal attributes for the unspecified attributes are:

| Data Attribute | Default      |
|----------------|--------------|
| Data Type      | double       |
| Size           | [1 1] scalar |
| Complexity     | real         |

## MATLAB System Block Limitations

These capabilities are currently not supported.

| Category       | Limitation Description                                                                                                                                                                                                                                                                               | Workaround |
|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------|
| System Objects | Tunable logical and character vector properties of the System object are nontunable parameters in the MATLAB System block.                                                                                                                                                                           | —          |
| Data Types     | <ul style="list-style-type: none"> <li>The MATLAB System block does not support virtual buses as input or output.</li> <li>System objects cannot use fixed-point signals with nonbinary point scaling or nonzero bias.</li> <li>System objects cannot use user-defined opaque data types.</li> </ul> | —          |
| Sample Time    | Cannot use MATLAB System blocks to model continuous time or multirate systems.                                                                                                                                                                                                                       | —          |
| Linearizations | Cannot use Jacobian based linearization.                                                                                                                                                                                                                                                             | —          |

| Category                                                      | Limitation Description                                                                                                                                                                                         | Workaround                                                                                                                                                                                  |
|---------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## Implement a MATLAB System Block

Implement a block and assign a System object to it. You can then explore the block to see the effect.

- 1 Create a new model and add the MATLAB System block from the User-Defined Functions library.

- 2 In the block dialog box, from the **New** list, select **Basic**, **Advanced**, or **Simulink Extension** if you want to create a new System object from a template. Modify the template according to your needs and save the System object.
- 3 Enter the full path name for the System object in the **System object name**. Click the list arrow. If valid System objects exist in the current folder, the names appear in the list.

The MATLAB System block icon and port labels update to those of the corresponding System object. For example, suppose you selected a System object named `lmsSysObj` in your current folder. The block updates as shown in the figure:

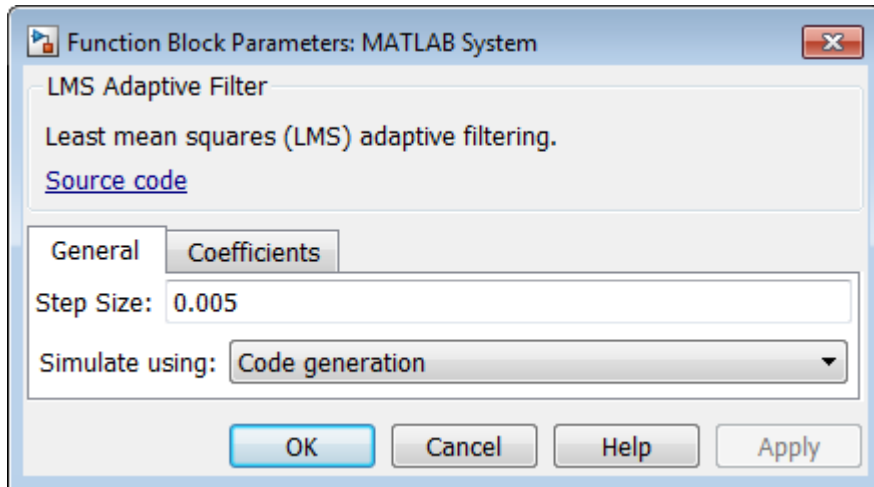

---

**Note** After you associate the block with a System object class name, you cannot assign a new System object using the same MATLAB System block dialog box. Instead, right-click the MATLAB System block, select **Block Parameters (MATLABSystem)** and enter a new class name in **System object name**.

---

## Understanding the MATLAB System Block

- 1 Double-click the block. The MATLAB System dialog box reflects the System object parameters. The dialog box usually includes a **Source code** link that leads to the System object class file. For example:

The **Source code** link appears if the System object uses MATLAB language. It does not appear if you have:

- Converted the System object to P-code
  - Overridden the default behavior using the `getHeaderImpl` method
- 2 Click **Source code** and observe that the public and active properties in the System object appear in the MATLAB System block dialog box as block parameters.
  - 3 Select how you want the model to simulate the block using the **Simulate using** parameter. (This parameter appears at the bottom of each MATLAB System block if there is only one tab, or the bottom of the first of multiple tabs.)

## Call Simulink Functions from MATLAB System Block

A Simulink Function is a graphical representation of a computational unit in the Simulink environment. Once you create the Simulink function, it can be executed by any computational unit and can be called in multiple places. You can only call a Simulink function inside the `stepImpl`, `outputImpl`, or `updateImpl` method of a System object. See “Simulink Functions Overview” on page 10-141 for more information on Simulink functions.

---

**Note** Interpreted mode is not supported for a model that contains a MATLAB System block calling a Simulink Function.

---

### Create a Simulink Function Block

Set up a Simulink Function block that implements a simple function such as  $y = 2 * u$ .

- 1 Open a new model from **Simulink Editor** and add a Simulink Function block by typing Simulink Function on Simulink canvas.
- 2 When **Function prototype** window opens, type `y = timestwo_func(u)` as the function definition. This indicates that you define a function called `timestwo_func` that takes `u` as the input argument and produces `y` as the output argument. Alternatively, define the function name from Simulink Function block parameters.
- 3 Double-click the Simulink Function block and observe that a Trigger Port function block appears as well as an input and an output argument block.
- 4 Double-click the Trigger Port block in the Simulink Function, and observe that the **Function visibility** is set to **scoped**. To learn more about **scoped** Simulink Functions, see “Scoped and Global Simulink Function Blocks Overview” on page 10-184.
- 5 Add a Gain block and set its value to 2. Connect it with the input and output argument block. Click **Up to Parent** to return to the main model.

---

**Note** To determine which Simulink Function a MATLAB System block is calling, turn the function tracing lines from **Simulink Editor** menu, select **Display > Function Connectors**.

---

## Create a MATLAB System Block and Define System Object

Drag a MATLAB System block into the model and implement a System object to this block.

- 1 Add a MATLAB System block to your Simulink model.
- 2 In the block dialog box, from the **New** list, select **Basic**. This opens a basic System object template for you to type your code.
- 3 To subclass an object from `matlab.System`, replace `Untitled` with the name of your System object. For this example, name it `SimulinkFcnCaller`.
- 4 In the `stepImpl` method of your System object, declare the Simulink Function using `getSimulinkFunctionNamesImpl`.

See an example of the System object code below. To learn more about how to write a System object, see “Define Basic System Objects” (MATLAB).

```
classdef SimulinkFcnCaller < matlab.System
 % Public, tunable properties

 % SimulinkFcnCaller calls a Simulink Function from a
 % MATLAB System block to multiply the signal's value by 2.

 methods(Access = protected)

 function y = stepImpl(obj,u)
 % Implement algorithm. Calculate y as a function of input u and
 % discrete states.
 y = timestwo_func(u);
 end
 function names = getSimulinkFunctionNamesImpl(obj)
 % Use 'getSimulinkFunctionNamesImpl' method to declare
 % the name of the Simulink Function that will be called
 % from the MATLAB System block's System object code.
 names = {'timestwo_func'};
 end
 end
end
```

- 5 Save the file and name it `SimulinkFcnCaller.m`.

## Call a Simulink Function in a Subsystem from a MATLAB System Block

The hierarchy of the Simulink Function block affects the function calls in the System object. For example, if the Simulink function is defined at a higher hierarchy in the Simulink model, the function is defined for all blocks in that hierarchy. If the Simulink

function is defined at a lower hierarchy, you need to qualify the Subsystem and the function name. For example, suppose you have a Subsystem that contains a Simulink Function block at the same level as a MATLAB System block. When a Simulink Function block is placed in a subsystem, the function name is not visible to the outside the subsystem. You can call the Simulink Function block by qualifying the function name using the Subsystem name in your System object. To qualify the Subsystem and the function name follow these steps:

- 1 In the `stepImpl` method of your System object code, call the Simulink Function using dot notation. For example, in the code `y = Subsystem1.timestwo_func(u)`, `Subsystem1` corresponds to the Subsystem, and `timestwo_func` corresponds to the Simulink Function name.
- 2 Similarly, declare the Subsystem and the Simulink Function in the `getSimulinkFunctionNamesImpl` method using the dot notation. The System object code shows the `timestwo` example written for a Simulink Function defined at a lower hierarchy than the MATLAB System block.

```
classdef SimulinkFcnCallerQualified < matlab.System

 % SimulinkFcnCallerQualified calls a Simulink Function embedded in a Subsystem
 % from a MATLAB System block, and multiplies the signal's value by 2.

 methods(Access = protected)

 function y = stepImpl(obj,u)
 % Use the '.' notation to call a scoped Simulink Function from
 % a Simulink Function block.
 % Subsystem1 corresponds to the block name, where
 % timestwo_func is the Simulink Function name.
 y = Subsystem1.timestwo_func(u);
 end

 function names = getSimulinkFunctionNamesImpl(obj)
 % Use the 'getSimulinkFunctionNamesImpl' method with the '.'
 % notation to declare the name of a Simulink Function in
 % MATLAB System block's System object code.
 names = {'Subsystem1.timestwo_func'};
 end
 end
end
```

- 3 Save the System object file and name it `SimulinkFcnCallerQualified.m`.

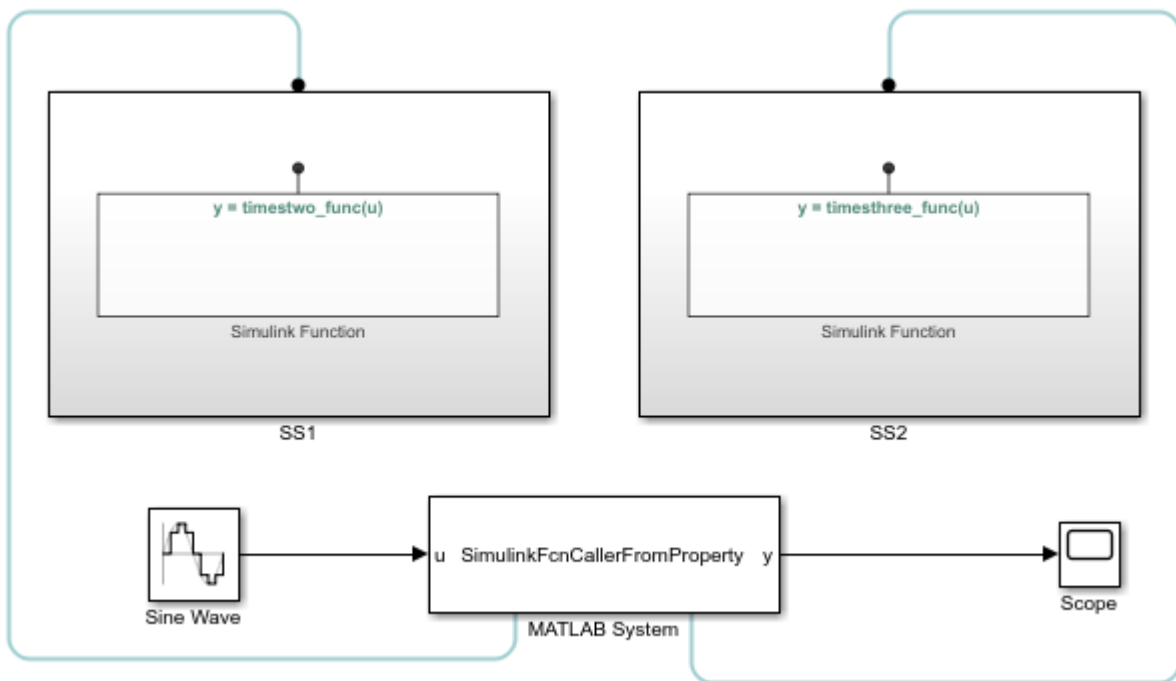

## Call Simulink Functions from a MATLAB System Block

This example shows two Simulink Functions conditionally called by a MATLAB System block using the nontunable properties of the System object®.

The MATLAB System block calls one of the Simulink Functions inside two different subsystems, depending on the value of the signal coming from the Sine Wave block. If the value of the signal is less than 10, the MATLAB System block calls the `timestwo_func` Simulink Function inside the SS1 Subsystem block. If the value is larger than 10, it calls the `timesthree_func` in the SS2 Subsystem block.

Function names are defined as nontunable properties, are switched from string to functions using the `str2func` function. Then, these functions are declared as properties in the `getSimulinkFunctionNamesImpl` method.

## Specify Sample Time for MATLAB System Block

The sample time of a block is a parameter that indicates when the block produces an output, and eventually updates its internal state. To specify sample time for MATLAB System block, you can use `matlab.system.mixin.SampleTime` methods.

To specify sample time, implement the `getSampleTimeImpl` method. To query the MATLAB System block for current sample time and simulation time, use the `getSampleTime` and `getCurrentTime` methods. For more information, see “Specify Sample Time for MATLAB System Block System Objects” on page 44-58.

### Types of Sample Time for MATLAB System Block

If you use discrete sample time on page 7-15 in simulation, Simulink only calculates the output of a simulation for each of the fixed time intervals. The simulation times that the Simulink calculates the output of a block is called sample time hits. To specify discrete sample time, set the type in the `createSampleTime` to `Discrete` and specify the `SampleTime` property.

When the sample time is inherited on page 7-16, Simulink determines the best sample time for the block based on the block's role within the model. To specify inherited sample time, set the type in the `createSampleTime` to `Inherited`. When using inherited sample time, if you use 'Disallow', 'Controllable' Name-Value pair argument, MATLAB System block disallows the inherited controllable sample time.

In fixed-in-minor-step on page 7-16 sample time, Simulink does not execute the block at the minor time steps, the updates only occur at the major time steps. To specify the fixed-in-minor time step, set the type in `createSampleTime` to `Fixed In Minor Step`.

To use controllable sample time, configure a block to specify controllable sample time with a resolution  $T_{base}$ , where  $T_{base}$  is the smallest allowable time interval between block executions. To specify  $T_{base}$  in MATLAB System block, set the type in `createSampleTime` to `Controllable` and set the `TickTime` property to  $T_{base}$ . A block using controllable sample time can be dynamically set to execute at  $n$  multiples of  $T_{base}$ , then the block's next execution is

$$T_{next} = n T_{base} + T$$

You can set the  $n$  in your MATLAB System block using `setNumTicksUntilNextHit`.

For more information on types of sample time, see “Types of Sample Time” on page 7-15. To see an example on how to control the sample time of the MATLAB System block using System object methods, see “Specify Sample Time for MATLAB System Block System Objects” on page 44-58.

## Change Block Icon and Port Labels

To change the icon appearance of your block, you must use the `matlab.system.mixin.CustomIcon` class. You can define port labels using System object methods.

- 1 Add the `matlab.system.mixin.CustomIcon` class name to the System object, after the `matlab.System` class. For example:

```
classdef lmsSysObj < matlab.System & matlab.system.mixin.CustomIcon
```

This code subclasses from the `matlab.system.mixin.CustomIcon` class in addition to the `matlab.System` base class.

- 2 To define the icon, implement the `getIconImpl` method.
- 3 To define the port labels, implement the following optional methods to change the input and output port labels. You do not need the `matlab.system.mixin.CustomIcon` class to use these methods.

```
getInputNamesImpl
getOutputNamesImpl
```

If you do not implement these methods, the System object uses the input and output port names from the `stepImpl` method. If you are using the `matlab.system.mixin.Nondirect` class and do not implement these methods, the System object uses the input names from `updateImpl` and the output port names from `OutputImpl`.

## Modify MATLAB System Block Dialog

To change the MATLAB System block dialog, implement the methods for the following classes:

| Description                            | <code>matlab.system.display</code> Methods      |
|----------------------------------------|-------------------------------------------------|
| Define header text for property group. | <code>matlab.system.display.Header</code>       |
| Group properties together.             | <code>matlab.system.display.Section</code>      |
| Group properties into a separate tab.  | <code>matlab.system.display.SectionGroup</code> |

## Change the MATLAB System Block Icon to an Image

You can change the image of MATLAB System block in MATLAB Editor. For a list of accepted image files, see `image`. To use an existing image file for the MATLAB System block:

- 1 Double-click your MATLAB System block.
- 2 In the block dialog box, click the **Source code**. The MATLAB Editor that contains the System object code opens.
- 3 In the MATLAB Editor, from the **System Block** drop-down list, select **Add Image Icon**.
- 4 In the **Add image icon** dialog window, click **Browse** to select an image of your choice.
- 5 Click **OK** to insert the corresponding code for the `getIconImpl` method in your System object.

For more information, see “Customize System Block Appearance” on page 44-2.

## Nonvirtual Buses and MATLAB System Block

The MATLAB System block supports nonvirtual buses as input and output signals. The corresponding System object input or output must be a MATLAB structure whose fields match those defined by the nonvirtual bus. If the System object output is a MATLAB structure, it must define propagator methods. In addition, the `getOutputDataTypeImpl` method must return the name of the corresponding bus object. This bus object must exist in the base workspace or a data dictionary linked to the model.

---

**Note** If the output is the same bus type as the input, do not use the `propagatedInputDataType` method to obtain the name of the bus object. Instead, you must return the name of the bus object directly.

---

## Use System Objects in Feedback Loops

If your algorithm needs to process nondirect feedthrough data through the System object, use the `matlab.system.mixin.Nondirect` class. This class uses the `output` and `update` methods to process nondirect feedthrough data through a System object.

Most System objects use direct feedthrough, where the object's input is needed to generate the output. For these direct feedthrough objects, the `step` method calculates the output and updates the state values. For nondirect feedthrough, however, the object's output depends on internal states and not directly on the inputs. The inputs, or a subset of the inputs, are used to update the object states. For these objects, calculating the output is separated from updating the state values. This enables you to use an object as a feedback element in a feedback loop.

A delay object is an example of a nondirect feedthrough object.

- 1 Add the `matlab.system.mixin.Nondirect` class to the top of the parent class file for the System object, after the `matlab.System` class. For example:

```
IntegerDelaySysObj < matlab.System & matlab.system.mixin.Nondirect
```

This step subclasses from the `matlab.system.mixin.Nondirect` class in addition to the `matlab.System` base class.

- 2 Implement the following methods:

```
outputImpl
updateImpl
```

When implementing the `outputImpl` method, do not access the System object inputs for which the direct feedthrough flag is false.

- 3 If the System object supports code generation and does not inherit from `matlab.system.mixin.Propagates`, Simulink can automatically infer the direct feedthrough settings from the System object MATLAB code. However, if the System object does not support code generation, the default `isInputDirectFeedthroughImpl` method returns false (no direct feedthrough). In this case, override this method if you want nondefault behavior.

The processing of the nondirect feedthrough changes the way that the software calls the System object methods within the context of the Simulink engine.

## Simulation Modes

### Interpreted Execution vs. Code Generation

You can use MATLAB System block in Simulink models for simulation via interpreted execution or code generation. Implementing a MATLAB System block with a valid System object class name enables the **Simulate using** parameter. This parameter appears at the bottom of each MATLAB System block if there is only one tab, or the bottom of the first of multiple tabs. Use the **Simulate using** parameter to control how the block simulates. The table describes how to choose the right value for your purpose.

- With interpreted execution, the model simulates the block using the MATLAB execution engine.

---

**Note** With interpreted execution, if you set the **Use division for fixed-point net slope computation** parameter to `On` or `Use division for reciprocals of integers only` in the Configuration Parameters dialog box, you might get unoptimized numeric results. This is because MATLAB code does not support this parameter.

---

- With code generation, the model simulates the block using code generation, using the subset of MATLAB code supported for code generation.

| Action                                                                                                                                                                                                            | Select                    | Pros                            | Cons                                                                                                                        |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------|---------------------------------|-----------------------------------------------------------------------------------------------------------------------------|
| Upon first model run, simulate and generate code for MATLAB System using only the subset of MATLAB functions supported for code generation. Choosing this option causes the simulation to run the generated code. | Code generation (default) | Potentially better performance. | System object is limited to the subset of MATLAB functions supported for code generation. Simulation may start more slowly. |

| Action                                                                                                     | Select                | Pros                                                                             | Cons                                                                                                                                                             |
|------------------------------------------------------------------------------------------------------------|-----------------------|----------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Simulate model using all supported MATLAB functions. Choosing this option can slow simulation performance. | Interpreted execution | System object can contain any supported MATLAB function.<br>Faster startup time. | Potentially slower performance. If the MATLAB functions in the System object do not support code generation, the System object must contain propagation methods. |

To take advantage of faster performance, consider using propagation methods in your System object. For more information, see “Add and Implement Propagation Methods” on page 45-38.

## Simulation Using Code Generation

While simulating and generating code for one or more simulation targets (in this case, System object blocks), the model displays status messages in the bottom left of the Simulink Editor window. A model can have multiple copies of the same block, where blocks are considered the same if they

- Use the same System object.
- Have inputs and tunable parameters that have identical signals, data types, and complexities.
- Have nontunable parameters that have the same value.

When the model has multiple copies of the same block, the software does not regenerate the code for each block. It reuses the code from the first time that code was generated for one of these blocks. The status messages reflect this and do not show status messages for each of these blocks.

When the code generation process is complete, Simulink creates a MEX-file for the generated code.

## Mapping System Objects to Block Dialog Box

The System object source code controls the appearance of the block dialog box. This section describes System object to block dialog box mapping using the System Identification for an FIR System Using MATLAB System Blocks example. This example uses two System objects, one that uses default System object to block dialog box mapping, and one that uses a custom mapping.

### System Object to Block Dialog Box Default Mapping

The following figure shows how the source code corresponds to the dialog box elements if you do not customize the dialog using the `getHeaderImpl` or `getPropertyGroupsImpl` methods. (The link to open the source code and the **Simulate using** parameter appear on all MATLAB System block dialog boxes.)

y = u;
end
end
end
end

```

The Delay block from the System Identification for an FIR System Using MATLAB System Blocks is an example of a block that uses a System object that draws the dialog box using the default mapping. This block has one input and one output.

This block uses a System object that has direct feedthrough set to false (nondirect feedthrough). This setting means that the System object does not directly use the input to compute the output, enabling the model to use this block safely in a feedback system without introducing an algebraic loop. For more information on nondirect feedthrough, see “Use System Objects in Feedback Loops” on page 45-22.

For an example of a custom block dialog box, see “System Object to Block Dialog Box Custom Mapping” on page 45-29.

## System Object to Block Dialog Box Custom Mapping

The LMS Adaptive block is an example of a block with a custom header and property groups. The System object code uses the `getHeaderImpl` and `getPropertyGroupsImpl` methods from `matlab.System` to customize these block dialog elements.

The LMS Adaptive Filter block estimates the coefficients of an unknown system (formed by the Unknown System and Delay blocks). Its inputs are the desired signal and the actual signal. Its outputs are the estimated signal and the vector norm of the error in the estimated coefficients. It uses the `lmsSysObj` System object.

