`e = edge(Mdl, tbl, Y)` returns the classification edge (e) for the naive Bayes classifier `Mdl` using predictor data in table `tbl` and the class labels in vector `Y`.

`e = edge(Mdl, X, Y)` returns the classification edge on page 32-1512 (e) for the naive Bayes classifier `Mdl` using predictor data `X` and class labels `Y`.

`e = edge(____, Name, Value)` computes the classification edge with additional options specified by one or more `Name, Value` pair arguments, using any of the previous syntaxes.

Input Arguments

Mdl — Naive Bayes classifier

`ClassificationNaiveBayes model` | `CompactClassificationNaiveBayes model`

Naive Bayes classifier, specified as a `ClassificationNaiveBayes` model or `CompactClassificationNaiveBayes` model returned by `fitcnb` or `compact`, respectively.

tbl — Sample data

table

Sample data, specified as a table. Each row of `tbl` corresponds to one observation, and each column corresponds to one predictor variable. Optionally, `tbl` can contain additional columns for the response variable and observation weights. `tbl` must contain all the predictors used to train `Mdl`. Multi-column variables and cell arrays other than cell arrays of character vectors are not allowed.

If you trained `Mdl` using sample data contained in a `table`, then the input data for this method must also be in a table.

Data Types: `table`

ResponseVarName — Response variable name

name of a variable in `tbl`

Response variable name, specified as the name of a variable in `tbl`.

You must specify `ResponseVarName` as a character vector or string scalar. For example, if the response variable `y` is stored as `tbl.y`, then specify it as `'y'`. Otherwise, the software treats all columns of `tbl`, including `y`, as predictors when training the model.

The response variable must be a categorical, character, or string array, logical or numeric vector, or cell array of character vectors. If the response variable is a character array, then each element must correspond to one row of the array.

Data Types: `char` | `string`

X — Predictor data

numeric matrix

Predictor data, specified as a numeric matrix.

Each row of `X` corresponds to one observation (also known as an instance or example), and each column corresponds to one variable (also known as a feature). The variables making up the columns of `X` should be the same as the variables that trained `Mdl`.

The length of `Y` and the number of rows of `X` must be equal.

Data Types: `double` | `single`

Y — Class labels

categorical array | character array | string array | logical vector | vector of numeric values
| cell array of character vectors

Class labels, specified as a categorical, character, or string array, logical or numeric vector, or cell array of character vectors. `Y` must be the same as the data type of `Mdl.ClassNames`. (The software treats string arrays as cell arrays of character vectors.)

The length of `Y` and the number of rows of `tbl` or `X` must be equal.

Data Types: `categorical` | `char` | `string` | `logical` | `single` | `double` | `cell`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Weights — Observation weights

`ones(size(X,1),1)` (default) | numeric vector | name of a variable in `tbl`

Observation weights, specified as the comma-separated pair consisting of `'Weights'` and a numeric vector or the name of a variable in `tbl`. The software weighs the observations in each row of `X` or `tbl` with the corresponding weight in `Weights`.

If you specify `Weights` as a vector, then the size of `Weights` must be equal to the number of rows of `X` or `tbl`.

If you specify `Weights` as the name of a variable in `tbl`, you must do so as a character vector or string scalar. For example, if the weights are stored as `tbl.w`, then specify `Weights` as `'w'`. Otherwise, the software treats all columns of `tbl`, including `tbl.w`, as predictors.

If you do not specify your own loss function, then the software normalizes `Weights` to add up to 1.

Data Types: `double` | `char` | `string`

Output Arguments

e — Classification edge

scalar

Classification edge on page 32-1512, returned as a scalar. If you supply `Weights`, then `e` is the weighted classification edge.

Examples

Estimate the Test Sample Edge of Naive Bayes Classifiers

Load Fisher's iris data set.

```
load fisheriris
X = meas;      % Predictors
Y = species;  % Response
rng(1);       % For reproducibility
```

Train a naive Bayes classifier. Specify a 30% holdout sample for testing. It is good practice to specify the class order. Assume that each predictor is conditionally, normally distributed given its label.

```
CVMDL = fitcnb(X,Y,'Holdout',0.30,...
    'ClassNames',{'setosa','versicolor','virginica'});
CMDL = CVMDL.Trained{1};      % Extract trained, compact classifier
testInds = test(CVMDL.Partition); % Extract the test indices
XTest = X(testInds,:);
YTest = Y(testInds);
```

`CVMDL` is a `ClassificationPartitionedModel` classifier. It contains the property `Trained`, which is a 1-by-1 cell array holding a `CompactClassificationNaiveBayes` classifier that the software trained using the training set.

Estimate the test sample edge.

```
e = edge(CMDL,XTest,YTest)

e = 0.8244
```

The estimated test sample margin average is approximately `0.82`. This indicates that, on average, the test sample difference between the estimated posterior probability for the

predicted class and the posterior probability for the class with the next lowest posterior probability is approximately 0.82. This indicates that the classifier labels with high confidence.

Estimate the Test Sample Weighted Margin Mean of Naive Bayes Classifiers

Load Fisher's iris data set.

```
load fisheriris
X = meas;    % Predictors
Y = species; % Response
rng(1);
```

Suppose that the setosa iris measurements are lower quality because they were measured with an older technology. One way to incorporate this is to weigh the setosa iris measurements less than the other observations.

Define a weight vector that weighs the better quality observations twice the other observations.

```
n = size(X,1);
idx = strcmp(Y,'setosa');
weights = ones(size(X,1),1);
weights(idx) = 0.5;
```

Train a naive Bayes classifier. Specify the weighting scheme and a 30% holdout sample for testing. It is good practice to specify the class order. Assume that each predictor is conditionally, normally distributed given its label.

```
CVMdl = fitcnb(X,Y,'Weights',weights,'Holdout',0.30,...
    'ClassNames',{'setosa','versicolor','virginica'});
CModel = CVMdl.Trained{1};           % Extract trained, compact classifier
testInds = test(CVMdl.Partition); % Extract the test indices
XTest = X(testInds,:);
YTest = Y(testInds);
wTest = weights(testInds);
```

CVMdl is a `ClassificationPartitionedModel` classifier. It contains the property `Trained`, which is a 1-by-1 cell array holding a `CompactClassificationNaiveBayes` classifier that the software trained using the training set.

Estimate the test sample weighted edge using the weighting scheme.

```
e = edge(CMDL,XTest,YTest,'Weights',wTest)
e = 0.7893
```

The test sample weighted average margin is approximately 0.79. This indicates that, on average, the test sample difference between the estimated posterior probability for the predicted class and the posterior probability for the class with the next lowest posterior probability is approximately 0.79. This indicates that the classifier labels with high confidence.

Select Naive Bayes Classifier Features by Comparing Test Sample Edges

The classifier edge measures the average of the classifier margins. One way to perform feature selection is to compare test sample edges from multiple models. Based solely on this criterion, the classifier with the highest edge is the best classifier.

Load Fisher's iris data set.

```
load fisheriris
X = meas;    % Predictors
Y = species; % Response
rng(1);
```

Partition the data set into training and test sets. Specify a 30% holdout sample for testing.

```
Partition = cvpartition(Y,'Holdout',0.30);
testInds = test(Partition); % Indices for the test set
XTest = X(testInds,:);
YTest = Y(testInds,:);
```

Partition defines the data set partition.

Define these two data sets:

- `fullX` contains all predictors.
- `partX` contains the last two predictors.

```
fullX = X;
partX = X(:,3:4);
```

Train naive Bayes classifiers for each predictor set. Specify the partition definition.

```
FCVMdl = fitcnb(fullX,Y,'CVPartition',Partition);  
PCVMdl = fitcnb(partX,Y,'CVPartition',Partition);  
FCMdl = FCVMdl.Trained{1};  
PCMdl = PCVMdl.Trained{1};
```

FCVMdl and PCVMdl are `ClassificationPartitionedModel` classifiers. They contain the property `Trained`, which is a 1-by-1 cell array holding a `CompactClassificationNaiveBayes` classifier that the software trained using the training set.

Estimate the test sample edge for each classifier.

```
fullEdge = edge(FCMdl,XTest,YTest)  
  
fullEdge = 0.8244  
  
partEdge = edge(PCMdl,XTest(:,3:4),YTest)  
  
partEdge = 0.8420
```

The test-sample edges of the classifiers are nearly the same. However, the model trained using two predictors (PCMdl) is less complex.

Definitions

Classification Edge

The classification edge is the weighted mean of the classification margins.

If you supply weights, then the software normalizes them to sum to the prior probability of their respective class. The software uses the normalized weights to compute the weighted mean.

One way to choose among multiple classifiers, e.g., to perform feature selection, is to choose the classifier that yields the highest edge.

Classification Margins

The classification margins are, for each observation, the difference between the score for the true class and maximal score for the false classes. Provided that they are on the same

scale, margins serve as a classification confidence measure, i.e., among multiple classifiers, those that yield larger margins are better.

Posterior Probability

The posterior probability is the probability that an observation belongs in a particular class, given the data.

For naive Bayes, the posterior probability that a classification is k for a given observation (x_1, \dots, x_p) is

$$\widehat{P}(Y = k | x_1, \dots, x_p) = \frac{P(X_1, \dots, X_p | y = k)\pi(Y = k)}{P(X_1, \dots, X_p)},$$

where:

- $P(X_1, \dots, X_p | y = k)$ is the conditional joint density of the predictors given they are in class k . `Mdl.DistributionNames` stores the distribution names of the predictors.
- $\pi(Y = k)$ is the class prior probability distribution. `Mdl.Prior` stores the prior distribution.
- $P(X_1, \dots, X_p)$ is the joint density of the predictors. The classes are discrete, so

$$P(X_1, \dots, X_p) = \sum_{k=1}^K P(X_1, \dots, X_p | y = k)\pi(Y = k).$$

Prior Probability

The prior probability of a class is the believed relative frequency with which observations from that class occur in a population.

Score

The naive Bayes score is the class posterior probability given the observation.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. For more information, see “Tall Arrays” (MATLAB).

Topics

“Naive Bayes Classification” on page 21-2

edge

Package: classreg.learning.classif

Find classification edge for support vector machine (SVM) classifier

Syntax

```
e = edge(SVMModel, TBL, ResponseVarName)
```

```
e = edge(SVMModel, TBL, Y)
```

```
e = edge(SVMModel, X, Y)
```

```
e = edge( ___, 'Weights', weights)
```

Description

`e = edge(SVMModel, TBL, ResponseVarName)` returns the classification edge on page 32-1521 (e) for the support vector machine (SVM) classifier `SVMModel` using the predictor data in table `TBL` and the class labels in `TBL.ResponseVarName`.

The classification edge (e) is a scalar value that represents the weighted mean of the classification margins on page 32-1521.

`e = edge(SVMModel, TBL, Y)` returns the classification edge on page 32-1521 (e) for the SVM classifier `SVMModel` using the predictor data in table `TBL` and the class labels in `Y`.

`e = edge(SVMModel, X, Y)` returns the classification edge for `SVMModel` using the predictor data in matrix `X` and the class labels in `Y`.

`e = edge(___, 'Weights', weights)` computes the classification edge for the observation weights supplied in `weights` using any of the input arguments in the previous syntaxes.

Examples

Estimate Test Sample Edge of SVM Classifiers

Load the ionosphere data set.

```
load ionosphere
rng(1); % For reproducibility
```

Train an SVM classifier. Specify a 15% holdout sample for testing, standardize the data, and specify that 'g' is the positive class.

```
CVSVMModel = fitcsvm(X,Y,'Holdout',0.15,'ClassNames',{'b','g'},...
    'Standardize',true);
CompactSVMModel = CVSVMModel.Trained{1}; % Extract trained, compact classifier
testInds = test(CVSVMModel.Partition); % Extract the test indices
XTest = X(testInds,:);
YTest = Y(testInds,:);
```

CVSVMModel is a `ClassificationPartitionedModel` classifier. It contains the property `Trained`, which is a 1-by-1 cell array holding a `CompactClassificationSVM` classifier that the software trained using the training set.

Estimate the test sample edge.

```
e = edge(CompactSVMModel,XTest,YTest)
e = 5.0765
```

The margin average of the test sample is approximately 5.

Estimate Test Sample Weighted Margin Mean of SVM Classifiers

Suppose that the observations in a data set are measured sequentially, and that the last 150 observations have better quality due to a technology upgrade. Incorporate this advancement by weighing the better quality observations more than the other observations.

Load the ionosphere data set.

```
load ionosphere
rng(1); % For reproducibility
```

Define a weight vector that weighs the better quality observations two times the other observations.

```
n = size(X,1);
weights = [ones(n-150,1);2*ones(150,1)];
```

Train an SVM classifier. Specify the weighting scheme and a 15% holdout sample for testing. Also, standardize the data and specify that 'g' is the positive class.

```
CVSVMModel = fitcsvm(X,Y,'Weights',weights,'Holdout',0.15,...
    'ClassNames',{'b','g'},'Standardize',true);
CompactSVMModel = CVSVMModel.Trained{1};
testInds = test(CVSVMModel.Partition); % Extract the test indices
XTest = X(testInds,:);
YTest = Y(testInds,:);
wTest = weights(testInds,:);
```

CVSVMModel is a trained ClassificationPartitionedModel classifier. It contains the property Trained, which is a 1-by-1 cell array holding a CompactClassificationSVM classifier that the software trained using the training set.

Estimate the test sample weighted edge using the weighting scheme.

```
e = edge(CompactSVMModel,XTest,YTest,'Weights',wTest)
e = 4.8341
```

The weighted average margin of the test sample is approximately 5.

Select SVM Classifier Features by Comparing Test Sample Edges

Perform feature selection by comparing test sample edges from multiple models. Based solely on this comparison, the classifier with the highest edge is the best classifier.

Load the ionosphere data set.

```
load ionosphere
rng(1); % For reproducibility
```

Partition the data set into training and test sets. Specify a 15% holdout sample for testing.

```
Partition = cvpartition(Y, 'Holdout', 0.15);  
testInds = test(Partition); % Indices for the test set  
XTest = X(testInds,:);  
YTest = Y(testInds,:);
```

Partition defines the data set partition.

Define these two data sets:

- `fullX` contains all predictors (except the removed column of 0s).
- `partX` contains the last 20 predictors.

```
fullX = X;  
partX = X(:, end-20:end);
```

Train SVM classifiers for each predictor set. Specify the partition definition.

```
FullCVSVMModel = fitcsvm(fullX, Y, 'CVPartition', Partition);  
PartCVSVMModel = fitcsvm(partX, Y, 'CVPartition', Partition);  
FCSVMModel = FullCVSVMModel.Trained{1};  
PCSVMModel = PartCVSVMModel.Trained{1};
```

`FullCVSVMModel` and `PartCVSVMModel` are `ClassificationPartitionedModel` classifiers. They contain the property `Trained`, which is a 1-by-1 cell array holding a `CompactClassificationSVM` classifier that the software trained using the training set.

Estimate the test sample edge for each classifier.

```
fullEdge = edge(FCSVMModel, XTest, YTest)  
  
fullEdge = 2.8319  
  
partEdge = edge(PCSVMModel, XTest(:, end-20:end), YTest)  
  
partEdge = 1.5540
```

The edge for the classifier trained on the complete data set is greater, suggesting that the classifier trained with all the predictors is better.

Input Arguments

SVMModel — SVM classification model

ClassificationSVM model object | CompactClassificationSVM model object

SVM classification model, specified as a ClassificationSVM model object or CompactClassificationSVM model object returned by fitcsvm or compact, respectively.

TBL — Sample data

table

Sample data, specified as a table. Each row of TBL corresponds to one observation, and each column corresponds to one predictor variable. Optionally, TBL can contain additional columns for the response variable and observation weights. TBL must contain all of the predictors used to train SVMModel. Multicolumn variables and cell arrays other than cell arrays of character vectors are not allowed.

If TBL contains the response variable used to train SVMModel, then you do not need to specify ResponseVarName or Y.

If you trained SVMModel using sample data contained in a table, then the input data for edge must also be in a table.

If you set 'Standardize', true in fitcsvm when training SVMModel, then the software standardizes the columns of the predictor data using the corresponding means in SVMModel.Mu and the standard deviations in SVMModel.Sigma.

Data Types: table

X — Predictor data

numeric matrix

Predictor data, specified as a numeric matrix.

Each row of X corresponds to one observation (also known as an instance or example), and each column corresponds to one variable (also known as a feature). The variables in the columns of X must be the same as the variables that trained the SVMModel classifier.

The length of Y and the number of rows in X must be equal.

If you set 'Standardize', true in `fitcsvm` to train `SVMModel`, then the software standardizes the columns of `X` using the corresponding means in `SVMModel.Mu` and the standard deviations in `SVMModel.Sigma`.

Data Types: `double` | `single`

ResponseVarName — Response variable name

name of variable in TBL

Response variable name, specified as the name of a variable in TBL. If TBL contains the response variable used to train `SVMModel`, then you do not need to specify `ResponseVarName`.

If you specify `ResponseVarName`, then you must do so as a character vector or string scalar. For example, if the response variable is stored as `TBL.Response`, then specify `ResponseVarName` as 'Response'. Otherwise, the software treats all columns of TBL, including `TBL.Response`, as predictors.

The response variable must be a categorical, character, or string array, logical or numeric vector, or cell array of character vectors. If the response variable is a character array, then each element must correspond to one row of the array.

Data Types: `char` | `string`

Y — Class labels

categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Class labels, specified as a categorical, character, or string array, logical or numeric vector, or cell array of character vectors. `Y` must be the same as the data type of `SVMModel.ClassNames`. (The software treats string arrays as cell arrays of character vectors.)

The length of `Y` must equal the number of rows in TBL or the number of rows in `X`.

weights — Observation weights

`ones(size(X,1),1)` (default) | numeric vector | name of variable in TBL

Observation weights, specified as a numeric vector or the name of a variable in TBL.

If you specify `weights` as a numeric vector, then the size of `weights` must be equal to the number of rows in `X` or TBL.

If you specify `weights` as the name of a variable in TBL, you must do so as a character vector or string scalar. For example, if the weights are stored as `TBL.W`, then specify `weights` as `'W'`. Otherwise, the software treats all columns of TBL, including `TBL.W`, as predictors.

If you supply `weights`, `edge` computes the weighted classification edge on page 32-1521. The software weights the observations in each row of X or TBL with the corresponding weight in `weights`.

Example: `'Weights', 'W'`

Data Types: `single | double | char | string`

Definitions

Classification Edge

The edge is the weighted mean of the classification margins.

The weights are the prior class probabilities. If you supply `weights`, then the software normalizes them to sum to the prior probabilities in the respective classes. The software uses the renormalized weights to compute the weighted mean.

One way to choose among multiple classifiers, for example, to perform feature selection, is to choose the classifier that yields the highest edge.

Classification Margin

The classification margin for binary classification is, for each observation, the difference between the classification score for the true class and the classification score for the false class.

The software defines the classification margin for binary classification as

$$m = 2yf(x).$$

x is an observation. If the true label of x is the positive class, then y is 1, and -1 otherwise. $f(x)$ is the positive-class classification score for the observation x . The classification margin is commonly defined as $m = yf(x)$.

If the margins are on the same scale, then they serve as a classification confidence measure. Among multiple classifiers, those that yield greater margins are better.

Classification Score

The SVM classification score for classifying observation x is the signed distance from x to the decision boundary ranging from $-\infty$ to $+\infty$. A positive score for a class indicates that x is predicted to be in that class. A negative score indicates otherwise.

The positive class classification score $f(x)$ is the trained SVM classification function. $f(x)$ is also the numerical, predicted response for x , or the score for predicting x into the positive class.

$$f(x) = \sum_{j=1}^n \alpha_j y_j G(x_j, x) + b,$$

where $(\alpha_1, \dots, \alpha_n, b)$ are the estimated SVM parameters, $G(x_j, x)$ is the dot product in the predictor space between x and the support vectors, and the sum includes the training set observations. The negative class classification score for x , or the score for predicting x into the negative class, is $-f(x)$.

If $G(x_j, x) = x_j'x$ (the linear kernel), then the score function reduces to

$$f(x) = (x/s)'\beta + b.$$

s is the kernel scale and β is the vector of fitted linear coefficients.

For more details, see “Understanding Support Vector Machines” on page 18-189.

Algorithms

For binary classification, the software defines the margin for observation j , m_j , as

$$m_j = 2y_j f(x_j),$$

where $y_j \in \{-1, 1\}$, and $f(x_j)$ is the predicted score of observation j for the positive class. However, $m_j = y_j f(x_j)$ is commonly used to define the margin.

Introduced in R2014a

edge

Classification edge

Syntax

```
E = edge(tree, TBL, ResponseVarName)
E = edge(tree, X, Y)
E = edge( ____, Name, Value)
```

Description

`E = edge(tree, TBL, ResponseVarName)` returns the classification edge for `tree` with data `TBL` and classification `TBL.ResponseVarName`.

`E = edge(tree, X, Y)` returns the classification edge for `tree` with data `X` and classification `Y`.

`E = edge(____, Name, Value)` computes the edge with additional options specified by one or more `Name, Value` pair arguments, using any of the previous syntaxes. For example, you can specify observation weights.

Input Arguments

tree — Trained classification tree

`ClassificationTree` model object | `CompactClassificationTree` model object

Trained classification tree, specified as a `ClassificationTree` or `CompactClassificationTree` model object. That is, `tree` is a trained classification model returned by `fitctree` or `compact`.

TBL — Sample data

table

Sample data, specified as a table. Each row of `TBL` corresponds to one observation, and each column corresponds to one predictor variable. Optionally, `TBL` can contain additional

columns for the response variable and observation weights. `TBL` must contain all the predictors used to train `tree`. Multi-column variables and cell arrays other than cell arrays of character vectors are not allowed.

If `TBL` contains the response variable used to train `tree`, then you do not need to specify `ResponseVarName` or `Y`.

If you train `tree` using sample data contained in a `table`, then the input data for this method must also be in a `table`.

Data Types: `table`

X — Data to classify

numeric matrix

Data to classify, specified as a numeric matrix. Each row of `X` represents one observation, and each column represents one predictor. `X` must have the same number of columns as the data used to train `tree`. `X` must have the same number of rows as the number of elements in `Y`.

Data Types: `single` | `double`

ResponseVarName — Response variable name

name of a variable in `TBL`

Response variable name, specified as the name of a variable in `TBL`. If `TBL` contains the response variable used to train `tree`, then you do not need to specify `ResponseVarName`.

If you specify `ResponseVarName`, then you must do so as a character vector or string scalar. For example, if the response variable is stored as `TBL.Response`, then specify it as `'Response'`. Otherwise, the software treats all columns of `TBL`, including `TBL.ResponseVarName`, as predictors.

The response variable must be a categorical, character, or string array, logical or numeric vector, or cell array of character vectors. If the response variable is a character array, then each element must correspond to one row of the array.

Data Types: `char` | `string`

Y — Class labels

categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Class labels, specified as a categorical, character, or string array, a logical or numeric vector, or a cell array of character vectors. `Y` must be of the same type as the classification used to train `tree`, and its number of elements must equal the number of rows of `X`.

Data Types: `categorical` | `char` | `string` | `logical` | `single` | `double` | `cell`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Weights — Observation weights

`ones(size(X,1),1)` (default) | name of a variable in TBL | numeric vector

Observation weights, specified as the comma-separated pair consisting of `'Weights'` and a numeric vector or the name of a variable in TBL.

If you specify `Weights` as a numeric vector, then the size of `Weights` must be equal to the number of rows in `X` or TBL.

If you specify `Weights` as the name of a variable in TBL, you must do so as a character vector or string scalar. For example, if the weights are stored as `TBL.W`, then specify it as `'W'`. Otherwise, the software treats all columns of TBL, including `TBL.W`, as predictors.

If you supply weights, `edge` computes the weighted classification edge on page 32-1521. The software weights the observations in each row of `X` or TBL with the corresponding weight in `Weights`.

Data Types: `single` | `double` | `char` | `string`

Output Arguments

E — Classification edge

scalar value

Classification edge, returned as a scalar representing the weighted average value of the margin.

Examples

Compute the classification margin and edge for the Fisher iris data, trained on its first two columns of data, and view the last 10 entries:

```
load fisheriris
X = meas(:,1:2);
tree = fitctree(X,species);
E = edge(tree,X,species)
```

```
E =
    0.6299
```

```
M = margin(tree,X,species);
M(end-10:end)
```

```
ans =
    0.1111
    0.1111
    0.1111
   -0.2857
    0.6364
    0.6364
    0.1111
    0.7500
    1.0000
    0.6364
    0.2000
```

The classification tree trained on all the data is better.

```
tree = fitctree(meas,species);
E = edge(tree,meas,species)
```

```
E =
    0.9384
```

```
M = margin(tree,meas,species);
M(end-10:end)
```

```
ans =

Definitions

Margin

The classification margin is the difference between the classification score for the true class and maximal classification score for the false classes. Margin is a column vector with the same number of rows as the matrix X .

Score (tree)

For trees, the score of a classification of a leaf node is the posterior probability of the classification at that node. The posterior probability of the classification at a node is the number of training sequences that lead to that node with the classification, divided by the number of training sequences that lead to that node.

For example, consider classifying a predictor X as `true` when $X < 0.15$ or $X > 0.95$, and X is false otherwise.

Generate 100 random points and classify them:

```
rng(0, 'twister') % for reproducibility
X = rand(100,1);
Y = (abs(X - .55) > .4);
tree = fitctree(X,Y);
view(tree, 'Mode', 'Graph')
```

Prune the tree:

```
tree1 = prune(tree, 'Level', 1);  
view(tree1, 'Mode', 'Graph')
```

The pruned tree correctly classifies observations that are less than 0.15 as `true`. It also correctly classifies observations from .15 to .94 as `false`. However, it incorrectly classifies observations that are greater than .94 as `false`. Therefore, the score for observations that are greater than .15 should be about $.05/.85=.06$ for `true`, and about $.8/.85=.94$ for `false`.

Compute the prediction scores for the first 10 rows of `X`:

```
[~,score] = predict(tree1,X(1:10));
[score X(1:10,:)]
```

```
ans = 10x3
    0.9059    0.0941    0.8147
    0.9059    0.0941    0.9058
         0     1.0000    0.1270
    0.9059    0.0941    0.9134
    0.9059    0.0941    0.6324
         0     1.0000    0.0975
    0.9059    0.0941    0.2785
    0.9059    0.0941    0.5469
    0.9059    0.0941    0.9575
    0.9059    0.0941    0.9649
```

Indeed, every value of X (the right-most column) that is less than 0.15 has associated scores (the left and center columns) of 0 and 1, while the other values of X have associated scores of 0.91 and 0.09. The difference (score 0.09 instead of the expected .06) is due to a statistical fluctuation: there are 8 observations in X in the range (.95, 1) instead of the expected 5 observations.

Edge

The edge is the weighted mean value of the classification margin. The weights are the class probabilities in `tree.Prior`. If you supply weights in the `weights` name-value pair, those weights are normalized to sum to the prior probabilities in the respective classes, and are then used to compute the weighted average.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. For more information, see “Tall Arrays” (MATLAB).

See Also

`fitctree` | `loss` | `margin` | `predict`

end

Class: dataset

Last index in indexing expression for dataset array

Note The dataset data type might be removed in a future release. To work with heterogeneous data, use the MATLAB® table data type instead. See MATLAB table documentation for more information.

Syntax

`end(A, k, n)`

Description

`end(A, k, n)` is called for indexing expressions involving the dataset A when `end` is part of the k-th index out of n indices. For example, the expression `A(end-1, :)` calls A's `end` method with `end(A, 1, 2)`.

See Also

`size`

epsilon

Class: RepeatedMeasuresModel

Epsilon adjustment for repeated measures anova

Syntax

```
tbl = epsilon(rm)
tbl = epsilon(rm,C)
```

Description

`tbl = epsilon(rm)` returns the epsilon adjustment factors for repeated measures model `rm`.

`tbl = epsilon(rm,C)` returns the epsilon adjustment factors for the test based on the contrast matrix `C`.

Input Arguments

rm — Repeated measures model

RepeatedMeasuresModel object

Repeated measures model, returned as a RepeatedMeasuresModel object.

For properties and methods of this object, see RepeatedMeasuresModel.

C — Contrasts

matrix

Contrasts, specified as a matrix. The default value of `C` is the `Q` factor in a QR decomposition of the matrix `M`, where `M` is defined so that `Y*M` is the difference between all successive pairs of columns of the repeated measures matrix `Y`.

Data Types: single | double

Output Arguments

tbl — Epsilon adjustment factors

table

Epsilon adjustment factors for the repeated measures model `rm`, returned as a table. `tbl` contains four different adjustments for `epsilon`.

Correction	Definition
Uncorrected	No adjustments, $\epsilon = 1$
Greenhouse-Geiser	Greenhouse-Geiser approximation
Huynh-Feldt	Huynh-Feldt approximation
Lower bound	Lower bound on the p -value

For details, see “Compound Symmetry Assumption and Epsilon Corrections” on page 9-79.

Data Types: table

Examples

Epsilon Corrections for Repeated Measures ANOVA

Load the sample data.

```
load fisheriris
```

The column vector, `species` consists of iris flowers of three different species: `setosa`, `versicolor`, `virginica`. The double matrix `meas` consists of four types of measurements on the flowers: the length and width of sepals and petals in centimeters, respectively.

Store the data in a table array.

```
t = table(species,meas(:,1),meas(:,2),meas(:,3),meas(:,4),...
'VariableNames',{'species','meas1','meas2','meas3','meas4'});
Meas = dataset([1 2 3 4]','VarNames',{'Measurements'});
```

Fit a repeated measures model, where the measurements are the responses and the `species` is the predictor variable.

```
rm = fitrm(t, 'meas1-meas4~species', 'WithinDesign', Meas);
```

Perform repeated measures analysis of variance.

```
ranovatbl = ranova(rm)
```

```
ranovatbl=3×8 table
```

	SumSq	DF	MeanSq	F	pValue
(Intercept):Measurements	1656.3	3	552.09	6873.3	0
species:Measurements	282.47	6	47.078	586.1	1.4271e-206
Error(Measurements)	35.423	441	0.080324		

`ranova` computes the last three p -values using Greenhouse-Geisser, Huynh-Feldt, and lower bound corrections, respectively.

Display the epsilon correction values.

```
epsilon(rm)
```

```
ans=1×4 table
```

Uncorrected	GreenhouseGeisser	HuynhFeldt	LowerBound
1	0.75179	0.76409	0.33333

You can check the compound symmetry (sphericity) assumption using the `mauchly` method.

Tips

- The `mauchly` method tests for sphericity.
- The `ranova` method contains p -values based on each epsilon value.

Algorithms

`ranova` computes the regular p -value (in the `pValue` column of the `rmanova` table) using the F -statistic cumulative distribution function:

$$p\text{-value} = 1 - \text{fcdf}(F, v_1, v_2).$$

When the compound symmetry assumption is not satisfied, `ranova` uses a correction factor epsilon, ε , to compute the corrected p -values as follows:

$$p\text{-value_corrected} = 1 - \text{fcdf}(F, \varepsilon * v_1, \varepsilon * v_2).$$

The `epsilon` method returns the epsilon adjustment values.

evcdf

Extreme value cumulative distribution function

Syntax

```
p = evcdf(x,mu,sigma)
[p,plo,pup] = evcdf(x,mu,sigma,pcov,alpha)
[p,plo,pup] = evcdf( __ , 'upper')
```

Description

`p = evcdf(x,mu,sigma)` returns the cumulative distribution function (cdf) for the type 1 extreme value distribution, with location parameter `mu` and scale parameter `sigma`, at each of the values in `x`. `x`, `mu`, and `sigma` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array of the same size as the other inputs. The default values for `mu` and `sigma` are 0 and 1, respectively.

`[p,plo,pup] = evcdf(x,mu,sigma,pcov,alpha)` returns confidence bounds for `p` when the input parameters `mu` and `sigma` are estimates. `pcov` is a 2-by-2 covariance matrix of the estimated parameters. `alpha` has a default value of 0.05, and specifies 100(1 - `alpha`)% confidence bounds. `plo` and `pup` are arrays of the same size as `p`, containing the lower and upper confidence bounds.

`[p,plo,pup] = evcdf(__ , 'upper')` returns the complement of the type 1 extreme value distribution cdf at each value in `x`, using an algorithm that more accurately computes the extreme upper tail probabilities. You can use the 'upper' argument with any of the previous syntaxes.

The function `evcdf` computes confidence bounds for `P` using a normal approximation to the distribution of the estimate

$$\frac{X - \hat{\mu}}{\hat{\sigma}}$$

and then transforming those bounds to the scale of the output `P`. The computed bounds give approximately the desired confidence level when you estimate `mu`, `sigma`, and `pcov`

from large samples, but in smaller samples other methods of computing the confidence bounds might be more accurate.

The type 1 extreme value distribution is also known as the Gumbel distribution. The version used here is suitable for modeling minima; the mirror image of this distribution can be used to model maxima by negating X and subtracting the resulting distribution values from 1. See “Extreme Value Distribution” on page B-36 for more details. If x has a Weibull distribution, then $X = \log(x)$ has the type 1 extreme value distribution.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU arrays. For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

evfit

Extreme value parameter estimates

Syntax

```
parmhat = evfit(data)
[parmhat,parmci] = evfit(data)
[parmhat,parmci] = evfit(data,alpha)
[...] = evfit(data,alpha,censoring)
[...] = evfit(data,alpha,censoring,freq)
[...] = evfit(data,alpha,censoring,freq,options)
```

Description

`parmhat = evfit(data)` returns maximum likelihood estimates of the parameters of the type 1 extreme value distribution given the data in the vector `data`. `parmhat(1)` is the location parameter, μ , and `parmhat(2)` is the scale parameter, σ .

`[parmhat,parmci] = evfit(data)` returns 95% confidence intervals for the parameter estimates on the μ and σ parameters in the 2-by-2 matrix `parmci`. The first column of the matrix of the extreme value fit contains the lower and upper confidence bounds for the parameter μ , and the second column contains the confidence bounds for the parameter σ .

`[parmhat,parmci] = evfit(data,alpha)` returns $100(1 - \text{alpha})\%$ confidence intervals for the parameter estimates, where `alpha` is a value in the range `[0 1]` specifying the width of the confidence intervals. By default, `alpha` is `0.05`, which corresponds to 95% confidence intervals.

`[...] = evfit(data,alpha,censoring)` accepts a Boolean vector, `censoring`, of the same size as `data`, which is 1 for observations that are right-censored and 0 for observations that are observed exactly.

`[...] = evfit(data,alpha,censoring,freq)` accepts a frequency vector, `freq` of the same size as `data`. Typically, `freq` contains integer frequencies for the corresponding

elements in `data`, but can contain any nonnegative values. Pass in `[]` for `alpha`, `censoring`, or `freq` to use their default values.

`[...] = evfit(data,alpha,censoring,freq,options)` accepts a structure, `options`, that specifies control parameters for the iterative algorithm the function uses to compute maximum likelihood estimates. You can create `options` using the function `statset`. Enter `statset('evfit')` to see the names and default values of the parameters that `evfit` accepts in the `options` structure. See the reference page for `statset` for more information about these options.

The type 1 extreme value distribution is also known as the Gumbel distribution. The version used here is suitable for modeling minima; the mirror image of this distribution can be used to model maxima by negating X . See “Extreme Value Distribution” on page B-36 for more details. If x has a Weibull distribution, then $X = \log(x)$ has the type 1 extreme value distribution.

evinv

Extreme value inverse cumulative distribution function

Syntax

```
X = evinv(P,mu,sigma)
[X,XLO,XUP] = evinv(P,mu,sigma,pcov,alpha)
```

Description

`X = evinv(P,mu,sigma)` returns the inverse cumulative distribution function (cdf) for a type 1 extreme value distribution with location parameter `mu` and scale parameter `sigma`, evaluated at the values in `P`. `P`, `mu`, and `sigma` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array of the same size as the other inputs. The default values for `mu` and `sigma` are 0 and 1, respectively.

`[X,XLO,XUP] = evinv(P,mu,sigma,pcov,alpha)` produces confidence bounds for `X` when the input parameters `mu` and `sigma` are estimates. `pcov` is the covariance matrix of the estimated parameters. `alpha` is a scalar that specifies $100(1 - \alpha)\%$ confidence bounds for the estimated parameters, and has a default value of 0.05. `XLO` and `XUP` are arrays of the same size as `X` containing the lower and upper confidence bounds.

The function `evinv` computes confidence bounds for `P` using a normal approximation to the distribution of the estimate

$$\hat{\mu} + \hat{\sigma}q$$

where q is the P th quantile from an extreme value distribution with parameters $\mu = 0$ and $\sigma = 1$. The computed bounds give approximately the desired confidence level when you estimate `mu`, `sigma`, and `pcov` from large samples, but in smaller samples other methods of computing the confidence bounds might be more accurate.

The type 1 extreme value distribution is also known as the Gumbel distribution. The version used here is suitable for modeling minima; the mirror image of this distribution can be used to model maxima by negating `X`. See “Extreme Value Distribution” on page B-

36 for more details. If x has a Weibull distribution, then $X = \log(x)$ has the type 1 extreme value distribution.

eq

Class: grandstream

Test handle equality

Syntax

```
h1 == h2  
tf = eq(h1, h2)
```

Description

`h1 == h2` performs element-wise comparisons between handle arrays `h1` and `h2`. `h1` and `h2` must be of the same dimensions unless one is a scalar. The result is a logical array of the same dimensions, where each element is an element-wise equality result. If one of `h1` or `h2` is scalar, scalar expansion is performed and the result will match the dimensions of the array that is not scalar.

`tf = eq(h1, h2)` stores the result in a logical array of the same dimensions.

error

Class: CompactTreeBagger

Error (misclassification probability or MSE)

Syntax

```
err = error(B, TBLnew, Ynew)
err = error(B, Xnew, Ynew)
err = error(B, TBLnew, Ynew, 'param1', val1, 'param2', val2, ...)
err = error(B, Xnew, Ynew, 'param1', val1, 'param2', val2, ...)
```

Description

`err = error(B, TBLnew, Ynew)` computes the misclassification probability for classification trees or mean squared error (MSE) for regression trees for each tree, for the predictors contained in the table `TBLnew` given true response `Ynew`. You can omit `Ynew` if `TBLnew` contains the response variable. If you trained `B` using sample data contained in a table, then the input data for this method must also be in a table.

`err = error(B, Xnew, Ynew)` computes the misclassification probability for classification trees or mean squared error (MSE) for regression trees for each tree, the for predictors contained in the matrix `Xnew` given true response `Ynew`. If you trained `B` using sample data contained in a matrix, then the input data for this method must also be in a matrix.

For classification, `Ynew` can be a numeric vector, character matrix, string array, cell array of character vectors, categorical vector, or logical vector. For regression, `Y` must be a numeric vector. `err` is a vector with one error measure for each of the `NTrees` trees in the ensemble `B`.

`err = error(B, TBLnew, Ynew, 'param1', val1, 'param2', val2, ...)` or `err = error(B, Xnew, Ynew, 'param1', val1, 'param2', val2, ...)` specifies optional parameter name-value pairs:

'Mode'	Character vector or string scalar indicating how the method computes errors. If set to 'cumulative' (default), error computes cumulative errors and <code>err</code> is a vector of length <code>NTrees</code> , where the first element gives error from <code>trees(1)</code> , second element gives error from <code>trees(1:2)</code> etc., up to <code>trees(1:NTrees)</code> . If set to 'individual', <code>err</code> is a vector of length <code>NTrees</code> , where each element is an error from each tree in the ensemble. If set to 'ensemble', <code>err</code> is a scalar showing the cumulative error for the entire ensemble.
'Weights'	Vector of observation weights to use for error averaging. By default the weight of every observation is 1. The length of this vector must be equal to the number of rows in <code>X</code> .
'Trees'	Vector of indices indicating what trees to include in this calculation. By default, this argument is set to 'all' and the method uses all trees. If 'Trees' is a numeric vector, the method returns a vector of length <code>NTrees</code> for 'cumulative' and 'individual' modes, where <code>NTrees</code> is the number of elements in the input vector, and a scalar for 'ensemble' mode. For example, in the 'cumulative' mode, the first element gives error from <code>trees(1)</code> , the second element gives error from <code>trees(1:2)</code> etc.
'TreeWeights'	Vector of tree weights. This vector must have the same length as the 'Trees' vector. The method uses these weights to combine output from the specified trees by taking a weighted average instead of the simple non-weighted majority vote. You cannot use this argument in the 'individual' mode.
'UseInstanceForTree'	Logical matrix of size <code>Nobs-by-NTrees</code> indicating which trees should be used to make predictions for each observation. By default the method uses all trees for all observations.

Algorithms

When estimating the ensemble error:

- Using the 'Mode' name-value pair argument, you can specify to return the error any of these three ways:
 - The error for individual trees in the ensemble

- The cumulative error over all trees
- The error for the entire ensemble
- Using the 'Trees' name-value pair argument, you can specify which trees to use in the ensemble error calculations.
- Using the 'UseInstanceForTree' name-value pair argument, you can specify which observations in the input data (X and Y) to use in the ensemble error calculation for each selected tree.
- Using the 'Weights' name-value pair argument, you can attribute each *observation* with a weight. For the formulae that follow, w_j is the weight of observation j .
- Using the 'TreeWeights' name-value pair argument, you can attribute each *tree* with a weight.

For regression problems, `error` estimates the weighted MSE of the ensemble of bagged regression trees for predicting Y given X using selected trees and observations.

- 1 `error` predicts responses for selected observations in X using the selected regression trees in the ensemble.
- 2 The MSE estimate depends on the value of 'Mode'.
 - If you specify 'Mode', 'Individual', then the weighted MSE for tree t is

$$\text{MSE}_t = \frac{1}{\sum_{j=1}^n w_j} \sum_{j=1}^n w_j (y_j - \hat{y}_{tj})^2.$$

\hat{y}_{tj} is the predicted response of observation j from selected regression tree t . `error` sets any unselected observations within a selected tree to the weighted sample average of the observed, training data responses.

- If you specify 'Mode', 'Cumulative', then the weighted MSE is a vector of size T^* containing cumulative, weighted MSEs over the $T^* \leq T$ selected trees. `error` follows these steps to estimate MSE_t^* , the cumulative, weighted MSE using the first t selected trees.
 - a For selected observation j , $j = 1, \dots, n$, `error` estimates $\hat{y}_{\text{bag}, t, j}$, the weighted average of the predictions among the first t selected trees (for details, see `predict`). For this computation, `error` uses the tree weights.
 - b `error` estimates the cumulative, weighted MSE through tree t .

$$\text{MSE}_t^* = \frac{1}{\sum_{j=1}^n w_j} \sum_{j=1}^n w_j (y_j - \widehat{y}_{\text{bag},tj})^2.$$

error sets observations that are unselected for all selected trees to the weighted sample average of the observed, training data responses.

- If you specify 'Mode', 'Ensemble', then the weighted MSE is the last element of the cumulative, weighted MSE vector.

For classification problems, error estimates the weighted misclassification rate of the ensemble of bagged classification trees for predicting Y given X using selected trees and observations.

- If you specify 'Mode', 'Individual', then the weighted misclassification rate for tree t is

$$e_t = \frac{1}{\sum_{j=1}^n w_j} \sum_{j=1}^n w_j I(y_j \neq \widehat{y}_{tj}).$$

\widehat{y}_{tj} is the predicted class for selected observation j using from selected classification tree t . error sets any unselected observations within a selected tree to the predicted, weighted, most popular class over all training responses. If there are multiple most popular classes, error considers the one listed first in the `ClassNames` property of the `TreeBagger` model the most popular.

- If you specify 'Mode', 'Cumulative' then the weighted misclassification rate is a vector of size T^* containing cumulative, weighted misclassification rates over the $T^* \leq T$ selected trees. error follows these steps to estimate e_t^* , the cumulative, weighted misclassification rate using the first t selected trees.

- 1 For selected observation j , $j = 1, \dots, n$, error estimates $\widehat{y}_{\text{bag},tj}$, the weighted, most popular class among the first t selected trees (for details, see `predict`). For this computation, error uses the tree weights.
- 2 error estimates the cumulative, weighted misclassification rate through tree t .

$$e_t^* = \frac{1}{\sum_{j=1}^n w_j} \sum_{j=1}^n w_j I(y_j \neq \widehat{y}_{\text{bag},tj}).$$

`error` sets any observations that are unselected for all selected trees to the predicted, weighted, most popular class over all training responses. If there are multiple most popular classes, `error` considers the one listed first in the `ClassNames` property of the `TreeBagger` model the most popular.

- If you specify `'Mode'`, `'Ensemble'`, then the weighted misclassification rate is the last element of the cumulative, weighted misclassification rate vector.

error

Class: TreeBagger

Error (misclassification probability or MSE)

Syntax

```
err = error(B,TBLnew,Ynew)
err = error(B,Xnew,Ynew)
err = error(B,TBLnew,Ynew,'param1',val1,'param2',val2,...)
err = error(B,Xnew,Ynew,'param1',val1,'param2',val2,...)
```

Description

`err = error(B,TBLnew,Ynew)` computes the misclassification probability for classification trees or mean squared error (MSE) for regression trees for each tree, for the predictors contained in the table `TBLnew` given true response `Ynew`. You can omit `Ynew` if `TBLnew` contains the response variable. If you trained `B` using sample data contained in a table, then the input data for this method must also be in a table.

`err = error(B,Xnew,Ynew)` computes the misclassification probability for classification trees or mean squared error (MSE) for regression trees for each tree, the for predictors contained in the matrix `Xnew` given true response `Ynew`. If you trained `B` using sample data contained in a matrix, then the input data for this method must also be in a matrix.

For classification, `Ynew` can be a numeric vector, character matrix, string array, cell array of character vectors, categorical vector or logical vector. For regression, `Y` must be a numeric vector. `err` is a vector with one error measure for each of the `Ntrees` trees in the ensemble `B`.

`err = error(B,TBLnew,Ynew,'param1',val1,'param2',val2,...)` or `err = error(B,Xnew,Ynew,'param1',val1,'param2',val2,...)` specifies optional parameter name-value pairs:

'Mode'	Character vector or string scalar indicating how the method computes errors. If set to 'cumulative' (default), error computes cumulative errors and err is a vector of length NTrees, where the first element gives error from trees(1), second element gives error from trees(1:2) etc., up to trees(1:NTrees). If set to 'individual', err is a vector of length NTrees, where each element is an error from each tree in the ensemble. If set to 'ensemble', err is a scalar showing the cumulative error for the entire ensemble.
'Weights'	Vector of observation weights to use for error averaging. By default the weight of every observation is 1. The length of this vector must be equal to the number of rows in X.
'Trees'	Vector of indices indicating what trees to include in this calculation. By default, this argument is set to 'all' and the method uses all trees. If 'Trees' is a numeric vector, the method returns a vector of length NTrees for 'cumulative' and 'individual' modes, where NTrees is the number of elements in the input vector, and a scalar for 'ensemble' mode. For example, in the 'cumulative' mode, the first element gives error from trees(1), the second element gives error from trees(1:2) etc.
'TreeWeights'	Vector of tree weights. This vector must have the same length as the 'Trees' vector. The method uses these weights to combine output from the specified trees by taking a weighted average instead of the simple non-weighted majority vote. You cannot use this argument in the 'individual' mode.
'UseInstanceForTree'	Logical matrix of size Nobs-by-NTrees indicating which trees should be used to make predictions for each observation. By default the method uses all trees for all observations.

Algorithms

When estimating the ensemble error:

- Using the 'Mode' name-value pair argument, you can specify to return the error any of these three ways:
 - The error for individual trees in the ensemble

- The cumulative error over all trees
- The error for the entire ensemble
- Using the 'Trees' name-value pair argument, you can specify which trees to use in the ensemble error calculations.
- Using the 'UseInstanceForTree' name-value pair argument, you can specify which observations in the input data (X and Y) to use in the ensemble error calculation for each selected tree.
- Using the 'Weights' name-value pair argument, you can attribute each *observation* with a weight. For the formulae that follow, w_j is the weight of observation j .
- Using the 'TreeWeights' name-value pair argument, you can attribute each *tree* with a weight.

For regression problems, `error` estimates the weighted MSE of the ensemble of bagged regression trees for predicting Y given X using selected trees and observations.

- 1 `error` predicts responses for selected observations in X using the selected regression trees in the ensemble.
- 2 The MSE estimate depends on the value of 'Mode'.
 - If you specify 'Mode', 'Individual', then the weighted MSE for tree t is

$$\text{MSE}_t = \frac{1}{\sum_{j=1}^n w_j} \sum_{j=1}^n w_j (y_j - \hat{y}_{tj})^2.$$

\hat{y}_{tj} is the predicted response of observation j from selected regression tree t . `error` sets any unselected observations within a selected tree to the weighted sample average of the observed, training data responses.

- If you specify 'Mode', 'Cumulative', then the weighted MSE is a vector of size T^* containing cumulative, weighted MSEs over the $T^* \leq T$ selected trees. `error` follows these steps to estimate MSE_t^* , the cumulative, weighted MSE using the first t selected trees.
 - a For selected observation j , $j = 1, \dots, n$, `error` estimates $\hat{y}_{\text{bag},tj}$, the weighted average of the predictions among the first t selected trees (for details, see `predict`). For this computation, `error` uses the tree weights.
 - b `error` estimates the cumulative, weighted MSE through tree t .

$$\text{MSE}_t^* = \frac{1}{\sum_{j=1}^n w_j} \sum_{j=1}^n w_j (y_j - \widehat{y}_{\text{bag},tj})^2.$$

error sets observations that are unselected for all selected trees to the weighted sample average of the observed, training data responses.

- If you specify 'Mode', 'Ensemble', then the weighted MSE is the last element of the cumulative, weighted MSE vector.

For classification problems, error estimates the weighted misclassification rate of the ensemble of bagged classification trees for predicting Y given X using selected trees and observations.

- If you specify 'Mode', 'Individual', then the weighted misclassification rate for tree t is

$$e_t = \frac{1}{\sum_{j=1}^n w_j} \sum_{j=1}^n w_j I(y_j \neq \widehat{y}_{tj}).$$

\widehat{y}_{tj} is the predicted class for selected observation j using from selected classification tree t . error sets any unselected observations within a selected tree to the predicted, weighted, most popular class over all training responses. If there are multiple most popular classes, error considers the one listed first in the `ClassNames` property of the `TreeBagger` model the most popular.

- If you specify 'Mode', 'Cumulative' then the weighted misclassification rate is a vector of size T^* containing cumulative, weighted misclassification rates over the $T^* \leq T$ selected trees. error follows these steps to estimate e_t^* , the cumulative, weighted misclassification rate using the first t selected trees.
 - 1 For selected observation j , $j = 1, \dots, n$, error estimates $\widehat{y}_{\text{bag},tj}$, the weighted, most popular class among the first t selected trees (for details, see `predict`). For this computation, error uses the tree weights.
 - 2 error estimates the cumulative, weighted misclassification rate through tree t .

$$e_t^* = \frac{1}{\sum_{j=1}^n w_j} \sum_{j=1}^n w_j I(y_j \neq \widehat{y}_{\text{bag},tj}).$$

`error` sets any observations that are unselected for all selected trees to the predicted, weighted, most popular class over all training responses. If there are multiple most popular classes, `error` considers the one listed first in the `ClassNames` property of the `TreeBagger` model the most popular.

- If you specify `'Mode'`, `'Ensemble'`, then the weighted misclassification rate is the last element of the cumulative, weighted misclassification rate vector.

evalclusters

Evaluate clustering solutions

Syntax

```
eva = evalclusters(x,clust,criterion)
eva = evalclusters(x,clust,criterion,Name,Value)
```

Description

`eva = evalclusters(x,clust,criterion)` creates a clustering evaluation object containing data used to evaluate the optimal number of data clusters.

`eva = evalclusters(x,clust,criterion,Name,Value)` creates a clustering evaluation object using additional options specified by one or more name-value pair arguments.

Examples

Evaluate the Clustering Solution Using Calinski-Harabasz Criterion

Evaluate the optimal number of clusters using the Calinski-Harabasz clustering evaluation criterion.

Load the sample data.

```
load fisheriris;
```

The data contains length and width measurements from the sepals and petals of three species of iris flowers.

Evaluate the optimal number of clusters using the Calinski-Harabasz criterion. Cluster the data using `kmeans`.

```

rng('default'); % For reproducibility
eva = evalclusters(meas,'kmeans','CalinskiHarabasz','KList',[1:6])

eva =
    CalinskiHarabaszEvaluation with properties:

        NumObservations: 150
           InspectedK: [1 2 3 4 5 6]
    CriterionValues: [NaN 513.9245 561.6278 530.4871 456.1279 469.5068]
           OptimalK: 3

```

The `OptimalK` value indicates that, based on the Calinski-Harabasz criterion, the optimal number of clusters is three.

Evaluate a Matrix of Clustering Solutions

Use an input matrix of proposed clustering solutions to evaluate the optimal number of clusters.

Load the sample data.

```
load fisheriris;
```

The data contains length and width measurements from the sepals and petals of three species of iris flowers.

Use `kmeans` to create an input matrix of proposed clustering solutions for the sepal length measurements, using 1, 2, 3, 4, 5, and 6 clusters.

```

clust = zeros(size(meas,1),6);
for i=1:6
    clust(:,i) = kmeans(meas,i,'emptyaction','singleton',...
        'replicate',5);
end

```

Each row of `clust` corresponds to one sepal length measurement. Each of the six columns corresponds to a clustering solution containing 1 to 6 clusters.

Evaluate the optimal number of clusters using the Calinski-Harabasz criterion.

```
eva = evalclusters(meas,clust,'CalinskiHarabasz')
```

```
eva =  
  CalinskiHarabaszEvaluation with properties:  
  
  NumObservations: 150  
    InspectedK: [1 2 3 4 5 6]  
  CriterionValues: [NaN 513.9245 561.6278 530.4871 456.1279 469.5068]  
    OptimalK: 3
```

The `OptimalK` value indicates that, based on the Calinski-Harabasz criterion, the optimal number of clusters is three.

Specify Clustering Algorithm with a Function Handle

Use a function handle to specify the clustering algorithm, then evaluate the optimal number of clusters.

Load the sample data.

```
load fisheriris;
```

The data contains length and width measurements from the sepals and petals of three species of iris flowers.

Use a function handle to specify the clustering algorithm.

```
myfunc = @(X,K)(kmeans(X, K, 'emptyaction','singleton',...  
  'replicate',5));
```

Evaluate the optimal number of clusters for the sepal length data using the Calinski-Harabasz criterion.

```
eva = evalclusters(meas,myfunc,'CalinskiHarabasz',...  
  'klist',[1:6])
```

```
eva =  
  CalinskiHarabaszEvaluation with properties:  
  
  NumObservations: 150  
    InspectedK: [1 2 3 4 5 6]  
  CriterionValues: [NaN 513.9245 561.6278 530.4871 456.1279 469.5068]
```

OptimalK: 3

The OptimalK value indicates that, based on the Calinski-Harabasz criterion, the optimal number of clusters is three.

Input Arguments

x — Input data

matrix

Input data, specified as an N -by- P matrix. N is the number of observations, and P is the number of variables.

Data Types: `single` | `double`

clust — Clustering algorithm

'kmeans' | 'linkage' | 'gmdistribution' | matrix of clustering solutions | function handle

Clustering algorithm, specified as one of the following.

'kmeans'	Cluster the data in x using the kmeans clustering algorithm, with 'EmptyAction' set to 'singleton' and 'Replicates' set to 5.
'linkage'	Cluster the data in x using the clusterdata agglomerative clustering algorithm, with 'Linkage' set to 'ward'.
'gmdistribution'	Cluster the data in x using the gmdistribution Gaussian mixture distribution algorithm, with 'SharedCov' set to true and 'Replicates' set to 5.

If criterion is 'CalinskiHarabasz', 'DaviesBouldin', or 'silhouette', you can specify a clustering algorithm using a function handle (MATLAB). The function must be of the form $C = \text{clustfun}(DATA, K)$, where $DATA$ is the data to be clustered, and K is the number of clusters. The output of `clustfun` must be one of the following:

- A vector of integers representing the cluster index for each observation in $DATA$. There must be K unique values in this vector.

- A numeric n -by- K matrix of score for n observations and K classes. In this case, the cluster index for each observation is determined by taking the largest score value in each row.

If `criterion` is `'CalinskiHarabasz'`, `'DaviesBouldin'`, or `'silhouette'`, you can also specify `clust` as a n -by- K matrix containing the proposed clustering solutions. n is the number of observations in the sample data, and K is the number of proposed clustering solutions. Column j contains the cluster indices for each of the N points in the j th clustering solution.

Data Types: `single` | `double` | `char` | `string` | `function_handle`

criterion — Clustering evaluation criterion

`'CalinskiHarabasz'` | `'DaviesBouldin'` | `'gap'` | `'silhouette'`

Clustering evaluation criterion, specified as one of the following.

<code>'CalinskiHarabasz'</code>	Create a <code>CalinskiHarabaszEvaluation</code> clustering evaluation object containing Calinski-Harabasz index values.
<code>'DaviesBouldin'</code>	Create a <code>DaviesBouldinEvaluation</code> cluster evaluation object containing Davies-Bouldin index values.
<code>'gap'</code>	Create a <code>GapEvaluation</code> cluster evaluation object containing gap criterion values.
<code>'silhouette'</code>	Create a <code>SilhouetteEvaluation</code> cluster evaluation object containing silhouette values.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'KList', [1:5], 'Distance', 'cityblock'` specifies to test 1, 2, 3, 4, and 5 clusters using the city block distance metric.

For All Criteria**KList — List of number of clusters to evaluate**

vector

List of number of clusters to evaluate, specified as the comma-separated pair consisting of 'KList' and a vector of positive integer values. You must specify KList when `clust` is a clustering algorithm name or a function handle. When `criterion` is 'gap', `clust` must be a character vector, a string scalar, or a function handle, and you must specify KList.

Example: 'KList',[1:6]

Data Types: single | double

For Silhouette and Gap**Distance — Distance metric**

'sqEuclidean' (default) | 'Euclidean' | 'cityblock' | vector | function | ...

Distance metric used for computing the criterion values, specified as the comma-separated pair consisting of 'Distance' and one of the following.

'sqEuclidean'	Squared Euclidean distance
'Euclidean'	Euclidean distance. This option is not valid for the <code>kmeans</code> clustering algorithm.
'cityblock'	Sum of absolute differences
'cosine'	One minus the cosine of the included angle between points (treated as vectors)
'correlation'	One minus the sample correlation between points (treated as sequences of values)
'Hamming'	Percentage of coordinates that differ. This option is only valid for the <code>Silhouette</code> criterion.
'Jaccard'	Percentage of nonzero coordinates that differ. This option is only valid for the <code>Silhouette</code> criterion.

For detailed information about each distance metric, see `pdist`.

You can also specify a function for the distance metric using a function handle (MATLAB). The distance function must be of the form `d2 = distfun(XI,XJ)`, where `XI` is a 1-by- n vector corresponding to a single row of the input matrix X , and `XJ` is an m_2 -by- n matrix

corresponding to multiple rows of X . `distfun` must return an m_2 -by-1 vector of distances d_2 , whose k th element is the distance between XI and $XJ(k, :)$.

`Distance` only accepts a function handle if the clustering algorithm `clust` accepts a function handle as the distance metric. For example, the `kmeans` clustering algorithm does not accept a function handle as the distance metric. Therefore, if you use the `kmeans` algorithm and then specify a function handle for `Distance`, the software errors.

- If `criterion` is `'silhouette'`, you can also specify `Distance` as the output vector created by the function `pdist`.
- When `clust` is `'kmeans'` or `'gmdistribution'`, `evalclusters` uses the distance metric specified for `Distance` to cluster the data.
- If `clust` is `'linkage'`, and `Distance` is either `'sqEuclidean'` or `'Euclidean'`, then the clustering algorithm uses the Euclidean distance and Ward linkage.
- If `clust` is `'linkage'` and `Distance` is any other metric, then the clustering algorithm uses the specified distance metric and average linkage.
- In all other cases, the distance metric specified for `Distance` must match the distance metric used in the clustering algorithm to obtain meaningful results.

Example: `'Distance', 'Euclidean'`

Data Types: `single` | `double` | `char` | `string` | `function_handle`

For Silhouette Only

ClusterPriors — Prior probabilities for each cluster

`'empirical'` (default) | `'equal'`

Prior probabilities for each cluster, specified as the comma-separated pair consisting of `'ClusterPriors'` and one of the following.

<code>'empirical'</code>	Compute the overall silhouette value for the clustering solution by averaging the silhouette values for all points. Each cluster contributes to the overall silhouette value proportionally to its size.
<code>'equal'</code>	Compute the overall silhouette value for the clustering solution by averaging the silhouette values for all points within each cluster, and then averaging those values across all clusters. Each cluster contributes equally to the overall silhouette value, regardless of its size.

Example: 'ClusterPriors', 'empirical'

For Gap Only

B — Number of reference data sets

100 (default) | positive integer value

Number of reference data sets generated from the reference distribution `ReferenceDistribution`, specified as the comma-separated pair consisting of 'B' and a positive integer value.

Example: 'B', 150

Data Types: single | double

ReferenceDistribution — Reference data generation method

'PCA' (default) | 'uniform'

Reference data generation method, specified as the comma-separated pair consisting of 'ReferenceDistributions' and one of the following.

'PCA'	Generate reference data from a uniform distribution over a box aligned with the principal components of the data matrix x .
'uniform'	Generate reference data uniformly over the range of each feature in the data matrix x .

Example: 'ReferenceDistribution', 'uniform'

SearchMethod — Method for selecting optimal number of clusters

'globalMaxSE' (default) | 'firstMaxSE'

Method for selecting the optimal number of clusters, specified as the comma-separated pair consisting of 'SearchMethod' and one of the following.

'globalMaxSE'

Evaluate each proposed number of clusters in `KList` and select the smallest number of clusters satisfying

$$\text{Gap}(K) \geq \text{GAPMAX} - \text{SE}(\text{GAPMAX}),$$

where K is the number of clusters, $\text{Gap}(K)$ is the gap value for the clustering solution with K clusters, GAPMAX is the largest gap value, and $\text{SE}(\text{GAPMAX})$ is the standard error corresponding to the largest gap value.

'firstMaxSE'

Evaluate each proposed number of clusters in `KList` and select the smallest number of clusters satisfying

$$\text{Gap}(K) \geq \text{Gap}(K + 1) - \text{SE}(K + 1),$$

where K is the number of clusters, $\text{Gap}(K)$ is the gap value for the clustering solution with K clusters, and $\text{SE}(K + 1)$ is the standard error of the clustering solution with $K + 1$ clusters.

Example: 'SearchMethod', 'globalMaxSE'

Output Arguments

eva — Clustering evaluation data

clustering evaluation object

Clustering evaluation data, returned as a clustering evaluation object.

Introduced in R2013b

evlike

Extreme value negative log-likelihood

Syntax

```
nlogL = evlike(params,data)
[nlogL,AVAR] = evlike(params,data)
[...] = evlike(params,data,censoring)
[...] = evlike(params,data,censoring,freq)
```

Description

`nlogL = evlike(params,data)` returns the negative of the log-likelihood for the type 1 extreme value distribution. `params(1)` is the tail location parameter, `mu`, and `params(2)` is the scale parameter, `sigma`. `nlogL` is a scalar.

`[nlogL,AVAR] = evlike(params,data)` returns the inverse of Fisher's information matrix, `AVAR`. If the input parameter values in `params` are the maximum likelihood estimates, the diagonal elements of `AVAR` are their asymptotic variances. `AVAR` is based on the observed Fisher's information, not the expected information.

`[...] = evlike(params,data,censoring)` accepts a Boolean vector of the same size as `data`, which is 1 for observations that are right-censored and 0 for observations that are observed exactly.

`[...] = evlike(params,data,censoring,freq)` accepts a frequency vector of the same size as `data`. `freq` typically contains integer frequencies for the corresponding elements in `data`, but can contain any nonnegative values. Pass in `[]` for `censoring` to use its default value.

The type 1 extreme value distribution is also known as the Gumbel distribution. The version used here is suitable for modeling minima; the mirror image of this distribution can be used to model maxima by negating `data`. See “Extreme Value Distribution” on page B-36 for more details. If `x` has a Weibull distribution, then `X = log(x)` has the type 1 extreme value distribution.

Extended Capabilities

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU arrays. For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

Introduced before R2006a

evpdf

Extreme value probability density function

Syntax

```
Y = evpdf(X,mu,sigma)
```

Description

`Y = evpdf(X,mu,sigma)` returns the pdf of the type 1 extreme value distribution with location parameter `mu` and scale parameter `sigma`, evaluated at the values in `X`. `X`, `mu`, and `sigma` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array of the same size as the other inputs. The default values for `mu` and `sigma` are `0` and `1`, respectively.

The type 1 extreme value distribution is also known as the Gumbel distribution. The version used here is suitable for modeling minima; the mirror image of this distribution can be used to model maxima by negating `X`. See “Extreme Value Distribution” on page B-36 for more details. If `x` has a Weibull distribution, then `X = log(x)` has the type 1 extreme value distribution.

Extended Capabilities

evrnd

Extreme value random numbers

Syntax

```
R = evrnd(mu, sigma)
R = evrnd(mu, sigma, m, n, ...)
R = evrnd(mu, sigma, [m, n, ...])
```

Description

`R = evrnd(mu, sigma)` generates random numbers from the extreme value distribution with parameters specified by location parameter `mu` and scale parameter `sigma`. `mu` and `sigma` can be vectors, matrices, or multidimensional arrays that have the same size, which is also the size of `R`. A scalar input for `mu` or `sigma` is expanded to a constant array with the same dimensions as the other input.

`R = evrnd(mu, sigma, m, n, ...)` or `R = evrnd(mu, sigma, [m, n, ...])` generates an `m`-by-`n`-by-... array containing random numbers from the extreme value distribution with parameters `mu` and `sigma`. `mu` and `sigma` can each be scalars or arrays of the same size as `R`.

The type 1 extreme value distribution is also known as the Gumbel distribution. The version used here is suitable for modeling minima; the mirror image of this distribution can be used to model maxima by negating `R`. See “Extreme Value Distribution” on page B-36 for more details. If x has a Weibull distribution, then $X = \log(x)$ has the type 1 extreme value distribution.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

The generated code can return a different sequence of numbers than MATLAB if either of the following is true:

- The output is nonscalar.
- An input parameter is invalid for the distribution.

For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “General Code Generation Workflow” on page 31-5.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

evstat

Extreme value mean and variance

Syntax

```
[M,V] = evstat(mu,sigma)
```

Description

`[M,V] = evstat(mu,sigma)` returns the mean and variance for the type 1 extreme value distribution with location parameter `mu` and scale parameter `sigma`. `mu` and `sigma` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array of the same size as the other input. The default values for `mu` and `sigma` are 0 and 1, respectively.

The type 1 extreme value distribution is also known as the Gumbel distribution. The version used here is suitable for modeling minima; the mirror image of this distribution can be used to model maxima. See “Extreme Value Distribution” on page B-36 for more details. If x has a Weibull distribution, then $X = \log(x)$ has the type 1 extreme value distribution.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

expcdf

Exponential cumulative distribution function

Syntax

```
p = expcdf(x,mu)
[p,plo,pup] = expcdf(x,mu,pcov,alpha)
[p,plo,pup] = expcdf( __ , 'upper')
```

Description

`p = expcdf(x,mu)` computes the exponential cdf at each of the values in `x` using the corresponding mean parameter `mu`. `x` and `mu` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other input. The parameters in `mu` must be positive.

`[p,plo,pup] = expcdf(x,mu,pcov,alpha)` produces confidence bounds for `p` when the input mean parameter `mu` is an estimate. `pcov` is the variance of the estimated `mu`. `alpha` specifies $100(1 - \text{alpha})\%$ confidence bounds. The default value of `alpha` is 0.05. `plo` and `pup` are arrays of the same size as `p` containing the lower and upper confidence bounds. The bounds are based on a normal approximation for the distribution of the log of the estimate of `mu`. If you estimate `mu` from a set of data, you can get a more accurate set of bounds by applying `expfit` to the data to get a confidence interval for `mu`, and then evaluating `expinv` at the lower and upper endpoints of that interval.

`[p,plo,pup] = expcdf(__ , 'upper')` returns the complement of the exponential cdf at each value in `x`, using an algorithm that more accurately computes the extreme upper tail probabilities. You can use the `'upper'` argument with any of the prior syntaxes.

The exponential cdf is

$$p = F(x|u) = \int_0^x \frac{1}{\mu} e^{-\frac{t}{\mu}} dt = 1 - e^{-\frac{x}{\mu}}$$

The result, p , is the probability that a single observation from an exponential distribution will fall in the interval $[0, x]$.

Examples

Compute the Exponential CDF

The following code shows that the median of the exponential distribution is $\mu \cdot \log(2)$.

```
mu = 10:10:60;  
p = expcdf(log(2)*mu, mu)  
  
p = 1x6  
    0.5000    0.5000    0.5000    0.5000    0.5000    0.5000
```

What is the probability that an exponential random variable is less than or equal to the mean, μ ?