```

classdef lmsSysObj < matlab.System & matlab.system.mixin.CustomIcon
%lmsSysObj Least mean squares (LMS) adaptive filtering.

methods(Static, Access=protected)

function header = getHeaderImpl
header = matlab.system.display.Header(...
'Title', 'LMS Adaptive Filter');
end

function groups = getPropertyGroupsImpl
firstGroup = matlab.system.display.SectionGroup(...
'Title', 'General', ...
'PropertyList', {'Mu'});

secondGroup = matlab.system.display.SectionGroup(...
'Title', 'Coefficients', ...
'PropertyList', {'TrueCoefficients', 'NumCoeff'});

groups = [firstGroup, secondGroup];
end
end

```

Header description from class help summary

## Considerations for Using System Objects in Simulink

### In this section...

“System Objects in Simulink” on page 45-32

“System Objects in For Each Subsystems” on page 45-33

“Input Validation” on page 45-33

### System Objects in Simulink

There are differences in how you can use System objects in a MATLAB System block in Simulink versus using the same object in MATLAB. You see these differences when working with variable-size signals and tunable parameters and when using System objects as properties.

#### Variable-Size Signals

To use variable-size signals in a System object, you must implement `matlab.system.mixin.Propagates` methods. In particular, use the `isOutputFixedSizeImpl` method to specify if an output is variable-size or fixed-size. This is true for interpreted execution and code generation simulation methods.

#### Tunable Parameters

Simulink registers public tunable properties of a System object as tunable parameters of the corresponding MATLAB System block. If a System object property is tunable, it is also tunable in the MATLAB System block. At runtime, you can change the parameter using one of the following approaches. The change applies at the top of the simulation loop.

- At the MATLAB command line, use the `set_param` to change the parameter value.
- In the Simulink editor, edit the MATLAB System block dialog box to change the parameter value, and then update the block diagram.

You cannot change public tunable properties from System object internal methods such as `stepImpl`.

During simulation, setting an invalid value on a tunable parameter causes an error message and stops simulation.

## System Objects as Properties

The MATLAB System block allows a System object to have other System objects as public or private properties. However:

- System objects and other MATLAB objects stored as public properties are read only. As a result, you cannot set the value of the parameter, you can only get the value of a parameter.
- System objects stored as property values appear dimmed in the MATLAB System block dialog box.

## Default Property Values

MATLAB does not require that objects assign default values to properties. However, in Simulink, if your System object has properties with no assigned default values, the associated dialog box parameter requires that the value data type be a built-in Simulink data type.

## System Objects in For Each Subsystems

To use the MATLAB System block within a For Each Subsystem block, implement the `matlab.system.supportsMultipleInstanceImpl` method. This method should return `true`. The MATLAB System block clones the System object for each For Each Subsystem iteration.

## Input Validation

In Simulink, use the `validateInputsImpl` method to validate only attributes (size, data type, and complexity) of the input. Do not use this method to validate the value of the input.

# **Simulink Engine Interaction with System Object Methods**

## **Simulink Engine Phases Mapped to System Object Methods**

This diagram shows a process view of the order in which the MATLAB System block invokes System object methods within the context of the Simulink engine.

### Initialization

Note the following:

- Simulink calls the `stepImpl`, `outputImpl`, and `updateImpl` methods multiple times during simulation at each time step. Simulink typically calls other methods once per simulation.
- The Simulink engine calls the `isOutputFixedSizeImpl`, `getDiscreteStateSpecificationImpl`, `isOutputComplexImpl`, `getOutputDataTypeImpl`, `getOutputSizeImpl` when using `matlab.system.mixin.Propagates`.
- Simulink calls `saveObjectImpl` and `loadObjectImpl` for saving and restoring `SimState`, the Simulation Stepper, and Fast Restart.
- Default implementations save and restore all properties with public access, including `DiscreteState`.

## Add and Implement Propagation Methods

| In this section...                                        |
|-----------------------------------------------------------|
| “When to Use Propagation Methods” on page 45-38           |
| “Add Propagation Methods to System Objects” on page 45-38 |
| “Implement Propagation Methods” on page 45-39             |

### When to Use Propagation Methods

Propagation methods define output specifications. Use them when the output specifications cannot be inferred directly from the inputs during Simulink model compilation.

Consider using propagation methods in your System object when:

- The System object requires access to all MATLAB functions that do not support code generation, which means that you cannot generate code for simulation. You must use propagation methods in this case. Use these methods to specify information for the outputs.
- You want to use variable-size signals.
- You do not care whether code is generated, but you want to improve startup performance. Use propagation methods to specify information for the inputs and outputs, enabling quicker startup time.

At startup, the Simulink software tries to evaluate the input and output ports of the model blocks for signal attribute propagation. In the case of MATLAB System blocks, if the software cannot perform this evaluation, it displays a message prompting you to add propagation methods to the System object.

### Add Propagation Methods to System Objects

Propagation methods are in the class `matlab.system.mixin.Propagates`. To add these methods to the System object, add the `matlab.system.mixin.Propagates` class to the top of the parent class file for the System object, after the `matlab.System` class. For example:

```
classdef Counter < matlab.System & matlab.system.mixin.Propagates
```

## Implement Propagation Methods

Simulink evaluates the uses of the propagation methods to evaluate the input and output ports of the MATLAB System block for startup.

Each method has a default implementation, listed in the **Default Implementation Should Suffice if** column. If your System object does not use the default implementation, you must implement a version of the propagation method for your System object.

| Description                                                                                | Propagation Method                 | Default Implementation Should Suffice if                                                                                                                         | Example                                                                                                                                                                                                                               |

“Use Shared Data with P-Coded System Objects” on page 45-49

Share data between MATLAB System and other blocks using the `global` keyword and the Data Store Memory block or `Simulink.Signal` object. You might need to use global data with a MATLAB System block if:

- You have an existing model that uses a large amount of global data, you are adding a MATLAB System block to this model, and you want to avoid cluttering your model with additional inputs and outputs.
- You want to scope the visibility of data to parts of the model.

### Data Sharing with the MATLAB System Block

In Simulink, you store global data using data store memory. You implement data store memory using either Data Store Memory blocks or `Simulink.Signal` objects. How you store global data depends on the number and scope of your global variables.

#### Scoping Rules for Shared Data in MATLAB System Blocks

The MATLAB System block uses these scoping rules:

- If you use the same name for both Data Store Memory block and `Simulink.Signal` object, Data Store Memory block scopes the data to the model.
- A global variable resolves hierarchically to the closest Data Store Memory block with the same name in the model. The same global variable appearing in two different MATLAB System blocks might resolve to different Data Store Memory blocks depending on the hierarchy of the model. You can use this ability to scope the visibility of data to a subsystem.

## Using Shared Data in MATLAB System Blocks

MATLAB System blocks support data store memory for:

- MATLAB structures (buses)
- Enumerated data types

## How to Use Data Sharing with the MATLAB System Block

To use shared data in your MATLAB System block:

- 1 Declare a global variable in the System object that you associate with the MATLAB System block.

You can use the `global` keyword in these methods of the System object:

- `stepImpl`
  - `outputImpl`
  - `updateImpl`
- 2 Add a Data Store Memory block or `Simulink.Signal` object that has the same name as the global variable in the System object.

To share data between referenced models using the `Simulink.Signal` object, define the `Simulink.Signal` object in the base workspace and use the same global variable name as in the MATLAB System block.

## Choose How to Store Shared Data

You can use Data Store Memory blocks or `Simulink.Signal` objects to store shared data.

| Type of Data                                                                            | Global Data Storage Method                                                                                | Related Links                                                                   |

## How to Use Data Store Memory Blocks for the MATLAB System Block

- 1 Declare a global keyword in the System object methods that support globals. For example:
 

```
global A;
```
- 2 Add a MATLAB System block to your model.
- 3 Double-click the MATLAB System block and associate the System object.
- 4 Add a Data Store Memory block to your model and set:

- a **Data store name** to match the name of the global variable in your MATLAB System block code.
  - b **Data type** to an explicit data type.
- The data type cannot be auto.
- c **Signal type**.
  - d **Initial value**.

The initial value of the Data Store Memory block cannot be unspecified.

### Use Data Store Memory with the MATLAB System Block

This model demonstrates how a MATLAB System block uses the global data stored in Data Store Memory block B. The MATLAB System block is associated with the `globalSysObjMatrix1` System object. To see the completed model, open the `ex_globalsys_objmatrix1` model.

- 1 Drag these blocks into a new model:
  - MATLAB System
  - Data Store Memory
  - Display
- 2 Create a System object to associate with the MATLAB System block. To start, from the MATLAB System block, create a Basic System object template file.
- 3 In MATLAB Editor, create a System object with code like the following. Save the System object as `globalSysObjMatrix1.m`. The System object modifies B each time it executes.

```
classdef globalSysObjMatrix1 < matlab.System
 % Global/DSM support scalar example
```

```

methods(Access = protected)
 function setupImpl(obj)
 % Perform one-time calculations, such as computing constants
 end

 function y = stepImpl(obj)
 global B;
 B(:,1)= B(:,1)+100;
 y = B;
 end
end
end

```

4 Double-click the MATLAB System block and associate the `globalSysObjMatrix1` System object with the block.

5 In the model, double-click the Data Store Memory block B.

6 In the Signal Attributes tab, enter an initial value, for example:

```
[74 75 5 1;22 23 24 32;33 44 55 22]
```

7 Simulate the model.

The MATLAB System block reads the initial value of global data stored in B and updates the value of B each time it executes. This model executes for five time steps.

8 Save and close your model.

## How to Set Up Simulink.Signal Objects

Create a `Simulink.Signal` object in the model workspace.

---

**Tip** Create a `Simulink.Signal` object in the base workspace to use the global data with multiple models.

---

- 1 In the Model Explorer, navigate to *model\_name* > **Model Workspace** in the **Model Hierarchy** pane.

Select **Add > Simulink Signal**.

- 2 Ensure that these settings apply to the `Simulink.Signal` object:

- a Set **Data type** to an explicit data type.

The data type cannot be `auto`.

- b Set **Dimensions** to be fully specified.

The signal dimensions cannot be `-1` or `inherited`.

- c Set the **Complexity**.

- d Specify an **Initial value**.

The initial value of the signal cannot be unspecified.

- e Set **Name** to the name of the global variable.

### Use a `Simulink.Signal` Object with a MATLAB System Block

This simple model demonstrates how a MATLAB System block uses a `Simulink.Signal` with signal B. The MATLAB System block is associated with the `globalSysObjScalar` System object. To see the completed model, open the `ex_globalsys_simulink_signal_share` model.

- 1 Drag these blocks into a new model:
  - MATLAB System
  - Display
- 2 Create a System object to associate with the MATLAB System block. To start, from the MATLAB System block, create a Basic System object template file.

- 3 In MATLAB Editor, create a System object. Save the System object as `globalSysObjScalar.m`. The System object modifies B each time it executes.

```
classdef globalSysObjScalar < matlab.System
 % Global/DSM support scalar example

 methods(Access = protected)
 function setupImpl(obj)
 % Perform one-time calculations, such as computing constants
 end

 function y = stepImpl(obj)
 global B;
 B= B+100;
 y = B;
 end
 end
 end
end
```

- 4 Double-click the MATLAB System block and associate the `globalSysObjScalar` System object with the block.
- 5 From the model menu, select **View > Model Explorer**.
- 6 In the left pane of the Model Explorer, select the model workspace for this model.

The **Contents** pane displays the data in the model workspace.

- 7 In the Model Explorer, in the **Model Hierarchy** pane, navigate to *model\_name* > **Model Workspace**. In the **Contents** pane, set **Name** to B.
- 8 Navigate back to *model\_name* > **Model Workspace**.
- Select **Add > Simulink Signal**.
  - Make these settings for the `Simulink.Signal` object:

| Attribute            | Value  |
|----------------------|--------|
| <b>Data type</b>     | double |
| <b>Complexity</b>    | real   |
| <b>Dimensions</b>    | 1      |
| <b>Initial value</b> | 25     |

- 9 Simulate the model.

The MATLAB System block reads the initial value of global data stored in B and updates the value of B each time it executes. The model runs for five time steps.

**10** Save and close your model.

## Using Data Store Diagnostics to Detect Memory Access Issues

You can configure your model to provide run-time and compile-time diagnostics to avoid problems with data stores. Diagnostics are available in the Configuration Parameters dialog box and the Parameters dialog box for the Data Store Memory block. These diagnostics are available for Data Store Memory blocks only, not for `Simulink.Signal` objects. For more information on using data store diagnostics, see “Data Store Diagnostics” on page 65-3.

## Limitations of Using Shared Data in MATLAB System Blocks

The MATLAB System block does not support data store memory for variable-sized data

## Use Shared Data with P-Coded System Objects

If the System object is P-code, you must implement the `getGlobalNamesImpl` method to provide the global variable names you use in the System object. For example:

```

classdef GlobalSysObjMatrix < matlab.System
 % Matrix DSM support: Increment first row by 1 at each time step
 methods (Access = protected)
 function y = stepImpl(obj)
 global B;
 B(1,:) = B(1,:)+1;
 y = B;
 end

 function globalNames = getGlobalNamesImpl(~)
 globalNames = {'B'};
 end
 end
end

```

```
 end
end
```

## Troubleshoot System Objects in Simulink

### In this section...

“Class Not Found” on page 45-51

“Error Invoking Object Method” on page 45-51

“Performance” on page 45-52

### Class Not Found

The MATLAB System block **System object name** parameter requires that you enter the full path to the System object class. In addition:

- Check that the System object class is on your MATLAB path.
- Check capitalization to make sure it matches.
- Check that the class name is a supported System object.
- Do not include the file extension.

### Error Invoking Object Method

The MATLAB System block supports only System objects written in the MATLAB language. If the software can identify an alternative block, it suggests that block in the error message, for example:

This message indicates that there is an existing dedicated and optimized block that you should use.

## Performance

For fastest performance, set the block **Simulate using** parameter to `Code generation`. This setting allows the MATLAB System block to run as fast as it can. The parameter is set to this value by default.

This setting causes a slower startup time, as the software generates C code and creates a MEX-file from it. However, after code generation, later simulations have better performance. When the block uses generated code to simulate, performance is typically better than simulation without generated code.

In some cases, the implementation of your System object does not allow you to generate code, which requires you to set **Simulate using** to `Interpreted execution`. For example, your System object can require MATLAB functions beyond the subset supported for code generation. In this case, use propagation methods to specify the block input and output port information. The MATLAB System block then propagates this signal attribution information.

# Customize MATLAB System Block Dialog

## Introduction

This example shows you how to customize the block dialog for a MATLAB System block.

## System objects

System objects allow you to implement algorithms using MATLAB. System objects are a specialized kind of MATLAB object, designed specifically for implementing and simulating dynamic systems with inputs that change over time.

After you define a System object, you can include it in a Simulink model using a MATLAB System block.

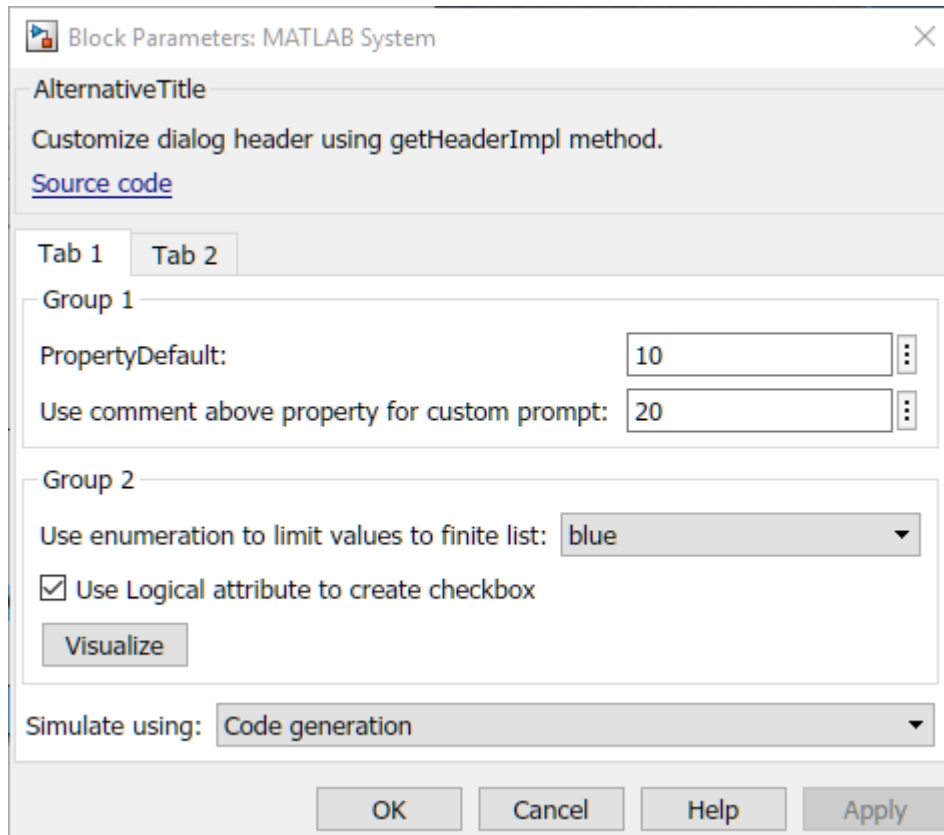

## Model Description

This example contains a MATLAB System block that implements the System object `CustomDialog`. Use the MATLAB System block dialog box to modify properties of the System object. This example shows how to customize the prompt for a property and how to create check boxes, lists, groups, tabs, and buttons in the dialog box.

## Customizing the Block Dialog

**Double Click on MATLAB System Block to Open Dialog**

### System Object Class Definition

You can access MATLAB source code used by the MATLAB System block by clicking the "Source Code" hyperlink from the block dialog. The System object `CustomDialog` implements the `getPropertyGroupsImpl` and `getHeaderImpl` methods that are used to customize the appearance of the block dialog and organize the System object properties.

- 1 PropertyDefault - Property with no customization
- 2 PropertyCustomPrompt - Property with custom prompt
- 3 PropertyEnum - Enumeration property with a finite list of options
- 4 PropertyLogical - Logical attribute property to create check box

## 5 PropertyInDifferentTab - Property shown on a different tab of the dialog box

The `getPropertyGroupsImpl` method uses the `matlab.system.display.Section` and `matlab.system.display.SectionGroup` classes to create property sections and tabs in the dialog box. `getPropertyGroupsImpl` also creates a button in the "Group 2" section which calls the `visualize` method of the System object.

```

classdef CustomDialog < matlab.System
% CustomDialog Customize System block dialog

 properties
 PropertyDefault = 10
 % For PropertyDefault, with no comment above, property name is used
 % as prompt

 % PropertyCustomPrompt Use comment above property for custom prompt
 PropertyCustomPrompt = 20

 % PropertyEnum Use enumeration to limit values to finite list
 PropertyEnum (1,1) ColorValues = ColorValues.blue
 end

 properties(Logical, Nontunable)
 % PropertyLogical Use Logical attribute to create checkbox
 % Logical properties need to be Nontunable for use in Simulink
 PropertyLogical = true
 end

 properties
 % PropertyInDifferentTab Use getPropertyGroupsImpl to create tabs
 PropertyInDifferentTab = 30
 end

 methods(Access = protected)
 function y = stepImpl(~, u)
 y = u;
 end
 end

 methods (Static, Access = protected)
 function groups = getPropertyGroupsImpl
 % Use getPropertyGroupsImpl to create property sections in the
 % dialog. Create two sections with titles "Group1" and

```

```
% "Group2". "Group1" contains PropertyDefault and

## Break Algebraic Loops

### Introduction

This example shows how to create a MATLAB System block that can break an algebraic loop in the model.

### System objects

System objects allow you to implement algorithms using MATLAB. System objects are a specialized kind of MATLAB object, designed specifically for implementing and simulating dynamic systems with inputs that change over time.

After you define a System object, you can include it in a Simulink model using a MATLAB System block.

### Model Description

This example has a MATLAB System block that is used in a feedback loop in the model. The feedback loop is used to accumulate input values and the result is displayed in the Scope block. The feedback in the model creates an algebraic loop. To solve the algebraic loop, Simulink needs a block that has nondirect feedthrough. Blocks that have nondirect feedthrough are used in the feedback loops to break algebraic loops. This block can produce an output in the current time step without receiving the input first. In this example, MATLAB System block has nondirect feedthrough.

## Breaking Algebraic Loops

Copyright 2018 The MathWorks, Inc.

The MATLAB System block uses the System object `UnitDelayNondirect` that implements a unit delay. The output shows how the feedback loop accumulates the input signal values.

## System Object Class Definition

You can access MATLAB source code used by the MATLAB System block by clicking the "Source Code" hyperlink from the block dialog. The `UnitDelayNondirect` System object implements the `resetImpl`, `outputImpl`, and `updateImpl` methods. To use `outputImpl` and `updateImpl`, the System object inherits from the `matlab.system.mixin.Nondirect` class. The System object has one property called `State`.

- `resetImpl` initializes the `State` property to 0.
- `outputImpl` returns the value stored in `State`. This System object has nondirect feedthrough because `outputImpl` does not use any inputs.
- `updateImpl` uses the inputs to update `State`.

```
classdef UnitDelayNondirect < matlab.System & matlab.system.mixin.Nondirect
% UnitDelayNondirect Delay input by one time step
% Using Nondirect mixin enables use of this System object to create a
% MATLAB System block with nondirect feedthrough.

 properties(DiscreteState)
 State
 end

 methods(Access = protected)
 function resetImpl(obj)
 obj.State = 0; % Initialize states
 end
 function y = outputImpl(obj, ~)
 y = obj.State; % Output current state
 % Input is not used in this method
 end
 function updateImpl(obj,u)
 obj.State = u; % Update state with input
 end
 end
end
```

# Customize MATLAB System Block Appearance

## Introduction

This example shows how to customize the appearance of the MATLAB System block.

## System objects

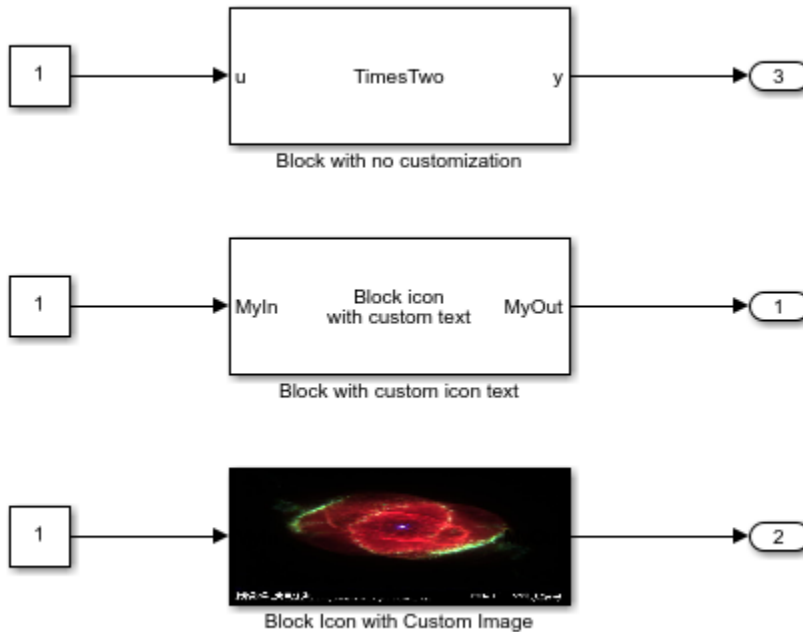

System objects allow you to implement algorithms using MATLAB. System objects are a specialized kind of MATLAB object, designed specifically for implementing and simulating dynamic systems with inputs that change over time.

After you define a System object, you can include it in a Simulink model using a MATLAB System block.

## Model Description

There are three MATLAB System blocks in this model. The first block does not have any customization for block appearance and by default shows the name of the System object on the block. The port labels for this block are obtained from the name of the arguments in `stepImpl` method of the System object. Second block shows custom text and custom port labels on the block icon. The third block shows a custom block icon image.

## Customizing the Block Icon and Ports

Copyright 2018 The MathWorks, Inc.

### System Object Class Definition

You can access MATLAB source code used by the MATLAB System block by clicking the "Source Code" hyperlink from the block dialog. The `TimesTwo` System object used in the first block has no customization and implements only the `stepImpl` method. The `CustomBlockIconExample` System object implements the following methods for customizing block appearance.

- `getInputNamesImpl` - Customize input port labels
- `getOutputNamesImpl` - Customize output port labels
- `getIconImpl` - Display text or an image on the block

To use the `getIconImpl` method, the System object inherits from `matlab.system.mixin.CustomIcon` class. The System object has a `DisplayImage` property to choose between text and image for display on the block.

### TimesTwo System object

```
classdef TimesTwo < matlab.System
%TimesTwo Multiply input by 2
% obj = TimesTwo returns a System object, obj, that
% multiplies its input by two.

 methods(Access = protected)
 function y = stepImpl(~, u)
 y = 2 * u;
 end
 end
end
```

### CustomBlockIconExample System object

```
classdef CustomBlockIconExample < matlab.System & ...
 matlab.system.mixin.CustomIcon
% SystemObjectBlockIconExample Customize Block Icon

 properties(Nontunable, Logical)
 % DisplayImage Select to display image as block icon
 DisplayImage = false
 end

 methods(Access = protected)
 function y = stepImpl(~, u)
 y = u;
 end
 function inputName = getInputNamesImpl(~)
 inputName = "MyIn";
 end
 function outputName = getOutputNamesImpl(~)
 outputName = "MyOut";
 end
 function icon = getIconImpl(obj)
 % Return text or image to be displayed on the block icon
 % Use array of strings to display multiple lines of text
 if obj.DisplayImage
```

```
 % Display image
 icon = matlab.system.display.Icon('slexngc6543aPix.jpg');
 else
 % Display text
 icon = ["Block icon", "with custom text"];
 end
end
end
end
end
```

# Implement Algorithm with Tunable Parameters

## Introduction

This example shows how to implement an algorithm with tunable parameters by using a MATLAB System block.

## System objects

System objects allow you to implement algorithms using MATLAB. System objects are a specialized kind of MATLAB object, designed specifically for implementing and simulating dynamic systems with inputs that change over time.

After you define a System object, you can include it in a Simulink model using a MATLAB System block.

## Model Description

The MATLAB System block implements the System object `TunableNontunableProperties` that multiplies input by a `Gain` parameter and adds a `Bias` parameter to the input. The input to MATLAB System block is provided by a Constant block and the Display block shows the result of applying the gain and bias. The `Gain` parameter is tunable and can be changed when the simulation is running. The `Bias` parameter is nontunable and cannot be changed during the simulation. When the model is running, you can change tunable properties, but you cannot change nontunable properties.

## Tuning a Parameter During Simulation

Double Click to Open MATLAB System Block Dialog and Change Gain parameter when the model is running

Copyright 2018 The MathWorks, Inc.

### System Object Class Definition

You can access MATLAB source code used by the MATLAB System block by clicking the "Source Code" hyperlink from the block dialog. The System object `TunableNontunableProperties` implements the `setupImpl`, `stepImpl` and `processTunedPropertiesImpl` methods. The System object has two public properties: `Gain` and `Bias`. The `Bias` property has the attribute `Nontunable`, which makes this property read-only during simulation. The `Gain` property has no attributes, so by default, it is tunable and can be modified during the simulation.