```
mu = 1:6;  
x = mu;  
p = expcdf(x, mu)  
  
p = 1x6  
    0.6321    0.6321    0.6321    0.6321    0.6321    0.6321
```

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU arrays. For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

Introduced before R2006a

expfit

Exponential parameter estimates

Syntax

```
muhat = expfit(data)
[muhat,muci] = expfit(data)
[muhat,muci] = expfit(data,alpha)
[...] = expfit(data,alpha,censoring)
[...] = expfit(data,alpha,censoring,freq)
```

Description

`muhat = expfit(data)` estimates the mean of an exponentially distributed sample data. Each entry of `muhat` corresponds to the data in a column of `data`.

`[muhat,muci] = expfit(data)` returns 95% confidence intervals for the mean parameter estimates in matrix `muci`. The first row of `muci` contains the lower bounds of the confidence intervals, and the second row contains the upper bounds.

`[muhat,muci] = expfit(data,alpha)` returns $100(1 - \alpha)\%$ confidence intervals for the parameter estimates, where `alpha` is a value in the range $[0 \ 1]$ specifying the width of the confidence intervals. By default, `alpha` is `0.05`, which corresponds to 95% confidence intervals.

`[...] = expfit(data,alpha,censoring)` accepts a Boolean vector, `censoring`, of the same size as `data`, which is 1 for observations that are right-censored and 0 for observations that are observed exactly. `data` must be a vector in order to pass in the argument `censoring`.

`[...] = expfit(data,alpha,censoring,freq)` accepts a frequency vector, `freq` of the same size as `data`. Typically, `freq` contains integer frequencies for the corresponding elements in `data`, but can contain any nonnegative values. Pass in `[]` for `alpha`, `censoring`, or `freq` to use their default values.

Examples

The following estimates the mean μ of exponentially distributed data, and returns a 95% confidence interval for the estimate:

```
mu = 3;
data = exprnd(mu,100,1); % Simulated data

[muhat,muci] = expfit(data)
muhat =
    2.7511
muci =
    2.2826
    3.3813
```

Extended Capabilities

Introduced before R2006a

ExhaustiveSearcher

Create exhaustive nearest neighbor searcher

Description

ExhaustiveSearcher model objects store the training data, distance metric, and parameter values of the distance metric for an exhaustive nearest neighbor search. The exhaustive search algorithm finds the distance from each query observation to all n observations in the training data, which is an n -by- K numeric matrix.

Once you create an ExhaustiveSearcher model object, find neighboring points in the training data to the query data by performing a nearest neighbor search using `knnsearch` or a radius search using `rangesearch`. The exhaustive search algorithm is more efficient than the Kd -tree algorithm when K is large (that is, $K > 10$), and it is more flexible than the Kd -tree algorithm with respect to distance metric choices. The ExhaustiveSearcher model object also supports sparse data.

Creation

Use either the `createns` function or the `ExhaustiveSearcher` function (described here) to create an ExhaustiveSearcher object. Both functions use the same syntax except that the `createns` function has the 'NSMethod' name-value pair argument, which you use to choose the nearest neighbor search method. The `createns` function also creates a `KDTreeSearcher` object. Specify 'NSMethod', 'exhaustive' to create an ExhaustiveSearcher object. The default is 'exhaustive' if $K > 10$, the training data is sparse, or the distance metric is not the Euclidean, city block, Chebychev, or Minkowski.

Syntax

```
Mdl = ExhaustiveSearcher(X)
Mdl = ExhaustiveSearcher(X,Name,Value)
```

Description

`Mdl = ExhaustiveSearcher(X)` creates an exhaustive nearest neighbor searcher object (`Mdl`) using the n -by- K numeric matrix of training data (`X`).

`Mdl = ExhaustiveSearcher(X, Name, Value)` specifies additional options using one or more name-value pair arguments. You can specify the distance metric and set the distance metric parameter (`DistParameter`) property. For example, `ExhaustiveSearcher(X, 'Distance', 'chebychev')` creates an exhaustive nearest neighbor searcher object that uses the Chebychev distance. To specify `DistParameter`, use the `Cov`, `P`, or `Scale` name-value pair argument.

Input Arguments

X — Training data

numeric matrix

Training data that prepares the exhaustive searcher algorithm, specified as a numeric matrix. `X` has n rows, each corresponding to an observation (that is, an instance or example), and K columns, each corresponding to a predictor (that is, a feature).

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'Distance', 'mahalanobis', 'Cov', eye(3)` specifies to use the Mahalanobis distance when searching for nearest neighbors and a 3-by-3 identity matrix for the covariance matrix in the Mahalanobis distance metric.

Distance — Distance metric

'euclidean' (default) | character vector | string scalar | custom distance function

Distance metric used when you call `knnsearch` or `rangesearch` to find nearest neighbors for future query points, specified as the comma-separated pair consisting of 'Distance' and a character vector, string scalar, or function handle.

This table describes the supported distance metrics specified as character vectors or string scalars.

Value	Description
'chebychev'	Chebychev distance (maximum coordinate difference).
'cityblock'	City block distance.
'correlation'	One minus the sample linear correlation between observations (treated as sequences of values).
'cosine'	One minus the cosine of the included angle between observations (treated as row vectors).
'euclidean'	Euclidean distance.
'hamming'	Hamming distance, which is the percentage of coordinates that differ.
'jaccard'	One minus the Jaccard coefficient, which is the percentage of nonzero coordinates that differ.
'minkowski'	Minkowski distance. The default exponent is 2. To specify a different exponent, use the 'P' name-value pair argument.
'mahalanobis'	Mahalanobis distance, computed using a positive definite covariance matrix. To change the value of the covariance matrix, use the 'Cov' name-value pair argument.
'seuclidean'	Standardized Euclidean distance. Each coordinate difference between rows in <code>Mdl.X</code> and the query matrix is scaled by dividing by the corresponding element of the standard deviation computed from <code>Mdl.X</code> . To specify another scaling, use the 'Scale' name-value pair argument.
'spearman'	One minus the sample Spearman's rank correlation between observations (treated as sequences of values).

For more details, see “Distance Metrics” on page 18-16.

You can specify a function handle for a custom distance metric by using @ (for example, @distfun). A custom distance function must:

- Have the form `function D2 = distfun(ZI, ZJ)`.
- Take as arguments:

- A 1-by- K vector ZI containing a single row from X or from the query points Y , where K is the number of columns in X .
- An m -by- K matrix ZJ containing multiple rows of X or Y , where m is a positive integer.
- Return an m -by-1 vector of distance $D2$, where $D2(j)$ is the distance between the observations ZI and $ZJ(j, :)$.

The software does not use the distance metric for creating an `ExhaustiveSearcher` model object, so you can alter the distance metric by using dot notation after creating the object.

Example: `'Distance', 'mahalanobis'`

Cov — Covariance matrix for Mahalanobis distance metric

`nancov(X)` (default) | positive definite matrix

Covariance matrix for the Mahalanobis distance metric, specified as the comma-separated pair consisting of `'Cov'` and a K -by- K positive definite matrix, where K is the number of columns in X . This argument is valid only if `'Distance'` is `'mahalanobis'`.

Example: `'Cov', eye(3)`

Data Types: `single` | `double`

P — Exponent for Minkowski distance metric

`2` (default) | positive scalar

Exponent for the Minkowski distance metric, specified as the comma-separated pair consisting of `'P'` and a positive scalar. This argument is valid only if `'Distance'` is `'minkowski'`.

Example: `'P', 3`

Data Types: `single` | `double`

Scale — Scale parameter value for standardized Euclidean distance metric

`nanstd(X)` (default) | nonnegative numeric vector

Scale parameter value for the standardized Euclidean distance metric, specified as the comma-separated pair consisting of `'Scale'` and a nonnegative numeric vector of length K , where K is the number of columns in X . The software scales each difference between the training and query data using the corresponding element of `Scale`. This argument is valid only if `'Distance'` is `'seuclidean'`.

Example: `'Scale', quantile(X,0.75) - quantile(X,0.25)`

Data Types: `single` | `double`

Properties

X — Training data

numeric matrix

This property is read-only.

Training data that prepares the exhaustive searcher algorithm, specified as a numeric matrix. X has n rows, each corresponding to an observation (that is, an instance or example), and K columns, each corresponding to a predictor (that is, a feature).

The input argument X of `createns` or `ExhaustiveSearcher` sets this property.

Data Types: `single` | `double`

Distance — Distance metric

character vector | string scalar | custom distance function

Distance metric used when you call `knnsearch` or `rangesearch` to find nearest neighbors for future query points, specified as a character vector or string scalar ('chebychev', 'cityblock', 'correlation', 'cosine', 'euclidean', 'hamming', 'jaccard', 'minkowski', 'mahalanobis', 'seuclidean', or 'spearman'), or a function handle.

The 'Distance' name-value pair argument of `createns` or `ExhaustiveSearcher` sets this property.

The software does not use the distance metric for creating an `ExhaustiveSearcher` model object, so you can alter it by using dot notation.

DistParameter — Distance metric parameter values

`[]` | positive scalar

Distance metric parameter values, specified as empty (`[]`) or a positive scalar.

This table describes the distance parameters of the supported distance metrics.

Distance Metric	Parameter Description
'mahalanobis'	<p>A positive definite matrix representing the covariance matrix used for computing the Mahalanobis distance. By default, the software sets the covariance using <code>nancov(Mdl.X)</code>.</p> <p>The 'Cov' name-value pair argument of <code>createns</code> or <code>ExhaustiveSearcher</code> sets this property.</p> <p>You can alter <code>DistParameter</code> by using dot notation, for example, <code>Mdl.DistParameter = CovNew</code>, where <code>CovNew</code> is a K-by-K positive definite numeric matrix.</p>
'minkowski'	<p>A positive scalar indicating the exponent of the Minkowski distance. By default, the exponent is 2.</p> <p>The 'P' name-value pair argument of <code>createns</code> or <code>ExhaustiveSearcher</code> sets this property.</p> <p>You can alter <code>DistParameter</code> by using dot notation, for example, <code>Mdl.DistParameter = PNew</code>, where <code>PNew</code> is a positive scalar.</p>
'seuclidean'	<p>A positive numeric vector indicating the values used by the software to scale the predictors when computing the standardized Euclidean distance. By default, the software:</p> <ol style="list-style-type: none"> 1 Estimates the standard deviation of each predictor (column) of X using <code>scale = nanstd(Mdl.X)</code> 2 Scales each coordinate difference between the rows in X and the query matrix by dividing by the corresponding element of <code>scale</code> <p>The 'Scale' name-value pair argument of <code>createns</code> or <code>ExhaustiveSearcher</code> sets this property.</p> <p>You can alter <code>DistParameter</code> by using dot notation, for example, <code>Mdl.DistParameter = sNew</code>, where <code>sNew</code> is a K-dimensional positive numeric vector.</p>

If `Mdl.Distance` is not one of the parameters listed in this table, then `Mdl.DistParameter` is `[]`, which means that the specified distance metric formula has no parameters.

Data Types: single | double

Object Functions

knnsearch Find k-nearest neighbors using searcher object

rangearch Find all neighbors within specified distance using searcher object

Examples

Train Default Exhaustive Nearest Neighbor Searcher

Load Fisher's iris data set.

```
load fisheriris
X = meas;
[n,k] = size(X)
```

```
n = 150
```

```
k = 4
```

X has 150 observations and 4 predictors.

Prepare an exhaustive nearest neighbor searcher using the entire data set as training data.

```
Mdl1 = ExhaustiveSearcher(X)
```

```
Mdl1 =
ExhaustiveSearcher with properties:
    Distance: 'euclidean'
  DistParameter: []
           X: [150x4 double]
```

Mdl1 is an ExhaustiveSearcher model object, and its properties appear in the Command Window. The object contains information about the trained algorithm, such as the distance metric. You can alter property values using dot notation.

Alternatively, you can prepare an exhaustive nearest neighbor searcher by using `createns` and specifying `'exhaustive'` as the search method.

```
Mdl2 = createns(X, 'NSMethod', 'exhaustive')
```

```
Mdl2 =  
ExhaustiveSearcher with properties:  
  
    Distance: 'euclidean'  
  DistParameter: []  
           X: [150x4 double]
```

`Mdl2` is also an `ExhaustiveSearcher` model object, and it is equivalent to `Mdl1`.

To search `X` for the nearest neighbors to a batch of query data, pass the `ExhaustiveSearcher` model object and the query data to `knnsearch` or `rangesearch`.

Specify the Mahalanobis Distance for Nearest Neighbor Search

Load Fisher's iris data set. Focus on the petal dimensions.

```
load fisheriris  
X = meas(:, [3 4]); % Predictors
```

Prepare an exhaustive nearest neighbor searcher. Specify the Mahalanobis distance metric.

```
Mdl = createns(X, 'Distance', 'mahalanobis')
```

```
Mdl =  
ExhaustiveSearcher with properties:  
  
    Distance: 'mahalanobis'  
  DistParameter: [2x2 double]  
           X: [150x2 double]
```

Because the distance metric is Mahalanobis, `createns` creates an `ExhaustiveSearcher` model object by default.

Access properties of `Mdl` by using dot notation. For example, use `Mdl.DistParameter` to access the Mahalanobis covariance parameter.

```
Mdl.DistParameter
```

```
ans = 2x2
```

```
    3.1163    1.2956  
    1.2956    0.5810
```

You can pass query data and Mdl to:

- `knnsearch` to find indices and distances of nearest neighbors
- `rangearch` to find indices of all nearest neighbors within a distance that you specify

Alter Properties of ExhaustiveSearcher Model

Create an ExhaustiveSearcher model object and alter the Distance property by using dot notation.

Load Fisher's iris data set.

```
load fisheriris  
X = meas;
```

Train a default exhaustive searcher algorithm using the entire data set as training data.

```
Mdl = ExhaustiveSearcher(X)
```

```
Mdl =  
ExhaustiveSearcher with properties:
```

```
    Distance: 'euclidean'  
    DistParameter: []  
           X: [150x4 double]
```

Specify that the neighbor searcher use the Mahalanobis metric to compute the distances between the training and query data.

```
Mdl.Distance = 'mahalanobis'
```

```
Mdl =  
ExhaustiveSearcher with properties:
```

```
Distance: 'mahalanobis'  
DistParameter: [4x4 double]  
X: [150x4 double]
```

You can pass `Mdl` and the query data to either `knnsearch` or `rangesearch` to find the nearest neighbors to the points in the query data based on the Mahalanobis distance.

Search for Nearest Neighbors of Query Data Using Mahalanobis Distance

Create an exhaustive searcher object by using the `createns` function. Pass the object and query data to the `knnsearch` function to find k -nearest neighbors.

Load Fisher's iris data set.

```
load fisheriris
```

Remove five irises randomly from the predictor data to use as a query set.

```
rng('default');           % For reproducibility  
n = size(meas,1);         % Sample size  
qIdx = randsample(n,5);   % Indices of query data  
X = meas(~ismember(1:n,qIdx),:);  
Y = meas(qIdx,:);
```

Prepare an exhaustive nearest neighbor searcher using the training data. Specify the Mahalanobis distance for finding nearest neighbors.

```
Mdl = createns(X, 'Distance', 'mahalanobis')
```

```
Mdl =  
ExhaustiveSearcher with properties:
```

```
Distance: 'mahalanobis'  
DistParameter: [4x4 double]  
X: [145x4 double]
```

Because the distance metric is Mahalanobis, `createns` creates an `ExhaustiveSearcher` model object by default.

The software uses the covariance matrix of the predictors (columns) in the training data for computing the Mahalanobis distance. To display this value, use `Mdl.DistParameter`.

`Mdl.DistParameter`

`ans = 4×4`

```

    0.6547    -0.0368    1.2320    0.5026
   -0.0368    0.1914   -0.3227   -0.1193
    1.2320   -0.3227    3.0671    1.2842
    0.5026   -0.1193    1.2842    0.5800

```

Find the indices of the training data (`Mdl.X`) that are the two nearest neighbors of each point in the query data (`Y`).

`IdxNN = knnsearch(Mdl,Y,'K',2)`

`IdxNN = 5×2`

```

     5     6
    98    95
   104   128
   135    65
   102   115

```

Each row of `IdxNN` corresponds to a query data observation. The column order corresponds to the order of the nearest neighbors with respect to ascending distance. For example, based on the Mahalanobis metric, the second nearest neighbor of `Y(3, :)` is `X(128, :)`.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The `knnsearch` and `rangesearch` functions support code generation.
- When you train an `ExhaustiveSearcher` model object, the value of the 'Distance' name-value pair argument cannot be a custom distance function.

For more information, see “Introduction to Code Generation” on page 31-2 and “Code Generation for Nearest Neighbor Searcher” on page 31-15.

expinv

Exponential inverse cumulative distribution function

Syntax

```
X = expinv(P,mu)
[X,XL0,XUP] = expinv(P,mu,pcov,alpha)
```

Description

`X = expinv(P,mu)` computes the inverse of the exponential cdf with parameters specified by mean parameter `mu` for the corresponding probabilities in `P`. `P` and `mu` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other input. The parameters in `mu` must be positive and the values in `P` must lie on the interval [0 1].

`[X,XL0,XUP] = expinv(P,mu,pcov,alpha)` produces confidence bounds for `X` when the input mean parameter `mu` is an estimate. `pcov` is the variance of the estimated `mu`. `alpha` specifies $100(1 - \alpha)\%$ confidence bounds. The default value of `alpha` is 0.05. `XL0` and `XUP` are arrays of the same size as `X` containing the lower and upper confidence bounds. The bounds are based on a normal approximation for the distribution of the log of the estimate of `mu`. If you estimate `mu` from a set of data, you can get a more accurate set of bounds by applying `expfit` to the data to get a confidence interval for `mu`, and then evaluating `expinv` at the lower and upper end points of that interval.

The inverse of the exponential cdf is

$$x = F^{-1}(p|\mu) = -\mu \ln(1 - p)$$

The result, `x`, is the value such that an observation from an exponential distribution with parameter `mu` will fall in the range [0 `x`] with probability `p`.

Examples

Let the lifetime of light bulbs be exponentially distributed with $\mu = 700$ hours. What is the median lifetime of a bulb?

```
expinv(0.50,700)
ans =
    485.2030
```

Suppose you buy a box of “700 hour” light bulbs. If 700 hours is the mean life of the bulbs, half of them will burn out in less than 500 hours.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU arrays. For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

explike

Exponential negative log-likelihood

Syntax

```
nlogL = explike(param,data)
[nlogL,avar] = explike(param,data)
[...] = explike(param,data,censoring)
[...] = explike(param,data,censoring,freq)
```

Description

`nlogL = explike(param,data)` returns the negative of the log-likelihood for the exponential distribution. `param` is the mean parameter, μ . `nlogL` is a scalar.

`[nlogL,avar] = explike(param,data)` returns the inverse of Fisher's information, `avar`, a scalar. If the input parameter value in `param` is the maximum likelihood estimate, `avar` is its asymptotic variance. `avar` is based on the observed Fisher's information, not the expected information.

`[...] = explike(param,data,censoring)` accepts a Boolean vector, `censoring`, of the same size as `data`, which is 1 for observations that are right-censored and 0 for observations that are observed exactly.

`[...] = explike(param,data,censoring,freq)` accepts a frequency vector, `freq`, of the same size as `data`. The vector `freq` typically contains integer frequencies for the corresponding elements in `data`, but can contain any nonnegative values. Pass in `[]` for `censoring` to use its default value.

Extended Capabilities

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

export

Class: dataset

Write dataset array to file

Note The dataset data type might be removed in a future release. To work with heterogeneous data, use the MATLAB® table data type instead. See MATLAB table documentation for more information.

Syntax

```
export(DS,'file',filename)
export(DS)
export(DS,'file',filename,'Delimiter',delim)
export(DS,'XLSfile',filename)
export(DS,'XPTFile',filename)
export(DS,...,'WriteVarNames',false)
export(DS,...,'WriteObsNames',false)
```

Description

`export(DS,'file',filename)` writes the dataset array `DS` to a tab-delimited text file, including variable names and observation names, if present. If the observation names exist, the name in the first column of the first line of the file is the first dimension name for the dataset (by default, 'Observations'). `export` overwrites any existing file named `filename`.

`export(DS)` writes to a text file whose default name is the name of the dataset array `DS` appended by '.txt'. If `export` cannot construct the file name from the dataset array input, it writes to the file 'dataset.txt'. `export` overwrites any existing file.

`export(DS,'file',filename,'Delimiter',delim)` writes the dataset array `DS` to a text file using the delimiter `delim`. `delim` must be one of the following:

- ' ' or 'space'
- '\t' or 'tab'
- ',' or 'comma'
- ';' or 'semi'
- '|' or 'bar'

`export(DS, 'XLSfile', filename)` writes the dataset array `DS` to a Microsoft® Excel spreadsheet file, including variable names and observation names (if present). You can specify the 'Sheet' and 'Range' parameter name/value pairs, with parameter values as accepted by the `xlsread` function. Since `export` uses the `xlswrite` function internally, this syntax is only compatible with Microsoft Excel for Windows, and does not work on a Mac. For more information, see `xlswrite`.

`export(DS, 'XPTfile', filename)` writes the dataset array `DS` to a SAS XPORT format file. When writing to an XPORT format file, variables must be scalar valued. `export` saves observation names to a variable called `obsnames`, unless the `WriteObsNames` parameter described below is `false`. The XPORT format restricts the length of variable names to eight characters; longer variable names are truncated.

`export(DS, ..., 'WriteVarNames', false)` does not write the variable names to the text file. `export(DS, ..., 'WriteVarNames', true)` is the default, writing the names as column headings in the first line of the file.

`export(DS, ..., 'WriteObsNames', false)` does not write the observation names to the text file. `export(DS, ..., 'WriteObsNames', true)` is the default, writing the names as the first column of the file.

In some cases, `export` creates a text file that does not represent `A` exactly, as described below. If you use `dataset` to read the file back into MATLAB, the new dataset array may not have exactly the same contents as the original dataset array. Save `A` as a MAT-file if you need to import it again as a dataset array.

`export` writes out numeric variables using long `g` format, and categorical or character variables as unquoted text.

For non-character variables with more than one column, `export` writes out multiple delimiter-separated fields on each line, and constructs suitable column headings for the first line of the file.

`export` writes out variables that have more than two dimensions as a single empty field in each line of the file.

For cell-valued variables, `export` writes out the contents of each cell only when the cell contains a single row, and writes out a single empty field otherwise.

In some cases, `export` creates a file that cannot be read back into MATLAB using `dataset`. Writing a dataset array that contains a cell-valued variable whose cell contents are not scalars results in a mismatch in the file between the number of fields on each line and the number of column headings on the first line. Writing a dataset array that contains a cell-valued variable whose cell contents are not all the same length results in a different number of fields on each line in the file. Therefore, if you might need to import a dataset array again, save it as a `.mat` file.

Examples

Move data between external text files and dataset arrays in the MATLAB workspace:

```
A = dataset('file','sat2.dat','delimiter','(',')
```

```
A =
```

Test	Gender	Score
'Verbal'	'Male'	470
'Verbal'	'Female'	530
'Quantitative'	'Male'	520
'Quantitative'	'Female'	480

```
export(A(A.Score > 500,:), 'file', 'HighScores.txt')
```

```
B = dataset('file', 'HighScores.txt', 'delimiter', '\t')
```

```
B =
```

Test	Gender	Score
'Verbal'	'Female'	530
'Quantitative'	'Male'	520

See Also

`dataset`

exppdf

Exponential probability density function

Syntax

```
Y = exppdf(X,mu)
```

Description

`Y = exppdf(X,mu)` returns the pdf of the exponential distribution with mean parameter `mu`, evaluated at the values in `X`. `X` and `mu` can be vectors, matrices, or multidimensional arrays that have the same size. A scalar input is expanded to a constant array with the same dimensions as the other input. The parameters in `mu` must be positive.

The exponential pdf is

$$y = f(x|\mu) = \frac{1}{\mu} e^{-\frac{x}{\mu}}$$

The exponential pdf is the gamma pdf with its first parameter equal to 1.

The exponential distribution is appropriate for modeling waiting times when the probability of waiting an additional period of time is independent of how long you have already waited. For example, the probability that a light bulb will burn out in its next minute of use is relatively independent of how many minutes it has already burned.

Examples

```
y = exppdf(5,1:5)
y =
    0.0067    0.0410    0.0630    0.0716    0.0736
```

```
y = exppdf(1:5,1:5)
y =
    0.3679    0.1839    0.1226    0.0920    0.0736
```

Extended Capabilities

exprnd

Exponential random numbers

Syntax

```
R = exprnd(mu)
R = exprnd(mu,m,n,...)
R = exprnd(mu,[m,n,...])
```

Description

`R = exprnd(mu)` generates random numbers from the exponential distribution with mean parameter `mu`. `mu` can be a vector, a matrix, or a multidimensional array. The size of `R` is the size of `mu`.

`R = exprnd(mu,m,n,...)` or `R = exprnd(mu,[m,n,...])` generates an `m`-by-`n`-by-... array containing random numbers from the exponential distribution with mean parameter `mu`. `mu` can be a scalar or an array of the same size as `R`.

Examples

```
n1 = exprnd(5:10)
n1 =
    7.5943  18.3400  2.7113  3.0936  0.6078  9.5841

n2 = exprnd(5:10,[1 6])
n2 =
    3.2752  1.1110  23.5530  23.4303  5.7190  3.9876

n3 = exprnd(5,2,3)
n3 =
    24.3339  13.5271  1.8788
     4.7932   4.3675  2.6468
```

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

The generated code can return a different sequence of numbers than MATLAB if either of the following is true:

- The output is nonscalar.
- An input parameter is invalid for the distribution.

For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “General Code Generation Workflow” on page 31-5.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

expstat

Exponential mean and variance

Syntax

```
[m,v] = expstat(mu)
```

Description

`[m,v] = expstat(mu)` returns the mean of and variance for the exponential distribution with parameters `mu`. `mu` can be a vectors, matrix, or multidimensional array. The mean of the exponential distribution is μ , and the variance is μ^2 .

Examples

```
[m,v] = expstat([1 10 100 1000])  
m =  
    1    10    100   1000  
v =  
    1    100  10000 1000000
```

“Exponential Distribution” on page B-32

Introduced before R2006a

factoran

Factor analysis

Syntax

```
lambda = factoran(X,m)
[lambda,psi] = factoran(X,m)
[lambda,psi,T] = factoran(X,m)
[lambda,psi,T,stats] = factoran(X,m)
[lambda,psi,T,stats,F] = factoran(X,m)
[...] = factoran(...,param1,val1,param2,val2,...)
```

Description

`lambda = factoran(X,m)` returns the maximum likelihood estimate, `lambda`, of the factor loadings matrix, in a common factor analysis model with `m` common factors. `X` is an `n`-by-`d` matrix where each row is an observation of `d` variables. The (i, j) th element of the `d`-by-`m` matrix `lambda` is the coefficient, or loading, of the j th factor for the i th variable. By default, `factoran` calls the function `rotatefactors` to rotate the estimated factor loadings using the 'varimax' option.

`[lambda,psi] = factoran(X,m)` also returns maximum likelihood estimates of the specific variances as a column vector `psi` of length `d`.

`[lambda,psi,T] = factoran(X,m)` also returns the `m`-by-`m` factor loadings rotation matrix `T`.

`[lambda,psi,T,stats] = factoran(X,m)` also returns a structure `stats` containing information relating to the null hypothesis, H_0 , that the number of common factors is `m`. `stats` includes the following fields:

Field	Description
<code>loglike</code>	Maximized log-likelihood value
<code>dfe</code>	Error degrees of freedom = $((d-m)^2 - (d+m))/2$

Field	Description
chisq	Approximate chi-squared statistic for the null hypothesis
p	Right-tail significance level for the null hypothesis

factoran does not compute the `chisq` and `p` fields unless `dfe` is positive and all the specific variance estimates in `psi` are positive (see “Heywood Case” on page 32-1613 below). If `X` is a covariance matrix, then you must also specify the `'nobs'` parameter if you want factoran to compute the `chisq` and `p` fields.

`[lambda,psi,T,stats,F] = factoran(X,m)` also returns, in `F`, predictions of the common factors, known as factor scores. `F` is an `n`-by-`m` matrix where each row is a prediction of `m` common factors. If `X` is a covariance matrix, factoran cannot compute `F`. factoran rotates `F` using the same criterion as for `lambda`.

`[...] = factoran(...,param1,val1,param2,val2,...)` enables you to specify optional parameter name/value pairs to control the model fit and the outputs. The following are the valid parameter/value pairs.

Parameter	Value	
'xtype'	Type of input in the matrix <code>X</code> . 'xtype' can be one of:	
	'data'	Raw data (default)
	'covariance'	Positive definite covariance or correlation matrix
'scores'	Method for predicting factor scores. 'scores' is ignored if <code>X</code> is not raw data.	
	'wls' 'Bartlett'	Synonyms for a weighted least-squares estimate that treats <code>F</code> as fixed (default)
	'regression' 'Thomson'	Synonyms for a minimum mean squared error prediction that is equivalent to a ridge regression
'start'	Starting point for the specific variances <code>psi</code> in the maximum likelihood optimization. Can be specified as:	
	'random'	Chooses <code>d</code> uniformly distributed values on the interval <code>[0,1]</code> .

Parameter	Value	
	'Rsquared'	Chooses the starting vector as a scale factor times <code>diag(inv(corrcoef(X)))</code> (default). For examples, see Jöreskog [2].
	Positive integer	Performs the given number of maximum likelihood fits, each initialized as with 'random'. <code>factoran</code> returns the fit with the highest likelihood.
	Matrix	Performs one maximum likelihood fit for each column of the specified matrix. The <i>i</i> th optimization is initialized with the values from the <i>i</i> th column. The matrix must have <i>d</i> rows.
'rotate'	Method used to rotate factor loadings and scores. 'rotate' can have the same values as the 'Method' parameter of <code>rotatefactors</code> . See the reference page for <code>rotatefactors</code> for a full description of the available methods.	
	'none'	Performs no rotation.
	'equamax'	Special case of the orthomax rotation. Use the 'normalize', 'reltol', and 'maxit' parameters to control the details of the rotation.
	'orthomax'	Orthogonal rotation that maximizes a criterion based on the variance of the loadings. Use the 'coeff', 'normalize', 'reltol', and 'maxit' parameters to control the details of the rotation.
	'parsimax'	Special case of the orthomax rotation (default). Use the 'normalize', 'reltol', and 'maxit' parameters to control the details of the rotation.

Parameter	Value	
	'pattern'	Performs either an oblique rotation (the default) or an orthogonal rotation to best match a specified pattern matrix. Use the 'type' parameter to choose the type of rotation. Use the 'target' parameter to specify the pattern matrix.
	'procrustes'	Performs either an oblique (the default) or an orthogonal rotation to best match a specified target matrix in the least squares sense. Use the 'type' parameter to choose the type of rotation. Use 'target' to specify the target matrix.
	'promax'	Performs an oblique procrustes rotation to a target matrix determined by factoran as a function of an orthomax solution. Use the 'power' parameter to specify the exponent for creating the target matrix. Because 'promax' uses 'orthomax' internally, you can also specify the parameters that apply to 'orthomax'.
	'quartimax'	Special case of the orthomax rotation (default). Use the 'normalize', 'reltol', and 'maxit' parameters to control the details of the rotation.
	'varimax'	Special case of the orthomax rotation (default). Use the 'normalize', 'reltol', and 'maxit' parameters to control the details of the rotation.

Parameter	Value
	<p>Function</p> <p>Function handle to rotation function of the form</p> <pre>[B,T] = myrotation(A,...)</pre> <p>where A is a d-by-m matrix of unrotated factor loadings, B is a d-by-m matrix of rotated loadings, and T is the corresponding m-by-m rotation matrix.</p> <p>Use the <code>factoran</code> parameter <code>'userargs'</code> to pass additional arguments to this rotation function. See “User-Defined Rotation Function” on page 32-1611.</p>
<code>'coeff'</code>	Coefficient, often denoted as γ , defining the specific <code>'orthomax'</code> criterion. Must be from 0 to 1. The value 0 corresponds to <code>quartimax</code> , and 1 corresponds to <code>varimax</code> . Default is 1.
<code>'normalize'</code>	Flag indicating whether the loading matrix should be row-normalized (1) or left unnormalized (0) for <code>'orthomax'</code> or <code>'varimax'</code> rotation. Default is 1.
<code>'reltol'</code>	Relative convergence tolerance for <code>'orthomax'</code> or <code>'varimax'</code> rotation. Default is <code>sqrt(eps)</code> .
<code>'maxit'</code>	Iteration limit for <code>'orthomax'</code> or <code>'varimax'</code> rotation. Default is 250.
<code>'target'</code>	Target factor loading matrix for <code>'procrustes'</code> rotation. Required for <code>'procrustes'</code> rotation. No default value.
<code>'type'</code>	Type of <code>'procrustes'</code> rotation. Can be <code>'oblique'</code> (default) or <code>'orthogonal'</code> .
<code>'power'</code>	Exponent for creating the target matrix in the <code>'promax'</code> rotation. Must be ≥ 1 . Default is 4.
<code>'userargs'</code>	Denotes the beginning of additional input values for a user-defined rotation function. <code>factoran</code> appends all subsequent values, in order and without processing, to the rotation function argument list, following the unrotated factor loadings matrix A. See “User-Defined Rotation Function” on page 32-1611.

Parameter	Value
'nobs'	If X is a covariance or correlation matrix, indicates the number of observations that were used in its estimation. This allows calculation of significance for the null hypothesis even when the original data are not available. There is no default. 'nobs' is ignored if X is raw data.
'delta'	Lower bound for the specific variances ψ_i during the maximum likelihood optimization. Default is 0.005.
'optimopts'	Structure that specifies control parameters for the iterative algorithm the function uses to compute maximum likelihood estimates. Create this structure with the function <code>statset</code> . Enter <code>statset('factoran')</code> to see the names and default values of the parameters that <code>factoran</code> accepts in the <code>options</code> structure. See the reference page for <code>statset</code> for more information about these options.

Examples

Estimate and Plot Factor Loadings

Load the sample data.

```
load carbig
```

Define the variable matrix.

```
X = [Acceleration Displacement Horsepower MPG Weight];
X = X(all(~isnan(X),2),:);
```

Estimate the factor loadings using a minimum mean squared error prediction for a factor analysis with two common factors.

```
[Lambda,Psi,T,stats,F] = factoran(X,2,'scores','regression');
inv(T'*T); % Estimated correlation matrix of F, == eye(2)
Lambda*Lambda' + diag(Psi); % Estimated correlation matrix
Lambda*inv(T); % Unrotate the loadings
F*T'; % Unrotate the factor scores
```

Create biplot of two factors.

```
biplot(Lambda, 'LineWidth', 2, 'MarkerSize', 20)
```

Estimate the factor loadings using the covariance (or correlation) matrix.

```
[Lambda, Psi, T] = factoran(cov(X), 2, 'xtype', 'cov')
```

```
Lambda = 5x2
```

```
-0.2432    -0.8500  
 0.8773     0.3871  
 0.7618     0.5930  
-0.7978    -0.2786  
 0.9692     0.2129
```

```
Psi = 5x1
```

```
0.2184
0.0804
0.0680
0.2859
0.0152
```

```
T = 2x2
```

```
0.9476    0.3195
0.3195   -0.9476
```

```
% [Lambda,Psi,T] = factoran(corrcoef(X),2,'xtype','cov')
```

Although the estimates are the same, the use of a covariance matrix rather than raw data doesn't let you request scores or significance level.

Use promax rotation.

```
[Lambda,Psi,T,stats,F] = factoran(X,2,'rotate','promax',...
    'powerpm',4);
inv(T'*T) % Estimated correlation of F,
```

```
ans = 2x2
```

```
1.0000    -0.6391
-0.6391    1.0000
```

```
Lambda*inv(T'*T)*Lambda'+diag(Psi) % no longer eye(2)
    % Estimated correlation of X
```

```
ans = 5x5
```

```
1.0000    -0.5424   -0.6893    0.4309   -0.4167
-0.5424    1.0000    0.8979   -0.8078    0.9328
-0.6893    0.8979    1.0000   -0.7730    0.8647
0.4309   -0.8078   -0.7730    1.0000   -0.8326
-0.4167    0.9328    0.8647   -0.8326    1.0000
```

Plot the unrotated variables with oblique axes superimposed.

```

invT = inv(T);
Lambda0 = Lambda*invT;
figure()
line([-invT(1,1) invT(1,1) NaN -invT(2,1) invT(2,1)], ...
      [-invT(1,2) invT(1,2) NaN -invT(2,2) invT(2,2)], ...
      'Color','r','linewidth',2)
grid on
hold on
biplot(Lambda0,'LineWidth',2,'MarkerSize',20)
xlabel('Loadings for unrotated Factor 1')
ylabel('Loadings for unrotated Factor 2')

```

Plot the rotated variables against the oblique axes.

```
figure()  
biplot(Lambda, 'LineWidth', 2, 'MarkerSize', 20)
```

User-Defined Rotation Function

Syntax for passing additional arguments to a user-defined rotation function:

```
[Lambda,Psi,T] = ...  
    factoran(X,2,'rotate',@myrotation,'userargs',1,'two');
```

Definitions

Factor Analysis Model

`factoran` computes the maximum likelihood estimate (MLE) of the factor loadings matrix Λ in the factor analysis model

$$x = \mu + \Lambda f + e$$

where x is a vector of observed variables, μ is a constant vector of means, Λ is a constant d -by- m matrix of factor loadings, f is a vector of independent, standardized common factors, and e is a vector of independent specific factors. x , μ , and e are of length d . f is of length m .

Alternatively, the factor analysis model can be specified as

$$\text{cov}(x) = \Lambda\Lambda^T + \Psi$$

where $\Psi = \text{cov}(e)$ is a d -by- d diagonal matrix of specific variances.

Tips

Observed Data Variables

The variables in the observed data matrix X must be linearly independent, i.e., $\text{cov}(X)$ must have full rank, for maximum likelihood estimation to succeed. `factoran` reduces both raw data and a covariance matrix to a correlation matrix before performing the fit.

`factoran` standardizes the observed data X to zero mean and unit variance before estimating the loadings `lambda`. This does not affect the model fit, because MLEs in this model are invariant to scale. However, `lambda` and `psi` are returned in terms of the standardized variables, i.e., `lambda*lambda'+diag(psi)` is an estimate of the correlation matrix of the original data X (although not after an oblique rotation). See “Estimate and Plot Factor Loadings” on page 32-1607 and “User-Defined Rotation Function” on page 32-1611.

Heywood Case

If elements of ψ are equal to the value of the 'delta' parameter (i.e., they are essentially zero), the fit is known as a Heywood case, and interpretation of the resulting estimates is problematic. In particular, there can be multiple local maxima of the likelihood, each with different estimates of the loadings and the specific variances. Heywood cases can indicate overfitting (i.e., m is too large), but can also be the result of underfitting.

Rotation of Factor Loadings and Scores

Unless you explicitly specify no rotation using the 'rotate' parameter, factoran rotates the estimated factor loadings, λ , and the factor scores, F . The output matrix T is used to rotate the loadings, i.e., $\lambda = \lambda_0 * T$, where λ_0 is the initial (unrotated) MLE of the loadings. T is an orthogonal matrix for orthogonal rotations, and the identity matrix for no rotation. The inverse of T is known as the primary axis rotation matrix, while T itself is related to the reference axis rotation matrix. For orthogonal rotations, the two are identical.

factoran computes factor scores that have been rotated by $\text{inv}(T')$, i.e., $F = F_0 * \text{inv}(T')$, where F_0 contains the unrotated predictions. The estimated covariance of F is $\text{inv}(T' * T)$, which, for orthogonal or no rotation, is the identity matrix. Rotation of factor loadings and scores is an attempt to create a more easily interpretable structure in the loadings matrix after maximum likelihood estimation.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

`pcacov` and `factoran` do *not* work directly on tall arrays. Instead, use `C = gather(cov(X))` to compute the covariance matrix of a tall array. Then, you can use `pcacov` or `factoran` on the in-memory covariance matrix. Alternatively, you can use `pca` directly on a tall array.

For more information, see “Tall Arrays” (MATLAB).

fcdf

F cumulative distribution function

Syntax

```
p = fcdf(x, v1, v2)
p = fcdf(x, v1, v2, 'upper')
```

Description

`p = fcdf(x, v1, v2)` computes the F cdf at each of the values in x using the corresponding numerator degrees of freedom v_1 and denominator degrees of freedom v_2 . x , v_1 , and v_2 can be vectors, matrices, or multidimensional arrays that are all the same size. A scalar input is expanded to a constant matrix with the same dimensions as the other inputs. v_1 and v_2 parameters must contain real positive values, and the values in x must lie on the interval $[0 \text{ Inf}]$.

`p = fcdf(x, v1, v2, 'upper')` returns the complement of the F cdf at each value in x , using an algorithm that more accurately computes the extreme upper tail probabilities.

The F cdf is

$$p = F(x) \left| \nu_1, \nu_2 \right. = \int_0^x \frac{\Gamma\left[\frac{(\nu_1 + \nu_2)}{2}\right]}{\Gamma\left(\frac{\nu_1}{2}\right)\Gamma\left(\frac{\nu_2}{2}\right)} \left(\frac{\nu_1}{\nu_2}\right)^{\frac{\nu_1}{2}} \frac{t^{\frac{\nu_1}{2} - 2}}{\left[1 + \left(\frac{\nu_1}{\nu_2}\right)t\right]^{\frac{\nu_1 + \nu_2}{2}}} dt$$

The result, p , is the probability that a single observation from an F distribution with parameters ν_1 and ν_2 will fall in the interval $[0 \ x]$.

Examples

Compute F Distribution CDF

The following illustrates a useful mathematical identity for the F distribution.

```
nu1 = 1:5;  
nu2 = 6:10;  
x = 2:6;
```

```
F1 = fcdf(x,nu1,nu2)
```

```
F1 = 1x5
```

```
    0.7930    0.8854    0.9481    0.9788    0.9919
```

```
F2 = 1 - fcdf(1./x,nu2,nu1)
```

```
F2 = 1x5
```

```
    0.7930    0.8854    0.9481    0.9788    0.9919
```

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU arrays. For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

Topics

“F Distribution” on page B-42

Introduced before R2006a

feval

Evaluate generalized linear regression model prediction

Syntax

```
ypred = feval mdl, Xnew1, Xnew2, ..., Xnewn
```

Description

`ypred = feval(mdl, Xnew1, Xnew2, ..., Xnewn)` returns the predicted response of `mdl` to the input `[Xnew1, Xnew_2, ..., Xnewn]`.

Input Arguments

`mdl`

Generalized linear model, specified as a full `GeneralizedLinearModel` object constructed using `fitglm` or `stepwiseglm`, or a compacted `CompactGeneralizedLinearModel` object constructed using `compact`.

`Xnew1, Xnew2, ..., Xnewn`

Predictor components. `Xnewi` can be one of:

- Scalar
- Vector
- Array

Each nonscalar component must have the same size (number of elements in each dimension).

If you pass just one `Xnew` array, `Xnew` can be a table, dataset array, or an array of doubles, where each column of the array represents one predictor.

Output Arguments

ypred

Predicted mean values at `Xnew`. `ypred` is the same size as each component of `Xnew`.

For binomial models, `feval` uses 1 as the `BinomialSize` parameter, so `ypred` is predicted probabilities.

For models with an offset, `feval` uses 0 as the offset value.

Examples

Predict Responses Using feval

Generate a generalized linear model, and plot its responses to a range of input data.

Generate artificial data for the model, Poisson random numbers with two underlying predictors `X(1)` and `X(2)`.

```
rng('default') % for reproducibility
rndvars = randn(100,2);
X = [2+rndvars(:,1),rndvars(:,2)];
mu = exp(1 + X*[1;2]);
y = poissrnd(mu);
```

Create a generalized linear regression model of Poisson data.

```
mdl = fitglm(X,y,'y ~ x1 + x2','distr','poisson');
```

Generate a range of values for `X(1)` and `X(2)`, and plot the model predictions at those values.

```
[Xtest1 Xtest2] = meshgrid(-1:.5:3,-2:.5:2);
Z = feval(mdl,Xtest1,Xtest2);
surf(Xtest1,Xtest2,Z)
```

Tips

- `feval` allows you to easily evaluate predictions of a model when the model was fitted using a table or dataset array. `predict` requires a table or dataset array with the same predictor names, but you can use simple arrays of scalars with `feval`.

Alternatives

`predict` gives the same predictions, but uses a single input array with one observation in each row, rather than one component in each input argument.

random predicts with added noise.

feval

Package:

Predict responses of linear regression model using one input for each predictor

Syntax

```
ypred = feval mdl, Xnew1, Xnew2, ..., Xnewn
```

Description

`ypred = feval(mdl, Xnew1, Xnew2, ..., Xnewn)` returns the predicted response of `mdl` to the new input predictors `[Xnew1, Xnew2, ..., Xnewn]`.

Examples

Plot Different Categorical Levels

Fit a mileage model to the `carsmall` data set, including the `Year` categorical predictor. Superimpose fitted curves on a scatter plot of the data.

Load the data set and fit the model.

```
load carsmall
tbl = table(MPG, Weight);
tbl.Year = categorical(Model_Year);
mdl = fitlm(tbl, 'MPG ~ Year + Weight^2');
```

Create a scatter plot of `MPG` versus `Weight`, grouped by `Year`.

```
gscatter(tbl.Weight, tbl.MPG, tbl.Year);
```

Plot curves of the model predictions for the various years and weights by using feval.

```
w = linspace(min(tbl.Weight),max(tbl.Weight))';  
line(w,feval mdl,w,'70'),'Color','r')  
line(w,feval mdl,w,'76'),'Color','g')  
line(w,feval mdl,w,'82'),'Color','b')
```

Input Arguments

mdl — Linear regression model object

LinearModel object | CompactLinearModel object

Linear regression model object, specified as a LinearModel object created by using fitlm or stepwiselm, or a CompactLinearModel object created by using compact.

Xnew1, Xnew2, . . . , Xnewn — New predictor input values

vector | matrix | table | dataset array

New predictor values, specified as a vector, matrix, table, or dataset array.

- If you pass multiple inputs `Xnew1`, `Xnew2`, . . . , `Xnewn` and each includes observations for one predictor variable, then each input must be a vector. Each vector must have the same size. If you specify a predictor variable as a scalar, then `feval` expands the scalar argument into a constant vector of the same size as the other arguments.
- If you pass a single input `Xnew1`, then `Xnew1` must be a table, dataset array, or matrix.
 - If `Xnew1` is a table or dataset array, it must contain predictors that have the same predictor names as in the `PredictorNames` property of `mdl`.
 - If `Xnew1` is a matrix, it must have the same number of variables (columns) in the same order as the predictor input used to create `mdl`. Note that `Xnew1` must also contain any predictor variables that are not used as predictors in the fitted model. Also, all variables used in creating `mdl` must be numeric or logical. To treat numerical predictors as categorical, identify the predictors using the `'CategoricalVars'` name-value pair argument when you create `mdl`.

Data Types: `single` | `double` | `table`

Output Arguments

ypred — Predicted mean values

numeric vector

Predicted mean values at `Xnew1`, `Xnew2`, . . . , `Xnewn`, returned as a numeric vector.

Tips

- A `LinearModel` object is, mathematically, a function that estimates the relationship between the response and predictors. The `feval` function enables an object to behave like a function in MATLAB. You can pass `feval` to another function that accepts a function input, such as `fminsearch` and `integral`. Also, `feval` can be simpler to use with a model created from a table or dataset array. When you have new predictor data, you can pass it to `feval` without creating a table or matrix.

Alternative Functionality

- `predict` gives the same predictions as `feval` by using a single input argument with one observation in each row, rather than multiple input arguments with one input for each predictor variable. `predict` also gives confidence intervals on its predictions.
- `random` predicts responses with added noise.

Introduced in R2012a

feval

Class: NonLinearModel

Evaluate nonlinear regression model prediction

Syntax

```
ypred = feval mdl, Xnew1, Xnew2, ..., Xnewn
```

Description

`ypred = feval(mdl, Xnew1, Xnew2, ..., Xnewn)` returns the predicted response of `mdl` to the input `[Xnew1, Xnew2, ..., Xnewn]`.

Input Arguments

mdl

Nonlinear regression model, constructed by `fitnlm`.

Xnew1, Xnew2, ..., Xnewn

Predictor components. `Xnewi` can be one of:

- Scalar
- Vector
- Array

Each nonscalar component must have the same size (number of elements in each dimension).

If you pass just one `Xnew` array, `Xnew` can be a table, dataset array, or an array of doubles, where each column of the array represents one predictor.

Output Arguments

ypred

Predicted mean values at Xnew. ypred is the same size as each component of Xnew.

Examples

Predict a Nonlinear Model from a Table

Create a nonlinear model for auto mileage based on the `carbig` data. Predict the mileage of an average automobile.

Load the data and create a nonlinear model.

```
load carbig
tbl = table(Horsepower,Weight,MPG);
modelfun = @(b,x)b(1) + b(2)*x(:,1).^b(3) + ...
    b(4)*x(:,2).^b(5);
beta0 = [-50 500 -1 500 -1];
mdl = fitnlm(tbl,modelfun,beta0);
```

Find the predicted mileage of an average auto. The data contain some observations with NaN, so compute the mean using `nanmean`.

```
Xnew = nanmean([Horsepower Weight]);
MPGnew = feval(mdl,Xnew)
```

```
MPGnew = 21.8073
```

Alternatives

`predict` gives the same predictions, but uses a single input array with one observation in each row, rather than one component in each input argument. `predict` also gives confidence intervals on its predictions.

`random` predicts with added noise.

ff2n

Two-level full factorial design

Syntax

dFF2 = ff2n(n)

Description

dFF2 = ff2n(n) gives factor settings dFF2 for a two-level full factorial design with n factors. dFF2 is m -by- n , where m is the number of treatments in the full-factorial design. Each row of dFF2 corresponds to a single treatment. Each column contains the settings for a single factor, with values of 0 and 1 for the two levels.

Examples

dFF2 = ff2n(3)

```
dFF2 =  
  0  0  0  
  0  0  1  
  0  1  0  
  0  1  1  
  1  0  0  
  1  0  1  
  1  1  0  
  1  1  1
```

fillprox

Class: TreeBagger

Proximity matrix for training data

Syntax

```
B = fillprox(B)
B = fillprox(B, 'param1', val1, 'param2', val2, ...)
```

Description

`B = fillprox(B)` computes a proximity matrix for the training data and stores it in the `Properties` field of `B`.

`B = fillprox(B, 'param1', val1, 'param2', val2, ...)` specifies optional parameter name/value pairs:

'Trees'	Either 'all' or a vector of indices of the trees in the ensemble to be used in computing the proximity matrix. Default is 'all'.
'NumPrint'	Number of training cycles (grown trees) after which <code>TreeBagger</code> displays a diagnostic message showing training progress. Default is no diagnostic messages.

See Also

`outlierMeasure` | `proximity`

findobj

Class: grandstream

Find objects matching specified conditions

Syntax

```
hm = findobj(h, 'conditions')
```

Description

The `findobj` method of the `handle` class follows the same syntax as the MATLAB `findobj` command, except that the first argument must be an array of handles to objects.

`hm = findobj(h, 'conditions')` searches the handle object array `h` and returns an array of handle objects matching the specified conditions. Only the public members of the objects of `h` are considered when evaluating the conditions.

See Also

`findobj` | `grandstream`

findprop

Class: grandstream

Find property of MATLAB handle object

Syntax

```
p = findprop(h, 'propname')
```

Description

`p = findprop(h, 'propname')` finds and returns the `meta.property` object associated with property name `propname` of scalar handle object `h`. `propname` must be a character vector. It can be the name of a property defined by the class of `h` or a dynamic property added to scalar object `h`.

If no property named `propname` exists for object `h`, an empty `meta.property` array is returned.

See Also

[dynamicprops](#) | [findobj](#) | [meta.property](#) | [grandstream](#)

finv

F inverse cumulative distribution function

Syntax

$X = \text{finv}(P, V1, V2)$

Description

$X = \text{finv}(P, V1, V2)$ computes the inverse of the F cdf with numerator degrees of freedom $V1$ and denominator degrees of freedom $V2$ for the corresponding probabilities in P . P , $V1$, and $V2$ can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other inputs. $V1$ and $V2$ parameters must contain real positive values, and the values in P must lie on the interval $[0\ 1]$.

The F inverse function is defined in terms of the F cdf as

$$x = F^{-1}(p | \nu_1, \nu_2) = \{x: F(x | \nu_1, \nu_2) = p\}$$

where

$$p = F(x | \nu_1, \nu_2) = \int_0^x \frac{\Gamma\left(\frac{\nu_1 + \nu_2}{2}\right)}{\Gamma\left(\frac{\nu_1}{2}\right)\Gamma\left(\frac{\nu_2}{2}\right)} \left(\frac{\nu_1}{\nu_2}\right)^{\frac{\nu_1}{2}} \frac{t^{\frac{\nu_1 - 2}{2}}}{\left[1 + \left(\frac{\nu_1}{\nu_2}\right)t\right]^{\frac{\nu_1 + \nu_2}{2}}} dt$$

Examples

Find a value that should exceed 95% of the samples from an F distribution with 5 degrees of freedom in the numerator and 10 degrees of freedom in the denominator.

```
x = finv(0.95,5,10)
x =
    3.3258
```

You would observe values greater than 3.3258 only 5% of the time by chance.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU arrays. For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

fishertest

Fisher's exact test

Syntax

```
h = fishertest(x)
[h,p,stats] = fishertest(x)
[___] = fishertest(x,Name,Value)
```

Description

`h = fishertest(x)` returns a test decision for Fisher's exact test of the null hypothesis that there are no nonrandom associations between the two categorical variables in `x`, against the alternative that there is a nonrandom association. The result `h` is `1` if the test rejects the null hypothesis at the 5% significance level, or `0` otherwise.

`[h,p,stats] = fishertest(x)` also returns the significance level `p` of the test and a structure `stats` containing additional test results, including the odds ratio and its asymptotic confidence interval.

`[___] = fishertest(x,Name,Value)` returns a test decision using additional options specified by one or more name-value pair arguments. For example, you can change the significance level of the test or conduct a one-sided test.

Examples

Conduct Fisher's Exact Test

In a small survey, a researcher asked 17 individuals if they received a flu shot this year, and whether they caught the flu this winter. The results indicate that, of the nine people who did not receive a flu shot, three got the flu and six did not. Of the eight people who received a flu shot, one got the flu and seven did not.

Create a 2-by-2 contingency table containing the survey data. Row 1 contains data for the individuals who did not receive a flu shot, and row 2 contains data for the individuals who received a flu shot. Column 1 contains the number of individuals who got the flu, and column 2 contains the number of individuals who did not.

```
x = table([3;1],[6;7], 'VariableNames', {'Flu', 'NoFlu'}, 'RowNames', {'NoShot', 'Shot'})
```

```
x=2x2 table
```

	Flu	NoFlu
NoShot	3	6
Shot	1	7

Use Fisher's exact test to determine if there is a nonrandom association between receiving a flu shot and getting the flu.

```
h = fishertest(x)
```

```
h = logical  
    0
```

The returned test decision $h = 0$ indicates that `fishertest` does not reject the null hypothesis of no nonrandom association between the categorical variables at the default 5% significance level. Therefore, based on the test results, individuals who do not get a flu shot do not have different odds of getting the flu than those who got the flu shot.

Conduct a One-Sided Fisher's Exact Test

In a small survey, a researcher asked 17 individuals if they received a flu shot this year, and whether they caught the flu. The results indicate that, of the nine people who did not receive a flu shot, three got the flu and six did not. Of the eight people who received a flu shot, one got the flu and seven did not.

```
x = [3,6;1,7];
```

Use a right-tailed Fisher's exact test to determine if the odds of getting the flu is higher for individuals who did not receive a flu shot than for individuals who did. Conduct the test at the 1% significance level.

```
[h,p,stats] = fishertest(x, 'Tail', 'right', 'Alpha', 0.01)
h = logical
  0

p = 0.3353

stats = struct with fields:
    OddsRatio: 3.5000
    ConfidenceInterval: [0.1289 95.0408]
```

The returned test decision $h = 0$ indicates that `fishertest` does not reject the null hypothesis of no nonrandom association between the categorical variables at the 1% significance level. Since this is a right-tailed hypothesis test, the conclusion is that individuals who do not get a flu shot do not have greater odds of getting the flu than those who got the flu shot.

Generate a Contingency Table Using `crosstab`

Load the hospital data.

```
load hospital
```

The `hospital` dataset array contains data on 100 hospital patients, including last name, gender, age, weight, smoking status, and systolic and diastolic blood pressure measurements.

To determine if smoking status is independent of gender, use `crosstab` to create a 2-by-2 contingency table of smokers and nonsmokers, grouped by gender.

```
[tbl,chi2,p,labels] = crosstab(hospital.Sex,hospital.Smoker)
tbl = 2x2

    40    13
    26    21

chi2 = 4.5083
p = 0.0337
```

```
labels = 2x2 cell array
      {'Female'}      {'0'}
      {'Male'  }      {'1'}
```

The rows of the resulting contingency table `tbl` correspond to the patient's gender, with row 1 containing data for females and row 2 containing data for males. The columns correspond to the patient's smoking status, with column 1 containing data for nonsmokers and column 2 containing data for smokers. The returned result `chi2 = 4.5083` is the value of the chi-squared test statistic for a chi-squared test of independence. The returned value `p = 0.0337` is an approximate *p*-value based on the chi-squared distribution.

Use the contingency table generated by `crosstab` to perform Fisher's exact test on the data.

```
[h,p,stats] = fishertest(tbl)

h = logical
   1

p = 0.0375

stats = struct with fields:
    OddsRatio: 2.4852
    ConfidenceInterval: [1.0624 5.8135]
```

The result `h = 1` indicates that `fishertest` rejects the null hypothesis of nonassociation between smoking status and gender at the 5% significance level. In other words, there is an association between gender and smoking status. The odds ratio indicates that the male patients have about 2.5 times greater odds of being smokers than the female patients.

The returned *p*-value of the test, `p = 0.0375`, is close to, but not exactly the same as, the result obtained by `crosstab`. This is because `fishertest` computes an exact *p*-value using the sample data, while `crosstab` uses a chi-squared approximation to compute the *p*-value.

Input Arguments

x — Contingency table

2-by-2 matrix of nonnegative integer values | 2-by-2 table of nonnegative integer values

Contingency table, specified as a 2-by-2 matrix or table containing nonnegative integer values. A contingency table contains the frequency distribution of the variables in the sample data. You can use `crosstab` to generate a contingency table from sample data.

Example: `[4,0;0,4]`

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'Alpha', 0.01, 'Tail', 'right'` specifies a right-tailed hypothesis test at the 1% significance level.

Alpha — Significance level

0.05 (default) | scalar value in the range (0,1)

Significance level of the hypothesis test, specified as the comma-separated pair consisting of `'Alpha'` and a scalar value in the range (0,1).

Example: `'Alpha', 0.01`

Data Types: `single` | `double`

Tail — Type of alternative hypothesis

`'both'` (default) | `'right'` | `'left'`

Type of alternative hypothesis, specified as the comma-separated pair consisting of `'Tail'` and one of the following.

'both'	Two-tailed test. The alternative hypothesis is that there is a nonrandom association between the two variables in <code>x</code> , and the odds ratio is not equal to 1.
'right'	Right-tailed test. The alternative hypothesis is that the odds ratio is greater than 1.
'left'	Left-tailed test. The alternative hypothesis is that the odds ratio is less than 1.

Example: `'Tail', 'right'`

Output Arguments

h — Hypothesis test result

1 | 0

Hypothesis test result, returned as a logical value.

- If `h` is 1, then `fishertest` rejects the null hypothesis at the `Alpha` significance level.
- If `h` is 0, then `fishertest` fails to reject the null hypothesis at the `Alpha` significance level.

p — *p*-value

scalar value in the range [0,1]

p-value of the test, returned as a scalar value in the range [0,1]. *p* is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. Small values of *p* cast doubt on the validity of the null hypothesis.

stats — Test data

structure

Test data, returned as a structure with the following fields:

- `OddsRatio` — A measure of association between the two variables.
- `ConfidenceInterval` — Asymptotic confidence interval for the odds ratio. If any of the cell frequencies in `x` are 0, then `fishertest` does not compute a confidence interval and instead displays `[-Inf Inf]`.

Definitions

Fisher's Exact Test

Fisher's exact test is a nonparametric statistical test used to test the null hypothesis that no nonrandom associations exist between two categorical variables, against the alternative that there is a nonrandom association between the variables.

Fisher's exact test provides an alternative to the chi-squared test for small samples, or samples with very uneven marginal distributions. Unlike the chi-squared test, Fisher's exact test does not depend on large-sample distribution assumptions, and instead calculates an exact p -value based on the sample data. Although Fisher's exact test is valid for samples of any size, it is not recommended for large samples because it is computationally intensive. If all of the frequency counts in the contingency table are greater than or equal to $1e7$, then `fishertest` errors. For contingency tables that contain large count values or are well-balanced, use `crosstab` or `chi2gof` instead.

`fishertest` accepts a 2-by-2 contingency table as input, and computes the p -value of the test as follows:

- 1 Calculate the sums for each row, column, and total number of observations in the contingency table.
- 2 Using a multivariate generalization of the hypergeometric probability function, calculate the conditional probability of observing the exact result in the contingency table if the null hypothesis were true, given its row and column sums. The conditional probability is

$$P_{cutoff} = \frac{(R_1!R_2!)(C_1!C_2!)}{N! \prod_{i,j} n_{ij}!},$$

where R_1 and R_2 are the row sums, C_1 and C_2 are the column sums, N is the total number of observations in the contingency table, and n_{ij} is the value in the i th row and j th column of the table.

- 3 Find all possible matrices of nonnegative integers consistent with the row and column sums. For each matrix, calculate the associated conditional probability using the equation for P_{cutoff} .
- 4 Use these values to calculate the p -value of the test, based on the alternative hypothesis of interest.

- For a two-sided test, sum all of the conditional probabilities less than or equal to P_{cutoff} for the observed contingency table. This represents the probability of observing a result as extreme as, or more extreme than, the actual outcome if the null hypothesis were true. Small p -values cast doubt on the validity of the null hypothesis, in favor of the alternative hypothesis of association between the variables.
- For a left-sided test, sum the conditional probabilities of all the matrices with a (1,1) cell frequency less than or equal to n_{11} .
- For a right-sided test, sum the conditional probabilities of all the matrices with a (1,1) cell frequency greater than or equal to n_{11} in the observed contingency table.

The odds ratio is

$$OR = \frac{n_{11}n_{22}}{n_{21}n_{12}} .$$

The null hypothesis of conditional independence is equivalent to the hypothesis that the odds ratio equals 1. The left-sided alternative is equivalent to an odds ratio less than 1, and the right-sided alternative is equivalent to an odds ratio greater than 1.

The asymptotic $100(1 - \alpha)\%$ confidence interval for the odds ratio is

$$CI = \left[\exp\left(L - \Phi^{-1}\left(\frac{1 - \alpha}{2}\right)SE\right), \exp\left(L + \Phi^{-1}\left(\frac{1 - \alpha}{2}\right)SE\right) \right],$$

where L is the log odds ratio, $\Phi^{-1}(\bullet)$ is the inverse of the normal inverse cumulative distribution function, and SE is the standard error for the log odds ratio. If the $100(1 - \alpha)\%$ confidence interval does not contain the value 1, then the association is significant at the α significance level. If any of the four cell frequencies are 0, then `fishertest` does not compute the confidence interval and instead displays [-Inf Inf].

`fishertest` only accepts 2-by-2 contingency tables as input. To test the independence of categorical variables with more than two levels, use the chi-squared test provided by `crosstab`.

Introduced in R2014b

ClassificationDiscriminant.fit

Class: ClassificationDiscriminant

(Not Recommended) Fit discriminant analysis classifier

Note ClassificationDiscriminant.fit is not recommended. Use fitcdiscr instead.

Syntax

```
obj = ClassificationDiscriminant.fit(x,y)
obj = ClassificationDiscriminant.fit(x,y,Name,Value)
```

Description

obj = ClassificationDiscriminant.fit(x,y) returns a discriminant analysis classifier based on the input variables (also known as predictors, features, or attributes) x and output (response) y.

obj = ClassificationDiscriminant.fit(x,y,Name,Value) fits a classifier with additional options specified by one or more Name,Value pair arguments. If you use one of the following five options, obj is of class ClassificationPartitionedModel: 'CrossVal', 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'. Otherwise, obj is of class ClassificationDiscriminant.

Input Arguments

x — Predictor values

matrix of numeric values

Predictor values, specified as a matrix of numeric values. Each column of x represents one variable, and each row represents one observation.

`ClassificationDiscriminant.fit` considers NaN values in `x` as missing values. `ClassificationDiscriminant.fit` does not use observations with missing values for `x` in the fit.

Data Types: `single` | `double`

y — Classification values

numeric vector | categorical vector | logical vector | character array | cell array of character vectors

Classification values, specified as a numeric vector, categorical vector (nominal or ordinal), logical vector, character array, or cell array of character vectors. Each row of `y` represents the classification of the corresponding row of `x`.

`ClassificationDiscriminant.fit` considers NaN values in `y` to be missing values. `ClassificationDiscriminant.fit` does not use observations with missing values for `y` in the fit.

Data Types: `single` | `double` | `logical` | `char` | `cell`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

ClassNames — Class names

array

Class names, specified as the comma-separated pair consisting of `'ClassNames'` and an array. Use the data type that exists in `y`. The default is the class names that exist in `y`. Use `ClassNames` to order the classes or to select a subset of classes for training.

Data Types: `single` | `double` | `logical` | `char`

Cost — Cost of misclassification

square matrix | structure

Cost of misclassification, specified as the comma-separated pair consisting of `'Cost'` and a square matrix, where `Cost(i, j)` is the cost of classifying a point into class `j` if its true class is `i`. Alternatively, `Cost` can be a structure `S` having two fields: `S.ClassNames`

containing the group names as a variable of the same type as `y`, and `S.ClassificationCosts` containing the cost matrix.

The default is `Cost(i, j)=1` if `i~j`, and `Cost(i, j)=0` if `i=j`.

Data Types: `single` | `double` | `struct`

CrossVal — Cross-validation flag

`'off'` (default) | `'on'`

Cross-validation flag, specified as the comma-separated pair consisting of `'Crossval'` and `'on'` or `'off'`.

If you specify `'on'`, then the software implements 10-fold cross-validation.

To override this cross-validation setting, use one of these name-value pair arguments: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`. To create a cross-validated model, you can use one cross-validation name-value pair argument at a time only.

Alternatively, cross-validate later by passing `Mdl` to `crossval`.

Example: `'CrossVal', 'on'`

CVPartition — Cross-validated model partition

`cvpartition` object

Cross-validated model partition, specified as the comma-separated pair consisting of `'CVPartition'` and an object created using `cvpartition`.

To create a cross-validated model, you can use one of these four name-value pair arguments only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Delta — Linear coefficient threshold

`0` (default) | nonnegative scalar value

Linear coefficient threshold, specified as the comma-separated pair consisting of `'Delta'` and a nonnegative scalar value. If a coefficient of `Mdl` has magnitude smaller than `Delta`, `Mdl` sets this coefficient to `0`, and you can eliminate the corresponding predictor from the model. Set `Delta` to a higher value to eliminate more predictors.

`Delta` must be `0` for quadratic discriminant models.

Data Types: `single` | `double`

DiscrimType – Discriminant type

'linear' (default) | 'quadratic' | 'diaglinear' | 'diagquadratic' |
 'pseudolinear' | 'pseudoquadratic'

Discriminant type, specified as the comma-separated pair consisting of 'DiscrimType' and a character vector in this table.

Value	Description	Predictor Covariance Treatment
'linear'	Regularized linear discriminant analysis (LDA)	<ul style="list-style-type: none"> All classes have the same covariance matrix. $\widehat{\Sigma}_\gamma = (1 - \gamma)\widehat{\Sigma} + \gamma\text{diag}(\widehat{\Sigma})$. <p>$\widehat{\Sigma}$ is the empirical, pooled covariance matrix and γ is the amount of regularization.</p>
'diaglinear'	LDA	All classes have the same, diagonal covariance matrix.
'pseudolinear'	LDA	All classes have the same covariance matrix. The software inverts the covariance matrix using the pseudo inverse.
'quadratic'	Quadratic discriminant analysis (QDA)	The covariance matrices can vary among classes.
'diagquadratic'	QDA	The covariance matrices are diagonal and can vary among classes.
'pseudoquadratic'	QDA	The covariance matrices can vary among classes. The software inverts the covariance matrix using the pseudo inverse.

Note To use regularization, you must specify `'linear'`. To specify the amount of regularization, use the `Gamma` name-value pair argument.

Example: `'DiscrimType','quadratic'`

FillCoeffs — Coeffs property flag

`'on' | 'off'`

`Coeffs` property flag, specified as the comma-separated pair consisting of `'FillCoeffs'` and `'on'` or `'off'`. Setting the flag to `'on'` populates the `Coeffs` property in the classifier object. This can be computationally intensive, especially when cross-validating. The default is `'on'`, unless you specify a cross-validation name-value pair, in which case the flag is set to `'off'` by default.

Example: `'FillCoeffs','off'`

Gamma — Amount of regularization

scalar value in the interval $[0,1]$

Amount of regularization to apply when estimating the covariance matrix of the predictors, specified as the comma-separated pair consisting of `'Gamma'` and a scalar value in the interval $[0,1]$. `Gamma` provides finer control over the covariance matrix structure than `DiscrimType`.

- If you specify 0 , then the software does not use regularization to adjust the covariance matrix. That is, the software estimates and uses the unrestricted, empirical covariance matrix.
 - For linear discriminant analysis, if the empirical covariance matrix is singular, then the software automatically applies the minimal regularization required to invert the covariance matrix. You can display the chosen regularization amount by entering `Mdl.Gamma` at the command line.
 - For quadratic discriminant analysis, if at least one class has an empirical covariance matrix that is singular, then the software throws an error.
- If you specify a value in the interval $(0,1)$, then you must implement linear discriminant analysis, otherwise the software throws an error. Consequently, the software sets `DiscrimType` to `'linear'`.
- If you specify 1 , then the software uses maximum regularization for covariance matrix estimation. That is, the software restricts the covariance matrix to be diagonal. Alternatively, you can set `DiscrimType` to `'diagLinear'` or `'diagQuadratic'` for diagonal covariance matrices.

Example: 'Gamma',1

Data Types: single | double

Holdout — Fraction of data for holdout validation

scalar value in the range (0,1)

Fraction of the data used for holdout validation, specified as the comma-separated pair consisting of 'Holdout' and a scalar value in the range (0,1). If you specify 'Holdout', p , then the software completes these steps:

- 1 Randomly select and reserve $p*100\%$ of the data as validation data, and train the model using the rest of the data.
- 2 Store the compact, trained model in the Trained property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: 'Holdout',0.1

Data Types: double | single

KFold — Number of folds

10 (default) | positive integer value greater than 1

Number of folds to use in a cross-validated classifier, specified as the comma-separated pair consisting of 'KFold' and a positive integer value greater than 1. If you specify, e.g., 'KFold', k , then the software:

- 1 Randomly partitions the data into k sets
- 2 For each set, reserves the set as validation data, and trains the model using the other $k - 1$ sets
- 3 Stores the k compact, trained models in the cells of a k -by-1 cell vector in the Trained property of the cross-validated model.

To create a cross-validated model, you can use one of these four options only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: 'KFold',8

Data Types: single | double

Leaveout — Leave-one-out cross-validation flag`'off'` (default) | `'on'`

Leave-one-out cross-validation flag, specified as the comma-separated pair consisting of `'Leaveout'` and `'on'` or `'off'`. If you specify `'Leaveout'`, `'on'`, then, for each of the n observations, where n is `size(Mdl.X,1)`, the software:

- 1 Reserves the observation as validation data, and trains the model using the other $n - 1$ observations
- 2 Stores the n compact, trained models in the cells of a n -by-1 cell vector in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can use one of these four options only: `'CVPartition'`, `'Holdout'`, `'KFold'`, or `'Leaveout'`.

Example: `'Leaveout','on'`

PredictorNames — Predictor variable names`{'X1','X2',...}` (default) | cell array of character vectors

Predictor variable names, specified as the comma-separated pair consisting of `'PredictorNames'` and a cell array of character vectors containing the names for the predictor variables, in the order in which they appear in X .

Data Types: cell

Prior — Prior probabilities`'empirical'` (default) | `'uniform'` | vector of scalar values | structure

Prior probabilities for each class, specified as the comma-separated pair consisting of `'Prior'` and one of the following.

- `'empirical'` determines class probabilities from class frequencies in y . If you pass observation weights, they are used to compute the class probabilities.
- `'uniform'` sets all class probabilities equal.
- A vector containing one scalar value for each class.
- A structure S with two fields:
 - `S.ClassNames` containing the class names as a variable of the same type as y
 - `S.ClassProbs` containing a vector of corresponding probabilities

Example: `'Prior','uniform'`

Data Types: single | double | char | struct

ResponseName — Response variable name

'Y' (default) | character vector

Response variable name, specified as the comma-separated pair consisting of 'ResponseName' and a character vector containing the name of the response variable y.

Example: 'ResponseName', 'Response'

Data Types: char

SaveMemory — Flag to save covariance matrix

'off' (default) | 'on'

Flag to save covariance matrix, specified as the comma-separated pair consisting of 'SaveMemory' and either 'on' or 'off'. If you specify 'on', then `fitcdiscr` does not store the full covariance matrix, but instead stores enough information to compute the matrix. The `predict` method computes the full covariance matrix for prediction, and does not store the matrix. If you specify 'off', then `fitcdiscr` computes and stores the full covariance matrix in `Mdl`.

Specify `SaveMemory` as 'on' when the input matrix contains thousands of predictors.

Example: 'SaveMemory', 'on'

ScoreTransform — Score transformation

'none' (default) | 'doublelogit' | 'invlogit' | 'ismax' | 'logit' | function handle | ...

Score transformation, specified as the comma-separated pair consisting of 'ScoreTransform' and a character vector or function handle.

This table summarizes the available character vectors.

Value	Description
'doublelogit'	$1/(1 + e^{-2x})$
'invlogit'	$\log(x / (1-x))$
'ismax'	Sets the score for the class with the largest score to 1, and sets the scores for all other classes to 0
'logit'	$1/(1 + e^{-x})$

Value	Description
'none' or 'identity'	x (no transformation)
'sign'	-1 for $x < 0$ 0 for $x = 0$ 1 for $x > 0$
'symmetric'	$2x - 1$
'symmetricismax'	Sets the score for the class with the largest score to 1, and sets the scores for all other classes to -1
'symmetriclogit'	$2/(1 + e^{-x}) - 1$

For a MATLAB function or a function you define, use its function handle for score transform. The function handle must accept a matrix (the original scores) and return a matrix of the same size (the transformed scores).

Example: 'ScoreTransform', 'logit'

Data Types: char | function_handle

Weights — Observation weights

`ones(size(X,1),1)` (default) | vector of scalar values

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a vector of scalar values. The length of `Weights` is the number of rows in `X`. `fitcdiscr` normalizes the weights to sum to 1.

Data Types: single | double

Output Arguments

obj — Discriminant analysis classifier

classifier object

Discriminant analysis classifier, returned as a classifier object.

Note that using the 'CrossVal', 'KFold', 'Holdout', 'Leaveout', or 'CVPartition' options results in a tree of class `ClassificationPartitionedModel`. You cannot use a partitioned tree for prediction, so this kind of tree does not have a `predict` method.

Otherwise, `obj` is of class `ClassificationDiscriminant`, and you can use the `predict` method to predict the response of new data.

Examples

Construct a Discriminant Analysis Classifier

Load the sample data.

```
load fisheriris
```

Construct a discriminant analysis classifier using the sample data.

```
obj = ClassificationDiscriminant.fit(meas,species)
```

```
obj =  
  ClassificationDiscriminant  
    ResponseName: 'Y'  
    CategoricalPredictors: []  
      ClassNames: {'setosa' 'versicolor' 'virginica'}  
    ScoreTransform: 'none'  
    NumObservations: 150  
    DiscrimType: 'linear'  
      Mu: [3x4 double]  
      Coeffs: [3x3 struct]
```

Properties, Methods

Definitions

Discriminant Classification

The model for discriminant analysis is:

- Each class (Y) generates data (X) using a multivariate normal distribution. That is, the model assumes X has a Gaussian mixture distribution (`gmdistribution`).

- For linear discriminant analysis, the model has the same covariance matrix for each class, only the means vary.
- For quadratic discriminant analysis, both means and covariances of each class vary.

predict classifies so as to minimize the expected classification cost:

$$\hat{y} = \operatorname{argmin}_{y=1, \dots, K} \sum_{k=1}^K \hat{P}(k|x)C(y|k),$$

where

- \hat{y} is the predicted classification.
- K is the number of classes.
- $\hat{P}(k|x)$ is the posterior probability on page 20-6 of class k for observation x .
- $C(y|k)$ is the cost on page 20-7 of classifying an observation as y when its true class is k .

For details, see “Prediction Using Discriminant Analysis Models” on page 20-6.

Alternatives

The `classify` function also performs discriminant analysis. `classify` is usually more awkward to use:

- `classify` requires you to fit the classifier every time you make a new prediction.
- `classify` does not perform cross validation.
- `classify` requires you to fit the classifier when changing prior probabilities.

ClassificationKNN.fit

(Not Recommended) Fit k -nearest neighbor classifier

Note `ClassificationKNN.fit` is not recommended. Use `fitcknn` instead.

Syntax

```
mdl = ClassificationKNN.fit(X,y)
mdl = ClassificationKNN.fit(X,y,Name,Value)
```

Description

`mdl = ClassificationKNN.fit(X,y)` returns a classification model based on the input variables (also known as predictors, features, or attributes) X and output (response) y .

`mdl = ClassificationKNN.fit(X,y,Name,Value)` fits a model with additional options specified by one or more `Name,Value` pair arguments.

If you use one of these options, `mdl` is of class `ClassificationPartitionedModel`: 'CrossVal', 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'. Otherwise, `mdl` is of class `ClassificationKNN`.

Input Arguments

X — Predictor data

numeric matrix

Predictor data, specified as a numeric matrix. Each column of X represents one variable, and each row represents one observation.

The length of Y and the number of observations in X must be equal.

To specify the names of the predictors in the order of their appearance in X , use the `PredictorNames` name-value pair argument.

Data Types: `single` | `double`

Y — Classification values

numeric vector | categorical vector | logical vector | character array | cell array of character vectors

Classification values, specified as a numeric vector, categorical vector, logical vector, character array, or cell array of character vectors, with the same number of rows as X . Each row of Y represents the classification of the corresponding row of X .

Data Types: `single` | `double` | `cell` | `logical` | `char`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

BreakTies — Tie-breaking algorithm

'smallest' (default) | 'nearest' | 'random'

Tie-breaking algorithm used by the `predict` method if multiple classes have the same smallest cost, specified as the comma-separated pair consisting of `'BreakTies'` and one of the following:

- `'smallest'` — Use the smallest index among tied groups.
- `'nearest'` — Use the class with the nearest neighbor among tied groups.
- `'random'` — Use a random tiebreaker among tied groups.

By default, ties occur when multiple classes have the same number of nearest points among the K nearest neighbors.

Example: `'BreakTies', 'nearest'`

BucketSize — Maximum data points in node

50 (default) | positive integer value

Maximum number of data points in the leaf node of the *kd*-tree, specified as the comma-separated pair consisting of 'BucketSize' and a positive integer value. This argument is meaningful only when *NSMethod* is 'kdtree'.

Example: 'BucketSize',40

Data Types: single | double

CategoricalPredictors — Categorical predictor flag

[] (default) | 'all'

Categorical predictor flag, specified as the comma-separated pair consisting of 'CategoricalPredictors' and one of the following:

- 'all' — All predictors are categorical.
- [] — No predictors are categorical.

When you set *CategoricalPredictors* to 'all', the default *Distance* is 'hamming'.

Example: 'CategoricalPredictors','all'

ClassNames — Class names

numeric vector | categorical vector | logical vector | character array | cell array of character vectors

Class names, specified as the comma-separated pair consisting of 'ClassNames' and an array representing the class names. Use the same data type as the values that exist in *y*.

Use *ClassNames* to order the classes or to select a subset of classes for training. The default is the class names in *y*.

Data Types: single | double | char | logical | cell

Cost — Cost of misclassification

square matrix | structure

Cost of misclassification of a point, specified as the comma-separated pair consisting of 'Cost' and one of the following:

- Square matrix, where $Cost(i, j)$ is the cost of classifying a point into class *j* if its true class is *i* (i.e., the rows correspond to the true class and the columns correspond to the predicted class). To specify the class order for the corresponding rows and columns of *Cost*, additionally specify the *ClassNames* name-value pair argument.

- Structure `S` having two fields: `S.ClassNames` containing the group names as a variable of the same type as `Y`, and `S.ClassificationCosts` containing the cost matrix.

The default is $\text{Cost}(i, j) = 1$ if $i \neq j$, and $\text{Cost}(i, j) = 0$ if $i = j$.

Data Types: `single` | `double` | `struct`

Cov — Covariance matrix

`nancov(X)` (default) | positive definite matrix of scalar values

Covariance matrix, specified as the comma-separated pair consisting of `'Cov'` and a positive definite matrix of scalar values representing the covariance matrix when computing the Mahalanobis distance. This argument is only valid when `'Distance'` is `'mahalanobis'`.

You cannot simultaneously specify `'Standardize'` and either of `'Scale'` or `'Cov'`.

Data Types: `single` | `double`

CrossVal — Cross-validation flag

`'off'` (default) | `'on'`

Cross-validation flag, specified as the comma-separated pair consisting of `'CrossVal'` and either `'on'` or `'off'`. If `'on'`, `fitcknn` creates a cross-validated model with 10 folds. Use the `'KFold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'` parameters to override this cross-validation setting. You can only use one cross-validation name-value pair argument at a time to create a cross-validated model.

Alternatively, cross validate `mdl` later using the `crossval` method.

Example: `'Crossval', 'on'`

CVPartition — Cross-validated model partition

`cvpartition` object

Cross-validated model partition, specified as the comma-separated pair consisting of `'CVPartition'` and an object created using `cvpartition`. You can only use one of these four options at a time to create a cross-validated model: `'KFold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'`.

Distance — Distance metric

`'cityblock'` | `'chebychev'` | `'correlation'` | `'cosine'` | `'euclidean'` | `'hamming'` | function handle | ...

Distance metric, specified as the comma-separated pair consisting of 'Distance' and a valid distance metric name or function handle. The allowable distance metric names depend on your choice of a neighbor-searcher method (see NSMethod).

NSMethod	Distance Metric Names
exhaustive	Any distance metric of ExhaustiveSearcher
kdtree	'cityblock', 'chebychev', 'euclidean', or 'minkowski'

This table includes valid distance metrics of ExhaustiveSearcher.

Distance Metric Names	Description
'cityblock'	City block distance.
'chebychev'	Chebychev distance (maximum coordinate difference).
'correlation'	One minus the sample linear correlation between observations (treated as sequences of values).
'cosine'	One minus the cosine of the included angle between observations (treated as vectors).
'euclidean'	Euclidean distance.
'hamming'	Hamming distance, percentage of coordinates that differ.
'jaccard'	One minus the Jaccard coefficient, the percentage of nonzero coordinates that differ.
'mahalanobis'	Mahalanobis distance, computed using a positive definite covariance matrix C . The default value of C is the sample covariance matrix of X , as computed by <code>nancov(X)</code> . To specify a different value for C , use the 'Cov' name-value pair argument.
'minkowski'	Minkowski distance. The default exponent is 2. To specify a different exponent, use the 'Exponent' name-value pair argument.
'seuclidean'	Standardized Euclidean distance. Each coordinate difference between X and a query point is scaled, meaning divided by a scale value S . The default value of S is the standard deviation computed from X , $S = \text{nanstd}(X)$. To specify another value for S , use the Scale name-value pair argument.

Distance Metric Names	Description
'spearman'	One minus the sample Spearman's rank correlation between observations (treated as sequences of values).
@ <i>distfun</i>	Distance function handle. <i>distfun</i> has the form <pre>function D2 = distfun(ZI,ZJ) % calculation of distance ...</pre> where <ul style="list-style-type: none"> • ZI is a 1-by-N vector containing one row of X or Y. • ZJ is an M2-by-N matrix containing multiple rows of X or Y. • D2 is an M2-by-1 vector of distances, and D2(k) is the distance between observations ZI and ZJ(k, :).

If you specify `CategoricalPredictors` as 'all', then the default distance metric is 'hamming'. Otherwise, the default distance metric is 'euclidean'.

For definitions, see “Distance Metrics” on page 18-16.

Example: 'Distance', 'minkowski'

Data Types: char | function_handle

DistanceWeight — Distance weighting function

'equal' (default) | 'inverse' | 'squaredinverse' | function handle

Distance weighting function, specified as the comma-separated pair consisting of 'DistanceWeight' and either a function handle or one of the values in this table.

Value	Description
'equal'	No weighting
'inverse'	Weight is 1/distance
'squaredinverse'	Weight is 1/distance ²

Value	Description
@ <i>fcn</i>	<i>fcn</i> is a function that accepts a matrix of nonnegative distances, and returns a matrix the same size containing nonnegative distance weights. For example, 'squaredinverse' is equivalent to $@(d) d.^{-2}$.

Example: 'DistanceWeight', 'inverse'

Data Types: char | function_handle

Exponent — Minkowski distance exponent

2 (default) | positive scalar value

Minkowski distance exponent, specified as the comma-separated pair consisting of 'Exponent' and a positive scalar value. This argument is only valid when 'Distance' is 'minkowski'.

Example: 'Exponent', 3

Data Types: single | double

Holdout — Fraction of data for holdout validation

0 (default) | scalar value in the range [0, 1]

Fraction of data used for holdout validation, specified as the comma-separated pair consisting of 'Holdout' and a scalar value in the range [0, 1]. Holdout validation tests the specified fraction of the data, and uses the remaining data for training.

If you use Holdout, you cannot use any of the 'CVPartition', 'Kfold', or 'Leaveout' name-value pair arguments.

Example: 'Holdout', 0.1

Data Types: single | double

IncludeTies — Tie inclusion flag

false (default) | true

Tie inclusion flag, specified as the comma-separated pair consisting of 'IncludeTies' and a logical value indicating whether predict includes all the neighbors whose distance values are equal to the Kth smallest distance. If IncludeTies is true, predict includes all these neighbors. Otherwise, predict uses exactly K neighbors.

Example: 'IncludeTies', true

Data Types: `logical`

KFold — Number of folds

`10` (default) | positive integer value

Number of folds to use in a cross-validated model, specified as the comma-separated pair consisting of `'KFold'` and a positive integer value.

If you use `'KFold'`, you cannot use any of the `'CVPartition'`, `'Holdout'`, or `'Leaveout'` name-value pair arguments.

Example: `'KFold',8`

Data Types: `single` | `double`

Leaveout — Leave-one-out cross-validation flag

`'off'` (default) | `'on'`

Leave-one-out cross-validation flag, specified as the comma-separated pair consisting of `'Leaveout'` and either `'on'` or `'off'`. Specify `'on'` to use leave-one-out cross validation.

If you use `'Leaveout'`, you cannot use any of the `'CVPartition'`, `'Holdout'`, or `'KFold'` name-value pair arguments.

Example: `'Leaveout','on'`

NSMethod — Nearest neighbor search method

`'kdtree'` | `'exhaustive'`

Nearest neighbor search method, specified as the comma-separated pair consisting of `'NSMethod'` and `'kdtree'` or `'exhaustive'`.

- `'kdtree'` — Creates and uses a *kd*-tree to find nearest neighbors. `'kdtree'` is valid when the distance metric is one of the following:
 - `'euclidean'`
 - `'cityblock'`
 - `'minkowski'`
 - `'chebychev'`
- `'exhaustive'` — Uses the exhaustive search algorithm. When predicting the class of a new point `xnew`, the software computes the distance values from all points in `X` to `xnew` to find nearest neighbors.

The default is 'kdtree' when X has 10 or fewer columns, X is not sparse, and the distance metric is a 'kdtree' type; otherwise, 'exhaustive'.

Example: 'NSMethod', 'exhaustive'

NumNeighbors — Number of nearest neighbors to find

1 (default) | positive integer value

Number of nearest neighbors in X to find for classifying each point when predicting, specified as the comma-separated pair consisting of 'NumNeighbors' and a positive integer value.

Example: 'NumNeighbors', 3

Data Types: single | double

PredictorNames — Predictor variable names

{'x1', 'x2', ...} (default) | cell array of character vectors

Predictor variable names, specified as the comma-separated pair consisting of 'PredictorNames' and a cell array of character vectors containing the names for the predictor variables, in the order in which they appear in X.

If you specify the predictors as a table (tbl), then PredictorNames must be a subset of the variable names in tbl. In this case, the software uses only the variables in PredictorNames to train the model. If you use formula to specify the model, then you cannot use the PredictorNames name-value pair.

Example: 'PredictorNames', {'PedalWidth', 'PedalLength'}

Data Types: cell

Prior — Prior probabilities

'empirical' (default) | 'uniform' | vector of scalar values | structure

Prior probabilities for each class, specified as the comma-separated pair consisting of 'Prior' and a value in this table.

Value	Description
'empirical'	The class prior probabilities are the class relative frequencies in Y.

Value	Description
'uniform'	All class prior probabilities are equal to $1/K$, where K is the number of classes.
numeric vector	Each element is a class prior probability. Order the elements according to <code>Mdl.ClassNames</code> or specify the order using the <code>ClassNames</code> name-value pair argument. The software normalizes the elements such that they sum to 1.
structure	A structure S with two fields: <ul style="list-style-type: none"> • <code>S.ClassNames</code> contains the class names as a variable of the same type as Y. • <code>S.ClassProbs</code> contains a vector of corresponding prior probabilities. The software normalizes the elements such that they sum to 1.

If you set values for both `Weights` and `Prior`, the weights are renormalized to add up to the value of the prior probability in the respective class.

Example: `'Prior', 'uniform'`

Data Types: `char` | `single` | `double` | `struct`

ResponseName — Response variable name

`'Y'` (default) | character vector

Response variable name, specified as the comma-separated pair consisting of `'ResponseName'` and a character vector containing the name of the response variable Y .

This name-value pair is not valid when using the `ResponseVarName` or `formula` input arguments.

Example: `'ResponseName', 'Response'`

Data Types: `char`

Scale — Distance scale

`nanstd(X)` (default) | vector of nonnegative scalar values

Distance scale, specified as the comma-separated pair consisting of 'Scale' and a vector containing nonnegative scalar values with length equal to the number of columns in X. Each coordinate difference between X and a query point is scaled by the corresponding element of Scale. This argument is only valid when 'Distance' is 'seuclidean'.

You cannot simultaneously specify 'Standardize' and either of 'Scale' or 'Cov'.

Data Types: single | double

Weights — Observation weights

`ones(size(X,1),1)` (default) | vector of scalar values

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a vector of scalar values. The software weighs the observations in each row of X or tbl with the corresponding value in Weights. The size of Weights must equal the number of rows of X or tbl.

If you specify the input data as a table tbl, then Weights can be the name of a variable in tbl that contains a numeric vector. In this case, you must specify Weights as a character vector containing the variable name. For example, if the weights vector w is stored as tbl.w, then specify it as 'w'. Otherwise, the software treats all columns of tbl, including w, as predictors when training the model.

The software normalizes the weights in each class to add up to the value of the prior probability of the class.

Data Types: single | double

Output Arguments

mdl — k-nearest neighbor classifier model

ClassificationKNN object

k-nearest neighbor classifier model, specified as a ClassificationKNN object.

Examples

Train k -Nearest Neighbor Classifier

Train a k -nearest neighbor classifier for Fisher's iris data, where k , the number of nearest neighbors in the predictors, is 5.

Load Fisher's iris data.

```
load fisheriris
X = meas;
Y = species;
```

X is a numeric matrix that contains four petal measurements for 150 irises. Y is a cell array of character vectors that contains the corresponding iris species.

Train a 5-nearest neighbor classifier. Standardize the noncategorical predictor data.

```
Mdl = fitcknn(X,Y,'NumNeighbors',5,'Standardize',1)
```

```
Mdl =
  ClassificationKNN
      ResponseName: 'Y'
  CategoricalPredictors: []
      ClassNames: {'setosa' 'versicolor' 'virginica'}
      ScoreTransform: 'none'
  NumObservations: 150
      Distance: 'euclidean'
      NumNeighbors: 5
```

Properties, Methods

Mdl is a trained `ClassificationKNN` classifier, and some of its properties appear in the Command Window.

To access the properties of Mdl , use dot notation.

$Mdl.ClassNames$

```
ans = 3x1 cell array
    {'setosa' }
    {'versicolor'}
    {'virginica' }
```

```
Mdl.Prior
```

```
ans = 1x3
```

```
    0.3333    0.3333    0.3333
```

`Mdl.Prior` contains the class prior probabilities, which you can specify using the 'Prior' name-value pair argument in `fitcknn`. The order of the class prior probabilities corresponds to the order of the classes in `Mdl.ClassNames`. By default, the prior probabilities are the respective relative frequencies of the classes in the data.

You can also reset the prior probabilities after training. For example, set the prior probabilities to 0.5, 0.2, and 0.3, respectively.

```
Mdl.Prior = [0.5 0.2 0.3];
```

You can pass `Mdl` to `predict` to label new measurements or `crossval` to cross-validate the classifier.

Train a *k*-Nearest Neighbor Classifier Using the Minkowski Metric

Load Fisher's iris data set.

```
load fisheriris
X = meas;
Y = species;
```

`X` is a numeric matrix that contains four petal measurements for 150 irises. `Y` is a cell array of character vectors that contains the corresponding iris species.

Train a 3-nearest neighbors classifier using the Minkowski metric. To use the Minkowski metric, you must use an exhaustive searcher. It is good practice to standardize noncategorical predictor data.

```
Mdl = fitcknn(X,Y,'NumNeighbors',3,...
    'NSMethod','exhaustive','Distance','minkowski',...
    'Standardize',1);
```

`Mdl` is a `ClassificationKNN` classifier.

You can examine the properties of Mdl by double-clicking Mdl in the Workspace window. This opens the Variable Editor.

Name	Value	Min	Max
Mdl	1x1 ClassificationKNN		
meas	150x4 double	0.1000	7.9
species	150x1 cell		
X	150x4 double	0.1000	7.9
Y	150x1 cell		

Property	Value	Min	Max
NumNeighbors	3	3	3
Distance	'minkowski'		
DistParameter	2	2	2
IncludeTies	0		
DistanceWeight	'equal'		
BreakTies	'smallest'		
NSMethod	'exhaustive'		

Definitions

Prediction

ClassificationKNN predicts the classification of a point x_{new} using a procedure equivalent to this:

- 1 Find the NumNeighbors points in the training set X that are nearest to x_{new} .
- 2 Find the NumNeighbors response values Y to those nearest points.
- 3 Assign the classification label y_{new} that has the largest posterior probability among the values in Y .

For details, see “Posterior Probability” on page 32-5188 in the `predict` documentation.

Topics

“Construct KNN Classifier” on page 18-36

“Modify KNN Classifier” on page 18-38

“Classification Using Nearest Neighbors” on page 18-16

ClassificationTree.fit

Class: ClassificationTree

(Not Recommended) Fit classification tree

Note ClassificationTree.fit is not recommended. Use fitctree instead.

Syntax

```
tree = ClassificationTree.fit(x,y)
tree = ClassificationTree.fit(x,y,Name,Value)
```

Description

tree = ClassificationTree.fit(x,y) returns a classification tree based on the input variables (also known as predictors, features, or attributes) x and output (response) y. tree is a binary tree, where each branching node is split based on the values of a column of x.

tree = ClassificationTree.fit(x,y,Name,Value) fits a tree with additional options specified by one or more Name,Value pair arguments. You can specify several name-value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Note that using the 'CrossVal', 'KFold', 'Holdout', 'Leaveout', or 'CVPartition' options results in a tree of class ClassificationPartitionedModel. You cannot use a partitioned tree for prediction, so this kind of tree does not have a predict method.

Otherwise, tree is of class ClassificationTree, and you can use the predict method to make predictions.

Input Arguments

x — Predictor values

matrix of floating point values

Predictor values, specified as a matrix of floating point values.

`ClassificationTree.fit` considers NaN values in `x` as missing values.

`ClassificationTree.fit` does not use observations with all missing values for `x` in the fit. `ClassificationTree.fit` uses observations with some missing values for `x` to find splits on variables for which these observations have valid values.

Data Types: `single` | `double`

y — predictor values

numeric vector | categorical vector | logical vector | character array | cell array of character vectors

Predictor values, specified as a numeric vector, categorical vector, logical vector, character array, or cell array of character vectors.

Each row of `y` represents the classification of the corresponding row of `x`. For numeric `y`, consider using `fitrtree` instead. `ClassificationTree.fit` considers NaN values in `y` to be missing values.

`ClassificationTree.fit` does not use observations with missing values for `y` in the fit.

Data Types: `single` | `double` | `char` | `logical` | `cell`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

AlgorithmForCategorical — Algorithm for best split on categorical predictor

'Exact' | 'PullLeft' | 'PCA' | 'OVAbyClass'

Algorithm to find the best split on a categorical predictor with L levels for data with $K \geq 3$ classes, specified as the comma-separated pair consisting of 'AlgorithmForCategorical' and one of the following.

'Exact'	Consider all $2^{L-1} - 1$ combinations
'PullLeft'	Pull left by purity
'PCA'	Principal component-based partition
'OVabyClass'	One versus all by class

`ClassificationTree.fit` selects the optimal subset of algorithms for each split using the known number of classes and levels of a categorical predictor. For $K = 2$ classes, `ClassificationTree.fit` always performs the exact search.

Example: 'AlgorithmForCategorical', 'PCA'

CategoricalPredictors — Categorical predictors list

numeric or logical vector | cell array of character vectors | character matrix | 'all'

Categorical predictors list, specified as the comma-separated pair consisting of 'CategoricalPredictors' and one of the following.

- A numeric vector with indices from 1 to p , where p is the number of columns of x .
- A logical vector of length p , where a `true` entry means that the corresponding column of x is a categorical variable.
- A cell array of character vectors, where each element in the array is the name of a predictor variable. The names must match entries in `PredictorNames` values.
- A character matrix, where each row of the matrix is a name of a predictor variable. The names must match entries in `PredictorNames` values. Pad the names with extra blanks so each row of the character matrix has the same length.
- 'all', meaning all predictors are categorical.

Example: 'CategoricalPredictors', 'all'

Data Types: single | double | char

ClassNames — Class names

numeric vector | categorical vector | logical vector | character array | cell array of character vectors

Class names, specified as the comma-separated pair consisting of 'ClassNames' and an array representing the class names. Use the same data type as the values that exist in y .

Use `ClassNames` to order the classes or to select a subset of classes for training. The default is the class names that exist in `y`.

Data Types: `single` | `double` | `char` | `logical` | `cell`

Cost — Cost of misclassification

`square matrix` | `structure`

Cost of misclassification a point, specified as the comma-separated pair consisting of `'Cost'` and one of the following.

- Square matrix, where `Cost(i, j)` is the cost of classifying a point into class `j` if its true class is `i`.
- Structure `S` having two fields: `S.ClassNames` containing the group names as a variable of the same type as `y`, and `S.ClassificationCosts` containing the cost matrix.

The default is `Cost(i, j)=1` if `i~j`, and `Cost(i, j)=0` if `i=j`

Data Types: `single` | `double` | `struct`

CrossVal — Flag to grow cross-validated tree

`'off'` (default) | `'on'`

Flag to grow a cross-validated decision tree, specified as the comma-separated pair consisting of `'CrossVal'` and either `'on'` or `'off'`.

If `'on'`, `ClassificationTree.fit` grows a cross-validated decision tree with 10 folds. You can override this cross-validation setting using one of the `'KFold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'` name-value pair arguments. Note that you can only use one of these four options (`'KFold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'`) at a time when creating a cross-validated tree.

Alternatively, cross-validate tree later using the `crossval` method.

Example: `'CrossVal', 'on'`

CVPartition — Partition for cross-validation tree

`cvpartition` object

Partition to use in a cross-validated tree, specified as the comma-separated pair consisting of `'CVPartition'` and an object of the `cvpartition` class created using `cvpartition`.

Note that if you use 'CVPartition', you cannot use any of the 'KFold', 'Holdout', or 'Leaveout' name-value pair arguments.

Holdout — Fraction of data for holdout validation

1 (default) | scalar value in the range (0,1]

Fraction of data used for holdout validation, specified as the comma-separated pair consisting of 'Holdout' and a scalar value in the range [0,1]. Holdout validation tests the specified fraction of the data, and uses the rest of the data for training.

Note that if you use 'Holdout', you cannot use any of the 'CVPartition', 'KFold', or 'Leaveout' name-value pair arguments.

Example: 'Holdout',0.1

Data Types: single | double

KFold — Number of folds

10 (default) | positive integer value

Number of folds to use in a cross-validated tree, specified as the comma-separated pair consisting of 'KFold' and a positive integer value.

Note that if you use 'KFold', you cannot use any of the 'CVPartition', 'Holdout', or 'Leaveout' name-value pair arguments.

Example: 'KFold',8

Data Types: single | double

Leaveout — Leave-one-out cross validation flag

'off' (default) | 'on'

Leave-one-out cross validation flag, specified as the comma-separated pair consisting of 'Leaveout' and either 'on' or 'off'. Use leave-one-out cross validation by setting to 'on'.

Note that if you use 'Leaveout', you cannot use any of the 'CVPartition', 'Holdout', or 'KFold' name-value pair arguments.

Example: 'Leaveout','on'

MaxCat — Maximum category levels

10 (default) | nonnegative scalar value

Maximum category levels, specified as the comma-separated pair consisting of 'MaxCat' and a nonnegative scalar value. `ClassificationTree.fit` splits a categorical predictor using the exact search algorithm if the predictor has at most MaxCat levels in the split node. Otherwise, `ClassificationTree.fit` finds the best categorical split using one of the inexact algorithms.

Note that passing a small value can lead to loss of accuracy and passing a large value can lead to long computation time and memory overload.

Example: 'MaxCat',8

MergeLeaves — Leaf merge flag

'on' (default) | 'off'

Leaf merge flag, specified as the comma-separated pair consisting of 'MergeLeaves' and either 'on' or 'off'. When 'on', `ClassificationTree.fit` merges leaves that originate from the same parent node, and that give a sum of risk values greater or equal to the risk associated with the parent node. When 'off', `ClassificationTree.fit` does not merge leaves.

Example: 'MergeLeaves','off'

MinLeaf — Minimum number of leaf node observations

1 (default) | positive integer value

Minimum number of leaf node observations, specified as the comma-separated pair consisting of 'MinLeaf' and a positive integer value. Each leaf has at least MinLeaf observations per tree leaf. If you supply both MinParent and MinLeaf, `ClassificationTree.fit` uses the setting that gives larger leaves: $\text{MinParent} = \max(\text{MinParent}, 2 * \text{MinLeaf})$.

Example: 'MinLeaf',3

Data Types: single | double

MinParent — Minimum number of branch node observations

10 (default) | positive integer value

Minimum number of branch node observations, specified as the comma-separated pair consisting of 'MinParent' and a positive integer value. Each branch node in the tree has at least MinParent observations. If you supply both MinParent and MinLeaf, `ClassificationTree.fit` uses the setting that gives larger leaves: $\text{MinParent} = \max(\text{MinParent}, 2 * \text{MinLeaf})$.

Example: `'MinParent',8`

Data Types: `single | double`

NVarToSample — Number of predictors for split

`'all' | positive integer value`

Number of predictors to select at random for each split, specified as the comma-separated pair consisting of `'NVarToSample'` and a positive integer value. You can also specify `'all'` to use all available predictors.

Example: `'NVarToSample',3`

Data Types: `single | double`

PredictorNames — Predictor variable names

`{'x1','x2',...}` (default) | cell array of character vectors

Predictor variable names, specified as the comma-separated pair consisting of `'PredictorNames'` and a cell array of character vectors containing the names for the predictor variables, in the order in which they appear in `x`.

Prior — Prior probabilities

`'empirical'` (default) | `'uniform'` | vector of scalar values | structure

Prior probabilities for each class, specified as the comma-separated pair consisting of `'Prior'` and one of the following.

- `'empirical'` determines class probabilities from class frequencies in `y`. If you pass observation weights, they are used to compute the class probabilities.
- `'uniform'` sets all class probabilities equal.
- A vector (one scalar value for each class)
- A structure `S` with two fields:
 - `S.ClassNames` containing the class names as a variable of the same type as `y`
 - `S.ClassProbs` containing a vector of corresponding probabilities

If you set values for both `weights` and `prior`, the weights are renormalized to add up to the value of the prior probability in the respective class.

Example: `'Prior','uniform'`

Prune — Pruning flag`'on' (default) | 'off'`

Pruning flag, specified as the comma-separated pair consisting of 'Prune' and either 'on' or 'off'. When 'on', `ClassificationTree.fit` grows the classification tree, and computes the optimal sequence of pruned subtrees. When 'off' `ClassificationTree.fit` grows the classification tree without pruning.

Example: `'Prune', 'off'`

PruneCriterion — Pruning criterion`'error' (default) | 'impurity'`

Pruning criterion, specified as the comma-separated pair consisting of 'PruneCriterion' and either 'error' or 'impurity'.

Example: `'PruneCriterion', 'impurity'`

ResponseName — Response variable name`'Y' (default) | character vector`

Response variable name, specified as the comma-separated pair consisting of 'ResponseName' and a character vector representing the name of the response variable y .

Example: `'ResponseName', 'Response'`

ScoreTransform — Score transform function`'none' | 'symmetric' | 'invlogit' | 'ismax' | function handle | ...`

Score transform function, specified as the comma-separated pair consisting of 'ScoreTransform' and a function handle for transforming scores. Your function should accept a matrix (the original scores) and return a matrix of the same size (the transformed scores).

Alternatively, you can specify one of the following values representing a built-in transformation function.

Value	Description
'doublelogit'	$1/(1 + e^{-2x})$
'invlogit'	$\log(x / (1 - x))$

Value	Description
'ismax'	Sets the score for the class with the largest score to 1, and sets the scores for all other classes to 0
'logit'	$1/(1 + e^{-x})$
'none' or 'identity'	x (no transformation)
'sign'	-1 for $x < 0$ 0 for $x = 0$ 1 for $x > 0$
'symmetric'	$2x - 1$
'symmetricismax'	Sets the score for the class with the largest score to 1, and sets the scores for all other classes to -1
'symmetriclogit'	$2/(1 + e^{-x}) - 1$

Example: 'ScoreTransform', 'logit'

SplitCriterion — Split criterion

'gdi' (default) | 'twoing' | 'deviance'

Split criterion, specified as the comma-separated pair consisting of 'SplitCriterion' and 'gdi' (Gini's diversity index), 'twoing' for the twoing rule, or 'deviance' for maximum deviance reduction (also known as cross entropy).

Example: 'SplitCriterion', 'deviance'

Surrogate — Surrogate decision splits flag

'off' | 'on' | 'all' | positive integer value

Surrogate decision splits flag, specified as the comma-separated pair consisting of 'Surrogate' and 'on', 'off', 'all', or a positive integer value.

- When set to 'on', `ClassificationTree.fit` finds at most 10 surrogate splits at each branch node.
- When set to a positive integer value, `ClassificationTree.fit` finds at most the specified number of surrogate splits at each branch node.
- When set to 'all', `ClassificationTree.fit` finds all surrogate splits at each branch node. The 'all' setting can use much time and memory.

Use surrogate splits to improve the accuracy of predictions for data with missing values. The setting also enables you to compute measures of predictive association between predictors.

Example: 'Surrogate', 'on'

Weights — Observation weights

`ones(size(x,1),1)` (default) | vector of scalar values

Vector of observation weights, specified as the comma-separated pair consisting of 'Weights' and a vector of scalar values. The length of `Weights` is equal to the number of rows in `x`. `ClassificationTree.fit` normalizes the weights in each class to add up to the value of the prior probability of the class.

Data Types: `single` | `double`

Output Arguments

tree — Classification tree

classification tree object

Classification tree object, returned as a classification tree object.

Note that using the 'CrossVal', 'KFold', 'Holdout', 'Leaveout', or 'CVPartition' options results in a tree of class `ClassificationPartitionedModel`. You cannot use a partitioned tree for prediction, so this kind of tree does not have a `predict` method. Instead, use `kfoldPredict` to predict responses for observations not used for training.

Otherwise, `tree` is of class `ClassificationTree`, and you can use the `predict` method to make predictions.

Examples

Construct a Classification Tree

Construct a classification tree for the data in `ionosphere.mat`.

```
load ionosphere
tc = ClassificationTree.fit(X,Y)

tc =
  ClassificationTree
    ResponseName: 'Y'
    CategoricalPredictors: []
    ClassNames: {'b' 'g'}
    ScoreTransform: 'none'
    NumObservations: 351
```

Properties, Methods

Definitions

Impurity and Node Error

`ClassificationTree` splits nodes based on either impurity or node error.

Impurity means one of several things, depending on your choice of the `SplitCriterion` name-value pair argument:

- Gini's Diversity Index (`gdi`) — The Gini index of a node is

$$1 - \sum_i p^2(i),$$

where the sum is over the classes i at the node, and $p(i)$ is the observed fraction of classes with class i that reach the node. A node with just one class (a pure node) has Gini index 0; otherwise the Gini index is positive. So the Gini index is a measure of node impurity.

- Deviance ('`deviance`') — With $p(i)$ defined the same as for the Gini index, the deviance of a node is

$$- \sum_i p(i) \log_2 p(i).$$

A pure node has deviance 0; otherwise, the deviance is positive.

- Twoing rule ('twoing') — Twoing is not a purity measure of a node, but is a different measure for deciding how to split a node. Let $L(i)$ denote the fraction of members of class i in the left child node after a split, and $R(i)$ denote the fraction of members of class i in the right child node after a split. Choose the split criterion to maximize

$$P(L)P(R)\left(\sum_i |L(i) - R(i)|\right)^2,$$

where $P(L)$ and $P(R)$ are the fractions of observations that split to the left and right respectively. If the expression is large, the split made each child node purer. Similarly, if the expression is small, the split made each child node similar to each other, and therefore similar to the parent node. The split did not increase node purity.

- Node error — The node error is the fraction of misclassified classes at a node. If j is the class with the largest number of training samples at a node, the node error is

$$1 - \max_j p(j).$$

GeneralizedLinearModel.fit

Class: GeneralizedLinearModel

(Not Recommended) Create generalized linear regression model

Note GeneralizedLinearModel.fit is not recommended. Use fitglm instead.

Syntax

```
mdl = GeneralizedLinearModel.fit(tbl)
mdl = GeneralizedLinearModel.fit(X,y)
mdl = GeneralizedLinearModel.fit(...,modelspec)
mdl = GeneralizedLinearModel.fit(...,Name,Value)
mdl = GeneralizedLinearModel.fit(...,modelspec,Name,Value)
```

Description

`mdl = GeneralizedLinearModel.fit(tbl)` creates a generalized linear model of a table or dataset array `tbl`.

`mdl = GeneralizedLinearModel.fit(X,y)` creates a generalized linear model of the responses `y` to a data matrix `X`.

`mdl = GeneralizedLinearModel.fit(...,modelspec)` creates a generalized linear model as specified by `modelspec`.

`mdl = GeneralizedLinearModel.fit(...,Name,Value)` or `mdl = GeneralizedLinearModel.fit(...,modelspec,Name,Value)` creates a generalized linear model with additional options specified by one or more `Name, Value` pair arguments.

Input Arguments

tbl — Input data

table | dataset array

Input data, specified as a table or dataset array. When `modelspec` is a formula, the formula specifies the predictor and response variables. Otherwise, if you do not specify the predictor and response variables, the last variable in `tbl` is the response variable and the others are the predictor variables by default.

The predictor variables and response variable can be numeric, logical, categorical, character, or string. The response variable can have a data type other than numeric only if 'Distribution' is 'binomial'.

To set a different column as the response variable, use the `ResponseVar` name-value pair argument. To use a subset of the columns as predictors, use the `PredictorVars` name-value pair argument.

X — Predictor variables

matrix

Predictor variables, specified as an n -by- p matrix, where n is the number of observations and p is the number of predictor variables. Each column of `X` represents one variable, and each row represents one observation.

By default, there is a constant term in the model, unless you explicitly remove it, so do not include a column of 1s in `X`.

Data Types: single | double

y — Response variable

vector

Response variable, specified as an n -by-1 vector, where n is the number of observations. Each entry in `y` is the response for the corresponding row of `X`.

Data Types: single | double | logical | categorical

modelspec — Model specification

character vector or string scalar specifying the model | t -by- $(p+1)$ terms matrix | character vector or string scalar of the form 'Y ~ terms'

Model specification, specified as one of the following:

- Character vector or string scalar specifying the type of model.

Value	Model Type
'constant'	Model contains only a constant (intercept) term.
'linear'	Model contains an intercept and linear term for each predictor.
'interactions'	Model contains an intercept, linear term for each predictor, and all products of pairs of distinct predictors (no squared terms).
'purequadratic'	Model contains an intercept term and linear and squared terms for each predictor.
'quadratic'	Model contains an intercept term, linear and squared terms for each predictor, and all products of pairs of distinct predictors.
'polyijk'	Model is a polynomial with all terms up to degree i in the first predictor, degree j in the second predictor, and so on. Specify the maximum degree for each predictor by using numerals 0 through 9. The model contains interaction terms, but the degree of each interaction term does not exceed the maximum value of the specified degrees. For example, 'poly13' has an intercept and x_1 , x_2 , x_2^2 , x_2^3 , x_1*x_2 , and $x_1*x_2^2$ terms, where x_1 and x_2 are the first and second predictors, respectively.

- t -by- $(p+1)$ matrix, namely terms matrix on page 32-1694, specifying terms to include in model, where t is the number of terms and p is the number of predictor variables, and plus one is for the response variable.
- Character vector or string scalar representing a formula on page 32-1694 in the form

'Y ~ terms',

where the terms are in "Wilkinson Notation" on page 32-1695.

Example: 'quadratic'

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

BinomialSize — Number of trials for binomial distribution

1 (default) | scalar value | vector

Number of trials for binomial distribution, that is the sample size, specified as the comma-separated pair consisting of a scalar value or a vector of the same length as the response. This is the parameter `n` for the fitted binomial distribution. `BinomialSize` applies only when the `Distribution` parameter is `'binomial'`.

If `BinomialSize` is a scalar value, that means all observations have the same number of trials.

As an alternative to `BinomialSize`, you can specify the response as a two-column vector with counts in column 1 and `BinomialSize` in column 2.

Data Types: `single` | `double`

CategoricalVars — Categorical variable list

string array | cell array of character vectors | logical or numeric index vector

Categorical variable list, specified as the comma-separated pair consisting of `'CategoricalVars'` and either a string array or cell array of character vectors containing categorical variable names in the table or dataset array `tbl`, or a logical or numeric index vector indicating which columns are categorical.

- If data is in a table or dataset array `tbl`, then, by default, `GeneralizedLinearModel.fit` treats all categorical values, logical values, character arrays, string arrays, and cell arrays of character vectors as categorical variables.
- If data is in matrix `X`, then the default value of `'CategoricalVars'` is an empty matrix `[]`. That is, no variable is categorical unless you specify it as categorical.

For example, you can specify the observations 2 and 3 out of 6 as categorical using either of the following examples.

Example: `'CategoricalVars',[2,3]`

Example: `'CategoricalVars',logical([0 1 1 0 0 0])`

Data Types: `single | double | logical | string | cell`

DispersionFlag — Indicator to compute dispersion parameter

`false` for 'binomial' and 'poisson' distributions (default) | `true`

Indicator to compute dispersion parameter for 'binomial' and 'poisson' distributions, specified as the comma-separated pair consisting of 'DispersionFlag' and one of the following.

<code>true</code>	Estimate a dispersion parameter when computing standard errors
<code>false</code>	Default. Use the theoretical value when computing standard errors

The fitting function always estimates the dispersion for other distributions.

Example: `'DispersionFlag',true`

Distribution — Distribution of the response variable

`'normal'` (default) | `'binomial'` | `'poisson'` | `'gamma'` | `'inverse gaussian'`

Distribution of the response variable, specified as the comma-separated pair consisting of 'Distribution' and one of the following.

<code>'normal'</code>	Normal distribution
<code>'binomial'</code>	Binomial distribution
<code>'poisson'</code>	Poisson distribution
<code>'gamma'</code>	Gamma distribution
<code>'inverse gaussian'</code>	Inverse Gaussian distribution

Example: `'Distribution','gamma'`

Exclude — Observations to exclude

`logical` or `numeric` index vector

Observations to exclude from the fit, specified as the comma-separated pair consisting of 'Exclude' and a logical or numeric index vector indicating which observations to exclude from the fit.

For example, you can exclude observations 2 and 3 out of 6 using either of the following examples.

Example: `'Exclude', [2,3]`

Example: `'Exclude', logical([0 1 1 0 0 0])`

Data Types: `single` | `double` | `logical`

Intercept — Indicator for constant term

`true` (default) | `false`

Indicator for the constant term (intercept) in the fit, specified as the comma-separated pair consisting of `'Intercept'` and either `true` to include or `false` to remove the constant term from the model.

Use `'Intercept'` only when specifying the model using a character vector or string scalar, not a formula or matrix.

Example: `'Intercept', false`

Link — Link function

canonical link function (default) | scalar value | structure

Link function to use in place of the canonical link function, specified as the comma-separated pair consisting of `'Link'` and one of the following.

Link Function Name	Link Function	Mean (Inverse) Function
<code>'identity'</code>	$f(\mu) = \mu$	$\mu = Xb$
<code>'log'</code>	$f(\mu) = \log(\mu)$	$\mu = \exp(Xb)$
<code>'logit'</code>	$f(\mu) = \log(\mu/(1-\mu))$	$\mu = \exp(Xb) / (1 + \exp(Xb))$
<code>'probit'</code>	$f(\mu) = \Phi^{-1}(\mu)$	$\mu = \Phi(Xb)$
<code>'comploglog'</code>	$f(\mu) = \log(-\log(1 - \mu))$	$\mu = 1 - \exp(-\exp(Xb))$
<code>'reciprocal'</code>	$f(\mu) = 1/\mu$	$\mu = 1/(Xb)$
<code>p</code> (a number)	$f(\mu) = \mu^p$	$\mu = Xb^{1/p}$

Link Function Name	Link Function	Mean (Inverse) Function
<p>S (a structure) with three fields. Each field holds a function handle that accepts a vector of inputs and returns a vector of the same size:</p> <ul style="list-style-type: none"> • S.Link — The link function • S.Inverse — The inverse link function • S.Derivative — The derivative of the link function 	$f(\mu) = S.Link(\mu)$	$\mu = S.Inverse(Xb)$

The link function defines the relationship $f(\mu) = X*b$ between the mean response μ and the linear combination of predictors $X*b$.

For more information on the canonical link functions, see “Canonical Link Function” on page 32-1696.

Example: 'Link', 'probit'

Data Types: char | string | single | double | struct

Offset — Offset variable

[] (default) | vector | character vector | string scalar

Offset variable in the fit, specified as the comma-separated pair consisting of 'Offset' and a vector or name of a variable with the same length as the response.

GeneralizedLinearModel.fit uses Offset as an additional predictor, with a coefficient value fixed at 1.0. In other words, the formula for fitting is

$$f(\mu) \sim \text{Offset} + (\text{terms involving real predictors})$$

with the Offset predictor having coefficient 1.

For example, consider a Poisson regression model. Suppose the number of counts is known for theoretical reasons to be proportional to a predictor A. By using the log link

function and by specifying $\log(A)$ as an offset, you can force the model to satisfy this theoretical constraint.

Data Types: `single` | `double` | `char` | `string`

PredictorVars — Predictor variables

string array | cell array of character vectors | logical or numeric index vector

Predictor variables to use in the fit, specified as the comma-separated pair consisting of 'PredictorVars' and either a string array or cell array of character vectors of the variable names in the table or dataset array `tbl`, or a logical or numeric index vector indicating which columns are predictor variables.

The string values or character vectors should be among the names in `tbl`, or the names you specify using the 'VarNames' name-value pair argument.

The default is all variables in X , or all variables in `tbl` except for `ResponseVar`.

For example, you can specify the second and third variables as the predictor variables using either of the following examples.

Example: `'PredictorVars',[2,3]`

Example: `'PredictorVars',logical([0 1 1 0 0 0])`

Data Types: `single` | `double` | `logical` | `string` | `cell`

ResponseVar — Response variable

last column in `tbl` (default) | character vector or string scalar containing variable name | logical or numeric index vector

Response variable to use in the fit, specified as the comma-separated pair consisting of 'ResponseVar' and either a character vector or string scalar containing the variable name in the table or dataset array `tbl`, or a logical or numeric index vector indicating which column is the response variable. You typically need to use 'ResponseVar' when fitting a table or dataset array `tbl`.

For example, you can specify the fourth variable, say `yield`, as the response out of six variables, in one of the following ways.

Example: `'ResponseVar','yield'`

Example: `'ResponseVar',[4]`

Example: `'ResponseVar',logical([0 0 0 1 0 0])`

Data Types: `single` | `double` | `logical` | `char` | `string`

VarNames — Names of variables

`{'x1', 'x2', ..., 'xn', 'y'}` (default) | string array | cell array of character vectors

Names of variables, specified as the comma-separated pair consisting of `'VarNames'` and a string array or cell array of character vectors including the names for the columns of X first, and the name for the response variable y last.

`'VarNames'` is not applicable to variables in a table or dataset array, because those variables already have names.

For example, if in your data, horsepower, acceleration, and model year of the cars are the predictor variables, and miles per gallon (MPG) is the response variable, then you can name the variables as follows.

Example: `'VarNames', {'Horsepower', 'Acceleration', 'Model_Year', 'MPG'}`

Data Types: `string` | `cell`

Weights — Observation weights

`ones(n, 1)` (default) | n -by-1 vector of nonnegative scalar values

Observation weights, specified as the comma-separated pair consisting of `'Weights'` and an n -by-1 vector of nonnegative scalar values, where n is the number of observations.

Data Types: `single` | `double`

Output Arguments

mdl — Generalized linear model

`GeneralizedLinearModel` object

Generalized linear model representing a least-squares fit of the link of the response to the data, returned as a `GeneralizedLinearModel` object.

For properties and methods of the generalized linear model object, `mdl`, see the `GeneralizedLinearModel` class page.

Examples

Fit a Generalized Linear Model

Fit a logistic regression model of probability of smoking as a function of age, weight, and sex, using a two-way interactions model.

Load the hospital dataset array.

```
load hospital
ds = hospital; % just to use the ds name
```

Specify the model using a formula that allows up to two-way interactions.

```
modelspec = 'Smoker ~ Age*Weight*Sex - Age:Weight:Sex';
```

Create the generalized linear model.

```
mdl = fitglm(ds,modelspec,'Distribution','binomial')
```

```
mdl =
```

```
Generalized linear regression model:
```

```
logit(Smoker) ~ 1 + Sex*Age + Sex*Weight + Age*Weight
Distribution = Binomial
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	-6.0492	19.749	-0.3063	0.75938
Sex_Male	-2.2859	12.424	-0.18399	0.85402
Age	0.11691	0.50977	0.22934	0.81861
Weight	0.031109	0.15208	0.20455	0.83792
Sex_Male:Age	0.020734	0.20681	0.10025	0.92014
Sex_Male:Weight	0.01216	0.053168	0.22871	0.8191
Age:Weight	-0.00071959	0.0038964	-0.18468	0.85348

100 observations, 93 error degrees of freedom

Dispersion: 1

Chi²-statistic vs. constant model: 5.07, p-value = 0.535

The large *p*-value indicates the model might not differ statistically from a constant.

Definitions

Terms Matrix

A terms matrix T is a t -by- $(p + 1)$ matrix specifying terms in a model, where t is the number of terms, p is the number of predictor variables, and $+1$ accounts for the response variable. The value of $T(i, j)$ is the exponent of variable j in term i .

For example, suppose that an input includes three predictor variables A , B , and C and the response variable Y in the order A , B , C , and Y . Each row of T represents one term:

- $[0 \ 0 \ 0 \ 0]$ — Constant term or intercept
- $[0 \ 1 \ 0 \ 0]$ — B ; equivalently, $A^0 * B^1 * C^0$
- $[1 \ 0 \ 1 \ 0]$ — $A * C$
- $[2 \ 0 \ 0 \ 0]$ — A^2
- $[0 \ 1 \ 2 \ 0]$ — $B * (C^2)$

The 0 at the end of each term represents the response variable. In general, a column vector of zeros in a terms matrix represents the position of the response variable. If you have the predictor and response variables in a matrix and column vector, then you must include 0 for the response variable in the last column of each row.

Formula

A formula for model specification is a character vector or string scalar of the form ' $Y \sim terms$ '.

- Y is the response name.
- $terms$ represents the predictor terms in a model using Wilkinson notation.

For example:

- ' $Y \sim A + B + C$ ' specifies a three-variable linear model with intercept.
- ' $Y \sim A + B + C - 1$ ' specifies a three-variable linear model without intercept. Note that formulas include a constant (intercept) term by default. To exclude a constant term from the model, you must include -1 in the formula.

Wilkinson Notation

Wilkinson notation describes the terms present in a model. The notation relates to the terms present in a model, not to the multipliers (coefficients) of those terms.

Wilkinson notation uses these symbols:

- $+$ means include the next variable.
- $-$ means do not include the next variable.
- $:$ defines an interaction, which is a product of terms.
- $*$ defines an interaction and all lower-order terms.
- $^$ raises the predictor to a power, exactly as in $*$ repeated, so $^$ includes lower-order terms as well.
- $()$ groups terms.

This table shows typical examples of Wilkinson notation.

Wilkinson Notation	Term in Standard Notation
1	Constant (intercept) term
A^k , where k is a positive integer	A, A^2, \dots, A^k
$A + B$	A, B
$A*B$	$A, B, A*B$
$A:B$	$A*B$ only
$-B$	Do not include B
$A*B + C$	$A, B, C, A*B$
$A + B + C + A:B$	$A, B, C, A*B$
$A*B*C - A:B:C$	$A, B, C, A*B, A*C, B*C$
$A*(B + C)$	$A, B, C, A*B, A*C$

Statistics and Machine Learning Toolbox notation always includes a constant term unless you explicitly remove the term using -1 .

For more details, see “Wilkinson Notation” on page 11-117.

Canonical Link Function

The default link function for a generalized linear model is the canonical link function.

Canonical Link Functions for Generalized Linear Models

Distribution	Link Function Name	Link Function	Mean (Inverse) Function
'normal'	'identity'	$f(\mu) = \mu$	$\mu = Xb$
'binomial'	'logit'	$f(\mu) = \log(\mu/(1-\mu))$	$\mu = \exp(Xb) / (1 + \exp(Xb))$
'poisson'	'log'	$f(\mu) = \log(\mu)$	$\mu = \exp(Xb)$
'gamma'	-1	$f(\mu) = 1/\mu$	$\mu = 1/(Xb)$
'inverse gaussian'	-2	$f(\mu) = 1/\mu^2$	$\mu = (Xb)^{-1/2}$

Tips

- The generalized linear model `mdl` is a standard linear model unless you specify otherwise with the `Distribution` name-value pair.
- For other methods such as `devianceTest`, or properties of the `GeneralizedLinearModel` object, see `GeneralizedLinearModel`.

Alternatives

You can also construct a generalized linear model using `fitglm`.

Use `stepwiseglm` to select a model specification automatically. Use `step`, `addTerms`, or `removeTerms` to adjust a fitted model.

gmdistribution.fit

(Not Recommended) Gaussian mixture parameter estimates

Note `gmdistribution.fit` is not recommended. Use `fitgmdist` instead.

Syntax

```
obj = gmdistribution.fit(X,k)
obj = gmdistribution.fit(...,param1, val1, param2, val2, ...)
```

Description

`obj = gmdistribution.fit(X,k)` uses an Expectation Maximization (EM) algorithm to construct an object `obj` of the `gmdistribution` class containing maximum likelihood estimates of the parameters in a Gaussian mixture model with `k` components for data in the n -by- m matrix `X`, where n is the number of observations and m is the dimension of the data.

`gmdistribution` treats NaN values as missing data. Rows of `X` with NaN values are excluded from the fit.

`obj = gmdistribution.fit(...,param1, val1, param2, val2, ...)` provides control over the iterative EM algorithm. Parameters and values are listed below.

Parameter	Value
'Start'	<p>Method used to choose initial component parameters. One of the following:</p> <ul style="list-style-type: none"> 'randSample' — To select k observations from X at random as initial component means. The mixing proportions are uniform. The initial covariance matrices for all components are diagonal, where the element j on the diagonal is the variance of $X(:, j)$. This is the default. 'plus' — The software selects k observations from X using the <code>kmeans++</code> algorithm. The initial mixing proportions are uniform. The initial covariance matrices for all components are diagonal, where the element j on the diagonal is the variance of $X(:, j)$. S — A structure array with fields <code>mu</code>, <code>Sigma</code>, and <code>PComponents</code>. See <code>gmdistribution</code> for descriptions of values. s — A vector of length n containing an initial guess of the component index for each point.
'Replicates'	A positive integer giving the number of times to repeat the EM algorithm, each time with a new set of parameters. The solution with the largest likelihood is returned. A value larger than 1 requires the 'randSample' start method. The default is 1.
'CovType'	'diagonal' if the covariance matrices are restricted to be diagonal; 'full' otherwise. The default is 'full'.
'SharedCov'	Logical <code>true</code> if all the covariance matrices are restricted to be the same (pooled estimate); logical <code>false</code> otherwise.
'Regularize'	A nonnegative regularization number added to the diagonal of covariance matrices to make them positive-definite. The default is 0.
'Options'	Options structure for the iterative EM algorithm, as created by <code>statset.gmdistribution.fit</code> uses the parameters 'Display' with a default value of 'off', 'MaxIter' with a default value of 100, and 'TolFun' with a default value of $1e-6$.

In some cases, `gmdistribution` may converge to a solution where one or more of the components has an ill-conditioned or singular covariance matrix.

The following issues may result in an ill-conditioned covariance matrix:

- The number of dimension of your data is relatively high and there are not enough observations.
- Some of the features (variables) of your data are highly correlated.
- Some or all the features are discrete.
- You tried to fit the data to too many components.

In general, you can avoid getting ill-conditioned covariance matrices by using one of the following precautions:

- Pre-process your data to remove correlated features.
- Set 'SharedCov' to `true` to use an equal covariance matrix for every component.
- Set 'CovType' to 'diagonal'.
- Use 'Regularize' to add a very small positive number to the diagonal of every covariance matrix.
- Try another set of initial values.

In other cases `gmdistribution` may pass through an intermediate step where one or more of the components has an ill-conditioned covariance matrix. Trying another set of initial values may avoid this issue without altering your data or model.

Examples

Generate data from a mixture of two bivariate Gaussian distributions using the `mvnrnd` function:

```
MU1 = [1 2];  
SIGMA1 = [2 0; 0 .5];  
MU2 = [-3 -5];  
SIGMA2 = [1 0; 0 1];  
X = [mvnrnd(MU1,SIGMA1,1000);mvnrnd(MU2,SIGMA2,1000)];  
  
scatter(X(:,1),X(:,2),10,'.')  
hold on
```

Next, fit a two-component Gaussian mixture model:

```
options = statset('Display','final');  
obj = gmdistribution.fit(X,2,'Options',options);  
10 iterations, log-likelihood = -7046.78  
  
h = ezcontour(@(x,y)pdf(obj,[x y]),[-8 6],[-8 6]);
```

Among the properties of the fit are the parameter estimates:

```
ComponentMeans = obj.mu
ComponentMeans =
    0.9391    2.0322
   -2.9823   -4.9737

ComponentCovariances = obj.Sigma
ComponentCovariances(:,:,1) =
    1.7786   -0.0528
   -0.0528    0.5312
ComponentCovariances(:,:,2) =
    1.0491   -0.0150
   -0.0150    0.9816
```

```
MixtureProportions = obj.PComponents
MixtureProportions =
    0.5000    0.5000
```

The Akaike information is minimized by the two-component model:

```
AIC = zeros(1,4);
obj = cell(1,4);
for k = 1:4
    obj{k} = gmdistribution.fit(X,k);
    AIC(k) = obj{k}.AIC;
end
```

```
[minAIC,numComponents] = min(AIC);
numComponents
numComponents =
    2
```

```
model = obj{2}
model =
Gaussian mixture distribution
with 2 components in 2 dimensions
Component 1:
Mixing proportion: 0.500000
Mean:      0.9391    2.0322
Component 2:
Mixing proportion: 0.500000
Mean:     -2.9823   -4.9737
```

Both the Akaike and Bayes information are negative log-likelihoods for the data with penalty terms for the number of estimated parameters. They are often used to determine an appropriate number of components for a model when the number of components is unspecified.

LinearModel.fit

(Not Recommended) Create linear regression model

Note `LinearModel.fit` is not recommended. Use `fitlm` instead.

Syntax

```
mdl = LinearModel.fit(tbl)
mdl = LinearModel.fit(X,y)
mdl = LinearModel.fit( ____,modelspec)
mdl = LinearModel.fit( ____,Name,Value)
mdl = LinearModel.fit( ____,modelspec,Name,Value)
```

Description

`mdl = LinearModel.fit(tbl)` creates a linear model of a table or dataset array `tbl`.

`mdl = LinearModel.fit(X,y)` creates a linear model of the responses `y` to a data matrix `X`.

`mdl = LinearModel.fit(____,modelspec)` creates a linear model of the type specified by `modelspec`, using any of the previous syntaxes.

`mdl = LinearModel.fit(____,Name,Value)` or `mdl = LinearModel.fit(____,modelspec,Name,Value)` creates a linear model with additional options specified by one or more `Name,Value` pair arguments. For example, you can specify which predictor variables to include in the fit or include observation weights.

Input Arguments

tbl — Input data

table | dataset array

Input data, specified as a table or dataset array. When `modelspec` is a formula, the formula specifies the predictor and response variables. Otherwise, if you do not specify

the predictor and response variables, the last variable in `tbl` is the response variable and the others are the predictor variables by default.

The predictor variables can be numeric, logical, categorical, character, or string. The response variable must be numeric or logical.

To set a different column as the response variable, use the `ResponseVar` name-value pair argument. To use a subset of the columns as predictors, use the `PredictorVars` name-value pair argument.

X — Predictor variables

matrix

Predictor variables, specified as an n -by- p matrix, where n is the number of observations and p is the number of predictor variables. Each column of `X` represents one variable, and each row represents one observation.

By default, there is a constant term in the model, unless you explicitly remove it, so do not include a column of 1s in `X`.

Data Types: `single` | `double`

y — Response variable

vector

Response variable, specified as an n -by-1 vector, where n is the number of observations. Each entry in `y` is the response for the corresponding row of `X`.

Data Types: `single` | `double` | `logical`

modelspec — Model specification

character vector or string scalar naming the model | t -by- $(p + 1)$ terms matrix | character vector or string scalar of the form `'Y ~ terms'`

Model specification, specified as one of the following.

- A character vector or string scalar naming the model.

Value	Model Type
'constant'	Model contains only a constant (intercept) term.
'linear'	Model contains an intercept and linear term for each predictor.

Value	Model Type
'interactions'	Model contains an intercept, linear term for each predictor, and all products of pairs of distinct predictors (no squared terms).
'purequadratic'	Model contains an intercept term and linear and squared terms for each predictor.
'quadratic'	Model contains an intercept term, linear and squared terms for each predictor, and all products of pairs of distinct predictors.
'polyijk'	Model is a polynomial with all terms up to degree i in the first predictor, degree j in the second predictor, and so on. Specify the maximum degree for each predictor by using numerals 0 through 9. The model contains interaction terms, but the degree of each interaction term does not exceed the maximum value of the specified degrees. For example, 'poly13' has an intercept and x_1 , x_2 , x_2^2 , x_2^3 , x_1*x_2 , and $x_1*x_2^2$ terms, where x_1 and x_2 are the first and second predictors, respectively.

- t -by- $(p + 1)$ matrix, namely terms matrix on page 32-1721, specifying terms to include in the model, where t is the number of terms and p is the number of predictor variables, and plus 1 is for the response variable.
- A character vector or string scalar representing a formula on page 32-1721 in the form

'Y ~ _____ terms',

where the terms are specified using Wilkinson Notation on page 32-1722.

Example: 'quadratic'

Example: 'y ~ X1 + X2^2 + X1:X2'

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

CategoricalVars — Categorical variable list

string array | cell array of character vectors | logical or numeric index vector

Categorical variable list, specified as the comma-separated pair consisting of 'CategoricalVars' and either a string array or cell array of character vectors containing categorical variable names in the table or dataset array `tbl`, or a logical or numeric index vector indicating which columns are categorical.

- If data is in a table or dataset array `tbl`, then, by default, `LinearModel.fit` treats all categorical values, logical values, character arrays, string arrays, and cell arrays of character vectors as categorical variables.
- If data is in matrix X , then the default value of 'CategoricalVars' is an empty matrix `[]`. That is, no variable is categorical unless you specify it as categorical.

For example, you can specify the observations 2 and 3 out of 6 as categorical using either of the following examples.

```
Example: 'CategoricalVars',[2,3]
```

```
Example: 'CategoricalVars',logical([0 1 1 0 0 0])
```

```
Data Types: single | double | logical | string | cell
```

Exclude — Observations to exclude

logical or numeric index vector

Observations to exclude from the fit, specified as the comma-separated pair consisting of 'Exclude' and a logical or numeric index vector indicating which observations to exclude from the fit.

For example, you can exclude observations 2 and 3 out of 6 using either of the following examples.

```
Example: 'Exclude',[2,3]
```

```
Example: 'Exclude',logical([0 1 1 0 0 0])
```

```
Data Types: single | double | logical
```

Intercept — Indicator for constant term

true (default) | false

Indicator for the constant term (intercept) in the fit, specified as the comma-separated pair consisting of 'Intercept' and either `true` to include or `false` to remove the constant term from the model.

Use `'Intercept'` only when specifying the model using a character vector or string scalar, not a formula or matrix.

Example: `'Intercept', false`

PredictorVars — Predictor variables

string array | cell array of character vectors | logical or numeric index vector

Predictor variables to use in the fit, specified as the comma-separated pair consisting of `'PredictorVars'` and either a string array or cell array of character vectors of the variable names in the table or dataset array `tbl`, or a logical or numeric index vector indicating which columns are predictor variables.

The string values or character vectors should be among the names in `tbl`, or the names you specify using the `'VarNames'` name-value pair argument.

The default is all variables in `X`, or all variables in `tbl` except for `ResponseVar`.

For example, you can specify the second and third variables as the predictor variables using either of the following examples.

Example: `'PredictorVars', [2,3]`

Example: `'PredictorVars', logical([0 1 1 0 0 0])`

Data Types: `single` | `double` | `logical` | `string` | `cell`

ResponseVar — Response variable

last column in `tbl` (default) | character vector or string scalar containing variable name | logical or numeric index vector

Response variable to use in the fit, specified as the comma-separated pair consisting of `'ResponseVar'` and either a character vector or string scalar containing the variable name in the table or dataset array `tbl`, or a logical or numeric index vector indicating which column is the response variable. You typically need to use `'ResponseVar'` when fitting a table or dataset array `tbl`.

For example, you can specify the fourth variable, say `yield`, as the response out of six variables, in one of the following ways.

Example: `'ResponseVar', 'yield'`

Example: `'ResponseVar', [4]`

Example: `'ResponseVar', logical([0 0 0 1 0 0])`

Data Types: `single` | `double` | `logical` | `char` | `string`

RobustOpts — Indicator of robust fitting type

'off' (default) | 'on' | character vector | string scalar | structure

Indicator of the robust fitting type to use, specified as the comma-separated pair consisting of 'RobustOpts' and one of these values.

- 'off' — No robust fitting. `LinearModel.fit` uses ordinary least squares.
- 'on' — Robust fitting using the 'bisquare' weight function with the default tuning constant.
- Character vector or string scalar — Name of a robust fitting weight function from the following table. `LinearModel.fit` uses the corresponding default tuning constant specified in the table.
- Structure with the two fields `RobustWgtFun` and `Tune`.
 - The `RobustWgtFun` field contains the name of a robust fitting weight function from the following table or a function handle of a custom weight function.
 - The `Tune` field contains a tuning constant. If you do not set the `Tune` field, `LinearModel.fit` uses the corresponding default tuning constant.

Weight Function	Description	Default Tuning Constant
'andrews'	$w = (\text{abs}(r) < \pi) .* \sin(r) ./ r$	1.339
'bisquare'	$w = (\text{abs}(r) < 1) .* (1 - r.^2).^2$ (also called biweight)	4.685
'cauchy'	$w = 1 ./ (1 + r.^2)$	2.385
'fair'	$w = 1 ./ (1 + \text{abs}(r))$	1.400
'huber'	$w = 1 ./ \max(1, \text{abs}(r))$	1.345
'logistic'	$w = \tanh(r) ./ r$	1.205
'ols'	Ordinary least squares (no weighting function)	None
'talwar'	$w = 1 * (\text{abs}(r) < 1)$	2.795
'welsch'	$w = \exp(-(r.^2))$	2.985

Weight Function	Description	Default Tuning Constant
function handle	Custom weight function that accepts a vector r of scaled residuals, and returns a vector of weights the same size as r	1

- The default tuning constants of built-in weight functions give coefficient estimates that are approximately 95% as statistically efficient as the ordinary least-squares estimates, provided the response has a normal distribution with no outliers. Decreasing the tuning constant increases the downweight assigned to large residuals; increasing the tuning constant decreases the downweight assigned to large residuals.
- The value r in the weight functions is

$$r = \text{resid} / (\text{tune} * s * \sqrt{1-h}),$$

where resid is the vector of residuals from the previous iteration, tune is the tuning constant, h is the vector of leverage values from a least-squares fit, and s is an estimate of the standard deviation of the error term given by

$$s = \text{MAD} / 0.6745.$$

MAD is the median absolute deviation of the residuals from their median. The constant 0.6745 makes the estimate unbiased for the normal distribution. If X has p columns, the software excludes the smallest p absolute deviations when computing the median.

For robust fitting, `LinearModel.fit` uses M-estimation to formulate estimating equations and solves them using the method of iterative reweighted least squares (IRLS).

Example: `'RobustOpts', 'andrews'`

VarNames — Names of variables

`{'x1', 'x2', ..., 'xn', 'y'}` (default) | string array | cell array of character vectors

Names of variables, specified as the comma-separated pair consisting of `'VarNames'` and a string array or cell array of character vectors including the names for the columns of X first, and the name for the response variable y last.

`'VarNames'` is not applicable to variables in a table or dataset array, because those variables already have names.

For example, if in your data, horsepower, acceleration, and model year of the cars are the predictor variables, and miles per gallon (MPG) is the response variable, then you can name the variables as follows.

```
Example: 'VarNames', {'Horsepower', 'Acceleration', 'Model_Year', 'MPG'}
```

```
Data Types: string | cell
```

Weights — Observation weights

```
ones(n,1) (default) | n-by-1 vector of nonnegative scalar values
```

Observation weights, specified as the comma-separated pair consisting of 'Weights' and an *n*-by-1 vector of nonnegative scalar values, where *n* is the number of observations.

```
Data Types: single | double
```

Output Arguments

mdl — Linear model

```
LinearModel object
```

Linear model representing a least-squares fit of the response to the data, returned as a `LinearModel` object.

If the value of the 'RobustOpts' name-value pair is not [] or 'ols', the model is not a least-squares fit, but uses the robust fitting function.

For properties and methods of the linear model object, see the `LinearModel` class page.

Examples

Fit Linear Regression Using Data in Matrix

Fit a linear regression model using a matrix input data set.

Load the `carsmall` data set, a matrix input data set.

```
load carsmall  
X = [Weight,Horsepower,Acceleration];
```

Fit a linear regression model by using `fitlm`.

```
mdl = fitlm(X,MPG)
```

```
mdl =  
Linear regression model:  
y ~ 1 + x1 + x2 + x3
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	47.977	3.8785	12.37	4.8957e-21
x1	-0.0065416	0.0011274	-5.8023	9.8742e-08
x2	-0.042943	0.024313	-1.7663	0.08078
x3	-0.011583	0.19333	-0.059913	0.95236

Number of observations: 93, Error degrees of freedom: 89

Root Mean Squared Error: 4.09

R-squared: 0.752, Adjusted R-Squared: 0.744

F-statistic vs. constant model: 90, p-value = 7.38e-27

The model display includes the model formula, estimated coefficients, and model summary statistics.

The model formula in the display, $y \sim 1 + x1 + x2 + x3$, corresponds to $y = \beta_0 + \beta_1 X_1 + \beta_2 X_2 + \beta_3 X_3 + \epsilon$.

The model display also shows the estimated coefficient information, which is stored in the `Coefficients` property. Display the `Coefficients` property.

```
mdl.Coefficients
```

```
ans=4x4 table
```

	Estimate	SE	tStat	pValue
(Intercept)	47.977	3.8785	12.37	4.8957e-21
x1	-0.0065416	0.0011274	-5.8023	9.8742e-08
x2	-0.042943	0.024313	-1.7663	0.08078
x3	-0.011583	0.19333	-0.059913	0.95236

The `Coefficient` property includes these columns:

- **Estimate** — Coefficient estimates for each corresponding term in the model. For example, the estimate for the constant term (`intercept`) is 47.977.
- **SE** — Standard error of the coefficients.
- **tStat** — t -statistic for each coefficient to test the null hypothesis that the corresponding coefficient is zero against the alternative that it is different from zero, given the other predictors in the model. Note that $tStat = Estimate/SE$. For example, the t -statistic for the intercept is $47.977/3.8785 = 12.37$.
- **pValue** — p -value for the t -statistic of the hypothesis test that the corresponding coefficient is equal to zero or not. For example, the p -value of the t -statistic for `x2` is greater than 0.05, so this term is not significant at the 5% significance level given the other terms in the model.

The summary statistics of the model are:

- **Number of observations** — Number of rows without any `NaN` values. For example, `Number of observations` is 93 because the `MPG` data vector has six `NaN` values and the `Horsepower` data vector has one `NaN` value for a different observation, where the number of rows in `X` and `MPG` is 100.
- **Error degrees of freedom** — $n - p$, where n is the number of observations, and p is the number of coefficients in the model, including the intercept. For example, the model has four predictors, so the `Error degrees of freedom` is $93 - 4 = 89$.
- **Root mean squared error** — Square root of the mean squared error, which estimates the standard deviation of the error distribution.
- **R-squared and Adjusted R-squared** — Coefficient of determination and adjusted coefficient of determination, respectively. For example, the `R-squared` value suggests that the model explains approximately 75% of the variability in the response variable `MPG`.
- **F-statistic vs. constant model** — Test statistic for the F -test on the regression model, which tests whether the model fits significantly better than a degenerate model consisting of only a constant term.
- **p-value** — p -value for the F -test on the model. For example, the model is significant with a p -value of $7.3816e-27$.

You can find these statistics in the model properties (`NumObservations`, `DFE`, `RMSE`, and `Rsquared`) and by using the `anova` function.

```
anova mdl, 'summary'
```

```
ans=3x5 table
```

SumSq	DF	MeanSq	F	pValue
-------	----	--------	---	--------

Total	6004.8	92	65.269		
Model	4516	3	1505.3	89.987	7.3816e-27
Residual	1488.8	89	16.728		

Linear Regression with Categorical Predictor

Fit a linear regression model that contains a categorical predictor. Reorder the categories of the categorical predictor to control the reference level in the model. Then, use `anova` to test the significance of the categorical variable.

Model with Categorical Predictor

Load the `carsmall` data set and create a linear regression model of MPG as a function of `Model_Year`. To treat the numeric vector `Model_Year` as a categorical variable, identify the predictor using the `'CategoricalVars'` name-value pair argument.