The System object has a private property called `pGain`. `pGain` stores the value of the public `Gain` property after the range of `Gain` is restricted between 1 and 2. You can initialize `pGain` by copying the value of `Gain` in the `setupImpl` method. In this example, `pGain` is used in the `stepImpl` method to compute the output. In a System object, whenever public tunable properties are changed, `processTunedPropertiesImpl` is called. In this example, `processTunedPropertiesImpl` updates the private property `pGain` based on the value from the public `Gain` property.

```
classdef TunableNontunableProperties < matlab.System
% TunableNontunableProperties Multiply input by Gain and add Bias
```

```
properties
 Gain = 1.5
end

properties(Nontunable)
 Bias = 0.1
end

properties(Access = private)
 pGain
end

methods(Access = protected)
 function setupImpl(obj, ~)
 % Copy public property value Gain to private property pGain and
 % restrict its range between 1 and 2
 obj.pGain = obj.Gain;
 if obj.pGain < 1
 obj.pGain = 1;
 elseif obj.pGain > 2
 obj.pGain = 2;
 end
 end
end

function y = stepImpl(obj, u)
 y = u * obj.pGain + obj.Bias;
end

function processTunedPropertiesImpl(obj)
 % Update private property pGain from the public Gain property
 % and restrict its range between 1 and 2.
 obj.pGain = obj.Gain;
 if obj.pGain < 1
 obj.pGain = 1;
 elseif obj.pGain > 2
 obj.pGain = 2;
 end
end
```

```
 end
end
```

# Implement a Simple Algorithm

## Introduction

This example shows how to use a simple System object in Simulink with the MATLAB System block.

## System objects

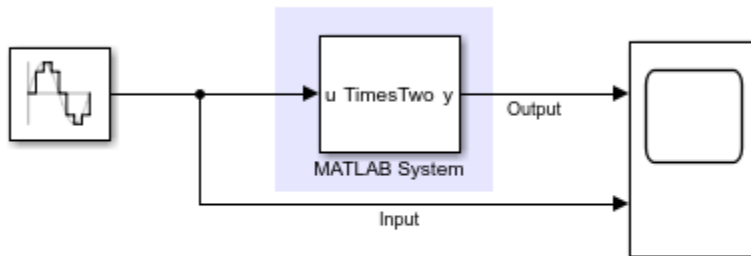

System objects allow you to implement algorithms using MATLAB. System objects are a specialized kind of MATLAB object, designed specifically for implementing and simulating dynamic systems with inputs that change over time.

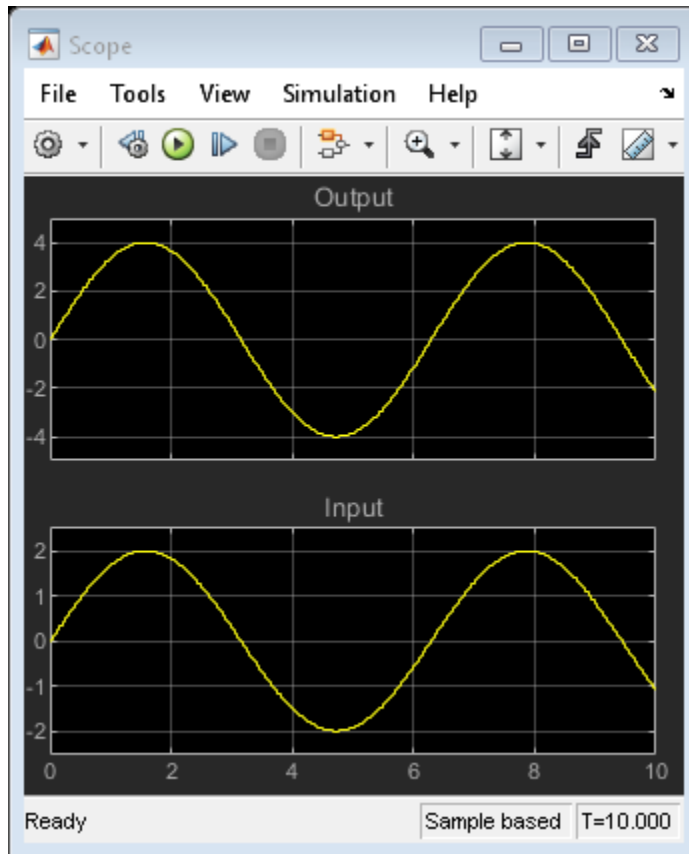

After you define a System object, you can include it in a Simulink model using a MATLAB System block.

## Model Description

This model has a MATLAB System block using the System object `TimesTwo` that multiplies the input by two. The input to the MATLAB System block is provided by the Sine Wave block. The output along with the input is displayed in the Scope block. When you run the model, you can see that the input to MATLAB System block is multiplied by two in the Scope block.

## Basic MATLAB System Block

### System Object Class Definition

You can access MATLAB source code used by the MATLAB System block by clicking the "Source Code" hyperlink from the block dialog. The System object implements only the `stepImpl` method. The algorithm does not need any properties or additional methods.

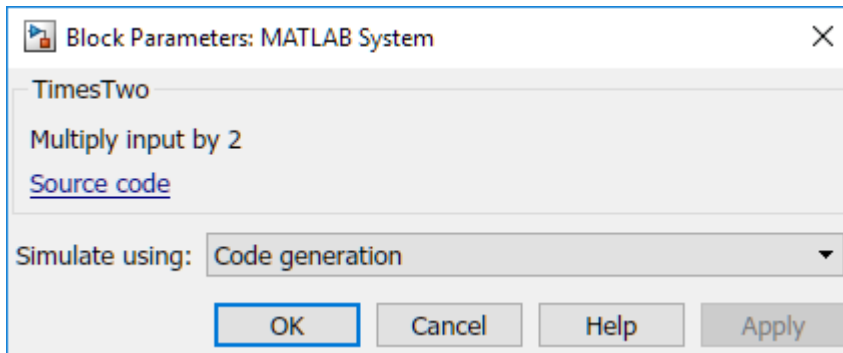

```
classdef TimesTwo < matlab.System
%TimesTwo Multiply input by 2
% obj = TimesTwo returns a System object, obj, that
% multiplies its input by two.

 methods(Access = protected)
 function y = stepImpl(~, u)
```

```
 y = 2 * u;
 end
end
end
```

## MATLAB System Block Icon and Dialog

The MATLAB System block displays the name of the System object `TimesTwo` on the block and uses the input and output variable names from `stepImpl` method of the `TimesTwo` class as port labels. If you open the MATLAB System block dialog by double clicking on the block, the dialog shows title as `TimesTwo` and a description as "Multiply input by 2" as shown below. The title comes from the name of the System object used and the description is created from the class help summary in the System object.

## Specify Output Characteristics of MATLAB System Block

### Introduction

This example shows how to specify output size, data type and complexity of a MATLAB System block.

### System objects

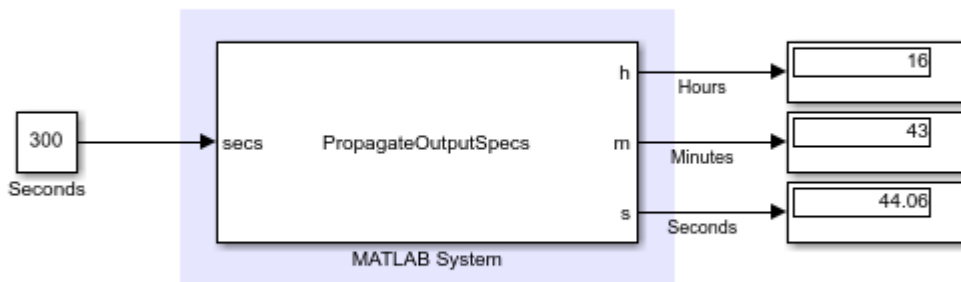

System objects allow you to implement algorithms using MATLAB. System objects are a specialized kind of MATLAB object, designed specifically for implementing and simulating dynamic systems with inputs that change over time.

After you define a System object, you can include it in a Simulink model using a MATLAB System block.

### Model Description

This example has a MATLAB System block that adds input number of seconds to the current time and produces the resulting hours, minutes and seconds as outputs. The output values from each output port are displayed in the Display blocks.

### Propagating Output Data Type

Copyright 2018 The MathWorks, Inc.

This example, shows how to specify output size, data type and complexity of a System object. You specify the output properties when MATLAB System block cannot infer them automatically. The MATLAB System block uses the System object `PropagateOutputSpecs` that implements methods to propagate input data type, size and complexity.

### System Object Class Definition

You can access MATLAB source code used by the MATLAB System block by clicking the "Source code" hyperlink from the block dialog. The System object `PropagateOutputSpecs` implements the `stepImpl` method that adds the input value in seconds to current time and outputs the resulting hours, minutes and seconds. The `stepImpl` method uses `datetime` function to calculate its output. Since `datetime` function is not supported for code generation, MATLAB System block cannot infer the output specifications automatically. The System object inherits from the `matlab.system.mixin.Propagates` class and implements the following methods to specify output properties.

- `getOutputSizeImpl` - Specify output size
- `getOutputDataTypeImpl` - Specify output data type
- `isOutputComplexImpl` - Specify output complexity
- `isOutputFixedSizeImpl` - Specify whether output can be variable-size

```
classdef PropagateOutputSpecs < matlab.System & matlab.system.mixin.Propagates
% PropagateOutputSpecs Uses Propagates mixin for Simulink
```

```
 methods(Access = protected)
 function [h, m, s] = stepImpl(~, secs)
 % Add input hours, minutes and seconds to current time
 d = datetime;
 d = d + seconds(secs);
 h = hour(d);
 m = minute(d);
 s = second(d);
 end

 function [o1, o2, o3] = getOutputSizeImpl(obj)
 % Return size for output port to be same as input port
 inSize = propagatedInputSize(obj, 1);
 o1 = inSize;
 o2 = inSize;
```

```
 o3 = inSize;
 end

 function [o1, o2, o3] = getOutputDataTypeImpl(obj)
 % Return data type for output port to be same as input port
 inType = propagatedInputDataType(obj, 1);
 o1 = inType;
 o2 = inType;
 o3 = inType;
 end

 function [o1, o2, o3] = isOutputComplexImpl(~)
 % Return output port complexity to be real
 o1 = false;
 o2 = false;
 o3 = false;
 end

 function [o1, o2, o3] = isOutputFixedSizeImpl(~)
 % Return true for each output port with fixed size
 o1 = true;
 o2 = true;
 o3 = true;
 end
end
end
```

# Implement Algorithm that Calls External C Code

## Introduction

This example shows how to use external C code in a System object.

## System objects

System objects allow you to implement algorithms using MATLAB. System objects are a specialized kind of MATLAB object, designed specifically for implementing and simulating dynamic systems with inputs that change over time.

After you define a System object, you can include it in a Simulink model using a MATLAB System block.

## Model Description

The MATLAB System block uses the System object `ExternalCCode` that calls external C function `extSum` to compute the sum of its input elements. The Display block shows the result of the sum of values from the source block.

## Using External C Code

## System Object Class Definition

You can access MATLAB source code used by the MATLAB System block by clicking the "Source code" hyperlink from the block dialog. The System object `ExternalCCode` implements the `stepImpl` method to compute its output. `stepImpl` calls external C function `extSum` to do the computation. The System object inherits from the `coder.ExternalDependency` class and implements the following methods to use external C code.

- `getDescriptiveName` - Return the name you want to associate with external dependency
- `isSupportedContext` - Return true if external dependency is supported in the current build context
- `updateBuildInfo` - Provide additional information required to link external code

The System object also calls `coder.cinclude` from `stepImpl` method to include external C header file `sum.h`.

```
classdef ExternalCCode < matlab.System & coder.ExternalDependency
% ExternalCCode Compute output by calling into external C Code

 methods(Access = protected)
 function y = stepImpl(~, a)
 % Add header file sum.h to build
 coder.cinclude('sum.h');
 y = 0.0; %#ok<NASGU> % Pre-initialize y since coder cannot
 % identify the type of output y from an
 % external C function
 % Call external C function to calculate sum of input elements
 y = coder.ceval('extSum', coder.rref(a), int32(numel(a)));
 end
 end

 methods(Static)
 function bName = getDescriptiveName(~)
 % Return a descriptive name for the external dependency. Code
 % generator uses this name for error messages.
 bName = 'SumAPI';
 end

 function tf = isSupportedContext(~)
 % Use this function to determine whether current build context
```

```
% supports external dependency. Build context includes information
% about target language and code generation target.
 tf = true;
end

function updateBuildInfo(buildInfo, ~)
 % Add source file sum.c to build
 buildInfo.addSourceFiles('sum.c');
end
end
end
```

### External C code

External C function `extSum` is defined in `sum.c` file.

```
#include "sum.h"

double extSum(const double *a, int numElems)
{
 int ii;
 double sum = 0.0;
 for (ii=0; ii < numElems; ii++) {
 sum += a[ii];
 }
 return sum;
}
```

`extSum` is declared in `sum.h`.

```
#ifndef SUM_H
#define SUM_H

extern double extSum(const double *a, int numElems);

#endif
```

# FMUs and Co-Simulation in Simulink

---

- “Import FMUs” on page 46-2
- “Implement an FMU Block” on page 46-6
- “Export a Model as a Tool-Coupling FMU” on page 46-15
- “Co-Simulation Execution and Numerical Compensation” on page 46-19
- “Run Co-Simulation Components on Multiple Cores” on page 46-30
- “Simulink Community and Connection Partner Program” on page 46-35

## Import FMUs

| In this section...                                |
|---------------------------------------------------|
| “FMU XML File Directives” on page 46-2            |
| “Additional Support and Limitations” on page 46-3 |
| “FMU Import Examples” on page 46-4                |

Use the FMU block to import Functional Mockup Units (FMUs) into Simulink.

The FMU block automatically selects the FMU mode based on the existing FMU you want to import:

- **Co-Simulation** — Integrate FMUs that implement an FMI Co-Simulation interface. These FMUs can contain local solvers used for tool coupling.
- **Model Exchange** — Integrate FMUs that implement an FMI model exchange interface. These FMUs do not contain local solvers. Instead, these FMUs inherit solvers from Simulink.

This block supports FMI versions 1.0 and 2.0. For FMI version 2.0, if your FMU contains both Co-Simulation and Model Exchange elements, the block detects this state and prompts you to select the operation mode for the block.

You can use your FMU block as you do other Simulink blocks. The FMU block supports normal, rapid accelerator, and accelerator modes. Rapid accelerator mode is unsupported for FMU blocks in referenced models or with FMU logging.

This topic assumes that you provide a .fmu file.

### FMU XML File Directives

The default parameter values derive from the corresponding parameter `start` value defined in the FMU `ModelDescription.xml` file. A block parameter value overwrites the initial value of the corresponding parameter defined in the FMU binary implementation.

Simulink interprets these FMU tags accordingly.

| FMU Tag                                                                                                                                                                                                   | Simulink                                             |
|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------|
| ScalarVariable has attributes set as follows: <ul style="list-style-type: none"> <li>causality="none" or causality="internal"</li> <li>variability="parameter"</li> <li>start value is defined</li> </ul> | Interprets ScalarVariable element as block parameter |
| Real                                                                                                                                                                                                      | Interprets block parameter as edit field             |
| Integer                                                                                                                                                                                                   | Interprets block parameter as edit field             |
| Boolean                                                                                                                                                                                                   | Interprets block parameter as check box              |
| Enumeration                                                                                                                                                                                               | Interprets block parameter as drop-down list         |
| String                                                                                                                                                                                                    | Interprets as UTF-8 encoded string                   |

The FMU block supports the following encoding formats for the model description XML file:

- ISO-8859-1
- UTF-8
- UTF-16

| Model reference in accelerator mode                              |                         |                         |

Simulink supports stepping back and forth, tuning parameters in between, and saving states for the FMU Import block as long as the FMU itself supports these features. FMU flags that it supports these features by setting `canGetAndSetFMUstate` and `canSerializeFMUstate` fields in its model description XML to `true`.

## FMU Import Examples

For examples of importing FMUs into and System objects, see **Integrating FMUs for Simulation** in Simulink Examples:

| Example                                        | Description                                                                                      |
|------------------------------------------------|--------------------------------------------------------------------------------------------------|

## Implement an FMU Block

### In this section...

“Explore the FMU Block” on page 46-6

“Change Block Input, Output, and Parameter Structures” on page 46-10

“Timing Considerations” on page 46-13

“Troubleshooting FMUs” on page 46-14

Implement a block and assign a functional mockup unit (FMU) to it. You can then explore the block to see the FMU. This example uses the FMU block with the vehicle FMU.

- 1 Create a model and add the FMU block.
- 2 In the block dialog box, enter the path name for an FMU file in the **FMU name** parameter and click **OK** or **Apply**. The file extension `.fmu` is optional.

The first time you click **OK** or **Apply**, the block identifies which FMU mode to set your FMU to, co-simulation or model exchange.

The block also creates a `slprj/_fmu/fmu_name` folder and unpacks the contents of the FMU file into this folder, which optionally include:

- `binaries` — FMU binary files
- `documentation` — FMU documentation HTML files
- `resources` — FMU source files
- `sources` — FMU source files
- Other supporting files, such as block mask and description files

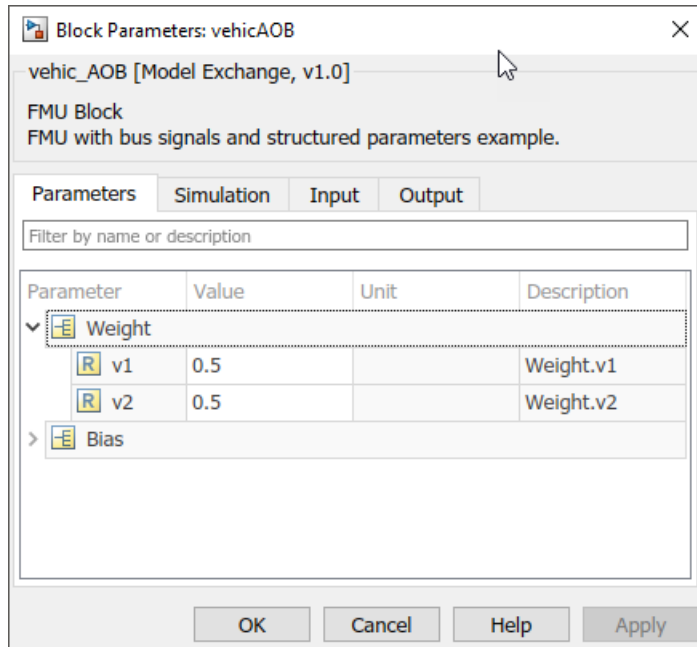

The FMU block icon and port labels update to the labels of the corresponding FMU. After you associate the block with an FMU, if you want to change the FMU, right-click the FMU block, and select **Block Parameters**, and enter a new FMU name in **FMU name**.

### Explore the FMU Block

Double-click the block. Suppose that you entered an FMU named `slxCoSimMassSpringFMU` from your current folder. The FMU block dialog box reflects the FMU parameters defined in the `slxCoSimMassSpringFMU` file.

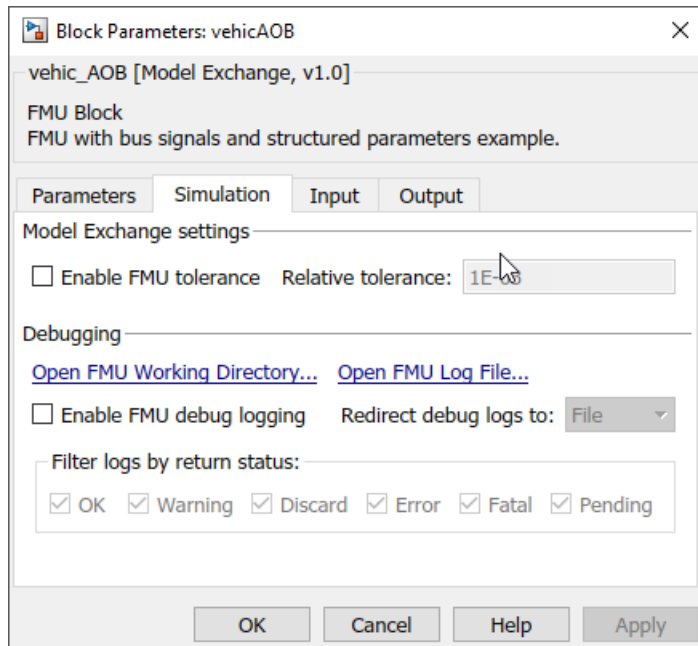

## Parameters Tab

Lists the FMU block parameters. Edit the values as necessary. You can edit the elements of a structure parameter by expanding the tree view.

## Simulation Tab

Enables logging and associated customizations.

- To enter a relative tolerance, select **Enable FMU tolerance** and set it.
- To determine the sample time of the block in the model, set **Communication step size**. To inherit the step size from the Simulink solver, set to -1. This option is available only if the FMU is a co-simulation FMU.
- To enable logging, select the **Enable FMU Debug Logging**.
- In **Redirect debug logs to**, select the destination for the logs.
  - File, saved to `slprj\_fmu\_logs\_modelname\modelname_blockname.txt`
  - Display, displayed in the MATLAB Command Window.

If the **Enable FMU Debug Logging** check box is selected and the **Redirect debug logs to** parameter is set to **Display**, you cannot use the FMU block for co-simulation. For more information on co-simulation and multiple cores, see “Run Co-Simulation Components on Multiple Cores” on page 46-30

- In the **Filter logs by return status**, select the check box for the return status you want.

### Input and Output Tabs

These two tabs list the input and output bus objects that the block defines.

In the **Bus Object Name** parameter, you can change the bus object names to match the bus objects defined in the workspace.

To create a bus object in the workspace:

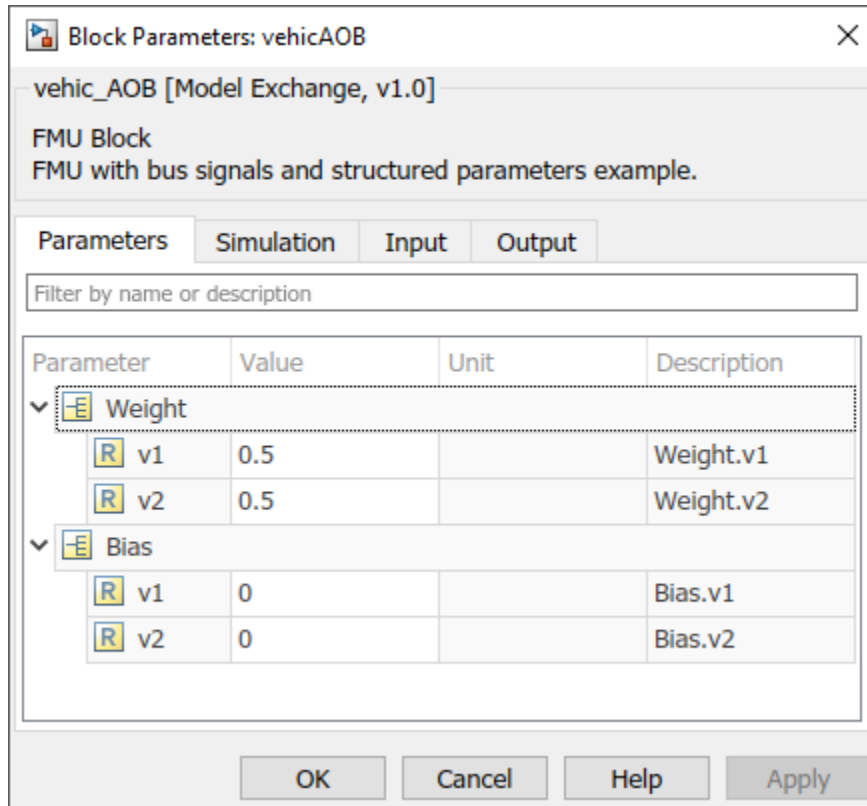

```
fmudialog.createBusType(gcb)
```

## Change Block Input, Output, and Parameter Structures

You can change the layout of FMU block input ports, output ports, and parameters with these parameters:

| Parameter        | Action                            | Settings                                                                                                                                                                                   |
|------------------|-----------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| FMUInputMapping  | Change hierarchy of input ports.  | 'Flat' — Separates input into individual signals.<br><br>'Structured' — Combines input into a structure of signals (bus).                                                                  |
| FMUOutputMapping | Change hierarchy of output ports. | 'Flat' — Separates output into individual signals.<br><br>'Structured' — Combines output into a structure of signals (bus).                                                                |
| FMUParamMapping  | Change hierarchy of parameters.   | 'Flat' — Separates parameters into individual parameters, listed by the parameter name and value.<br><br>'Structured' — Combines parameters into a structure of parameter values (struct). |

Use the `get_param` and `set_param` functions to set these values. For example, assume a block parameter tab with a structure construct:

The parameters are contained in a struct. To list the parameters individually, set the `FMUParamMapping` property to 'Flat':

```
set_param(gcb, 'FMUParamMapping', 'Flat')
```

## Timing Considerations

You can set the sample time for the FMU block with the **Communication step size** parameter. This block sample time setting,  $t_C$ , like all Simulink blocks, must be an integer multiple of the model sample time,  $t_M$ . Simulink generates an error if the communication step size  $t_C$  is not a multiple of the model step size  $t_M$ .

The local step size of the FMU  $t_L$ , on the other hand, is part of the FMU specification and is known to the FMU only internally. For proper operation, the communication step size,  $t_C$  must also be an integer multiple of  $t_L$ . If the model sample time  $t_M$  or the block sample time  $t_C$  is incompatible with the FMU local step size  $t_L$ , the FMU may or may not produce an error at run time, depending on its implementation.