```
load carsmall
mdl = fitlm(Model_Year,MPG,'CategoricalVars',1,'VarNames',{'Model_Year','MPG'})
```

```
mdl =
Linear regression model:
    MPG ~ 1 + Model_Year
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	17.69	1.0328	17.127	3.2371e-30
Model_Year_76	3.8839	1.4059	2.7625	0.0069402
Model_Year_82	14.02	1.4369	9.7571	8.2164e-16

```
Number of observations: 94, Error degrees of freedom: 91
Root Mean Squared Error: 5.56
R-squared: 0.531, Adjusted R-Squared: 0.521
F-statistic vs. constant model: 51.6, p-value = 1.07e-15
```

The model formula in the display, `MPG ~ 1 + Model_Year`, corresponds to

$$\text{MPG} = \beta_0 + \beta_1 I_{\text{Year} = 76} + \beta_2 I_{\text{Year} = 82} + \epsilon,$$

where $I_{\text{Year} = 76}$ and $I_{\text{Year} = 82}$ are indicator variables whose value is one if the value of `Model_Year` is 76 and 82, respectively. The `Model_Year` variable includes three distinct values, which you can check by using the `unique` function.

```
unique(Model_Year)
```

```
ans = 3×1
```

```
70
76
82
```

`fitlm` chooses the smallest value in `Model_Year` as a reference level ('70') and creates two indicator variables $I_{\text{Year} = 76}$ and $I_{\text{Year} = 82}$. The model includes only two indicator variables because the design matrix becomes rank deficient if the model includes three indicator variables (one for each level) and an intercept term.

Model with Full Indicator Variables

You can interpret the model formula of `mdl` as a model that has three indicator variables without an intercept term:

$$y = \beta_0 I_{x_1 = 70} + (\beta_0 + \beta_1) I_{x_1 = 76} + (\beta_0 + \beta_2) I_{x_2 = 82} + \epsilon.$$

Alternatively, you can create a model that has three indicator variables without an intercept term by manually creating indicator variables and specifying the model formula.

```
temp_Year = dummyvar(categorical(Model_Year));
Model_Year_70 = temp_Year(:,1);
Model_Year_76 = temp_Year(:,2);
Model_Year_82 = temp_Year(:,3);
tbl = table(Model_Year_70,Model_Year_76,Model_Year_82,MPG);
mdl = fitlm(tbl,'MPG ~ Model_Year_70 + Model_Year_76 + Model_Year_82 - 1')
```

```
mdl =
```

```
Linear regression model:
```

```
MPG ~ Model_Year_70 + Model_Year_76 + Model_Year_82
```

```
Estimated Coefficients:
```

Estimate	SE	tStat	pValue
_____	_____	_____	_____

Model_Year_70	17.69	1.0328	17.127	3.2371e-30
Model_Year_76	21.574	0.95387	22.617	4.0156e-39
Model_Year_82	31.71	0.99896	31.743	5.2234e-51

Number of observations: 94, Error degrees of freedom: 91
 Root Mean Squared Error: 5.56

Choose Reference Level in Model

You can choose a reference level by modifying the order of categories in a categorical variable. First, create a categorical variable `Year`.

```
Year = categorical(Model_Year);
```

Check the order of categories by using the `categories` function.

```
categories(Year)

ans = 3x1 cell array
    {'70'}
    {'76'}
    {'82'}
```

If you use `Year` as a predictor variable, then `fitlm` chooses the first category '70' as a reference level. Reorder `Year` by using the `reordercats` function.

```
Year_reordered = reordercats(Year,{'76','70','82'});
categories(Year_reordered)
```

```
ans = 3x1 cell array
    {'76'}
    {'70'}
    {'82'}
```

The first category of `Year_reordered` is '76'. Create a linear regression model of MPG as a function of `Year_reordered`.

```
mdl2 = fitlm(Year_reordered,MPG,'VarNames',{'Model_Year','MPG'})

mdl2 =
Linear regression model:
```

```
MPG ~ 1 + Model_Year
```

```
Estimated Coefficients:
```

	Estimate	SE	tStat	pValue
(Intercept)	21.574	0.95387	22.617	4.0156e-39
Model_Year_70	-3.8839	1.4059	-2.7625	0.0069402
Model_Year_82	10.136	1.3812	7.3385	8.7634e-11

```
Number of observations: 94, Error degrees of freedom: 91
```

```
Root Mean Squared Error: 5.56
```

```
R-squared: 0.531, Adjusted R-Squared: 0.521
```

```
F-statistic vs. constant model: 51.6, p-value = 1.07e-15
```

`mdl2` uses '76' as a reference level and includes two indicator variables $I_{\text{Year} = 70}$ and $I_{\text{Year} = 82}$.

Evaluate Categorical Predictor

The model display of `mdl2` includes a p -value of each term to test whether or not the corresponding coefficient is equal to zero. Each p -value examines each indicator variable. To examine the categorical variable `Model_Year` as a group of indicator variables, use `anova`. Specify 'components' to return a component ANOVA table that includes ANOVA statistics for each variable in the model except the constant term.

```
anova(mdl2, 'components')
```

```
ans=2x5 table
```

	SumSq	DF	MeanSq	F	pValue
Model_Year	3190.1	2	1595.1	51.56	1.0694e-15
Error	2815.2	91	30.936		

The component ANOVA table includes the p -value of the `Model_Year` variable, which is smaller than the p -values of the indicator variables.

Specify Response and Predictor Variables for Linear Model

Fit a linear regression model to sample data. Specify the response and predictor variables, and include only pairwise interaction terms in the model.

Load sample data.

```
load hospital
```

Fit a linear model with interaction terms to the data. Specify weight as the response variable, and sex, age, and smoking status as the predictor variables. Also, specify that sex and smoking status are categorical variables.

```
mdl = fitlm(hospital, 'interactions', 'ResponseVar', 'Weight', ...
    'PredictorVars', {'Sex', 'Age', 'Smoker'}, ...
    'CategoricalVar', {'Sex', 'Smoker'})
```

```
mdl =
Linear regression model:
    Weight ~ 1 + Sex*Age + Sex*Smoker + Age*Smoker
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	118.7	7.0718	16.785	6.821e-30
Sex_Male	68.336	9.7153	7.0339	3.3386e-10
Age	0.31068	0.18531	1.6765	0.096991
Smoker_1	3.0425	10.446	0.29127	0.77149
Sex_Male:Age	-0.49094	0.24764	-1.9825	0.050377
Sex_Male:Smoker_1	0.9509	3.8031	0.25003	0.80312
Age:Smoker_1	-0.07288	0.26275	-0.27737	0.78211

```
Number of observations: 100, Error degrees of freedom: 93
Root Mean Squared Error: 8.75
R-squared: 0.898, Adjusted R-Squared: 0.892
F-statistic vs. constant model: 137, p-value = 6.91e-44
```

The weight of the patients do not seem to differ significantly according to age, or the status of smoking, or interaction of these factors with patient sex at the 5% significance level.

Fit Robust Linear Regression Model

Load the `hald` data set, which measures the effect of cement composition on its hardening heat.

```
load hald
```

This data set includes the variables `ingredients` and `heat`. The matrix `ingredients` contains the percent composition of four chemicals present in the cement. The vector `heat` contains the values for the heat hardening after 180 days for each cement sample.

Fit a robust linear regression model to the data.

```
mdl = fitlm(ingredients,heat,'RobustOpts','on')
```

```
mdl =  
Linear regression model (robust fit):  
y ~ 1 + x1 + x2 + x3 + x4
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	60.09	75.818	0.79256	0.4509
x1	1.5753	0.80585	1.9548	0.086346
x2	0.5322	0.78315	0.67957	0.51596
x3	0.13346	0.8166	0.16343	0.87424
x4	-0.12052	0.7672	-0.15709	0.87906

```
Number of observations: 13, Error degrees of freedom: 8  
Root Mean Squared Error: 2.65  
R-squared: 0.979, Adjusted R-Squared: 0.969  
F-statistic vs. constant model: 94.6, p-value = 9.03e-07
```

For more details, see the topic “Robust Regression — Reduce Outlier Effects” on page 11-132, which compares the results of a robust fit to a standard least-squares fit.

Definitions

Terms Matrix

A terms matrix T is a t -by- $(p + 1)$ matrix specifying terms in a model, where t is the number of terms, p is the number of predictor variables, and $+1$ accounts for the response variable. The value of $T(i, j)$ is the exponent of variable j in term i .

For example, suppose that an input includes three predictor variables A , B , and C and the response variable Y in the order A , B , C , and Y . Each row of T represents one term:

- $[0 \ 0 \ 0 \ 0]$ — Constant term or intercept
- $[0 \ 1 \ 0 \ 0]$ — B ; equivalently, $A^0 * B^1 * C^0$
- $[1 \ 0 \ 1 \ 0]$ — $A * C$
- $[2 \ 0 \ 0 \ 0]$ — A^2
- $[0 \ 1 \ 2 \ 0]$ — $B * (C^2)$

The 0 at the end of each term represents the response variable. In general, a column vector of zeros in a terms matrix represents the position of the response variable. If you have the predictor and response variables in a matrix and column vector, then you must include 0 for the response variable in the last column of each row.

Formula

A formula for model specification is a character vector or string scalar of the form ' $Y \sim terms$ '.

- Y is the response name.
- $terms$ represents the predictor terms in a model using Wilkinson notation.

For example:

- ' $Y \sim A + B + C$ ' specifies a three-variable linear model with intercept.
- ' $Y \sim A + B + C - 1$ ' specifies a three-variable linear model without intercept. Note that formulas include a constant (intercept) term by default. To exclude a constant term from the model, you must include -1 in the formula.

Wilkinson Notation

Wilkinson notation describes the terms present in a model. The notation relates to the terms present in a model, not to the multipliers (coefficients) of those terms.

Wilkinson notation uses these symbols:

- $+$ means include the next variable.
- $-$ means do not include the next variable.
- $:$ defines an interaction, which is a product of terms.
- $*$ defines an interaction and all lower-order terms.
- $^$ raises the predictor to a power, exactly as in $*$ repeated, so $^$ includes lower-order terms as well.
- $()$ groups terms.

This table shows typical examples of Wilkinson notation.

Wilkinson Notation	Term in Standard Notation
1	Constant (intercept) term
A^k , where k is a positive integer	A, A^2, \dots, A^k
$A + B$	A, B
$A*B$	$A, B, A*B$
$A:B$	$A*B$ only
$-B$	Do not include B
$A*B + C$	$A, B, C, A*B$
$A + B + C + A:B$	$A, B, C, A*B$
$A*B*C - A:B:C$	$A, B, C, A*B, A*C, B*C$
$A*(B + C)$	$A, B, C, A*B, A*C$

Statistics and Machine Learning Toolbox notation always includes a constant term unless you explicitly remove the term using -1 .

For more details, see “Wilkinson Notation” on page 11-117.

Tips

- Use robust fitting (`RobustOpts` name-value pair) to reduce the effect of outliers automatically.
- Do not use robust fitting when you want to subsequently adjust a model using `step`.
- For other methods or properties of the `LinearModel` object, see `LinearModel`.

Algorithms

The main fitting algorithm is QR decomposition. For robust fitting, the algorithm is `robustfit`.

Alternatives

You can also construct a linear model using `fitlm`.

You can construct a model in a range of possible models using `stepwiselm`. However, you cannot use robust regression and stepwise regression together.

LinearMixedModel.fit

Class: LinearMixedModel

(Not Recommended) Fit linear mixed-effects model using tables

Note `LinearMixedModel.fit` is not recommended. Use `fitlme` instead.

Syntax

```
lme = LinearMixedModel.fit(tbl, formula)
```

```
lme = LinearMixedModel.fit(tbl, formula, Name, Value)
```

Description

`lme = LinearMixedModel.fit(tbl, formula)` returns a linear mixed-effects model, specified by `formula`, fitted to the variables in the table or dataset array `tbl`.

`lme = LinearMixedModel.fit(tbl, formula, Name, Value)` returns a linear mixed-effects model with additional options specified by one or more `Name, Value` pair arguments.

For example, you can specify the covariance pattern of the random-effects terms, the method to use in estimating the parameters, or options for the optimization algorithm.

Input Arguments

tbl — Input data

table | dataset array

Input data, which includes the response variable, predictor variables, and grouping variables, specified as a table or dataset array. The predictor variables can be continuous or grouping variables (see “Grouping Variables” on page 2-57). You must specify the model for the variables using `formula`.

Data Types: table

formula — Formula for model specification

character vector or string scalar of the form `'y ~ fixed + (random1|grouping1) + ... + (randomR|groupingR)'`

Formula for model specification, specified as a character vector or string scalar of the form `'y ~ fixed + (random1|grouping1) + ... + (randomR|groupingR)'`. For full description, see “Formula” on page 32-1744.

Example: `'y ~ treatment +(1|block)'`

Data Types: char | string

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

CovariancePattern — Pattern of covariance matrix

`'FullCholesky'` (default) | character vector | string scalar | square symmetric logical matrix | string array | cell array of character vectors or logical matrices

Pattern of the covariance matrix of the random effects, specified as the comma-separated pair consisting of `'CovariancePattern'` and a character vector, a string scalar, a square symmetric logical matrix, a string array, or a cell array of character vectors or logical matrices.

If there are R random-effects terms, then the value of `'CovariancePattern'` must be a string array or cell array of length R , where each element r of the array specifies the pattern of the covariance matrix of the random-effects vector associated with the r th random-effects term. The options for each element follow.

`'FullCholesky'`

Default. Full covariance matrix using the Cholesky parameterization. `fitlme` estimates all elements of the covariance matrix.

'Full'

Full covariance matrix, using the log-Cholesky parameterization. `fitlme` estimates all elements of the covariance matrix.

'Diagonal'

Diagonal covariance matrix. That is, off-diagonal elements of the covariance matrix are constrained to be 0.

$$\begin{pmatrix} \sigma_{b1}^2 & 0 & 0 \\ 0 & \sigma_{b2}^2 & 0 \\ 0 & 0 & \sigma_{b3}^2 \end{pmatrix}$$

'Isotropic'

Diagonal covariance matrix with equal variances. That is, off-diagonal elements of the covariance matrix are constrained to be 0, and the diagonal elements are constrained to be equal. For example, if there are three random-effects terms with an isotropic covariance structure, this covariance matrix looks like

$$\begin{pmatrix} \sigma_b^2 & 0 & 0 \\ 0 & \sigma_b^2 & 0 \\ 0 & 0 & \sigma_b^2 \end{pmatrix}$$

where σ_b^2 is the common variance of the random-effects terms.

`'CompSymm'`

Compound symmetry structure. That is, common variance along diagonals and equal correlation between all random effects. For example, if there are three random-effects terms with a covariance matrix having a compound symmetry structure, this covariance matrix looks like

$$\begin{pmatrix} \sigma_{b_1}^2 & \sigma_{b_1,b_2} & \sigma_{b_1,b_2} \\ \sigma_{b_1,b_2} & \sigma_{b_1}^2 & \sigma_{b_1,b_2} \\ \sigma_{b_1,b_2} & \sigma_{b_1,b_2} & \sigma_{b_1}^2 \end{pmatrix}$$

where $\sigma_{b_1}^2$ is the common variance of the random-effects terms and σ_{b_1,b_2} is the common covariance between any two random-effects term .

`PAT`

Square symmetric logical matrix. If `'CovariancePattern'` is defined by the matrix `PAT`, and if `PAT(a,b) = false`, then the `(a,b)` element of the corresponding covariance matrix is constrained to be 0.

Example: `'CovariancePattern', 'Diagonal'`

Example: `'CovariancePattern', {'Full', 'Diagonal'}`

Data Types: `char | string | logical | cell`

FitMethod — Method for estimating parameters

`'ML'` (default) | `'REML'`

Method for estimating parameters of the linear mixed-effects model, specified as the comma-separated pair consisting of `'FitMethod'` and either of the following.

`'ML'`

Default. Maximum likelihood estimation

`'REML'`

Restricted maximum likelihood estimation

Example: `'FitMethod', 'REML'`

Weights — Observation weights

vector of scalar values

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a vector of length n , where n is the number of observations.

Data Types: single | double

Exclude — Indices for rows to exclude

use all rows without NaNs (default) | vector of integer or logical values

Indices for rows to exclude from the linear mixed-effects model in the data, specified as the comma-separated pair consisting of 'Exclude' and a vector of integer or logical values.

For example, you can exclude the 13th and 67th rows from the fit as follows.

Example: 'Exclude', [13,67]

Data Types: single | double | logical

DummyVarCoding — Coding to use for dummy variables

'reference' (default) | 'effects' | 'full'

Coding to use for dummy variables created from the categorical variables, specified as the comma-separated pair consisting of 'DummyVarCoding' and one of the following.

Value	Description
'reference'	Default. Coefficient for first category set to 0.
'effects'	Coefficients sum to 0.
'full'	One dummy variable for each category.

Example: 'DummyVarCoding', 'effects'

Optimizer — Optimization algorithm

'quasinevton' (default) | 'fminunc'

Optimization algorithm, specified as the comma-separated pair consisting of 'Optimizer' and either of the following.

'quasinevton'	Default. Uses a trust region based quasi-Newton optimizer. Change the options of the algorithm using <code>statset('LinearMixedModel')</code> . If you don't specify the options, then <code>LinearMixedModel</code> uses the default options of <code>statset('LinearMixedModel')</code> .
'fminunc'	You must have Optimization Toolbox to specify this option. Change the options of the algorithm using <code>optimoptions('fminunc')</code> . If you don't specify the options, then <code>LinearMixedModel</code> uses the default options of <code>optimoptions('fminunc')</code> with 'Algorithm' set to 'quasi-newton'.

Example: 'Optimizer', 'fminunc'

OptimizerOptions — Options for optimization algorithm

structure returned by `statset` | object returned by `optimoptions`

Options for the optimization algorithm, specified as the comma-separated pair consisting of 'OptimizerOptions' and a structure returned by `statset('LinearMixedModel')` or an object returned by `optimoptions('fminunc')`.

- If 'Optimizer' is 'fminunc', then use `optimoptions('fminunc')` to change the options of the optimization algorithm. See `optimoptions` for the options 'fminunc' uses. If 'Optimizer' is 'fminunc' and you do not supply 'OptimizerOptions', then the default for `LinearMixedModel` is the default options created by `optimoptions('fminunc')` with 'Algorithm' set to 'quasi-newton'.
- If 'Optimizer' is 'quasinevton', then use `statset('LinearMixedModel')` to change the optimization parameters. If you don't change the optimization parameters, then `LinearMixedModel` uses the default options created by `statset('LinearMixedModel')`:

The 'quasinevton' optimizer uses the following fields in the structure created by `statset('LinearMixedModel')`.

ToIFun — Relative tolerance on gradient of objective function

1e-6 (default) | positive scalar value

Relative tolerance on the gradient of the objective function, specified as a positive scalar value.

ToIX — Absolute tolerance on step size

1e-12 (default) | positive scalar value

Absolute tolerance on the step size, specified as a positive scalar value.

MaxIter — Maximum number of iterations allowed

10000 (default) | positive scalar value

Maximum number of iterations allowed, specified as a positive scalar value.

Display — Level of display

'off' (default) | 'iter' | 'final'

Level of display, specified as one of 'off', 'iter', or 'final'.

StartMethod — Method to start iterative optimization

'default' (default) | 'random'

Method to start iterative optimization, specified as the comma-separated pair consisting of 'StartMethod' and either of the following.

Value	Description
'default'	An internally defined default value
'random'	A random initial value

Example: 'StartMethod', 'random'

Verbose — Indicator to display optimization process on screen

false (default) | true

Indicator to display the optimization process on screen, specified as the comma-separated pair consisting of 'Verbose' and either false or true. Default is false.

The setting for 'Verbose' overrides the field 'Display' in 'OptimizerOptions'.

Example: 'Verbose', true

CheckHessian — Indicator to check positive definiteness of Hessian

false (default) | true

Indicator to check the positive definiteness of the Hessian of the objective function with respect to unconstrained parameters at convergence, specified as the comma-separated pair consisting of 'CheckHessian' and either false or true. Default is false.

Specify 'CheckHessian' as true to verify optimality of the solution or to determine if the model is overparameterized in the number of covariance parameters.

Example: 'CheckHessian',true

Output Arguments

lme — Linear mixed-effects model

LinearMixedModel object

Linear mixed-effects model, returned as a LinearMixedModel object.

Examples

Random-Intercept Model

Load the sample data.

```
load flu
```

The flu dataset array has a Date variable, and 10 variables containing estimated influenza rates (in 9 different regions, estimated from Google® searches, plus a nationwide estimate from the CDC).

To fit a linear-mixed effects model, your data must be in a properly formatted dataset array. To fit a linear mixed-effects model with the influenza rates as the responses, combine the nine columns corresponding to the regions into an array. The new dataset array, flu2, must have the response variable FluRate, the nominal variable Region that shows which region each estimate is from, the nationwide estimate WtdILI, and the grouping variable Date.

```
flu2 = stack(flu,2:10,'NewDataVarName','FluRate',...
            'IndVarName','Region');
flu2.Date = nominal(flu2.Date);
```

Fit a linear mixed-effects model with the nationwide a random intercept that varies by Date. The model corresponds to

$$y_{im} = \beta_0 + \beta_1 \text{WtdILI}_{im} + b_{0m} + \varepsilon_{im}, \quad i = 1, 2, \dots, 468, \quad m = 1, 2, \dots, 52,$$

where y_{im} is the observation i for level m of grouping variable Date, b_{0m} is the random effect for level m of the grouping variable Date, and ε_{im} is the observation error for observation i . The random effect has the prior distribution,

$$b_{0m} \sim N(0, \sigma_b^2),$$

and the error term has the distribution,

$$\varepsilon_{im} \sim N(0, \sigma^2).$$

```
lme = LinearMixedModel.fit(flu2,'FluRate ~ 1 + WtdILI + (1|Date)')
```

```
lme =
Linear mixed-effects model fit by ML
```

```
Model information:
```

Number of observations	468
Fixed effects coefficients	2
Random effects coefficients	52
Covariance parameters	2

```
Formula:
```

```
FluRate ~ 1 + WtdILI + (1 | Date)
```

```
Model fit statistics:
```

AIC	BIC	LogLikelihood	Deviance
286.24	302.83	-139.12	278.24

```
Fixed effects coefficients (95% CIs):
```

Name	Estimate	SE	tStat	DF	pValue
'(Intercept)'	0.16385	0.057525	2.8484	466	0.0045885
'WtdILI'	0.7236	0.032219	22.459	466	3.0502e-76

Lower	Upper
0.050813	0.27689
0.66028	0.78691

Random effects covariance parameters (95% CIs):

Group: Date (52 Levels)

Name1	Name2	Type	Estimate	Lower
'(Intercept)'	'(Intercept)'	'std'	0.17146	0.13227

Upper
0.22226

Group: Error

Name	Estimate	Lower	Upper
'Res Std'	0.30201	0.28217	0.32324

The confidence limits for the standard deviation of the random-effects term, σ_b , do not include 0 (0.13227, 0.22226), which indicates that the random-effects term is significant. You can also test the significance of the random-effects terms using the `compare` method.

The estimated value of an observation is the sum of the fixed effects and the random-effect value at the grouping variable level corresponding to that observation. For example, the estimated flu rate for observation 28 is

$$\begin{aligned}\hat{y}_{28} &= \hat{\beta}_0 \hat{\beta}_1 \text{WtdILI}_{28} + \hat{b}_{10/30/2005} \\ &= 0.1639 + 0.7236 * (1.343) + 0.3318 \\ &= 1.46749,\end{aligned}$$

where \hat{b} is the BLUP of the random effects for the intercept. You can compute this value in the following way.

```
beta = fixedEffects(lme);
[~,~,STATS] = randomEffects(lme); % Compute the random-effects statistics (STATS)
STATS.Level = nominal(STATS.Level);
y_hat = beta(1) + beta(2)*flu2.WtdILI(28) + STATS.Estimate(STATS.Level=='10/30/2005')

y_hat = 1.4674
```

You can display the fitted value using the `fitted` method.

```
F = fitted(lme);  
F(28)  
  
ans = 1.4674
```

Randomized-Block Design

Load the sample data.

```
load(fullfile(matlabroot, 'examples', 'stats', 'shift.mat'));
```

The dataset array shows the absolute deviations from the target quality characteristic measured from the products each of five operators manufacture over three different shifts, morning, evening, and night. This is a randomized block design, where the operators are the blocks. The experiment is designed to study the impact of the time of shift on the performance. The performance measure is the absolute deviations of the quality characteristics from the target value. This is simulated data.

Fit a linear mixed-effects model with a random intercept grouped by operator, to assess if there is significant difference in the performance according to the time of the shift. Use the restricted maximum likelihood method and 'effects' contrasts.

'effects' contrasts mean that the coefficients sum to 0, and `LinearMixedModel.fit` creates a matrix called a *fixed effects design matrix* to describe the effect of Shift. This matrix has two columns, `Shift_Evening` and `Shift_Morning`, where

$$\text{Shift_Evening} = \begin{cases} 0, & \text{if Morning} \\ 1, & \text{if Evening} \\ -1, & \text{if Night} \end{cases}$$
$$\text{Shift_Morning} = \begin{cases} 1, & \text{if Morning} \\ 0, & \text{if Evening} \\ -1, & \text{if Night} \end{cases}$$

The model corresponds to

$$\text{Morning Shift: } \text{QCDev}_{im} = \beta_0 + \beta_2 \text{Shift_Morning}_i + b_{0m} + \epsilon_{im},$$

$$\text{Evening Shift: } \text{QCDev}_{im} = \beta_0 + \beta_1 \text{Shift_Evening}_i + b_{0m} + \epsilon_{im},$$

$$\text{Night Shift: } \text{QCDev}_{im} = \beta_0 - \beta_1 \text{Shift_Evening}_i - \beta_2 \text{Shift_Morning}_i + b_{0m} + \epsilon_{im},$$

where i represents the observations, and m represents the operators, $i = 1, 2, \dots, 15$, and $m = 1, 2, \dots, 5$. The random effects and the observation error have the following distributions:

$$b_{0m} \sim N(0, \sigma_b^2)$$

and

$$\varepsilon_{im} \sim N(0, \sigma^2).$$

```
lme = LinearMixedModel.fit(shift, 'QCDev ~ Shift + (1|Operator)', ...
'FitMethod', 'REML', 'DummyVarCoding', 'effects')
```

```
lme =
Linear mixed-effects model fit by REML
```

Model information:

Number of observations	15

```

The estimated absolute deviation from the target quality characteristics for the third operator working in the evening shift is

$$\begin{aligned}\hat{Y}_{\text{Evening, Operator3}} &= \hat{\beta}_0 + \hat{\beta}_1 \text{Shift_Evening} + \hat{b}_{03} \\ &= 3.6525 - 0.53293 - 2.1715 \\ &= 0.94807.\end{aligned}$$

You can also display this value as follows.

```
F = fitted(lme);  
F(shift.Shift=='Evening' & shift.Operator=='3')  
ans = 0.9481
```

Similarly, you can calculate the estimated absolute deviation from the target quality characteristics for the third operator working in the morning shift is

$$\begin{aligned}\hat{Y}_{\text{Morning, Operator3}} &= \hat{\beta}_0 + \hat{\beta}_2 \text{Shift_Morning} + \hat{b}_{03} \\ &= 3.6525 - 0.91973 - 2.1715 \\ &= 0.56127.\end{aligned}$$

You can also display this value in the following way.

```
F(shift.Shift=='Morning' & shift.Operator=='3')
ans = 0.5613
```

The operator tends to make a smaller magnitude of error in the morning shift.

Split-Plot Experiment

Load the sample data.

```
load(fullfile(matlabroot, 'examples', 'stats', 'fertilizer.mat'));
```

The dataset array includes data from a split-plot experiment, where soil is divided into three blocks based on the soil type: sandy, silty, and loamy. Each block is divided into five plots, where five types of tomato plants, (cherry, heirloom, grape, vine, and plum) are randomly assigned to these plots. Then, the tomato plants in the plots are divided into subplots, where each subplot is treated by one of the four fertilizers. This is simulated data.

Store the data in a dataset array called `ds`, for practical purposes, and define `Tomato`, `Soil`, and `Fertilizer` as categorical variables.

```
ds = fertilizer;
ds.Tomato = nominal(ds.Tomato);
ds.Soil = nominal(ds.Soil);
ds.Fertilizer = nominal(ds.Fertilizer);
```

Fit a linear mixed-effects model, where `Fertilizer` and `Tomato` are the fixed-effects variables, and the mean yield varies by the block (soil type) and the plots within blocks (tomato types within soil types) independently.

This model corresponds to

$$y_{imjk} = \beta_0 + \sum_{m=2}^4 \beta_{1m} I[F]_{im} + \sum_{j=2}^5 \beta_{2j} I[T]_{ij} + \sum_{j=2}^5 \sum_{m=2}^4 \beta_{3mj} I[F]_{im} I[T]_{ij} + b_{0k} S_k + b_{0jk} (S^*T)_{jk} + \epsilon_{imjk},$$

where $i = 1, 2, \dots, 60$, the index m corresponds to the fertilizer types, j corresponds to the tomato types, and $k = 1, 2, 3$ corresponds to the blocks (soil). S_k represents the k th

soil type, and $(S*T)_{jk}$ represents the j th tomato type nested in the k th soil type. $I[F]_{im}$ is the dummy variable representing level m of the fertilizer. Similarly, $I[T]_{ij}$ is the dummy variable representing the level j of the tomato type.

The random effects and observation error have the following prior distributions:

$$b_{0k} \sim N(0, \sigma_S^2)$$

$$b_{0jk} \sim N(0, \sigma_{S*T}^2)$$

$$\epsilon_{imjk} \sim N(0, \sigma^2)$$

```
lme = LinearMixedModel.fit(ds, 'Yield ~ Fertilizer * Tomato + (1|Soil) + (1|Soil:Tomato)

The p -values corresponding to the last 12 rows in the fixed-effects coefficients display (0.82701 to 0.47881) indicate that interaction coefficients between the tomato and fertilizer types are not significant. To test for the overall interaction between tomato and fertilizer, use the `anova` method after refitting the model using `'effects'` contrasts.

The confidence interval for the standard deviations of the random-effects terms (σ_S^2), where the intercept is grouped by soil is very large. This term does not appear significant.

Refit the model after removing the interaction term `Tomato:Fertilizer` and the random-effects term `(1 | Soil)`.

You can compare the two models using the `compare` method with the simulated likelihood ratio test since both a fixed-effect and a random-effect term will be tested.

Longitudinal Study with a Covariate

Load the sample data.

```
load(fullfile(matlabroot, 'examples', 'stats', 'weight.mat'));
```

`weight` contains data from a longitudinal study, where 20 subjects are randomly assigned to 4 exercise programs (A, B, C, D), and their weight loss is recorded over six two-week time periods. This is simulated data.

Store the data in a table. Define `Subject` and `Program` as categorical variables.

```
tbl = table(InitialWeight, Program, Subject, Week, y);
tbl.Subject = nominal(tbl.Subject);
tbl.Program = nominal(tbl.Program);
```

Fit a linear mixed-effects model where the initial weight, type of program, week, and the interaction between the week and type of program are the fixed effects. The intercept and week vary by subject.

`LinearMixedModel.fit` uses Program A as a reference and creates the necessary dummy variables $I[\cdot]$. Since the model already has an intercept, `LinearMixedModel.fit` only creates dummy variables for program types B, C, D. This is also known as the 'reference' method of coding dummy variables.

This model corresponds to

$$y_{im} = \beta_0 + \beta_1 IW_i + \beta_2 \text{Week}_i + \beta_3 I[\text{PB}]_i + \beta_4 I[\text{PC}]_i + \beta_5 I[\text{PD}]_i \\ + \beta_6 (\text{Week}_i * I[\text{PB}]_i) + \beta_7 (\text{Week}_i * I[\text{PC}]_i) + \beta_8 (\text{Week}_i * I[\text{PD}]_i) \\ + b_{0m} + b_{1m} \text{Week}_{im} + \varepsilon_{im},$$

where $i = 1, 2, \dots, 120$, and $m = 1, 2, \dots, 20$. β_j are the fixed-effects coefficients, $j = 0, 1, \dots, 8$, and b_{0m} and b_{1m} are random effects. `IW` stands for initial weight and $I[\cdot]$ is a dummy variable representing a type of program. For example, $I[\text{PB}]_i$ is the dummy variable representing program type B. The random effects and observation error have the following prior distributions:

$$b_{0m} \sim N(0, \sigma_0^2)$$

$$b_{1m} \sim N(0, \sigma_1^2)$$

$$\varepsilon_{im} \sim N(0, \sigma^2).$$

```
lme = LinearMixedModel.fit(tbl, 'y ~ InitialWeight + Program*Week + (Week|Subject)')
lme =
Linear mixed-effects model fit by ML
```

'Res Std'	0.10261	0.087882	0.11981

The p -values 0.022863 and 0.011567 indicate significant effects of subject initial weights and time in the amount of weight lost. The weight loss of subjects who are in Program B is significantly different relative to the weight loss of subjects who are in Program A. The lower and upper limits of the covariance parameters for the random effects do not include 0, thus they are significant. You can also test the significance of the random effects using the `compare` method.

Definitions

Formula

In general, a formula for model specification is a character vector or string scalar of the form `'y ~ terms'`. For the linear mixed-effects models, this formula is in the form `'y ~ fixed + (random1|grouping1) + ... + (randomR|groupingR)'`, where `fixed` and `random` contain the fixed-effects and the random-effects terms.

Suppose a table `tbl` contains the following:

- A response variable, y
- Predictor variables, X_j , which can be continuous or grouping variables
- Grouping variables, g_1, g_2, \dots, g_R ,

where the grouping variables in X_j and g_r can be categorical, logical, character arrays, string arrays, or cell arrays of character vectors.

Then, in a formula of the form, `'y ~ fixed + (random1|g1) + ... + (randomR|gR)'`, the term `fixed` corresponds to a specification of the fixed-effects design matrix X ,

random_1 is a specification of the random-effects design matrix Z_1 corresponding to grouping variable g_1 , and similarly random_R is a specification of the random-effects design matrix Z_R corresponding to grouping variable g_R . You can express the fixed and random terms using Wilkinson notation.

Wilkinson notation describes the factors present in models. The notation relates to factors present in models, not to the multipliers (coefficients) of those factors.

Wilkinson Notation	Factors in Standard Notation
1	Constant (intercept) term
X^k , where k is a positive integer	X, X^2, \dots, X^k
$X1 + X2$	$X1, X2$
$X1 * X2$	$X1, X2, X1.*X2$ (elementwise multiplication of $X1$ and $X2$)
$X1 : X2$	$X1.*X2$ only
$- X2$	Do not include $X2$
$X1 * X2 + X3$	$X1, X2, X3, X1 * X2$
$X1 + X2 + X3 + X1 : X2$	$X1, X2, X3, X1 * X2$
$X1 * X2 * X3 - X1 : X2 : X3$	$X1, X2, X3, X1 * X2, X1 * X3, X2 * X3$
$X1 * (X2 + X3)$	$X1, X2, X3, X1 * X2, X1 * X3$

Statistics and Machine Learning Toolbox notation always includes a constant term unless you explicitly remove the term using -1 . Here are some examples for linear mixed-effects model specification.

Examples:

Formula	Description
'y ~ X1 + X2'	Fixed effects for the intercept, X1 and X2. This is equivalent to 'y ~ 1 + X1 + X2'.
'y ~ -1 + X1 + X2'	No intercept and fixed effects for X1 and X2. The implicit intercept term is suppressed by including -1 .

Formula	Description
'y ~ 1 + (1 g1)'	Fixed effects for the intercept plus random effect for the intercept for each level of the grouping variable g1.
'y ~ X1 + (1 g1)'	Random intercept model with a fixed slope.
'y ~ X1 + (X1 g1)'	Random intercept and slope, with possible correlation between them. This is equivalent to 'y ~ 1 + X1 + (1 + X1 g1)'.
'y ~ X1 + (1 g1) + (-1 + X1 g1)'	Independent random effects terms for intercept and slope.
'y ~ 1 + (1 g1) + (1 g2) + (1 g1:g2)'	Random intercept model with independent main effects for g1 and g2, plus an independent interaction effect.

Cholesky Parameterization

One of the assumptions of linear mixed-effects models is that the random effects have the following prior distribution.

$$b \sim N(0, \sigma^2 D(\theta)),$$

where D is a q -by- q symmetric and positive semidefinite matrix, parameterized by a variance component vector θ , q is the number of variables in the random-effects term, and σ^2 is the observation error variance. Since the covariance matrix of the random effects, D , is symmetric, it has $q(q+1)/2$ free parameters. Suppose L is the lower triangular Cholesky factor of $D(\theta)$ such that

$$D(\theta) = L(\theta)L(\theta)^T,$$

then the $q^*(q+1)/2$ -by-1 unconstrained parameter vector θ is formed from elements in the lower triangular part of L .

For example, if

$$L = \begin{bmatrix} L_{11} & 0 & 0 \\ L_{21} & L_{22} & 0 \\ L_{31} & L_{32} & L_{33} \end{bmatrix},$$

then

$$\theta = \begin{bmatrix} L_{11} \\ L_{21} \\ L_{31} \\ L_{22} \\ L_{32} \\ L_{33} \end{bmatrix}.$$

Log-Cholesky Parameterization

When the diagonal elements of L in Cholesky parameterization are constrained to be positive, then the solution for L is unique. Log-Cholesky parameterization is the same as Cholesky parameterization except that the logarithm of the diagonal elements of L are used to guarantee unique parameterization.

For example, for the 3-by-3 example in Cholesky parameterization, enforcing $L_{ii} \geq 0$,

$$\theta = \begin{bmatrix} \log(L_{11}) \\ L_{21} \\ L_{31} \\ \log(L_{22}) \\ L_{32} \\ \log(L_{33}) \end{bmatrix}.$$

Tips

- If your model is not easily described using a formula, you can create matrices to define the fixed and random effects, and fit the model using `fitlmematrix`.

Alternatives

You can also construct a linear mixed-effects model using `fitlme`. If your data is in matrix format, then use `fitlmematrix`.

NonLinearModel.fit

Class: NonLinearModel

(Not Recommended) Fit nonlinear regression model

Note NonLinearModel.fit is not recommended. Use fitnlm instead.

Syntax

```
mdl = NonLinearModel.fit(tbl,modelfun,beta0)
mdl = NonLinearModel.fit(X,y,modelfun,beta0)
mdl = NonLinearModel.fit(...,modelfun,beta0,Name,Value)
```

Description

`mdl = NonLinearModel.fit(tbl,modelfun,beta0)` fits the model specified by `modelfun` to variables in the table or dataset array `tbl`, and returns the nonlinear model `mdl`. `NonLinearModel.fit` estimates model coefficients using an iterative procedure starting from the initial values in `beta0`.

`mdl = NonLinearModel.fit(X,y,modelfun,beta0)` fits a nonlinear regression model using the column vector `y` as a response variable and the columns of the matrix `X` as predictor variables.

`mdl = NonLinearModel.fit(...,modelfun,beta0,Name,Value)` fits a nonlinear regression model with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

tbl — Input data

table | dataset array

Input data, specified as a table or dataset array. If you do not specify the predictor and response variables, the last variable is the response variable and the others are the predictor variables by default.

Predictor variables and response variable must be numeric.

To set a different column as the response variable, use the `ResponseVar` name-value pair argument. To use a subset of the columns as predictors, use the `PredictorVars` name-value pair argument.

Data Types: `single` | `double` | `logical`

X — Predictor variables

matrix

Predictor variables, specified as an n -by- p matrix, where n is the number of observations and p is the number of predictor variables. Each column of X represents one variable, and each row represents one observation.

Data Types: `single` | `double`

y — Response variable

vector

Response variable, specified as an n -by-1 vector, where n is the number of observations. Each entry in y is the response for the corresponding row of X .

Data Types: `single` | `double`

modelfun — Functional form of the model

function handle | character vector or string scalar of the form ' $y \sim f(b_1, b_2, \dots, b_j, x_1, x_2, \dots, x_k)$ '

Functional form of the model, specified as either of the following.

- Function handle `@modelfun` or `@(b,x)modelfun`, where
 - b is a coefficient vector with the same number of elements as `beta0`.
 - x is a matrix with the same number of columns as X or the number of predictor variable columns of `tbl`.

`modelfun(b,x)` returns a column vector that contains the same number of rows as x . Each row of the vector is the result of evaluating `modelfun` on the corresponding row

of x . In other words, *modelfun* is a vectorized function, one that operates on all data rows and returns all evaluations in one function call. *modelfun* should return real numbers to obtain meaningful coefficients.

- Character vector or string scalar of the form ' $y \sim f(b_1, b_2, \dots, b_j, x_1, x_2, \dots, x_k)$ ', where f represents a scalar function of the scalar coefficient variables b_1, \dots, b_j and the scalar data variables x_1, \dots, x_k .

Data Types: `function_handle` | `char` | `string`

beta0 — Coefficients

numeric vector

Coefficients for the nonlinear model, specified as a numeric vector. `NonLinearModel` starts its search for optimal coefficients from `beta0`.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

CoefficientNames — Names of the model coefficients

{'b1', 'b2', ..., 'bk'} (default) | character vector | string array | cell array of character vectors

Names of the model coefficients, specified as a character vector, string array, or cell array of character vectors.

Data Types: `char` | `string` | `cell`

ErrorModel — Form of the error variance model

'constant' (default) | 'proportional' | 'combined'

Form of the error variance model, specified as one of the following. Each model defines the error using a standard mean-zero and unit-variance variable e in combination with independent components: the function value f , and one or two parameters a and b

'constant' (default)	$y = f + ae$
----------------------	--------------

'proportional'	$y = f + bfe$
'combined'	$y = f + (a + b f)e$

The only allowed error model when using `Weights` is 'constant'.

Note `options.RobustWgtFun` must have value `[]` when using an error model other than 'constant'.

Example: `'ErrorModel', 'proportional'`

ErrorParameters — Initial estimates of the error model parameters

numeric array

Initial estimates of the error model parameters for the chosen `ErrorModel`, specified as a numeric array.

Error Model	Parameters	Default Values
'constant'	a	1
'proportional'	b	1
'combined'	a, b	[1, 1]

You can only use the 'constant' error model when using `Weights`.

Note `options.RobustWgtFun` must have value `[]` when using an error model other than 'constant'.

For example, if `'ErrorModel'` has the value 'combined', you can specify the starting value 1 for a and the starting value 2 for b as follows.

Example: `'ErrorParameters', [1, 2]`

Exclude — Observations to exclude

logical or numeric index vector

Observations to exclude from the fit, specified as the comma-separated pair consisting of 'Exclude' and a logical or numeric index vector indicating which observations to exclude from the fit.

For example, you can exclude observations 2 and 3 out of 6 using either of the following examples.

Example: `'Exclude',[2,3]`

Example: `'Exclude',logical([0 1 1 0 0 0])`

Data Types: `single` | `double` | `logical`

Options — Options for controlling the iterative fitting procedure

`[]` (default) | `structure`

Options for controlling the iterative fitting procedure, specified as a structure created by `statset`. The relevant fields are the nonempty fields in the structure returned by the call `statset('nlinfit')`.

Option	Meaning	Default
<code>DerivStep</code>	Relative difference used in finite difference derivative calculations. A positive scalar, or a vector of positive scalars the same size as the vector of parameters estimated by the Statistics and Machine Learning Toolbox function using the options structure.	<code>eps^(1/3)</code>
<code>Display</code>	Amount of information displayed by the fitting algorithm. <ul style="list-style-type: none"> <code>'off'</code> — Displays no information. <code>'final'</code> — Displays the final output. <code>'iter'</code> — Displays iterative output to the Command Window. 	<code>'off'</code>
<code>FunValCheck</code>	Character vector or string scalar indicating to check for invalid values, such as <code>NaN</code> or <code>Inf</code> , from the model function.	<code>'on'</code>
<code>MaxIter</code>	Maximum number of iterations allowed. Positive integer.	<code>200</code>

Option	Meaning	Default
RobustWgtFun	Weight function for robust fitting. Can also be a function handle that accepts a normalized residual as input and returns the robust weights as output. If you use a function handle, give a Tune constant. See “Robust Options” on page 32-2501	[]
Tune	Tuning constant used in robust fitting to normalize the residuals before applying the weight function. A positive scalar. Required if the weight function is specified as a function handle.	See “Robust Options” on page 32-2501 for the default, which depends on RobustWgtFun.
TolFun	Termination tolerance for the objective function value. Positive scalar.	1e-8
TolX	Termination tolerance for the parameters. Positive scalar.	1e-8

Data Types: struct

PredictorVars — Predictor variables

string array | cell array of character vectors | logical or numeric index vector

Predictor variables to use in the fit, specified as the comma-separated pair consisting of 'PredictorVars' and either a string array or cell array of character vectors of the variable names in the table or dataset array `tbl`, or a logical or numeric index vector indicating which columns are predictor variables.

The string values or character vectors should be among the names in `tbl`, or the names you specify using the 'VarNames' name-value pair argument.

The default is all variables in `X`, or all variables in `tbl` except for `ResponseVar`.

For example, you can specify the second and third variables as the predictor variables using either of the following examples.

Example: 'PredictorVars', [2,3]

Example: 'PredictorVars', logical([0 1 1 0 0 0])

Data Types: single | double | logical | string | cell

ResponseVar — Response variable

last column in `tbl` (default) | character vector or string scalar containing variable name | logical or numeric index vector

Response variable to use in the fit, specified as the comma-separated pair consisting of 'ResponseVar' and either a character vector or string scalar containing the variable name in the table or dataset array `tbl`, or a logical or numeric index vector indicating which column is the response variable. You typically need to use 'ResponseVar' when fitting a table or dataset array `tbl`.

For example, you can specify the fourth variable, say `yield`, as the response out of six variables, in one of the following ways.

Example: 'ResponseVar','yield'

Example: 'ResponseVar',[4]

Example: 'ResponseVar',logical([0 0 0 1 0 0])

Data Types: single | double | logical | char | string

VarNames — Names of variables

{'x1','x2',..., 'xn','y'} (default) | string array | cell array of character vectors

Names of variables, specified as the comma-separated pair consisting of 'VarNames' and a string array or cell array of character vectors including the names for the columns of `X` first, and the name for the response variable `y` last.

'VarNames' is not applicable to variables in a table or dataset array, because those variables already have names.

For example, if in your data, horsepower, acceleration, and model year of the cars are the predictor variables, and miles per gallon (MPG) is the response variable, then you can name the variables as follows.

Example: 'VarNames',{'Horsepower','Acceleration','Model_Year','MPG'}

Data Types: string | cell

Weights — Observation weights

`ones(n,1)` (default) | vector of nonnegative scalar values | function handle

Observation weights, specified as a vector of nonnegative scalar values or function handle.

- If you specify a vector, then it must have n elements, where n is the number of rows in `tbl` or `y`.
- If you specify a function handle, then the function must accept a vector of predicted response values as input, and return a vector of real positive weights as output.

Given weights, W , `NonLinearModel` estimates the error variance at observation i by $MSE \cdot (1/W(i))$, where MSE is the mean squared error.

Data Types: `single` | `double` | `function_handle`

Output Arguments

`mdl` — Nonlinear model

`NonLinearModel` object

Nonlinear model representing a least-squares fit of the response to the data, returned as a `NonLinearModel` object.

If the `Options` structure contains a nonempty `RobustWgtFun` field, the model is not a least-squares fit, but uses the `RobustWgtFun` robust fitting function.

For properties and methods of the nonlinear model object, `mdl`, see the `NonLinearModel` class page.

Examples

Nonlinear Model from a Table

Create a nonlinear model for auto mileage based on the `carbig` data.

Load the data and create a nonlinear model.

```
load carbig
tbl = table(Horsepower,Weight,MPG);
modelfun = @(b,x)b(1) + b(2)*x(:,1).^b(3) + ...
    b(4)*x(:,2).^b(5);
beta0 = [-50 500 -1 500 -1];
mdl = NonLinearModel.fit(tbl,modelfun,beta0)
```

```
mdl =
Nonlinear regression model:
  MPG ~ b1 + b2*Horsepower^b3 + b4*Weight^b5

Estimated Coefficients:
      Estimate      SE      tStat      pValue
-----
b1      -49.383    119.97    -0.41164    0.68083
b2       376.43    567.05     0.66384    0.50719
b3     -0.78193    0.47168    -1.6578    0.098177
b4       422.37    776.02     0.54428    0.58656
b5     -0.24127    0.48325    -0.49926    0.61788
```

```
Number of observations: 392, Error degrees of freedom: 387
Root Mean Squared Error: 3.96
R-Squared: 0.745, Adjusted R-Squared 0.743
F-statistic vs. constant model: 283, p-value = 1.79e-113
```

Nonlinear Model from Matrix Data

Create a nonlinear model for auto mileage based on the `carbig` data.

Load the data and create a nonlinear model.

```
load carbig
X = [Horsepower,Weight];
y = MPG;
modelfun = @(b,x)b(1) + b(2)*x(:,1).^b(3) + ...
  b(4)*x(:,2).^b(5);
beta0 = [-50 500 -1 500 -1];
mdl = NonLinearModel.fit(X,y,modelfun,beta0)

mdl =
Nonlinear regression model:
  y ~ b1 + b2*x1^b3 + b4*x2^b5
```

```
Estimated Coefficients:
      Estimate      SE      tStat      pValue
-----
```

b1	-49.383	119.97	-0.41164	0.68083
b2	376.43	567.05	0.66384	0.50719
b3	-0.78193	0.47168	-1.6578	0.098177
b4	422.37	776.02	0.54428	0.58656
b5	-0.24127	0.48325	-0.49926	0.61788

Number of observations: 392, Error degrees of freedom: 387
Root Mean Squared Error: 3.96
R-Squared: 0.745, Adjusted R-Squared 0.743
F-statistic vs. constant model: 283, p-value = 1.79e-113

Adjust Fitting Options in the Nonlinear Model

Create a nonlinear model for auto mileage based on the `carbig` data. Strive for more accuracy by lowering the `TolFun` option, and observe the iterations by setting the `Display` option.

Load the data and create a nonlinear model.

```
load carbig
X = [Horsepower,Weight];
y = MPG;
modelfun = @(b,x)b(1) + b(2)*x(:,1).^b(3) + ...
    b(4)*x(:,2).^b(5);
beta0 = [-50 500 -1 500 -1];
```

Create options to lower `TolFun` and to report iterative display, and create a model using the options.

```
opts = statset('Display','iter','TolFun',1e-10);
mdl = NonLinearModel.fit(X,y,modelfun,beta0,'Options',opts);
```

Specify Nonlinear Regression Using Model Character Vector

Specify a nonlinear regression model for estimation using a function handle or character vector.

Load sample data.

```
S = load('reaction');
X = S.reactants;
y = S.rate;
beta0 = S.beta;
```

Use a function handle to specify the Hougen-Watson model for the rate data.

```
mdl = NonLinearModel.fit(X,y,@hougen,beta0)
```

```
mdl =
Nonlinear regression model:
y ~ hougen(b,X)
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
b1	1.2526	0.86701	1.4447	0.18654
b2	0.062776	0.043561	1.4411	0.18753
b3	0.040048	0.030885	1.2967	0.23089
b4	0.11242	0.075157	1.4957	0.17309
b5	1.1914	0.83671	1.4239	0.1923

```
Number of observations: 13, Error degrees of freedom: 8
Root Mean Squared Error: 0.193
R-Squared: 0.999, Adjusted R-Squared 0.998
F-statistic vs. zero model: 3.91e+03, p-value = 2.54e-13
```

Alternatively, you can use a character vector to specify the Hougen-Watson model for the rate data.

```
myfun = 'y~(b1*x2-x3/b5)/(1+b2*x1+b3*x2+b4*x3)';
mdl2 = NonLinearModel.fit(X,y,myfun,beta0)
```

```
mdl2 =
Nonlinear regression model:
y ~ (b1*x2 - x3/b5)/(1 + b2*x1 + b3*x2 + b4*x3)
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
b1	1.2526	0.86701	1.4447	0.18654
b2	0.062776	0.043561	1.4411	0.18753

b3	0.040048	0.030885	1.2967	0.23089
b4	0.11242	0.075157	1.4957	0.17309
b5	1.1914	0.83671	1.4239	0.1923

Number of observations: 13, Error degrees of freedom: 8
 Root Mean Squared Error: 0.193
 R-Squared: 0.999, Adjusted R-Squared 0.998
 F-statistic vs. zero model: 3.91e+03, p-value = 2.54e-13

Estimate Nonlinear Regression Using Robust Fitting Options

Generate sample data from the nonlinear regression model

$$y = b_1 + b_2 \exp[-b_3 x] + \epsilon,$$

where b_1 , b_2 , and b_3 are coefficients, and the error term is normally distributed with mean 0 and standard deviation 0.5.

```
modelfun = @(b,x)(b(1)+b(2)*exp(-b(3)*x));
```

```
rng('default') % for reproducibility
b = [1;3;2];
x = exprnd(2,100,1);
y = modelfun(b,x) + normrnd(0,0.5,100,1);
```

Set robust fitting options.

```
opts = statset('nlinfit');
opts.RobustWgtFun = 'bisquare';
```

Fit the nonlinear model using the robust fitting options. Here, use a character vector to specify the model.

```
b0 = [2;2;2];
modelstr = 'y ~ b1 + b2*exp(-b3*x)';

mdl = NonLinearModel.fit(x,y,modelstr,b0,'Options',opts)

mdl =
Nonlinear regression model (robust fit):
y ~ b1 + b2*exp(- b3*x)
```

Estimated	Coefficients:			
	Estimate	SE	tStat	pValue
b1	1.0218	0.07202	14.188	2.1344e-25
b2	3.6619	0.25429	14.401	7.974e-26
b3	2.9732	0.38496	7.7232	1.0346e-11

Number of observations: 100, Error degrees of freedom: 97
Root Mean Squared Error: 0.501
R-Squared: 0.807, Adjusted R-Squared 0.803
F-statistic vs. constant model: 203, p-value = 2.34e-35

Fit Nonlinear Regression Model Using Weights Function Handle

Load sample data.

```
S = load('reaction');  
X = S.reactants;  
y = S.rate;  
beta0 = S.beta;
```

Specify a function handle for observation weights. The function accepts the model fitted values as input, and returns a vector of weights.

```
a = 1; b = 1;  
weights = @(yhat) 1./((a + b*abs(yhat)).^2);
```

Fit the Hougen-Watson model to the rate data using the specified observation weights function.

```
mdl = NonLinearModel.fit(X,y,@hougen,beta0,'Weights',weights)
```

```
mdl =  
Nonlinear regression model:  
y ~ hougen(b,X)
```

Algorithms

`NonLinearModel.fit` uses the same fitting algorithm as `nlinfit`.

Alternatives

You can also construct a nonlinear model using `fitnlm`.

RegressionTree.fit

Class: RegressionTree

(Not Recommended) Binary decision tree for regression

Note RegressionTree.fit is not recommended. Use fitrtree instead.

Syntax

```
tree = RegressionTree.fit(x,y)
tree = RegressionTree.fit(x,y,Name,Value)
```

Description

tree = RegressionTree.fit(x,y) returns a regression tree based on the input variables (also known as predictors, features, or attributes) x and output (response) y. tree is a binary tree where each branching node is split based on the values of a column of x.

tree = RegressionTree.fit(x,y,Name,Value) fits a tree with additional options specified by one or more Name,Value pair arguments. You can specify several name-value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Note that using the 'CrossVal', 'KFold', 'Holdout', 'Leaveout', or 'CVPartition' options results in a tree of class RegressionPartitionedModel. You cannot use a partitioned tree for prediction, so this kind of tree does not have a predict method.

Otherwise, tree is of class RegressionTree, and you can use the predict method to make predictions.

Input Arguments

x — Predictor values

matrix of scalar values

Predictor values, specified as a matrix of scalar values. Each column of `x` represents one variable, and each row represents one observation.

`RegressionTree.fit` considers NaN values in `x` as missing values.

`RegressionTree.fit` does not use observations with all missing values for `x` the fit.

`RegressionTree.fit` uses observations with some missing values for `x` to find splits on variables for which these observations have valid values.

Data Types: `single` | `double`

y — Response values

vector of scalar values

Response values, specified as a vector of scalar values with the same number of rows as `x`. Each entry in `y` is the response to the data in the corresponding row of `x`.

`RegressionTree.fit` considers NaN values in `y` to be missing values.

`RegressionTree.fit` does not use observations with missing values for `y` in the fit.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes.

You can specify several name and value pair arguments in any order as

`Name1, Value1, ..., NameN, ValueN`.

CategoricalPredictors — Categorical predictors list

numeric or logical vector | cell array of character vectors | character matrix | `'all'`

Categorical predictors list, specified as the comma-separated pair consisting of `'CategoricalPredictors'` and one of the following.

- A numeric vector with indices from 1 to `p`, where `p` is the number of columns of `x`.
- A logical vector of length `p`, where a `true` entry means that the corresponding column of `x` is a categorical variable.

- A cell array of character vectors, where each element in the array is the name of a predictor variable. The names must match entries in the `PredictorNames` property.
- A character matrix, where each row of the matrix is a name of a predictor variable. Pad the names with extra blanks so each row of the character matrix has the same length.
- `'all'`, meaning all predictors are categorical.

Example: `'CategoricalPredictors','all'`

Data Types: `single | double | logical | char | struct | cell`

CrossVal — Cross-validation flag

`'off'` (default) | `'on'`

Cross-validation flag, specified as the comma-separated pair consisting of `'CrossVal'` and either `'on'` or `'off'`.

If `'on'`, `RegressionTree.fit` grows a cross-validated decision tree with 10 folds. You can override this cross-validation setting using one of the `'KFold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'` name-value pair arguments. Note that you can only use one of these four options (`'KFold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'`) at a time when creating a cross-validated tree.

Alternatively, cross-validate `tree` later using the `crossval` method.

Example: `'CrossVal','on'`

CVPartition — Partition for cross-validation tree

`cvpartition` object

Partition for cross-validated tree, specified as the comma-separated pair consisting of `'CVPartition'` and an object of the `cvpartition` class created using `cvpartition`.

Note that if you use `'CVPartition'`, you cannot use any of the `'KFold'`, `'Holdout'`, or `'Leaveout'` name-value pair arguments.

Holdout — Fraction of data for holdout validation

scalar value in the range `[0,1]`

Fraction of data used for holdout validation, specified as the comma-separated pair consisting of `'Holdout'` and a scalar value in the range `[0,1]`. Holdout validation tests the specified fraction of the data, and uses the rest of the data for training.

Note that if you use 'Holdout', you cannot use any of the 'CVPartition', 'KFold', or 'Leaveout' name-value pair arguments.

Example: 'Holdout',0.1

Data Types: single | double

KFold — Number of folds

10 (default) | positive integer value

Number of folds to use in a cross-validated tree, specified as the comma-separated pair consisting of 'KFold' and a positive integer value.

Note that if you use 'KFold', you cannot use any of the 'CVPartition', 'Holdout', or 'Leaveout' name-value pair arguments.

Example: 'KFold',8

Data Types: single | double

Leaveout — Leave-one-out cross-validation flag

'off' (default) | 'on'

Leave-one-out cross-validation flag, specified as the comma-separated pair consisting of 'Leaveout' and either 'on' or 'off'. Use leave-one-out cross validation by setting to 'on'.

Note that if you use 'Leaveout', you cannot use any of the 'CVPartition', 'Holdout', or 'KFold' name-value pair arguments.

Example: 'Leaveout','on'

MergeLeaves — Leaf merge flag

'on' (default) | 'off'

Leaf merge flag, specified as the comma-separated pair consisting of 'MergeLeaves' and either 'on' or 'off'. When 'on', RegressionTree.fit merges leaves that originate from the same parent node, and that give a sum of risk values greater or equal to the risk associated with the parent node. When 'off', RegressionTree.fit does not merge leaves.

Example: 'MergeLeaves','off'

MinLeaf — Minimum number of leaf node observations

1 (default) | positive integer value

Minimum number of leaf node observations, specified as the comma-separated pair consisting of 'MinLeaf' and a positive integer value. Each leaf has at least MinLeaf observations per tree leaf. If you supply both MinParent and MinLeaf, RegressionTree.fit uses the setting that gives larger leaves: $\text{MinParent}=\max(\text{MinParent},2*\text{MinLeaf})$.

Example: 'MinLeaf',3

Data Types: single | double

MinParent — Minimum number of branch node observations

10 (default) | positive integer value

Minimum number of branch node observations, specified as the comma-separated pair consisting of 'MinParent' and a positive integer value. Each branch node in the tree has at least MinParent observations. If you supply both MinParent and MinLeaf, RegressionTree.fit uses the setting that gives larger leaves: $\text{MinParent}=\max(\text{MinParent},2*\text{MinLeaf})$.

Example: 'MinParent',8

Data Types: single | double

NVarToSample — Number of predictors for split

'all' (default) | positive integer value

Number of predictors to select at random for each split, specified as the comma-separated pair consisting of 'NVarToSample' and a positive integer value. You can also specify 'all' to use all available predictors.

Example: 'NVarToSample',3

Data Types: single | double

PredictorNames — Predictor variable names

{'x1','x2',...} (default) | cell array of character vectors

Predictor variable names, specified as the comma-separated pair consisting of 'PredictorNames' and a cell array of character vectors containing the names for the predictor variables, in the order in which they appear in x.

Example: 'PredictorNames',
{'SepalLength','SepalWidth','PetalLength','PetalWidth'}

Data Types: cell

Prune — Pruning flag`'on' (default) | 'off'`

Pruning flag, specified as the comma-separated pair consisting of 'Prune' and either 'on' or 'off'. When 'on', `RegressionTree.fit` computes the full tree and the optimal sequence of pruned subtrees. When 'off', `RegressionTree.fit` computes the full tree without pruning.

Example: `'Prune', 'off'`

PruneCriterion — Pruning criterion`'mse' (default)`

Pruning criterion, specified as the comma-separated pair consisting of 'PruneCriterion' and 'mse'.

Example: `'PruneCriterion', 'mse'`

QEToler — Quadratic error tolerance`1e-6 (default) | positive scalar value`

Quadratic error tolerance per node, specified as the comma-separated pair consisting of 'QEToler' and a positive scalar value. Splitting nodes stops when quadratic error per node drops below $QEToler * QED$, where QED is the quadratic error for the entire data computed before the decision tree is grown.

Example: `'QEToler', 1e4`

ResponseName — Response variable name`'Y' (default) | character vector`

Response variable name, specified as the comma-separated pair consisting of 'ResponseName' and a character vector containing the name of the response variable in y .

Example: `'ResponseName', 'Response'`

Data Types: char

ResponseTransform — Response transform function`'none' (default) | function handle`

Response transform function for transforming the raw response values, specified as the comma-separated pair consisting of 'ResponseTransform' and either a function handle

or 'none'. The function handle should accept a matrix of response values and return a matrix of the same size. The default character vector 'none' means $@(x)x$, or no transformation.

Add or change a `ResponseTransform` function using dot notation:

```
tree.ResponseTransform = @function
```

Example: 'ResponseTransform', 'none'

Data Types: `function_handle`

SplitCriterion — Split criterion

'MSE' (default)

Split criterion, specified as the comma-separated pair consisting of 'SplitCriterion' and 'MSE', meaning mean squared error.

Example: 'SplitCriterion', 'MSE'

Surrogate — Surrogate decision splits flag

'off' | 'on' | 'all' | positive integer value

Surrogate decision splits flag, specified as the comma-separated pair consisting of 'Surrogate' and 'on', 'off', 'all', or a positive integer value.

- When 'on', `RegressionTree.fit` finds at most 10 surrogate splits at each branch node.
- When set to a positive integer value, `RegressionTree.fit` finds at most the specified number of surrogate splits at each branch node.
- When set to 'all', `RegressionTree.fit` finds all surrogate splits at each branch node. The 'all' setting can use much time and memory.

Use surrogate splits to improve the accuracy of predictions for data with missing values. The setting also enables you to compute measures of predictive association between predictors.

Example: 'Surrogate', 'on'

Data Types: `single` | `double`

Weights — Observation weights

`ones(size(X,1),1)` (default) | vector of scalar values

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a vector of scalar values. The length of `Weights` is the number of rows in `x`.

Data Types: `single` | `double`

Output Arguments

tree — Regression tree

regression tree object

Regression tree, returned as a regression tree object. Note that using the 'Crossval', 'Kfold', 'Holdout', 'Leaveout', or 'CVPartition' options results in a tree of class `RegressionPartitionedModel`. You cannot use a partitioned tree for prediction, so this kind of tree does not have a `predict` method.

Otherwise, `tree` is of class `RegressionTree`, and you can use the `predict` method to make predictions.

Examples

Predict Values Using a Regression Tree

Load the sample data.

```
load carsmall
```

Construct a regression tree to predict the mileage of cars based on their weights and numbers of cylinders.

```
tree = RegressionTree.fit([Weight, Cylinders],MPG,...
    'MinParent',20,...
    'PredictorNames',{'W','C'})
```

```
tree =
  RegressionTree
    PredictorNames: {'W' 'C'}
    ResponseName: 'Y'
    CategoricalPredictors: []
    ResponseTransform: 'none'
    NumObservations: 94
```

Properties, Methods

Predict the mileage of a car that weighs 2200 lbs and has four cylinders.

```
predict(tree, [2200, 4])
```

```
ans = 29.6111
```

fitcdiscr

Fit discriminant analysis classifier

Syntax

```
Mdl = fitcdiscr(Tbl,ResponseVarName)
```

```
Mdl = fitcdiscr(Tbl,formula)
```

```
Mdl = fitcdiscr(Tbl,Y)
```

```
Mdl = fitcdiscr(X,Y)
```

```
Mdl = fitcdiscr( ____,Name,Value)
```

Description

`Mdl = fitcdiscr(Tbl,ResponseVarName)` returns a fitted discriminant analysis model based on the input variables (also known as predictors, features, or attributes) contained in the table `Tbl` and output (response or labels) contained in `ResponseVarName`.

`Mdl = fitcdiscr(Tbl,formula)` returns a fitted discriminant analysis model based on the input variables contained in the table `Tbl`. `formula` is an explanatory model of the response and a subset of predictor variables in `Tbl` used to fit `Mdl`.

`Mdl = fitcdiscr(Tbl,Y)` returns a fitted discriminant analysis model based on the input variables contained in the table `Tbl` and response `Y`.

`Mdl = fitcdiscr(X,Y)` returns a discriminant analysis classifier based on the input variables `X` and response `Y`.

`Mdl = fitcdiscr(____,Name,Value)` fits a classifier with additional options specified by one or more name-value pair arguments, using any of the previous syntaxes. For example, you can optimize hyperparameters to minimize the model's cross-validation loss, or specify the cost of misclassification, the prior probabilities for each class, or the observation weights.

Examples

Train Discriminant Analysis Model

Load Fisher's iris data set.

```
load fisheriris
```

Train a discriminant analysis model using the entire data set.

```
Mdl = fitcdiscr(meas,species)
```

```
Mdl =  
  ClassificationDiscriminant  
      ResponseName: 'Y'  
      CategoricalPredictors: []  
          ClassNames: {'setosa' 'versicolor' 'virginica'}  
      ScoreTransform: 'none'  
      NumObservations: 150  
      DiscrimType: 'linear'  
          Mu: [3x4 double]  
          Coeffs: [3x3 struct]
```

Properties, Methods

`Mdl` is a `ClassificationDiscriminant` model. To access its properties, use dot notation. For example, display the group means for each predictor.

```
Mdl.Mu
```

```
ans = 3×4
```

```
  5.0060    3.4280    1.4620    0.2460  
  5.9360    2.7700    4.2600    1.3260  
  6.5880    2.9740    5.5520    2.0260
```

To predict labels for new observations, pass `Mdl` and predictor data to `predict`.

Optimize Discriminant Analysis Model

This example shows how to optimize hyperparameters automatically using `fitcdiscr`. The example uses Fisher's iris data.

Load the data.

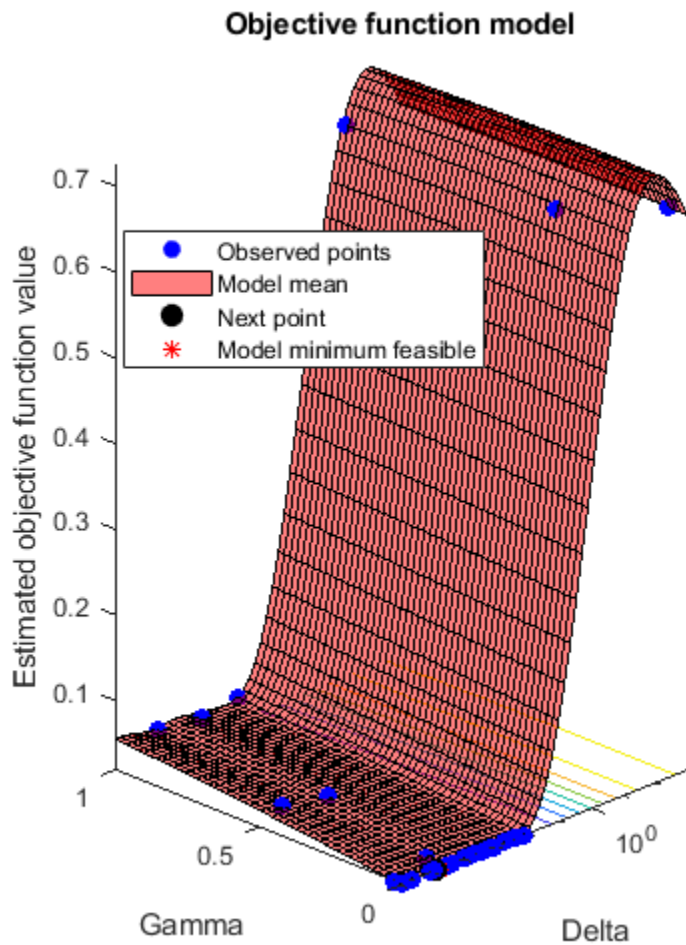

```
load fisheriris
```

Find hyperparameters that minimize five-fold cross-validation loss by using automatic hyperparameter optimization.

For reproducibility, set the random seed and use the 'expected-improvement-plus' acquisition function.

```
rng(1)
Mdl = fitcdiscr(meas,species,'OptimizeHyperparameters','auto',...
    'HyperparameterOptimizationOptions',...
    struct('AcquisitionFunctionName','expected-improvement-plus'))
```

The fit achieved about 2% loss for the default 5-fold cross validation.

Optimize Discriminant Analysis Model on Tall Array

This example shows how to optimize hyperparameters of a discriminant analysis model automatically using a tall array. The sample data set `airlinesmall.csv` is a large data set that contains a tabular file of airline flight data. This example creates a tall table containing the data and uses it to run the optimization procedure.

Create a datastore that references the folder location with the data. Select a subset of the variables to work with, and treat 'NA' values as missing data so that `datastore` replaces them with NaN values. Create a tall table that contains the data in the datastore.

```
ds = datastore('airlinesmall.csv');
ds.SelectedVariableNames = {'Month', 'DayofMonth', 'DayOfWeek', ...
                            'DepTime', 'ArrDelay', 'Distance', 'DepDelay'};
ds.TreatAsMissing = 'NA';
tt = tall(ds) % Tall table

tt =
```

M×7 tall table

Month	DayofMonth	DayOfWeek	DepTime	ArrDelay	Distance	DepDelay
10	21	3	642	8	308	12
10	26	1	1021	8	296	1
10	23	5	2055	21	480	20
10	23	5	1332	13	296	12
10	22	4	629	4	373	-1
10	28	3	1446	59	308	63
10	8	4	928	3	447	-2
10	10	6	859	11	954	-1
:	:	:	:	:	:	:
:	:	:	:	:	:	:

When you execute calculations on tall arrays, the default execution environment uses either the local MATLAB session or a local parallel pool (if you have Parallel Computing Toolbox™). You can use the `mapreducer` function to change the execution environment.

Determine the flights that are late by 10 minutes or more by defining a logical variable that is true for a late flight. This variable contains the class labels. A preview of this variable includes the first few rows.

```
Y = tt.DepDelay > 10 % Class labels
```

```
Y =
```

M×1 tall logical array

Remove rows in X and Y that contain missing data.

```
R = rmmissing([X Y]); % Data with missing entries removed
```

```
X = R(:,1:end-1);
```

```
Y = R(:,end);
```

Standardize the predictor variables.

```
Z = zscore(X);
```

Optimize hyperparameters automatically using the 'OptimizeHyperparameters' name-value pair argument. Find the optimal 'DiscrimType' value that minimizes holdout cross-validation loss. (Specifying 'auto' uses 'DiscrimType'.) For reproducibility, use the 'expected-improvement-plus' acquisition function and set the seeds of the random number generators using `rng` and `tallrng`. The results can vary depending on the number of workers and the execution environment for the tall arrays. For details, see “Control Where Your Code Runs” (MATLAB).

```
rng('default')
tallrng('default')
[Mdl,FitInfo,HyperparameterOptimizationResults] = fitcdiscr(Z,Y,...
    'OptimizeHyperparameters','auto',...
    'HyperparameterOptimizationOptions',struct('Holdout',0.3,...
    'AcquisitionFunctionName','expected-improvement-plus'))
```

Input Arguments

Tbl — Sample data

table

Sample data used to train the model, specified as a table. Each row of Tbl corresponds to one observation, and each column corresponds to one predictor variable. Optionally, Tbl can contain one additional column for the response variable. Multicolumn variables and cell arrays other than cell arrays of character vectors are not allowed.