## Troubleshooting FMUs

If there are problems with using the FMU:

- Check the compliance of the FMU with the FMI standard. Use the FMU compliance checker.
- Select the **Enable FMU Debug Logging** check box on the FMU block Simulation tab.
- Contact the FMU supplier.

## Export a Model as a Tool-Coupling FMU

To integrate Simulink components into third-party software, export a Simulink model as a tool-coupling functional mockup unit (FMU). When a third-party tool runs the FMU, it checks out required licenses and starts a local installation of Simulink to start the model.

Use a project to export an FMU. Open the model and select **File > Project > Create Project from Model** to create a project from a model.

You can export a FMU from a project interactively.

- 1 In the project, select **Share > FMU**.

- 2 Type in the **Copyright**, **Description**, and **FMU Icon** fields. Click **Save Settings and Export as** and provide a name.

The generated FMU includes model implementation, as well as the metadata provided during export.

```
<?xml version="1.0" encoding="utf-8"?>
<fmiModelDescription author="" copyright="" description="" fmiVersion="2.0"
generationDateAndTime="2018-08-16T15:51:48Z"
```

```

generationTool="Simulink (R2018b)"
guid="5bd096be-a08d-020e-fc96-847aa21def5b"
license=""
modelName="vdpSlave"
variableNamingConvention="structured"
version="1.8">

```

You can also create and export a project to a FMU from the command line as follows:

```

>> p = slproject.create('vdpProject')
>> copyfile(which('vdp'), './vdpSlave.slx')
>> p.addFile('./vdpSlave.slx')
>> Simulink.fmuexport.ExportSimulinkProjectToFMU(p, 'vdpSlave.slx', '-fmuName', 'vdpFMU')

```

For more FMU export options from the command line, type:

```
help Simulink.fmuexport.ExportSimulinkProjectToFMU
```

The model must satisfy these conditions for exporting:

- Model must be in Normal or Accelerator simulation mode.
- Root input and output ports must be of numerical data type.

If the co-simulation component is an FMU exported from Simulink, the local sample time for that FMU is the sample time of the original model.

## Use the Exported Tool-Coupling FMU

The exported FMU requires a local installation of Simulink to run. The MATLAB version used for co-simulation must be the same as the MATLAB version where the FMU is exported. On Windows, the application that runs the FMU can check out the required licenses automatically. For other operating systems, apply these settings:

- On Linux:

```

setenv LD_LIBRARY_PATH ${LD_LIBRARY_PATH}:<InstallationFolder>/bin/glnxa64:<InstallationFolder>/bin/glnxa64
export LD_LIBRARY_PATH=${LD_LIBRARY_PATH}:<InstallationFolder>/bin/glnxa64:<InstallationFolder>/bin/glnxa64

```

- On Mac OS:

```

setenv DYLD_LIBRARY_PATH ${LD_LIBRARY_PATH}:<InstallationFolder>/bin/glnxa64:<InstallationFolder>/bin/glnxa64
export DYLD_LIBRARY_PATH=${LD_LIBRARY_PATH}:<InstallationFolder>/bin/glnxa64:<InstallationFolder>/bin/glnxa64

```

For Mac OS, due to System Integrity Protection (SIP), `setenv` command does not work for applications that starts new processes, such as MATLAB. Follow <https://>

[www.mathworks.com/matlabcentral/answers/170268-how-do-i-set-environment-variables-on-mac-os-x](http://www.mathworks.com/matlabcentral/answers/170268-how-do-i-set-environment-variables-on-mac-os-x) to set `DYLD_LIBRARY_PATH` to `<InstallationFolder>/bin/glnxa64:<InstallationFolder>/extern/bin/glnxa64`.

Before you can run the FMU, you must set up a MATLAB session from your operating system console. After you set up this session, start the third-party application and import the tool-coupling FMU. Each FMU instance requires a new MATLAB session.

### Start a Dedicated Session from MATLAB

If the application that imports the FMU runs a single instance of the FMU, you can use MATLAB to start a session.

```
>> shareMATLABForFMUCoSim
```

This dedicates the current MATLAB session available for requests from the external tool to co-simulate an imported FMU. When an FMU is connected this session, Simulink editor and Simulink project are loaded, and co-simulation starts automatically. You can use this session to pause, resume co-simulation, as well as tune parameters or plot signals from the command window while co-simulation is running. If co-simulation is finished, stopped by user, or interrupted by a runtime error, MATLAB closes, unloads Simulink editor and Simulink project, and discards changes to the model. If an error occurs, it displays in the simulation tool that imports this FMU. Each session can connect to one FMU instance at the same time.

### Start a Dedicated Session from the Operating System

If the application that imports the FMU runs multiple FMU instances, you can use the operating system console to start dedicated MATLAB sessions.

- On Windows:

```
<matlabroot>\toolbox\shared\fm_u_share\script\fm_u-matlab-setup.cmd
```

- On Linux and Mac OS:

```
<matlabroot>/toolbox/shared/fm_u_share/script/fm_u-matlab-setup
```

Run `matlabroot` in MATLAB to find out `<matlabroot>`. The setup program starts and waits for a command. See available commands by typing `help`:

```
> help
Command list:
quit - Close all shared MATLABs and exit.
```

```
list - List shared MATLABs.
start NUMBER_OF_MATLABS - Start NUMBER_OF_MATLABS more MATLABs.
stop NUMBER_OF_MATLABS - Stop NUMBER_OF_MATLABS MATLABs.
ignore - Stop asking about the hardware core count when launching MATLABs.
clean MATLAB_NUMBER - Clean up the MATLAB workspace for MATLAB #MATLAB_NUMBER. Use 0 for all.
help - Print the command list.
```

Launch one session for each FMU to run concurrently. If there is a single FMU, type:

```
> start 1
```

If there are three FMUs running concurrently, type:

```
> start 3
```

Only one MATLAB management tool should be running on a single machine.

- “Identify co-simulation signals for numerical compensation”

## Co-Simulation Execution and Numerical Compensation

Simulink supports co-simulation between components with local solvers or involves external simulation tools. For example, co-simulation can involve an S-function implemented as a co-simulation gateway between Simulink and third-party tools or custom code. A co-simulation component can be a Functional Mockup Unit (FMU) in co-simulation mode imported to Simulink.

### Execution Timing

In Simulink simulation, the solver step size must be an integer divisor of each periodic, discrete block sample time. In other words, if a co-simulation component defines its own sample time, Simulink must communicate with the component at those time steps. Co-simulation can involve components whose time steps are determined internally and are not known to Simulink. The only information available to Simulink is the block sample time, either through the communication step size parameter of an FMU block, or the sample time definition in an S-function implementation. The block sample time determines the time steps Simulink must communicate with the co-simulation component. If the solver step size is not automatic, the communication step size must be an integer multiple of the solver step size.

If the co-simulation component internally uses a local solver, then this local solver should also be taken into account when determining the communication step size of the block. The step size of the local solver is not exposed to Simulink, and knowledge of the implementation is necessary to set the communication step size correctly. The behavior of co-simulation in case of a potential incompatibility also depends on this internal solver implementation.

## Numerical Compensation

Co-simulation signals typically represent continuous physical quantities that are discretized due to co-simulation. Data exchanges between co-simulation components such as C MEX S-functions and Co-Simulation FMU blocks can introduce numerical inaccuracies from signal delays. Use numerical compensation to improve numerical behavior for simulation involving components that use their own solver. Model Advisor includes a check that detects co-simulation components and advises numerical compensation.

## Numerical Compensation Prerequisites

Simulink automatically performs numerical compensation for co-simulation signals between co-simulation components. Simulink performs numerical compensation at the input of the destination block. A signal is automatically qualified for numerical compensation if its source port and destination port satisfy these conditions:

- The source port for the signal must satisfy these requirements:
  - S-Function
    - Output port data type is double
    - Output port sample time is periodic and discrete
    - Output port complexity is real
    - `ssSetOutputPortIsContinuousQuantity()` is set to `true` for the port
  - FMU
    - Output port data type is double
    - FMU is in co-simulation mode
    - Block sample time is periodic and discrete
    - Output port maps to a variable with `variability='continuous'` in `modelDescription.xml`
- The destination port for the signal must satisfy these requirements:
  - S-Function
    - Input port data type is double
    - Input port sample time is periodic and discrete
    - Input port complexity is real
    - `ssSetInputPortIsContinuousQuantity()` is set to `true` for this port
    - `ssSetInputPortDirectFeedThrough()` is set to `false` for this port
  - FMU
    - Input port data type is double
    - FMU is in co-simulation mode
    - Block sample time is periodic and discrete

- Input port maps to a variable with `variability='continuous'` in `modelDescription.xml`

For an example of identifying co-simulation signals for numerical compensation, see the `slexCoSimTripleMassSpringExample` model.

### Manage Numerical Compensation Options Using the Dialog

When Simulink detects the signals that can have numerical compensation, it marks the corresponding input ports with the  icon.

The following model includes co-simulation signals that can have numerical compensation:

- 1 Open the model.  
`slxCoSimTripleMassSpringExample`
- 2 Update the diagram. Simulink detects the signals that can have numerical compensation, and marks the corresponding ports with the  icon.

- 3 Adjust the parameters for compensation accuracy: Right-click the icon and select **Configure Cosimulation Signal Compensation** and adjust the calculation parameters:
  - **Extrapolation Method** — This method computes a compensated signal value for the current time step of simulation using extrapolation of simulation signal values

generated from previous time steps. Three types of extrapolations are offered for selection.

- **Linear** is the default, it uses signal values generated from previous two time steps to linearly estimate the signal value for use in the current time step of simulation.
- **Quadratic** uses signal values of the previous three time steps to fit the data to a quadratic polynomial.
- **Cubic** uses signal values of the previous four time steps to fit the data to a cubic polynomial.

In the beginning of the simulation, when there is an insufficient number of past signal values, a lower order extrapolation method is used automatically. Higher order extrapolation methods use more past signal values to predict the current signal value and can improve accuracy of the prediction. However, high order extrapolation methods can also be numerically unstable. The best extrapolation method depends on the nature of the signal.

- **Signal correction coefficient** — This method further adjusts the extrapolated signal value based on past simulation results and past estimated signal values. A correction coefficient is offered for selection between 0 and 1, where 0 means no adjustment to be made to the extrapolated signal value. The default setting for the correction coefficient is 1. For a given extrapolated signal at a given time step, the larger the signal correction coefficient is, the more adjustment is made to the given extrapolated signal.

If numerical compensation is not beneficial, disable it by left-clicking the  icon. When disabled, the icon appears with a red slash.

### Manage Numerical Compensation Options from the Command Line

If automatic compensation is not possible, you can manually enable numerical compensation using the `CoSimSignalCompensationMode` property.

The `CoSimSignalCompensationMode` property has these values:

| Icon                                                                                | Setting    | Behavior                                                                                                                                                                                                       |
|-------------------------------------------------------------------------------------|------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|    | 'Auto'     | Enable automatic numerical compensation, allowing Simulink to detect if the port has a signal eligible for numerical compensation.                                                                             |
|  | 'Auto_Off' | Disable automatic numerical compensation. Icon appears with a red slash.                                                                                                                                       |
|  | 'Always'   | Force the port to be considered numerical compensation compliant, even if the signal is not eligible for numerical compensation. This setting lets you add compensation without declaring it to be continuous. |

| Icon                                                                              | Setting      | Behavior                                                                    |
|-----------------------------------------------------------------------------------|--------------|-----------------------------------------------------------------------------|
|  | 'Always_Off' | Disable forcing the port to be considered numerical compensation compliant. |

For example, to disable numerical compensation for the first input port from the previous model:

- 1 Select the block for which you want to select the port for numerical compensation. For example, get all the port handles for the currently selected block, `gcb`.

```
p = get_param(gcb, 'PortHandles')
```

This function returns all the ports for the currently selected block. For example,

```
p =
```

```
struct with fields:
```

```

 Inport: [22.0001 20.0001]
 Output: [23.0001 25.0001]
 Enable: []
 Trigger: []
 State: []
 LConn: []
 RConn: []
 Ifaction: []
 Reset: []

```

- 2 To disable numerical compensation for the first port:

```
set_param(p.Inport(1), 'CoSimSignalCompensationMode', 'Auto_Off')
```

The associated port appears with a red slash.

You can also set signal compensation parameters from the command line. The first step, again, is to obtain the port handles:

```
p = get_param(block, 'PortHandles')
```

Set the compensation parameters using the `CoSimSignalCompensationConfig` parameter, in this format:

```
set_param(p.Inport, 'CoSimSignalCompensationConfig', '{<CompensationParam>:<ParamValue>}
```

Find compensation parameter names and possible values in this table:

| Compensation parameter  | Parameter name           | Parameter value                                                                |
|-------------------------|--------------------------|--------------------------------------------------------------------------------|
| ExtrapolationMethod     | Extrapolation method     | 'LinearExtrapolation',<br>'QuadraticExtrapolation', or<br>'CubicExtrapolation' |
| CompensationCoefficient | Compensation coefficient | Scalar between 0 and 1                                                         |

For example, set the extrapolation method for the port:

```
set_param(p.Inport, 'CoSimSignalCompensationConfig', '{"ExtrapolationMethod":"LinearExtrapolation"}')
```

Set both the extrapolation method and the compensation coefficient:

```
set_param(p.Inport, 'CoSimSignalCompensationConfig', '{"ExtrapolationMethod":"QuadraticExtrapolation", "CompensationCoefficient":0.5}')
```

## Run Co-Simulation Components on Multiple Cores

Simulink supports co-simulation between components using local solvers or that involves simulation tools. For example, co-simulation can involve an S-function implemented as a co-simulation gateway between Simulink and third-party tools or custom code. It can also involve an FMU in co-simulation mode imported to Simulink.

To improve performance, consider running models that contain co-simulation blocks (components) on multiple threads if:

- You are integrating multiple co-simulation components
- Integration at the component level is computationally intense

This topic assumes that you are familiar with multithreaded programming and concepts.

Simulink lets you run C MEX S-functions and Co-Simulation FMU blocks on multiple threads if they satisfy these requirements:

- The block is nondirect feedthrough.
- The block is threadsafe, that is, the block can work with multiple threads accessing shared data, resources, and objects without any conflicts.

---

**Note** Multithreaded co-simulation for Level-2 MATLAB S-Function blocks is not supported.

---

By default, Simulink configures all models to run on multiple threads. However, not all models have co-simulation components that can run on multiple threads, and not all models benefit from running on multiple threads. To see if a model has co-simulation components that can benefit from running on multiple threads, follow these steps:

- 1 Open your model.
- 2 Start the Performance Advisor tool (**Analysis > Performance Tools > Performance Advisor**).

**3** Select **Simulation > Checks that Require Simulation to Run > Select multi-thread co-simulation setting on or off.**

This check verifies that the model or block is optimally configured to take advantage of multithreaded or singlethreaded processing. If the configuration is not optimal, Performance Advisor shows the current setting and warns you that the model is not a good candidate to run on multiple threads.

**4** Run the selected check.

Alternatively, you can manually measure the simulation of the model before and after changing the `MultiThreadCoSim` parameter. For example:

```
tic; sim('sfunction_components'); toc
```

```
Elapsed time is 2.323264 seconds.
```

```
get_param(gcs, 'MultiThreadCoSim')
```

```
ans =
'on'
```

```
set_param(gcs, 'MultiThreadCoSim', 'off')
```

```
tic; sim('sfunction_components'); toc
```

```
Elapsed time is 4.112674 seconds.
```

For an example of running co-simulation components on multiple cores, see the `slexCoSimPrimeExample` model.

## Using the `MultiThreadCoSim` Parameter

You can specify that an entire model run on multiple threads, or specify that particular blocks run on multiple threads, using the `MultiThreadCoSim` parameter. Specify that an entire model run on multiple threads if all the co-simulation blocks in the model are nondirect feedthrough and threadsafe. If some, but not all blocks, are nondirect feedthrough and threadsafe, identify only those blocks to run on multiple threads. The model and blocks use the `MultiThreadCoSim` parameter as follows.

| Setting | Model | Block | Description                                                             |
|---------|-------|-------|-------------------------------------------------------------------------|
| 'on'    | ✓     |       | (Default) Model can run on multiple threads.                            |
| 'off'   | ✓     | ✓     | Disable the block or model from running on multiple threads.            |
| 'auto'  |       | ✓     | (Default) Let Simulink decide if the block can run on multiple threads. |

Enabling the `MultiThreadCoSim` parameter does not mean that the block or model simulates on multiple threads. Simulation on multiple threads occurs when `MultiThreadCoSim` is enabled and:

- The block and/or model operate at a single rate.
- The block and/or model are threadsafe. (For example, they do not use static or global data).
- The block and/or model are nondirect feedthrough.
  - For S-function blocks, use the `ssSetInputPortDirectFeedThrough` function.
  - For FMU blocks, leave the `dependencies` attribute in the FMU model description file for the `FMU ModelStructure/Outputs` and `ModelStructure/InitialUnknowns` field as empty. This attribute must be (" ").
- The block and/or model is exception-free. For S-function blocks, use the `ssSetOptions` function to set `SS_OPTION_EXCEPTION_FREE_CODE`.

Multithreading does not allow solver reset checks, and therefore skips over any use of the `ssSetSolverNeedsReset` and `ssBlockStateForSolverChangedAtMajorStep` functions. Conversely, in accelerator mode, if these functions are used or there are continuous states, multithreading is automatically turned off.

## Configuring S-Function Blocks to Run Single or Multithreaded

Whether an S-function block runs single or multithreaded depends on the `MultiThreadCoSim` parameter value and the `ssSetRuntimeThreadSafetyCompliance` function.

| MultiThreadCoSim Setting | ssSetRuntimeThreadSafety Compliance Setting | Single or Multithread                                               |
|--------------------------|---------------------------------------------|---------------------------------------------------------------------|
| 'auto'                   | RUNTIME_THREAD_SAFETY_COMPLIANCE_UNKNOWN    | Single thread                                                       |
| 'auto'                   | RUNTIME_THREAD_SAFETY_COMPLIANCE_TRUE       | Multithread                                                         |
| 'auto'                   | RUNTIME_THREAD_SAFETY_COMPLIANCE_FALSE      | Single thread                                                       |
| 'off'                    | —                                           | The setting is ignored and the S-function block runs singlethreaded |

## Co-Simulation on Multiple Threads Limitations

- The simulation runs on a single thread for accelerator and rapid accelerator modes.
- There is no code generation for co-simulation components.
- When the FMU block has these settings, it does not support co-simulation:

### S-Function Block Limitations

- Must have a single rate — `ssSetSampleTime(SimStruct *S, int_T st_index, time_T period)` must be called to register only one discrete rate.
- Must have a fixed sample time — In `time_T ssSetSampleTime(SimStruct *S, int_T st_index, time_T period)`, `period` cannot be `VARIABLE_SAMPLE_TIME`.
- Cannot have continuous states — In `ssSetNumContStates(SimStruct *S, int_T n)`, `n` must be 0.
- Must have no direct feedthrough ports — In `ssSetInputPortDirectFeedthrough(SimStruct *S, int_T port, int_T dirFeed)`, `dirFeed` must be 0 for each input port.
- Must be thread safe — In `ssSetRuntimeThreadSafetyCompliance(SimStruct *S, int_T val)`, `val` must be `RUNTIME_THREAD_SAFETY_COMPLIANCE_TRUE`.
- Must be exception-free — In `ssSetOptions(SimStruct *S, uint_T options)`, `options` must include `SS_OPTION_EXCEPTION_FREE_CODE`.

### **FMU Import Block Limitations**

- Has to be in co-simulation mode.
- Has to be thread-safe, that is, multiple FMUs must not access the same file at the same time.
- Debug logging must be disabled — For example,  
`set_param(block1, 'FMUDebugLogging', 'on')`
- Debug logging redirect is set to File — For example,  
`set_param(block1, 'FMUDebugLoggingRedirect', 'File')`

### **Model Block Limitations**

- Cannot expose any IRT ports for scheduling.
- Cannot be inside a for-each subsystem.
- Must be in accelerator mode.
- Has to have single rate.
- Cannot use blocks with variable sample time.
- Cannot have continuous states.
- Cannot have direct feedthrough on any input port.
- Must have a fixed-step solver.
- Cannot access any global data stores.
- Cannot use any Simulink functions or caller blocks.
- Cannot contain To/From File blocks.

## Simulink Community and Connection Partner Program

Simulink supports the integration of multiple third-party functionalities, including apps, models, and toolboxes, from the Simulink community and commercial software tools.

For the integration of third-party functionality, this program includes:

- Simulink community — Provides direct access to all available Simulink apps, models, and toolboxes (Simulink community) using MATLAB® Add-Ons. (To open the Add-On Explorer, go to the MATLAB Command Window toolbar and click Add-Ons > get Add-Ons.)
- Third-Party Products — The MathWorks Connections Program includes commercially offered products and services that complement MATLAB and Simulink.

## When to Generate Code from MATLAB Algorithms

Generating code from MATLAB algorithms for desktop and embedded systems allows you to perform your software design, implementation, and testing completely within the MATLAB workspace. You can:

- Verify that your algorithms are suitable for code generation
- Generate efficient, readable, and compact C/C++ code automatically, which eliminates the need to manually translate your MATLAB algorithms and minimizes the risk of introducing errors in the code.
- Modify your design in MATLAB code to take into account the specific requirements of desktop and embedded applications, such as data type management, memory use, and speed.
- Test the generated code and easily verify that your modified algorithms are functionally equivalent to your original MATLAB algorithms.
- Generate MEX functions to:
  - Accelerate MATLAB algorithms in certain applications.
  - Speed up fixed-point MATLAB code.
- Generate hardware description language (HDL) from MATLAB code.

## When Not to Generate Code from MATLAB Algorithms

Do not generate code from MATLAB algorithms for the following applications. Use the recommended MathWorks product instead.

| To:                                                             | Use:                                                                     |

## **Prerequisites for C/C++ Code Generation from MATLAB**

To generate C/C++ or MEX code from MATLAB algorithms, you must install the following software:

- MATLAB Coder product
- C/C++ compiler

## MATLAB Code Design Considerations for Code Generation

When writing MATLAB code that you want to convert into efficient, standalone C/C++ code, you must consider the following:

- Data types

C and C++ use static typing. To determine the types of your variables before use, MATLAB Coder requires a complete assignment to each variable.

- Array sizing

Variable-size arrays and matrices are supported for code generation. You can define inputs, outputs, and local variables in MATLAB functions to represent data that varies in size at run time.

- Memory

You can choose whether the generated code uses static or dynamic memory allocation.

With dynamic memory allocation, you potentially use less memory at the expense of time to manage the memory. With static memory, you get better speed, but with higher memory usage. Most MATLAB code takes advantage of the dynamic sizing features in MATLAB, therefore dynamic memory allocation typically enables you to generate code from existing MATLAB code without modifying it much. Dynamic memory allocation also allows some programs to compile even when upper bounds cannot be found.

Static allocation reduces the memory footprint of the generated code, and therefore is suitable for applications where there is a limited amount of available memory, such as embedded applications.

- Speed

Because embedded applications must run in real time, the code must be fast enough to meet the required clock rate.

To improve the speed of the generated code:

- Choose a suitable C/C++ compiler. Do not use the default compiler that MathWorks supplies with MATLAB for Windows 64-bit platforms.
- Consider disabling run-time checks.

By default, for safety, the code generated for your MATLAB code contains memory integrity checks and responsiveness checks. Generally, these checks result in more generated code and slower simulation. Disabling run-time checks usually results in streamlined generated code and faster simulation. Disable these checks only if you have verified that array bounds and dimension checking is unnecessary.

## Differences Between Generated Code and MATLAB Code

To convert MATLAB code to efficient C/C++ code, the code generator introduces optimizations that intentionally cause the generated code to behave differently, and sometimes produce different results, than the original source code.

Here are some of the differences:

### Loop Index Overflow

Suppose that a for-loop end value is equal to or close to the maximum or minimum value for the loop index data type. In the generated code, the last increment or decrement of

the loop index might cause the index variable to overflow. The index overflow might result in an infinite loop.

When memory integrity checks are enabled, if the code generator detects that the loop index might overflow, it reports an error. The software error checking is conservative. It might incorrectly report a loop index overflow. By default, memory-integrity checks are enabled for MEX code and disabled for standalone C/C++ code. See “Why Test MEX Functions in MATLAB?” (MATLAB Coder) and “Run-Time Error Detection and Reporting in Standalone C/C++ Code” (MATLAB Coder).

To avoid a loop index overflow, use the workarounds in this table.

| <b>Loop Conditions Causing the Potential Overflow</b>                                                                                                      | <b>Workaround</b>                                                                                                                                                                                                                                                                    |

For example, replace:</p> <pre>N=intmin('int32') for k=N+10:-1:N</pre> <p>with:</p> <pre>for k=10:-1:1</pre> |

| Loop Conditions Causing the Potential Overflow                                                                                                                                                                                                                    | Workaround                                                                                                                                                                                                                                                                                                                                                                 |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <ul style="list-style-type: none"> <li>The loop index increments or decrements by 1.</li> <li>The start value equals the minimum or maximum value of the integer type.</li> <li>The end value equals the maximum or minimum value of the integer type.</li> </ul> | <p>If the loop must cover the full range of the integer type, cast the type of the loop start, step, and end values to a bigger integer or to double. For example, rewrite:</p> <pre>M= intmin('int16'); N= intmax('int16'); for k=M:N     % Loop body end</pre> <p>as:</p> <pre>M= intmin('int16'); N= intmax('int16'); for k=int32(M):int32(N)     % Loop body end</pre> |
| <ul style="list-style-type: none"> <li>The loop index increments or decrements by a value not equal to 1.</li> <li>On the last loop iteration, the loop index is not equal to the end value.</li> </ul>                                                           | <p>Rewrite the loop so that the loop index in the last loop iteration is equal to the end value.</p>                                                                                                                                                                                                                                                                       |

## Character Size

MATLAB supports 16-bit characters, but the generated code represents characters in 8 bits, the standard size for most embedded languages like C. See “Encoding of Characters in Code Generation” on page 51-9.

## Order of Evaluation in Expressions

Generated code does not enforce order of evaluation in expressions. For most expressions, order of evaluation is not significant. However, for expressions with side effects, the generated code may produce the side effects in different order from the original MATLAB code. Expressions that produce side effects include those that:

- Modify persistent or global variables

- Display data to the screen
- Write data to files
- Modify the properties of handle class objects

In addition, the generated code does not enforce order of evaluation of logical operators that do not short circuit.

For more predictable results, it is good coding practice to split expressions that depend on the order of evaluation into multiple statements.

- Rewrite

```
A = f1() + f2();
```

as

```
A = f1();
A = A + f2();
```

so that the generated code calls `f1` before `f2`.

- Assign the outputs of a multi-output function call to variables that do not depend on one another. For example, rewrite

```
[y, y.f, y.g] = foo;
```

as

```
[y, a, b] = foo;
y.f = a;
y.g = b;
```

- When you access the contents of multiple cells of a cell array, assign the results to variables that do not depend on one another. For example, rewrite

```
[y, y.f, y.g] = z{:};
```

as

```
[y, a, b] = z{:};
y.f = a;
y.g = b;
```

## Termination Behavior

Generated code does not match the termination behavior of MATLAB source code. For example, if infinite loops do not have side effects, optimizations remove them from generated code. As a result, the generated code can possibly terminate even though the corresponding MATLAB code does not.

## Size of Variable-Size N-D Arrays

For variable-size N-D arrays, the `size` function might return a different result in generated code than in MATLAB source code. The `size` function sometimes returns trailing ones (singleton dimensions) in generated code, but always drops trailing ones in MATLAB. For example, for an N-D array `X` with dimensions `[4 2 1 1]`, `size(X)` might return `[4 2 1 1]` in generated code, but always returns `[4 2]` in MATLAB. See “Incompatibility with MATLAB in Determining Size of Variable-Size N-D Arrays” on page 52-19.

## Size of Empty Arrays

The size of an empty array in generated code might be different from its size in MATLAB source code. See “Incompatibility with MATLAB in Determining Size of Empty Arrays” on page 52-19.

## Size of Empty Array That Results from Deleting Elements of an Array

Deleting all elements of an array results in an empty array. The size of this empty array in generated code might differ from its size in MATLAB source code.

| Case                                                                    | Example Code                                                        | Size of Empty Array in MATLAB | Size of Empty Array in Generated Code |
|-------------------------------------------------------------------------|---------------------------------------------------------------------|-------------------------------|---------------------------------------|
| Delete all elements of an m-by-n array by using the colon operator (:). | <pre>coder.varsize('X',[4,4],[1,1]); X = zeros(2); X(:) = [];</pre> | 0-by-0                        | 1-by-0                                |

| Case                                                                      | Example Code                                                                              | Size of Empty Array in MATLAB | Size of Empty Array in Generated Code |
|---------------------------------------------------------------------------|-------------------------------------------------------------------------------------------|-------------------------------|---------------------------------------|
| Delete all elements of a row vector by using the colon operator (:).      | <pre>coder.varsize('X',[1,4],[0,1]); X = zeros(1,4); X(:) = [];</pre>                     | 0-by-0                        | 1-by-0                                |
| Delete all elements of a column vector by using the colon operator (:).   | <pre>coder.varsize('X',[4,1],[1,0]); X = zeros(4,1); X(:) = [];</pre>                     | 0-by-0                        | 0-by-1                                |
| Delete all elements of a column vector by deleting one element at a time. | <pre>coder.varsize('X',[4,1],[1,0]); X = zeros(4,1); for i = 1:4     X(i) = []; end</pre> | 1-by-0                        | 0-by-1                                |

## Floating-Point Numerical Results

The generated code might not produce the same floating-point numerical results as MATLAB in these:

### When computer hardware uses extended precision registers

Results vary depending on how the C/C++ compiler allocates extended precision floating-point registers. Computation results might not match MATLAB calculations because of different compiler optimization settings or different code surrounding the floating-point calculations.

### For certain advanced library functions

The generated code might use different algorithms to implement certain advanced library functions, such as `fft`, `svd`, `eig`, `mldivide`, and `mrdivide`.

For example, the generated code uses a simpler algorithm to implement `svd` to accommodate a smaller footprint. Results might also vary according to matrix properties. For example, MATLAB might detect symmetric or Hermitian matrices at run time and switch to specialized algorithms that perform computations faster than implementations in the generated code.

## For implementation of BLAS library functions

For implementations of BLAS library functions, generated C/C++ code uses reference implementations of BLAS functions. These reference implementations might produce different results from platform-specific BLAS implementations in MATLAB.

## NaN and Infinity

The generated code might not produce exactly the same pattern of NaN and Inf values as MATLAB code when these values are mathematically meaningless. For example, if MATLAB output contains a NaN, output from the generated code should also contain a NaN, but not necessarily in the same place.

The bit pattern for NaN can differ between MATLAB code output and generated code output because the C99 standard math library that is used to generate code does not specify a unique bit pattern for NaN across all implementations. Avoid comparing bit patterns across different implementations, for example, between MATLAB output and SIL or PIL output.

## Negative Zero

In a floating-point type, the value 0 has either a positive sign or a negative sign. Arithmetically, 0 is equal to -0, but some operations are sensitive to the sign of a 0 input. Examples include `rdivide`, `atan2`, `atan2d`, and `angle`. Division by 0 produces `Inf`, but division by -0 produces `-Inf`. Similarly, `atan2d(0, -1)` produces `180`, but `atan2d(-0, -1)` produces `-180`.

If the code generator detects that a floating-point variable takes only integer values of a suitable range, then the code generator can use an integer type for the variable in the generated code. If the code generator uses an integer type for the variable, then the variable stores -0 as +0 because an integer type does not store a sign for the value 0. If the generated code casts the variable back to a floating-point type, the sign of 0 is positive. Division by 0 produces `Inf`, not `-Inf`. Similarly, `atan2d(0, -1)` produces `180`, not `-180`.

## Code Generation Target

The `coder.target` function returns different values in MATLAB than in the generated code. The intent is to help you determine whether your function is executing in MATLAB or has been compiled for a simulation or code generation target. See `coder.target`.

## **MATLAB Class Property Initialization**

Before code generation, at class loading time, MATLAB computes class default values. The code generator uses the values that MATLAB computes. It does not recompute default values. If the property definition uses a function call to compute the initial value, the code generator does not execute this function. If the function has side effects such as modifying a global variable or a persistent variable, then it is possible that the generated code can produce different results that MATLAB produces. For more information, see “Defining Class Properties for Code Generation” on page 56-4.

## **MATLAB Class Property Access Methods That Modify Property Values**

When using objects with property access methods, simulation results can differ from MATLAB results. These differences occur when the objects are:

- Input to or output from an entry-point function.
- Passed to or returned from an extrinsic function.
- Loaded into memory by using `load`.

The results can differ under these conditions:

- A get method returns a different value from the stored property value.
- A set method modifies an input value before assigning it to the property.
- A get method or a set method has side effects such as modifying a global variable or writing to a file.

Results can differ due to inconsistencies in the use of property access methods when MATLAB and the simulation software pass objects to each other:

- If you return an object from an extrinsic function, MATLAB passes the object to the simulation software. The simulation software creates its own version of the object. To provide property values to the object creation process, MATLAB calls get methods. The object creation process assigns these property values from MATLAB directly to the new object without calling set methods.
- When you pass an object to an extrinsic function for execution in MATLAB, the simulation software passes the object to MATLAB. MATLAB creates its own version of the object. To provide property values to MATLAB, instead of using get methods, the

simulation software directly reads the property values. To assign property values in the MATLAB version of the object, the creation process uses set methods.

To avoid differences in results between MATLAB and simulation, do not use classes with property access methods in these cases.

For more information, see “Defining Class Properties for Code Generation” on page 56-4.

## **MATLAB Classes in Nested Property Assignments That Have Set Methods**

When you assign a value to a handle object property, which is itself a property of another object, and so on, then the generated code can call set methods for handle classes that MATLAB does not call.

For example, suppose that you define a set of variables such that `x` is a handle object, `pa` is an object, `pb` is a handle object, and `pc` is a property of `pb`. Then you make a nested property assignment, such as:

```
x.pa.pb.pc = 0;
```

In this case, the generated code calls the set method for the object `pb` and the set method for `x`. MATLAB calls only the set method for `pb`.

## **MATLAB Handle Class Destructors**

The behavior of handle class destructors in the generated code can be different from the behavior in MATLAB in these situations:

- The order of destruction of several independent objects might be different in MATLAB than in the generated code.
- The lifetime of objects in the generated code can be different from their lifetime in MATLAB.
- The generated code does not destroy partially constructed objects. If a handle object is not fully constructed at run time, the generated code produces an error message but does not call the `delete` method for that object. For a System object, if there is a run-time error in `setupImpl`, the generated code does not call `releaseImpl` for that object.

MATLAB does call the `delete` method to destroy a partially constructed object.

For more information, see “Code Generation for Handle Class Destructors” on page 56-18.

## Variable-Size Data

See “Incompatibilities with MATLAB in Variable-Size Support for Code Generation” on page 52-17.

## Complex Numbers

See “Code Generation for Complex Data” on page 51-4.

## Converting Strings with Consecutive Unary Operators to `double`

Converting a string that contains multiple, consecutive unary operators to `double` can produce different results between MATLAB and the generated code. Consider this function:

```
function out = foo(op)
out = double(op + 1);
end
```

For an input value `--`, the function converts the string `--1` to `double`. In MATLAB, the answer is `NaN`. In the generated code, the answer is `1`.

# MATLAB Language Features Supported for C/C++ Code Generation

## MATLAB Features That Code Generation Supports

Code generation from MATLAB code supports the following language features:

- n-dimensional arrays (see “Array Size Restrictions for Code Generation” on page 51-10)
- matrix operations, including deletion of rows and columns
- variable-size data (see “Code Generation for Variable-Size Arrays” on page 52-2)
- subscripting (see “Incompatibility with MATLAB in Matrix Indexing Operations for Code Generation” on page 52-23)
- complex numbers (see “Code Generation for Complex Data” on page 51-4)
- numeric classes (see “Supported Variable Types” on page 50-13)
- double-precision, single-precision, and integer math
- fixed-point arithmetic
- program control statements `if`, `switch`, `for`, `while`, and `break`
- arithmetic, relational, and logical operators
- local functions
- persistent variables
- global variables
- structures (see “Structure Definition for Code Generation” on page 53-2)
- cell arrays (see “Cell Arrays”)
- categorical arrays (see “Code Generation for Categorical Arrays” on page 55-2)
- characters (see “Encoding of Characters in Code Generation” on page 51-9)
- string scalars (see “Code Generation for Strings” on page 51-13)
- sparse matrices (see “Code Generation for Sparse Matrices” on page 51-15)
- function handles (see “Function Handle Limitations for Code Generation” on page 57-2)
- anonymous functions (see “Code Generation for Anonymous Functions” on page 58-3)

- recursive functions (see “Code Generation for Recursive Functions” on page 59-19)
- nested functions (see “Code Generation for Nested Functions” on page 58-4)
- variable length input and output argument lists (see “Code Generation for Variable Length Argument Lists” on page 58-2)
- subset of MATLAB toolbox functions (see “Functions and Objects Supported for C/C++ Code Generation — Alphabetical List” on page 48-2)
- subset of functions and System objects in several toolboxes (see “Functions and Objects Supported for C/C++ Code Generation — Category List” on page 48-91)
- MATLAB classes (see “MATLAB Classes Definition for Code Generation” on page 56-2)
- function calls (see “Resolution of Function Calls for Code Generation” on page 59-2)

## **MATLAB Language Features That Code Generation Does Not Support**

Code generation from MATLAB does not support the following frequently used MATLAB features:

- scripts
- implicit expansion

Code generation does not support implicit expansion of arrays with compatible sizes during execution of element-wise operations or functions. If your MATLAB code relies on implicit expansion, code generation results in a size-mismatch error. For fixed-size arrays, the error occurs at compile time. For variable-size arrays, the error occurs at run time. For more information about implicit expansion, see “Compatible Array Sizes for Basic Operations” (MATLAB). For code generation, to achieve implicit expansion, use `bsxfun`.

- GPU arrays

MATLAB Coder does not support GPU arrays. However, if you have GPU Coder™, you can generate CUDA® MEX code that takes GPU array inputs.

- date and time arrays
- Java
- Map containers
- tables

- time series objects
- try/catch statements

This list is not exhaustive. To see if a feature is supported for code generation, see “MATLAB Features That Code Generation Supports” on page 47-19.

# Functions, Classes, and System Objects Supported for Code Generation

---

- “Functions and Objects Supported for C/C++ Code Generation — Alphabetical List” on page 48-2
- “Functions and Objects Supported for C/C++ Code Generation — Category List” on page 48-91

## Functions and Objects Supported for C/C++ Code Generation — Alphabetical List

You can generate efficient C/C++ code for a subset of MATLAB built-in functions and toolbox functions and System objects that you call from MATLAB code. These functions and System objects appear in alphabetical order in the following table.

To find supported functions and System objects by MATLAB category or toolbox, see “Functions and Objects Supported for C/C++ Code Generation — Category List” on page 48-91.

---

**Note** For more information on code generation for fixed-point algorithms, refer to “Code Acceleration and Code Generation from MATLAB” (Fixed-Point Designer).

---

In the following table, an asterisk (\*) indicates that the reference page has usage notes and limitations for C/C++ code generation.

## Functions and Objects Supported for C/C++ Code Generation — Category List

You can generate efficient C/C++ code for a subset of MATLAB built-in functions and toolbox functions and System objects that you call from MATLAB code. These functions and System objects are listed by MATLAB category or toolbox category in the following tables.

For an alphabetical list of supported functions and System objects, see “Functions and Objects Supported for C/C++ Code Generation — Alphabetical List” on page 48-2.

---

**Note** For more information on code generation for fixed-point algorithms, refer to “Code Acceleration and Code Generation from MATLAB” (Fixed-Point Designer).

| SeriesNetwork* |

You can use `genFunction` in the Deep Learning Toolbox to generate a standalone MATLAB function for a trained neural network. You can generate C/C++ code from this standalone MATLAB function. To generate Simulink blocks, use the `gensim` function. See “Deploy Shallow Neural Network Functions” (Deep Learning Toolbox).

## Descriptive Statistics in MATLAB

An asterisk (\*) indicates that the reference page has usage notes and limitations for C/C++ code generation.

## Fixed-Point Designer

The following general limitations apply to the use of Fixed-Point Designer functions in generated code, with `fiaccel`:

- `fipref` and `quantizer` objects are not supported.
- Word lengths greater than 128 bits are not supported.
- You cannot change the `fi`math or `numericType` of a given `fi` variable after that variable has been created.
- The `boolean` value of the `DataTypeMode` and `DataType` properties are not supported.
- For all `SumMode` property settings other than `FullPrecision`, the `CastBeforeSum` property must be set to `true`.
- You can use parallel `for` (`parfor`) loops in code compiled with `fiaccel`, but those loops are treated like regular `for` loops.
- When you compile code containing `fi` objects with nontrivial slope and bias scaling, you may see different results in generated code than you achieve by running the same code in MATLAB.

- The general limitations of C/C++ code generated from MATLAB apply. For more information, see “MATLAB Language Features Supported for C/C++ Code Generation” (MATLAB Coder).

## Image Processing Toolbox

The following table lists the Image Processing Toolbox functions that have been enabled for code generation. You must have the MATLAB Coder software installed to generate C code from MATLAB for these functions.

Image Processing Toolbox provides three types of code generation support:

- Functions that generate C code.
- Functions that generate C code that depends on a platform-specific shared library (.dll, .so, or .dylib). Use of a shared library preserves performance optimizations in these functions, but this limits the target platforms for which you can generate code. For more information, see “Code Generation for Image Processing” (Image Processing Toolbox).
- Functions that generate C code or C code that depends on a shared library, depending on which target platform you specify in MATLAB Coder. If you specify the generic MATLAB Host Computer target platform, these functions generate C code that depends on a shared library. If you specify any other target platform, these functions generate C code.

In generated code, each supported toolbox function has the same name, arguments, and functionality as its Image Processing Toolbox counterpart. However, some functions have

limitations. The following table includes information about code generation limitations that might exist for each function. In the following table, all the functions generate C code. The table identifies those functions that generate C code that depends on a shared library, and those functions that can do both, depending on which target platform you choose.

An asterisk (\*) indicates that the reference page has usage notes and limitations for C/C++ code generation.

## Signal Processing Toolbox

C and C++ code generation for the following functions requires the Signal Processing Toolbox software. These functions do not support variable-size inputs, you must define the size and type of the function inputs. For more information, see “Specifying Inputs in Code Generation from MATLAB” (Signal Processing Toolbox).

---

**Note** Many Signal Processing Toolbox functions require constant inputs in generated code. To specify a constant input for `codegen`, use `coder.Constant`.

---

An asterisk (\*) indicates that the reference page has usage notes and limitations for C/C++ code generation.

## System Identification Toolbox

C and C++ code generation for the following functions and System objects requires the System Identification Toolbox software.

An asterisk (\*) indicates that the reference page has usage notes and limitations for C/C++ code generation.

# System Objects Supported for Code Generation

---

## Code Generation for System Objects

You can generate C and C++ code for a subset of System objects provided by the following toolboxes.

| Toolbox Name                  | See                                                                                                                                                                       |
|-------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Communications Toolbox        | "System Objects in MATLAB Code Generation" (MATLAB Coder)                                                                                                                 |
| Computer Vision Toolbox       | "System Objects in MATLAB Code Generation" (MATLAB Coder)                                                                                                                 |
| DSP System Toolbox            | "System Objects in MATLAB Code Generation" (MATLAB Coder)                                                                                                                 |
| Image Acquisition Toolbox     | <ul style="list-style-type: none"> <li>• <code>imaq.VideoDevice</code></li> <li>• "Code Generation with VideoDevice System Object" (Image Acquisition Toolbox)</li> </ul> |
| Phased Array System Toolbox   | "Code Generation" (Phased Array System Toolbox)                                                                                                                           |
| System Identification Toolbox | "Generate Code for Online Parameter Estimation in MATLAB" (System Identification Toolbox)                                                                                 |
| WLAN Toolbox                  | "System Objects in MATLAB Code Generation" (MATLAB Coder)                                                                                                                 |

To use these System objects, you need to install the requisite toolbox. For a list of System objects supported for C and C++ code generation, see "Functions and Objects Supported for C/C++ Code Generation — Alphabetical List" on page 48-2 and "Functions and Objects Supported for C/C++ Code Generation — Category List" on page 48-91.

System objects are MATLAB object-oriented implementations of algorithms. They extend MATLAB by enabling you to model dynamic systems represented by time-varying algorithms. System objects are well integrated into the MATLAB language, regardless of whether you are writing simple functions, working interactively in the command window, or creating large applications.

In contrast to MATLAB functions, System objects automatically manage state information, data indexing, and buffering, which is particularly useful for iterative computations or

stream data processing. This enables efficient processing of long data sets. For general information about MATLAB objects, see “Classes” (MATLAB).

# Defining MATLAB Variables for C/C++ Code Generation

---

- “Reuse the Same Variable with Different Properties” on page 50-10
- “Supported Variable Types” on page 50-13

## Variables Definition for Code Generation

In the MATLAB language, variables can change their properties dynamically at run time so you can use the same variable to hold a value of any class, size, or complexity. For example, the following code works in MATLAB:

```
function x = foo(c) %#codegen
if(c>0)
 x = 0;
else
 x = [1 2 3];
end
disp(x);
end
```

However, statically-typed languages like C must be able to determine variable properties at compile time. Therefore, for C/C++ code generation, you must explicitly define the class, size, and complexity of variables in MATLAB source code before using them. For example, rewrite the above source code with a definition for `x`:

```
function x = foo(c) %#codegen
x = zeros(1,3);
if(c>0)
 x = 0;
else
 x = [1 2 3];
end
disp(x);
end
```

For more information, see “Best Practices for Defining Variables for C/C++ Code Generation” on page 50-3.

## Best Practices for Defining Variables for C/C++ Code Generation

### In this section...

“Define Variables By Assignment Before Using Them” on page 50-3

“Use Caution When Reassigning Variables” on page 50-5

“Use Type Cast Operators in Variable Definitions” on page 50-5

“Define Matrices Before Assigning Indexed Variables” on page 50-6

### Define Variables By Assignment Before Using Them

For C/C++ code generation, you should explicitly and unambiguously define the class, size, and complexity of variables before using them in operations or returning them as outputs. Define variables by assignment, but note that the assignment copies not only the value, but also the size, class, and complexity represented by that value to the new variable. For example:

| Assignment:                              | Defines:                                     |
|------------------------------------------|----------------------------------------------|
| <code>a = 14.7;</code>                   | a as a real double scalar.                   |
| <code>b = a;</code>                      | b with properties of a (real double scalar). |
| <code>c = zeros(5,2);</code>             | c as a real 5-by-2 array of doubles.         |
| <code>d = [1 2 3 4 5; 6 7 8 9 0];</code> | d as a real 5-by-2 array of doubles.         |
| <code>y = int16(3);</code>               | y as a real 16-bit integer scalar.           |

Define properties this way so that the variable is defined on the required execution paths during C/C++ code generation.

The data that you assign to a variable can be a scalar, matrix, or structure. If your variable is a structure, define the properties of each field explicitly.

Initializing the new variable to the value of the assigned data sometimes results in redundant copies in the generated code. To avoid redundant copies, you can define variables without initializing their values by using the `coder.nullcopy` construct as described in “Eliminate Redundant Copies of Variables in Generated Code” on page 50-7.

When you define variables, they are local by default; they do not persist between function calls. To make variables persistent, see `persistent`.

### Example 50.1. Defining a Variable for Multiple Execution Paths

Consider the following MATLAB code:

```
...
if c > 0
 x = 11;
end
% Later in your code ...
if c > 0
 use(x);
end
...
```

Here, `x` is assigned only if `c > 0` and used only when `c > 0`. This code works in MATLAB, but generates a compilation error during code generation because it detects that `x` is undefined on some execution paths (when `c <= 0`).

To make this code suitable for code generation, define `x` before using it:

```
x = 0;
...
if c > 0
 x = 11;
end
% Later in your code ...
if c > 0
 use(x);
end
...
```

### Example 50.2. Defining Fields in a Structure

Consider the following MATLAB code:

```
...
if c > 0
 s.a = 11;
 disp(s);
else
 s.a = 12;
 s.b = 12;
end
```

```

end
% Try to use s
use(s);
...

```

Here, the first part of the `if` statement uses only the field `a`, and the `else` clause uses fields `a` and `b`. This code works in MATLAB, but generates a compilation error during C/C++ code generation because it detects a structure type mismatch. To prevent this error, do not add fields to a structure after you perform certain operations on the structure. For more information, see “Structure Definition for Code Generation” on page 53-2.

To make this code suitable for C/C++ code generation, define all fields of `s` before using it.

```

...
% Define all fields in structure s
s = struct('a',0, 'b', 0);
if c > 0
 s.a = 11;
 disp(s);
else
 s.a = 12;
 s.b = 12;
end
% Use s
use(s);
...

```

## Use Caution When Reassigning Variables

In general, you should adhere to the "one variable/one type" rule for C/C++ code generation; that is, each variable must have a specific class, size and complexity. Generally, if you reassign variable properties after the initial assignment, you get a compilation error during code generation, but there are exceptions, as described in “Reassignment of Variable Properties” on page 50-9.

## Use Type Cast Operators in Variable Definitions

By default, constants are of type `double`. To define variables of other types, you can use type cast operators in variable definitions. For example, the following code defines variable `y` as an integer:

```
...
x = 15; % x is of type double by default.
y = uint8(x); % y has the value of x, but cast to uint8.
...
```

## **Define Matrices Before Assigning Indexed Variables**

When generating C/C++ code from MATLAB, you cannot grow a variable by writing into an element beyond its current size. Such indexing operations produce run-time errors. You must define the matrix first before assigning values to its elements.

For example, the following initial assignment is not allowed for code generation:

```
g(3,2) = 14.6; % Not allowed for creating g
 % OK for assigning value once created
```

For more information about indexing matrices, see “Incompatibility with MATLAB in Matrix Indexing Operations for Code Generation” on page 52-23.