If `Tbl` contains the response variable, and you want to use all remaining variables in `Tbl` as predictors, then specify the response variable by using `ResponseVarName`.

If `Tbl` contains the response variable, and you want to use only a subset of the remaining variables in `Tbl` as predictors, then specify a formula by using `formula`.

If `Tbl` does not contain the response variable, then specify a response variable by using `Y`. The length of the response variable and the number of rows in `Tbl` must be equal.

Data Types: `table`

ResponseVarName — Response variable name

name of variable in `Tbl`

Response variable name, specified as the name of a variable in `Tbl`.

You must specify `ResponseVarName` as a character vector or string scalar. For example, if the response variable `Y` is stored as `Tbl.Y`, then specify it as `'Y'`. Otherwise, the software treats all columns of `Tbl`, including `Y`, as predictors when training the model.

The response variable must be a categorical, character, or string array, logical or numeric vector, or cell array of character vectors. If `Y` is a character array, then each element of the response variable must correspond to one row of the array.

It is a good practice to specify the order of the classes by using the `ClassNames` name-value pair argument.

Data Types: `char` | `string`

formula — Explanatory model of response and subset of predictor variables

character vector | string scalar

Explanatory model of the response and a subset of the predictor variables, specified as a character vector or string scalar in the form `'Y~X1+X2+X3'`. In this form, `Y` represents the response variable, and `X1`, `X2`, and `X3` represent the predictor variables. The variables must be variable names in `Tbl` (`Tbl.Properties.VariableNames`).

To specify a subset of variables in `Tbl` as predictors for training the model, use a formula. If you specify a formula, then the software does not use any variables in `Tbl` that do not appear in `formula`.

Data Types: `char` | `string`

Y — Class labels

categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Class labels, specified as a categorical, character, or string array, a logical or numeric vector, or a cell array of character vectors. Each row of Y represents the classification of the corresponding row of X.

The software considers NaN, '' (empty character vector), "" (empty string), <missing>, and <undefined> values in Y to be missing values. Consequently, the software does not train using observations with a missing response.

Data Types: categorical | char | string | logical | single | double | cell

X — Predictor data

numeric matrix

Predictor values, specified as a numeric matrix. Each column of X represents one variable, and each row represents one observation.

fitcdiscr considers NaN values in X as missing values. fitcdiscr does not use observations with missing values for X in the fit.

Data Types: single | double

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Note You cannot use any cross-validation name-value pair argument along with the 'OptimizeHyperparameters' name-value pair argument. You can modify the cross-validation for 'OptimizeHyperparameters' only by using the 'HyperparameterOptimizationOptions' name-value pair argument.

Example: 'DiscrimType', 'quadratic', 'SaveMemory', 'on' specifies a quadratic discriminant classifier and does not store the covariance matrix in the output object.

Model Parameters

ClassNames — Names of classes to use for training

categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Names of classes to use for training, specified as the comma-separated pair consisting of 'ClassNames' and a categorical, character, or string array, a logical or numeric vector, or a cell array of character vectors. ClassNames must have the same data type as Y.

If ClassNames is a character array, then each element must correspond to one *row* of the array.

Use ClassNames to:

- Order the classes during training.
- Specify the order of any input or output argument dimension that corresponds to the class order. For example, use ClassNames to specify the order of the dimensions of Cost or the column order of classification scores returned by predict.
- Select a subset of classes for training. For example, suppose that the set of all distinct class names in Y is {'a', 'b', 'c'}. To train the model using observations from classes 'a' and 'c' only, specify 'ClassNames', {'a', 'c'}.

The default value for ClassNames is the set of all distinct class names in Y.

Example: 'ClassNames', {'b', 'g'}

Data Types: categorical | char | string | logical | single | double | cell

Cost — Cost of misclassification

square matrix | structure

Cost of misclassification of a point, specified as the comma-separated pair consisting of 'Cost' and one of the following:

- Square matrix, where Cost(i, j) is the cost of classifying a point into class j if its true class is i (i.e., the rows correspond to the true class and the columns correspond to the predicted class). To specify the class order for the corresponding rows and columns of Cost, additionally specify the ClassNames name-value pair argument.
- Structure S having two fields: S.ClassNames containing the group names as a variable of the same type as Y, and S.ClassificationCosts containing the cost matrix.

The default is $\text{Cost}(i, j) = 1$ if $i \neq j$, and $\text{Cost}(i, j) = 0$ if $i = j$.

Data Types: `single` | `double` | `struct`

FillCoeffs — Coeffs property flag

`'on'` | `'off'`

`Coeffs` property flag, specified as the comma-separated pair consisting of `'FillCoeffs'` and `'on'` or `'off'`. Setting the flag to `'on'` populates the `Coeffs` property in the classifier object. This can be computationally intensive, especially when cross-validating. The default is `'on'`, unless you specify a cross-validation name-value pair, in which case the flag is set to `'off'` by default.

Example: `'FillCoeffs', 'off'`

PredictorNames — Predictor variable names

string array of unique names | cell array of unique character vectors

Predictor variable names, specified as the comma-separated pair consisting of `'PredictorNames'` and a string array of unique names or cell array of unique character vectors. The functionality of `'PredictorNames'` depends on the way you supply the training data.

- If you supply `X` and `Y`, then you can use `'PredictorNames'` to give the predictor variables in `X` names.
 - The order of the names in `PredictorNames` must correspond to the column order of `X`. That is, `PredictorNames{1}` is the name of `X(:, 1)`, `PredictorNames{2}` is the name of `X(:, 2)`, and so on. Also, `size(X, 2)` and `numel(PredictorNames)` must be equal.
 - By default, `PredictorNames` is `{'x1', 'x2', ...}`.
- If you supply `Tbl`, then you can use `'PredictorNames'` to choose which predictor variables to use in training. That is, `fitcdiscr` uses only the predictor variables in `PredictorNames` and the response variable in training.
 - `PredictorNames` must be a subset of `Tbl.Properties.VariableNames` and cannot include the name of the response variable.
 - By default, `PredictorNames` contains the names of all predictor variables.
 - It is a good practice to specify the predictors for training using either `'PredictorNames'` or `formula` only.

Example: 'PredictorNames',
 {'SepalLength', 'SepalWidth', 'PetalLength', 'PetalWidth'}

Data Types: string | cell

Prior — Prior probabilities

'empirical' (default) | 'uniform' | vector of scalar values | structure

Prior probabilities for each class, specified as the comma-separated pair consisting of 'Prior' and a value in this table.

Value	Description
'empirical'	The class prior probabilities are the class relative frequencies in Y .
'uniform'	All class prior probabilities are equal to $1/K$, where K is the number of classes.
numeric vector	Each element is a class prior probability. Order the elements according to <code>Mdl.ClassNames</code> or specify the order using the <code>ClassNames</code> name-value pair argument. The software normalizes the elements such that they sum to 1.
structure	A structure S with two fields: <ul style="list-style-type: none"> • <code>S.ClassNames</code> contains the class names as a variable of the same type as Y. • <code>S.ClassProbs</code> contains a vector of corresponding prior probabilities. The software normalizes the elements such that they sum to 1.

If you set values for both `Weights` and `Prior`, the weights are renormalized to add up to the value of the prior probability in the respective class.

Example: 'Prior', 'uniform'

Data Types: char | string | single | double | struct

ResponseName — Response variable name

'Y' (default) | character vector | string scalar

Response variable name, specified as the comma-separated pair consisting of 'ResponseName' and a character vector or string scalar.

- If you supply Y, then you can use 'ResponseName' to specify a name for the response variable.
- If you supply ResponseVarName or formula, then you cannot use 'ResponseName'.

Example: 'ResponseName', 'response'

Data Types: char | string

SaveMemory — Flag to save covariance matrix

'off' (default) | 'on'

Flag to save covariance matrix, specified as the comma-separated pair consisting of 'SaveMemory' and either 'on' or 'off'. If you specify 'on', then fitcdiscr does not store the full covariance matrix, but instead stores enough information to compute the matrix. The predict method computes the full covariance matrix for prediction, and does not store the matrix. If you specify 'off', then fitcdiscr computes and stores the full covariance matrix in Mdl.

Specify SaveMemory as 'on' when the input matrix contains thousands of predictors.

Example: 'SaveMemory', 'on'

ScoreTransform — Score transformation

'none' (default) | 'doublelogit' | 'invlogit' | 'ismax' | 'logit' | function handle | ...

Score transformation, specified as the comma-separated pair consisting of 'ScoreTransform' and a character vector, string scalar, or function handle.

This table summarizes the available character vectors and string scalars.

Value	Description
'doublelogit'	$1/(1 + e^{-2x})$
'invlogit'	$\log(x / (1 - x))$
'ismax'	Sets the score for the class with the largest score to 1, and sets the scores for all other classes to 0
'logit'	$1/(1 + e^{-x})$

Value	Description
'none' or 'identity'	x (no transformation)
'sign'	-1 for $x < 0$ 0 for $x = 0$ 1 for $x > 0$
'symmetric'	$2x - 1$
'symmetricismax'	Sets the score for the class with the largest score to 1, and sets the scores for all other classes to -1
'symmetriclogit'	$2/(1 + e^{-x}) - 1$

For a MATLAB function or a function you define, use its function handle for `score transform`. The function handle must accept a matrix (the original scores) and return a matrix of the same size (the transformed scores).

Example: `'ScoreTransform', 'logit'`

Data Types: `char` | `string` | `function_handle`

Weights — Observation weights

numeric vector of positive values | name of variable in `Tbl`

Observation weights, specified as the comma-separated pair consisting of `'Weights'` and a numeric vector of positive values or name of a variable in `Tbl`. The software weighs the observations in each row of `X` or `Tbl` with the corresponding value in `Weights`. The size of `Weights` must equal the number of rows of `X` or `Tbl`.

If you specify the input data as a table `Tbl`, then `Weights` can be the name of a variable in `Tbl` that contains a numeric vector. In this case, you must specify `Weights` as a character vector or string scalar. For example, if the weights vector `W` is stored as `Tbl.W`, then specify it as `'W'`. Otherwise, the software treats all columns of `Tbl`, including `W`, as predictors or the response when training the model.

The software normalizes `Weights` to sum up to the value of the prior probability in the respective class.

By default, `Weights` is `ones(n, 1)`, where `n` is the number of observations in `X` or `Tbl`.

Data Types: `double` | `single` | `char` | `string`

Cross-Validation

CrossVal — Cross-validation flag

'off' (default) | 'on'

Cross-validation flag, specified as the comma-separated pair consisting of 'Crossval' and 'on' or 'off'.

If you specify 'on', then the software implements 10-fold cross-validation.

To override this cross-validation setting, use one of these name-value pair arguments: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`. To create a cross-validated model, you can use one cross-validation name-value pair argument at a time only.

Alternatively, cross-validate later by passing `Mdl` to `crossval`.

Example: 'CrossVal', 'on'

CVPartition — Cross-validation partition

[] (default) | `cvpartition` partition object

Cross-validation partition, specified as the comma-separated pair consisting of 'CVPartition' and a `cvpartition` partition object created by `cvpartition`. The partition object specifies the type of cross-validation and the indexing for the training and validation sets.

To create a cross-validated model, you can use one of these four name-value pair arguments only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: Suppose you create a random partition for 5-fold cross-validation on 500 observations by using `cvp = cvpartition(500, 'KFold', 5)`. Then, you can specify the cross-validated model by using 'CVPartition', `cvp`.

Holdout — Fraction of data for holdout validation

scalar value in the range (0,1)

Fraction of the data used for holdout validation, specified as the comma-separated pair consisting of 'Holdout' and a scalar value in the range (0,1). If you specify 'Holdout', `p`, then the software completes these steps:

- 1 Randomly select and reserve $p \times 100\%$ of the data as validation data, and train the model using the rest of the data.

- 2 Store the compact, trained model in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: `'Holdout',0.1`

Data Types: `double` | `single`

KFold — Number of folds

`10` (default) | positive integer value greater than 1

Number of folds to use in a cross-validated model, specified as the comma-separated pair consisting of `'KFold'` and a positive integer value greater than 1. If you specify `'KFold',k`, then the software completes these steps:

- 1 Randomly partition the data into k sets.
- 2 For each set, reserve the set as validation data, and train the model using the other $k - 1$ sets.
- 3 Store the k compact, trained models in the cells of a k -by-1 cell vector in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: `'KFold',5`

Data Types: `single` | `double`

Leaveout — Leave-one-out cross-validation flag

`'off'` (default) | `'on'`

Leave-one-out cross-validation flag, specified as the comma-separated pair consisting of `'Leaveout'` and `'on'` or `'off'`. If you specify `'Leaveout','on'`, then, for each of the n observations (where n is the number of observations excluding missing observations, specified in the `NumObservations` property of the model), the software completes these steps:

- 1 Reserve the observation as validation data, and train the model using the other $n - 1$ observations.
- 2 Store the n compact, trained models in the cells of an n -by-1 cell vector in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: `'Leaveout', 'on'`

Hyperparameter Optimization

Delta — Linear coefficient threshold

θ (default) | nonnegative scalar value

Linear coefficient threshold, specified as the comma-separated pair consisting of `'Delta'` and a nonnegative scalar value. If a coefficient of `Mdl` has magnitude smaller than `Delta`, `Mdl` sets this coefficient to θ , and you can eliminate the corresponding predictor from the model. Set `Delta` to a higher value to eliminate more predictors.

`Delta` must be θ for quadratic discriminant models.

Data Types: `single` | `double`

DiscrimType — Discriminant type

`'linear'` (default) | `'quadratic'` | `'diaglinear'` | `'diagquadratic'` | `'pseudolinear'` | `'pseudoquadratic'`

Discriminant type, specified as the comma-separated pair consisting of `'DiscrimType'` and a character vector or string scalar in this table.

Value	Description	Predictor Covariance Treatment
<code>'linear'</code>	Regularized linear discriminant analysis (LDA)	<ul style="list-style-type: none"> All classes have the same covariance matrix. $\widehat{\Sigma}_\gamma = (1 - \gamma)\widehat{\Sigma} + \gamma\text{diag}(\widehat{\Sigma})$. <p>$\widehat{\Sigma}$ is the empirical, pooled covariance matrix and γ is the amount of regularization.</p>
<code>'diaglinear'</code>	LDA	All classes have the same, diagonal covariance matrix.

Value	Description	Predictor Covariance Treatment
'pseudolinear'	LDA	All classes have the same covariance matrix. The software inverts the covariance matrix using the pseudo inverse.
'quadratic'	Quadratic discriminant analysis (QDA)	The covariance matrices can vary among classes.
'diagquadratic'	QDA	The covariance matrices are diagonal and can vary among classes.
'pseudoquadratic'	QDA	The covariance matrices can vary among classes. The software inverts the covariance matrix using the pseudo inverse.

Note To use regularization, you must specify 'linear'. To specify the amount of regularization, use the Gamma name-value pair argument.

Example: 'DiscrimType', 'quadratic'

Gamma — Amount of regularization

scalar value in the interval [0,1]

Amount of regularization to apply when estimating the covariance matrix of the predictors, specified as the comma-separated pair consisting of 'Gamma' and a scalar value in the interval [0,1]. Gamma provides finer control over the covariance matrix structure than DiscrimType.

- If you specify 0, then the software does not use regularization to adjust the covariance matrix. That is, the software estimates and uses the unrestricted, empirical covariance matrix.
- For linear discriminant analysis, if the empirical covariance matrix is singular, then the software automatically applies the minimal regularization required to invert the

covariance matrix. You can display the chosen regularization amount by entering `Mdl.Gamma` at the command line.

- For quadratic discriminant analysis, if at least one class has an empirical covariance matrix that is singular, then the software throws an error.
- If you specify a value in the interval (0,1), then you must implement linear discriminant analysis, otherwise the software throws an error. Consequently, the software sets `DiscrimType` to `'linear'`.
- If you specify 1, then the software uses maximum regularization for covariance matrix estimation. That is, the software restricts the covariance matrix to be diagonal. Alternatively, you can set `DiscrimType` to `'diagLinear'` or `'diagQuadratic'` for diagonal covariance matrices.

Example: `'Gamma',1`

Data Types: `single | double`

Hyperparameter Optimization

OptimizeHyperparameters — Parameters to optimize

`'none'` (default) | `'auto'` | `'all'` | string array or cell array of eligible parameter names | vector of `optimizableVariable` objects

Parameters to optimize, specified as the comma-separated pair consisting of `'OptimizeHyperparameters'` and one of the following:

- `'none'` — Do not optimize.
- `'auto'` — Use `{'Delta', 'Gamma'}`.
- `'all'` — Optimize all eligible parameters.
- String array or cell array of eligible parameter names.
- Vector of `optimizableVariable` objects, typically the output of hyperparameters.

The optimization attempts to minimize the cross-validation loss (error) for `fitcdiscr` by varying the parameters. For information about cross-validation loss (albeit in a different context), see “Classification Loss” on page 32-3352. To control the cross-validation type and other aspects of the optimization, use the `HyperparameterOptimizationOptions` name-value pair.

Note `'OptimizeHyperparameters'` values override any values you set using other name-value pair arguments. For example, setting `'OptimizeHyperparameters'` to `'auto'` causes the `'auto'` values to apply.

The eligible parameters for `fitcdiscr` are:

- **Delta** — `fitcdiscr` searches among positive values, by default log-scaled in the range `[1e-6,1e3]`.
- **DiscrimType** — `fitcdiscr` searches among `'linear'`, `'quadratic'`, `'diagLinear'`, `'diagQuadratic'`, `'pseudoLinear'`, and `'pseudoQuadratic'`.
- **Gamma** — `fitcdiscr` searches among real values in the range `[0,1]`.

Set nondefault parameters by passing a vector of `optimizableVariable` objects that have nondefault values. For example,

```
load fisheriris
params = hyperparameters('fitcdiscr',meas,species);
params(1).Range = [1e-4,1e6];
```

Pass `params` as the value of `OptimizeHyperparameters`.

By default, iterative display appears at the command line, and plots appear according to the number of hyperparameters in the optimization. For the optimization and plots, the objective function is $\log(1 + \text{cross-validation loss})$ for regression and the misclassification rate for classification. To control the iterative display, set the `Verbose` field of the `'HyperparameterOptimizationOptions'` name-value pair argument. To control the plots, set the `ShowPlots` field of the `'HyperparameterOptimizationOptions'` name-value pair argument.

For an example, see “Optimize Discriminant Analysis Model” on page 32-1778.

Example: `'auto'`

HyperparameterOptimizationOptions — Options for optimization structure

Options for optimization, specified as the comma-separated pair consisting of `'HyperparameterOptimizationOptions'` and a structure. This argument modifies the effect of the `OptimizeHyperparameters` name-value pair argument. All fields in the structure are optional.

Field Name	Values	Default
Optimizer	<ul style="list-style-type: none"> • 'bayesopt' — Use Bayesian optimization. Internally, this setting calls bayesopt. • 'gridsearch' — Use grid search with NumGridDivisions values per dimension. • 'randomsearch' — Search at random among MaxObjectiveEvaluations points. <p>'gridsearch' searches in a random order, using uniform sampling without replacement from the grid. After optimization, you can get a table in grid order by using the command <code>sortrows(Mdl.HyperparameterOptimizationResults)</code>.</p>	'bayesopt'
AcquisitionFunctionName	<ul style="list-style-type: none"> • 'expected-improvement-per-second-plus' • 'expected-improvement' • 'expected-improvement-plus' • 'expected-improvement-per-second' • 'lower-confidence-bound' • 'probability-of-improvement' <p>Acquisition functions whose names include <code>per-second</code> do not yield reproducible results because the optimization depends on the runtime of the objective function. Acquisition functions whose names include <code>plus</code> modify their behavior when they are overexploiting an area. For more details, see “Acquisition Function Types” on page 10-4.</p>	'expected-improvement-per-second-plus'

Field Name	Values	Default
MaxObjectiveEvaluations	Maximum number of objective function evaluations.	30 for 'bayesopt' or 'randomsearch', and the entire grid for 'gridsearch'
MaxTime	Time limit, specified as a positive real. The time limit is in seconds, as measured by tic and toc. Run time can exceed MaxTime because MaxTime does not interrupt function evaluations.	Inf
NumGridDivisions	For 'gridsearch', the number of values in each dimension. The value can be a vector of positive integers giving the number of values for each dimension, or a scalar that applies to all dimensions. This field is ignored for categorical variables.	10
ShowPlots	Logical value indicating whether to show plots. If true, this field plots the best objective function value against the iteration number. If there are one or two optimization parameters, and if Optimizer is 'bayesopt', then ShowPlots also plots a model of the objective function against the parameters.	true
SaveIntermediateResults	Logical value indicating whether to save results when Optimizer is 'bayesopt'. If true, this field overwrites a workspace variable named 'BayesoptResults' at each iteration. The variable is a BayesianOptimization object.	false

Field Name	Values	Default
Verbose	Display to the command line. <ul style="list-style-type: none"> • 0 — No iterative display • 1 — Iterative display • 2 — Iterative display with extra information For details, see the <code>bayesopt</code> <code>Verbose</code> name-value pair argument.	1
UseParallel	Logical value indicating whether to run Bayesian optimization in parallel, which requires Parallel Computing Toolbox. For details, see “Parallel Bayesian Optimization” on page 10-8.	false
Repartition	Logical value indicating whether to repartition the cross-validation at every iteration. If <code>false</code> , the optimizer uses a single partition for the optimization. <code>true</code> usually gives the most robust results because this setting takes partitioning noise into account. However, for good results, <code>true</code> requires at least twice as many function evaluations.	false
Use no more than one of the following three field names.		
CVPartition	A <code>cvpartition</code> object, as created by <code>cvpartition</code> .	'Kfold', 5 if you do not specify any cross-validation field
Holdout	A scalar in the range (0, 1) representing the holdout fraction.	
Kfold	An integer greater than 1.	

Example:

```
'HyperparameterOptimizationOptions', struct('MaxObjectiveEvaluations', 60)
```

Data Types: struct

Output Arguments

Mdl — Trained discriminant analysis classification model

ClassificationDiscriminant model object | ClassificationPartitionedModel
cross-validated model object

Trained discriminant analysis classification model, returned as a ClassificationDiscriminant model object or a ClassificationPartitionedModel cross-validated model object.

If you set any of the name-value pair arguments `KFold`, `Holdout`, `CrossVal`, or `CVPartition`, then `Mdl` is a ClassificationPartitionedModel cross-validated model object. Otherwise, `Mdl` is a ClassificationDiscriminant model object.

To reference properties of `Mdl`, use dot notation. For example, to display the estimated component means at the Command Window, enter `Mdl.Mu`.

Definitions

Discriminant Classification

The model for discriminant analysis is:

- Each class (Y) generates data (X) using a multivariate normal distribution. That is, the model assumes X has a Gaussian mixture distribution (`gmdistribution`).
 - For linear discriminant analysis, the model has the same covariance matrix for each class, only the means vary.
 - For quadratic discriminant analysis, both means and covariances of each class vary.

`predict` classifies so as to minimize the expected classification cost:

$$\hat{y} = \operatorname{argmin}_{y=1, \dots, K} \sum_{k=1}^K \hat{P}(k|x)C(y|k),$$

where

- \hat{y} is the predicted classification.

- K is the number of classes.
- $\widehat{P}(k|x)$ is the posterior probability on page 20-6 of class k for observation x .
- $C(y|k)$ is the cost on page 20-7 of classifying an observation as y when its true class is k .

For details, see “Prediction Using Discriminant Analysis Models” on page 20-6.

Tips

After training a model, you can generate C/C++ code that predicts labels for new data. Generating C/C++ code requires MATLAB Coder. For details, see “Introduction to Code Generation” on page 31-2.

Alternative Functionality

Functions

The `classify` function also performs discriminant analysis. `classify` is usually more awkward to use.

- `classify` requires you to fit the classifier every time you make a new prediction.
- `classify` does not perform cross-validation or hyperparameter optimization.
- `classify` requires you to fit the classifier when changing prior probabilities.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

Usage notes and limitations:

- Supported syntaxes are:

- `Mdl = fitcdiscr(Tbl,Y)`
- `Mdl = fitcdiscr(X,Y)`
- `Mdl = fitcdiscr(___,Name,Value)`
- `[Mdl,FitInfo,HyperparameterOptimizationResults] = fitcdiscr(___,Name,Value)` — `fitcdiscr` returns the additional output arguments `FitInfo` and `HyperparameterOptimizationResults` when you specify the `'OptimizeHyperparameters'` name-value pair argument.
- The `FitInfo` output argument is an empty structure array currently reserved for possible future use.
- The `HyperparameterOptimizationResults` output argument is a `BayesianOptimization` object or a table of hyperparameters with associated values that describe the cross-validation optimization of hyperparameters.

`'HyperparameterOptimizationResults'` is nonempty when the `'OptimizeHyperparameters'` name-value pair argument is nonempty at the time you create the model. The values in `'HyperparameterOptimizationResults'` depend on the value you specify for the `'HyperparameterOptimizationOptions'` name-value pair argument when you create the model.

- If you specify `'bayesopt'` (default), then `HyperparameterOptimizationResults` is an object of class `BayesianOptimization`.
- If you specify `'gridsearch'` or `'randomsearch'`, then `HyperparameterOptimizationResults` is a table of the hyperparameters used, observed objective function values (cross-validation loss), and rank of observations from lowest (best) to highest (worst).
- Supported name-value pair arguments, and any differences, are:
 - `'ClassNames'`
 - `'Cost'`
 - `'DiscrimType'`
 - `'HyperparameterOptimizationOptions'` — For cross-validation, tall optimization supports only `'Holdout'` validation. For example, you can specify `fitcdiscr(X,Y,'OptimizeHyperparameters','auto','HyperparameterOptimizationOptions',struct('Holdout',0.2))`.
 - `'OptimizeHyperparameters'` — The only eligible parameter to optimize is `'DiscrimType'`. Specifying `'auto'` uses `'DiscrimType'`.

- 'PredictorNames'
- 'Prior'
- 'ResponseName'
- 'ScoreTransform'
- 'Weights'
- For tall arrays and tall tables, `fitcdiscr` returns a `CompactClassificationDiscriminant` object, which contains most of the same properties as a `ClassificationDiscriminant` object. The main difference is that the compact object is sensitive to memory requirements. The compact object does not include properties that include the data, or that include an array of the same size as the data. The compact object does not contain these `ClassificationDiscriminant` properties:
 - `ModelParameters`
 - `NumObservations`
 - `HyperparameterOptimizationResults`
 - `RowsUsed`
 - `XCentered`
 - `W`
 - `X`
 - `Y`

Additionally, the compact object does not support these `ClassificationDiscriminant` methods:

- `compact`
- `crossval`
- `cvshrink`
- `resubEdge`
- `resubLoss`
- `resubMargin`
- `resubPredict`

For more information, see “Tall Arrays” (MATLAB).

Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the 'UseParallel' option to true.

To perform parallel hyperparameter optimization, use the 'HyperparameterOptions', struct('UseParallel', true) name-value pair argument in the call to this function.

For more information on parallel hyperparameter optimization, see “Parallel Bayesian Optimization” on page 10-8.

For more general information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

Topics

“Discriminant Analysis Classification” on page 20-2

Introduced in R2014a

fitcecoc

Fit multiclass models for support vector machines or other classifiers

Syntax

```
Mdl = fitcecoc(Tbl,ResponseVarName)
```

```
Mdl = fitcecoc(Tbl,formula)
```

```
Mdl = fitcecoc(Tbl,Y)
```

```
Mdl = fitcecoc(X,Y)
```

```
Mdl = fitcecoc( ____,Name,Value)
```

```
[Mdl,HyperparameterOptimizationResults] = fitcecoc( ____,Name,Value)
```

Description

`Mdl = fitcecoc(Tbl,ResponseVarName)` returns a full, trained, multiclass, error-correcting output codes (ECOC) model on page 32-1870 using the predictors in table `Tbl` and the class labels in `Tbl.ResponseVarName`. `fitcecoc` uses $K(K - 1)/2$ binary support vector machine (SVM) models using the one-versus-one coding design on page 32-1867, where K is the number of unique class labels (levels). `Mdl` is a `ClassificationECOC` model.

`Mdl = fitcecoc(Tbl,formula)` returns an ECOC model using the predictors in table `Tbl` and the class labels. `formula` is an explanatory model of the response and a subset of predictor variables in `Tbl` used for training.

`Mdl = fitcecoc(Tbl,Y)` returns an ECOC model using the predictors in table `Tbl` and the class labels in vector `Y`.

`Mdl = fitcecoc(X,Y)` returns a trained ECOC model using the predictors `X` and the class labels `Y`.

`Mdl = fitcecoc(____,Name,Value)` returns an ECOC model with additional options specified by one or more `Name,Value` pair arguments, using any of the previous syntaxes.

For example, specify different binary learners, a different coding design, or to cross-validate. It is good practice to cross-validate using the `Kfold Name, Value` pair argument. The cross-validation results determine how well the model generalizes.

`[Mdl,HyperparameterOptimizationResults] = fitcecoc(____, Name, Value)` also returns hyperparameter optimization details when you specify the `OptimizeHyperparameters` name-value pair argument and use linear or kernel binary learners. For other Learners, the `HyperparameterOptimizationResults` property of `Mdl` contains the results.

Examples

Train Multiclass Model Using SVM Learners

Train a multiclass error-correcting output codes (ECOC) model using support vector machine (SVM) binary learners.

Load Fisher's iris data set. Specify the predictor data `X` and the response data `Y`.

```
load fisheriris
X = meas;
Y = species;
```

Train a multiclass ECOC model using the default options.

```
Mdl = fitcecoc(X,Y)

Mdl =
  ClassificationECOC
      ResponseName: 'Y'
  CategoricalPredictors: []
          ClassNames: {'setosa' 'versicolor' 'virginica'}
      ScoreTransform: 'none'
    BinaryLearners: {3x1 cell}
          CodingName: 'onevsone'
```

Properties, Methods

`Mdl` is a `ClassificationECOC` model. By default, `fitcecoc` uses SVM binary learners and a one-versus-one coding design. You can access `Mdl` properties using dot notation.

Display the class names and the coding design matrix.

```
Mdl.ClassNames
```

```
ans = 3x1 cell array
    {'setosa'   }
    {'versicolor'}
    {'virginica' }
```

```
CodingMat = Mdl.CodingMatrix
```

```
CodingMat = 3x3
```

```
    1    1    0
   -1    0    1
    0   -1   -1
```

A one-versus-one coding design for three classes yields three binary learners. The columns of `CodingMat` correspond to the learners, and the rows correspond to the classes. The class order is the same as the order in `Mdl.ClassNames`. For example, `CodingMat(:,1)` is `[1; -1; 0]` and indicates that the software trains the first SVM binary learner using all observations classified as 'setosa' and 'versicolor'. Because 'setosa' corresponds to 1, it is the positive class; 'versicolor' corresponds to -1, so it is the negative class.

You can access each binary learner using cell indexing and dot notation.

```
Mdl.BinaryLearners{1} % The first binary learner
```

```
ans =
  classreg.learning.classif.CompactClassificationSVM
      ResponseName: 'Y'
  CategoricalPredictors: []
          ClassNames: [-1 1]
      ScoreTransform: 'none'
              Beta: [4x1 double]
              Bias: 1.4505
  KernelParameters: [1x1 struct]
```

Properties, Methods

Compute the resubstitution classification error.

```
error = resubLoss(Mdl)
error = 0.0067
```

The classification error on the training data is small, but the classifier might be an overfitted model. You can cross-validate the classifier using `crossval` and compute the cross-validation classification error instead.

Train Multiclass Linear Classification Model

Train an ECOC model composed of multiple binary, linear classification models.

Load the NLP data set.

```
load nlpdata
```

X is a sparse matrix of predictor data, and Y is a categorical vector of class labels. There are more than two classes in the data.

Create a default linear-classification-model template.

```
t = templateLinear();
```

To adjust the default values, see the “Name-Value Pair Arguments” on page 32-6735 on `templateLinear` page.

Train an ECOC model composed of multiple binary, linear classification models that can identify the product given the frequency distribution of words on a documentation web page. For faster training time, transpose the predictor data, and specify that observations correspond to columns.

```
X = X';
rng(1); % For reproducibility
Mdl = fitcecoc(X,Y,'Learners',t,'ObservationsIn','columns')

Mdl =
  classreg.learning.classif.CompactClassificationECOC
    ResponseName: 'Y'
    ClassNames: [1x13 categorical]
    ScoreTransform: 'none'
```

```
BinaryLearners: {78x1 cell}
CodingMatrix: [13x78 double]
```

Properties, Methods

Alternatively, you can train an ECOC model composed of default linear classification models using 'Learners', 'Linear'.

To conserve memory, `fitcecoc` returns trained ECOC models composed of linear classification learners in `CompactClassificationECOC` model objects.

Cross-Validate ECOC Classifier

Cross-validate an ECOC classifier with SVM binary learners, and estimate the generalized classification error.

Load Fisher's iris data set. Specify the predictor data X and the response data Y.

```
load fisheriris
X = meas;
Y = species;
rng(1); % For reproducibility
```

Create an SVM template, and standardize the predictors.

```
t = templateSVM('Standardize',true)
```

```
t =
Fit template for classification SVM.
```

```
Alpha: [0x1 double]
BoxConstraint: []
CacheSize: []
CachingMethod: ''
ClipAlphas: []
DeltaGradientTolerance: []
Epsilon: []
GapTolerance: []
KKTolerance: []
IterationLimit: []
```

```
KernelFunction: ''
KernelScale: []
KernelOffset: []
KernelPolynomialOrder: []
NumPrint: []
Nu: []
OutlierFraction: []
RemoveDuplicates: []
ShrinkagePeriod: []
Solver: ''
StandardizeData: 1
SaveSupportVectors: []
VerbosityLevel: []
Version: 2
Method: 'SVM'
Type: 'classification'
```

`t` is an SVM template. Most of the template object properties are empty. When training the ECOC classifier, the software sets the applicable properties to their default values.

Train the ECOC classifier, and specify the class order.

```
Mdl = fitcecoc(X,Y,'Learners',t,...
    'ClassNames',{'setosa','versicolor','virginica'});
```

`Mdl` is a `ClassificationECOC` classifier. You can access its properties using dot notation.

Cross-validate `Mdl` using 10-fold cross-validation.

```
CVMDL = crossval(Mdl);
```

`CVMDL` is a `ClassificationPartitionedECOC` cross-validated ECOC classifier.

Estimate the generalized classification error.

```
genError = kfoldLoss(CVMDL)
```

```
genError = 0.0400
```

The generalized classification error is 4%, which indicates that the ECOC classifier generalizes fairly well.

Estimate Posterior Probabilities Using ECOC Classifier

Train an ECOC classifier using SVM binary learners. First predict the training-sample labels and class posterior probabilities. Then predict the maximum class posterior probability at each point in a grid. Visualize the results.

Load Fisher's iris data set. Specify the petal dimensions as the predictors and the species names as the response.

```
load fisheriris
X = meas(:,3:4);
Y = species;
rng(1); % For reproducibility
```

Create an SVM template. Standardize the predictors, and specify the Gaussian kernel.

```
t = templateSVM('Standardize',true,'KernelFunction','gaussian');
```

`t` is an SVM template. Most of its properties are empty. When the software trains the ECOC classifier, it sets the applicable properties to their default values.

Train the ECOC classifier using the SVM template. Transform classification scores to class posterior probabilities (which are returned by `predict` or `resubPredict`) using the 'FitPosterior' name-value pair argument. Specify the class order using the 'ClassNames' name-value pair argument. Display diagnostic messages during training by using the 'Verbose' name-value pair argument.

```
Mdl = fitcecoc(X,Y,'Learners',t,'FitPosterior',true,...
    'ClassNames',{'setosa','versicolor','virginica'},...
    'Verbose',2);
```

```
Training binary learner 1 (SVM) out of 3 with 50 negative and 50 positive observations
Negative class indices: 2
Positive class indices: 1
```

```
Fitting posterior probabilities for learner 1 (SVM).
Training binary learner 2 (SVM) out of 3 with 50 negative and 50 positive observations
Negative class indices: 3
Positive class indices: 1
```

```
Fitting posterior probabilities for learner 2 (SVM).
Training binary learner 3 (SVM) out of 3 with 50 negative and 50 positive observations
```

```
Negative class indices: 3
Positive class indices: 2
```

```
Fitting posterior probabilities for learner 3 (SVM).
```

Mdl is a `ClassificationECOC` model. The same SVM template applies to each binary learner, but you can adjust options for each binary learner by passing in a cell vector of templates.

Predict the training-sample labels and class posterior probabilities. Display diagnostic messages during the computation of labels and class posterior probabilities by using the `'Verbose'` name-value pair argument.

```
[label,~,~,Posterior] = resubPredict(Mdl,'Verbose',1);
```

```
Predictions from all learners have been computed.
Loss for all observations has been computed.
Computing posterior probabilities...
```

```
Mdl.BinaryLoss
```

```
ans =
'quadratic'
```

The software assigns an observation to the class that yields the smallest average binary loss. Because all binary learners are computing posterior probabilities, the binary loss function is `quadratic`.

Display a random set of results.

```
idx = randsample(size(X,1),10,1);
Mdl.ClassNames
```

```
ans = 3x1 cell array
    {'setosa'   }
    {'versicolor'}
    {'virginica' }
```

```
table(Y(idx),label(idx),Posterior(idx,:),...
    'VariableNames',{'TrueLabel','PredLabel','Posterior'})
```

```
ans=10x3 table
    TrueLabel      PredLabel      Posterior
```

'virginica'	'virginica'	0.0039321	0.0039869	0.99208
'virginica'	'virginica'	0.017067	0.018263	0.96467
'virginica'	'virginica'	0.014948	0.015856	0.9692
'versicolor'	'versicolor'	2.2197e-14	0.87317	0.12683
'setosa'	'setosa'	0.999	0.00025091	0.00074639
'versicolor'	'virginica'	2.2195e-14	0.059429	0.94057
'versicolor'	'versicolor'	2.2194e-14	0.97001	0.029986
'setosa'	'setosa'	0.999	0.0002499	0.00074741
'versicolor'	'versicolor'	0.0085646	0.98259	0.008849
'setosa'	'setosa'	0.999	0.00025013	0.00074718

The columns of Posterior correspond to the class order of `Mdl.ClassNames`.

Define a grid of values in the observed predictor space. Predict the posterior probabilities for each instance in the grid.

```
xMax = max(X);
xMin = min(X);

x1Pts = linspace(xMin(1),xMax(1));
x2Pts = linspace(xMin(2),xMax(2));
[x1Grid,x2Grid] = meshgrid(x1Pts,x2Pts);

[~,~,~,PosteriorRegion] = predict(Mdl,[x1Grid(:),x2Grid(:)]);
```

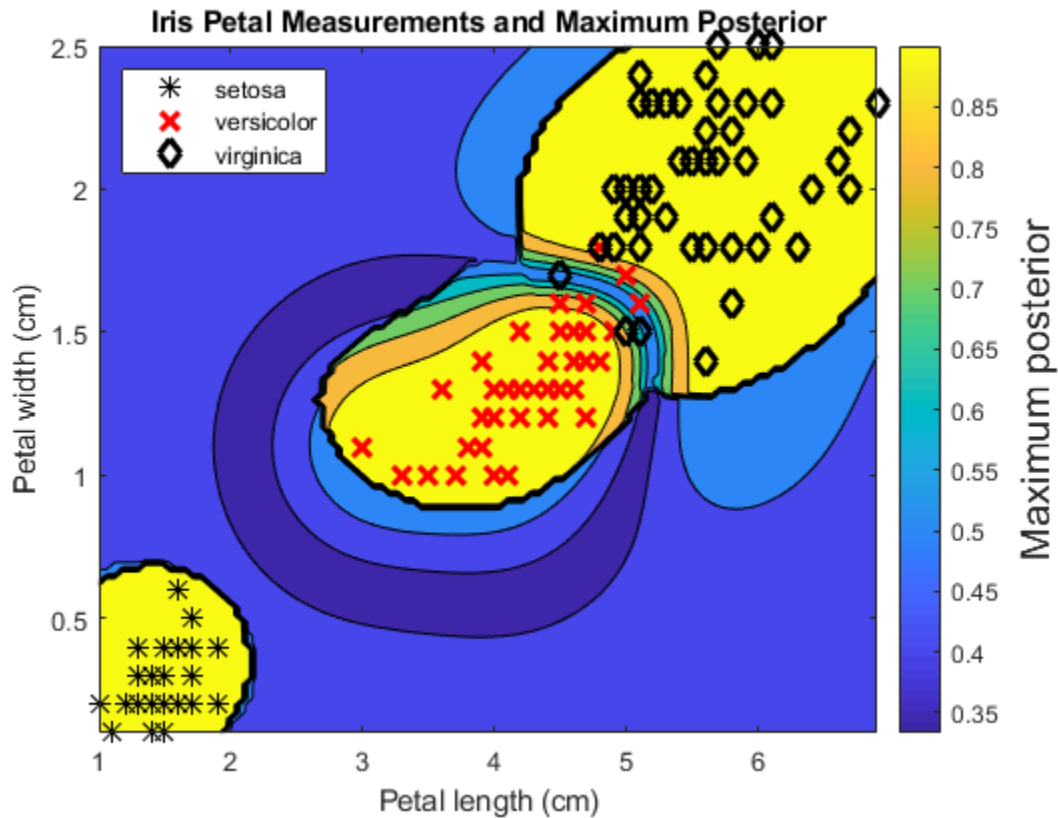

For each coordinate on the grid, plot the maximum class posterior probability among all classes.

```
contourf(x1Grid,x2Grid,...
         reshape(max(PosteriorRegion,[],2),size(x1Grid,1),size(x1Grid,2)));
h = colorbar;
h.YLabel.String = 'Maximum posterior';
h.YLabel.FontSize = 15;

hold on
gh = gscatter(X(:,1),X(:,2),Y,'krk','*xd',8);
gh(2).LineWidth = 2;
gh(3).LineWidth = 2;

title('Iris Petal Measurements and Maximum Posterior')
xlabel('Petal length (cm)')
ylabel('Petal width (cm)')
axis tight
```

```
legend(gh, 'Location', 'NorthWest')
hold off
```

Speed Up Training ECOC Classifiers Using Binning and Parallel Computing

Train a one-versus-all ECOC classifier using a GentleBoost ensemble of decision trees with surrogate splits. To speed up training, bin numeric predictors and use parallel computing. Binning is valid only when `fitcecoc` uses a tree learner. After training, estimate the classification error using 10-fold cross-validation. Note that parallel computing requires Parallel Computing Toolbox™.

Load Sample Data

Load and inspect the arrhythmia data set.

```
load arrhythmia
[n,p] = size(X)

n = 452

p = 279

isLabels = unique(Y);
nLabels = numel(isLabels)

nLabels = 13

tabulate(categorical(Y))
```

Value	Count	Percent
1	245	54.20%
2	44	9.73%
3	15	3.32%
4	15	3.32%
5	13	2.88%
6	25	5.53%
7	3	0.66%
8	2	0.44%
9	9	1.99%
10	50	11.06%
14	4	0.88%
15	5	1.11%
16	22	4.87%

The data set contains 279 predictors, and the sample size of 452 is relatively small. Of the 16 distinct labels, only 13 are represented in the response (Y). Each label describes various degrees of arrhythmia, and 54.20% of the observations are in class 1.

Train One-Versus-All ECOC Classifier

Create an ensemble template. You must specify at least three arguments: a method, a number of learners, and the type of learner. For this example, specify 'GentleBoost' for the method, 100 for the number of learners, and a decision tree template that uses surrogate splits because there are missing observations.

```
tTree = templateTree('surrogate','on');
tEnsemble = templateEnsemble('GentleBoost',100,tTree);
```

`tEnsemble` is a template object. Most of its properties are empty, but the software fills them with their default values during training.

Train a one-versus-all ECOC classifier using the ensembles of decision trees as binary learners. To speed up training, use binning and parallel computing.

- Binning (`'NumBins',50`) — When you have a large training data set, you can speed up training (a potential decrease in accuracy) by using the `'NumBins'` name-value pair argument. This argument is valid only when `fitcecoc` uses a tree learner. If you specify the `'NumBins'` value, then the software bins every numeric predictor into a specified number of equiprobable bins, and then grows trees on the bin indices instead of the original data. You can try `'NumBins',50` first, and then change the `'NumBins'` value depending on the accuracy and training speed.
- Parallel computing (`'Options',statset('UseParallel',true)`) — With a Parallel Computing Toolbox license, you can speed up the computation by using parallel computing, which sends each binary learner to a worker in the pool. The number of workers depends on your system configuration. When you use decision trees for binary learners, `fitcecoc` parallelizes training using Intel® Threading Building Blocks (TBB) for dual-core systems and above. Therefore, specifying the `'UseParallel'` option is not helpful on a single computer. Use this option on a cluster.

Additionally, specify that the prior probabilities are $1/K$, where $K = 13$ is the number of distinct classes.

```
options = statset('UseParallel',true);
Mdl = fitcecoc(X,Y,'Coding','onevsall','Learners',tEnsemble,...
    'Prior','uniform','NumBins',50,'Options',options);
```

```
Starting parallel pool (parpool) using the 'local' profile ...
Connected to the parallelpool (number of workers: 6).
```

`Mdl` is a `ClassificationECOC` model.

Cross-Validation

Cross-validate the ECOC classifier using 10-fold cross-validation.

```
CVMDL = crossval(Mdl,'Options',options);
```

```
Warning: One or more folds do not contain points from all the groups.
```

`CVMDL` is a `ClassificationPartitionedECOC` model. The warning indicates that some classes are not represented while the software trains at least one fold. Therefore, those

folds cannot predict labels for the missing classes. You can inspect the results of a fold using cell indexing and dot notation. For example, access the results of the first fold by entering `CVMDL.Trained{1}`.

Use the cross-validated ECOC classifier to predict validation-fold labels. You can compute the confusion matrix by using `confusionchart`. Move and resize the chart by changing the inner position property to ensure that the percentages appear in the row summary.

```
oofLabel = kfoldPredict(CVMDL, 'Options', options);
ConfMat = confusionchart(Y, oofLabel, 'RowSummary', 'total-normalized');
ConfMat.InnerPosition = [0.10 0.12 0.85 0.85];
```

1	212	13			1	2				8			9	46.9%	7.3%
2	19	20		1		1				1		1	1	4.4%	5.3%
3		1	14											3.1%	0.2%
4	3	1		10	1									2.2%	1.1%
5	7				3					2			1	0.7%	2.2%
6	1	1				22							1	4.9%	0.7%
7	2		1												0.7%
8	2														0.4%
9									9					2.0%	
10	15				2	1				27			5	6.0%	5.1%
14	3												1		0.9%
15	1	1	1	1	1										1.1%
16	14	2	1			2	1					1	1		4.9%
	1	2	3	4	5	6	7	8	9	10	14	15	16		

Predicted Class

Reproduce Binned Data

Reproduce binned predictor data by using the `BinEdges` property of the trained model and the `discretize` function.

```
X = Mdl.X; % Predictor data
Xbinned = zeros(size(X));
edges = Mdl.BinEdges;
% Find indices of binned predictors.
idxNumeric = find(~cellfun(@isempty,edges));
if iscolumn(idxNumeric)
    idxNumeric = idxNumeric';
end
for j = idxNumeric
    x = X(:,j);
    % Convert x to array if x is a table.
    if istable(x)
        x = table2array(x);
    end
    % Group x into bins by using the discretize function.
    xbinned = discretize(x,[-inf; edges{j}; inf]);
    Xbinned(:,j) = xbinned;
end
```

`Xbinned` contains the bin indices, ranging from 1 to the number of bins, for numeric predictors. `Xbinned` values are 0 for categorical predictors. If `X` contains NaNs, then the corresponding `Xbinned` values are NaNs.

Optimize ECOC Classifier

Optimize hyperparameters automatically using `fitcecoc`.

Load the `fisheriris` data set.

```
load fisheriris
X = meas;
Y = species;
```

Find hyperparameters that minimize five-fold cross-validation loss by using automatic hyperparameter optimization. For reproducibility, set the random seed and use the 'expected-improvement-plus' acquisition function.

```

rng default
Mdl = fitcecoc(X,Y,'OptimizeHyperparameters','auto',...
'HyperparameterOptimizationOptions',struct('AcquisitionFunctionName',...
'expected-improvement-plus'))

```

Train Multiclass ECOC Model with SVMs and Tall Arrays

Create two multiclass ECOC models trained on tall data. Use linear binary learners for one of the models and kernel binary learners for the other. Compare the resubstitution classification error of the two models.

In general, you can perform multiclass classification of tall data by using `fitcecoc` with linear or kernel binary learners. When you use `fitcecoc` to train a model on tall arrays, you cannot use SVM binary learners directly. However, you can use either linear or kernel binary classification models that use SVMs.

Create a datastore that references the folder containing Fisher's iris data set. Specify 'NA' values as missing data so that `datastore` replaces them with NaN values. Create tall versions of the predictor and response data.

```
ds = datastore('fisheriris.csv','TreatAsMissing','NA');  
t = tall(ds);
```

```
Starting parallel pool (parpool) using the 'local' profile ...  
Connected to the parallel pool (number of workers: 6).
```

```
X = [t.SepalLength t.SepalWidth t.PetalLength t.PetalWidth];  
Y = t.Species;
```

Standardize the predictor data.

```
Z = zscore(X);
```

Train a multiclass ECOC model that uses tall data and linear binary learners. By default, when you pass tall arrays to `fitcecoc`, the software trains linear binary learners that use SVMs. Because the response data contains only three unique classes, change the coding scheme from one-versus-all (which is the default when you use tall data) to one-versus-one (which is the default when you use in-memory data).

For reproducibility, set the seeds of the random number generators using `rng` and `tallrng`. The results can vary depending on the number of workers and the execution environment for the tall arrays. For details, see “Control Where Your Code Runs” (MATLAB).

```
rng('default')  
tallrng('default')  
mdlLinear = fitcecoc(Z,Y,'Coding','onevsone')
```

```
Training binary learner 1 (Linear) out of 3.  
Training binary learner 2 (Linear) out of 3.  
Training binary learner 3 (Linear) out of 3.
```

```
mdlLinear =  
  classreg.learning.classif.CompactClassificationECOC  
    ResponseName: 'Y'  
    ClassNames: {'setosa' 'versicolor' 'virginica'}  
    ScoreTransform: 'none'  
    BinaryLearners: {3×1 cell}  
    CodingMatrix: [3×3 double]
```

Properties, Methods

`mdlLinear` is a `CompactClassificationECOC` model composed of three binary learners.

Train a multiclass ECOC model that uses tall data and kernel binary learners. First, create a `templateKernel` object to specify the properties of the kernel binary learners; in particular, increase the number of expansion dimensions to 2^{16} .

```
tKernel = templateKernel('NumExpansionDimensions',2^16)
```

```
tKernel =
Fit template for classification Kernel.

        BetaTolerance: []
           BlockSize: []
        BoxConstraint: []
            Epsilon: []
NumExpansionDimensions: 65536
      GradientTolerance: []
HessianHistorySize: []
      IterationLimit: []
          KernelScale: []
             Lambda: []
           Learner: 'svm'
      LossFunction: []
             Stream: []
VerbosityLevel: []
           Version: 1
          Method: 'Kernel'
             Type: 'classification'
```

By default, the kernel binary learners use SVMs.

Pass the `templateKernel` object to `fitcecoc` and change the coding scheme to one-versus-one.

```
mdlKernel = fitcecoc(Z,Y,'Learners',tKernel,'Coding','onevsone')
```

```
Training binary learner 1 (Kernel) out of 3.
Training binary learner 2 (Kernel) out of 3.
Training binary learner 3 (Kernel) out of 3.
```

```
mdlKernel =
classreg.learning.classif.CompactClassificationECOC
ResponseName: 'Y'
```

```
ClassNames: {'setosa' 'versicolor' 'virginica'}
ScoreTransform: 'none'
BinaryLearners: {3×1 cell}
CodingMatrix: [3×3 double]
```

Properties, Methods

`mdlKernel` is also a `CompactClassificationECOC` model composed of three binary learners.

Compare the resubstitution classification error of the two models.

```
errorLinear = gather(loss(mdlLinear,Z,Y))
```

```
Evaluating tall expression using the Parallel Pool 'local':
- Pass 1 of 1: Completed in 1.8 sec
Evaluation completed in 1.9 sec
```

```
errorLinear = 0.0333
```

```
errorKernel = gather(loss(mdlKernel,Z,Y))
```

```
Evaluating tall expression using the Parallel Pool 'local':
- Pass 1 of 1: Completed in 18 sec
Evaluation completed in 18 sec
```

```
errorKernel = 0.0067
```

`mdlKernel` misclassifies a smaller percentage of the training data than `mdlLinear`.

Input Arguments

Tbl — Sample data

table

Sample data, specified as a table. Each row of `Tbl` corresponds to one observation, and each column corresponds to one predictor. Optionally, `Tbl` can contain one additional column for the response variable. Multicolumn variables and cell arrays other than cell arrays of character vectors are not accepted.

If `Tbl` contains the response variable, and you want to use all remaining variables in `Tbl` as predictors, then specify the response variable using `ResponseVarName`.

If `Tbl` contains the response variable, and you want to use only a subset of the remaining variables in `Tbl` as predictors, specify a formula using `formula`.

If `Tbl` does not contain the response variable, specify a response variable using `Y`. The length of response variable and the number of `Tbl` rows must be equal.

Note For training linear or kernel classification models, `fitcecoc` does not support tables. That is, if `Learners` is `'linear'` or `'kernel'`, contains a linear classification model learner template (see `templateLinear`), or contains a kernel classification learner template (see `templateKernel`), you cannot supply `Tbl`, `ResponseVarName`, or `formula`. Supply a matrix of predictor data (`X`) and an array of responses (`Y`) instead.

Data Types: `table`

ResponseVarName — Response variable name

name of variable in `Tbl`

Response variable name, specified as the name of a variable in `Tbl`.

You must specify `ResponseVarName` as a character vector or string scalar. For example, if the response variable `Y` is stored as `Tbl.Y`, then specify it as `'Y'`. Otherwise, the software treats all columns of `Tbl`, including `Y`, as predictors when training the model.

The response variable must be a categorical, character, or string array, logical or numeric vector, or cell array of character vectors. If `Y` is a character array, then each element of the response variable must correspond to one row of the array.

It is a good practice to specify the order of the classes by using the `ClassNames` name-value pair argument.

Data Types: `char` | `string`

formula — Explanatory model of response and subset of predictor variables

character vector | string scalar

Explanatory model of the response and a subset of the predictor variables, specified as a character vector or string scalar in the form `'Y~X1+X2+X3'`. In this form, `Y` represents

the response variable, and `X1`, `X2`, and `X3` represent the predictor variables. The variables must be variable names in `Tbl` (`Tbl.Properties.VariableNames`).

To specify a subset of variables in `Tbl` as predictors for training the model, use a formula. If you specify a formula, then the software does not use any variables in `Tbl` that do not appear in `formula`.

Data Types: `char` | `string`

Y — Class labels

categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Class labels to which the ECOC model is trained, specified as a categorical, character, or string array, logical or numeric vector, or cell array of character vectors.

If `Y` is a character array, then each element must correspond to one row of the array.

The length of `Y` and the number of rows of `Tbl` or `X` must be equal.

It is good practice to specify the class order using the `ClassNames` name-value pair argument.

Data Types: `categorical` | `char` | `string` | `logical` | `single` | `double` | `cell`

X — Predictor data

full matrix | sparse matrix

Predictor data, specified as a full or sparse matrix.

The length of `Y` and the number of observations in `X` must be equal.

To specify the names of the predictors in the order of their appearance in `X`, use the `PredictorNames` name-value pair argument.

Note

- For linear classification learners, if you orient `X` so that observations correspond to columns and specify `'ObservationsIn'`, `'columns'`, then you can experience a significant reduction in optimization-execution time.
- For all other learners, orient `X` so that observations correspond to rows.

- `fitcecoc` supports sparse matrices for training linear classification models only.

Data Types: `double` | `single`

Note The software treats NaN, empty character vector (' '), empty string (""), <missing>, and <undefined> elements as missing data. The software removes rows of X corresponding to missing values in Y. However, the treatment of missing values in X varies among binary learners. For details, see the training functions for your binary learners: `fitcdiscr`, `fitckernel`, `fitcknn`, `fitclinear`, `fitcnb`, `fitcsvm`, `fitctree`, or `fitcensemble`. Removing observations decreases the effective training or cross-validation sample size.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Note You cannot use any cross-validation name-value pair argument along with the `'OptimizeHyperparameters'` name-value pair argument. You can modify the cross-validation for `'OptimizeHyperparameters'` only by using the `'HyperparameterOptimizationOptions'` name-value pair argument.

Example: `'Learners', 'tree', 'Coding', 'onevsone', 'CrossVal', 'on'` specifies to use decision trees for all binary learners, a one-versus-one coding design, and to implement 10-fold cross-validation.

ECOC Classifier Options

Coding — Coding design

`'onevsone'` (default) | `'allpairs'` | `'binarycomplete'` | `'denserandom'` | `'onevsall'` | `'ordinal'` | `'sparserandom'` | `'ternarycomplete'` | numeric matrix

Coding design name, specified as the comma-separated pair consisting of `'Coding'` and a numeric matrix or a value in this table.

Value	Number of Binary Learners	Description
'allpairs' and 'onevsone'	$K(K - 1)/2$	For each binary learner, one class is positive, another is negative, and the software ignores the rest. This design exhausts all combinations of class pair assignments.
'binarycomplete'	$2^{(K - 1)} - 1$	This design partitions the classes into all binary combinations, and does not ignore any classes. For each binary learner, all class assignments are -1 and 1 with at least one positive and negative class in the assignment.
'denserandom'	Random, but approximately $10 \log_2 K$	For each binary learner, the software randomly assigns classes into positive or negative classes, with at least one of each type. For more details, see "Random Coding Design Matrices" on page 32-1874.
'onevsall'	K	For each binary learner, one class is positive and the rest are negative. This design exhausts all combinations of positive class assignments.
'ordinal'	$K - 1$	For the first binary learner, the first class is negative, and the rest positive. For the second binary learner, the first two classes are negative, the rest positive, and so on.

Value	Number of Binary Learners	Description
'sparsestrandom'	Random, but approximately $15 \log_2 K$	For each binary learner, the software randomly assigns classes as positive or negative with probability 0.25 for each, and ignores classes with probability 0.5. For more details, see "Random Coding Design Matrices" on page 32-1874.
'ternarycomplete'	$(3^K - 2^{(K+1)} + 1)/2$	This design partitions the classes into all ternary combinations. All class assignments are 0, -1, and 1 with at least one positive and one negative class in the assignment.

You can also specify a coding design using a custom coding matrix. The custom coding matrix is a K -by- L matrix. Each row corresponds to a class and each column corresponds to a binary learner. The class order (rows) corresponds to the order in `ClassNames`. Compose the matrix by following these guidelines:

- Every element of the custom coding matrix must be -1, 0, or 1, and the value must correspond to a dichotomous class assignment. This table describes the meaning of `Coding(i, j)`, that is, the class that learner j assigns to observations in class i .

Value	Dichotomous Class Assignment
-1	Learner j assigns observations in class i to a negative class.
0	Before training, learner j removes observations in class i from the data set.
1	Learner j assigns observations in class i to a positive class.

- Every column must contain at least one -1 or 1.

- For all column indices i, j such that $i \neq j$, `Coding(:, i)` cannot equal `Coding(:, j)` and `Coding(:, i)` cannot equal `-Coding(:, j)`.
- All rows of the custom coding matrix must be different.

For more details on the form of custom coding design matrices, see “Custom Coding Design Matrices” on page 32-1872.

Example: `'Coding', 'ternarycomplete'`

Data Types: `char | string | double | single | int16 | int32 | int64 | int8`

FitPosterior — Flag indicating whether to transform scores to posterior probabilities

`false` or `0` (default) | `true` or `1`

Flag indicating whether to transform scores to posterior probabilities, specified as the comma-separated pair consisting of `'FitPosterior'` and a `true` (1) or `false` (0).

If `FitPosterior` is `true`, then the software transforms binary-learner classification scores to posterior probabilities. You can obtain posterior probabilities by using `kfoldPredict`, `predict`, or `resubPredict`.

`fitcecoc` does not support fitting posterior probabilities if:

- The ensemble method is `AdaBoostM2`, `LPBoost`, `RUSBoost`, `RobustBoost`, or `TotalBoost`.
- The binary learners (`Learners`) are linear or kernel classification models that implement SVM. To obtain posterior probabilities for linear or kernel classification models, implement logistic regression instead.

Example: `'FitPosterior', true`

Data Types: `logical`

Learners — Binary learner templates

`'svm'` (default) | `'discriminant'` | `'kernel'` | `'knn'` | `'linear'` | `'naivebayes'` | `'tree'` | template object | cell vector of template objects

Binary learner templates, specified as the comma-separated pair consisting of `'Learners'` and a character vector, string scalar, template object, or cell vector of template objects. Specifically, you can specify binary classifiers such as SVM, and the ensembles that use `GentleBoost`, `LogitBoost`, and `RobustBoost`, to solve multiclass problems. However, `fitcecoc` also supports multiclass models as binary classifiers.

- If `Learners` is a character vector or string scalar, then the software trains each binary learner using the default values of the specified algorithm. This table summarizes the available algorithms.

Value	Description
'discriminant'	Discriminant analysis. For default options, see <code>templateDiscriminant</code> .
'kernel'	Kernel classification model. For default options, see <code>templateKernel</code> .
'knn'	k -nearest neighbors. For default options, see <code>templateKNN</code> .
'linear'	Linear classification model. For default options, see <code>templateLinear</code> .
'naivebayes'	Naive Bayes. For default options, see <code>templateNaiveBayes</code> .
'svm'	SVM. For default options, see <code>templateSVM</code> .
'tree'	Classification trees. For default options, see <code>templateTree</code> .

- If `Learners` is a template object, then each binary learner trains according to the stored options. You can create a template object using:
 - `templateDiscriminant`, for discriminant analysis.
 - `templateEnsemble`, for ensemble learning. You must at least specify the learning method (`Method`), the number of learners (`NLearn`), and the type of learner (`Learners`). You cannot use the `AdaBoostM2` ensemble method for binary learning.
 - `templateKernel`, for kernel classification.
 - `templateKNN`, for k -nearest neighbors.
 - `templateLinear`, for linear classification.
 - `templateNaiveBayes`, for naive Bayes.
 - `templateSVM`, for SVM.
 - `templateTree`, for classification trees.
- If `Learners` is a cell vector of template objects, then:

- Cell j corresponds to binary learner j (in other words, column j of the coding design matrix), and the cell vector must have length L . L is the number of columns in the coding design matrix. For details, see `Coding`.
- To use one of the built-in loss functions for prediction, then all binary learners must return a score in the same range. For example, you cannot include default SVM binary learners with default naive Bayes binary learners. The former returns a score in the range $(-\infty, \infty)$, and the latter returns a posterior probability as a score. Otherwise, you must provide a custom loss as a function handle to functions such as `predict` and `loss`.
- You cannot specify linear classification model learner templates with any other template.
- Similarly, you cannot specify kernel classification model learner templates with any other template.

By default, the software trains learners using default SVM templates.

Example: `'Learners', 'tree'`

NumBins — Number of bins for numeric predictors

`[]` (empty) (default) | positive integer scalar

Number of bins for numeric predictors, specified as the comma-separated pair consisting of `'NumBins'` and a positive integer scalar. This argument is valid only when `fitcecoc` uses a tree learner, that is, `'Learner'` is either `'tree'` or a template object created by using `templateTree`, or a template object created by using `templateEnsemble` with tree weak learners.

- If the `'NumBins'` value is empty (default), then the software does not bin any predictors.
- If you specify the `'NumBins'` value as a positive integer scalar, then the software bins every numeric predictor into a specified number of equiprobable bins, and then grows trees on the bin indices instead of the original data.
 - If the `'NumBins'` value exceeds the number (u) of unique values for a predictor, then `fitcecoc` bins the predictor into u bins.
 - `fitcecoc` does not bin categorical predictors.

When you use a large training data set, this binning option speeds up training but causes a potential decrease in accuracy. You can try `'NumBins', 50` first, and then change the `'NumBins'` value depending on the accuracy and training speed.

A trained model stores the bin edges in the BinEdges property.

Example: 'NumBins',50

Data Types: single | double

NumConcurrent — Number of binary learners concurrently trained

1 (default) | positive integer scalar

Number of binary learners concurrently trained, specified as the comma-separated pair consisting of 'NumConcurrent' and a positive integer scalar. The default value is 1, which means fitcecoc trains the binary learners sequentially.

Note This option applies only when you use fitcecoc on tall arrays. See “Tall Arrays” on page 32-1876 for more information.

Data Types: single | double

ObservationsIn — Predictor data observation dimension

'rows' (default) | 'columns'

Predictor data observation dimension, specified as the comma-separated pair consisting of 'ObservationsIn' and 'columns' or 'rows'.

Note

- For linear classification learners, if you orient X so that observations correspond to columns and specify 'ObservationsIn', 'columns', then you can experience a significant reduction in optimization-execution time.
 - For all other learners, orient X so that observations correspond to rows.
-

Example: 'ObservationsIn','columns'

Verbose — Verbosity level

0 (default) | 1 | 2

Verbosity level, specified as the comma-separated pair consisting of 'Verbose' and 0, 1, or 2. Verbose controls the amount of diagnostic information per binary learner that the software displays in the Command Window.

This table summarizes the available verbosity level options.

Value	Description
0	The software does not display diagnostic information.
1	The software displays diagnostic messages every time it trains a new binary learner.
2	The software displays extra diagnostic messages every time it trains a new binary learner.

Each binary learner has its own verbosity level that is independent of this name-value pair argument. To change the verbosity level of a binary learner, create a template object and specify the 'Verbose' name-value pair argument. Then, pass the template object to `fitcecoc` by using the 'Learners' name-value pair argument.

Example: 'Verbose', 1

Data Types: double | single

Cross-Validation Options

CrossVal — Flag to train cross-validated classifier

'off' (default) | 'on'

Flag to train a cross-validated classifier, specified as the comma-separated pair consisting of 'Crossval' and 'on' or 'off'.

If you specify 'on', then the software trains a cross-validated classifier with 10 folds.

You can override this cross-validation setting using one of the `CVPartition`, `Holdout`, `KFold`, or `Leaveout` name-value pair arguments. You can only use one cross-validation name-value pair argument at a time to create a cross-validated model.

Alternatively, cross-validate later by passing `Mdl` to `crossval`.

Example: 'Crossval', 'on'

CVPartition — Cross-validation partition

[] (default) | `cvpartition` partition object

Cross-validation partition, specified as the comma-separated pair consisting of 'CVPartition' and a `cvpartition` partition object created by `cvpartition`. The

partition object specifies the type of cross-validation and the indexing for the training and validation sets.

To create a cross-validated model, you can use one of these four name-value pair arguments only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: Suppose you create a random partition for 5-fold cross-validation on 500 observations by using `cvp = cvpartition(500, 'KFold', 5)`. Then, you can specify the cross-validated model by using `'CVPartition', cvp`.

Holdout — Fraction of data for holdout validation

scalar value in the range (0,1)

Fraction of the data used for holdout validation, specified as the comma-separated pair consisting of `'Holdout'` and a scalar value in the range (0,1). If you specify `'Holdout', p`, then the software completes these steps:

- 1 Randomly select and reserve $p \times 100\%$ of the data as validation data, and train the model using the rest of the data.
- 2 Store the compact, trained model in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: `'Holdout', 0.1`

Data Types: `double` | `single`

KFold — Number of folds

10 (default) | positive integer value greater than 1

Number of folds to use in a cross-validated model, specified as the comma-separated pair consisting of `'KFold'` and a positive integer value greater than 1. If you specify `'KFold', k`, then the software completes these steps:

- 1 Randomly partition the data into k sets.
- 2 For each set, reserve the set as validation data, and train the model using the other $k - 1$ sets.
- 3 Store the k compact, trained models in the cells of a k -by-1 cell vector in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: `'KFold',5`

Data Types: `single` | `double`

Leaveout — Leave-one-out cross-validation flag

`'off'` (default) | `'on'`

Leave-one-out cross-validation flag, specified as the comma-separated pair consisting of `'Leaveout'` and `'on'` or `'off'`. If you specify `'Leaveout', 'on'`, then, for each of the n observations, where n is `size(Mdl.X,1)`, the software:

- 1 Reserves the observation as validation data, and trains the model using the other $n - 1$ observations
- 2 Stores the n compact, trained models in the cells of a n -by-1 cell vector in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can use one of these four options only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Note Leave-one-out is not recommended for cross-validating ECOC models composed of linear or kernel classification model learners.

Example: `'Leaveout', 'on'`

Other Classification Options

CategoricalPredictors — Categorical predictors list

vector of positive integers | logical vector | character matrix | string array | cell array of character vectors | `'all'`

Categorical predictors list, specified as the comma-separated pair consisting of `'CategoricalPredictors'` and one of the values in this table.

Value	Description
Vector of positive integers	An entry in the vector is the index value corresponding to the column of the predictor data (<code>X</code> or <code>Tbl</code>) that contains a categorical variable.

Value	Description
Logical vector	A <code>true</code> entry means that the corresponding column of predictor data (<code>X</code> or <code>Tbl</code>) is a categorical variable.
Character matrix	Each row of the matrix is the name of a predictor variable. The names must match the entries in <code>PredictorNames</code> . Pad the names with extra blanks so each row of the character matrix has the same length.
String array or cell array of character vectors	Each element in the array is the name of a predictor variable. The names must match the entries in <code>PredictorNames</code> .
'all'	All predictors are categorical.

Specification of `CategoricalPredictors` is appropriate if:

- At least one predictor is categorical and all binary learners are classification trees, naive Bayes learners, SVM, or ensembles of classification trees.
- All predictors are categorical and at least one binary learner is *k*NN.

If you specify `CategoricalPredictors` for any other learner, then the software warns that it cannot train that binary learner. For example, the software cannot train linear or kernel classification model learners using categorical predictors.

By default, if the predictor data is in a table (`Tbl`), `fitcecoc` assumes that a variable is categorical if it contains logical values, categorical values, a string array, or a cell array of character vectors. If the predictor data is a matrix (`X`), `fitcecoc` assumes all predictors are continuous. To identify any categorical predictors when the data is a matrix, use the '`CategoricalPredictors`' name-value pair argument.

Example: '`CategoricalPredictors`', 'all'

Data Types: `single` | `double` | `logical` | `char` | `string` | `cell`

ClassNames — Names of classes to use for training

categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Names of classes to use for training, specified as the comma-separated pair consisting of '`ClassNames`' and a categorical, character, or string array, a logical or numeric vector, or a cell array of character vectors. `ClassNames` must have the same data type as `Y`.

If `ClassNames` is a character array, then each element must correspond to one *row* of the array.

Use `ClassNames` to:

- Order the classes during training.
- Specify the order of any input or output argument dimension that corresponds to the class order. For example, use `ClassNames` to specify the order of the dimensions of `Cost` or the column order of classification scores returned by `predict`.
- Select a subset of classes for training. For example, suppose that the set of all distinct class names in `Y` is `{'a', 'b', 'c'}`. To train the model using observations from classes `'a'` and `'c'` only, specify `'ClassNames', {'a', 'c'}`.

The default value for `ClassNames` is the set of all distinct class names in `Y`.

Example: `'ClassNames', {'b', 'g'}`

Data Types: `categorical` | `char` | `string` | `logical` | `single` | `double` | `cell`

Cost — Misclassification cost

`square matrix` | `structure array`

Misclassification cost, specified as the comma-separated pair consisting of `'Cost'` and a square matrix or structure. If you specify:

- The square matrix `Cost`, then `Cost(i, j)` is the cost of classifying a point into class `j` if its true class is `i`. That is, the rows correspond to the true class and the columns correspond to the predicted class. To specify the class order for the corresponding rows and columns of `Cost`, additionally specify the `ClassNames` name-value pair argument.
- The structure `S`, then it must have two fields:
 - `S.ClassNames`, which contains the class names as a variable of the same data type as `Y`
 - `S.ClassificationCosts`, which contains the cost matrix with rows and columns ordered as in `S.ClassNames`

The default is `ones(K) - eye(K)`, where `K` is the number of distinct classes.

Example: `'Cost', [0 1 2 ; 1 0 2; 2 2 0]`

Data Types: `double` | `single` | `struct`

Options — Parallel computing options

[] (default) | structure array returned by `statset`

Parallel computing options, specified as the comma-separated pair consisting of 'Options' and a structure array returned by `statset`. These options require Parallel Computing Toolbox. `fitcecoc` uses 'Streams', 'UseParallel', and 'UseSubstreams' fields.

This table summarizes the available options.

Option	Description
'Streams'	<p>A <code>RandStream</code> object or cell array of such objects. If you do not specify <code>Streams</code>, the software uses the default stream or streams. If you specify <code>Streams</code>, use a single object except when the following are true:</p> <ul style="list-style-type: none"> • You have an open parallel pool. • <code>UseParallel</code> is true. • <code>UseSubstreams</code> is false. <p>In that case, use a cell array of the same size as the parallel pool. If a parallel pool is not open, then the software tries to open one (depending on your preferences), and <code>Streams</code> must supply a single random number stream.</p>

Option	Description
'UseParallel'	<p>If you have Parallel Computing Toolbox, then you can invoke a pool of workers by setting 'UseParallel', true. The <code>fitcecoc</code> function sends each binary learner to a worker in the pool.</p> <p>When you use decision trees for binary learners, <code>fitcecoc</code> parallelizes training using Intel Threading Building Blocks (TBB) for dual-core systems and above. Therefore, specifying the 'UseParallel' option is not helpful on a single computer. Use this option on a cluster. For details on Intel TBB, see https://software.intel.com/en-us/intel-tbb.</p>
'UseSubstreams'	<p>Set to <code>true</code> to compute in parallel using the stream specified by 'Streams'. Default is <code>false</code>. For example, set <code>Streams</code> to a type allowing substreams, such as 'mlfg6331_64' or 'mrg32k3a'.</p>

A best practice to ensure more predictable results is to use `parpool` and explicitly create a parallel pool before you invoke parallel computing using `fitcecoc`.

Example: `'Options',statset('UseParallel',true)`

Data Types: `struct`

PredictorNames — Predictor variable names

string array of unique names | cell array of unique character vectors

Predictor variable names, specified as the comma-separated pair consisting of 'PredictorNames' and a string array of unique names or cell array of unique character vectors. The functionality of 'PredictorNames' depends on the way you supply the training data.

- If you supply X and Y, then you can use 'PredictorNames' to give the predictor variables in X names.

- The order of the names in `PredictorNames` must correspond to the column order of `X`. That is, `PredictorNames{1}` is the name of `X(:,1)`, `PredictorNames{2}` is the name of `X(:,2)`, and so on. Also, `size(X,2)` and `numel(PredictorNames)` must be equal.
- By default, `PredictorNames` is `{'x1','x2',...}`.
- If you supply `Tbl`, then you can use `'PredictorNames'` to choose which predictor variables to use in training. That is, `fitcecoc` uses only the predictor variables in `PredictorNames` and the response variable in training.
 - `PredictorNames` must be a subset of `Tbl.Properties.VariableNames` and cannot include the name of the response variable.
 - By default, `PredictorNames` contains the names of all predictor variables.
 - It is a good practice to specify the predictors for training using either `'PredictorNames'` or formula only.

Example: `'PredictorNames'`,
`{'SepalLength','SepalWidth','PetalLength','PetalWidth'}`

Data Types: `string` | `cell`

Prior — Prior probabilities

`'empirical'` (default) | `'uniform'` | numeric vector | structure array

Prior probabilities for each class, specified as the comma-separated pair consisting of `'Prior'` and a value in this table.

Value	Description
<code>'empirical'</code>	The class prior probabilities are the class relative frequencies in <code>Y</code> .
<code>'uniform'</code>	All class prior probabilities are equal to $1/K$, where K is the number of classes.
numeric vector	Each element is a class prior probability. Order the elements according to <code>Mdl.ClassNames</code> or specify the order using the <code>ClassNames</code> name-value pair argument. The software normalizes the elements such that they sum to 1.

Value	Description
structure	<p>A structure <code>S</code> with two fields:</p> <ul style="list-style-type: none"> • <code>S.ClassNames</code> contains the class names as a variable of the same type as <code>Y</code>. • <code>S.ClassProbs</code> contains a vector of corresponding prior probabilities. The software normalizes the elements such that they sum to 1.

For more details on how the software incorporates class prior probabilities, see “Prior Probabilities and Cost” on page 32-1873.

Example: `struct('ClassNames',
{'setosa','versicolor','virginica'},'ClassProbs',1:3)`

Data Types: `single` | `double` | `char` | `string` | `struct`

ResponseName — Response variable name

'Y' (default) | character vector | string scalar

Response variable name, specified as the comma-separated pair consisting of 'ResponseName' and a character vector or string scalar.

- If you supply `Y`, then you can use 'ResponseName' to specify a name for the response variable.
- If you supply `ResponseVarName` or `formula`, then you cannot use 'ResponseName'.

Example: `'ResponseName','response'`

Data Types: `char` | `string`

ScoreTransform — Score transformation

'none' (default) | 'doublelogit' | 'invlogit' | 'ismax' | 'logit' | function handle | ...

Score transformation, specified as the comma-separated pair consisting of 'ScoreTransform' and a character vector, string scalar, or function handle.

This table summarizes the available character vectors and string scalars.

Value	Description
'doublelogit'	$1/(1 + e^{-2x})$
'invlogit'	$\log(x / (1 - x))$
'ismax'	Sets the score for the class with the largest score to 1, and sets the scores for all other classes to 0
'logit'	$1/(1 + e^{-x})$
'none' or 'identity'	x (no transformation)
'sign'	-1 for $x < 0$ 0 for $x = 0$ 1 for $x > 0$
'symmetric'	$2x - 1$
'symmetricismax'	Sets the score for the class with the largest score to 1, and sets the scores for all other classes to -1
'symmetriclogit'	$2/(1 + e^{-x}) - 1$

For a MATLAB function or a function you define, use its function handle for score transform. The function handle must accept a matrix (the original scores) and return a matrix of the same size (the transformed scores).

Example: 'ScoreTransform', 'logit'

Data Types: char | string | function_handle

Weights — Observation weights

numeric vector of positive values | name of variable in Tbl

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a numeric vector of positive values or name of a variable in Tbl. The software weighs the observations in each row of X or Tbl with the corresponding value in Weights. The size of Weights must equal the number of rows of X or Tbl.

If you specify the input data as a table Tbl, then Weights can be the name of a variable in Tbl that contains a numeric vector. In this case, you must specify Weights as a character vector or string scalar. For example, if the weights vector W is stored as Tbl.W, then specify it as 'W'. Otherwise, the software treats all columns of Tbl, including W, as predictors or the response when training the model.

The software normalizes `Weights` to sum up to the value of the prior probability in the respective class.

By default, `Weights` is `ones(n, 1)`, where n is the number of observations in `X` or `Tbl`.

Data Types: `double` | `single` | `char` | `string`

Hyperparameter Optimization

OptimizeHyperparameters — Parameters to optimize

'none' (default) | 'auto' | 'all' | string array or cell array of eligible parameter names | vector of `optimizableVariable` objects

Parameters to optimize, specified as the comma-separated pair consisting of 'OptimizeHyperparameters' and one of the following:

- 'none' — Do not optimize.
- 'auto' — Use {'Coding'} along with the default parameters for the specified Learners:
 - Learners = 'svm' (default) — {'BoxConstraint', 'KernelScale'}
 - Learners = 'discriminant' — {'Delta', 'Gamma'}
 - Learners = 'kernel' — {'KernelScale', 'Lambda'}
 - Learners = 'knn' — {'Distance', 'NumNeighbors'}
 - Learners = 'linear' — {'Lambda', 'Learner'}
 - Learners = 'naivebayes' — {'DistributionNames', 'Width'}
 - Learners = 'tree' — {'MinLeafSize'}
- 'all' — Optimize all eligible parameters.
- String array or cell array of eligible parameter names
- Vector of `optimizableVariable` objects, typically the output of `hyperparameters`

The optimization attempts to minimize the cross-validation loss (error) for `fitcecoc` by varying the parameters. For information about cross-validation loss in a different context, see "Classification Loss" on page 32-3352. To control the cross-validation type and other aspects of the optimization, use the `HyperparameterOptimizationOptions` name-value pair.

Note 'OptimizeHyperparameters' values override any values you set using other name-value pair arguments. For example, setting 'OptimizeHyperparameters' to 'auto' causes the 'auto' values to apply.

The eligible parameters for fitcecoc are:

- Coding — fitcecoc searches among 'onevsall' and 'onevsone'.
- The eligible hyperparameters for the chosen Learners, as specified in this table.

Learners	Eligible Hyperparameters (Bold = Default)	Default Range
'discriminant'	Delta	Log-scaled in the range [1e-6, 1e3]
	DiscrimType	'linear', 'quadratic', 'diagLinear', 'diagQuadratic', 'pseudoLinear', and 'pseudoQuadratic'
	Gamma	Real values in [0, 1]
'kernel'	Lambda	Positive values log-scaled in the range [1e-3/NumObservations, 1e3/NumObservations]
	KernelScale	Positive values log-scaled in the range [1e-3, 1e3]
	Learner	'svm' and 'logistic'
	NumExpansionDimensions	Integers log-scaled in the range [100, 10000]
'knn'	Distance	'cityblock', 'chebychev', 'correlation', 'cosine', 'euclidean', 'hamming', 'jaccard', 'mahalanobis', 'minkowski', 'seuclidean', and 'spearman'

Learners	Eligible Hyperparameters (Bold = Default)	Default Range
	DistanceWeight	'equal', 'inverse', and 'squaredinverse'
	Exponent	Positive values in [0.5, 3]
	NumNeighbors	Positive integer values log-scaled in the range [1, max(2, round(NumObservations / 2))]
	Standardize	'true' and 'false'
'linear'	Lambda	Positive values log-scaled in the range [1e-5/NumObservations, 1e5/NumObservations]
	Learner	'svm' and 'logistic'
	Regularization	'ridge' and 'lasso'
'naivebayes'	DistributionNames	'normal' and 'kernel'
	Width	Positive values log-scaled in the range [MinPredictorDiff/4, max(MaxPredictorRange, MinPredictorDiff)]
	Kernel	'normal', 'box', 'epanechnikov', and 'triangle'
'svm'	BoxConstraint	Positive values log-scaled in the range [1e-3, 1e3]
	KernelScale	Positive values log-scaled in the range [1e-3, 1e3]
	KernelFunction	'gaussian', 'linear', and 'polynomial'
	PolynomialOrder	Integers in the range [2, 4]
	Standardize	'true' and 'false'

Learners	Eligible Hyperparameters (Bold = Default)	Default Range
'tree'	MaxNumSplits	Integers log-scaled in the range [1,max(2,NumObservations-1)]
	MinLeafSize	Integers log-scaled in the range [1,max(2,floor(NumObservations/2))]
	NumVariablesToSample	Integers in the range [1,max(2,NumPredictors)]
	SplitCriterion	'gdi', 'deviance', and 'twoing'

Alternatively, use hyperparameters with your chosen Learners, such as

```
load fisheriris % hyperparameters requires data and learner
params = hyperparameters('fitcecoc',meas,species,'svm');
```

To see the eligible and default hyperparameters, examine params.

Set nondefault parameters by passing a vector of `optimizableVariable` objects that have nondefault values. For example,

```
load fisheriris
params = hyperparameters('fitcecoc',meas,species,'svm');
params(2).Range = [1e-4,1e6];
```

Pass params as the value of `OptimizeHyperparameters`.

By default, iterative display appears at the command line, and plots appear according to the number of hyperparameters in the optimization. For the optimization and plots, the objective function is $\log(1 + \text{cross-validation loss})$ for regression and the misclassification rate for classification. To control the iterative display, set the `Verbose` field of the `'HyperparameterOptimizationOptions'` name-value pair argument. To control the plots, set the `ShowPlots` field of the `'HyperparameterOptimizationOptions'` name-value pair argument.

For an example, see “Optimize ECOC Classifier” on page 32-1830.

Example: 'auto'

HyperparameterOptimizationOptions — Options for optimization

structure

Options for optimization, specified as the comma-separated pair consisting of 'HyperparameterOptimizationOptions' and a structure. This argument modifies the effect of the `OptimizeHyperparameters` name-value pair argument. All fields in the structure are optional.

Field Name	Values	Default
Optimizer	<ul style="list-style-type: none"> 'bayesopt' — Use Bayesian optimization. Internally, this setting calls <code>bayesopt</code>. 'gridsearch' — Use grid search with <code>NumGridDivisions</code> values per dimension. 'randomsearch' — Search at random among <code>MaxObjectiveEvaluations</code> points. <p>'gridsearch' searches in a random order, using uniform sampling without replacement from the grid. After optimization, you can get a table in grid order by using the command <code>sortrows(Mdl.HyperparameterOptimizationResults)</code>.</p>	'bayesopt'

Field Name	Values	Default
AcquisitionFunctionName	<ul style="list-style-type: none"> • 'expected-improvement-per-second-plus' • 'expected-improvement' • 'expected-improvement-plus' • 'expected-improvement-per-second' • 'lower-confidence-bound' • 'probability-of-improvement' <p>Acquisition functions whose names include <code>per-second</code> do not yield reproducible results because the optimization depends on the runtime of the objective function. Acquisition functions whose names include <code>plus</code> modify their behavior when they are overexploiting an area. For more details, see “Acquisition Function Types” on page 10-4.</p>	'expected-improvement-per-second-plus'
MaxObjectiveEvaluations	Maximum number of objective function evaluations.	30 for 'bayesopt' or 'randomsearch', and the entire grid for 'gridsearch'
MaxTime	Time limit, specified as a positive real. The time limit is in seconds, as measured by <code>tic</code> and <code>toc</code> . Run time can exceed <code>MaxTime</code> because <code>MaxTime</code> does not interrupt function evaluations.	Inf
NumGridDivisions	For 'gridsearch', the number of values in each dimension. The value can be a vector of positive integers giving the number of values for each dimension, or a scalar that applies to all dimensions. This field is ignored for categorical variables.	10

Field Name	Values	Default
ShowPlots	Logical value indicating whether to show plots. If <code>true</code> , this field plots the best objective function value against the iteration number. If there are one or two optimization parameters, and if <code>Optimizer</code> is <code>'bayesopt'</code> , then <code>ShowPlots</code> also plots a model of the objective function against the parameters.	<code>true</code>
SaveIntermediateResults	Logical value indicating whether to save results when <code>Optimizer</code> is <code>'bayesopt'</code> . If <code>true</code> , this field overwrites a workspace variable named <code>'BayesoptResults'</code> at each iteration. The variable is a <code>BayesianOptimization</code> object.	<code>false</code>
Verbose	Display to the command line. <ul style="list-style-type: none"> • 0 — No iterative display • 1 — Iterative display • 2 — Iterative display with extra information For details, see the <code>bayesopt</code> <code>Verbose</code> name-value pair argument.	1
UseParallel	Logical value indicating whether to run Bayesian optimization in parallel, which requires Parallel Computing Toolbox. For details, see “Parallel Bayesian Optimization” on page 10-8.	<code>false</code>

Field Name	Values	Default
Repartition	Logical value indicating whether to repartition the cross-validation at every iteration. If <code>false</code> , the optimizer uses a single partition for the optimization. <code>true</code> usually gives the most robust results because this setting takes partitioning noise into account. However, for good results, <code>true</code> requires at least twice as many function evaluations.	<code>false</code>
Use no more than one of the following three field names.		
CVPartition	A <code>cvpartition</code> object, as created by <code>cvpartition</code> .	'Kfold', 5 if you do not specify any cross-validation field
Holdout	A scalar in the range (0, 1) representing the holdout fraction.	
Kfold	An integer greater than 1.	

Example:

```
'HyperparameterOptimizationOptions', struct('MaxObjectiveEvaluations', 60)
```

Data Types: struct

Output Arguments

Mdl — Trained ECOC model

ClassificationECOC model object | CompactClassificationECOC model object | ClassificationPartitionedECOC cross-validated model object | ClassificationPartitionedLinearECOC cross-validated model object | ClassificationPartitionedKernelECOC cross-validated model object

Trained ECOC classifier, returned as a `ClassificationECOC` or `CompactClassificationECOC` model object, or a `ClassificationPartitionedECOC`, `ClassificationPartitionedLinearECOC`, or `ClassificationPartitionedKernelECOC` cross-validated model object.

This table shows how the types of model objects returned by `fitcecoc` depend on the type of binary learners you specify and whether you perform cross-validation.

Linear Classification Model Learners	Kernel Classification Model Learners	Cross-Validation	Returned Model Object
No	No	No	<code>ClassificationECOC</code>
No	No	Yes	<code>ClassificationPartitionedECOC</code>
Yes	No	No	<code>CompactClassificationECOC</code>
Yes	No	Yes	<code>ClassificationPartitionedLinearECOC</code>
No	Yes	No	<code>CompactClassificationECOC</code>
No	Yes	Yes	<code>ClassificationPartitionedKernelECOC</code>

HyperparameterOptimizationResults — Description of cross-validation optimization of hyperparameters

BayesianOptimization object | table of hyperparameters and associated values

Description of the cross-validation optimization of hyperparameters, returned as a `BayesianOptimization` object or a table of hyperparameters and associated values. `HyperparameterOptimizationResults` is nonempty when the `OptimizeHyperparameters` name-value pair argument is nonempty and the `Learners` name-value pair argument designates linear or kernel binary learners. The value depends on the setting of the `HyperparameterOptimizationOptions` name-value pair argument:

- `'bayesopt'` (default) — Object of class `BayesianOptimization`
- `'gridsearch'` or `'randomsearch'` — Table of hyperparameters used, observed objective function values (cross-validation loss), and rank of observation from smallest (best) to highest (worst)

Data Types: table

Limitations

- For training linear or kernel classification models, `fitcecoc` does not support tables. That is, if `Learners` is 'linear' or 'kernel', contains a linear classification model learner template (see `templateLinear`), or contains a kernel classification model learner template (see `templateKernel`), then you cannot supply `Tbl`, `ResponseVarName`, or `formula`. Supply a matrix of predictor data (X) and an array of responses (Y) instead.
- `fitcecoc` supports sparse matrices for training linear classification models only. For all other models, supply a full matrix of predictor data instead.

Definitions

Binary Loss

A binary loss is a function of the class and classification score that determines how well a binary learner classifies an observation into the class.

Suppose the following:

- m_{kj} is element (k,j) of the coding design matrix M (that is, the code corresponding to class k of binary learner j).
- s_j is the score of binary learner j for an observation.
- g is the binary loss function.
- \hat{k} is the predicted class for the observation.

In loss-based decoding [Escalera et al.] on page 18-228, the class producing the minimum sum of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \operatorname{argmin}_k \sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j).$$

In loss-weighted decoding [Escalera et al.] on page 18-228, the class producing the minimum average of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \operatorname{argmin}_k \frac{\sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j)}{\sum_{j=1}^L |m_{kj}|}.$$

Allwein et al. on page 18-227 suggest that loss-weighted decoding improves classification accuracy by keeping loss values for all classes in the same dynamic range.

This table summarizes the supported loss functions, where y_j is a class label for a particular binary learner (in the set $\{-1, 1, 0\}$), s_j is the score for observation j , and $g(y_j, s_j)$.

Value	Description	Score Domain	$g(y_j, s_j)$
'binodeviance'	Binomial deviance	$(-\infty, \infty)$	$\log[1 + \exp(-2y_j s_j)] / [2\log(2)]$
'exponential'	Exponential	$(-\infty, \infty)$	$\exp(-y_j s_j) / 2$
'hamming'	Hamming	$[0, 1]$ or $(-\infty, \infty)$	$[1 - \operatorname{sign}(y_j s_j)] / 2$
'hinge'	Hinge	$(-\infty, \infty)$	$\max(0, 1 - y_j s_j) / 2$
'linear'	Linear	$(-\infty, \infty)$	$(1 - y_j s_j) / 2$
'logit'	Logistic	$(-\infty, \infty)$	$\log[1 + \exp(-y_j s_j)] / [2\log(2)]$
'quadratic'	Quadratic	$[0, 1]$	$[1 - y_j(2s_j - 1)]^2 / 2$

The software normalizes binary losses such that the loss is 0.5 when $y_j = 0$, and aggregates using the average of the binary learners [Allwein et al.] on page 18-227.

Do not confuse the binary loss with the overall classification loss (specified by the 'LossFun' name-value pair argument of the `loss` and `predict` object functions), which measures how well an ECOC classifier performs as a whole.

Coding Design

A coding design is a matrix where elements direct which classes are trained by each binary learner, that is, how the multiclass problem is reduced to a series of binary problems.

Each row of the coding design corresponds to a distinct class, and each column corresponds to a binary learner. In a ternary coding design, for a particular column (or binary learner):

- A row containing 1 directs the binary learner to group all observations in the corresponding class into a positive class.
- A row containing -1 directs the binary learner to group all observations in the corresponding class into a negative class.
- A row containing 0 directs the binary learner to ignore all observations in the corresponding class.

Coding design matrices with large, minimal, pairwise row distances based on the Hamming measure are optimal. For details on the pairwise row distance, see “Random Coding Design Matrices” on page 32-1874 and [4].

This table describes popular coding designs.

Coding Design	Description	Number of Learners	Minimal Pairwise Row Distance
one-versus-all (OVA)	For each binary learner, one class is positive and the rest are negative. This design exhausts all combinations of positive class assignments.	K	2

Coding Design	Description	Number of Learners	Minimal Pairwise Row Distance
one-versus-one (OVO)	For each binary learner, one class is positive, another is negative, and the rest are ignored. This design exhausts all combinations of class pair assignments.	$K(K - 1)/2$	1
binary complete	This design partitions the classes into all binary combinations, and does not ignore any classes. That is, all class assignments are -1 and 1 with at least one positive class and one negative class in the assignment for each binary learner.	$2^{K-1} - 1$	2^{K-2}
ternary complete	This design partitions the classes into all ternary combinations. That is, all class assignments are 0 , -1 , and 1 with at least one positive class and one negative class in the assignment for each binary learner.	$(3^K - 2^{K+1} + 1)/2$	3^{K-2}

Coding Design	Description	Number of Learners	Minimal Pairwise Row Distance
ordinal	For the first binary learner, the first class is negative and the rest are positive. For the second binary learner, the first two classes are negative and the rest are positive, and so on.	$K - 1$	1
dense random	For each binary learner, the software randomly assigns classes into positive or negative classes, with at least one of each type. For more details, see “Random Coding Design Matrices” on page 32-1874.	Random, but approximately $10 \log_2 K$	Variable
sparse random	For each binary learner, the software randomly assigns classes as positive or negative with probability 0.25 for each, and ignores classes with probability 0.5. For more details, see “Random Coding Design Matrices” on page 32-1874.	Random, but approximately $15 \log_2 K$	Variable

This plot compares the number of binary learners for the coding designs with increasing K .

Error-Correcting Output Codes Model

An error-correcting output codes (ECOC) model reduces the problem of classification with three or more classes to a set of binary classification problems.

ECOC classification requires a coding design, which determines the classes that the binary learners train on, and a decoding scheme, which determines how the results (predictions) of the binary classifiers are aggregated.

Assume the following:

- The classification problem has three classes.

- The coding design is one-versus-one. For three classes, this coding design is

	Learner 1	Learner 2	Learner 3
Class 1	1	1	0
Class 2	-1	0	1
Class 3	0	-1	-1

- The decoding scheme uses loss g .
- The learners are SVMs.

To build this classification model, the ECOC algorithm follows these steps.

- 1 Learner 1 trains on observations in Class 1 or Class 2, and treats Class 1 as the positive class and Class 2 as the negative class. The other learners are trained similarly.
- 2 Let M be the coding design matrix with elements m_{kl} , and s_l be the predicted classification score for the positive class of learner l . The algorithm assigns a new observation to the class (\hat{k}) that minimizes the aggregation of the losses for the L binary learners.

$$\hat{k} = \operatorname{argmin}_k \frac{\sum_{l=1}^L |m_{kl}| g(m_{kl}, s_l)}{\sum_{l=1}^L |m_{kl}|}.$$

ECOC models can improve classification accuracy, compared to other multiclass models [2].

Tips

- The number of binary learners grows with the number of classes. For a problem with many classes, the `binarycomplete` and `ternarycomplete` coding designs are not efficient. However:
 - If $K \leq 4$, then use `ternarycomplete` coding design rather than `sparserandom`.
 - If $K \leq 5$, then use `binarycomplete` coding design rather than `denserandom`.

You can display the coding design matrix of a trained ECOC classifier by entering `Mdl.CodingMatrix` into the Command Window.

- You should form a coding matrix using intimate knowledge of the application, and taking into account computational constraints. If you have sufficient computational power and time, then try several coding matrices and choose the one with the best performance (e.g., check the confusion matrices for each model using `confusionchart`).
- Leave-one-out cross-validation (`Leaveout`) is inefficient for data sets with many observations. Instead, use *k*-fold cross-validation (`KFold`).
- After training a model, you can generate C/C++ code that predicts labels for new data. Generating C/C++ code requires MATLAB Coder. For details, see “Introduction to Code Generation” on page 31-2.

Algorithms

Custom Coding Design Matrices

Custom coding matrices must have a certain form. The software validates custom coding matrices by ensuring:

- Every element is -1, 0, or 1.
- Every column contains at least one -1 and one 1.
- For all distinct column vectors u and v , $u \neq v$ and $u \neq -v$.
- All rows vectors are unique.
- The matrix can separate any two classes. That is, you can travel from any row to any other row following these rules:
 - You can move vertically from 1 to -1 or -1 to 1.
 - You can move horizontally from a nonzero element to another nonzero element.
 - You can use a column of the matrix for a vertical move only once.

If it is not possible to move from row i to row j using these rules, then classes i and j cannot be separated by the design. For example, in the coding design

$$\begin{bmatrix} 1 & 0 \\ -1 & 0 \\ 0 & 1 \\ 0 & -1 \end{bmatrix}$$

classes 1 and 2 cannot be separated from classes 3 and 4 (that is, you cannot move horizontally from the -1 in row 2 to column 2 since there is a 0 in that position). Therefore, the software rejects this coding design.

Parallel Computing

If you use parallel computing (see `Options`), then `fitcecoc` trains binary learners in parallel.

Prior Probabilities and Cost

- Prior probabilities — The software normalizes the specified class prior probabilities (`Prior`) for each binary learner. Let M be the coding design matrix and $I(A,c)$ be an indicator matrix. The indicator matrix has the same dimensions as A . If the corresponding element of A is c , then the indicator matrix has elements equaling one, and zero otherwise. Let M_{+1} and M_{-1} be K -by- L matrices such that:
 - $M_{+1} = M \circ I(M,1)$, where \circ is element-wise multiplication (that is, `Mplus = M.*(M == 1)`). Also, let $m_l^{(+1)}$ be column vector l of M_{+1} .
 - $M_{-1} = -M \circ I(M,-1)$ (that is, `Mminus = -M.*(M == -1)`). Also, let $m_l^{(-1)}$ be column vector l of M_{-1} .

Let $\pi_l^{+1} = m_l^{(+1) \circ \pi}$ and $\pi_l^{-1} = m_l^{(-1) \circ \pi}$, where π is the vector of specified, class prior probabilities (`Prior`).

Then, the positive and negative, scalar class prior probabilities for binary learner l are

$$\hat{\pi}_l^{(j)} = \frac{\|\pi_l^{(j)}\|_1}{\|\pi_l^{(+1)}\|_1 + \|\pi_l^{(-1)}\|_1},$$

where $j = \{-1,1\}$ and $\|a\|_1$ is the one-norm of a .

- **Cost** — The software normalizes the K -by- K cost matrix C (**Cost**) for each binary learner. For binary learner l , the cost of classifying a negative-class observation into the positive class is

$$c_l^{-+} = (\pi_l^{(-1)})^\top C \pi_l^{(+1)}.$$

Similarly, the cost of classifying a positive-class observation into the negative class is

$$c_l^{+-} = (\pi_l^{(+1)})^\top C \pi_l^{(-1)}.$$

The cost matrix for binary learner l is

$$C_l = \begin{bmatrix} 0 & c_l^{-+} \\ c_l^{+-} & 0 \end{bmatrix}.$$

ECOC models accommodate misclassification costs by incorporating them with class prior probabilities. If you specify **Prior** and **Cost**, then the software adjusts the class prior probabilities as follows:

$$\bar{\pi}_l^{-1} = \frac{c_l^{-+} \hat{\pi}_l^{-1}}{c_l^{-+} \hat{\pi}_l^{-1} + c_l^{+-} \hat{\pi}_l^{+1}}$$

$$\bar{\pi}_l^{+1} = \frac{c_l^{+-} \hat{\pi}_l^{+1}}{c_l^{-+} \hat{\pi}_l^{-1} + c_l^{+-} \hat{\pi}_l^{+1}}.$$

Random Coding Design Matrices

For a given number of classes K , the software generates random coding design matrices as follows.

- 1 The software generates one of these matrices:
 - a **Dense random** — The software assigns 1 or -1 with equal probability to each element of the K -by- L_d coding design matrix, where $L_d \approx \lceil 10 \log_2 K \rceil$.
 - b **Sparse random** — The software assigns 1 to each element of the K -by- L_s coding design matrix with probability 0.25, -1 with probability 0.25, and 0 with probability 0.5, where $L_s \approx \lceil 15 \log_2 K \rceil$.

- 2 If a column does not contain at least one 1 and at least one -1, then the software removes that column.
- 3 For distinct columns u and v , if $u = v$ or $u = -v$, then the software removes v from the coding design matrix.

The software randomly generates 10,000 matrices by default, and retains the matrix with the largest, minimal, pairwise row distance based on the Hamming measure ([4]) given by

$$\Delta(k_1, k_2) = 0.5 \sum_{l=1}^L |m_{k_1 l}| |m_{k_2 l}| |m_{k_1 l} - m_{k_2 l}|,$$

where $m_{k,l}$ is an element of coding design matrix j .

Support Vector Storage

By default and for efficiency, `fitcecoc` empties the `Alpha`, `SupportVectorLabels`, and `SupportVectors` properties for all linear SVM binary learners. `fitcecoc` lists `Beta`, rather than `Alpha`, in the model display.

To store `Alpha`, `SupportVectorLabels`, and `SupportVectors`, pass a linear SVM template that specifies storing support vectors to `fitcecoc`. For example, enter:

```
t = templateSVM('SaveSupportVectors', true)
Mdl = fitcecoc(X, Y, 'Learners', t);
```

You can remove the support vectors and related values by passing the resulting `ClassificationECOC` model to `discardSupportVectors`.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

Usage notes and limitations:

- Supported syntaxes are:
 - `Mdl = fitcecoc(X,Y)`
 - `Mdl = fitcecoc(X,Y,Name,Value)`
 - `[Mdl,FitInfo,HyperparameterOptimizationResults] = fitcecoc(X,Y,Name,Value)` — `fitcecoc` returns the additional output arguments `FitInfo` and `HyperparameterOptimizationResults` when you specify the `'OptimizeHyperparameters'` name-value pair argument.
- The `FitInfo` output argument is an empty structure array currently reserved for possible future use.
- Options related to cross-validation are not supported. The supported name-value pair arguments are:
 - `'ClassNames'`
 - `'Cost'`
 - `'Coding'` — Default value is `'onevsall'`.
 - `'HyperparameterOptimizationOptions'` — For cross-validation, tall optimization supports only `'Holdout'` validation. For example, you can specify `fitcecoc(X,Y,'OptimizeHyperparameters','auto','HyperparameterOptimizationOptions',struct('Holdout',0.2))`.

- 'Learners' — Default value is 'linear'. You can specify 'linear', 'kernel', a `templateLinear` or `templateKernel` object, or a cell array of such objects.
- 'OptimizeHyperparameters' — When you use linear binary learners, the value of the 'Regularization' hyperparameter must be 'ridge'.
- 'Prior'
- 'Verbose' — Default value is 1.
- 'Weights'
- This additional name-value pair argument is specific to tall arrays:
 - 'NumConcurrent' — A positive integer scalar specifying the number of binary learners that are trained concurrently by combining file I/O operations. The default value for 'NumConcurrent' is 1, which means `fitcecoc` trains the binary learners sequentially. 'NumConcurrent' is most beneficial when the input arrays cannot fit into the distributed cluster memory. Otherwise, the input arrays can be cached and speedup is negligible.

If you run your code on Apache Spark, `NumConcurrent` is upper bounded by the memory available for communications. Check the `'spark.executor.memory'` and `'spark.driver.memory'` properties in your Apache Spark configuration. See `parallel.cluster.Hadoop` for more details. For more information on Apache Spark and other execution environments that control where your code runs, see “Extend Tall Arrays with Other Products” (MATLAB).

For more information, see “Tall Arrays” (MATLAB).

Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the 'UseParallel' option to `true` in one of these ways:

- Set the 'UseParallel' field of the options structure to `true` using `statset` and specify the 'Options' name-value pair argument in the call to `fitcecoc`.

For example: `'Options',statset('UseParallel',true)`

For more information, see the 'Options' name-value pair argument.

- Perform parallel hyperparameter optimization by using the `'HyperparameterOptions', struct('UseParallel', true)` name-value pair argument in the call to `fitcecoc`.

For more information on parallel hyperparameter optimization, see “Parallel Bayesian Optimization” on page 10-8.

Introduced in R2014b

fitcensemble

Fit ensemble of learners for classification

Syntax

```
Mdl = fitcensemble(Tbl,ResponseVarName)
```

```
Mdl = fitcensemble(Tbl,formula)
```

```
Mdl = fitcensemble(Tbl,Y)
```

```
Mdl = fitcensemble(X,Y)
```

```
Mdl = fitcensemble( ____,Name,Value)
```

Description

`Mdl = fitcensemble(Tbl,ResponseVarName)` returns the trained classification ensemble model object (`Mdl`) that contains the results of boosting 100 classification trees and the predictor and response data in the table `Tbl`. `ResponseVarName` is the name of the response variable in `Tbl`. By default, `fitcensemble` uses `LogitBoost` for binary classification and `AdaBoostM2` for multiclass classification.

`Mdl = fitcensemble(Tbl,formula)` applies `formula` to fit the model to the predictor and response data in the table `Tbl`. `formula` is an explanatory model of the response and a subset of predictor variables in `Tbl` used to fit `Mdl`. For example, `'Y~X1+X2+X3'` fits the response variable `Tbl.Y` as a function of the predictor variables `Tbl.X1`, `Tbl.X2`, and `Tbl.X3`.

`Mdl = fitcensemble(Tbl,Y)` treats all variables in the table `Tbl` as predictor variables. `Y` is the array of class labels that is not in `Tbl`.

`Mdl = fitcensemble(X,Y)` uses the predictor data in the matrix `X` and the array of class labels in `Y`.

`Mdl = fitcensemble(____,Name,Value)` uses additional options specified by one or more `Name,Value` pair arguments and any of the input arguments in the previous

syntaxes. For example, you can specify the number of learning cycles, the ensemble aggregation method, or to implement 10-fold cross-validation.

Examples

Train Classification Ensemble

Create a predictive classification ensemble using all available predictor variables in the data. Then, train another ensemble using fewer predictors. Compare the in-sample predictive accuracies of the ensembles.

Load the census1994 data set.

```
load census1994
```

Train an ensemble of classification models using the entire data set and default options.

```
Mdl1 = fitensemble(adultdata, 'salary')
```

```
Mdl1 =  
  classreg.learning.classif.ClassificationEnsemble  
    PredictorNames: {1x14 cell}  
    ResponseName: 'salary'  
    CategoricalPredictors: [2 4 6 7 8 9 10 14]  
    ClassNames: [<=50K >50K]  
    ScoreTransform: 'none'  
    NumObservations: 32561  
    NumTrained: 100  
    Method: 'LogitBoost'  
    LearnerNames: {'Tree'}  
    ReasonForTermination: 'Terminated normally after completing the requested number o  
    FitInfo: [100x1 double]  
    FitInfoDescription: {2x1 cell}
```

Properties, Methods

Mdl is a `ClassificationEnsemble` model. Some notable characteristics of Mdl are:

- Because two classes are represented in the data, LogitBoost is the ensemble aggregation algorithm.

- Because the ensemble aggregation method is a boosting algorithm, classification trees that allow a maximum of 10 splits compose the ensemble.
- One hundred trees compose the ensemble.

Use the classification ensemble to predict the labels of a random set of five observations from the data. Compare the predicted labels with their true values.

```
rng(1) % For reproducibility
[pX,pIdx] = datasample(adultdata,5);
label = predict(Mdl1,pX);
table(label,adultdata.salary(pIdx), 'VariableNames', {'Predicted', 'Truth'})
```

```
ans=5x2 table
   Predicted   Truth
   _____   _____
   <=50K      <=50K
   <=50K      <=50K
   <=50K      <=50K
   <=50K      <=50K
   <=50K      <=50K
```

Train a new ensemble using age and education only.

```
Mdl2 = fitcensemble(adultdata, 'salary ~ age + education');
```

Compare the resubstitution losses between Mdl1 and Mdl2.

```
rsLoss1 = resubLoss(Mdl1)
```

```
rsLoss1 = 0.1058
```

```
rsLoss2 = resubLoss(Mdl2)
```

```
rsLoss2 = 0.2037
```

The in-sample misclassification rate for the ensemble that uses all predictors is lower.

Speed Up Training by Binning Numeric Predictor Values

Train an ensemble of boosted classification trees by using `fitcensemble`. Reduce training time by specifying the 'NumBins' name-value pair argument to bin numeric

predictors. This argument is valid only when `fitcensemble` uses a tree learner. After training, you can reproduce binned predictor data by using the `BinEdges` property of the trained model and the `discretize` function.

Generate a sample data set.

```
rng('default') % For reproducibility
N = 1e6;
X = [mvnrnd([-1 -1],eye(2),N); mvnrnd([1 1],eye(2),N)];
y = [zeros(N,1); ones(N,1)];
```

Visualize the data set.

```
figure
scatter(X(1:N,1),X(1:N,2), 'Marker', '.', 'MarkerEdgeAlpha', 0.01)
hold on
scatter(X(N+1:2*N,1),X(N+1:2*N,2), 'Marker', '.', 'MarkerEdgeAlpha', 0.01)
```

Train an ensemble of boosted classification trees using adaptive logistic regression (LogitBoost, the default for binary classification). Time the function for comparison purposes.

```
tic
Mdl1 = fitcensemble(X,y);
toc
```

Elapsed time is 478.988422 seconds.

Speed up training by using the 'NumBins' name-value pair argument. If you specify the 'NumBins' value as a positive integer scalar, then the software bins every numeric predictor into a specified number of equiprobable bins, and then grows trees on the bin indices instead of the original data. The software does not bin categorical predictors.

```
tic
Mdl2 = fitcensemble(X,y,'NumBins',50);
toc
```

Elapsed time is 165.598434 seconds.

The process is about three times faster when you use binned data instead of the original data. Note that the elapsed time can vary depending on your operating system.

Compare the classification errors by resubstitution.

```
rsLoss1 = resubLoss(Mdl1)
rsLoss1 = 0.0788
rsLoss2 = resubLoss(Mdl2)
rsLoss2 = 0.0788
```

In this example, binning predictor values reduces training time without loss of accuracy. In general, when you have a large data set like the one in this example, using the binning option speeds up training but causes a potential decrease in accuracy. If you want to reduce training time further, specify a smaller number of bins.

Reproduce binned predictor data by using the `BinEdges` property of the trained model and the `discretize` function.

```
X = Mdl2.X; % Predictor data
Xbinned = zeros(size(X));
edges = Mdl2.BinEdges;
% Find indices of binned predictors.
idxNumeric = find(~cellfun(@isempty,edges));
if iscolumn(idxNumeric)
    idxNumeric = idxNumeric';
end
for j = idxNumeric
    x = X(:,j);
    % Convert x to array if x is a table.
    if istable(x)
        x = table2array(x);
    end
    % Group x into bins by using the discretize function.
    xbinned = discretize(x,[-inf; edges{j}; inf]);
    Xbinned(:,j) = xbinned;
end
```

Xbinned contains the bin indices, ranging from 1 to the number of bins, for numeric predictors. Xbinned values are 0 for categorical predictors. If X contains NaNs, then the corresponding Xbinned values are NaNs.

Estimate Generalization Error of Boosting Ensemble

Estimate the generalization error of ensemble of boosted classification trees.

Load the ionosphere data set.

```
load ionosphere
```

Cross-validate an ensemble of classification trees using AdaBoostM1 and 10-fold cross-validation. Specify that each tree should be split a maximum of five times using a decision tree template.

```
rng(5); % For reproducibility
t = templateTree('MaxNumSplits',5);
Mdl = fitcensemble(X,Y,'Method','AdaBoostM1','Learners',t,'CrossVal','on');
```

Mdl is a ClassificationPartitionedEnsemble model.

Plot the cumulative, 10-fold cross-validated, misclassification rate. Display the estimated generalization error of the ensemble.

```
kflc = kfoldLoss(Mdl,'Mode','cumulative');
figure;
plot(kflc);
ylabel('10-fold Misclassification rate');
xlabel('Learning cycle');
```

```
estGenError = kflc(end)
```

```
estGenError = 0.0741
```

`kfoldLoss` returns the generalization error by default. However, plotting the cumulative loss allows you to monitor how the loss changes as weak learners accumulate in the ensemble.

The ensemble achieves a misclassification rate of around 0.06 after accumulating about 50 weak learners. Then, the misclassification rate increase slightly as more weak learners enter the ensemble.

If you are satisfied with the generalization error of the ensemble, then, to create a predictive model, train the ensemble again using all of the settings except cross-validation. However, it is good practice to tune hyperparameters, such as the maximum number of decision splits per tree and the number of learning cycles.

Optimize Classification Ensemble

Optimize hyperparameters automatically using `fitcensemble`.

Load the `ionosphere` data set.

```
load ionosphere
```

You can find hyperparameters that minimize five-fold cross-validation loss by using automatic hyperparameter optimization.

```
Mdl = fitcensemble(X,Y,'OptimizeHyperparameters','auto')
```

In this example, for reproducibility, set the random seed and use the `'expected-improvement-plus'` acquisition function. Also, for reproducibility of random forest algorithm, specify the `'Reproducible'` name-value pair argument as `true` for tree learners.

```
rng('default')  
t = templateTree('Reproducible',true);  
Mdl = fitcensemble(X,Y,'OptimizeHyperparameters','auto','Learners',t, ...  
    'HyperparameterOptimizationOptions',struct('AcquisitionFunctionName','expected-impr
```

Properties, Methods

The optimization searched over the ensemble aggregation methods for binary classification, over `NumLearningCycles`, over the `LearnRate` for applicable methods, and over the tree learner `MinLeafSize`. The output is the ensemble classifier with the minimum estimated cross-validation loss.

Optimize Classification Ensemble Using Cross-Validation

One way to create an ensemble of boosted classification trees that has satisfactory predictive performance is by tuning the decision tree complexity level using cross-validation. While searching for an optimal complexity level, tune the learning rate to minimize the number of learning cycles.

This example manually finds optimal parameters by using the cross-validation option (the `'Kfold'` name-value pair argument) and the `kfoldLoss` function. Alternatively, you can use the `'OptimizeHyperparameters'` name-value pair argument to optimize hyperparameters automatically. See “Optimize Classification Ensemble” on page 32-1887.

Load the ionosphere data set.

```
load ionosphere
```

To search for the optimal tree-complexity level:

- 1 Cross-validate a set of ensembles. Exponentially increase the tree-complexity level for subsequent ensembles from decision stump (one split) to at most $n - 1$ splits. n is the sample size. Also, vary the learning rate for each ensemble between 0.1 to 1.
- 2 Estimate the cross-validated misclassification rate of each ensemble.
- 3 For tree-complexity level j , $j = 1 \dots J$, compare the cumulative, cross-validated misclassification rate of the ensembles by plotting them against number of learning cycles. Plot separate curves for each learning rate on the same figure.
- 4 Choose the curve that achieves the minimal misclassification rate, and note the corresponding learning cycle and learning rate.

Cross-validate a deep classification tree and a stump. These classification trees serve as benchmarks.

```
rng(1) % For reproducibility
MdlDeep = fitctree(X,Y,'CrossVal','on','MergeLeaves','off', ...
    'MinParentSize',1);
MdlStump = fitctree(X,Y,'MaxNumSplits',1,'CrossVal','on');
```

Cross-validate an ensemble of 150 boosted classification trees using 5-fold cross-validation. Using a tree template, vary the maximum number of splits using the values in the sequence $\{3^0, 3^1, \dots, 3^m\}$. m is such that 3^m is no greater than $n - 1$. For each variant, adjust the learning rate using each value in the set $\{0.1, 0.25, 0.5, 1\}$;

```
n = size(X,1);
m = floor(log(n - 1)/log(3));
learnRate = [0.1 0.25 0.5 1];
numLR = numel(learnRate);
maxNumSplits = 3.^(0:m);
numMNS = numel(maxNumSplits);
numTrees = 150;
Mdl = cell(numMNS,numLR);

for k = 1:numLR
    for j = 1:numMNS
        t = templateTree('MaxNumSplits',maxNumSplits(j));
        Mdl{j,k} = fitcensemble(X,Y,'NumLearningCycles',numTrees,...
```

```

        'Learners',t,'KFold',5,'LearnRate',learnRate(k));
    end
end

```

Estimate the cumulative, cross-validated misclassification rate for each ensemble and the classification trees serving as benchmarks.

```

kflAll = @(x)kfoldLoss(x,'Mode','cumulative');
errorCell = cellfun(kflAll,Mdl,'Uniform',false);
error = reshape(cell2mat(errorCell),[numTrees numel(maxNumSplits) numel(learnRate)]);
errorDeep = kfoldLoss(MdlDeep);
errorStump = kfoldLoss(MdlStump);

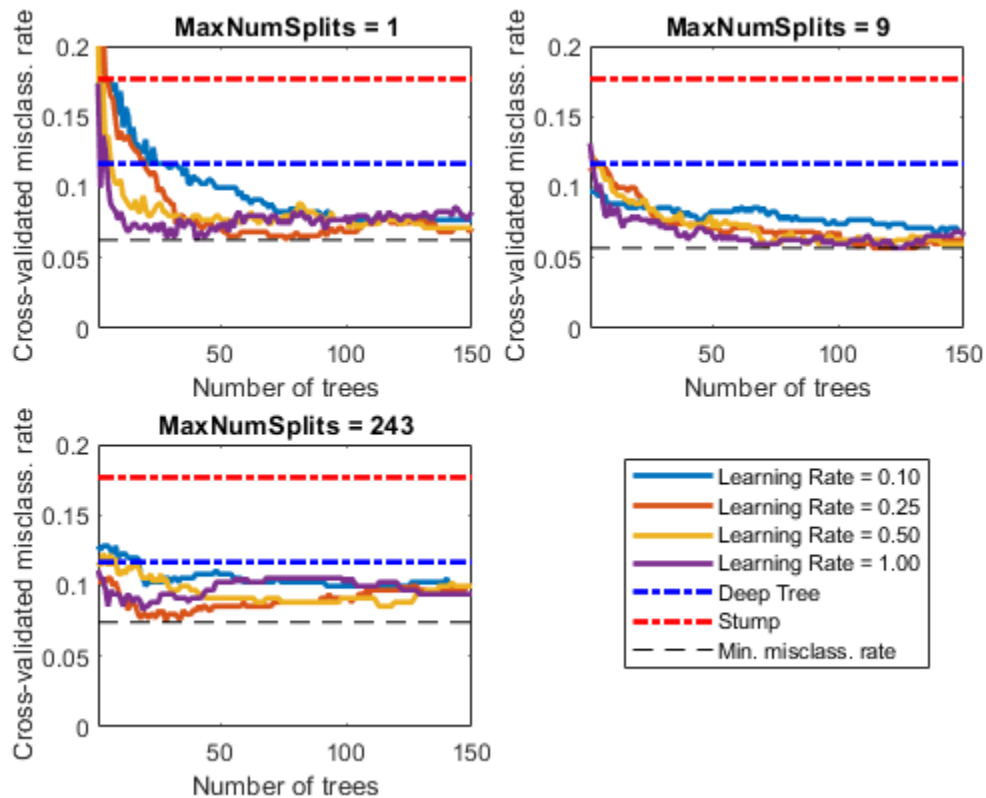

```

Plot how the cross-validated misclassification rate behaves as the number of trees in the ensemble increases. Plot the curves with respect to learning rate on the same plot, and plot separate plots for varying tree-complexity levels. Choose a subset of tree complexity levels to plot.

```

mnsPlot = [1 round(numel(maxNumSplits)/2) numel(maxNumSplits)];
figure
for k = 1:3
    subplot(2,2,k)
    plot(squeeze(error(:,mnsPlot(k),:)), 'LineWidth',2)
    axis tight
    hold on
    h = gca;
    plot(h.XLim,[errorDeep errorDeep], '-.b', 'LineWidth',2)
    plot(h.XLim,[errorStump errorStump], '-.r', 'LineWidth',2)
    plot(h.XLim,min(min(error(:,mnsPlot(k),:))).*[1 1], '--k')
    h.YLim = [0 0.2];
    xlabel('Number of trees')
    ylabel('Cross-validated misclass. rate')
    title(sprintf('MaxNumSplits = %0.3g', maxNumSplits(mnsPlot(k))))
    hold off
end
hL = legend([cellstr(num2str(learnRate),'Learning Rate = %0.2f')); ...
           'Deep Tree';'Stump';'Min. misclass. rate']);
hL.Position(1) = 0.6;

```

Each curve contains a minimum cross-validated misclassification rate occurring at the optimal number of trees in the ensemble.

Identify the maximum number of splits, number of trees, and learning rate that yields the lowest misclassification rate overall.

```
[minErr,minErrIdxLin] = min(error(:));
[idxNumTrees,idxMNS,idxLR] = ind2sub(size(error),minErrIdxLin);

fprintf('\nMin. misclass. rate = %0.5f',minErr)

Min. misclass. rate = 0.05413

fprintf('\nOptimal Parameter Values:\nNum. Trees = %d',idxNumTrees);
```

```
Optimal Parameter Values:  
Num. Trees = 47
```

```
fprintf('\nMaxNumSplits = %d\nLearning Rate = %0.2f\n',...  
        maxNumSplits(idxMNS),learnRate(idxLR))
```

```
MaxNumSplits = 3  
Learning Rate = 0.25
```

Create a predictive ensemble based on the optimal hyperparameters and the entire training set.

```
tFinal = templateTree('MaxNumSplits',maxNumSplits(idxMNS));  
MdlFinal = fitcensemble(X,Y,'NumLearningCycles',idxNumTrees,...  
    'Learners',tFinal,'LearnRate',learnRate(idxLR))
```

```
MdlFinal =  
classreg.learning.classif.ClassificationEnsemble  
    ResponseName: 'Y'  
    CategoricalPredictors: []  
    ClassNames: {'b' 'g'}  
    ScoreTransform: 'none'  
    NumObservations: 351  
    NumTrained: 47  
    Method: 'LogitBoost'  
    LearnerNames: {'Tree'}  
    ReasonForTermination: 'Terminated normally after completing the requested number of  
    FitInfo: [47x1 double]  
    FitInfoDescription: {2x1 cell}
```

Properties, Methods

`MdlFinal` is a `ClassificationEnsemble`. To predict whether a radar return is good given predictor data, you can pass the predictor data and `MdlFinal` to `predict`.

Instead of searching optimal values manually by using the cross-validation option ('`KFold`') and the `kfoldLoss` function, you can use the '`OptimizeHyperparameters`' name-value pair argument. When you specify '`OptimizeHyperparameters`', the software finds optimal parameters automatically using Bayesian optimization. The optimal values obtained by using '`OptimizeHyperparameters`' can be different from those obtained using manual search.

```
mdl = fitcensemble(X,Y,'OptimizeHyperparameters',{ 'NumLearningCycles', 'LearnRate', 'Max'
```

Properties, Methods

Input Arguments

Tbl — Sample data

table

Sample data used to train the model, specified as a table. Each row of Tbl corresponds to one observation, and each column corresponds to one predictor variable. Tbl can contain one additional column for the response variable. Multi-column variables and cell arrays other than cell arrays of character vectors are not allowed.

- If Tbl contains the response variable and you want to use all remaining variables as predictors, then specify the response variable using ResponseVarName.
- If Tbl contains the response variable, and you want to use a subset of the remaining variables only as predictors, then specify a formula using formula.

- If `Tbl` does not contain the response variable, then specify the response data using `Y`. The length of response variable and the number of rows of `Tbl` must be equal.

Note To save memory and execution time, supply `X` and `Y` instead of `Tbl`.

Data Types: `table`

ResponseVarName — Response variable name

name of response variable in `Tbl`

Response variable name, specified as the name of the response variable in `Tbl`.

You must specify `ResponseVarName` as a character vector or string scalar. For example, if `Tbl.Y` is the response variable, then specify `ResponseVarName` as `'Y'`. Otherwise, `fitcensemble` treats all columns of `Tbl` as predictor variables.

The response variable must be a categorical, character, or string array, logical or numeric vector, or cell array of character vectors. If the response variable is a character array, then each element must correspond to one row of the array.

For classification, you can specify the order of the classes using the `ClassNames` name-value pair argument. Otherwise, `fitcensemble` determines the class order, and stores it in the `Mdl.ClassNames`.

Data Types: `char` | `string`

formula — Explanatory model of response and subset of predictor variables

character vector | string scalar

Explanatory model of the response and a subset of the predictor variables, specified as a character vector or string scalar in the form `'Y~X1+X2+X3'`. In this form, `Y` represents the response variable, and `X1`, `X2`, and `X3` represent the predictor variables. The variables must be variable names in `Tbl` (`Tbl.Properties.VariableNames`).

To specify a subset of variables in `Tbl` as predictors for training the model, use a formula. If you specify a formula, then the software does not use any variables in `Tbl` that do not appear in `formula`.

Data Types: `char` | `string`

X — Predictor data

numeric matrix

Predictor data, specified as numeric matrix.

Each row corresponds to one observation, and each column corresponds to one predictor variable.

The length of `Y` and the number of rows of `X` must be equal.

To specify the names of the predictors in the order of their appearance in `X`, use the `PredictorNames` name-value pair argument.

Data Types: `single` | `double`

Y — Response data

categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Response data, specified as a categorical, character, or string array, logical or numeric vector, or cell array of character vectors. Each entry in `Y` is the response to or label for the observation in the corresponding row of `X` or `Tbl`. The length of `Y` and the number of rows of `X` or `Tbl` must be equal. If the response variable is a character array, then each element must correspond to one row of the array.

You can specify the order of the classes using the `ClassNames` name-value pair argument. Otherwise, `fitcensemble` determines the class order, and stores it in the `Mdl.ClassNames`.

Data Types: `categorical` | `char` | `string` | `logical` | `single` | `double` | `cell`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Note You cannot use any cross-validation name-value pair argument along with the `'OptimizeHyperparameters'` name-value pair argument. You can modify the cross-validation for `'OptimizeHyperparameters'` only by using the `'HyperparameterOptimizationOptions'` name-value pair argument.

Example: `'CrossVal', 'on', 'LearnRate', 0.05` specifies to implement 10-fold cross-validation and to use 0.05 as the learning rate.

General Ensemble Options

Method — Ensemble aggregation method

`'Bag' | 'Subspace' | 'AdaBoostM1' | 'AdaBoostM2' | 'GentleBoost' | 'LogitBoost' | 'LPBoost' | 'RobustBoost' | 'RUSBoost' | 'TotalBoost'`

Ensemble aggregation method, specified as the comma-separated pair consisting of `'Method'` and one of the following values.

Value	Method	Classification Problem Support	Related Name-Value Pair Arguments
<code>'Bag'</code>	Bootstrap aggregation (bagging, for example, <code>random forest[2]</code>) — If <code>'Method'</code> is <code>'Bag'</code> , then <code>fitensemble</code> uses bagging with random predictor selections at each split (random forest) by default. To use bagging without the random selections, use tree learners whose <code>'NumVariablesToSample'</code> value is <code>'all'</code> or use discriminant analysis classifier learners.	Binary and multiclass	N/A
<code>'Subspace'</code>	Random subspace	Binary and multiclass	<code>NPredToSample</code>
<code>'AdaBoostM1'</code>	Adaptive boosting	Binary only	<code>LearnRate</code>
<code>'AdaBoostM2'</code>	Adaptive boosting	Multiclass only	<code>LearnRate</code>

Value	Method	Classification Problem Support	Related Name-Value Pair Arguments
'GentleBoost'	Gentle adaptive boosting	Binary only	LearnRate
'LogitBoost'	Adaptive logistic regression	Binary only	LearnRate
'LPBoost'	Linear programming boosting — Requires Optimization Toolbox	Binary and multiclass	MarginPrecision
'RobustBoost'	Robust boosting — Requires Optimization Toolbox	Binary only	RobustErrorGoal, RobustMarginSigma, RobustMaxMargin
'RUSBoost'	Random undersampling boosting	Binary and multiclass	LearnRate, RatioToSmallest
'TotalBoost'	Totally corrective boosting — Requires Optimization Toolbox	Binary and multiclass	MarginPrecision

You can specify sampling options (`FResample`, `Replace`, `Resample`) for training data when you use bagging ('Bag') or boosting ('TotalBoost', 'RUSBoost', 'AdaBoostM1', 'AdaBoostM2', 'GentleBoost', 'LogitBoost', 'RobustBoost', or 'LPBoost').

The defaults are:

- 'LogitBoost' for binary problems and 'AdaBoostM2' for multiclass problems if 'Learners' includes only tree learners
- 'AdaBoostM1' for binary problems and 'AdaBoostM2' for multiclass problems if 'Learners' includes both tree and discriminant analysis learners
- 'Subspace' if 'Learners' does not include tree learners

For details about ensemble aggregation algorithms and examples, see “Algorithms” on page 32-1926, “Tips” on page 32-1924, “Ensemble Algorithms” on page 18-50, and “Choose an Applicable Ensemble Aggregation Method” on page 18-42.

Example: 'Method', 'Bag'

NumLearningCycles — Number of ensemble learning cycles

100 (default) | positive integer | 'AllPredictorCombinations'

Number of ensemble learning cycles, specified as the comma-separated pair consisting of 'NumLearningCycles' and a positive integer or 'AllPredictorCombinations'.

- If you specify a positive integer, then, at every learning cycle, the software trains one weak learner for every template object in Learners. Consequently, the software trains NumLearningCycles* numel(Learners) learners.
- If you specify 'AllPredictorCombinations', then set Method to 'Subspace' and specify one learner only for Learners. With these settings, the software trains learners for all possible combinations of predictors taken NPredToSample at a time. Consequently, the software trains nchoosek(size(X,2),NPredToSample) learners.

The software composes the ensemble using all trained learners and stores them in Mdl.Trained.

For more details, see “Tips” on page 32-1924.

Example: 'NumLearningCycles',500

Data Types: single | double | char | string

Learners — Weak learners to use in ensemble

'discriminant' | 'knn' | 'tree' | weak-learner template object | cell vector of weak-learner template objects

Weak learners to use in the ensemble, specified as the comma-separated pair consisting of 'Learners' and a weak-learner name, weak-learner template object, or cell vector of weak-learner template objects.

Weak Learner	Weak-Learner Name	Template Object Creation Function	Method Setting
Discriminant analysis	'discriminant'	templateDiscriminant	Recommended for 'Subspace'
<i>k</i> -nearest neighbors	'knn'	templateKNN	For 'Subspace' only
Decision tree	'tree'	templateTree	All methods except 'Subspace'

- Weak-learner name ('discriminant', 'knn', or 'tree') — `fitcensemble` uses weak learners created by a template object creation function with default settings. For example, specifying 'Learner', 'discriminant' is the same as specifying 'Learner', `templateDiscriminant()`. See the template object creation function pages for the default settings of a weak learner.
- Weak-learner template object — `fitcensemble` uses the weak learners created by a template object creation function. Use the name-value pair arguments of the template object creation function to specify the settings of the weak learners.
- Cell vector of m weak-learner template objects — `fitcensemble` grows m learners per learning cycle (see `NumLearningCycles`). For example, for an ensemble composed of two types of classification trees, supply `{t1 t2}`, where `t1` and `t2` are classification tree template objects returned by `templateTree`.

The default 'Learners' value is 'knn' if 'Method' is 'Subspace'.

The default 'Learners' value is 'tree' if 'Method' is 'Bag' or any boosting method. The default values of `templateTree()` depend on the value of 'Method'.

- For bagged decision trees, the maximum number of decision splits ('MaxNumSplits') is $n-1$, where n is the number of observations. The number of predictors to select at random for each split ('NumVariablesToSample') is the square root of the number of predictors. Therefore, `fitcensemble` grows deep decision trees. You can grow shallower trees to reduce model complexity or computation time.
- For boosted decision trees, 'MaxNumSplits' is 10 and 'NumVariablesToSample' is 'all'. Therefore, `fitcensemble` grows shallow decision trees. You can grow deeper trees for better accuracy.

For details on the number of learners to train, see `NumLearningCycles` and “Tips” on page 32-1924.

Example: `'Learners', templateTree('MaxNumSplits', 5)`

NPrint — Printout frequency

'off' (default) | positive integer

Printout frequency, specified as the comma-separated pair consisting of 'NPrint' and a positive integer or 'off'.

To track the number of *weak learners* or *folds* that `fitcensemble` trained so far, specify a positive integer. That is, if you specify the positive integer m :

- Without also specifying any cross-validation option (for example, `CrossVal`), then `fitcensemble` displays a message to the command line every time it completes training m weak learners.
- And a cross-validation option, then `fitcensemble` displays a message to the command line every time it finishes training m folds.

If you specify 'off', then `fitcensemble` does not display a message when it completes training weak learners.

Tip When training an ensemble of many weak learners on a large data set, specify a positive integer for `NPrint`.

Example: `'NPrint',5`

Data Types: `single | double | char | string`

NumBins — Number of bins for numeric predictors

`[]`(empty) (default) | positive integer scalar

Number of bins for numeric predictors, specified as the comma-separated pair consisting of 'NumBins' and a positive integer scalar. This argument is valid only when `fitcensemble` uses a tree learner, that is, 'Learner' is either 'tree' or a template object created by using `templateTree`.

- If the 'NumBins' value is empty (default), then the software does not bin any predictors.
- If you specify the 'NumBins' value as a positive integer scalar, then the software bins every numeric predictor into a specified number of equiprobable bins, and then grows trees on the bin indices instead of the original data.
 - If the 'NumBins' value exceeds the number (u) of unique values for a predictor, then `fitcensemble` bins the predictor into u bins.
 - `fitcensemble` does not bin categorical predictors.

When you use a large training data set, this binning option speeds up training but causes a potential decrease in accuracy. You can try `'NumBins',50` first, and then change the 'NumBins' value depending on the accuracy and training speed.

A trained model stores the bin edges in the `BinEdges` property.

Example: `'NumBins',50`

Data Types: `single` | `double`

CategoricalPredictors – Categorical predictors list

vector of positive integers | logical vector | character matrix | string array | cell array of character vectors | `'all'`

Categorical predictors list, specified as the comma-separated pair consisting of `'CategoricalPredictors'` and one of the values in this table.

Value	Description
Vector of positive integers	An entry in the vector is the index value corresponding to the column of the predictor data (<code>X</code> or <code>Tbl</code>) that contains a categorical variable.
Logical vector	A <code>true</code> entry means that the corresponding column of predictor data (<code>X</code> or <code>Tbl</code>) is a categorical variable.
Character matrix	Each row of the matrix is the name of a predictor variable. The names must match the entries in <code>PredictorNames</code> . Pad the names with extra blanks so each row of the character matrix has the same length.
String array or cell array of character vectors	Each element in the array is the name of a predictor variable. The names must match the entries in <code>PredictorNames</code> .
<code>'all'</code>	All predictors are categorical.

Specification of `CategoricalPredictors` is appropriate if:

- `'Learners'` is `'tree'`.
- `'Learners'` is `'knn'` when all predictors are categorical.

By default, if the predictor data is in a table (`Tbl`), `fitcensemble` assumes that a variable is categorical if it contains logical values, categorical values, a string array, or a cell array of character vectors. If the predictor data is a matrix (`X`), `fitcensemble` assumes all predictors are continuous. To identify any categorical predictors when the data is a matrix, use the `'CategoricalPredictors'` name-value pair argument.

Example: `'CategoricalPredictors','all'`

Data Types: `single` | `double` | `logical` | `char` | `string` | `cell`

PredictorNames — Predictor variable names

string array of unique names | cell array of unique character vectors

Predictor variable names, specified as the comma-separated pair consisting of 'PredictorNames' and a string array of unique names or cell array of unique character vectors. The functionality of 'PredictorNames' depends on the way you supply the training data.

- If you supply X and Y, then you can use 'PredictorNames' to give the predictor variables in X names.
 - The order of the names in PredictorNames must correspond to the column order of X. That is, PredictorNames{1} is the name of X(:,1), PredictorNames{2} is the name of X(:,2), and so on. Also, size(X,2) and numel(PredictorNames) must be equal.
 - By default, PredictorNames is {'x1', 'x2', ...}.
- If you supply Tbl, then you can use 'PredictorNames' to choose which predictor variables to use in training. That is, fitcensemble uses only the predictor variables in PredictorNames and the response variable in training.
 - PredictorNames must be a subset of Tbl.Properties.VariableNames and cannot include the name of the response variable.
 - By default, PredictorNames contains the names of all predictor variables.
 - It is a good practice to specify the predictors for training using either 'PredictorNames' or formula only.

Example: 'PredictorNames',
{'SepalLength', 'SepalWidth', 'PetalLength', 'PetalWidth'}

Data Types: string | cell

ResponseName — Response variable name

'Y' (default) | character vector | string scalar

Response variable name, specified as the comma-separated pair consisting of 'ResponseName' and a character vector or string scalar.

- If you supply Y, then you can use 'ResponseName' to specify a name for the response variable.
- If you supply ResponseVarName or formula, then you cannot use 'ResponseName'.

Example: 'ResponseName', 'response'

Data Types: char | string

Cross-Validation Options

CrossVal — Cross-validation flag

'off' (default) | 'on'

Cross-validation flag, specified as the comma-separated pair consisting of 'Crossval' and 'on' or 'off'.

If you specify 'on', then the software implements 10-fold cross-validation.

To override this cross-validation setting, use one of these name-value pair arguments: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`. To create a cross-validated model, you can use one cross-validation name-value pair argument at a time only.

Alternatively, cross-validate later by passing `Mdl` to `crossval` or `crossval`.

Example: 'Crossval', 'on'

CVPartition — Cross-validation partition

[] (default) | `cvpartition` partition object

Cross-validation partition, specified as the comma-separated pair consisting of 'CVPartition' and a `cvpartition` partition object created by `cvpartition`. The partition object specifies the type of cross-validation and the indexing for the training and validation sets.

To create a cross-validated model, you can use one of these four name-value pair arguments only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: Suppose you create a random partition for 5-fold cross-validation on 500 observations by using `cvp = cvpartition(500, 'KFold', 5)`. Then, you can specify the cross-validated model by using 'CVPartition', `cvp`.

Holdout — Fraction of data for holdout validation

scalar value in the range (0,1)

Fraction of the data used for holdout validation, specified as the comma-separated pair consisting of 'Holdout' and a scalar value in the range (0,1). If you specify 'Holdout', `p`, then the software completes these steps:

- 1 Randomly select and reserve $p*100\%$ of the data as validation data, and train the model using the rest of the data.
- 2 Store the compact, trained model in the Trained property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: `'Holdout',0.1`

Data Types: `double` | `single`

KFold — Number of folds

10 (default) | positive integer value greater than 1

Number of folds to use in a cross-validated model, specified as the comma-separated pair consisting of `'KFold'` and a positive integer value greater than 1. If you specify `'KFold',k`, then the software completes these steps:

- 1 Randomly partition the data into k sets.
- 2 For each set, reserve the set as validation data, and train the model using the other $k - 1$ sets.
- 3 Store the k compact, trained models in the cells of a k -by-1 cell vector in the Trained property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: `'KFold',5`

Data Types: `single` | `double`

Leaveout — Leave-one-out cross-validation flag

'off' (default) | 'on'

Leave-one-out cross-validation flag, specified as the comma-separated pair consisting of `'Leaveout'` and `'on'` or `'off'`. If you specify `'Leaveout','on'`, then, for each of the n observations (where n is the number of observations excluding missing observations, specified in the `NumObservations` property of the model), the software completes these steps:

- 1 Reserve the observation as validation data, and train the model using the other $n - 1$ observations.

- 2 Store the n compact, trained models in the cells of an n -by-1 cell vector in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: `'Leaveout', 'on'`

Other Classification Options

ClassNames — Names of classes to use for training

categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Names of classes to use for training, specified as the comma-separated pair consisting of `'ClassNames'` and a categorical, character, or string array, a logical or numeric vector, or a cell array of character vectors. `ClassNames` must have the same data type as `Y`.

If `ClassNames` is a character array, then each element must correspond to one *row* of the array.

Use `ClassNames` to:

- Order the classes during training.
- Specify the order of any input or output argument dimension that corresponds to the class order. For example, use `ClassNames` to specify the order of the dimensions of `Cost` or the column order of classification scores returned by `predict`.
- Select a subset of classes for training. For example, suppose that the set of all distinct class names in `Y` is `{'a', 'b', 'c'}`. To train the model using observations from classes `'a'` and `'c'` only, specify `'ClassNames', {'a', 'c'}`.

The default value for `ClassNames` is the set of all distinct class names in `Y`.

Example: `'ClassNames', {'b', 'g'}`

Data Types: categorical | char | string | logical | single | double | cell

Cost — Misclassification cost

square matrix | structure array

Misclassification cost, specified as the comma-separated pair consisting of `'Cost'` and a square matrix or structure. If you specify:

- The square matrix `Cost`, then `Cost(i, j)` is the cost of classifying a point into class `j` if its true class is `i`. That is, the rows correspond to the true class and the columns correspond to the predicted class. To specify the class order for the corresponding rows and columns of `Cost`, also specify the `ClassNames` name-value pair argument.
- The structure `S`, then it must have two fields:
 - `S.ClassNames`, which contains the class names as a variable of the same data type as `Y`
 - `S.ClassificationCosts`, which contains the cost matrix with rows and columns ordered as in `S.ClassNames`

The default is `ones(K) - eye(K)`, where `K` is the number of distinct classes.

Note `fitcensemble` uses `Cost` to adjust the prior class probabilities specified in `Prior`. Then, `fitcensemble` uses the adjusted prior probabilities for training and resets the cost matrix to its default.

Example: `'Cost',[0 1 2 ; 1 0 2; 2 2 0]`

Data Types: `double` | `single` | `struct`

Prior — Prior probabilities

`'empirical'` (default) | `'uniform'` | numeric vector | structure array

Prior probabilities for each class, specified as the comma-separated pair consisting of `'Prior'` and a value in this table.

Value	Description
<code>'empirical'</code>	The class prior probabilities are the class relative frequencies in <code>Y</code> .
<code>'uniform'</code>	All class prior probabilities are equal to $1/K$, where K is the number of classes.
numeric vector	Each element is a class prior probability. Order the elements according to <code>Mdl.ClassNames</code> or specify the order using the <code>ClassNames</code> name-value pair argument. The software normalizes the elements such that they sum to 1.

Value	Description
structure array	<p>A structure <code>S</code> with two fields:</p> <ul style="list-style-type: none"> • <code>S.ClassNames</code> contains the class names as a variable of the same type as <code>Y</code>. • <code>S.ClassProbs</code> contains a vector of corresponding prior probabilities. The software normalizes the elements such that they sum to 1.

`fitcensemble` normalizes the prior probabilities in `Prior` to sum to 1.

Example: `struct('ClassNames',
{{'setosa','versicolor','virginica'}},'ClassProbs',1:3)`

Data Types: `char` | `string` | `double` | `single` | `struct`

ScoreTransform — Score transformation

'none' (default) | 'doublelogit' | 'invlogit' | 'ismax' | 'logit' | function handle | ...

Score transformation, specified as the comma-separated pair consisting of 'ScoreTransform' and a character vector, string scalar, or function handle.

This table summarizes the available character vectors and string scalars.

Value	Description
'doublelogit'	$1/(1 + e^{-2x})$
'invlogit'	$\log(x / (1 - x))$
'ismax'	Sets the score for the class with the largest score to 1, and sets the scores for all other classes to 0
'logit'	$1/(1 + e^{-x})$
'none' or 'identity'	x (no transformation)
'sign'	-1 for $x < 0$ 0 for $x = 0$ 1 for $x > 0$
'symmetric'	$2x - 1$

Value	Description
'symmetricismax'	Sets the score for the class with the largest score to 1, and sets the scores for all other classes to -1
'symmetriclogit'	$2/(1 + e^{-x}) - 1$

For a MATLAB function or a function you define, use its function handle for score transform. The function handle must accept a matrix (the original scores) and return a matrix of the same size (the transformed scores).