# Eliminate Redundant Copies of Variables in Generated Code

## In this section...

“When Redundant Copies Occur” on page 50-7

“How to Eliminate Redundant Copies by Defining Uninitialized Variables” on page 50-7

“Defining Uninitialized Variables” on page 50-8

## When Redundant Copies Occur

During C/C++ code generation, the code generator checks for statements that attempt to access uninitialized memory. If it detects execution paths where a variable is used but is potentially not defined, it generates a compile-time error. To prevent these errors, define variables by assignment before using them in operations or returning them as function outputs.

Note, however, that variable assignments not only copy the properties of the assigned data to the new variable, but also initialize the new variable to the assigned value. This forced initialization sometimes results in redundant copies in C/C++ code. To eliminate redundant copies, define uninitialized variables by using the `coder.nullcopy` function, as described in “How to Eliminate Redundant Copies by Defining Uninitialized Variables” on page 50-7.

## How to Eliminate Redundant Copies by Defining Uninitialized Variables

- 1 Define the variable with `coder.nullcopy`.
- 2 Initialize the variable before reading it.

When the uninitialized variable is an array, you must initialize all of its elements before passing the array as an input to a function or operator — even if the function or operator does not read from the uninitialized portion of the array.

### What happens if you access uninitialized data?

Uninitialized memory contains arbitrary values. Therefore, accessing uninitialized data may lead to segmentation violations or nondeterministic program behavior (different runs of the same program may yield inconsistent results).

## Defining Uninitialized Variables

In the following code, the assignment statement `X = zeros(1,N)` not only defines `X` to be a 1-by-5 vector of real doubles, but also initializes each element of `X` to zero.

```
function X = withoutNullcopy %#codegen

N = 5;
X = zeros(1,N);
for i = 1:N
 if mod(i,2) == 0
 X(i) = i;
 elseif mod(i,2) == 1
 X(i) = 0;
 end
end
```

This forced initialization creates an extra copy in the generated code. To eliminate this overhead, use `coder.nullcopy` in the definition of `X`:

```
function X = withNullcopy %#codegen

N = 5;
X = coder.nullcopy(zeros(1,N));
for i = 1:N
 if mod(i,2) == 0
 X(i) = i;
 else
 X(i) = 0;
 end
end
```

## Reassignment of Variable Properties

For C/C++ code generation, there are certain variables that you can reassign after the initial assignment with a value of different class, size, or complexity:

### **Dynamically sized variables**

A variable can hold values that have the same class and complexity but different sizes. If the size of the initial assignment is not constant, the variable is dynamically sized in generated code. For more information, see “Variable-Size Data”.

### **Variables reused in the code for different purposes**

You can reassign the type (class, size, and complexity) of a variable after the initial assignment if each occurrence of the variable can have only one type. In this case, the variable is renamed in the generated code to create multiple independent variables. For more information, see “Reuse the Same Variable with Different Properties” on page 50-10.

## Reuse the Same Variable with Different Properties

### In this section...

“When You Can Reuse the Same Variable with Different Properties” on page 50-10

“When You Cannot Reuse Variables” on page 50-10

“Limitations of Variable Reuse” on page 50-12

### When You Can Reuse the Same Variable with Different Properties

You can reuse (reassign) an input, output, or local variable with different class, size, or complexity if the code generator can unambiguously determine the properties of each occurrence of this variable during C/C++ code generation. If so, MATLAB creates separate uniquely named local variables in the generated code. You can view these renamed variables in the code generation report.

A common example of variable reuse is in `if-elseif-else` or `switch-case` statements. For example, the following function `example1` first uses the variable `t` in an `if` statement, where it holds a scalar double, then reuses `t` outside the `if` statement to hold a vector of doubles.

```
function y = example1(u) %#codegen
if all(all(u>0))
 % First, t is used to hold a scalar double value
 t = mean(mean(u)) / numel(u);
 u = u - t;
end
% t is reused to hold a vector of doubles
t = find(u > 0);
y = sum(u(t(2:end-1)));
```

### When You Cannot Reuse Variables

You cannot reuse (reassign) variables if it is not possible to determine the class, size, and complexity of an occurrence of a variable unambiguously during code generation. In this case, variables cannot be renamed and a compilation error occurs.

For example, the following `example2` function assigns a fixed-point value to `x` in the `if` statement and reuses `x` to store a matrix of doubles in the `else` clause. It then uses `x`

after the if-else statement. This function generates a compilation error because after the if-else statement, variable `x` can have different properties depending on which if-else clause executes.

```
function y = example2(use_fixpoint, data) %#codegen
 if use_fixpoint
 % x is fixed-point
 x = fi(data, 1, 12, 3);
 else
 % x is a matrix of doubles
 x = data;
 end
 % When x is reused here, it is not possible to determine its
 % class, size, and complexity
 t = sum(sum(x));
 y = t > 0;
end
```

### Example 50.3. Variable Reuse in an if Statement

To see how MATLAB renames a reused variable `t`:

- 1 Create a MATLAB file `example1.m` containing the following code.

```
function y = example1(u) %#codegen
 if all(all(u>0))
 % First, t is used to hold a scalar double value
 t = mean(mean(u)) / numel(u);
 u = u - t;
 end
 % t is reused to hold a vector of doubles
 t = find(u > 0);
 y = sum(u(t(2:end-1)));
end
```

- 2 Generate a MEX function for `example1` and produce a code generation report.

```
codegen -o example1x -report example1.m -args {ones(5,5)}
```

- 3 Open the code generation report.

On the **Variables** tab, you see two uniquely named local variables `t>1` and `t>2`.

| SUMMARY     | ALL MESSAGES (0) | BUILD LOGS  | COD         |
|-------------|------------------|-------------|-------------|
| <b>Name</b> |                  | <b>Type</b> | <b>Size</b> |
| y           |                  | Output      | 1 × 1       |
| u           |                  | Input       | 5 × 5       |
| t > 1       |                  | Local       | 1 × 1       |
| t > 2       |                  | Local       | :25 × 1     |

- 4 In the list of variables, click `t>1`. The report highlights the instances of the variable `t` that are inside of the `if` statement. These instances of `t` are scalar double.
- 5 Click `t>2`. The code generation report highlights the instances of `t` that are outside of the `if` statement. These instances of `t` are variable-size column vectors with an upper bound of 25.

## Limitations of Variable Reuse

The following variables cannot be renamed in generated code:

- Persistent variables.
- Global variables.
- Variables passed to C code using `coder.ref`, `coder.rref`, `coder.wref`.
- Variables whose size is set using `coder.varsize`.
- The index variable of a `for`-loop when it is used inside the loop body.
- The block outputs of a MATLAB Function block in a Simulink model.
- Chart-owned variables of a MATLAB function in a Stateflow chart.

## Supported Variable Types

You can use the following data types for C/C++ code generation from MATLAB:

| Type                          | Description                                                     |
|-------------------------------|-----------------------------------------------------------------|
| char                          | Character array                                                 |
| complex                       | Complex data. Cast function takes real and imaginary components |
| double                        | Double-precision floating point                                 |
| int8, int16, int32, int64     | Signed integer                                                  |
| logical                       | Boolean true or false                                           |
| single                        | Single-precision floating point                                 |
| struct                        | Structure                                                       |
| uint8, uint16, uint32, uint64 | Unsigned integer                                                |
| Fixed-point                   | See “Fixed-Point Data Types” (Fixed-Point Designer).            |

# Defining Data for Code Generation

## Data Definition for Code Generation

To generate efficient standalone code, you must define the following types and classes of data differently than you normally would when running your code in MATLAB.

| Data            | What Is Different                                                                                                                                                                                                                                                                                                                                                                                                | More Information                                            |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------|
| Arrays          | Maximum number of elements is restricted                                                                                                                                                                                                                                                                                                                                                                         | "Array Size Restrictions for Code Generation" on page 51-10 |

## Code Generation for Complex Data

### In this section...

“Restrictions When Defining Complex Variables” on page 51-4

“Code Generation for Complex Data with Zero-Valued Imaginary Parts” on page 51-4

“Results of Expressions That Have Complex Operands” on page 51-7

“Results of Complex Multiplication with Nonfinite Values” on page 51-7

### Restrictions When Defining Complex Variables

For code generation, you must set the complexity of variables at the time of assignment. Assign a complex constant to the variable or use the `complex` function. For example:

```
x = 5 + 6i; % x is a complex number by assignment.
y = complex(5,6); % y is the complex number 5 + 6i.
```

After assignment, you cannot change the complexity of a variable. Code generation for the following function fails because `x(k) = 3 + 4i` changes the complexity of `x`.

```
function x = test1()
x = zeros(3,3); % x is real
for k = 1:numel(x)
 x(k) = 3 + 4i;
end
end
```

To resolve this issue, assign a complex constant to `x`.

```
function x = test1()
x = zeros(3,3)+ 0i; %x is complex
for k = 1:numel(x)
 x(k) = 3 + 4i;
end
end
```

### Code Generation for Complex Data with Zero-Valued Imaginary Parts

For code generation, complex data that has all zero-valued imaginary parts remains complex. This data does not become real. This behavior has the following implications:

- In some cases, results from functions that sort complex data by absolute value can differ from the MATLAB results. See “Functions That Sort Complex Values by Absolute Value” on page 51-5.
- For functions that require that complex inputs are sorted by absolute value, complex inputs with zero-valued imaginary parts must be sorted by absolute value. These functions include `ismember`, `union`, `intersect`, `setdiff`, and `setxor`.

### Functions That Sort Complex Values by Absolute Value

Functions that sort complex values by absolute value include `sort`, `issorted`, `sortrows`, `median`, `min`, and `max`. These functions sort complex numbers by absolute value even when the imaginary parts are zero. In general, sorting the absolute values produces a different result than sorting the real parts. Therefore, when inputs to these functions are complex with zero-valued imaginary parts in generated code, but real in MATLAB, the generated code can produce different results than MATLAB. In the following examples, the input to `sort` is real in MATLAB, but complex with zero-valued imaginary parts in the generated code:

#### • You Pass Real Inputs to a Function Generated for Complex Inputs

- 1 Write this function:

```
function myout = mysort(A)
myout = sort(A);
end
```

- 2 Call `mysort` in MATLAB.

```
A = -2:2;
mysort(A)

ans =

 -2 -1 0 1 2
```

- 3 Generate a MEX function for complex inputs.

```
A = -2:2;
codegen mysort -args {complex(A)} -report
```

- 4 Call the MEX Function with real inputs.

```
mysort_mex(A)
```

```
ans =

 0 1 -1 2 -2
```

You generated the MEX function for complex inputs, therefore, it treats the real inputs as complex numbers with zero-valued imaginary parts. It sorts the numbers by the absolute values of the complex numbers. Because the imaginary parts are zero, the MEX function returns the results to the MATLAB workspace as real numbers.

- **Input to sort Is Output from a Function That Returns Complex in Generated Code**

- 1 Write this function:

```
function y = myfun(A)
x = eig(A);
y = sort(x, 'descend');
```

The output from `eig` is the input to `sort`. In generated code, `eig` returns a complex result. Therefore, in the generated code, `x` is complex.

- 2 Call `myfun` in MATLAB.

```
A = [2 3 5;0 5 5;6 7 4];
myfun(A)
```

```
ans =

 12.5777
 2.0000
 -3.5777
```

The result of `eig` is real. Therefore, the inputs to `sort` are real.

- 3 Generate a MEX function for complex inputs.

```
codegen myfun -args {complex(A)}
```

- 4 Call the MEX function.

```
myfun_mex(A)

ans =

 12.5777
 -3.5777
 2.0000
```

In the MEX function, `eig` returns a complex result. Therefore, the inputs to `sort` are complex. The MEX function sorts the inputs in descending order of the absolute values.

## Results of Expressions That Have Complex Operands

In general, expressions that contain one or more complex operands produce a complex result in generated code, even if the value of the result is zero. Consider the following line of code:

```
z = x + y;
```

Suppose that at run time, `x` has the value  $2 + 3i$  and `y` has the value  $2 - 3i$ . In MATLAB, this code produces the real result  $z = 4$ . During code generation, the types for `x` and `y` are known, but their values are not known. Because either or both operands in this expression are complex, `z` is defined as a complex variable requiring storage for a real and an imaginary part. `z` equals the complex result  $4 + 0i$  in generated code, not  $4$ , as in MATLAB code.

Exceptions to this behavior are:

- Functions that take complex arguments but produce real results return real values.

```
y = real(x); % y is the real part of the complex number x.
y = imag(x); % y is the real-valued imaginary part of x.
y = isreal(x); % y is false (0) for a complex number x.
```

- Functions that take real arguments but produce complex results return complex values.

```
z = complex(x,y); % z is a complex number for a real x and y.
```

## Results of Complex Multiplication with Nonfinite Values

When an operand of a complex multiplication contains a nonfinite value, the generated code might produce a different result than the result that MATLAB produces. The difference is due to the way that code generation defines complex multiplication. For code generation:

- Multiplication of a complex value by a complex value  $(a + bi)(c + di)$  is defined as  $(ac - bd) + (ad + bc)i$ . The complete calculation is performed, even when a real or an imaginary part is zero.

- Multiplication of a real value by a complex value  $c(a + bi)$  is defined as  $ca + cbi$  .

## Encoding of Characters in Code Generation

MATLAB represents characters in 16-bit Unicode. The code generator represents characters in an 8-bit codeset that the locale setting determines. Differences in character encoding between MATLAB and code generation have these consequences:

- Code generation of characters with numeric values greater than 255 produces an error.
- For some characters in the range 128–255, it might not be possible to represent the character in the codeset of the locale setting or to convert the character to an equivalent 16-bit Unicode character. Passing characters in this range between MATLAB and generated code can result in errors or different answers.
- For code generation, some toolbox functions accept only 7-bit ASCII characters.
- Casting a character that is not in the 7-bit ASCII codeset to a numeric type, such as double, can produce a different result in the generated code than in MATLAB. As a best practice, for code generation, avoid performing arithmetic with characters.

## Array Size Restrictions for Code Generation

For code generation, the maximum number of elements of an array is constrained by the code generator and the target hardware.

For fixed-size arrays and variable-size arrays that use static memory allocation, the maximum number of elements is the smaller of:

- `intmax('int32')`.
- The largest integer that fits in the C `int` data type on the target hardware.

For variable-size arrays that use dynamic memory allocation, the maximum number of elements is the smaller of:

- `intmax('int32')`.
- The largest power of 2 that fits in the C `int` data type on the target hardware.

These restrictions apply even on a 64-bit platform.

For a fixed-size array, if the number of elements exceeds the maximum, the code generator reports an error at compile time. For a variable-size array, if the number of elements exceeds the maximum during simulation, the software reports an error. Generated standalone code cannot report array size violations.

## See Also

## Code Generation for Constants in Structures and Arrays

The code generator does not recognize constant structure fields or array elements in the following cases:

### Fields or elements are assigned inside control constructs

In the following code, the code generator recognizes that the structure fields `s.a` and `s.b` are constants.

```
function y = mystruct()
s.a = 3;
s.b = 5;
y = zeros(s.a,s.b);
```

If any structure field is assigned inside a control construct, the code generator does not recognize the constant fields. This limitation also applies to arrays with constant elements. Consider the following code:

```
function y = mystruct(x)
s.a = 3;
if x > 1
 s.b = 4;
else
 s.b = 5;
end
y = zeros(s.a,s.b);
```

The code generator does not recognize that `s.a` and `s.b` are constant. If variable-sizing is enabled, `y` is treated as a variable-size array. If variable-sizing is disabled, the code generator reports an error.

### Constants are assigned to array elements using non-scalar indexing

In the following code, the code generator recognizes that `a(1)` is constant.

```
function y = myarray()
a = zeros(1,3);
a(1) = 20;
y = coder.const(a(1));
```

In the following code, because `a(1)` is assigned using non-scalar indexing, the code generator does not recognize that `a(1)` is constant.

```
function y = myarray()
a = zeros(1,3);
a(1:2) = 20;
y = coder.const(a(1));
```

### **A function returns a structure or array that has constant and nonconstant elements**

For an output structure that has both constant and nonconstant fields, the code generator does not recognize the constant fields. This limitation also applies to arrays that have constant and nonconstant elements. Consider the following code:

```
function y = mystruct_out(x)
s = create_structure(x);
y = coder.const(s.a);

function s = create_structure(x)
s.a = 10;
s.b = x;
```

Because `create_structure` returns a structure `s` that has one constant field and one nonconstant field, the code generator does not recognize that `s.a` is constant. The `coder.const` call fails because `s.a` is not constant.

## Code Generation for Strings

Code generation supports 1-by-1 MATLAB string arrays. Code generation does not support string arrays that have more than one element.

A 1-by-1 string array, called a string scalar, contains one piece of text, represented as a 1-by-n character vector. An example of a string scalar is "Hello, world". For more information about strings, see "Represent Text with Character and String Arrays" (MATLAB).

### Limitations

For string scalars, code generation does not support:

- Global variables
- Indexing with curly braces { }
- Missing values
- Their use as Simulink signals, parameters, or data store memory

For code generation, limitations that apply to classes apply to strings. See "MATLAB Classes Definition for Code Generation" on page 56-2.

### Differences from MATLAB

Converting a string that contains multiple unary operators to `double` can produce different results between MATLAB and the generated code. Consider this function:

```
function out = foo(op)
out = double(op + 1);
end
```

For an input value " - - ", the function converts the string " - - 1 " to `double`. In MATLAB, the answer is NaN. In the generated code, the answer is 1.

- “Type Function Arguments” on page 43-61

## Code Generation for Sparse Matrices

Sparse matrices provide efficient storage in memory for arrays with many zero elements. Sparse matrices can provide improved performance and reduced memory usage for generated code. Computation time on sparse matrices scales only with the number of operations on nonzero elements.

Functions for creating and manipulating sparse matrices are listed in “Sparse Matrices” (MATLAB). To check if a function is supported for code generation, see the function reference page. Code generation does not support sparse matrix inputs for all functions.

### Code Generation Guidelines

Initialize matrices by using sparse constructors to maximize your code efficiency. For example, to construct a 3-by-3 identity matrix, use `speye(3,3)` rather than `sparse(eye(3,3))`.

Indexed assignment into sparse matrices incurs an overhead compared to indexed assignment into full matrices. For example:

```
S = speye(10);
S(7,7) = 42;
```

As in MATLAB, sparse matrices are stored in compressed sparse column format. When you insert a new nonzero element into a sparse matrix, all subsequent nonzero elements must be shifted downward, column by column. These extra manipulations can slow performance.

### Code Generation Limitations

Code generation does not support sparse matrices for Simulink signals, parameters, or data store memory. Simulation state save and restore is not supported.

To generate code that uses sparse matrices, dynamic memory allocation must be enabled. To store the changing number of nonzero elements, and their values, sparse matrices use variable-size arrays in the generated code. To change dynamic memory allocation settings, see “Control Memory Allocation for Variable-Size Arrays in a MATLAB Function Block” on page 43-105. Because sparse matrices use variable-size arrays for dynamic memory allocation, limitations on “Variable-Size Data” also apply to sparse matrices.

You cannot assign sparse data to data that is not sparse. The generated code uses distinct data type representations for sparse and full matrices. To convert to and from sparse data, use the explicit `sparse` and `full` conversion functions.

You cannot define a sparse matrix with competing size specifications. The code generator fixes the size of the sparse matrix when it produces the corresponding data type definition in C/C++. As an example, the function `foo` causes an error in code generation:

```
function y = foo(n)
%#codegen
if n > 0
 y = sparse(3,2);
else
 y = sparse(4,3);
end
```

Logical indexing into sparse matrices is not supported for code generation. For example, this syntax causes an error:

```
S = magic(3);
S(S > 7) = 42;
```

For sparse matrices, you cannot delete array elements by assigning empty arrays:

```
S(:,2) = [];
```

- “Diagnose and Fix Variable-Size Data Errors” on page 52-13
- “Incompatibilities with MATLAB in Variable-Size Support for Code Generation” on page 52-17
- “Variable-Sizing Restrictions for Code Generation of Toolbox Functions” on page 52-26

## Code Generation for Variable-Size Arrays

For code generation, an array dimension is fixed-size or variable-size. If the code generator can determine the size of the dimension and that the size of the dimension does not change, then the dimension is fixed-size. When all dimensions of an array are fixed-size, the array is a fixed-size array. In the following example, Z is a fixed-size array.

```
function Z = myfcn()
Z = zeros(1,4);
end
```

The size of the first dimension is 1 and the size of the second dimension is 4.

If the code generator cannot determine the size of a dimension or the code generator determines that the size changes, then the dimension is variable-size. When at least one of its dimensions is variable-size, an array is a variable-size array.

A variable-size dimension is either bounded or unbounded. A bounded dimension has a fixed upper size. An unbounded dimension does not have a fixed upper size.

In the following example, the second dimension of Z is bounded, variable-size. It has an upper bound of 16.

```
function s = myfcn(n)
if (n > 0)
 Z = zeros(1,4);
else
 Z = zeros(1,16);
end
s = length(Z);
```

In the following example, if the value of n is unknown at compile time, then the second dimension of Z is unbounded.

```
function s = myfcn(n)
Z = rand(1,n);
s = sum(Z);
end
```

You can define variable-size arrays by:

- Using constructors, such as `zeros`, with a nonconstant dimension

- Assigning multiple, constant sizes to the same variable before using it
- Declaring all instances of a variable to be variable-size by using `coder. varsize`

For more information, see “Define Variable-Size Data for Code Generation” on page 52-7.

You can control whether variable-size arrays are allowed for code generation. See “Enabling and Disabling Support for Variable-Size Arrays” on page 52-3.

## Memory Allocation for Variable-Size Arrays

For fixed-size arrays and variable-size arrays whose size is less than a threshold, the code generator allocates memory statically on the stack. For unbounded, variable-size arrays and variable-size arrays whose size is greater than or equal to a threshold, the code generator allocates memory dynamically on the heap.

For a MATLAB Function block, you cannot use dynamic memory allocation for:

- Input and output signals. Variable-size input and output signals must have an upper bound.
- Parameters or global variables. Parameters and global variables must be fixed-size.
- Fields of bus arrays. Bus arrays cannot have variable-size fields.

You can control whether dynamic memory allocation is allowed or when it is used for code generation. See “Control Memory Allocation for Variable-Size Arrays in a MATLAB Function Block” on page 43-105.

The code generator represents dynamically allocated data as a structure type called `emxArray`. The code generator generates utility functions that create and interact with `emxArrays`. If you use Embedded Coder, you can customize the generated identifiers for the `emxArray` types and utility functions. See “Identifier Format Control” (Embedded Coder).

## Enabling and Disabling Support for Variable-Size Arrays

By default, for MATLAB Function blocks, support for variable-size arrays is enabled. To disable this support:

- 1 In the MATLAB Function Block Editor, select **Edit Data**.

- 2 Clear the **Support variable-size arrays** check box.

## Variable-Size Arrays in a MATLAB Function Report

You can tell whether an array is fixed-size or variable-size by looking at the **Size** column of the **Variables** tab in a MATLAB Function Report.

| Name | Type   | Size   | Class  |
|------|--------|--------|--------|
| y    | Output | 1 × 1  | double |
| n    | Input  | 1 × 1  | double |
| x    | Local  | 1 × :? | double |

A colon (:) indicates that a dimension is variable-size. A question mark (?) indicates that the size is unbounded. For example, a size of 1-by-:? indicates that the size of the first dimension is fixed-size 1 and the size of the second dimension is unbounded, variable-size. Italics indicates that your code specifies that an array is variable-size, but the code generator determined that it does not change size.

| ALL MESSAGES (0) |        | VARIABLES |        |
|------------------|--------|-----------|--------|
| Name             | Type   | Size      | Class  |
| y                | Output | 1 × 2     | double |
| n                | Input  | 1 × 1     | double |
| Z                | Local  | 1 × 4     | double |

- “Define Variable-Size Data for Code Generation” on page 52-7
- “Use Dynamic Memory Allocation for Variable-Size Arrays in a MATLAB Function Block” on page 43-108

## Specify Upper Bounds for Variable-Size Arrays

Specify upper bounds for an array when:

- Dynamic memory allocation is disabled.

If dynamic memory allocation is disabled, you must specify upper bounds for all arrays.

- You do not want the code generator to use dynamic memory allocation for the array.

Specify upper bounds that result in an array size (in bytes) that is less than the dynamic memory allocation threshold.

## Specify Upper Bounds for MATLAB Function Block Inputs and Outputs

See “Declare Variable-Size Inputs and Outputs” on page 43-96.

## Specify Upper Bounds for Local Variables

When using static allocation, the code generator uses a sophisticated analysis to calculate the upper bounds of local data. However, when the analysis fails to detect an upper bound or calculates an upper bound that is not precise enough for your application, you must specify upper bounds explicitly for local variables.

## Constrain the Value of Variables That Specify the Dimensions of Variable-Size Arrays

To constrain the value of variables that specify the dimensions of variable-size arrays, use the `assert` function with relational operators. For example:

```
function y = dim_need_bound(n) %#codegen
assert (n <= 5);
L = ones(n,n);
M = zeros(n,n);
M = [L; M];
y = M;
```

This `assert` statement constrains input `n` to a maximum size of 5. `L` is variable-size with upper bounds of 5 in each dimension. `M` is variable-size with an upper bound of 10 in the first dimension and 5 in the second dimension.

### Specify the Upper Bounds for All Instances of a Local Variable

To specify the upper bounds for all instances of a local variable in a function, use the `coder. varsize` function. For example:

```
function Y = example_bounds1(u) %#codegen
Y = [1 2 3 4 5];
coder. varsize('Y',[1 10]);
if (u > 0)
 Y = [Y Y+u];
else
 Y = [Y Y*u];
end
```

The second argument of `coder. varsize` specifies the upper bound for each instance of the variable specified in the first argument. In this example, the argument `[1 10]` indicates that for every instance of `Y`:

- The first dimension is fixed at size 1.
- The second dimension can grow to an upper bound of 10.

## Define Variable-Size Data for Code Generation

For code generation, before using variables in operations or returning them as outputs, you must assign them a specific class, size, and complexity. Generally, after the initial assignment, you cannot reassign variable properties. Therefore, after assigning a fixed size to a variable or structure field, attempts to grow the variable or structure field might cause a compilation error. In these cases, you must explicitly define the data as variable-size by using one of these methods.

| Method                                                                                                                                                       | See                                                                                      |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------|
| Assign the data from a variable-size matrix constructor such as: <ul style="list-style-type: none"> <li>• ones</li> <li>• zeros</li> <li>• repmat</li> </ul> | “Use a Matrix Constructor with Nonconstant Dimensions” on page 52-7                      |
| Assign multiple, constant sizes to the same variable before using (reading) the variable.                                                                    | “Assign Multiple Sizes to the Same Variable” on page 52-8                                |
| Define all instances of a variable to be variable-size.                                                                                                      | “Define Variable-Size Data Explicitly by Using <code>coder.varsize</code> ” on page 52-8 |

### Use a Matrix Constructor with Nonconstant Dimensions

You can define a variable-size matrix by using a constructor with nonconstant dimensions. For example:

```
function s = var_by_assign(u) %#codegen
y = ones(3,u);
s = numel(y);
```

If you are not using dynamic memory allocation, you must also add an `assert` statement to provide upper bounds for the dimensions. For example:

```
function s = var_by_assign(u) %#codegen
assert (u < 20);
y = ones(3,u);
s = numel(y);
```

## Assign Multiple Sizes to the Same Variable

Before you use (read) a variable in your code, you can make it variable-size by assigning multiple, constant sizes to it. When the code generator uses static allocation on the stack, it infers the upper bounds from the largest size specified for each dimension. When you assign the same size to a given dimension across all assignments, the code generator assumes that the dimension is fixed at that size. The assignments can specify different shapes and sizes.

When the code generator uses dynamic memory allocation, it does not check for upper bounds. It assumes that the variable-size data is unbounded.

### Inferring Upper Bounds from Multiple Definitions with Different Shapes

```
function s = var_by_multiassign(u) %#codegen
if (u > 0)
 y = ones(3,4,5);
else
 y = zeros(3,1);
end
s = numel(y);
```

When the code generator uses static allocation, it infers that `y` is a matrix with three dimensions:

- The first dimension is fixed at size 3
- The second dimension is variable-size with an upper bound of 4
- The third dimension is variable-size with an upper bound of 5

When the code generator uses dynamic allocation, it analyzes the dimensions of `y` differently:

- The first dimension is fixed at size 3.
- The second and third dimensions are unbounded.

## Define Variable-Size Data Explicitly by Using `coder.ysize`

To explicitly define variable-size data, use the function `coder.ysize`. Optionally, you can also specify which dimensions vary along with their upper bounds. For example:

- Define `B` as a variable-size 2-dimensional array, where each dimension has an upper bound of 64.

```
coder.versize('B', [64 64]);
```

- Define B as a variable-size array:

```
coder.versize('B');
```

When you supply only the first argument, `coder.versize` assumes that all dimensions of B can vary and that the upper bound is `size(B)`.

If a MATLAB Function block input or output signal is variable-size, in the Ports and Data Manager, you must specify that the signal is variable-size. You must also provide the upper bounds. You do not have to use `coder.versize` with the corresponding input or output variable inside the MATLAB Function block. However, if you specify upper bounds with `coder.versize`, they must match the upper bounds in the Ports and Data Manager.

### Specify Which Dimensions Vary

You can use the function `coder.versize` to specify which dimensions vary. For example, the following statement defines B as an array whose first dimension is fixed at 2, but whose second dimension can grow to a size of 16:

```
coder.versize('B',[2, 16],[0 1])
```

.

The third argument specifies which dimensions vary. This argument must be a logical vector or a double vector containing only zeros and ones. Dimensions that correspond to zeros or `false` have fixed size. Dimensions that correspond to ones or `true` vary in size. `coder.versize` usually treats dimensions of size 1 as fixed. See “Define Variable-Size Matrices with Singleton Dimensions” on page 52-10.

For an input or output signal, if you specify the upper bounds with `coder.versize` inside the MATLAB Function block, they must match the upper bounds in the Ports and Data Manager.

### Allow a Variable to Grow After Defining Fixed Dimensions

Function `var_by_if` defines matrix Y with fixed 2-by-2 dimensions before the first use (where the statement `Y = Y + u` reads from Y). However, `coder.versize` defines Y as a variable-size matrix, allowing it to change size based on decision logic in the `else` clause:

```
function Y = var_by_if(u) %#codegen
if (u > 0)
```

```
Y = zeros(2,2);
coder.varsize('Y');
if (u < 10)
 Y = Y + u;
end
else
 Y = zeros(5,5);
end
```

Without `coder.varsize`, the code generator infers `Y` to be a fixed-size, 2-by-2 matrix. It generates a size mismatch error.

### Define Variable-Size Matrices with Singleton Dimensions

A singleton dimension is a dimension for which `size(A,dim) = 1`. Singleton dimensions are fixed in size when:

- You specify a dimension with an upper bound of 1 in `coder.varsize` expressions.

For example, in this function, `Y` behaves like a vector with one variable-size dimension:

```
function Y = dim_singleton(u) %#codegen
Y = [1 2];
coder.varsize('Y', [1 10]);
if (u > 0)
 Y = [Y 3];
else
 Y = [Y u];
end
```

- You initialize variable-size data with singleton dimensions by using matrix constructor expressions or matrix functions.

For example, in this function, `X` and `Y` behave like vectors where only their second dimensions are variable-size.

```
function [X,Y] = dim_singleton_vects(u) %#codegen
Y = ones(1,3);
X = [1 4];
coder.varsize('Y','X');
if (u > 0)
 Y = [Y u];
else
 X = [X u];
end
```

You can override this behavior by using `coder.versize` to specify explicitly that singleton dimensions vary. For example:

```
function Y = dim_singleton_vary(u) %#codegen
Y = [1 2];
coder.versize('Y', [1 10], [1 1]);
if (u > 0)
 Y = [Y Y+u];
else
 Y = [Y Y*u];
end
```

In this example, the third argument of `coder.versize` is a vector of ones, indicating that each dimension of `Y` varies in size.

### Define Variable-Size Structure Fields

To define structure fields as variable-size arrays, use a colon (`:`) as the index expression. The colon (`:`) indicates that all elements of the array are variable-size. For example:

```
function y=struct_example() %#codegen

d = struct('values', zeros(1,0), 'color', 0);
data = repmat(d, [3 3]);
coder.versize('data(:).values');

for i = 1:numel(data)
 data(i).color = rand-0.5;
 data(i).values = 1:i;
end

y = 0;
for i = 1:numel(data)
 if data(i).color > 0
 y = y + sum(data(i).values);
 end
end
```

The expression `coder.versize('data(:).values')` defines the field `values` inside each element of matrix `data` to be variable-size.

Here are other examples:

- `coder.versize('data.A(:).B')`

In this example, `data` is a scalar variable that contains matrix `A`. Each element of matrix `A` contains a variable-size field `B`.

- `coder.ysize('data(:).A(:).B')`

This expression defines field `B` inside each element of matrix `A` inside each element of matrix `data` to be variable-size.

## Diagnose and Fix Variable-Size Data Errors

### In this section...

“Diagnosing and Fixing Size Mismatch Errors” on page 52-13

“Diagnosing and Fixing Errors in Detecting Upper Bounds” on page 52-15

### Diagnosing and Fixing Size Mismatch Errors

Check your code for these issues:

#### Assigning Variable-Size Matrices to Fixed-Size Matrices

You cannot assign variable-size matrices to fixed-size matrices in generated code. Consider this example:

```
function Y = example_mismatch1(n) %#codegen
assert(n < 10);
B = ones(n,n);
A = magic(3);
A(1) = mean(A(:));
if (n == 3)
 A = B;
end
Y = A;
```

Compiling this function produces this error:

```
??? Dimension 1 is fixed on the left-hand side
but varies on the right ...
```

There are several ways to fix this error:

- Allow matrix A to grow by adding the `coder.varsize` construct:

```
function Y = example_mismatch1_fix1(n) %#codegen
coder.varsize('A');
assert(n < 10);
B = ones(n,n);
A = magic(3);
A(1) = mean(A(:));
if (n == 3)
 A = B;
```

```
end
Y = A;
```

- Explicitly restrict the size of matrix B to 3-by-3 by modifying the `assert` statement:

```
function Y = example_mismatch1_fix2(n) %#codegen
coder.varsize('A');
assert(n == 3)
B = ones(n,n);
A = magic(3);
A(1) = mean(A(:));
if (n == 3)
 A = B;
end
Y = A;
```

- Use explicit indexing to make B the same size as A:

```
function Y = example_mismatch1_fix3(n) %#codegen
assert(n < 10);
B = ones(n,n);
A = magic(3);
A(1) = mean(A(:));
if (n == 3)
 A = B(1:3, 1:3);
end
Y = A;
```

### Empty Matrix Reshaped to Match Variable-Size Specification

If you assign an empty matrix `[]` to variable-size data, MATLAB might silently reshape the data in generated code to match a `coder.varsize` specification. For example:

```
function Y = test(u) %#codegen
Y = [];
coder.varsize('Y', [1 10]);
if u < 0
 Y = [Y u];
end
```

In this example, `coder.varsize` defines `Y` as a column vector of up to 10 elements, so its first dimension is fixed at size 1. The statement `Y = []` designates the first dimension of `Y` as 0, creating a mismatch. The right hand side of the assignment is an empty matrix and the left hand side is a variable-size vector. In this case, MATLAB reshapes the empty matrix `Y = []` in generated code to `Y = zeros(1,0)` so it matches the `coder.varsize` specification.

## Performing Binary Operations on Fixed and Variable-Size Operands

You cannot perform binary operations on operands of different sizes. Operands have different sizes if one has fixed dimensions and the other has variable dimensions. For example:

```
function z = mismatch_operands(n) %#codegen
assert(n >= 3 && n < 10);
x = ones(n,n);
y = magic(3);
z = x + y;
```

When you compile this function, you get an error because `y` has fixed dimensions (3 x 3), but `x` has variable dimensions. Fix this problem by using explicit indexing to make `x` the same size as `y`:

```
function z = mismatch_operands_fix(n) %#codegen
assert(n >= 3 && n < 10);
x = ones(n,n);
y = magic(3);
z = x(1:3,1:3) + y;
```

## Diagnosing and Fixing Errors in Detecting Upper Bounds

Check your code for these issues:

### Using Nonconstant Dimensions in a Matrix Constructor

You can define variable-size data by assigning a variable to a matrix with nonconstant dimensions. For example:

```
function y = dims_vary(u) %#codegen
if (u > 0)
 y = ones(3,u);
else
 y = zeros(3,1);
end
```

However, compiling this function generates an error because you did not specify an upper bound for `u`.

To fix the problem, add an `assert` statement before the first use of `u`:

```
function y = dims_vary_fix(u) %#codegen
assert (u < 20);
if (u > 0)
 y = ones(3,u);
else
 y = zeros(3,1);
end
```

## Incompatibilities with MATLAB in Variable-Size Support for Code Generation

### In this section...

“Incompatibility with MATLAB in Vector-Vector Indexing” on page 52-22

“Incompatibility with MATLAB in Matrix Indexing Operations for Code Generation” on page 52-23

“Incompatibility with MATLAB in Concatenating Variable-Size Matrices” on page 52-24

“Differences When Curly-Brace Indexing of Variable-Size Cell Array Inside Concatenation Returns No Elements” on page 52-24

### Incompatibility with MATLAB for Scalar Expansion

Scalar expansion is a method of converting scalar data to match the dimensions of vector or matrix data. If one operand is a scalar and the other is not, scalar expansion applies the scalar to every element of the other operand.

During code generation, scalar expansion rules apply except when operating on two variable-size expressions. In this case, both operands must be the same size. The generated code does not perform scalar expansion even if one of the variable-size expressions turns out to be scalar at run time. Therefore, when run-time error checks are enabled, a run-time error can occur.

Consider this function:

```
function y = scalar_exp_test_err1(u) %#codegen
y = ones(3);
switch u
 case 0
 z = 0;
```

```

 case 1
 z = 1;
 otherwise
 z = zeros(3);
end
y(:) = z;

```

When you generate code for this function, the code generator determines that `z` is variable size with an upper bound of 3.

| SUMMARY     | ALL MESSAGES (0) | BUILD LOGS  | CODE INSIGHTS (1) | VARIABLES    |
|-------------|------------------|-------------|-------------------|--------------|
| <b>Name</b> |                  | <b>Type</b> | <b>Size</b>       | <b>Class</b> |
| y           |                  | Output      | 3 × 3             | double       |
| u           |                  | Input       | 1 × 1             | double       |
| z           |                  | Local       | :3 × :3           | double       |

If you run the MEX function with `u` equal to 0 or 1, the generated code does not perform scalar expansion, even though `z` is scalar at run time. Therefore, when run-time error checks are enabled, a run-time error can occur.

```

scalar_exp_test_err1_mex(0)
Subscripted assignment dimension mismatch: [9] ~= [1].

Error in scalar_exp_test_err1 (line 11)
y(:) = z;

```

To avoid this issue, use indexing to force `z` to be a scalar value.

```

function y = scalar_exp_test_err1(u) %#codegen
y = ones(3);
switch u
 case 0
 z = 0;
 case 1
 z = 1;
 otherwise
 z = zeros(3);
end
y(:) = z(1);

```

## Incompatibility with MATLAB in Determining Size of Variable-Size N-D Arrays

For variable-size N-D arrays, the `size` function can return a different result in generated code than in MATLAB. In generated code, `size(A)` returns a fixed-length output because it does not drop trailing singleton dimensions of variable-size N-D arrays. By contrast, `size(A)` in MATLAB returns a variable-length output because it drops trailing singleton dimensions.

For example, if the shape of array `A` is `?x:?x:?` and `size(A,3)==1`, `size(A)` returns:

- Three-element vector in generated code
- Two-element vector in MATLAB code

### Workarounds

If your application requires generated code to return the same size of variable-size N-D arrays as MATLAB code, consider one of these workarounds:

- Use the two-argument form of `size`.

For example, `size(A,n)` returns the same answer in generated code and MATLAB code.

- Rewrite `size(A)`:

```
B = size(A);
X = B(1:ndims(A));
```

This version returns `X` with a variable-length output. However, you cannot pass a variable-size `X` to matrix constructors such as `zeros` that require a fixed-size argument.

## Incompatibility with MATLAB in Determining Size of Empty Arrays

The size of an empty array in generated code might be different from its size in MATLAB source code. The size might be `1x0` or `0x1` in generated code, but `0x0` in MATLAB. Therefore, you should not write code that relies on the specific size of empty matrices.

For example, consider the following code:

```
function y = foo(n) %#codegen
x = [];
i = 0;
while (i < 10)
 x = [5 x];
 i = i + 1;
end
if n > 0
 x = [];
end
y = size(x);
end
```

Concatenation requires its operands to match on the size of the dimension that is not being concatenated. In the preceding concatenation, the scalar value has size  $1 \times 1$  and  $x$  has size  $0 \times 0$ . To support this use case, the code generator determines the size for  $x$  as  $[1 \times ?]$ . Because there is another assignment  $x = []$  after the concatenation, the size of  $x$  in the generated code is  $1 \times 0$  instead of  $0 \times 0$ .

For incompatibilities with MATLAB in determining the size of an empty array that results from deleting elements of an array, see “Size of Empty Array That Results from Deleting Elements of an Array” on page 47-13.

### Workaround

If your application checks whether a matrix is empty, use one of these workarounds:

- Rewrite your code to use the `isempty` function instead of the `size` function.
- Instead of using `x=[]` to create empty arrays, create empty arrays of a specific size using `zeros`. For example:

```
function y = test_empty(n) %#codegen
x = zeros(1,0);
i=0;
while (i < 10)
 x = [5 x];
 i = i + 1;
end
if n > 0
 x = zeros(1,0);
end
y=size(x);
end
```

## Incompatibility with MATLAB in Determining Class of Empty Arrays

The class of an empty array in generated code can be different from its class in MATLAB source code. Therefore, do not write code that relies on the class of empty matrices.

For example, consider the following code:

```
function y = fun(n)
x = [];
if n > 1
 x = ['a' x];
end
y=class(x);
end
```

`fun(0)` returns `double` in MATLAB, but `char` in the generated code. When the statement `n > 1` is false, MATLAB does not execute `x = ['a' x]`. The class of `x` is `double`, the class of the empty array. However, the code generator considers all execution paths. It determines that based on the statement `x = ['a' x]`, the class of `x` is `char`.

### Workaround

Instead of using `x=[]` to create an empty array, create an empty array of a specific class. For example, use `blanks(0)` to create an empty array of characters.

```
function y = fun(n)
x = blanks(0);
if n > 1
 x = ['a' x];
end
y=class(x);
end
```

## Incompatibility with MATLAB in Matrix-Matrix Indexing

In matrix-matrix indexing, you use one matrix to index into another matrix. In MATLAB, the general rule for matrix-matrix indexing is that the size and orientation of the result match the size and orientation of the index matrix. For example, if `A` and `B` are matrices, `size(A(B))` equals `size(B)`. When `A` and `B` are vectors, MATLAB applies a special rule. The special vector-vector indexing rule is that the orientation of the result is the

orientation of the data matrix. For example,  $A$  is 1-by-5 and  $B$  is 3-by-1, then  $A(B)$  is 1-by-3.

The code generator applies the same matrix-matrix indexing rules as MATLAB. If  $A$  and  $B$  are variable-size matrices, to apply the matrix-matrix indexing rules, the code generator assumes that the `size(A(B))` equals `size(B)`. If, at run time,  $A$  and  $B$  become vectors and have different orientations, then the assumption is incorrect. Therefore, when run-time error checks are enabled, an error can occur.

To avoid this issue, force your data to be a vector by using the colon operator for indexing. For example, suppose that your code intentionally toggles between vectors and regular matrices at run time. You can do an explicit check for vector-vector indexing.

```
...
if isvector(A) && isvector(B)
 C = A(:);
 D = C(B(:));
else
 D = A(B);
end
...
```

The indexing in the first branch specifies that  $C$  and  $B(:)$  are compile-time vectors. Therefore, the code generator applies the indexing rule for indexing one vector with another vector. The orientation of the result is the orientation of the data vector,  $C$ .

## Incompatibility with MATLAB in Vector-Vector Indexing

In MATLAB, the special rule for vector-vector indexing is that the orientation of the result is the orientation of the data vector. For example, if  $A$  is 1-by-5 and  $B$  is 3-by-1, then  $A(B)$  is 1-by-3. If, however, the data vector  $A$  is a scalar, then the orientation of  $A(B)$  is the orientation of the index vector  $B$ .

The code generator applies the same vector-vector indexing rules as MATLAB. If  $A$  and  $B$  are variable-size vectors, to apply the indexing rules, the code generator assumes that the orientation of  $B$  matches the orientation of  $A$ . At run time, if  $A$  is scalar and the orientation of  $A$  and  $B$  do not match, then the assumption is incorrect. Therefore, when run-time error checks are enabled, a run-time error can occur.

To avoid this issue, make the orientations of the vectors match. Alternatively, index single elements by specifying the row and column. For example, `A(row, column)`.

## Incompatibility with MATLAB in Matrix Indexing Operations for Code Generation

The following limitation applies to matrix indexing operations for code generation:

- Initialization of the following style:

```
for i = 1:10
 M(i) = 5;
end
```

In this case, the size of `M` changes as the loop is executed. Code generation does not support increasing the size of an array over time.

For code generation, preallocate `M`.

```
M = zeros(1,10);
for i = 1:10
 M(i) = 5;
end
```

The following limitation applies to matrix indexing operations for code generation when dynamic memory allocation is disabled:

- `M(i:j)` where `i` and `j` change in a loop

During code generation, memory is not dynamically allocated for the size of the expressions that change as the program executes. To implement this behavior, use `for`-loops as shown:

```
...
M = ones(10,10);
for i=1:10
 for j = i:10
 M(i,j) = 2*M(i,j);
 end
end
...
```

---

**Note** The matrix `M` must be defined before entering the loop.

---

## Incompatibility with MATLAB in Concatenating Variable-Size Matrices

For code generation, when you concatenate variable-size arrays, the dimensions that are not being concatenated must match exactly.

## Differences When Curly-Brace Indexing of Variable-Size Cell Array Inside Concatenation Returns No Elements

Suppose that:

- `c` is a variable-size cell array.
- You access the contents of `c` by using curly braces. For example, `c{2:4}`.
- You include the results in concatenation. For example, `[a c{2:4} b]`.
- `c{I}` returns no elements. Either `c` is empty or the indexing inside the curly braces produces an empty result.

For these conditions, MATLAB omits `c{I}` from the concatenation. For example, `[a c{I} b]` becomes `[a b]`. The code generator treats `c{I}` as the empty array `[c{I}]`. The concatenation becomes `[... [c{i}] ...]`. This concatenation then omits the array `[c{I}]`. So that the properties of `[c{I}]` are compatible with the concatenation `[... [c{i}] ...]`, the code generator assigns the class, size, and complexity of `[c{I}]` according to these rules:

- The class and complexity are the same as the base type of the cell array.
- The size of the second dimension is always 0.
- For the rest of the dimensions, the size of  $N_i$  depends on whether the corresponding dimension in the base type is fixed or variable size.
  - If the corresponding dimension in the base type is variable size, the dimension has size 0 in the result.
  - If the corresponding dimension in the base type is fixed size, the dimension has that size in the result.

Suppose that `c` has a base type with class `int8` and size `10x7x8x?`. In the generated code, the class of `[c{I}]` is `int8`. The size of `[c{I}]` is `0x0x8x0`. The second dimension is 0. The first and last dimensions are 0 because those dimensions are variable size in the base type. The third dimension is 8 because the size of the third dimension of the base type is a fixed size 8.

Inside concatenation, if curly-brace indexing of a variable-size cell array returns no elements, the generated code can have the following differences from MATLAB:

- The class of `[...c{i}...]` in the generated code can differ from the class in MATLAB.

When `c{I}` returns no elements, MATLAB removes `c{I}` from the concatenation. Therefore, `c{I}` does not affect the class of the result. MATLAB determines the class of the result based on the classes of the remaining arrays, according to a precedence of classes. See “Valid Combinations of Unlike Classes” (MATLAB). In the generated code, the class of `[c{I}]` affects the class of the result of the overall concatenation `[...[c{I}]...]` because the code generator treats `c{I}` as `[c{I}]`. The previously described rules determine the class of `[c{I}]`.

- In the generated code, the size of `[c{I}]` can differ from the size in MATLAB.

In MATLAB, the concatenation `[c{I}]` is a 0x0 double. In the generated code, the previously described rules determine the size of `[c{I}]`.

## Variable-Sizing Restrictions for Code Generation of Toolbox Functions

### In this section...

“Common Restrictions” on page 52-26

“Toolbox Functions with Restrictions for Variable-Size Data” on page 52-27

### Common Restrictions

The following common restrictions apply to multiple toolbox functions, but only for code generation. To determine which of these restrictions apply to specific library functions, see the table in “Toolbox Functions with Restrictions for Variable-Size Data” on page 52-27.

#### Variable-length vector restriction

Inputs to the library function must be variable-length vectors or fixed-size vectors. A variable-length vector is a variable-size array that has the shape  $1 \times n$  or  $n \times 1$  (one dimension is variable sized and the other is fixed at size 1). Other shapes are not permitted, even if they are vectors at run time.

#### Automatic dimension restriction

This restriction applies to functions that take the working dimension (the dimension along which to operate) as input. In MATLAB and in code generation, if you do not supply the working dimension, the function selects it. In MATLAB, the function selects the first dimension whose size does not equal 1. For code generation, the function selects the first dimension that has a variable size or that has a fixed size that does not equal 1. If the working dimension has a variable size and it becomes 1 at run time, then the working dimension is different from the working dimension in MATLAB. Therefore, when run-time error checks are enabled, an error can occur.

For example, suppose that  $X$  is a variable-size matrix with dimensions  $1 \times 3 \times 5$ . In the generated code, `sum(X)` behaves like `sum(X,2)`. In MATLAB, `sum(X)` behaves like `sum(X,2)` unless `size(X,2)` is 1. In MATLAB, when `size(X,2)` is 1, `sum(X)` behaves like `sum(X,3)`.