Example: 'ScoreTransform', 'logit'

Data Types: char | string | function_handle

Weights — Observation weights

numeric vector of positive values | name of variable in Tbl

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a numeric vector of positive values or name of a variable in Tbl. The software weighs the observations in each row of X or Tbl with the corresponding value in Weights. The size of Weights must equal the number of rows of X or Tbl.

If you specify the input data as a table Tbl, then Weights can be the name of a variable in Tbl that contains a numeric vector. In this case, you must specify Weights as a character vector or string scalar. For example, if the weights vector W is stored as Tbl.W, then specify it as 'W'. Otherwise, the software treats all columns of Tbl, including W, as predictors or the response when training the model.

The software normalizes Weights to sum up to the value of the prior probability in the respective class.

By default, Weights is ones ($n, 1$), where n is the number of observations in X or Tbl.

Data Types: double | single | char | string

Sampling Options for Boosting Methods and Bagging

FResample — Fraction of training set to resample

1 (default) | positive scalar in (0,1]

Fraction of the training set to resample for every weak learner, specified as the comma-separated pair consisting of 'FResample' and a positive scalar in (0,1].

To use 'FResample', specify 'bag' for Method or set Resample to 'on'.

Example: 'FResample',0.75

Data Types: single | double

Replace — Flag indicating to sample with replacement

'on' (default) | 'off'

Flag indicating sampling with replacement, specified as the comma-separated pair consisting of 'Replace' and 'off' or 'on'.

- For 'on', the software samples the training observations with replacement.
- For 'off', the software samples the training observations without replacement. If you set Resample to 'on', then the software samples training observations assuming uniform weights. If you also specify a boosting method, then the software boosts by reweighting observations.

Unless you set Method to 'bag' or set Resample to 'on', Replace has no effect.

Example: 'Replace','off'

Resample — Flag indicating to resample

'off' | 'on'

Flag indicating to resample, specified as the comma-separated pair consisting of 'Resample' and 'off' or 'on'.

- If Method is a boosting method, then:
 - 'Resample', 'on' specifies to sample training observations using updated weights as the multinomial sampling probabilities.
 - 'Resample', 'off' (default) specifies to reweight observations at every learning iteration.
- If Method is 'bag', then 'Resample' must be 'on'. The software resamples a fraction of the training observations (see FResample) with or without replacement (see Replace).

If you specify to resample using Resample, then it is good practice to resample to entire data set. That is, use the default setting of 1 for FResample.

AdaBoostM1, AdaBoostM2, LogitBoost, and GentleBoost Method Options**LearnRate — Learning rate for shrinkage**

1 (default) | numeric scalar in (0,1]

Learning rate for shrinkage, specified as the comma-separated pair consisting of a numeric scalar in the interval (0,1].

To train an ensemble using shrinkage, set `LearnRate` to a value less than 1, for example, 0.1 is a popular choice. Training an ensemble using shrinkage requires more learning iterations, but often achieves better accuracy.

Example: 'LearnRate',0.1

Data Types: single | double

RUSBoost Method Options**LearnRate — Learning rate for shrinkage**

1 (default) | numeric scalar in (0,1]

Learning rate for shrinkage, specified as the comma-separated pair consisting of a numeric scalar in the interval (0,1].

To train an ensemble using shrinkage, set `LearnRate` to a value less than 1, for example, 0.1 is a popular choice. Training an ensemble using shrinkage requires more learning iterations, but often achieves better accuracy.

Example: 'LearnRate',0.1

Data Types: single | double

RatioToSmallest — Sampling proportion with respect to lowest-represented class

positive numeric scalar | numeric vector of positive values

Sampling proportion with respect to the lowest-represented class, specified as the comma-separated pair consisting of 'RatioToSmallest' and a numeric scalar or numeric vector of positive values with length equal to the number of distinct classes in the training data.

Suppose that there are K classes in the training data and the lowest-represented class has m observations in the training data.

- If you specify the positive numeric scalar s , then `fitcensemble` samples $s*m$ observations from each class, that is, it uses the same sampling proportion for each class. For more details, see “Algorithms” on page 32-2481.
- If you specify the numeric vector $[s1, s2, \dots, sK]$, then `fitcensemble` samples s_i*m observations from class i , $i = 1, \dots, K$. The elements of `RatioToSmallest` correspond to the order of the class names specified using `ClassNames` (see “Tips” on page 32-2479).

The default value is `ones(K,1)`, which specifies to sample m observations from each class.

Example: `'RatioToSmallest',[2,1]`

Data Types: `single` | `double`

LPBoost and TotalBoost Method Options

MarginPrecision — Margin precision to control convergence speed

0.1 (default) | numeric scalar in [0,1]

Margin precision to control convergence speed, specified as the comma-separated pair consisting of `'MarginPrecision'` and a numeric scalar in the interval [0,1]. `MarginPrecision` affects the number of boosting iterations required for convergence.

Tip To train an ensemble using many learners, specify a small value for `MarginPrecision`. For training using a few learners, specify a large value.

Example: `'MarginPrecision',0.5`

Data Types: `single` | `double`

RobustBoost Method Options

RobustErrorGoal — Target classification error

0.1 (default) | nonnegative numeric scalar

Target classification error, specified as the comma-separated pair consisting of `'RobustErrorGoal'` and a nonnegative numeric scalar. The upper bound on possible values depends on the values of `RobustMarginSigma` and `RobustMaxMargin`. However, the upper bound cannot exceed 1.

Tip For a particular training set, usually there is an optimal range for `RobustErrorGoal`. If you set it too low or too high, then the software can produce a model with poor classification accuracy. Try cross-validating to search for the appropriate value.

Example: `'RobustErrorGoal',0.05`

Data Types: `single` | `double`

RobustMarginSigma — Classification margin distribution spread

0.1 (default) | positive numeric scalar

Classification margin distribution spread over the training data, specified as the comma-separated pair consisting of `'RobustMarginSigma'` and a positive numeric scalar. Before specifying `RobustMarginSigma`, consult the literature on `RobustBoost`, for example, [19].

Example: `'RobustMarginSigma',0.5`

Data Types: `single` | `double`

RobustMaxMargin — Maximal classification margin

0 (default) | nonnegative numeric scalar

Maximal classification margin in the training data, specified as the comma-separated pair consisting of `'RobustMaxMargin'` and a nonnegative numeric scalar. The software minimizes the number of observations in the training data having classification margins below `RobustMaxMargin`.

Example: `'RobustMaxMargin',1`

Data Types: `single` | `double`

Random Subspace Method Options

NPredToSample — Number of predictors to sample

1 (default) | positive integer

Number of predictors to sample for each random subspace learner, specified as the comma-separated pair consisting of `'NPredToSample'` and a positive integer in the interval $1, \dots, p$, where p is the number of predictor variables (`size(X,2)` or `size(Tbl,2)`).

Data Types: `single` | `double`

Hyperparameter Optimization

OptimizeHyperparameters — Parameters to optimize

'none' (default) | 'auto' | 'all' | string array or cell array of eligible parameter names | vector of `optimizableVariable` objects

Parameters to optimize, specified as the comma-separated pair consisting of 'OptimizeHyperparameters' and one of the following:

- 'none' — Do not optimize.
- 'auto' — Use {'Method', 'NumLearningCycles', 'LearnRate'} along with the default parameters for the specified Learners:
 - Learners = 'tree' (default) — {'MinLeafSize'}
 - Learners = 'discriminant' — {'Delta', 'Gamma'}
 - Learners = 'knn' — {'Distance', 'NumNeighbors'}

Note For hyperparameter optimization, Learners must be a single argument, not a string array or cell array.

- 'all' — Optimize all eligible parameters.
- String array or cell array of eligible parameter names
- Vector of `optimizableVariable` objects, typically the output of hyperparameters

The optimization attempts to minimize the cross-validation loss (error) for `fitcensemble` by varying the parameters. For information about cross-validation loss (albeit in a different context), see “Classification Loss” on page 32-3352. To control the cross-validation type and other aspects of the optimization, use the `HyperparameterOptimizationOptions` name-value pair.

Note 'OptimizeHyperparameters' values override any values you set using other name-value pair arguments. For example, setting 'OptimizeHyperparameters' to 'auto' causes the 'auto' values to apply.

The eligible parameters for `fitcensemble` are:

- Method — Depends on the number of classes.

- Two classes — Eligible methods are 'Bag', 'GentleBoost', 'LogitBoost', 'AdaBoostM1', and 'RUSBoost'.
- Three or more classes — Eligible methods are 'Bag', 'AdaBoostM2', and 'RUSBoost'.
- NumLearningCycles — fitcensemble searches among positive integers, by default log-scaled with range [10,500].
- LearnRate — fitcensemble searches among positive reals, by default log-scaled with range [1e-3,1].
- The eligible hyperparameters for the chosen Learners:

Learners	Eligible Hyperparameters Bold = Used By Default	Default Range
'discriminant'	Delta	Log-scaled in the range [1e-6,1e3]
	DiscrimType	'linear', 'quadratic', 'diagLinear', 'diagQuadratic', 'pseudoLinear', and 'pseudoQuadratic'
	Gamma	Real values in [0,1]
'knn'	Distance	'cityblock', 'chebychev', 'correlation', 'cosine', 'euclidean', 'hamming', 'jaccard', 'mahalanobis', 'minkowski', 'seuclidean', and 'spearman'
	DistanceWeight	'equal', 'inverse', and 'squaredinverse'
	Exponent	Positive values in [0.5,3]
	NumNeighbors	Positive integer values log-scaled in the range [1, max(2, round(NumObservations/2))]
	Standardize	'true' and 'false'

Learners	Eligible Hyperparameters Bold = Used By Default	Default Range
'tree'	MaxNumSplits	Integers log-scaled in the range [1,max(2,NumObservations-1)]
	MinLeafSize	Integers log-scaled in the range [1,max(2,floor(NumObservations/2))]
	NumVariablesToSample	Integers in the range [1,max(2,NumPredictors)]
	SplitCriterion	'gdi', 'deviance', and 'twoing'

Alternatively, use hyperparameters with your chosen Learners. Note that you must specify the predictor data and response when creating an `optimizableVariable` object.

```
load fisheriris
params = hyperparameters('fitcensemble',meas,species,'Tree');
```

To see the eligible and default hyperparameters, examine `params`.

Set nondefault parameters by passing a vector of `optimizableVariable` objects that have nondefault values. For example,

```
load fisheriris
params = hyperparameters('fitcensemble',meas,species,'Tree');
params(4).Range = [1,30];
```

Pass `params` as the value of `OptimizeHyperparameters`.

By default, iterative display appears at the command line, and plots appear according to the number of hyperparameters in the optimization. For the optimization and plots, the objective function is $\log(1 + \text{cross-validation loss})$ for regression and the misclassification rate for classification. To control the iterative display, set the `Verbose` field of the `'HyperparameterOptimizationOptions'` name-value pair argument. To control the plots, set the `ShowPlots` field of the `'HyperparameterOptimizationOptions'` name-value pair argument.

For an example, see “Optimize Classification Ensemble” on page 32-1887.

```
Example: 'OptimizeHyperparameters',
{'Method', 'NumLearningCycles', 'LearnRate', 'MinLeafSize', 'MaxNumSplits'}
```

HyperparameterOptimizationOptions — Options for optimization

structure

Options for optimization, specified as the comma-separated pair consisting of 'HyperparameterOptimizationOptions' and a structure. This argument modifies the effect of the `OptimizeHyperparameters` name-value pair argument. All fields in the structure are optional.

Field Name	Values	Default
Optimizer	<ul style="list-style-type: none"> 'bayesopt' — Use Bayesian optimization. Internally, this setting calls <code>bayesopt</code>. 'gridsearch' — Use grid search with <code>NumGridDivisions</code> values per dimension. 'randomsearch' — Search at random among <code>MaxObjectiveEvaluations</code> points. <p>'gridsearch' searches in a random order, using uniform sampling without replacement from the grid. After optimization, you can get a table in grid order by using the command <code>sortrows(Mdl.HyperparameterOptimizationResults)</code>.</p>	'bayesopt'

Field Name	Values	Default
AcquisitionFunctionName	<ul style="list-style-type: none"> • 'expected-improvement-per-second-plus' • 'expected-improvement' • 'expected-improvement-plus' • 'expected-improvement-per-second' • 'lower-confidence-bound' • 'probability-of-improvement' <p>Acquisition functions whose names include <code>per-second</code> do not yield reproducible results because the optimization depends on the runtime of the objective function. Acquisition functions whose names include <code>plus</code> modify their behavior when they are overexploiting an area. For more details, see “Acquisition Function Types” on page 10-4.</p>	'expected-improvement-per-second-plus'
MaxObjectiveEvaluations	Maximum number of objective function evaluations.	30 for 'bayesopt' or 'randomsearch', and the entire grid for 'gridsearch'
MaxTime	Time limit, specified as a positive real. The time limit is in seconds, as measured by <code>tic</code> and <code>toc</code> . Run time can exceed <code>MaxTime</code> because <code>MaxTime</code> does not interrupt function evaluations.	Inf
NumGridDivisions	For 'gridsearch', the number of values in each dimension. The value can be a vector of positive integers giving the number of values for each dimension, or a scalar that applies to all dimensions. This field is ignored for categorical variables.	10

Field Name	Values	Default
ShowPlots	Logical value indicating whether to show plots. If <code>true</code> , this field plots the best objective function value against the iteration number. If there are one or two optimization parameters, and if <code>Optimizer</code> is <code>'bayesopt'</code> , then <code>ShowPlots</code> also plots a model of the objective function against the parameters.	<code>true</code>
SaveIntermediateResults	Logical value indicating whether to save results when <code>Optimizer</code> is <code>'bayesopt'</code> . If <code>true</code> , this field overwrites a workspace variable named <code>'BayesoptResults'</code> at each iteration. The variable is a <code>BayesianOptimization</code> object.	<code>false</code>
Verbose	Display to the command line. <ul style="list-style-type: none"> • 0 — No iterative display • 1 — Iterative display • 2 — Iterative display with extra information For details, see the <code>bayesopt</code> <code>Verbose</code> name-value pair argument.	1
UseParallel	Logical value indicating whether to run Bayesian optimization in parallel, which requires Parallel Computing Toolbox. For details, see “Parallel Bayesian Optimization” on page 10-8.	<code>false</code>

Field Name	Values	Default
Repartition	Logical value indicating whether to repartition the cross-validation at every iteration. If <code>false</code> , the optimizer uses a single partition for the optimization. <code>true</code> usually gives the most robust results because this setting takes partitioning noise into account. However, for good results, <code>true</code> requires at least twice as many function evaluations.	<code>false</code>
Use no more than one of the following three field names.		
CVPartition	A <code>cvpartition</code> object, as created by <code>cvpartition</code> .	'Kfold', 5 if you do not specify any cross-validation field
Holdout	A scalar in the range (0, 1) representing the holdout fraction.	
Kfold	An integer greater than 1.	

Example:

```
'HyperparameterOptimizationOptions', struct('MaxObjectiveEvaluations', 60)
```

Data Types: `struct`

Output Arguments

Mdl — Trained classification ensemble model

`ClassificationBaggedEnsemble` model object | `ClassificationEnsemble` model object | `ClassificationPartitionedEnsemble` cross-validated model object

Trained ensemble model, returned as one of the model objects in this table.

Model Object	Specify Any Cross-Validation Options?	Method Setting	Resample Setting
<code>ClassificationBaggedEnsemble</code>	No	'Bag'	'on'

Model Object	Specify Any Cross-Validation Options?	Method Setting	Resample Setting
ClassificationEnsemble	No	Any ensemble aggregation method for classification	'off'
ClassificationPartitionedEnsemble	Yes	Any ensemble aggregation method for classification	'off' or 'on'

The name-value pair arguments that control cross-validation are `CrossVal`, `Holdout`, `KFold`, `Leaveout`, and `CVPartition`.

To reference properties of `Mdl`, use dot notation. For example, to access or display the cell vector of weak learner model objects for an ensemble that has not been cross-validated, enter `Mdl.Trained` at the command line.

Tips

- `NumLearningCycles` can vary from a few dozen to a few thousand. Usually, an ensemble with good predictive power requires from a few hundred to a few thousand weak learners. However, you do not have to train an ensemble for that many cycles at once. You can start by growing a few dozen learners, inspect the ensemble performance and then, if necessary, train more weak learners using `resume` for classification problems.
- Ensemble performance depends on the ensemble setting and the setting of the weak learners. That is, if you specify weak learners with default parameters, then the ensemble can perform poorly. Therefore, like ensemble settings, it is good practice to adjust the parameters of the weak learners using templates, and to choose values that minimize generalization error.
- If you specify to resample using `Resample`, then it is good practice to resample to entire data set. That is, use the default setting of 1 for `FResample`.
- If the ensemble aggregation method (`Method`) is 'bag' and:
 - The misclassification cost (`Cost`) is highly imbalanced, then, for in-bag samples, the software oversamples unique observations from the class that has a large penalty.
 - The class prior probabilities (`Prior`) are highly skewed, the software oversamples unique observations from the class that has a large prior probability.

For smaller sample sizes, these combinations can result in a low relative frequency of out-of-bag observations from the class that has a large penalty or prior probability. Consequently, the estimated out-of-bag error is highly variable and it can be difficult to interpret. To avoid large estimated out-of-bag error variances, particularly for small sample sizes, set a more balanced misclassification cost matrix using `Cost` or a less skewed prior probability vector using `Prior`.

- Because the order of some input and output arguments correspond to the distinct classes in the training data, it is good practice to specify the class order using the `ClassNames` name-value pair argument.
- To determine the class order quickly, remove all observations from the training data that are unclassified (that is, have a missing label), obtain and display an array of all the distinct classes, and then specify the array for `ClassNames`. For example, suppose the response variable (`Y`) is a cell array of labels. This code specifies the class order in the variable `classNames`.

```
Ycat = categorical(Y);  
classNames = categories(Ycat)
```

`categorical` assigns `<undefined>` to unclassified observations and `categories` excludes `<undefined>` from its output. Therefore, if you use this code for cell arrays of labels or similar code for categorical arrays, then you do not have to remove observations with missing labels to obtain a list of the distinct classes.

- To specify that the class order from lowest-represented label to most-represented, then quickly determine the class order (as in the previous bullet), but arrange the classes in the list by frequency before passing the list to `ClassNames`. Following from the previous example, this code specifies the class order from lowest- to most-represented in `classNamesLH`.

```
Ycat = categorical(Y);  
classNames = categories(Ycat);  
freq = countcats(Ycat);  
[~,idx] = sort(freq);  
classNamesLH = classNames(idx);
```

- After training a model, you can generate C/C++ code that predicts labels for new data. Generating C/C++ code requires MATLAB Coder. For details, see “Introduction to Code Generation” on page 31-2.

Algorithms

- For details of ensemble aggregation algorithms, see “Ensemble Algorithms” on page 18-50.
- If you set `Method` to be a boosting algorithm and `Learners` to be decision trees, then the software grows shallow decision trees by default. You can adjust tree depth by specifying the `MaxNumSplits`, `MinLeafSize`, and `MinParentSize` name-value pair arguments using `templateTree`.
- For bagging ('`Method`', '`Bag`'), `fitcensemble` generates in-bag samples by oversampling classes with large misclassification costs and undersampling classes with small misclassification costs. Consequently, out-of-bag samples have fewer observations from classes with large misclassification costs and more observations from classes with small misclassification costs. If you train a classification ensemble using a small data set and a highly skewed cost matrix, then the number of out-of-bag observations per class can be low. Therefore, the estimated out-of-bag error can have a large variance and can be difficult to interpret. The same phenomenon can occur for classes with large prior probabilities.
- For the RUSBoost ensemble aggregation method ('`Method`', '`RUSBoost`'), the name-value pair argument `RatioToSmallest` specifies the sampling proportion for each class with respect to the lowest-represented class. For example, suppose that there are two classes in the training data: *A* and *B*. *A* have 100 observations and *B* have 10 observations. and that the lowest-represented class has *m* observations in the training data.
 - If you set '`RatioToSmallest`', 2, then $s*m = 2*10 = 20$. Consequently, `fitcensemble` trains every learner using 20 observations from class *A* and 20 observations from class *B*. If you set '`RatioToSmallest`', [2 2], then you obtain the same result.
 - If you set '`RatioToSmallest`', [2,1], then $s1*m = 2*10 = 20$ and $s2*m = 1*10 = 10$. Consequently, `fitcensemble` trains every learner using 20 observations from class *A* and 10 observations from class *B*.
- For dual-core systems and above, `fitcensemble` parallelizes training using Intel Threading Building Blocks (TBB). For details on Intel TBB, see <https://software.intel.com/en-us/intel-tbb>.

Extended Capabilities

Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the 'UseParallel' option to true.

To perform parallel hyperparameter optimization, use the 'HyperparameterOptions', struct('UseParallel', true) name-value pair argument in the call to this function.

For more information on parallel hyperparameter optimization, see “Parallel Bayesian Optimization” on page 10-8.

For more general information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

fitcknn

Fit k -nearest neighbor classifier

Syntax

```
Mdl = fitcknn(Tbl,ResponseVarName)
```

```
Mdl = fitcknn(Tbl,formula)
```

```
Mdl = fitcknn(Tbl,Y)
```

```
Mdl = fitcknn(X,Y)
```

```
Mdl = fitcknn( ____,Name,Value)
```

Description

`Mdl = fitcknn(Tbl,ResponseVarName)` returns a k -nearest neighbor classification model based on the input variables (also known as predictors, features, or attributes) in the table `Tbl` and output (response) `Tbl.ResponseVarName`.

`Mdl = fitcknn(Tbl,formula)` returns a k -nearest neighbor classification model based on the input variables in the table `Tbl`. `formula` is an explanatory model of the response and a subset of predictor variables in `Tbl`.

`Mdl = fitcknn(Tbl,Y)` returns a k -nearest neighbor classification model based on the predictor variables in the table `Tbl` and response array `Y`.

`Mdl = fitcknn(X,Y)` returns a k -nearest neighbor classification model based on the predictor data `X` and response `Y`.

`Mdl = fitcknn(____,Name,Value)` fits a model with additional options specified by one or more name-value pair arguments, using any of the previous syntaxes. For example, you can specify the tie-breaking algorithm, distance metric, or observation weights.

Examples

Train k -Nearest Neighbor Classifier

Train a k -nearest neighbor classifier for Fisher's iris data, where k , the number of nearest neighbors in the predictors, is 5.

Load Fisher's iris data.

```
load fisheriris
X = meas;
Y = species;
```

X is a numeric matrix that contains four petal measurements for 150 irises. Y is a cell array of character vectors that contains the corresponding iris species.

Train a 5-nearest neighbor classifier. Standardize the noncategorical predictor data.

```
Mdl = fitcknn(X,Y,'NumNeighbors',5,'Standardize',1)
```

```
Mdl =
  ClassificationKNN
      ResponseName: 'Y'
  CategoricalPredictors: []
      ClassNames: {'setosa' 'versicolor' 'virginica'}
      ScoreTransform: 'none'
  NumObservations: 150
      Distance: 'euclidean'
      NumNeighbors: 5
```

Properties, Methods

Mdl is a trained `ClassificationKNN` classifier, and some of its properties appear in the Command Window.

To access the properties of Mdl , use dot notation.

```
Mdl.ClassNames
```

```
ans = 3x1 cell array
    {'setosa' }
    {'versicolor'}
    {'virginica' }
```

```
Mdl.Prior
```

```
ans = 1×3
```

```
    0.3333    0.3333    0.3333
```

`Mdl.Prior` contains the class prior probabilities, which you can specify using the 'Prior' name-value pair argument in `fitcknn`. The order of the class prior probabilities corresponds to the order of the classes in `Mdl.ClassNames`. By default, the prior probabilities are the respective relative frequencies of the classes in the data.

You can also reset the prior probabilities after training. For example, set the prior probabilities to 0.5, 0.2, and 0.3, respectively.

```
Mdl.Prior = [0.5 0.2 0.3];
```

You can pass `Mdl` to `predict` to label new measurements or `crossval` to cross-validate the classifier.

Train a *k*-Nearest Neighbor Classifier Using the Minkowski Metric

Load Fisher's iris data set.

```
load fisheriris
X = meas;
Y = species;
```

`X` is a numeric matrix that contains four petal measurements for 150 irises. `Y` is a cell array of character vectors that contains the corresponding iris species.

Train a 3-nearest neighbors classifier using the Minkowski metric. To use the Minkowski metric, you must use an exhaustive searcher. It is good practice to standardize noncategorical predictor data.

```
Mdl = fitcknn(X,Y,'NumNeighbors',3,...
    'NSMethod','exhaustive','Distance','minkowski',...
    'Standardize',1);
```

`Mdl` is a `ClassificationKNN` classifier.

You can examine the properties of Mdl by double-clicking Mdl in the Workspace window. This opens the Variable Editor.

Name	Value	Min	Max
Mdl	1x1 ClassificationKNN		
meas	150x4 double	0.1000	7.9
species	150x1 cell		
X	150x4 double	0.1000	7.9
Y	150x1 cell		

Property	Value	Min	Max
NumNeighbors	3	3	3
Distance	'minkowski'		
DistParameter	2	2	2
IncludeTies	0		
DistanceWeight	'equal'		
BreakTies	'smallest'		
NSMethod	'exhaustive'		

Train a k -Nearest Neighbor Classifier Using a Custom Distance Metric

Train a k -nearest neighbor classifier using the chi-square distance.

Load Fisher's iris data set.

```
load fisheriris
X = meas;    % Predictors
Y = species; % Response
```

The chi-square distance between j -dimensional points x and z is

$$\chi(x, z) = \sqrt{\sum_{j=1}^J w_j (x_j - z_j)^2},$$

where w_j is a weight associated with dimension j .

Specify the chi-square distance function. The distance function must:

- Take one row of X , e.g., x , and the matrix Z .
- Compare x to each row of Z .
- Return a vector D of length n_z , where n_z is the number of rows of Z . Each element of D is the distance between the observation corresponding to x and the observations corresponding to each row of Z .

```
chiSqrDist = @(x,Z,wt)sqrt((bsxfun(@minus,x,Z).^2)*wt);
```

This example uses arbitrary weights for illustration.

Train a 3-nearest neighbor classifier. It is good practice to standardize noncategorical predictor data.

```
k = 3;
w = [0.3; 0.3; 0.2; 0.2];
KNNMdl = fitcknn(X,Y,'Distance',@(x,Z)chiSqrDist(x,Z,w),...
    'NumNeighbors',k,'Standardize',1);
```

KNNMdl is a ClassificationKNN classifier.

Cross validate the KNN classifier using the default 10-fold cross validation. Examine the classification error.

```
rng(1); % For reproducibility
CVKNNMdl = crossval(KNNMdl);
classError = kfoldLoss(CVKNNMdl)

classError = 0.0600
```

CVKNNMdl is a `ClassificationPartitionedModel` classifier. The 10-fold classification error is 4%.

Compare the classifier with one that uses a different weighting scheme.

```
w2 = [0.2; 0.2; 0.3; 0.3];
CVKNNMdl2 = fitcknn(X,Y,'Distance',@(x,Z)chiSqrDist(x,Z,w2),...
    'NumNeighbors',k,'KFold',10,'Standardize',1);
classError2 = kfoldLoss(CVKNNMdl2)

classError2 = 0.0400
```

The second weighting scheme yields a classifier that has better out-of-sample performance.

Optimize Fitted KNN Classifier

This example shows how to optimize hyperparameters automatically using `fitcknn`. The example uses the Fisher iris data.

Load the data.

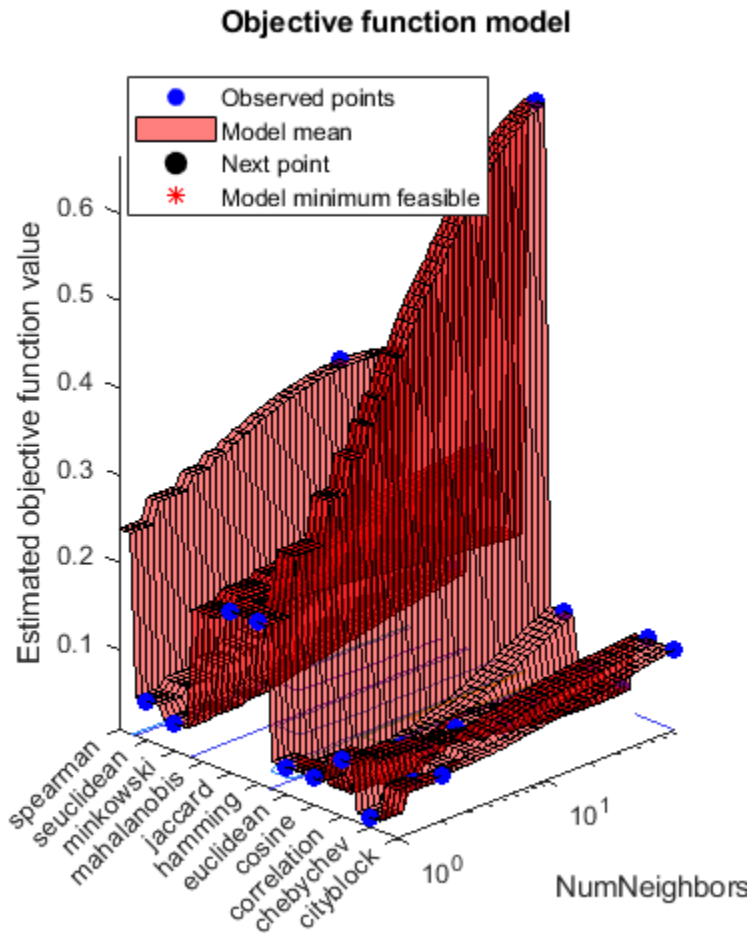

```
load fisheriris
X = meas;
Y = species;
```

Find hyperparameters that minimize five-fold cross-validation loss by using automatic hyperparameter optimization.

For reproducibility, set the random seed and use the 'expected-improvement-plus' acquisition function.

```
rng(1)
Mdl = fitcknn(X,Y,'OptimizeHyperparameters','auto',...
    'HyperparameterOptimizationOptions',...
    struct('AcquisitionFunctionName','expected-improvement-plus'))
```

Properties, Methods

Input Arguments

Tbl — Sample data

table

Sample data used to train the model, specified as a table. Each row of **Tbl** corresponds to one observation, and each column corresponds to one predictor variable. Optionally, **Tbl** can contain one additional column for the response variable. Multicolumn variables and cell arrays other than cell arrays of character vectors are not allowed.

If **Tbl** contains the response variable, and you want to use all remaining variables in **Tbl** as predictors, then specify the response variable by using **ResponseVarName**.

If `Tbl` contains the response variable, and you want to use only a subset of the remaining variables in `Tbl` as predictors, then specify a formula by using `formula`.

If `Tbl` does not contain the response variable, then specify a response variable by using `Y`. The length of the response variable and the number of rows in `Tbl` must be equal.

Data Types: `table`

ResponseVarName — Response variable name

name of variable in `Tbl`

Response variable name, specified as the name of a variable in `Tbl`.

You must specify `ResponseVarName` as a character vector or string scalar. For example, if the response variable `Y` is stored as `Tbl.Y`, then specify it as `'Y'`. Otherwise, the software treats all columns of `Tbl`, including `Y`, as predictors when training the model.

The response variable must be a categorical, character, or string array, logical or numeric vector, or cell array of character vectors. If `Y` is a character array, then each element of the response variable must correspond to one row of the array.

It is a good practice to specify the order of the classes by using the `ClassNames` name-value pair argument.

Data Types: `char` | `string`

formula — Explanatory model of response and subset of predictor variables

character vector | string scalar

Explanatory model of the response and a subset of the predictor variables, specified as a character vector or string scalar in the form `'Y~X1+X2+X3'`. In this form, `Y` represents the response variable, and `X1`, `X2`, and `X3` represent the predictor variables. The variables must be variable names in `Tbl` (`Tbl.Properties.VariableNames`).

To specify a subset of variables in `Tbl` as predictors for training the model, use a formula. If you specify a formula, then the software does not use any variables in `Tbl` that do not appear in `formula`.

Data Types: `char` | `string`

Y — Class labels

categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Class labels, specified as a categorical, character, or string array, a logical or numeric vector, or a cell array of character vectors. Each row of `Y` represents the classification of the corresponding row of `X`.

The software considers `NaN`, `''` (empty character vector), `""` (empty string), `<missing>`, and `<undefined>` values in `Y` to be missing values. Consequently, the software does not train using observations with a missing response.

Data Types: `categorical` | `char` | `string` | `logical` | `single` | `double` | `cell`

X — Predictor data

numeric matrix

Predictor data, specified as numeric matrix.

Each row corresponds to one observation (also known as an instance or example), and each column corresponds to one predictor variable (also known as a feature).

The length of `Y` and the number of rows of `X` must be equal.

To specify the names of the predictors in the order of their appearance in `X`, use the `PredictorNames` name-value pair argument.

Data Types: `double` | `single`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Note You cannot use any cross-validation name-value pair argument along with the `'OptimizeHyperparameters'` name-value pair argument. You can modify the cross-validation for `'OptimizeHyperparameters'` only by using the `'HyperparameterOptimizationOptions'` name-value pair argument.

Example:

`'NumNeighbors', 3, 'NSMethod', 'exhaustive', 'Distance', 'minkowski'` specifies a classifier for three-nearest neighbors using the nearest neighbor search method and the Minkowski metric.

Model Parameters

BreakTies — Tie-breaking algorithm

'smallest' (default) | 'nearest' | 'random'

Tie-breaking algorithm used by the `predict` method if multiple classes have the same smallest cost, specified as the comma-separated pair consisting of `'BreakTies'` and one of the following:

- `'smallest'` — Use the smallest index among tied groups.
- `'nearest'` — Use the class with the nearest neighbor among tied groups.
- `'random'` — Use a random tiebreaker among tied groups.

By default, ties occur when multiple classes have the same number of nearest points among the `K` nearest neighbors.

Example: `'BreakTies', 'nearest'`

BucketSize — Maximum data points in node

50 (default) | positive integer value

Maximum number of data points in the leaf node of the `kd`-tree, specified as the comma-separated pair consisting of `'BucketSize'` and a positive integer value. This argument is meaningful only when `NSMethod` is `'kdtree'`.

Example: `'BucketSize', 40`

Data Types: `single` | `double`

CategoricalPredictors — Categorical predictor flag

[] (default) | 'all'

Categorical predictor flag, specified as the comma-separated pair consisting of `'CategoricalPredictors'` and one of the following:

- `'all'` — All predictors are categorical.
- `[]` — No predictors are categorical.

When you set `CategoricalPredictors` to `'all'`, the default `Distance` is `'hamming'`.

Example: `'CategoricalPredictors', 'all'`

ClassNames — Names of classes to use for training

categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Names of classes to use for training, specified as the comma-separated pair consisting of 'ClassNames' and a categorical, character, or string array, a logical or numeric vector, or a cell array of character vectors. ClassNames must have the same data type as Y.

If ClassNames is a character array, then each element must correspond to one *row* of the array.

Use ClassNames to:

- Order the classes during training.
- Specify the order of any input or output argument dimension that corresponds to the class order. For example, use ClassNames to specify the order of the dimensions of Cost or the column order of classification scores returned by predict.
- Select a subset of classes for training. For example, suppose that the set of all distinct class names in Y is {'a', 'b', 'c'}. To train the model using observations from classes 'a' and 'c' only, specify 'ClassNames', {'a', 'c'}.

The default value for ClassNames is the set of all distinct class names in Y.

Example: 'ClassNames', {'b', 'g'}

Data Types: categorical | char | string | logical | single | double | cell

Cost — Cost of misclassification

square matrix | structure

Cost of misclassification of a point, specified as the comma-separated pair consisting of 'Cost' and one of the following:

- Square matrix, where Cost(i, j) is the cost of classifying a point into class j if its true class is i (i.e., the rows correspond to the true class and the columns correspond to the predicted class). To specify the class order for the corresponding rows and columns of Cost, additionally specify the ClassNames name-value pair argument.
- Structure S having two fields: S.ClassNames containing the group names as a variable of the same type as Y, and S.ClassificationCosts containing the cost matrix.

The default is Cost(i, j)=1 if i~j, and Cost(i, j)=0 if i=j.

Data Types: `single` | `double` | `struct`

Cov — Covariance matrix

`nancov(X)` (default) | positive definite matrix of scalar values

Covariance matrix, specified as the comma-separated pair consisting of 'Cov' and a positive definite matrix of scalar values representing the covariance matrix when computing the Mahalanobis distance. This argument is only valid when 'Distance' is 'mahalanobis'.

You cannot simultaneously specify 'Standardize' and either of 'Scale' or 'Cov'.

Data Types: `single` | `double`

IncludeTies — Tie inclusion flag

`false` (default) | `true`

Tie inclusion flag, specified as the comma-separated pair consisting of 'IncludeTies' and a logical value indicating whether `predict` includes all the neighbors whose distance values are equal to the Kth smallest distance. If `IncludeTies` is `true`, `predict` includes all these neighbors. Otherwise, `predict` uses exactly K neighbors.

Example: `'IncludeTies',true`

Data Types: `logical`

NSMethod — Nearest neighbor search method

`'kdtree'` | `'exhaustive'`

Nearest neighbor search method, specified as the comma-separated pair consisting of 'NSMethod' and 'kdtree' or 'exhaustive'.

- `'kdtree'` — Creates and uses a *kd*-tree to find nearest neighbors. `'kdtree'` is valid when the distance metric is one of the following:
 - `'euclidean'`
 - `'cityblock'`
 - `'minkowski'`
 - `'chebychev'`
- `'exhaustive'` — Uses the exhaustive search algorithm. When predicting the class of a new point `xnew`, the software computes the distance values from all points in `X` to `xnew` to find nearest neighbors.

The default is 'kdtree' when X has 10 or fewer columns, X is not sparse, and the distance metric is a 'kdtree' type; otherwise, 'exhaustive'.

Example: 'NSMethod', 'exhaustive'

PredictorNames — Predictor variable names

string array of unique names | cell array of unique character vectors

Predictor variable names, specified as the comma-separated pair consisting of 'PredictorNames' and a string array of unique names or cell array of unique character vectors. The functionality of 'PredictorNames' depends on the way you supply the training data.

- If you supply X and Y, then you can use 'PredictorNames' to give the predictor variables in X names.
 - The order of the names in PredictorNames must correspond to the column order of X. That is, PredictorNames{1} is the name of X(:,1), PredictorNames{2} is the name of X(:,2), and so on. Also, size(X,2) and numel(PredictorNames) must be equal.
 - By default, PredictorNames is {'x1', 'x2', ...}.
- If you supply Tbl, then you can use 'PredictorNames' to choose which predictor variables to use in training. That is, fitcknn uses only the predictor variables in PredictorNames and the response variable in training.
 - PredictorNames must be a subset of Tbl.Properties.VariableNames and cannot include the name of the response variable.
 - By default, PredictorNames contains the names of all predictor variables.
 - It is a good practice to specify the predictors for training using either 'PredictorNames' or formula only.

Example: 'PredictorNames',
{'SepalLength', 'SepalWidth', 'PetalLength', 'PetalWidth'}

Data Types: string | cell

Prior — Prior probabilities

'empirical' (default) | 'uniform' | vector of scalar values | structure

Prior probabilities for each class, specified as the comma-separated pair consisting of 'Prior' and a value in this table.

Value	Description
'empirical'	The class prior probabilities are the class relative frequencies in Y .
'uniform'	All class prior probabilities are equal to $1/K$, where K is the number of classes.
numeric vector	Each element is a class prior probability. Order the elements according to <code>Mdl.ClassNames</code> or specify the order using the <code>ClassNames</code> name-value pair argument. The software normalizes the elements such that they sum to 1.
structure	A structure S with two fields: <ul style="list-style-type: none"> • <code>S.ClassNames</code> contains the class names as a variable of the same type as Y. • <code>S.ClassProbs</code> contains a vector of corresponding prior probabilities. The software normalizes the elements such that they sum to 1.

If you set values for both `Weights` and `Prior`, the weights are renormalized to add up to the value of the prior probability in the respective class.

Example: 'Prior', 'uniform'

Data Types: char | string | single | double | struct

ResponseName — Response variable name

'Y' (default) | character vector | string scalar

Response variable name, specified as the comma-separated pair consisting of 'ResponseName' and a character vector or string scalar.

- If you supply Y , then you can use 'ResponseName' to specify a name for the response variable.
- If you supply `ResponseVarName` or `formula`, then you cannot use 'ResponseName'.

Example: 'ResponseName', 'response'

Data Types: char | string

Scale — Distance scale

`nanstd(X)` (default) | vector of nonnegative scalar values

Distance scale, specified as the comma-separated pair consisting of 'Scale' and a vector containing nonnegative scalar values with length equal to the number of columns in X. Each coordinate difference between X and a query point is scaled by the corresponding element of Scale. This argument is only valid when 'Distance' is 'seuclidean'.

You cannot simultaneously specify 'Standardize' and either of 'Scale' or 'Cov'.

Data Types: `single` | `double`

ScoreTransform — Score transformation

'none' (default) | 'doublelogit' | 'invlogit' | 'ismax' | 'logit' | function handle | ...

Score transformation, specified as the comma-separated pair consisting of 'ScoreTransform' and a character vector, string scalar, or function handle.

This table summarizes the available character vectors and string scalars.

Value	Description
'doublelogit'	$1/(1 + e^{-2x})$
'invlogit'	$\log(x / (1 - x))$
'ismax'	Sets the score for the class with the largest score to 1, and sets the scores for all other classes to 0
'logit'	$1/(1 + e^{-x})$
'none' or 'identity'	x (no transformation)
'sign'	-1 for $x < 0$ 0 for $x = 0$ 1 for $x > 0$
'symmetric'	$2x - 1$
'symmetricismax'	Sets the score for the class with the largest score to 1, and sets the scores for all other classes to -1
'symmetriclogit'	$2/(1 + e^{-x}) - 1$

For a MATLAB function or a function you define, use its function handle for score transform. The function handle must accept a matrix (the original scores) and return a matrix of the same size (the transformed scores).

Example: 'ScoreTransform', 'logit'

Data Types: char | string | function_handle

Weights — Observation weights

numeric vector of positive values | name of variable in Tbl

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a numeric vector of positive values or name of a variable in Tbl. The software weighs the observations in each row of X or Tbl with the corresponding value in Weights. The size of Weights must equal the number of rows of X or Tbl.

If you specify the input data as a table Tbl, then Weights can be the name of a variable in Tbl that contains a numeric vector. In this case, you must specify Weights as a character vector or string scalar. For example, if the weights vector W is stored as Tbl.W, then specify it as 'W'. Otherwise, the software treats all columns of Tbl, including W, as predictors or the response when training the model.

The software normalizes Weights to sum up to the value of the prior probability in the respective class.

By default, Weights is ones($n, 1$), where n is the number of observations in X or Tbl.

Data Types: double | single | char | string

Cross Validation

CrossVal — Cross-validation flag

'off' (default) | 'on'

Cross-validation flag, specified as the comma-separated pair consisting of 'Crossval' and 'on' or 'off'.

If you specify 'on', then the software implements 10-fold cross-validation.

To override this cross-validation setting, use one of these name-value pair arguments: CVPartition, Holdout, KFold, or Leaveout. To create a cross-validated model, you can use one cross-validation name-value pair argument at a time only.

Alternatively, cross-validate later by passing Mdl to crossval.

Example: `'CrossVal', 'on'`

CVPartition — Cross-validation partition

`[]` (default) | `cvpartition` partition object

Cross-validation partition, specified as the comma-separated pair consisting of `'CVPartition'` and a `cvpartition` partition object created by `cvpartition`. The partition object specifies the type of cross-validation and the indexing for the training and validation sets.

To create a cross-validated model, you can use one of these four name-value pair arguments only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: Suppose you create a random partition for 5-fold cross-validation on 500 observations by using `cvp = cvpartition(500, 'KFold', 5)`. Then, you can specify the cross-validated model by using `'CVPartition', cvp`.

Holdout — Fraction of data for holdout validation

scalar value in the range (0,1)

Fraction of the data used for holdout validation, specified as the comma-separated pair consisting of `'Holdout'` and a scalar value in the range (0,1). If you specify `'Holdout', p`, then the software completes these steps:

- 1 Randomly select and reserve $p*100\%$ of the data as validation data, and train the model using the rest of the data.
- 2 Store the compact, trained model in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: `'Holdout', 0.1`

Data Types: `double` | `single`

KFold — Number of folds

10 (default) | positive integer value greater than 1

Number of folds to use in a cross-validated model, specified as the comma-separated pair consisting of `'KFold'` and a positive integer value greater than 1. If you specify `'KFold', k`, then the software completes these steps:

- 1 Randomly partition the data into k sets.
- 2 For each set, reserve the set as validation data, and train the model using the other $k - 1$ sets.
- 3 Store the k compact, trained models in the cells of a k -by-1 cell vector in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: `'KFold',5`

Data Types: `single` | `double`

Leaveout — Leave-one-out cross-validation flag

`'off'` (default) | `'on'`

Leave-one-out cross-validation flag, specified as the comma-separated pair consisting of `'Leaveout'` and `'on'` or `'off'`. If you specify `'Leaveout', 'on'`, then, for each of the n observations (where n is the number of observations excluding missing observations, specified in the `NumObservations` property of the model), the software completes these steps:

- 1 Reserve the observation as validation data, and train the model using the other $n - 1$ observations.
- 2 Store the n compact, trained models in the cells of an n -by-1 cell vector in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: `'Leaveout', 'on'`

Hyperparameter Optimization

Distance — Distance metric

`'cityblock'` | `'chebychev'` | `'correlation'` | `'cosine'` | `'euclidean'` | `'hamming'` | function handle | ...

Distance metric, specified as the comma-separated pair consisting of `'Distance'` and a valid distance metric name or function handle. The allowable distance metric names depend on your choice of a neighbor-searcher method (see `NSMethod`).

NSMethod	Distance Metric Names
exhaustive	Any distance metric of ExhaustiveSearcher
kdtree	'cityblock', 'chebychev', 'euclidean', or 'minkowski'

This table includes valid distance metrics of ExhaustiveSearcher.

Distance Metric Names	Description
'cityblock'	City block distance.
'chebychev'	Chebychev distance (maximum coordinate difference).
'correlation'	One minus the sample linear correlation between observations (treated as sequences of values).
'cosine'	One minus the cosine of the included angle between observations (treated as vectors).
'euclidean'	Euclidean distance.
'hamming'	Hamming distance, percentage of coordinates that differ.
'jaccard'	One minus the Jaccard coefficient, the percentage of nonzero coordinates that differ.
'mahalanobis'	Mahalanobis distance, computed using a positive definite covariance matrix C. The default value of C is the sample covariance matrix of X, as computed by <code>nancov(X)</code> . To specify a different value for C, use the 'Cov' name-value pair argument.
'minkowski'	Minkowski distance. The default exponent is 2. To specify a different exponent, use the 'Exponent' name-value pair argument.
'seuclidean'	Standardized Euclidean distance. Each coordinate difference between X and a query point is scaled, meaning divided by a scale value S. The default value of S is the standard deviation computed from X, <code>S = nanstd(X)</code> . To specify another value for S, use the Scale name-value pair argument.
'spearman'	One minus the sample Spearman's rank correlation between observations (treated as sequences of values).

Distance Metric Names	Description
@ <i>distfun</i>	<p>Distance function handle. <i>distfun</i> has the form</p> <pre>function D2 = distfun(ZI,ZJ) % calculation of distance ...</pre> <p>where</p> <ul style="list-style-type: none"> • ZI is a 1-by-N vector containing one row of X or Y. • ZJ is an M2-by-N matrix containing multiple rows of X or Y. • D2 is an M2-by-1 vector of distances, and D2(k) is the distance between observations ZI and ZJ(k, :).

If you specify `CategoricalPredictors` as 'all', then the default distance metric is 'hamming'. Otherwise, the default distance metric is 'euclidean'.

For definitions, see “Distance Metrics” on page 18-16.

Example: 'Distance', 'minkowski'

Data Types: char | string | function_handle

DistanceWeight — Distance weighting function

'equal' (default) | 'inverse' | 'squaredinverse' | function handle

Distance weighting function, specified as the comma-separated pair consisting of 'DistanceWeight' and either a function handle or one of the values in this table.

Value	Description
'equal'	No weighting
'inverse'	Weight is 1/distance
'squaredinverse'	Weight is 1/distance ²
@ <i>fcn</i>	<i>fcn</i> is a function that accepts a matrix of nonnegative distances, and returns a matrix the same size containing nonnegative distance weights. For example, 'squaredinverse' is equivalent to @(d)d.^(-2).

Example: 'DistanceWeight', 'inverse'

Data Types: `char` | `string` | `function_handle`

Exponent — Minkowski distance exponent

2 (default) | positive scalar value

Minkowski distance exponent, specified as the comma-separated pair consisting of 'Exponent' and a positive scalar value. This argument is only valid when 'Distance' is 'minkowski'.

Example: 'Exponent',3

Data Types: `single` | `double`

NumNeighbors — Number of nearest neighbors to find

1 (default) | positive integer value

Number of nearest neighbors in X to find for classifying each point when predicting, specified as the comma-separated pair consisting of 'NumNeighbors' and a positive integer value.

Example: 'NumNeighbors',3

Data Types: `single` | `double`

Standardize — Flag to standardize predictors

false (default) | true

Flag to standardize the predictors, specified as the comma-separated pair consisting of 'Standardize' and true (1) or false (0).

If you set 'Standardize', true, then the software centers and scales each column of the predictor data (X) by the column mean and standard deviation, respectively.

The software does not standardize categorical predictors, and throws an error if all predictors are categorical.

You cannot simultaneously specify 'Standardize', 1 and either of 'Scale' or 'Cov'.

It is good practice to standardize the predictor data.

Example: 'Standardize',true

Data Types: `logical`

Hyperparameter Optimization

OptimizeHyperparameters — Parameters to optimize

'none' (default) | 'auto' | 'all' | string array or cell array of eligible parameter names | vector of `optimizableVariable` objects

Parameters to optimize, specified as the comma-separated pair consisting of 'OptimizeHyperparameters' and one of the following:

- 'none' — Do not optimize.
- 'auto' — Use {'Distance', 'NumNeighbors'}.
- 'all' — Optimize all eligible parameters.
- String array or cell array of eligible parameter names.
- Vector of `optimizableVariable` objects, typically the output of hyperparameters.

The optimization attempts to minimize the cross-validation loss (error) for `fitcknn` by varying the parameters. For information about cross-validation loss (albeit in a different context), see “Classification Loss” on page 32-3352. To control the cross-validation type and other aspects of the optimization, use the `HyperparameterOptimizationOptions` name-value pair.

Note 'OptimizeHyperparameters' values override any values you set using other name-value pair arguments. For example, setting 'OptimizeHyperparameters' to 'auto' causes the 'auto' values to apply.

The eligible parameters for `fitcknn` are:

- `Distance` — `fitcknn` searches among 'cityblock', 'chebychev', 'correlation', 'cosine', 'euclidean', 'hamming', 'jaccard', 'mahalanobis', 'minkowski', 'seuclidean', and 'spearman'.
- `DistanceWeight` — `fitcknn` searches among 'equal', 'inverse', and 'squaredinverse'.
- `Exponent` — `fitcknn` searches among positive real values, by default in the range [0.5,3].
- `NumNeighbors` — `fitcknn` searches among positive integer values, by default log-scaled in the range [1, max(2, round(NumObservations/2))].
- `Standardize` — `fitcknn` searches among the values 'true' and 'false'.

Set nondefault parameters by passing a vector of `optimizableVariable` objects that have nondefault values. For example,

```
load fisheriris
params = hyperparameters('fitcknn',meas,species);
params(1).Range = [1,20];
```

Pass `params` as the value of `OptimizeHyperparameters`.

By default, iterative display appears at the command line, and plots appear according to the number of hyperparameters in the optimization. For the optimization and plots, the objective function is $\log(1 + \text{cross-validation loss})$ for regression and the misclassification rate for classification. To control the iterative display, set the `Verbose` field of the `'HyperparameterOptimizationOptions'` name-value pair argument. To control the plots, set the `ShowPlots` field of the `'HyperparameterOptimizationOptions'` name-value pair argument.

For an example, see “Optimize Fitted KNN Classifier” on page 32-1934.

Example: 'auto'

HyperparameterOptimizationOptions — Options for optimization structure

Options for optimization, specified as the comma-separated pair consisting of `'HyperparameterOptimizationOptions'` and a structure. This argument modifies the effect of the `OptimizeHyperparameters` name-value pair argument. All fields in the structure are optional.

Field Name	Values	Default
Optimizer	<ul style="list-style-type: none"> • 'bayesopt' — Use Bayesian optimization. Internally, this setting calls bayesopt. • 'gridsearch' — Use grid search with NumGridDivisions values per dimension. • 'randomsearch' — Search at random among MaxObjectiveEvaluations points. <p>'gridsearch' searches in a random order, using uniform sampling without replacement from the grid. After optimization, you can get a table in grid order by using the command <code>sortrows(Mdl.HyperparameterOptimizationResults)</code>.</p>	'bayesopt'
AcquisitionFunctionName	<ul style="list-style-type: none"> • 'expected-improvement-per-second-plus' • 'expected-improvement' • 'expected-improvement-plus' • 'expected-improvement-per-second' • 'lower-confidence-bound' • 'probability-of-improvement' <p>Acquisition functions whose names include <code>per-second</code> do not yield reproducible results because the optimization depends on the runtime of the objective function. Acquisition functions whose names include <code>plus</code> modify their behavior when they are overexploiting an area. For more details, see “Acquisition Function Types” on page 10-4.</p>	'expected-improvement-per-second-plus'

Field Name	Values	Default
MaxObjectiveEvaluations	Maximum number of objective function evaluations.	30 for 'bayesopt' or 'randomsearch', and the entire grid for 'gridsearch'
MaxTime	Time limit, specified as a positive real. The time limit is in seconds, as measured by tic and toc. Run time can exceed MaxTime because MaxTime does not interrupt function evaluations.	Inf
NumGridDivisions	For 'gridsearch', the number of values in each dimension. The value can be a vector of positive integers giving the number of values for each dimension, or a scalar that applies to all dimensions. This field is ignored for categorical variables.	10
ShowPlots	Logical value indicating whether to show plots. If true, this field plots the best objective function value against the iteration number. If there are one or two optimization parameters, and if Optimizer is 'bayesopt', then ShowPlots also plots a model of the objective function against the parameters.	true
SaveIntermediateResults	Logical value indicating whether to save results when Optimizer is 'bayesopt'. If true, this field overwrites a workspace variable named 'BayesoptResults' at each iteration. The variable is a BayesianOptimization object.	false

Field Name	Values	Default
Verbose	Display to the command line. <ul style="list-style-type: none"> • 0 — No iterative display • 1 — Iterative display • 2 — Iterative display with extra information For details, see the <code>bayesopt</code> <code>Verbose</code> name-value pair argument.	1
UseParallel	Logical value indicating whether to run Bayesian optimization in parallel, which requires Parallel Computing Toolbox. For details, see “Parallel Bayesian Optimization” on page 10-8.	false
Repartition	Logical value indicating whether to repartition the cross-validation at every iteration. If <code>false</code> , the optimizer uses a single partition for the optimization. <code>true</code> usually gives the most robust results because this setting takes partitioning noise into account. However, for good results, <code>true</code> requires at least twice as many function evaluations.	false
Use no more than one of the following three field names.		
CVPartition	A <code>cvpartition</code> object, as created by <code>cvpartition</code> .	'Kfold', 5 if you do not specify any cross-validation field
Holdout	A scalar in the range (0, 1) representing the holdout fraction.	
Kfold	An integer greater than 1.	

Example:

```
'HyperparameterOptimizationOptions', struct('MaxObjectiveEvaluations', 60)
```

Data Types: struct

Output Arguments

Mdl — Trained *k*-nearest neighbor classification model

`ClassificationKNN` model object | `ClassificationPartitionedModel` cross-validated model object

Trained *k*-nearest neighbor classification model, returned as a `ClassificationKNN` model object or a `ClassificationPartitionedModel` cross-validated model object.

If you set any of the name-value pair arguments `KFold`, `Holdout`, `CrossVal`, or `CVPartition`, then `Mdl` is a `ClassificationPartitionedModel` cross-validated model object. Otherwise, `Mdl` is a `ClassificationKNN` model object.

To reference properties of `Mdl`, use dot notation. For example, to display the distance metric at the Command Window, enter `Mdl.Distance`.

Definitions

Prediction

`ClassificationKNN` predicts the classification of a point `xnew` using a procedure equivalent to this:

- 1 Find the `NumNeighbors` points in the training set `X` that are nearest to `xnew`.
- 2 Find the `NumNeighbors` response values `Y` to those nearest points.
- 3 Assign the classification label `ynew` that has the largest posterior probability among the values in `Y`.

For details, see “Posterior Probability” on page 32-5188 in the `predict` documentation.

Tips

After training a model, you can generate C/C++ code that predicts labels for new data. Generating C/C++ code requires MATLAB Coder. For details, see “Introduction to Code Generation” on page 31-2.

Algorithms

- NaNs or <undefined>s indicate missing observations. The following describes the behavior of `fitcknn` when the data set or weights contain missing observations.
 - If any value of Y or any weight is missing, then `fitcknn` removes those values from Y , the weights, and the corresponding rows of X from the data. The software renormalizes the weights to sum to 1.
 - If you specify to standardize predictors (`'Standardize', 1`) or the standardized Euclidean distance (`'Distance', 'seuclidean'`) without a scale, then `fitcknn` removes missing observations from individual predictors before computing the mean and standard deviation. In other words, the software implements `nanmean` and `nanstd` on each predictor.
 - If you specify the Mahalanobis distance (`'Distance', 'mahalanobis'`) without its covariance matrix, then `fitcknn` removes rows of X that contain at least one missing value. In other words, the software implements `nancov` on the predictor matrix X .
- Suppose that you set `'Standardize', 1`.

- If you also specify `Prior` or `Weights`, then the software takes the observation weights into account. Specifically, the weighted mean of predictor j is

$$\bar{x}_j = \sum_{B_j} w_k x_{jk}$$

and the weighted standard deviation is

$$s_j = \sum_{B_j} w_k (x_{jk} - \bar{x}_j),$$

where B_j is the set of indices k for which x_{jk} and w_k are not missing.

- If you also set `'Distance', 'mahalanobis'` or `'Distance', 'seuclidean'`, then you cannot specify `Scale` or `Cov`. Instead, the software:
 - 1 Computes the means and standard deviations of each predictor
 - 2 Standardizes the data using the results of step 1
 - 3 Computes the distance parameter values using their respective default.
- If you specify `Scale` and either of `Prior` or `Weights`, then the software scales observed distances by the weighted standard deviations.

- If you specify `Cov` and either of `Prior` or `Weights`, then the software applies the weighted covariance matrix to the distances. In other words,

$$Cov = \frac{\sum_B w_j}{\left(\sum_B w_j\right)^2 - \sum_B w_j^2} \sum_B w_j (x_j - \bar{x})(x_j - \bar{x}),$$

where B is the set of indices j for which the observation x_j does not have any missing values and w_j is not missing.

Alternatives

Although `fitcknn` can train a multiclass KNN classifier, you can reduce a multiclass learning problem to a series of KNN binary learners using `fitcecoc`.

Extended Capabilities

Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the `'UseParallel'` option to `true`.

To perform parallel hyperparameter optimization, use the `'HyperparameterOptions'`, `struct('UseParallel', true)` name-value pair argument in the call to this function.

For more information on parallel hyperparameter optimization, see “Parallel Bayesian Optimization” on page 10-8.

For more general information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

fitclinear

Fit linear classification model to high-dimensional data

`fitclinear` trains linear classification models for two-class (binary) learning with high-dimensional, full or sparse predictor data. Available linear classification models include regularized support vector machines (SVM) and logistic regression models. `fitclinear` minimizes the objective function using techniques that reduce computing time (e.g., stochastic gradient descent).

For reduced computation time on a high-dimensional data set that includes many predictor variables, train a linear classification model by using `fitclinear`. For low-through medium-dimensional predictor data sets, see “Alternatives for Lower-Dimensional Data” on page 32-2002.

To train a linear classification model for multiclass learning by combining SVM or logistic regression binary classifiers using error-correcting output codes, see `fitcecoc`.

Syntax

```
Mdl = fitclinear(X,Y)
Mdl = fitclinear(X,Y,Name,Value)
[Mdl,FitInfo] = fitclinear(____)
[Mdl,FitInfo,HyperparameterOptimizationResults] = fitclinear(____)
```

Description

`Mdl = fitclinear(X,Y)` returns a trained linear classification model object that contains the results of fitting a binary support vector machine to the predictors `X` and class labels `Y`.

`Mdl = fitclinear(X,Y,Name,Value)` returns a trained linear classification model with additional options specified by one or more `Name,Value` pair arguments. For example, you can specify that the columns of the predictor matrix correspond to observations, implement logistic regression, or specify to cross-validate. It is good practice to cross-validate using the `Kfold Name,Value` pair argument. The cross-validation results determine how well the model generalizes.

`[Mdl,FitInfo] = fitclinear(___)` also returns optimization details using any of the previous syntaxes. You cannot request `FitInfo` for cross-validated models.

`[Mdl,FitInfo,HyperparameterOptimizationResults] = fitclinear(___)` also returns hyperparameter optimization details when you pass an `OptimizeHyperparameters` name-value pair.

Examples

Train Linear Classification Model

Train a binary, linear classification model using support vector machines, dual SGD, and ridge regularization.

Load the NLP data set.

```
load nlpdata
```

`X` is a sparse matrix of predictor data, and `Y` is a categorical vector of class labels. There are more than two classes in the data.

Identify the labels that correspond to the Statistics and Machine Learning Toolbox™ documentation web pages.

```
Ystats = Y == 'stats';
```

Train a binary, linear classification model that can identify whether the word counts in a documentation web page are from the Statistics and Machine Learning Toolbox™ documentation. Train the model using the entire data set. Determine how well the optimization algorithm fit the model to the data by extracting a fit summary.

```
rng(1); % For reproducibility
[Mdl,FitInfo] = fitclinear(X,Ystats)
```

```
Mdl =
  ClassificationLinear
    ResponseName: 'Y'
    ClassNames: [0 1]
    ScoreTransform: 'none'
             Beta: [34023x1 double]
             Bias: -1.0059
```

```
Lambda: 3.1674e-05  
Learner: 'svm'
```

Properties, Methods

```
FitInfo = struct with fields:  
    Lambda: 3.1674e-05  
    Objective: 5.3783e-04  
    PassLimit: 10  
    NumPasses: 10  
    BatchLimit: []  
    NumIterations: 238561  
    GradientNorm: NaN  
    GradientTolerance: 0  
    RelativeChangeInBeta: 0.0562  
    BetaTolerance: 1.0000e-04  
    DeltaGradient: 1.4582  
    DeltaGradientTolerance: 1  
    TerminationCode: 0  
    TerminationStatus: {'Iteration limit exceeded.'}  
    Alpha: [31572x1 double]  
    History: []  
    FitTime: 0.2454  
    Solver: {'dual'}
```

`Mdl` is a `ClassificationLinear` model. You can pass `Mdl` and the training or new data to `loss` to inspect the in-sample classification error. Or, you can pass `Mdl` and new predictor data to `predict` to predict class labels for new observations.

`FitInfo` is a structure array containing, among other things, the termination status (`TerminationStatus`) and how long the solver took to fit the model to the data (`FitTime`). It is good practice to use `FitInfo` to determine whether optimization-termination measurements are satisfactory. Because training time is small, you can try to retrain the model, but increase the number of passes through the data. This can improve measures like `DeltaGradient`.

Find Good Lasso Penalty Using Cross-Validation

To determine a good lasso-penalty strength for a linear classification model that uses a logistic regression learner, implement 5-fold cross-validation.

Load the NLP data set.

```
load nlpdata
```

X is a sparse matrix of predictor data, and Y is a categorical vector of class labels. There are more than two classes in the data.

The models should identify whether the word counts in a web page are from the Statistics and Machine Learning Toolbox™ documentation. So, identify the labels that correspond to the Statistics and Machine Learning Toolbox™ documentation web pages.

```
Ystats = Y == 'stats';
```

Create a set of 11 logarithmically-spaced regularization strengths from 10^{-6} through $10^{-0.5}$.

```
Lambda = logspace(-6, -0.5, 11);
```

Cross-validate the models. To increase execution speed, transpose the predictor data and specify that the observations are in columns. Estimate the coefficients using SpARSA. Lower the tolerance on the gradient of the objective function to $1e-8$.

```
X = X';
rng(10); % For reproducibility
CVMdl = fitlinear(X, Ystats, 'ObservationsIn', 'columns', 'KFold', 5, ...
    'Learner', 'logistic', 'Solver', 'sparsa', 'Regularization', 'lasso', ...
    'Lambda', Lambda, 'GradientTolerance', 1e-8)
```

```
CVMdl =
  classreg.learning.partition.ClassificationPartitionedLinear
  CrossValidatedModel: 'Linear'
  ResponseName: 'Y'
  NumObservations: 31572
  KFold: 5
  Partition: [1×1 cvpartition]
  ClassNames: [0 1]
  ScoreTransform: 'none'
```

Properties, Methods

```
numCLModels = numel(CVMdl.Trained)
```

```
numCLModels = 5
```

`CVMdl` is a `ClassificationPartitionedLinear` model. Because `fitclinear` implements 5-fold cross-validation, `CVMdl` contains 5 `ClassificationLinear` models that the software trains on each fold.

Display the first trained linear classification model.

```
Mdl1 = CVMdl.Trained{1}
```

```
Mdl1 =
```

```
ClassificationLinear
```

```
    ResponseName: 'Y'
```

```
    ClassNames: [0 1]
```

```
    ScoreTransform: 'logit'
```

```
        Beta: [34023×11 double]
```

```
        Bias: [-13.2904 -13.2904 -13.2904 -13.2904 -9.9357 -7.0782 -5.4335 -4.547
```

```
        Lambda: [1.0000e-06 3.5481e-06 1.2589e-05 4.4668e-05 1.5849e-04 5.6234e-04
```

```
        Learner: 'logistic'
```

Properties, Methods

`Mdl1` is a `ClassificationLinear` model object. `fitclinear` constructed `Mdl1` by training on the first four folds. Because `Lambda` is a sequence of regularization strengths, you can think of `Mdl1` as 11 models, one for each regularization strength in `Lambda`.

Estimate the cross-validated classification error.

```
ce = kfoldLoss(CVMdl);
```

Because there are 11 regularization strengths, `ce` is a 1-by-11 vector of classification error rates.

Higher values of `Lambda` lead to predictor variable sparsity, which is a good quality of a classifier. For each regularization strength, train a linear classification model using the entire data set and the same options as when you cross-validated the models. Determine the number of nonzero coefficients per model.

```
Mdl = fitclinear(X,Ystats,'ObservationsIn','columns',...  
    'Learner','logistic','Solver','sparsa','Regularization','lasso',...  
    'Lambda',Lambda,'GradientTolerance',1e-8);  
numNZCoeff = sum(Mdl.Beta~=0);
```

In the same figure, plot the cross-validated, classification error rates and frequency of nonzero coefficients for each regularization strength. Plot all variables on the log scale.

```
figure;  
[h,hL1,hL2] = plotyy(log10(Lambda),log10(ce),...  
    log10(Lambda),log10(numNZCoeff));  
hL1.Marker = 'o';  
hL2.Marker = 'o';  
ylabel(h(1),'log10 classification error')  
ylabel(h(2),'log10 nonzero-coefficient frequency')  
xlabel('log10 Lambda')  
title('Test-Sample Statistics')  
hold off
```

Choose the index of the regularization strength that balances predictor variable sparsity and low classification error. In this case, a value between 10^{-4} to 10^{-1} should suffice.

```
idxFinal = 7;
```

Select the model from `Mdl` with the chosen regularization strength.

```
MdlFinal = selectModels(Mdl,idxFinal);
```

`MdlFinal` is a `ClassificationLinear` model containing one regularization strength. To estimate labels for new observations, pass `MdlFinal` and the new data to `predict`.

Optimize Linear Classifier

This example shows how to minimize the cross-validation error in a linear classifier using `fitclinear`. The example uses the NLP data set.

Load the NLP data set.

```
load nlpdata
```

X is a sparse matrix of predictor data, and Y is a categorical vector of class labels. There are more than two classes in the data.

The models should identify whether the word counts in a web page are from the Statistics and Machine Learning Toolbox™ documentation. Identify the relevant labels.

```
X = X';
Ystats = Y == 'stats';
```

Optimize the classification using the 'auto' parameters.

For reproducibility, set the random seed and use the 'expected-improvement-plus' acquisition function.

```
rng default
Mdl = fitclinear(X,Ystats,'ObservationsIn','columns','Solver','sparsa',...
    'OptimizeHyperparameters','auto','HyperparameterOptimizationOptions',...
    struct('AcquisitionFunctionName','expected-improvement-plus'))
```

Properties, Methods

Input Arguments

X — Predictor data

full matrix | sparse matrix

Predictor data, specified as an n -by- p full or sparse matrix.

The length of Y and the number of observations in X must be equal.

Note If you orient your predictor matrix so that observations correspond to columns and specify 'ObservationsIn', 'columns', then you might experience a significant reduction in optimization-execution time.

Data Types: single | double

Y — Class labels

categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Class labels to which the classification model is trained, specified as a categorical, character, or string array, logical or numeric vector, or cell array of character vectors.

- `fitclinear` only supports binary classification. Either Y must contain exactly two distinct classes, or you must specify two classes for training using the 'ClassNames' name-value pair argument. For multiclass learning, see `fitcecoc`.
- If Y is a character array, then each element must correspond to one row of the array.
- The length of Y and the number of observations in X must be equal.
- It is good practice to specify the class order using the `ClassNames` name-value pair argument.

Data Types: char | string | cell | categorical | logical | single | double

Note `fitclinear` removes missing observations, that is, observations with any of these characteristics:

- NaN, empty character vector (' '), empty string (""), <missing>, and <undefined> elements in the response (Y or `ValidationData{2}`)

- At least one NaN value in a predictor observation (row in `X` or `ValidationData{1}`)
- NaN value or 0 weight (`Weights` or `ValidationData{3}`)

For memory-usage economy, it is best practice to remove observations containing missing values from your training data manually before training.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Note You cannot use any cross-validation name-value pair argument along with the `'OptimizeHyperparameters'` name-value pair argument. You can modify the cross-validation for `'OptimizeHyperparameters'` only by using the `'HyperparameterOptimizationOptions'` name-value pair argument.

Example:

`'ObservationsIn', 'columns', 'Learner', 'logistic', 'CrossVal', 'on'` specifies that the columns of the predictor matrix corresponds to observations, to implement logistic regression, to implement 10-fold cross-validation.

Linear Classification Options

Lambda — Regularization term strength

`'auto'` (default) | nonnegative scalar | vector of nonnegative values

Regularization term strength, specified as the comma-separated pair consisting of `'Lambda'` and `'auto'`, a nonnegative scalar, or a vector of nonnegative values.

- For `'auto'`, $\text{Lambda} = 1/n$.
 - If you specify a cross-validation, name-value pair argument (e.g., `CrossVal`), then n is the number of in-fold observations.
 - Otherwise, n is the training sample size.
- For a vector of nonnegative values, the software sequentially optimizes the objective function for each distinct value in `Lambda` in ascending order.

- If Solver is 'sgd' or 'asgd' and Regularization is 'lasso', then the software does not use the previous coefficient estimates as a warm start on page 32-2002 for the next optimization iteration. Otherwise, the software uses warm starts.
- If Regularization is 'lasso', then any coefficient estimate of 0 retains its value when the software optimizes using subsequent values in Lambda.

Returns coefficient estimates for all optimization iterations.

Example: 'Lambda', 10.^(-(10:-2:2))

Data Types: char | string | double | single

Learner — Linear classification model type

'svm' (default) | 'logistic'

Linear classification model type, specified as the comma-separated pair consisting of 'Learner' and 'svm' or 'logistic'.

In this table, $f(x) = x\beta + b$.

- β is a vector of p coefficients.
- x is an observation from p predictor variables.
- b is the scalar bias.