To avoid this issue, specify the intended working dimension explicitly as a constant value. For example, `sum(X,2)`.

**Array-to-vector restriction**

The function issues an error when a variable-size array that is not a variable-length vector assumes the shape of a vector at run time. To avoid the issue, specify the input explicitly as a variable-length vector instead of a variable-size array.

**Array-to-scalar restriction**

The function issues an error if a variable-size array assumes a scalar value at run time. To avoid this issue, specify scalars as fixed size.

**Toolbox Functions with Restrictions for Variable-Size Data**

The following table lists functions that have code generation restrictions for variable-size data. For additional restrictions for these functions, and restrictions for all functions and objects supported for code generation, see “Functions and Objects Supported for C/C++ Code Generation — Alphabetical List” (MATLAB Coder).

| Function | Restrictions for Variable-Size Data                                                                                                                                                                               |

| mtimes   | <p>Consider the multiplication <math>A*B</math>. If the code generator is aware that <math>A</math> is scalar and <math>B</math> is a matrix, the code generator produces code for scalar-matrix multiplication. However, if the code generator is aware that <math>A</math> and <math>B</math> are variable-size matrices, it produces code for a general matrix multiplication. At run time, if <math>A</math> turns out to be scalar, the generated code does not change its behavior. Therefore, when run-time error checks are enabled, a size mismatch error can occur.</p> |

## Structure Definition for Code Generation

To generate efficient standalone code for structures, you must define and use structures differently than you normally would when running your code in the MATLAB environment:

| <b>What's Different</b>                                             | <b>More Information</b>                                         |
|---------------------------------------------------------------------|-----------------------------------------------------------------|
| Use a restricted set of operations.                                 | "Structure Operations Allowed for Code Generation" on page 53-3 |
| Observe restrictions on properties and values of scalar structures. | "Define Scalar Structures for Code Generation" on page 53-4     |
| Make structures uniform in arrays.                                  | "Define Arrays of Structures for Code Generation" on page 53-6  |
| Reference structure fields individually during indexing.            | "Index Substructures and Fields" on page 43-83                  |
| Avoid type mismatch when assigning values to structures and fields. | "Assign Values to Structures and Fields" on page 43-87          |

## Structure Operations Allowed for Code Generation

To generate efficient standalone code for MATLAB structures, you are restricted to the following operations:

- Index structure fields using dot notation
- Define primary function inputs as structures
- Pass structures to local functions

## Define Scalar Structures for Code Generation

### In this section...

“Restrictions When Defining Scalar Structures by Assignment” on page 53-4

“Adding Fields in Consistent Order on Each Control Flow Path” on page 53-4

“Restriction on Adding New Fields After First Use” on page 53-5

### Restrictions When Defining Scalar Structures by Assignment

When you define a scalar structure by assigning a variable to a preexisting structure, you do not need to define the variable before the assignment. However, if you already defined that variable, it must have the same class, size, and complexity as the structure you assign to it. In the following example, `p` is defined as a structure that has the same properties as the predefined structure `S`:

```
...
S = struct('a', 0, 'b', 1, 'c', 2);
p = S;
...
```

### Adding Fields in Consistent Order on Each Control Flow Path

When you create a structure, you must add fields in the same order on each control flow path. For example, the following code generates a compiler error because it adds the fields of structure `x` in a different order in each `if` statement clause:

```
function y = fcn(u) %#codegen
if u > 0
 x.a = 10;
 x.b = 20;
else
 x.b = 30; % Generates an error (on variable x)
 x.a = 40;
end
y = x.a + x.b;
```

In this example, the assignment to `x.a` comes before `x.b` in the first `if` statement clause, but the assignments appear in reverse order in the `else` clause. Here is the corrected code:

```
function y = fcn(u) %#codegen
if u > 0
 x.a = 10;
 x.b = 20;
else
 x.a = 40;
 x.b = 30;
end
y = x.a + x.b;
```

## Restriction on Adding New Fields After First Use

You cannot add fields to a structure after you perform the following operations on the structure:

- Reading from the structure
- Indexing into the structure array
- Passing the structure to a function

For example, consider this code:

```
...
x.c = 10; % Defines structure and creates field c
y = x; % Reads from structure
x.d = 20; % Generates an error
...
```

In this example, the attempt to add a new field `d` after reading from structure `x` generates an error.

This restriction extends across the structure hierarchy. For example, you cannot add a field to a structure after operating on one of its fields or nested structures, as in this example:

```
function y = fcn(u) %#codegen

x.c = 10;
y = x.c;
x.d = 20; % Generates an error
```

In this example, the attempt to add a new field `d` to structure `x` after reading from the structure's field `c` generates an error.

## Define Arrays of Structures for Code Generation

### In this section...

“Ensuring Consistency of Fields” on page 53-6

“Using repmat to Define an Array of Structures with Consistent Field Properties” on page 53-6

“Defining an Array of Structures by Using struct” on page 53-7

“Defining an Array of Structures Using Concatenation” on page 53-7

### Ensuring Consistency of Fields

For code generation, when you create an array of MATLAB structures, corresponding fields in the array elements must have the same size, type, and complexity.

Once you have created the array of structures, you can make the structure fields variable-size by using `coder.varsize`. See “Declare Variable-Size Structure Fields” (MATLAB Coder).

### Using repmat to Define an Array of Structures with Consistent Field Properties

You can create an array of structures from a scalar structure by using the MATLAB `repmat` function, which replicates and tiles an existing scalar structure:

- 1 Create a scalar structure, as described in “Define Scalar Structures for Code Generation” on page 53-4.
- 2 Call `repmat`, passing the scalar structure and the dimensions of the array.
- 3 Assign values to each structure using standard array indexing and structure dot notation.

For example, the following code creates `X`, a 1-by-3 array of scalar structures. Each element of the array is defined by the structure `s`, which has two fields, `a` and `b`:

```
...
s.a = 0;
s.b = 0;
X = repmat(s,1,3);
```

```

X(1).a = 1;
X(2).a = 2;
X(3).a = 3;
X(1).b = 4;
X(2).b = 5;
X(3).b = 6;
...

```

## Defining an Array of Structures by Using struct

To create an array of structures using the `struct` function, specify the field value arguments as cell arrays. Each cell array element is the value of the field in the corresponding structure array element. For code generation, corresponding fields in the structures must have the same type. Therefore, the elements in a cell array of field values must have the same type.

For example, the following code creates a 1-by-3 structure array. For each structure in the array of structures, `a` has type `double` and `b` has type `char`.

```
s = struct('a', {1 2 3}, 'b', {'a' 'b' 'c'});
```

## Defining an Array of Structures Using Concatenation

To create a small array of structures, you can use the concatenation operator, square brackets ( `[ ]` ), to join one or more structures into an array. See “Creating, Concatenating, and Expanding Matrices” (MATLAB). For code generation, the structures that you concatenate must have the same size, class, and complexity.

For example, the following code uses concatenation and a local function to create the elements of a 1-by-3 structure array:

```

...
W = [sab(1,2) sab(2,3) sab(4,5)];

function s = sab(a,b)
 s.a = a;
 s.b = b;
...

```

## Index Substructures and Fields

Use these guidelines when indexing substructures and fields for code generation:

### Reference substructure field values individually using dot notation

For example, the following MATLAB code uses dot notation to index fields and substructures:

```
...
substruct1.a1 = 15.2;
substruct1.a2 = int8([1 2;3 4]);

mystruct = struct('ele1',20.5,'ele2',single(100),
 'ele3',substruct1);

substruct2 = mystruct;
substruct2.ele3.a2 = 2*(substruct1.a2);
...
```

The generated code indexes elements of the structures in this example by resolving symbols as follows:

| Dot Notation            | Symbol Resolution                                                                                |
|-------------------------|--------------------------------------------------------------------------------------------------|
| substruct1.a1           | Field a1 of local structure substruct1                                                           |
| substruct2.ele3.a1      | Value of field a1 of field ele3, a substructure of local structure substruct2                    |
| substruct2.ele3.a2(1,1) | Value in row 1, column 1 of field a2 of field ele3, a substructure of local structure substruct2 |

### Reference field values individually in structure arrays

To reference the value of a field in a structure array, you must index into the array to the structure of interest and then reference that structure's field individually using dot notation, as in this example:

```
...
y = X(1).a % Extracts the value of field a
 % of the first structure in array X
...
```

To reference all the values of a particular field for each structure in an array, use this notation in a for loop, as in this example:

```
...
s.a = 0;
s.b = 0;
X = repmat(s,1,5);
for i = 1:5
 X(i).a = i;
 X(i).b = i+1;
end
```

This example uses the `repmat` function to define an array of structures, each with two fields `a` and `b` as defined by `s`. See “Define Arrays of Structures for Code Generation” on page 53-6 for more information.

### **Do not reference fields dynamically**

You cannot reference fields in a structure by using dynamic names, which express the field as a variable expression that MATLAB evaluates at run time (see “Generate Field Names from Variables” (MATLAB)).

## Assign Values to Structures and Fields

When assigning values to a structure, substructure, or field for code generation, use these guidelines:

### Field properties must be consistent across structure-to-structure assignments

| If:                                                                                | Then:                                                                                    |
|------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------|
| Assigning one structure to another structure.                                      | Define each structure with the same number, type, and size of fields.                    |
| Assigning one structure to a substructure of a different structure and vice versa. | Define the structure with the same number, type, and size of fields as the substructure. |
| Assigning an element of one structure to an element of another structure.          | The elements must have the same type and size.                                           |

### For structures with constant fields, do not assign field values inside control flow constructs

In the following code, the code generator recognizes that the structure fields `s.a` and `s.b` are constants.

```
function y = mystruct()
s.a = 3;
s.b = 5;
y = zeros(s.a,s.b);
```

If a field of a structure is assigned inside a control flow construct, the code generator does not recognize that `s.a` and `s.b` are constant. Consider the following code:

```
function y = mystruct(x)
s.a = 3;
if x > 1
 s.b = 4;
else
 s.b = 5;
end
y = zeros(s.a,s.b);
```

If variable-sizing is enabled, `y` is treated as a variable-size array. If variable-sizing is disabled, `y`, the code generator reports an error.

**Do not assign mxArray to structures**

You cannot assign mxArray to structure elements; convert mxArray to known types before code generation (see “Working with mxArray” on page 59-16).

**Do not assign handle classes or sparse arrays to global structure variables**

Global structure variables cannot contain handle objects or sparse arrays.

## Pass Large Structures as Input Parameters

If you generate a MEX function for a MATLAB function that takes a large structure as an input parameter, for example, a structure containing fields that are matrices, the MEX function might fail to load. This load failure occurs because, when you generate a MEX function from a MATLAB function that has input parameters, the code generator allocates memory for these input parameters on the stack. To avoid this issue, pass the structure by reference to the MATLAB function. For example, if the original function signature is:

```
y = foo(a, S)
```

where *S* is the structure input, rewrite the function to:

```
[y, S] = foo(a, S)
```

# Code Generation for Cell Arrays

- “Control Whether a Cell Array Is Variable-Size” on page 54-5
- “Cell Array Limitations for Code Generation” on page 54-8

## Code Generation for Cell Arrays

When you generate code from MATLAB code that contains cell arrays, the code generator classifies the cell arrays as homogeneous or heterogeneous. This classification determines how a cell array is represented in the generated code. It also determines how you can use the cell array in MATLAB code from which you generate code.

When you use cell arrays in MATLAB code that is intended for code generation, you must adhere to certain restrictions. See “Cell Array Limitations for Code Generation” on page 54-8.

### Homogeneous vs. Heterogeneous Cell Arrays

A homogeneous cell array has these characteristics:

- The cell array is represented as an array in the generated code.
- All elements have the same properties. The type associated with the cell array specifies the properties of all elements rather than the properties of individual elements.
- The cell array can be variable-size.
- You can index into the cell array with an index whose value is determined at run time.

A heterogeneous cell array has these characteristics:

- The cell array is represented as a structure in the generated code. Each element is represented as a field of the structure.
- The elements can have different properties. The type associated with the cell array specifies the properties of each element individually.
- The cell array cannot be variable-size.
- You must index into the cell array with a constant index or with `for`-loops that have constant bounds.

The code generator uses heuristics to determine the classification of a cell array as homogeneous or heterogeneous. It considers the properties (class, size, complexity) of the elements and other factors, such as how you use the cell array in your program. Depending on how you use a cell array, the code generator can classify a cell array as homogeneous in one case and heterogeneous in another case. For example, consider the cell array `{1 [2 3]}`. The code generator can classify this cell array as a heterogeneous

1-by-2 cell array. The first element is double scalar. The second element is a 1-by-2 array of doubles. However, if you index into this cell array with an index whose value is determined at run time, the code generator classifies it as a homogeneous cell array. The elements are variable-size arrays of doubles with an upper bound of 2.

## Controlling Whether a Cell Array Is Homogeneous or Heterogeneous

For cell arrays with certain characteristics, you cannot control the classification as homogeneous or heterogeneous:

- If the elements have different classes, the cell array must be heterogeneous.
- If the cell array is variable-size, it must be homogeneous.
- If you index into the cell array with an index whose value is determined at run time, the cell array must be homogeneous.

For other cell arrays, you can control the classification as homogeneous or heterogeneous.

- If the cell array elements have the same class, you can force a cell array to be homogeneous by using `coder. varsize`. See “Control Whether a Cell Array Is Variable-Size” on page 54-5.

## Cell Arrays in Reports

To see whether a cell array is homogeneous or heterogeneous, view the variable in the MATLAB Function report.

For a homogeneous cell array, the report has one entry that specifies the properties of all elements. The notation `{ : }` indicates that all elements of the cell array have the same properties.

| ALL MESSAGES (0) |        | VARIABLES |        |  |
|------------------|--------|-----------|--------|--|
| Name             | Type   | Size      | Class  |  |
| z                | Output | 1 × 1     | double |  |
| ▲ c              | Local  | 1 × 3     | cell   |  |
| { }              |        | 1 × 1     | double |  |

For a heterogeneous cell array, the report has an entry for each element. For example, for a heterogeneous cell array `c` with two elements, the entry for `c{1}` shows the properties for the first element. The entry for `c{2}` shows the properties for the second element.

| ALL MESSAGES (0) |        | VARIABLES |        |  |
|------------------|--------|-----------|--------|--|
| Name             | Type   | Size      | Class  |  |
| <code>z</code>   | Output | 1 × 1     | double |  |
| ▾ <code>c</code> | Local  | 1 × 2     | cell   |  |
| <code>{1}</code> |        | 1 × 1     | double |  |
| <code>{2}</code> |        | 1 × 1     | char   |  |

## Control Whether a Cell Array Is Variable-Size

The code generator classifies a variable-size cell array as homogeneous. The cell array elements must have the same class. In the generated code, the cell array is represented as an array.

To make a cell array variable-size:

- Create the cell array by using the `cell` function. For example:

```
function z = mycell(n, j)
%#codegen
assert (n < 100);
x = cell(1,n);
for i = 1:n
 x{i} = i;
end
z = x{j};
end
```

For code generation, when you create a variable-size cell array by using `cell`, you must adhere to certain restrictions. See “Definition of Variable-Size Cell Array by Using `cell`” on page 54-10.

- Grow the cell array. For example:

```
function z = mycell(n)
%#codegen
c = {1 2 3};
if n > 3
 c = {1 2 3 4};
end
z = c{n};
end
```

- Force the cell array to be variable-size by using `coder. varsize`. Consider this code:

```
function y = mycellfun()
%#codegen
c = {1 2 3};
coder. varsize('c', [1 10]);
y = c{1};
end
```

Without `coder. varsize`, `c` is fixed-size with dimensions 1-by-3. With `coder. varsize`, `c` is variable-size with an upper bound of 10.

Sometimes, using `coder. varsize` changes the classification of a cell array from heterogeneous to homogeneous. Consider this code:

```
function y = mycell()
 %#codegen
 c = {1 [2 3]};
 y = c{2};
end
```

The code generator classifies `c` as heterogeneous because the elements have different sizes. `c` is fixed-size with dimensions 1-by-2. If you use `coder. varsize` with `c`, it becomes homogeneous. For example:

```
function y = mycell()
 %#codegen
 c = {1 [2 3]};
 coder. varsize('c', [1 10], [0 1]);
 y = c{2};
end
```

`c` becomes a variable-size homogeneous cell array with dimensions 1-by-:10.

To force `c` to be homogeneous, but not variable-size, specify that none of the dimensions vary. For example:

```
function y = mycell()
 %#codegen
 c = {1 [2 3]};
 coder. varsize('c', [1 2], [0 0]);
 y = c{2};
end
```

## Cell Array Limitations for Code Generation

When you use cell arrays in MATLAB code that is intended for code generation, you must adhere to these restrictions:

- “Cell Array Element Assignment” on page 54-8
- “Variable-Size Cell Arrays” on page 54-9
- “Definition of Variable-Size Cell Array by Using `cell`” on page 54-10
- “Cell Array Indexing” on page 54-14
- “Growing a Cell Array by Using `{end + 1}`” on page 54-15
- “Cell Array Contents” on page 54-16
- “Passing Cell Arrays to External C/C++ Functions” on page 54-16
- “Use in MATLAB Function Block” on page 54-16

### Cell Array Element Assignment

You must assign a cell array element on all execution paths before you use it. For example:

```
function z = foo(n)
%#codegen
c = cell(1,3);
if n < 1
 c{2} = 1;

else
 c{2} = n;
end
z = c{2};
end
```

The code generator considers passing a cell array to a function or returning it from a function as a use of all elements of the cell array. Therefore, before you pass a cell array to a function or return it from a function, you must assign all of its elements. For example, the following code is not allowed because it does not assign a value to `c{2}` and `c` is a function output.

```
function c = foo()
%#codegen
```

```
c = cell(1,3);
c{1} = 1;
c{3} = 3;
end
```

The assignment of values to elements must be consistent on all execution paths. The following code is not allowed because `y{2}` is double on one execution path and char on the other execution path.

```
function y = foo(n)
y = cell(1,3)
if n > 1;
 y{1} = 1;
 y{2} = 2;
 y{3} = 3;
else
 y{1} = 10;
 y{2} = 'a';
 y{3} = 30;
end
```

## Variable-Size Cell Arrays

- `coder. varsize` is not supported for heterogeneous cell arrays.
- If you use the `cell` function to define a fixed-size cell array, you cannot use `coder. varsize` to specify that the cell array has a variable size. For example, this code causes a code generation error because `x = cell(1,3)` makes `x` a fixed-size, 1-by-3 cell array.

```
...
x = cell(1,3);
coder. varsize('x',[1 5])
...
```

You can use `coder. varsize` with a cell array that you define by using curly braces. For example:

```
...
x = {1 2 3};
coder. varsize('x',[1 5])
...
```

- To create a variable-size cell array by using the `cell` function, use this code pattern:

```
function mycell(n)
 %#codegen
 x = cell(1,n);
 for i = 1:n
 x{i} = i;
 end
end
```

See “Definition of Variable-Size Cell Array by Using cell” on page 54-10.

To specify upper bounds for the cell array, use `coder. varsize`.

```
function mycell(n)
 %#codegen
 x = cell(1,n);
 for i = 1:n
 x{i} = i;
 coder. varsize('x',[1,20]);
 end
end
```

## Definition of Variable-Size Cell Array by Using cell

For code generation, before you use a cell array element, you must assign a value to it. When you use `cell` to create a variable-size cell array, for example, `cell(1,n)`, MATLAB assigns an empty matrix to each element. However, for code generation, the elements are unassigned. For code generation, after you use `cell` to create a variable-size cell array, you must assign all elements of the cell array before any use of the cell array. For example:

```
function z = mycell(n, j)
 %#codegen
 assert(n < 100);
 x = cell(1,n);
 for i = 1:n
 x{i} = i;
 end
 z = x{j};
end
```

The code generator analyzes your code to determine whether all elements are assigned before the first use of the cell array. If the code generator detects that some elements are not assigned, code generation fails with an error message. For example, modify the upper bound of the `for`-loop to `j`.

```
function z = mycell(n, j)
%#codegen
assert(n < 100);
x = cell(1,n);
for i = 1:j %<- Modified here
 x{i} = i;
end
z = x{j};
end
```

With this modification and with inputs *j* less than *n*, the function does not assign values to all of the cell array elements. Code generation produces the error:

```
Unable to determine that every element of 'x{:}' is assigned
before this line.
```

Sometimes, even though your code assigns all elements of the cell array, the code generator reports this message because the analysis does not detect that all elements are assigned. See “Unable to Determine That Every Element of Cell Array Is Assigned” on page 61-11.

To avoid this error, follow these guidelines:

- When you use `cell` to define a variable-size cell array, write code that follows this pattern:

```
function z = mycell(n, j)
%#codegen
assert(n < 100);
x = cell(1,n);
for i = 1:n
 x{i} = i;
end
z = x{j};
end
```

Here is the pattern for a multidimensional cell array:

```
function z = mycell(m,n,p)
%#codegen
assert(m < 100);
assert(n < 100);
assert(p < 100);
x = cell(m,n,p);
for i = 1:m
```

```
 for j = 1:n
 for k = 1:p
 x{i,j,k} = i+j+k;
 end
 end
end
z = x{m,n,p};
end
```

- Increment or decrement the loop counter by 1.
- Define the cell array within one loop or one set of nested loops. For example, this code is not allowed:

```
function z = mycell(n, j)
assert(n < 50);
assert(j < 50);
x = cell(1,n);
for i = 1:5
 x{i} = 5;
end
for i = 6:n
 x{i} = 5;
end
z = x{j};
end
```

- Use the same variables for the cell dimensions and loop initial and end values. For example, code generation fails for the following code because the cell creation uses `n` and the loop end value uses `m`:

```
function z = mycell(n, j)
assert(n < 50);
assert(j < 50);
x = cell(1,n);
m = n;
for i = 1:m
 x{i} = 2;
end
z = x{j};
end
```

Rewrite the code to use `n` for the cell creation and the loop end value:

```
function z = mycell(n, j)
assert(n < 50);
```

```

assert(j < 50);
x = cell(1,n);
for i = 1:n
 x{i} = 2;
end
z = x{j};
end

```

- Create the cell array with this pattern:

```
x = cell(1,n)
```

Do not assign the cell array to a field of a structure or a property of an object. For example, this code is not allowed:

```

myobj.prop = cell(1,n)
for i = 1:n
 ...
end

```

Do not use the `cell` function inside the cell array constructor `{}`. For example, this code is not allowed:

```
x = {cell(1,n)};
```

- The cell array creation and the loop that assigns values to the cell array elements must be together in a unique execution path. For example, the following code is not allowed.

```

function z = mycell(n)
assert(n < 100);
if n > 3
 c = cell(1,n);
else
 c = cell(n,1);
end
for i = 1:n
 c{i} = i;
end
z = c{n};
end

```

To fix this code, move the assignment loop inside the code block that creates the cell array.

```

function z = cellerr(n)
assert(n < 100);

```

```
if n > 3
 c = cell(1,n);
 for i = 1:n
 c{i} = i;
 end
else
 c = cell(n,1);
 for i = 1:n
 c{i} = i;
 end
end
z = c{n};
end
```

## Cell Array Indexing

- You cannot index cell arrays by using smooth parentheses ( ). Consider indexing cell arrays by using curly braces { } to access the contents of the cell.
- You must index into heterogeneous cell arrays by using constant indices or by using for-loops with constant bounds.

For example, the following code is not allowed.

```
x = {1, 'mytext'};
disp(x{randi});
```

You can index into a heterogeneous cell array in a for-loop with constant bounds because the code generator unrolls the loop. Unrolling creates a separate copy of the loop body for each loop iteration, which makes the index in each loop iteration constant. However, if the for-loop has a large body or it has many iterations, the unrolling can increase compile time and generate inefficient code.

If A and B are constant, the following code shows indexing into a heterogeneous cell array in a for-loop with constant bounds.

```
x = {1, 'mytext'};
for i = A:B
 disp(x{i});
end
```

## Growing a Cell Array by Using `{end + 1}`

To grow a cell array `X`, you can use `X{end + 1}`. For example:

```
...
X = {1 2};
X{end + 1} = 'a';
...
```

When you use `{end + 1}` to grow a cell array, follow these restrictions:

- In a MATLAB Function block, do not use `{end + 1}` in a `for`-loop.
- Use only `{end + 1}`. Do not use `{end + 2}`, `{end + 3}`, and so on.
- Use `{end + 1}` with vectors only. For example, the following code is not allowed because `X` is a matrix, not a vector:

```
...
X = {1 2; 3 4};
X{end + 1} = 5;
```

- Use `{end + 1}` only with a variable. In the following code, `{end + 1}` does not cause `{1 2 3}` to grow. In this case, the code generator treats `{end + 1}` as an out-of-bounds index into `X{2}`.

```
...
X = {'a' { 1 2 3 }};
X{2}{end + 1} = 4;
...
```

- When `{end + 1}` grows a cell array in a loop, the cell array must be variable-size. Therefore, the cell array must be homogeneous on page 54-2.

This code is allowed because `X` is homogeneous.

```
...
X = {1 2};
for i=1:n
 X{end + 1} = 3;
end
...
```

This code is not allowed because `X` is heterogeneous.

```
...