Value	Algorithm	Response Range	Loss Function
'svm'	Support vector machine	$y \in \{-1, 1\}$; 1 for the positive class and -1 otherwise	Hinge: $\ell[y, f(x)] = \max[0, 1 - yf(x)]$
'logistic'	Logistic regression	Same as 'svm'	Deviance (logistic): $\ell[y, f(x)] = \log\{1 + \exp[-yf(x)]\}$

Example: 'Learner', 'logistic'

ObservationsIn — Predictor data observation dimension

'rows' (default) | 'columns'

Predictor data observation dimension, specified as the comma-separated pair consisting of 'ObservationsIn' and 'columns' or 'rows'.

Note If you orient your predictor matrix so that observations correspond to columns and specify 'ObservationsIn', 'columns', then you might experience a significant reduction in optimization-execution time.

Regularization — Complexity penalty type

'lasso' | 'ridge'

Complexity penalty type, specified as the comma-separated pair consisting of 'Regularization' and 'lasso' or 'ridge'.

The software composes the objective function for minimization from the sum of the average loss function (see Learner) and the regularization term in this table.

Value	Description
'lasso'	Lasso (L1) penalty: $\lambda \sum_{j=1}^p \beta_j $
'ridge'	Ridge (L2) penalty: $\frac{\lambda}{2} \sum_{j=1}^p \beta_j^2$

To specify the regularization term strength, which is λ in the expressions, use Lambda.

The software excludes the bias term (β_0) from the regularization penalty.

If Solver is 'sparsa', then the default value of Regularization is 'lasso'. Otherwise, the default is 'ridge'.

Tip

- For predictor variable selection, specify 'lasso'.
 - For optimization accuracy, specify 'ridge'.
-

Example: 'Regularization', 'lasso'

Solver — Objective function minimization technique

'sgd' | 'asgd' | 'dual' | 'bfgs' | 'lbfgs' | 'sparsa' | string array | cell array of character vectors

Objective function minimization technique, specified as the comma-separated pair consisting of 'Solver' and a character vector or string scalar, a string array, or a cell array of character vectors with values from this table.

Value	Description	Restrictions
'sgd'	Stochastic gradient descent (SGD) [5][3]	
'asgd'	Average stochastic gradient descent (ASGD) [8]	
'dual'	Dual SGD for SVM [2][7]	Regularization must be 'ridge' and Learner must be 'svm'.
'bfgs'	Broyden-Fletcher-Goldfarb-Shanno quasi-Newton algorithm (BFGS) [4]	Inefficient if X is very high-dimensional.
'lbfgs'	Limited-memory BFGS (LBFGS) [4]	Regularization must be 'ridge'.
'sparsa'	Sparse Reconstruction by Separable Approximation (SpARSA) [6]	Regularization must be 'lasso'.

If you specify:

- A ridge penalty (see `Regularization`) and X contains 100 or fewer predictor variables, then the default solver is 'bfgs'.
- An SVM model (see `Learner`), a ridge penalty, and X contains more than 100 predictor variables, then the default solver is 'dual'.
- A lasso penalty and X contains 100 or fewer predictor variables, then the default solver is 'sparsa'.

Otherwise, the default solver is 'sgd'.

If you specify a string array or cell array of solver names, then the software uses all solvers in the specified order for each `Lambda`.

For more details on which solver to choose, see “Tips” on page 32-2003.

Example: 'Solver', {'sgd', 'lbfgs'}

Beta — Initial linear coefficient estimates

zeros($p, 1$) (default) | numeric vector | numeric matrix

Initial linear coefficient estimates (β), specified as the comma-separated pair consisting of 'Beta' and a p -dimensional numeric vector or a p -by- L numeric matrix. p is the number of predictor variables in X and L is the number of regularization-strength values (for more details, see Lambda).

- If you specify a p -dimensional vector, then the software optimizes the objective function L times using this process.
 - 1 The software optimizes using Beta as the initial value and the minimum value of Lambda as the regularization strength.
 - 2 The software optimizes again using the resulting estimate from the previous optimization as a warm start on page 32-2002, and the next smallest value in Lambda as the regularization strength.
 - 3 The software implements step 2 until it exhausts all values in Lambda.
- If you specify a p -by- L matrix, then the software optimizes the objective function L times. At iteration j , the software uses Beta($:, j$) as the initial value and, after it sorts Lambda in ascending order, uses Lambda(j) as the regularization strength.

If you set 'Solver', 'dual', then the software ignores Beta.

Data Types: single | double

Bias — Initial intercept estimate

numeric scalar | numeric vector

Initial intercept estimate (b), specified as the comma-separated pair consisting of 'Bias' and a numeric scalar or an L -dimensional numeric vector. L is the number of regularization-strength values (for more details, see Lambda).

- If you specify a scalar, then the software optimizes the objective function L times using this process.
 - 1 The software optimizes using Bias as the initial value and the minimum value of Lambda as the regularization strength.
 - 2 The uses the resulting estimate as a warm start to the next optimization iteration, and uses the next smallest value in Lambda as the regularization strength.
 - 3 The software implements step 2 until it exhausts all values in Lambda.

- If you specify an L -dimensional vector, then the software optimizes the objective function L times. At iteration j , the software uses $\text{Bias}(j)$ as the initial value and, after it sorts Lambda in ascending order, uses $\text{Lambda}(j)$ as the regularization strength.
- By default:
 - If `Learner` is 'logistic', then let g_j be 1 if $Y(j)$ is the positive class, and -1 otherwise. `Bias` is the weighted average of the g for training or, for cross-validation, in-fold observations.
 - If `Learner` is 'svm', then `Bias` is 0.

Data Types: single | double

FitBias — Linear model intercept inclusion flag

true (default) | false

Linear model intercept inclusion flag, specified as the comma-separated pair consisting of 'FitBias' and true or false.

Value	Description
true	The software includes the bias term b in the linear model, and then estimates it.
false	The software sets $b = 0$ during estimation.

Example: 'FitBias', false

Data Types: logical

PostFitBias — Flag to fit linear model intercept after optimization

false (default) | true

Flag to fit the linear model intercept after optimization, specified as the comma-separated pair consisting of 'PostFitBias' and true or false.

Value	Description
false	The software estimates the bias term b and the coefficients β during optimization.

Value	Description
true	To estimate b , the software: <ol style="list-style-type: none"> 1 Estimates β and b using the model 2 Estimates classification scores 3 Refits b by placing the threshold on the classification scores that attains maximum accuracy

If you specify `true`, then `FitBias` must be `true`.

Example: `'PostFitBias', true`

Data Types: `logical`

Verbose — Verbosity level

0 (default) | nonnegative integer

Verbosity level, specified as the comma-separated pair consisting of `'Verbose'` and a nonnegative integer. `Verbose` controls the amount of diagnostic information `fitcllinear` displays at the command line.

Value	Description
0	<code>fitcllinear</code> does not display diagnostic information.
1	<code>fitcllinear</code> periodically displays and stores the value of the objective function, gradient magnitude, and other diagnostic information. <code>FitInfo.History</code> contains the diagnostic information.
Any other positive integer	<code>fitcllinear</code> displays and stores diagnostic information at each optimization iteration. <code>FitInfo.History</code> contains the diagnostic information.

Example: `'Verbose', 1`

Data Types: `double` | `single`

SGD and ASGD Solver Options**BatchSize — Mini-batch size**

positive integer

Mini-batch size, specified as the comma-separated pair consisting of 'BatchSize' and a positive integer. At each iteration, the software estimates the subgradient using BatchSize observations from the training data.

- If X is a numeric matrix, then the default value is 10.
- If X is a sparse matrix, then the default value is $\max([10, \text{ceil}(\text{sqrt}(\text{ff}))])$, where $\text{ff} = \text{numel}(X)/\text{nnz}(X)$ (the fullness factor of X).

Example: 'BatchSize', 100

Data Types: single | double

LearnRate — Learning rate

positive scalar

Learning rate, specified as the comma-separated pair consisting of 'LearnRate' and a positive scalar. LearnRate specifies how many steps to take per iteration. At each iteration, the gradient specifies the direction and magnitude of each step.

- If Regularization is 'ridge', then LearnRate specifies the initial learning rate γ_0 . The software determines the learning rate for iteration t , γ_t , using

$$\gamma_t = \frac{\gamma_0}{(1 + \lambda \gamma_0 t)^c}.$$

- λ is the value of Lambda.
- If Solver is 'sgd', then $c = 1$.
- If Solver is 'asgd', then c is 0.75 [7].
- If Regularization is 'lasso', then, for all iterations, LearnRate is constant.

By default, LearnRate is $1/\text{sqrt}(1 + \max((\text{sum}(X.^2, \text{obsDim}))))$, where obsDim is 1 if the observations compose the columns of the predictor data X , and 2 otherwise.

Example: 'LearnRate', 0.01

Data Types: single | double

OptimizeLearnRate — Flag to decrease learning rate

true (default) | false

Flag to decrease the learning rate when the software detects divergence (that is, overstepping the minimum), specified as the comma-separated pair consisting of 'OptimizeLearnRate' and true or false.

If `OptimizeLearnRate` is 'true', then:

- 1 For the few optimization iterations, the software starts optimization using `LearnRate` as the learning rate.
- 2 If the value of the objective function increases, then the software restarts and uses half of the current value of the learning rate.
- 3 The software iterates step 2 until the objective function decreases.

Example: 'OptimizeLearnRate', true

Data Types: logical

TruncationPeriod — Number of mini-batches between lasso truncation runs

10 (default) | positive integer

Number of mini-batches between lasso truncation runs, specified as the comma-separated pair consisting of 'TruncationPeriod' and a positive integer.

After a truncation run, the software applies a soft threshold to the linear coefficients. That is, after processing $k = \text{TruncationPeriod}$ mini-batches, the software truncates the estimated coefficient j using

$$\widehat{\beta}_j^* = \begin{cases} \widehat{\beta}_j - u_t & \text{if } \widehat{\beta}_j > u_t, \\ 0 & \text{if } |\widehat{\beta}_j| \leq u_t, \\ \widehat{\beta}_j + u_t & \text{if } \widehat{\beta}_j < -u_t. \end{cases}$$

- For SGD, $\widehat{\beta}_j$ is the estimate of coefficient j after processing k mini-batches. $u_t = k\gamma_t\lambda$. γ_t is the learning rate at iteration t . λ is the value of Lambda.
- For ASGD, $\widehat{\beta}_j$ is the averaged estimate coefficient j after processing k mini-batches, $u_t = k\lambda$.

If `Regularization` is 'ridge', then the software ignores `TruncationPeriod`.

Example: 'TruncationPeriod',100

Data Types: single | double

Other Classification Options

ClassNames — Names of classes to use for training

categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Names of classes to use for training, specified as the comma-separated pair consisting of 'ClassNames' and a categorical, character, or string array, a logical or numeric vector, or a cell array of character vectors. `ClassNames` must have the same data type as `Y`.

If `ClassNames` is a character array, then each element must correspond to one *row* of the array.

Use `ClassNames` to:

- Order the classes during training.
- Specify the order of any input or output argument dimension that corresponds to the class order. For example, use `ClassNames` to specify the order of the dimensions of `Cost` or the column order of classification scores returned by `predict`.
- Select a subset of classes for training. For example, suppose that the set of all distinct class names in `Y` is {'a', 'b', 'c'}. To train the model using observations from classes 'a' and 'c' only, specify 'ClassNames', {'a', 'c'}.

The default value for `ClassNames` is the set of all distinct class names in `Y`.

Example: 'ClassNames', {'b', 'g'}

Data Types: categorical | char | string | logical | single | double | cell

Cost — Misclassification cost

square matrix | structure array

Misclassification cost, specified as the comma-separated pair consisting of 'Cost' and a square matrix or structure.

- If you specify the square matrix `cost` ('Cost', `cost`), then `cost(i, j)` is the cost of classifying a point into class `j` if its true class is `i`. That is, the rows correspond to the true class, and the columns correspond to the predicted class. To specify the class order for the corresponding rows and columns of `cost`, use the `ClassNames` name-value pair argument.

- If you specify the structure `S ('Cost', S)`, then it must have two fields:
 - `S.ClassNames`, which contains the class names as a variable of the same data type as `Y`
 - `S.ClassificationCosts`, which contains the cost matrix with rows and columns ordered as in `S.ClassNames`

The default value for `Cost` is $\text{ones}(K) - \text{eye}(K)$, where K is the number of distinct classes.

`fitclinear` uses `Cost` to adjust the prior class probabilities specified in `Prior`. Then, `fitclinear` uses the adjusted prior probabilities for training and resets the cost matrix to its default.

Example: `'Cost', [0 2; 1 0]`

Data Types: `single` | `double` | `struct`

Prior — Prior probabilities

`'empirical'` (default) | `'uniform'` | numeric vector | structure array

Prior probabilities for each class, specified as the comma-separated pair consisting of `'Prior'` and `'empirical'`, `'uniform'`, a numeric vector, or a structure array.

This table summarizes the available options for setting prior probabilities.

Value	Description
<code>'empirical'</code>	The class prior probabilities are the class relative frequencies in <code>Y</code> .
<code>'uniform'</code>	All class prior probabilities are equal to $1/K$, where K is the number of classes.
numeric vector	Each element is a class prior probability. Order the elements according to their order in <code>Y</code> . If you specify the order using the <code>'ClassNames'</code> name-value pair argument, then order the elements accordingly.

Value	Description
structure array	<p>A structure <code>S</code> with two fields:</p> <ul style="list-style-type: none"> • <code>S.ClassNames</code> contains the class names as a variable of the same type as <code>Y</code>. • <code>S.ClassProbs</code> contains a vector of corresponding prior probabilities.

`fitclinear` normalizes the prior probabilities in `Prior` to sum to 1.

Example: `'Prior', struct('ClassNames',
{{'setosa', 'versicolor'}}, 'ClassProbs', 1:2)`

Data Types: `char` | `string` | `double` | `single` | `struct`

ScoreTransform — Score transformation

`'none'` (default) | `'doublelogit'` | `'invlogit'` | `'ismax'` | `'logit'` | function handle | ...

Score transformation, specified as the comma-separated pair consisting of `'ScoreTransform'` and a character vector, string scalar, or function handle.

This table summarizes the available character vectors and string scalars.

Value	Description
<code>'doublelogit'</code>	$1/(1 + e^{-2x})$
<code>'invlogit'</code>	$\log(x / (1 - x))$
<code>'ismax'</code>	Sets the score for the class with the largest score to 1, and sets the scores for all other classes to 0
<code>'logit'</code>	$1/(1 + e^{-x})$
<code>'none'</code> or <code>'identity'</code>	x (no transformation)
<code>'sign'</code>	-1 for $x < 0$ 0 for $x = 0$ 1 for $x > 0$
<code>'symmetric'</code>	$2x - 1$

Value	Description
'symmetricismax'	Sets the score for the class with the largest score to 1, and sets the scores for all other classes to -1
'symmetriclogit'	$2/(1 + e^{-x}) - 1$

For a MATLAB function or a function you define, use its function handle for score transform. The function handle must accept a matrix (the original scores) and return a matrix of the same size (the transformed scores).

Example: 'ScoreTransform', 'logit'

Data Types: char | string | function_handle

Weights — Observation weights

numeric vector of positive values

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a numeric vector of positive values. `fitclinear` weighs the observations in `X` with the corresponding value in `Weights`. The size of `Weights` must equal the number of observations in `X`.

`fitclinear` normalizes `Weights` to sum up to the value of the prior probability in the respective class.

By default, `Weights` is `ones(n, 1)`, where n is the number of observations in `X`.

Data Types: double | single

Cross-Validation Options

CrossVal — Cross-validation flag

'off' (default) | 'on'

Cross-validation flag, specified as the comma-separated pair consisting of 'Crossval' and 'on' or 'off'.

If you specify 'on', then the software implements 10-fold cross-validation.

To override this cross-validation setting, use one of these name-value pair arguments: `CVPartition`, `Holdout`, or `KFold`. To create a cross-validated model, you can use one cross-validation name-value pair argument at a time only.

Example: 'Crossval', 'on'

CVPartition — Cross-validation partition

[] (default) | `cvpartition` partition object

Cross-validation partition, specified as the comma-separated pair consisting of 'CVPartition' and a `cvpartition` partition object as created by `cvpartition`. The partition object specifies the type of cross-validation, and also the indexing for training and validation sets.

To create a cross-validated model, you can use one of these four options only: 'CVPartition', 'Holdout', or 'Kfold'.

Holdout — Fraction of data for holdout validation

scalar value in the range (0,1)

Fraction of data used for holdout validation, specified as the comma-separated pair consisting of 'Holdout' and a scalar value in the range (0,1). If you specify 'Holdout', p , then the software:

- 1 Randomly reserves $p*100\%$ of the data as validation data, and trains the model using the rest of the data
- 2 Stores the compact, trained model in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can use one of these four options only: 'CVPartition', 'Holdout', or 'Kfold'.

Example: 'Holdout', 0.1

Data Types: double | single

KFold — Number of folds

10 (default) | positive integer value greater than 1

Number of folds to use in a cross-validated classifier, specified as the comma-separated pair consisting of 'Kfold' and a positive integer value greater than 1. If you specify, e.g., 'Kfold', k , then the software:

- 1 Randomly partitions the data into k sets
- 2 For each set, reserves the set as validation data, and trains the model using the other $k - 1$ sets

- 3 Stores the k compact, trained models in the cells of a k -by-1 cell vector in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can use one of these four options only: `'CVPartition'`, `'Holdout'`, or `'KFold'`.

Example: `'KFold',8`

Data Types: `single` | `double`

SGD and ASGD Convergence Controls

BatchLimit — Maximal number of batches

positive integer

Maximal number of batches to process, specified as the comma-separated pair consisting of `'BatchLimit'` and a positive integer. When the software processes `BatchLimit` batches, it terminates optimization.

- By default:
 - The software passes through the data `PassLimit` times.
 - If you specify multiple solvers, and use (A)SGD to get an initial approximation for the next solver, then the default value is `ceil(1e6/BatchSize)`. `BatchSize` is the value of the `'BatchSize'` name-value pair argument.
- If you specify `'BatchLimit'` and `'PassLimit'`, then the software chooses the argument that results in processing the fewest observations.
- If you specify `'BatchLimit'` but not `'PassLimit'`, then the software processes enough batches to complete up to one entire pass through the data.

Example: `'BatchLimit',100`

Data Types: `single` | `double`

BetaTolerance — Relative tolerance on linear coefficients and bias term

`1e-4` (default) | nonnegative scalar

Relative tolerance on the linear coefficients and the bias term (intercept), specified as the comma-separated pair consisting of `'BetaTolerance'` and a nonnegative scalar.

Let $B_t = [\beta_t' \ b_t]$, that is, the vector of the coefficients and the bias term at optimization iteration t . If $\left\| \frac{B_t - B_{t-1}}{B_t} \right\|_2 < \text{BetaTolerance}$, then optimization terminates.

If the software converges for the last solver specified in `Solver`, then optimization terminates. Otherwise, the software uses the next solver specified in `Solver`.

Example: `'BetaTolerance', 1e-6`

Data Types: `single | double`

NumCheckConvergence — Number of batches to process before next convergence check

positive integer

Number of batches to process before next convergence check, specified as the comma-separated pair consisting of `'NumCheckConvergence'` and a positive integer.

To specify the batch size, see `BatchSize`.

The software checks for convergence about 10 times per pass through the entire data set by default.

Example: `'NumCheckConvergence', 100`

Data Types: `single | double`

PassLimit — Maximal number of passes

1 (default) | positive integer

Maximal number of passes through the data, specified as the comma-separated pair consisting of `'PassLimit'` and a positive integer.

`fitlinear` processes all observations when it completes one pass through the data.

When `fitlinear` passes through the data `PassLimit` times, it terminates optimization.

If you specify `'BatchLimit'` and `'PassLimit'`, then `fitlinear` chooses the argument that results in processing the fewest observations.

Example: `'PassLimit', 5`

Data Types: `single | double`

ValidationData — Validation data for optimization convergence detection

cell array

Data for optimization convergence detection, specified as the comma-separated pair consisting of `'ValidationData'` and a cell array.

During optimization, the software periodically estimates the loss of `ValidationData`. If the validation-data loss increases, then the software terminates optimization. For more details, see “Algorithms” on page 32-2005. To optimize hyperparameters using cross-validation, see cross-validation options such as `CrossVal`.

- `ValidationData(1)` must contain an m -by- p or p -by- m full or sparse matrix of predictor data that has the same orientation as `X`. The predictor variables in the training data `X` and `ValidationData{1}` must correspond. The number of observations in both sets can vary.
- `ValidationData{2}` and `Y` must be the same data type. The set of all distinct labels of `ValidationData{2}` must be a subset of all distinct labels of `Y`.
- Optionally, `ValidationData(3)` can contain an m -dimensional numeric vector of observation weights. The software normalizes the weights with the validation data so that they sum to 1.

If you specify `ValidationData`, then, to display validation loss at the command line, specify a value larger than 0 for `Verbose`.

If the software converges for the last solver specified in `Solver`, then optimization terminates. Otherwise, the software uses the next solver specified in `Solver`.

By default, the software does not detect convergence by monitoring validation-data loss.

Dual SGD Convergence Controls

BetaTolerance — Relative tolerance on linear coefficients and bias term

1e-4 (default) | nonnegative scalar

Relative tolerance on the linear coefficients and the bias term (intercept), specified as the comma-separated pair consisting of 'BetaTolerance' and a nonnegative scalar.

Let $B_t = [\beta_t' \ b_t]$, that is, the vector of the coefficients and the bias term at optimization iteration t . If $\left\| \frac{B_t - B_{t-1}}{B_t} \right\|_2 < \text{BetaTolerance}$, then optimization terminates.

If you also specify `DeltaGradientTolerance`, then optimization terminates when the software satisfies either stopping criterion.

If the software converges for the last solver specified in `Solver`, then optimization terminates. Otherwise, the software uses the next solver specified in `Solver`.

Example: 'BetaTolerance',1e-6

Data Types: `single` | `double`

DeltaGradientTolerance — Gradient-difference tolerance

1 (default) | nonnegative scalar

Gradient-difference tolerance between upper and lower pool Karush-Kuhn-Tucker (KKT) complementarity conditions on page 32-2088 violators, specified as the comma-separated pair consisting of `'DeltaGradientTolerance'` and a nonnegative scalar.

- If the magnitude of the KKT violators is less than `DeltaGradientTolerance`, then the software terminates optimization.
- If the software converges for the last solver specified in `Solver`, then optimization terminates. Otherwise, the software uses the next solver specified in `Solver`.

Example: `'DeltaGapTolerance', 1e-2`

Data Types: `double` | `single`

NumCheckConvergence — Number of passes through entire data set to process before next convergence check

5 (default) | positive integer

Number of passes through entire data set to process before next convergence check, specified as the comma-separated pair consisting of `'NumCheckConvergence'` and a positive integer.

Example: `'NumCheckConvergence', 100`

Data Types: `single` | `double`

PassLimit — Maximal number of passes

10 (default) | positive integer

Maximal number of passes through the data, specified as the comma-separated pair consisting of `'PassLimit'` and a positive integer.

When the software completes one pass through the data, it has processed all observations.

When the software passes through the data `PassLimit` times, it terminates optimization.

Example: `'PassLimit', 5`

Data Types: `single` | `double`

ValidationData — Validation data for optimization convergence detection

cell array

Data for optimization convergence detection, specified as the comma-separated pair consisting of 'ValidationData' and a cell array.

During optimization, the software periodically estimates the loss of `ValidationData`. If the validation-data loss increases, then the software terminates optimization. For more details, see “Algorithms” on page 32-2005. To optimize hyperparameters using cross-validation, see cross-validation options such as `CrossVal`.

- `ValidationData(1)` must contain an m -by- p or p -by- m full or sparse matrix of predictor data that has the same orientation as X . The predictor variables in the training data X and `ValidationData{1}` must correspond. The number of observations in both sets can vary.
- `ValidationData{2}` and Y must be the same data type. The set of all distinct labels of `ValidationData{2}` must be a subset of all distinct labels of Y .
- Optionally, `ValidationData(3)` can contain an m -dimensional numeric vector of observation weights. The software normalizes the weights with the validation data so that they sum to 1.

If you specify `ValidationData`, then, to display validation loss at the command line, specify a value larger than 0 for `Verbose`.

If the software converges for the last solver specified in `Solver`, then optimization terminates. Otherwise, the software uses the next solver specified in `Solver`.

By default, the software does not detect convergence by monitoring validation-data loss.

BFGS, LBFGS, and SpARSA Convergence Controls**BetaTolerance — Relative tolerance on linear coefficients and bias term**

1e-4 (default) | nonnegative scalar

Relative tolerance on the linear coefficients and the bias term (intercept), specified as the comma-separated pair consisting of 'BetaTolerance' and a nonnegative scalar.

Let $B_t = [\beta_t' \ b_t]$, that is, the vector of the coefficients and the bias term at optimization iteration t . If $\left\| \frac{B_t - B_{t-1}}{B_t} \right\|_2 < \text{BetaTolerance}$, then optimization terminates.

If you also specify `GradientTolerance`, then optimization terminates when the software satisfies either stopping criterion.

If the software converges for the last solver specified in `Solver`, then optimization terminates. Otherwise, the software uses the next solver specified in `Solver`.

Example: `'BetaTolerance', 1e-6`

Data Types: `single | double`

GradientTolerance — Absolute gradient tolerance

`1e-6 (default) | nonnegative scalar`

Absolute gradient tolerance, specified as the comma-separated pair consisting of `'GradientTolerance'` and a nonnegative scalar.

Let $\nabla \mathcal{L}_t$ be the gradient vector of the objective function with respect to the coefficients and bias term at optimization iteration t . If $\|\nabla \mathcal{L}_t\|_\infty = \max|\nabla \mathcal{L}_t| < \text{GradientTolerance}$, then optimization terminates.

If you also specify `BetaTolerance`, then optimization terminates when the software satisfies either stopping criterion.

If the software converges for the last solver specified in the software, then optimization terminates. Otherwise, the software uses the next solver specified in `Solver`.

Example: `'GradientTolerance', 1e-5`

Data Types: `single | double`

HessianHistorySize — Size of history buffer for Hessian approximation

`15 (default) | positive integer`

Size of history buffer for Hessian approximation, specified as the comma-separated pair consisting of `'HessianHistorySize'` and a positive integer. That is, at each iteration, the software composes the Hessian using statistics from the latest `HessianHistorySize` iterations.

The software does not support `'HessianHistorySize'` for `SpaRSA`.

Example: `'HessianHistorySize', 10`

Data Types: `single | double`

IterationLimit — Maximal number of optimization iterations

1000 (default) | positive integer

Maximal number of optimization iterations, specified as the comma-separated pair consisting of 'IterationLimit' and a positive integer. IterationLimit applies to these values of Solver: 'bfgs', 'lbfgs', and 'sparsa'.

Example: 'IterationLimit',500

Data Types: single | double

ValidationData — Validation data for optimization convergence detection

cell array

Data for optimization convergence detection, specified as the comma-separated pair consisting of 'ValidationData' and a cell array.

During optimization, the software periodically estimates the loss of ValidationData. If the validation-data loss increases, then the software terminates optimization. For more details, see “Algorithms” on page 32-2005. To optimize hyperparameters using cross-validation, see cross-validation options such as CrossVal.

- `ValidationData(1)` must contain an m -by- p or p -by- m full or sparse matrix of predictor data that has the same orientation as `X`. The predictor variables in the training data `X` and `ValidationData{1}` must correspond. The number of observations in both sets can vary.
- `ValidationData{2}` and `Y` must be the same data type. The set of all distinct labels of `ValidationData{2}` must be a subset of all distinct labels of `Y`.
- Optionally, `ValidationData(3)` can contain an m -dimensional numeric vector of observation weights. The software normalizes the weights with the validation data so that they sum to 1.

If you specify `ValidationData`, then, to display validation loss at the command line, specify a value larger than 0 for `Verbose`.

If the software converges for the last solver specified in `Solver`, then optimization terminates. Otherwise, the software uses the next solver specified in `Solver`.

By default, the software does not detect convergence by monitoring validation-data loss.

Hyperparameter Optimization

OptimizeHyperparameters — Parameters to optimize

'none' (default) | 'auto' | 'all' | string array or cell array of eligible parameter names | vector of `optimizableVariable` objects

Parameters to optimize, specified as the comma-separated pair consisting of 'OptimizeHyperparameters' and one of the following:

- 'none' — Do not optimize.
- 'auto' — Use {'Lambda', 'Learner'}.
- 'all' — Optimize all eligible parameters.
- String array or cell array of eligible parameter names.
- Vector of `optimizableVariable` objects, typically the output of hyperparameters.

The optimization attempts to minimize the cross-validation loss (error) for `fitclinear` by varying the parameters. For information about cross-validation loss (albeit in a different context), see “Classification Loss” on page 32-3352. To control the cross-validation type and other aspects of the optimization, use the `HyperparameterOptimizationOptions` name-value pair.

Note 'OptimizeHyperparameters' values override any values you set using other name-value pair arguments. For example, setting 'OptimizeHyperparameters' to 'auto' causes the 'auto' values to apply.

The eligible parameters for `fitclinear` are:

- `Lambda` — `fitclinear` searches among positive values, by default log-scaled in the range $[1e-5/\text{NumObservations}, 1e5/\text{NumObservations}]$.
- `Learner` — `fitclinear` searches among 'svm' and 'logistic'.
- `Regularization` — `fitclinear` searches among 'ridge' and 'lasso'.

Set nondefault parameters by passing a vector of `optimizableVariable` objects that have nondefault values. For example,

```
load fisheriris
params = hyperparameters('fitclinear', meas, species);
params(1).Range = [1e-4, 1e6];
```

Pass `params` as the value of `OptimizeHyperparameters`.

By default, iterative display appears at the command line, and plots appear according to the number of hyperparameters in the optimization. For the optimization and plots, the objective function is $\log(1 + \text{cross-validation loss})$ for regression and the misclassification rate for classification. To control the iterative display, set the `Verbose` field of the `'HyperparameterOptimizationOptions'` name-value pair argument. To control the plots, set the `ShowPlots` field of the `'HyperparameterOptimizationOptions'` name-value pair argument.

For an example, see “Optimize Linear Classifier” on page 32-1968.

Example: `'OptimizeHyperparameters','auto'`

HyperparameterOptimizationOptions — Options for optimization structure

Options for optimization, specified as the comma-separated pair consisting of `'HyperparameterOptimizationOptions'` and a structure. This argument modifies the effect of the `OptimizeHyperparameters` name-value pair argument. All fields in the structure are optional.

Field Name	Values	Default
Optimizer	<ul style="list-style-type: none"> 'bayesopt' — Use Bayesian optimization. Internally, this setting calls <code>bayesopt</code>. 'gridsearch' — Use grid search with <code>NumGridDivisions</code> values per dimension. 'randomsearch' — Search at random among <code>MaxObjectiveEvaluations</code> points. <p>'gridsearch' searches in a random order, using uniform sampling without replacement from the grid. After optimization, you can get a table in grid order by using the command <code>sortrows(Mdl.HyperparameterOptimizationResults)</code>.</p>	'bayesopt'

Field Name	Values	Default
AcquisitionFunctionName	<ul style="list-style-type: none"> • 'expected-improvement-per-second-plus' • 'expected-improvement' • 'expected-improvement-plus' • 'expected-improvement-per-second' • 'lower-confidence-bound' • 'probability-of-improvement' <p>Acquisition functions whose names include <code>per-second</code> do not yield reproducible results because the optimization depends on the runtime of the objective function. Acquisition functions whose names include <code>plus</code> modify their behavior when they are overexploiting an area. For more details, see “Acquisition Function Types” on page 10-4.</p>	'expected-improvement-per-second-plus'
MaxObjectiveEvaluations	Maximum number of objective function evaluations.	30 for 'bayesopt' or 'randomsearch', and the entire grid for 'gridsearch'
MaxTime	Time limit, specified as a positive real. The time limit is in seconds, as measured by <code>tic</code> and <code>toc</code> . Run time can exceed <code>MaxTime</code> because <code>MaxTime</code> does not interrupt function evaluations.	Inf
NumGridDivisions	For 'gridsearch', the number of values in each dimension. The value can be a vector of positive integers giving the number of values for each dimension, or a scalar that applies to all dimensions. This field is ignored for categorical variables.	10

Field Name	Values	Default
ShowPlots	Logical value indicating whether to show plots. If <code>true</code> , this field plots the best objective function value against the iteration number. If there are one or two optimization parameters, and if <code>Optimizer</code> is <code>'bayesopt'</code> , then <code>ShowPlots</code> also plots a model of the objective function against the parameters.	<code>true</code>
SaveIntermediateResults	Logical value indicating whether to save results when <code>Optimizer</code> is <code>'bayesopt'</code> . If <code>true</code> , this field overwrites a workspace variable named <code>'BayesoptResults'</code> at each iteration. The variable is a <code>BayesianOptimization</code> object.	<code>false</code>
Verbose	Display to the command line. <ul style="list-style-type: none"> • 0 — No iterative display • 1 — Iterative display • 2 — Iterative display with extra information For details, see the <code>bayesopt</code> <code>Verbose</code> name-value pair argument.	1
UseParallel	Logical value indicating whether to run Bayesian optimization in parallel, which requires Parallel Computing Toolbox. For details, see “Parallel Bayesian Optimization” on page 10-8.	<code>false</code>

Field Name	Values	Default
Repartition	Logical value indicating whether to repartition the cross-validation at every iteration. If <code>false</code> , the optimizer uses a single partition for the optimization. <code>true</code> usually gives the most robust results because this setting takes partitioning noise into account. However, for good results, <code>true</code> requires at least twice as many function evaluations.	<code>false</code>
Use no more than one of the following three field names.		
CVPartition	A <code>cvpartition</code> object, as created by <code>cvpartition</code> .	'Kfold', 5 if you do not specify any cross-validation field
Holdout	A scalar in the range (0, 1) representing the holdout fraction.	
Kfold	An integer greater than 1.	

Example:

```
'HyperparameterOptimizationOptions', struct('MaxObjectiveEvaluations', 60)
```

Data Types: `struct`

Output Arguments

Mdl — Trained linear classification model

`ClassificationLinear` model object | `ClassificationPartitionedLinear` cross-validated model object

Trained linear classification model, returned as a `ClassificationLinear` model object or `ClassificationPartitionedLinear` cross-validated model object.

If you set any of the name-value pair arguments `KFold`, `Holdout`, `CrossVal`, or `CVPartition`, then `Mdl` is a `ClassificationPartitionedLinear` cross-validated model object. Otherwise, `Mdl` is a `ClassificationLinear` model object.

To reference properties of `Mdl`, use dot notation. For example, enter `Mdl.Beta` in the Command Window to display the vector or matrix of estimated coefficients.

Note Unlike other classification models, and for economical memory usage, `ClassificationLinear` and `ClassificationPartitionedLinear` model objects do not store the training data or training process details (for example, convergence history).

FitInfo – Optimization details

structure array

Optimization details, returned as a structure array.

Fields specify final values or name-value pair argument specifications, for example, `Objective` is the value of the objective function when optimization terminates. Rows of multidimensional fields correspond to values of `Lambda` and columns correspond to values of `Solver`.

This table describes some notable fields.

Field	Description														
<code>TerminationStatus</code>	<ul style="list-style-type: none"> Reason for optimization termination Corresponds to a value in <code>TerminationCode</code> 														
<code>FitTime</code>	Elapsed, wall-clock time in seconds														
<code>History</code>	<p>A structure array of optimization information for each iteration. To access fields, use dot notation. For example, to access the vector of objective function values for each iteration, enter `FitInfo.History.Objective`.

It is good practice to examine `FitInfo` to assess whether convergence is satisfactory.

HyperparameterOptimizationResults — Cross-validation optimization of hyperparameters

`BayesianOptimization` object | table of hyperparameters and associated values

Cross-validation optimization of hyperparameters, returned as a `BayesianOptimization` object or a table of hyperparameters and associated values. The output is nonempty when the value of `'OptimizeHyperparameters'` is not `'none'`. The output value depends on the `Optimizer` field value of the `'HyperparameterOptimizationOptions'` name-value pair argument:

Value of <code>Optimizer</code> Field	Value of <code>HyperparameterOptimizationResults</code>
<code>'bayesopt'</code> (default)	Object of class <code>BayesianOptimization</code>
<code>'gridsearch'</code> or <code>'randomsearch'</code>	Table of hyperparameters used, observed objective function values (cross-validation loss), and rank of observations from lowest (best) to highest (worst)

Definitions

Warm Start

A warm start is initial estimates of the beta coefficients and bias term supplied to an optimization routine for quicker convergence.

Alternatives for Lower-Dimensional Data

High-dimensional linear classification and regression models minimize objective functions relatively quickly, but at the cost of some accuracy, the numeric-only predictor variables restriction, and the model must be linear with respect to the parameters. If your predictor data set is low- through medium-dimensional, or contains heterogeneous variables, then you should use the appropriate classification or regression fitting function. To help you decide which fitting function is appropriate for your low-dimensional data set, use this table.

Model to Fit	Function	Notable Algorithmic Differences
SVM	<ul style="list-style-type: none"> Binary classification: <code>fitcsvm</code> Multiclass classification: <code>fitcecoc</code> Regression: <code>fitrsvm</code> 	<ul style="list-style-type: none"> Computes the Gram matrix of the predictor variables, which is convenient for nonlinear kernel transformations. Solves dual problem using SMO, ISDA, or $L1$ minimization via quadratic programming using <code>quadprog</code>.
Linear regression	<ul style="list-style-type: none"> Least-squares without regularization: <code>fitlm</code> Regularized least-squares using a lasso penalty: <code>lasso</code> Ridge regression: <code>ridge</code> or <code>lasso</code> 	<ul style="list-style-type: none"> <code>lasso</code> implements cyclic coordinate descent.
Logistic regression	<ul style="list-style-type: none"> Logistic regression without regularization: <code>fitglm</code>. Regularized logistic regression using a lasso penalty: <code>lassoglm</code> 	<ul style="list-style-type: none"> <code>fitglm</code> implements iteratively reweighted least squares. <code>lassoglm</code> implements cyclic coordinate descent.

Tips

- It is a best practice to orient your predictor matrix so that observations correspond to columns and to specify `'ObservationsIn'`, `'columns'`. As a result, you can experience a significant reduction in optimization-execution time.
- For better optimization accuracy if `X` is high-dimensional and `Regularization` is `'ridge'`, set any of these combinations for `Solver`:
 - `'sgd'`
 - `'asgd'`
 - `'dual'` if `Learner` is `'svm'`

- {'sgd', 'lbfgs'}
- {'asgd', 'lbfgs'}
- {'dual', 'lbfgs'} if Learner is 'svm'

Other combinations can result in poor optimization accuracy.

- For better optimization accuracy if X is moderate- through low-dimensional and Regularization is 'ridge', set Solver to 'bfgs'.
- If Regularization is 'lasso', set any of these combinations for Solver:
 - 'sgd'
 - 'asgd'
 - 'sparsa'
 - {'sgd', 'sparsa'}
 - {'asgd', 'sparsa'}
- When choosing between SGD and ASGD, consider that:
 - SGD takes less time per iteration, but requires more iterations to converge.
 - ASGD requires fewer iterations to converge, but takes more time per iteration.
- If X has few observations, but many predictor variables, then:
 - Specify 'PostFitBias', true.
 - For SGD or ASGD solvers, set PassLimit to a positive integer that is greater than 1, for example, 5 or 10. This setting often results in better accuracy.
- For SGD and ASGD solvers, BatchSize affects the rate of convergence.
 - If BatchSize is too small, then fitlinear achieves the minimum in many iterations, but computes the gradient per iteration quickly.
 - If BatchSize is too large, then fitlinear achieves the minimum in fewer iterations, but computes the gradient per iteration slowly.
- Large learning rates (see LearnRate) speed up convergence to the minimum, but can lead to divergence (that is, over-stepping the minimum). Small learning rates ensure convergence to the minimum, but can lead to slow termination.
- When using lasso penalties, experiment with various values of TruncationPeriod. For example, set TruncationPeriod to 1, 10, and then 100.
- For efficiency, fitlinear does not standardize predictor data. To standardize X , enter

```
X = bsxfun(@rdivide,bsxfun(@minus,X,mean(X,2)),std(X,0,2));
```

The code requires that you orient the predictors and observations as the rows and columns of X , respectively. Also, for memory-usage economy, the code replaces the original predictor data the standardized data.

- After training a model, you can generate C/C++ code that predicts labels for new data. Generating C/C++ code requires MATLAB Coder. For details, see “Introduction to Code Generation” on page 31-2.

Algorithms

- If you specify `ValidationData`, then, during objective-function optimization:
 - `fitclinear` estimates the validation loss of `ValidationData` periodically using the current model, and tracks the minimal estimate.
 - When `fitclinear` estimates a validation loss, it compares the estimate to the minimal estimate.
 - When subsequent, validation loss estimates exceed the minimal estimate five times, `fitclinear` terminates optimization.
- If you specify `ValidationData` and to implement a cross-validation routine (`CrossVal`, `CVPartition`, `Holdout`, or `KFold`), then:
 - 1 `fitclinear` randomly partitions X and Y according to the cross-validation routine that you choose.
 - 2 `fitclinear` trains the model using the training-data partition. During objective-function optimization, `fitclinear` uses `ValidationData` as another possible way to terminate optimization (for details, see the previous bullet).
 - 3 Once `fitclinear` satisfies a stopping criterion, it constructs a trained model based on the optimized linear coefficients and intercept.
 - a If you implement k -fold cross-validation, and `fitclinear` has not exhausted all training-set folds, then `fitclinear` returns to Step 2 to train using the next training-set fold.
 - b Otherwise, `fitclinear` terminates training, and then returns the cross-validated model.
 - 4 You can determine the quality of the cross-validated model. For example:

- To determine the validation loss using the holdout or out-of-fold data from step 1, pass the cross-validated model to `kfoldLoss`.
- To predict observations on the holdout or out-of-fold data from step 1, pass the cross-validated model to `kfoldPredict`.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

Usage notes and limitations:

- Some name-value pair arguments have different defaults compared to the default values for the in-memory `fitclinear` function. Supported name-value pair arguments, and any differences, are:
 - 'ObservationsIn' — Supports only 'rows'.
 - 'Lambda' — Can be 'auto' (default) or a scalar.
 - 'Learner'
 - 'Regularization' — Supports only 'ridge'.
 - 'Solver' — Supports only 'lbfgs'.
 - 'FitBias' — Supports only true.
 - 'Verbose' — Default value is 1.
 - 'Beta'
 - 'Bias'
 - 'ClassNames'
 - 'Cost'
 - 'Prior'
 - 'Weights' — Value must be a tall array.
 - 'HessianHistorySize'
 - 'BetaTolerance' — Default value is relaxed to $1e-3$.
 - 'GradientTolerance' — Default value is relaxed to $1e-3$.
 - 'IterationLimit' — Default value is relaxed to 20.
 - 'OptimizeHyperparameters' — Value of 'Regularization' parameter must be 'ridge'.
 - 'HyperparameterOptimizationOptions' — For cross-validation, tall optimization supports only 'Holdout' validation. For example, you can specify `fitclinear(X,Y,'OptimizeHyperparameters','auto','HyperparameterOptimizationOptions',struct('Holdout',0.2))`.
- For tall arrays, `fitclinear` implements LBFGS by distributing the calculation of the loss and gradient among different parts of the tall array at each iteration. Other solvers are not available for tall arrays.

When initial values for `Beta` and `Bias` are not given, `fitclinear` refines the initial estimates of the parameters by fitting the model locally to parts of the data and combining the coefficients by averaging.

For more information, see “Tall Arrays” (MATLAB).

Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the 'UseParallel' option to `true`.

To perform parallel hyperparameter optimization, use the 'HyperparameterOptions', `struct('UseParallel', true)` name-value pair argument in the call to this function.

For more information on parallel hyperparameter optimization, see “Parallel Bayesian Optimization” on page 10-8.

For more general information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

Introduced in R2016a

fitcnb

Train multiclass naive Bayes model

Syntax

```
Mdl = fitcnb(Tbl,ResponseVarName)
```

```
Mdl = fitcnb(Tbl,formula)
```

```
Mdl = fitcnb(Tbl,Y)
```

```
Mdl = fitcnb(X,Y)
```

```
Mdl = fitcnb( ____,Name,Value)
```

Description

`Mdl = fitcnb(Tbl,ResponseVarName)` returns a multiclass naive Bayes model (`Mdl`), trained by the predictors in table `Tbl` and class labels in the variable `Tbl.ResponseVarName`.

`Mdl = fitcnb(Tbl,formula)` returns a multiclass naive Bayes model (`Mdl`), trained by the predictors in table `Tbl`. `formula` is an explanatory model of the response and a subset of predictor variables in `Tbl` used to fit `Mdl`.

`Mdl = fitcnb(Tbl,Y)` returns a multiclass naive Bayes model (`Mdl`), trained by the predictors in the table `Tbl` and class labels in the array `Y`.

`Mdl = fitcnb(X,Y)` returns a multiclass naive Bayes model (`Mdl`), trained by predictors `X` and class labels `Y`.

`Mdl = fitcnb(____,Name,Value)` returns a naive Bayes classifier with additional options specified by one or more `Name,Value` pair arguments, using any of the previous syntaxes. For example, you can specify a distribution to model the data, prior probabilities for the classes, or the kernel smoothing window bandwidth.

Examples

Train a Naive Bayes Classifier

Load Fisher's iris data set.

```
load fisheriris
X = meas(:,3:4);
Y = species;
tabulate(Y)
```

Value	Count	Percent
setosa	50	33.33%
versicolor	50	33.33%
virginica	50	33.33%

The software can classify data with more than two classes using naive Bayes methods.

Train a naive Bayes classifier. It is good practice to specify the class order.

```
Mdl = fitcnb(X,Y,...
    'ClassNames',{'setosa','versicolor','virginica'})

Mdl =
    ClassificationNaiveBayes
        ResponseName: 'Y'
    CategoricalPredictors: []
        ClassNames: {'setosa' 'versicolor' 'virginica'}
        ScoreTransform: 'none'
        NumObservations: 150
        DistributionNames: {'normal' 'normal'}
        DistributionParameters: {3x2 cell}
```

Properties, Methods

Mdl is a trained `ClassificationNaiveBayes` classifier.

By default, the software models the predictor distribution within each class using a Gaussian distribution having some mean and standard deviation. Use dot notation to display the parameters of a particular Gaussian fit, e.g., display the fit for the first feature within `setosa`.

```

setosaIndex = strcmp(Mdl.ClassNames, 'setosa');
estimates = Mdl.DistributionParameters{setosaIndex,1}

estimates = 2×1

    1.4620
    0.1737

```

The mean is 1.4620 and the standard deviation is 0.1737.

Plot the Gaussian contours.

```

figure
gscatter(X(:,1),X(:,2),Y);
h = gca;
cxlim = h.XLim;
cyylim = h.YLim;
hold on
Params = cell2mat(Mdl.DistributionParameters);
Mu = Params(2*(1:3)-1,1:2); % Extract the means
Sigma = zeros(2,2,3);
for j = 1:3
    Sigma(:,:,j) = diag(Params(2*j,:)).^2; % Create diagonal covariance matrix
    xlim = Mu(j,1) + 4*[-1 1]*sqrt(Sigma(1,1,j));
    ylim = Mu(j,2) + 4*[-1 1]*sqrt(Sigma(2,2,j));
    f = @(x1,x2)reshape(mvnpdf([x1(:),x2(:)],Mu(j,:),Sigma(:,:,j)),size(x1));
    fcontour(f,[xlim ylim]) % Draw contours for the multivariate normal distributions
end
h.XLim = xlim;
h.YLim = ylim;
title('Naive Bayes Classifier -- Fisher's Iris Data')
xlabel('Petal Length (cm)')
ylabel('Petal Width (cm)')
legend('setosa', 'versicolor', 'virginica')
hold off

```

You can change the default distribution using the name-value pair argument 'DistributionNames'. For example, if some predictors are categorical, then you can specify that they are multivariate, multinomial random variables using 'DistributionNames', 'mvmn'.

Specify Prior Probabilities When Training Naive Bayes Classifiers

Construct a naive Bayes classifier for Fisher's iris data set. Also, specify prior probabilities during training.

Load Fisher's iris data set.

```
load fisheriris
X = meas;
Y = species;
classNames = {'setosa','versicolor','virginica'}; % Class order
```

X is a numeric matrix that contains four petal measurements for 150 irises. Y is a cell array of character vectors that contains the corresponding iris species.

By default, the prior class probability distribution is the relative frequency distribution of the classes in the data set, which in this case is 33% for each species. However, suppose you know that in the population 50% of the irises are setosa, 20% are versicolor, and 30% are virginica. You can incorporate this information by specifying this distribution as a prior probability during training.

Train a naive Bayes classifier. Specify the class order and prior class probability distribution.

```
prior = [0.5 0.2 0.3];
Mdl = fitcnb(X,Y,'ClassNames',classNames,'Prior',prior)
```

```
Mdl =
  ClassificationNaiveBayes
      ResponseName: 'Y'
  CategoricalPredictors: []
      ClassNames: {'setosa' 'versicolor' 'virginica'}
      ScoreTransform: 'none'
      NumObservations: 150
  DistributionNames: {'normal' 'normal' 'normal' 'normal'}
  DistributionParameters: {3x4 cell}
```

Properties, Methods

Mdl is a trained `ClassificationNaiveBayes` classifier, and some of its properties appear in the Command Window. The software treats the predictors as independent given a class, and, by default, fits them using normal distributions.

The naive Bayes algorithm does not use the prior class probabilities during training. Therefore, you can specify prior class probabilities after training using dot notation. For example, suppose that you want to see the difference in performance between a model that uses the default prior class probabilities and a model that uses `prior`.

Create a new naive Bayes model based on `Mdl`, and specify that the prior class probability distribution is an empirical class distribution.

```
defaultPriorMdl = Mdl;  
FreqDist = cell2table(tabulate(Y));  
defaultPriorMdl.Prior = FreqDist{:,3};
```

The software normalizes the prior class probabilities to sum to 1.

Estimate the cross-validation error for both models using 10-fold cross-validation.

```
rng(1); % For reproducibility  
defaultCVMdl = crossval(defaultPriorMdl);  
defaultLoss = kfoldLoss(defaultCVMdl)
```

```
defaultLoss = 0.0533
```

```
CVMDL = crossval(Mdl);  
Loss = kfoldLoss(CVMDL)
```

```
Loss = 0.0340
```

`Mdl` performs better than `defaultPriorMdl`.

Specify Predictor Distributions for Naive Bayes Classifiers

Load Fisher's iris data set.

```
load fisheriris  
X = meas;  
Y = species;
```

Train a naive Bayes classifier using every predictor. It is good practice to specify the class order.

```
Mdl1 = fitcnb(X,Y,...  
    'ClassNames',{'setosa','versicolor','virginica'})  
  
Mdl1 =  
    ClassificationNaiveBayes  
        ResponseName: 'Y'  
    CategoricalPredictors: []  
        ClassNames: {'setosa' 'versicolor' 'virginica'}
```

```

    ScoreTransform: 'none'
    NumObservations: 150
    DistributionNames: {'normal' 'normal' 'normal' 'normal'}
    DistributionParameters: {3x4 cell}

```

Properties, Methods

Mdl1.DistributionParameters

```

ans = 3x4 cell array
    {2x1 double}    {2x1 double}    {2x1 double}    {2x1 double}
    {2x1 double}    {2x1 double}    {2x1 double}    {2x1 double}
    {2x1 double}    {2x1 double}    {2x1 double}    {2x1 double}

```

Mdl1.DistributionParameters{1,2}

```

ans = 2x1

    3.4280
    0.3791

```

By default, the software models the predictor distribution within each class as a Gaussian with some mean and standard deviation. There are four predictors and three class levels. Each cell in `Mdl1.DistributionParameters` corresponds to a numeric vector containing the mean and standard deviation of each distribution, e.g., the mean and standard deviation for setosa iris sepal widths are 3.4280 and 0.3791, respectively.

Estimate the confusion matrix for `Mdl1`.

```

isLabels1 = resubPredict(Mdl1);
ConfusionMat1 = confusionchart(Y,isLabels1);

```

	setosa			
True Class	setosa	50		
	versicolor			
	versicolor	47	3	
	virginica			
	virginica	3	47	
		setosa	versicolor	virginica
		Predicted Class		

Element (j, k) of the confusion matrix chart represents the number of observations that the software classifies as k , but are truly in class j according to the data.

Retrain the classifier using the Gaussian distribution for predictors 1 and 2 (the sepal lengths and widths), and the default normal kernel density for predictors 3 and 4 (the petal lengths and widths).

```
Mdl2 = fitcnb(X,Y,...
    'DistributionNames',{'normal','normal','kernel','kernel'},...
    'ClassNames',{'setosa','versicolor','virginica'});
Mdl2.DistributionParameters{1,2}

ans = 2×1
```

```
3.4280  
0.3791
```

The software does not train parameters to the kernel density. Rather, the software chooses an optimal width. However, you can specify a width using the 'Width' name-value pair argument.

Estimate the confusion matrix for Mdl2.

```
isLabels2 = resubPredict(Mdl2);  
ConfusionMat2 = confusionchart(Y,isLabels2);
```

Based on the confusion matrices, the two classifiers perform similarly in the training sample.

Compare Classifiers Using Cross-Validation

Load Fisher's iris data set.

```
load fisheriris
X = meas;
Y = species;
rng(1); % For reproducibility
```

Train and cross-validate a naive Bayes classifier using the default options and k -fold cross-validation. It is good practice to specify the class order.

```
CVMdl1 = fitcnb(X,Y,...
    'ClassNames',{'setosa','versicolor','virginica'},...
    'CrossVal','on');
```

By default, the software models the predictor distribution within each class as a Gaussian with some mean and standard deviation. CVMdl1 is a `ClassificationPartitionedModel` model.

Create a default naive Bayes binary classifier template, and train an error-correcting, output codes multiclass model.

```
t = templateNaiveBayes();
CVMdl2 = fitcecoc(X,Y,'CrossVal','on','Learners',t);
```

CVMdl2 is a `ClassificationPartitionedECOC` model. You can specify options for the naive Bayes binary learners using the same name-value pair arguments as for `fitcnb`.

Compare the out-of-sample k -fold classification error (proportion of misclassified observations).

```
classErr1 = kfoldLoss(CVMdl1,'LossFun','ClassifErr')
classErr1 = 0.0533
classErr2 = kfoldLoss(CVMdl2,'LossFun','ClassifErr')
classErr2 = 0.0467
```

Mdl2 has a lower generalization error.

Train Naive Bayes Classifiers Using Multinomial Predictors

Some spam filters classify an incoming email as spam based on how many times a word or punctuation (called tokens) occurs in an email. The predictors are the frequencies of particular words or punctuations in an email. Therefore, the predictors compose multinomial random variables.

This example illustrates classification using naive Bayes and multinomial predictors.

Create Training Data

Suppose you observed 1000 emails and classified them as spam or not spam. Do this by randomly assigning -1 or 1 to y for each email.

```
n = 1000; % Sample size
rng(1); % For reproducibility
Y = randsample([-1 1],n,true); % Random labels
```

To build the predictor data, suppose that there are five tokens in the vocabulary, and 20 observed tokens per email. Generate predictor data from the five tokens by drawing random, multinomial deviates. The relative frequencies for tokens corresponding to spam emails should differ from emails that are not spam.

```
tokenProbs = [0.2 0.3 0.1 0.15 0.25;... % Token relative frequencies
              0.4 0.1 0.3 0.05 0.15]; % Fixed for convenience
tokensPerEmail = 20;
X = zeros(n,5);
X(Y == 1,:) = mnrnd(tokensPerEmail,tokenProbs(1,:),sum(Y == 1));
X(Y == -1,:) = mnrnd(tokensPerEmail,tokenProbs(2,:),sum(Y == -1));
```

Train the Classifier

Train a naive Bayes classifier. Specify that the predictors are multinomial.

```
Mdl = fitcnb(X,Y,'DistributionNames','mn');
```

Mdl is a trained ClassificationNaiveBayes classifier.

Assess the in-sample performance of Mdl by estimating the misclassification error.

```
isGenRate = resubLoss(Mdl, 'LossFun', 'ClassifErr')  
isGenRate = 0.0200
```

The in-sample misclassification rate is 2%.

Create New Data

Randomly generate deviates that represent a new batch of emails.

```
newN = 500;  
newY = randsample([-1 1], newN, true);  
newX = zeros(newN, 5);  
newX(newY == 1, :) = mnrnd(tokensPerEmail, tokenProbs(1, :), ...  
    sum(newY == 1));  
newX(newY == -1, :) = mnrnd(tokensPerEmail, tokenProbs(2, :), ...  
    sum(newY == -1));
```

Assess Classifier Performance

Classify the new emails using the trained naive Bayes classifier `Mdl`, and determine whether the algorithm generalizes.

```
oosGenRate = loss(Mdl, newX, newY)  
oosGenRate = 0.0261
```

The out-of-sample misclassification rate is 2.6% indicating that the classifier generalizes fairly well.

Optimize Naive Bayes Classifier

This example shows how to use the `OptimizeHyperparameters` name-value pair to minimize cross-validation loss in a naive Bayes classifier using `fitcnb`. The example uses Fisher's iris data.

Load Fisher's iris data.

```
load fisheriris  
X = meas;  
Y = species;  
classNames = {'setosa', 'versicolor', 'virginica'};
```

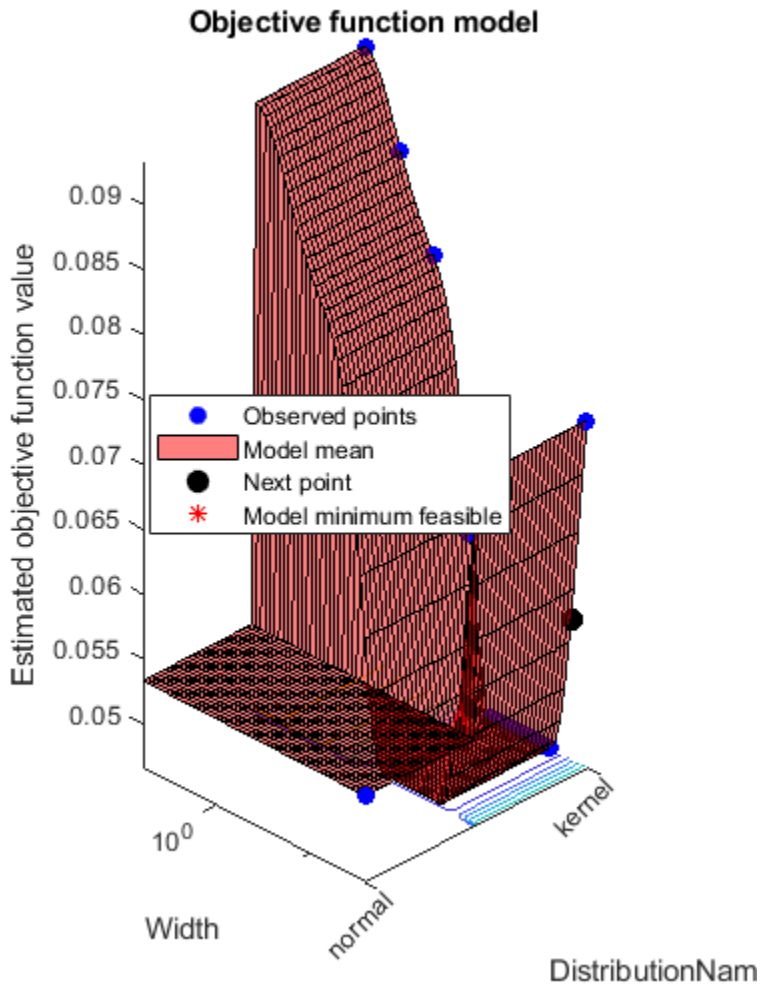

Optimize the classification using the 'auto' parameters.

For reproducibility, set the random seed and use the 'expected-improvement-plus' acquisition function.

```
rng default
Mdl = fitcnb(X,Y,'ClassNames',classNames,'OptimizeHyperparameters','auto',...
            'HyperparameterOptimizationOptions',struct('AcquisitionFunctionName',...
            'expected-improvement-plus'))
```

Warning: It is recommended that you first standardize all numeric predictors when opti

Input Arguments

Tbl — Sample data

table

Sample data used to train the model, specified as a table. Each row of `Tbl` corresponds to one observation, and each column corresponds to one predictor variable. Optionally, `Tbl` can contain one additional column for the response variable. Multicolumn variables and cell arrays other than cell arrays of character vectors are not allowed.

If `Tbl` contains the response variable, and you want to use all remaining variables in `Tbl` as predictors, then specify the response variable by using `ResponseVarName`.

If `Tbl` contains the response variable, and you want to use only a subset of the remaining variables in `Tbl` as predictors, then specify a formula by using `formula`.

If `Tbl` does not contain the response variable, then specify a response variable by using `Y`. The length of the response variable and the number of rows in `Tbl` must be equal.

Data Types: `table`

ResponseVarName — Response variable name

name of variable in `Tbl`

Response variable name, specified as the name of a variable in `Tbl`.

You must specify `ResponseVarName` as a character vector or string scalar. For example, if the response variable `Y` is stored as `Tbl.Y`, then specify it as `'Y'`. Otherwise, the software treats all columns of `Tbl`, including `Y`, as predictors when training the model.

The response variable must be a categorical, character, or string array, logical or numeric vector, or cell array of character vectors. If `Y` is a character array, then each element of the response variable must correspond to one row of the array.

It is a good practice to specify the order of the classes by using the `ClassNames` name-value pair argument.

Data Types: `char` | `string`

formula — Explanatory model of response and subset of predictor variables

character vector | string scalar

Explanatory model of the response and a subset of the predictor variables, specified as a character vector or string scalar in the form `'Y~X1+X2+X3'`. In this form, `Y` represents the response variable, and `X1`, `X2`, and `X3` represent the predictor variables. The variables must be variable names in `Tbl` (`Tbl.Properties.VariableNames`).

To specify a subset of variables in `Tbl` as predictors for training the model, use a formula. If you specify a formula, then the software does not use any variables in `Tbl` that do not appear in `formula`.

Data Types: `char` | `string`

Y — Class labels

categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Class labels to which the naive Bayes classifier is trained, specified as a categorical, character, or string array, a logical or numeric vector, or a cell array of character vectors. Each element of *Y* defines the class membership of the corresponding row of *X*. *Y* supports *K* class levels.

If *Y* is a character array, then each row must correspond to one class label.

The length of *Y* and the number of rows of *X* must be equivalent.

Data Types: categorical | char | string | logical | single | double | cell

X — Predictor data

numeric matrix

Predictor data, specified as a numeric matrix.

Each row of *X* corresponds to one observation (also known as an instance or example), and each column corresponds to one variable (also known as a feature).

The length of *Y* and the number of rows of *X* must be equivalent.

Data Types: double

Note: The software treats NaN, empty character vector (' '), empty string (""), <missing>, and <undefined> elements as missing data values.

- If *Y* contains missing values, then the software removes them and the corresponding rows of *X*.
- If *X* contains any rows composed entirely of missing values, then the software removes those rows and the corresponding elements of *Y*.
- If *X* contains missing values and you set 'DistributionNames', 'mn', then the software removes those rows of *X* and the corresponding elements of *Y*.
- If a predictor is not represented in a class, that is, if all of its values are NaN within a class, then the software returns an error.

Removing rows of *X* and corresponding elements of *Y* decreases the effective training or cross-validation sample size.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Note You cannot use any cross-validation name-value pair argument along with the `'OptimizeHyperparameters'` name-value pair argument. You can modify the cross-validation for `'OptimizeHyperparameters'` only by using the `'HyperparameterOptimizationOptions'` name-value pair argument.

Example: `'DistributionNames','mn','Prior','uniform','KSWidth',0.5` specifies that the data distribution is multinomial, the prior probabilities for all classes are equal, and the kernel smoothing window bandwidth for all classes is 0.5 units.

Naive Bayes Options

DistributionNames — Data distributions

`'kernel' | 'mn' | 'mvmn' | 'normal' | string array | cell array of character vectors`

Data distributions `fitcnb` uses to model the data, specified as the comma-separated pair consisting of `'DistributionNames'` and a character vector or string scalar, a string array, or a cell array of character vectors with values from this table.

Value	Description
<code>'kernel'</code>	Kernel smoothing density estimate.
<code>'mn'</code>	Multinomial distribution. If you specify <code>mn</code> , then all features are components of a multinomial distribution. Therefore, you cannot include <code>'mn'</code> as an element of a string array or a cell array of character vectors. For details, see “Algorithms” on page 32-2044.
<code>'mvmn'</code>	Multivariate multinomial distribution. For details, see “Algorithms” on page 32-2044.
<code>'normal'</code>	Normal (Gaussian) distribution.

If you specify a character vector or string scalar, then the software models all the features using that distribution. If you specify a 1-by- P string array or cell array of character vectors, then the software models feature j using the distribution in element j of the array.

By default, the software sets all predictors specified as categorical predictors (using the `CategoricalPredictors` name-value pair argument) to 'mvmn'. Otherwise, the default distribution is 'normal'.

You must specify that at least one predictor has distribution 'kernel' to additionally specify `Kernel`, `Support`, or `Width`.

Example: 'DistributionNames', 'mn'

Example: 'DistributionNames', {'kernel', 'normal', 'kernel'}

Kernel — Kernel smoother type

'normal' (default) | 'box' | 'epanechnikov' | 'triangle' | string array | cell array of character vectors

Kernel smoother type, specified as the comma-separated pair consisting of 'Kernel' and a character vector or string scalar, a string array, or a cell array of character vectors.

This table summarizes the available options for setting the kernel smoothing density region. Let $I\{u\}$ denote the indicator function.

Value	Kernel	Formula
'box'	Box (uniform)	$f(x) = 0.5I\{ x \leq 1\}$
'epanechnikov'	Epanechnikov	$f(x) = 0.75(1 - x^2)I\{ x \leq 1\}$
'normal'	Gaussian	$f(x) = \frac{1}{\sqrt{2\pi}} \exp(-0.5x^2)$
'triangle'	Triangular	$f(x) = (1 - x)I\{ x \leq 1\}$

If you specify a 1-by- P string array or cell array, with each element of the array containing any value in the table, then the software trains the classifier using the kernel smoother type in element j for feature j in X . The software ignores elements of `Kernel` not corresponding to a predictor whose distribution is 'kernel'.

You must specify that at least one predictor has distribution 'kernel' to additionally specify `Kernel`, `Support`, or `Width`.

Example: 'Kernel', {'epanechnikov', 'normal'}

Support — Kernel smoothing density support

'unbounded' (default) | 'positive' | string array | cell array | numeric row vector

Kernel smoothing density support, specified as the comma-separated pair consisting of 'Support' and 'positive', 'unbounded', a string array, a cell array, or a numeric row vector. The software applies the kernel smoothing density to the specified region.

This table summarizes the available options for setting the kernel smoothing density region.

Value	Description
1-by-2 numeric row vector	For example, [L,U], where L and U are the finite lower and upper bounds, respectively, for the density support.
'positive'	The density support is all positive real values.
'unbounded'	The density support is all real values.

If you specify a 1-by- P string array or cell array, with each element in the string array containing any text value in the table and each element in the cell array containing any value in the table, then the software trains the classifier using the kernel support in element j for feature j in X . The software ignores elements of `Kernel` not corresponding to a predictor whose distribution is 'kernel'.

You must specify that at least one predictor has distribution 'kernel' to additionally specify `Kernel`, `Support`, or `Width`.

Example: 'KSSupport', {[-10,20], 'unbounded'}

Data Types: char | string | cell | double

Width — Kernel smoothing window width

matrix of numeric values | numeric column vector | numeric row vector | scalar

Kernel smoothing window width, specified as the comma-separated pair consisting of 'Width' and a matrix of numeric values, numeric column vector, numeric row vector, or scalar.

Suppose there are K class levels and P predictors. This table summarizes the available options for setting the kernel smoothing window width.

Value	Description
K -by- P matrix of numeric values	Element (k,j) specifies the width for predictor j in class k .
K -by-1 numeric column vector	Element k specifies the width for all predictors in class k .
1-by- P numeric row vector	Element j specifies the width in all class levels for predictor j .
scalar	Specifies the bandwidth for all features in all classes.

By default, the software selects a default width automatically for each combination of predictor and class by using a value that is optimal for a Gaussian distribution. If you specify `Width` and it contains NaNs, then the software selects widths for the elements containing NaNs.

You must specify that at least one predictor has distribution 'kernel' to additionally specify `Kernel`, `Support`, or `Width`.

Example: `'Width', [NaN NaN]`

Data Types: `double` | `struct`

Cross-Validation Options

CrossVal — Cross-validation flag

`'off'` (default) | `'on'`

Cross-validation flag, specified as the comma-separated pair consisting of `'Crossval'` and `'on'` or `'off'`.

If you specify `'on'`, then the software implements 10-fold cross-validation.

To override this cross-validation setting, use one of these name-value pair arguments: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`. To create a cross-validated model, you can use one cross-validation name-value pair argument at a time only.

Alternatively, cross-validate later by passing `Mdl` to `crossval`.

Example: `'CrossVal', 'on'`

CVPartition — Cross-validation partition

`[]` (default) | `cvpartition` partition object

Cross-validation partition, specified as the comma-separated pair consisting of 'CVPartition' and a `cvpartition` partition object created by `cvpartition`. The partition object specifies the type of cross-validation and the indexing for the training and validation sets.

To create a cross-validated model, you can use one of these four name-value pair arguments only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: Suppose you create a random partition for 5-fold cross-validation on 500 observations by using `cvp = cvpartition(500, 'KFold', 5)`. Then, you can specify the cross-validated model by using 'CVPartition', `cvp`.

Holdout — Fraction of data for holdout validation

scalar value in the range (0,1)

Fraction of the data used for holdout validation, specified as the comma-separated pair consisting of 'Holdout' and a scalar value in the range (0,1). If you specify 'Holdout', `p`, then the software completes these steps:

- 1 Randomly select and reserve $p \times 100\%$ of the data as validation data, and train the model using the rest of the data.
- 2 Store the compact, trained model in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: 'Holdout', 0.1

Data Types: `double` | `single`

KFold — Number of folds

10 (default) | positive integer value greater than 1

Number of folds to use in a cross-validated model, specified as the comma-separated pair consisting of 'KFold' and a positive integer value greater than 1. If you specify 'KFold', `k`, then the software completes these steps:

- 1 Randomly partition the data into `k` sets.
- 2 For each set, reserve the set as validation data, and train the model using the other `k - 1` sets.
- 3 Store the `k` compact, trained models in the cells of a `k-by-1` cell vector in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: `'KFold',5`

Data Types: `single` | `double`

Leaveout — Leave-one-out cross-validation flag

`'off'` (default) | `'on'`

Leave-one-out cross-validation flag, specified as the comma-separated pair consisting of `'Leaveout'` and `'on'` or `'off'`. If you specify `'Leaveout', 'on'`, then, for each of the n observations (where n is the number of observations excluding missing observations, specified in the `NumObservations` property of the model), the software completes these steps:

- 1 Reserve the observation as validation data, and train the model using the other $n - 1$ observations.
- 2 Store the n compact, trained models in the cells of an n -by-1 cell vector in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: `'Leaveout', 'on'`

Other Classification Options

CategoricalPredictors — Categorical predictors list

vector of positive integers | logical vector | character matrix | string array | cell array of character vectors | `'all'`

Categorical predictors list, specified as the comma-separated pair consisting of `'CategoricalPredictors'` and one of the values in this table.

Value	Description
Vector of positive integers	An entry in the vector is the index value corresponding to the column of the predictor data (<code>X</code> or <code>Tbl</code>) that contains a categorical variable.
Logical vector	A <code>true</code> entry means that the corresponding column of predictor data (<code>X</code> or <code>Tbl</code>) is a categorical variable.

Value	Description
Character matrix	Each row of the matrix is the name of a predictor variable. The names must match the entries in <code>PredictorNames</code> . Pad the names with extra blanks so each row of the character matrix has the same length.
String array or cell array of character vectors	Each element in the array is the name of a predictor variable. The names must match the entries in <code>PredictorNames</code> .
'all'	All predictors are categorical.

By default, if the predictor data is in a table (`Tbl`), `fitcnb` assumes that a variable is categorical if it contains logical values, categorical values, a string array, or a cell array of character vectors. If the predictor data is a matrix (`X`), `fitcnb` assumes all predictors are continuous. To identify any categorical predictors when the data is a matrix, use the `'CategoricalPredictors'` name-value pair argument.

Example: `'CategoricalPredictors','all'`

Data Types: `single` | `double` | `logical` | `char` | `string` | `cell`

ClassNames — Names of classes to use for training

categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Names of classes to use for training, specified as the comma-separated pair consisting of `'ClassNames'` and a categorical, character, or string array, a logical or numeric vector, or a cell array of character vectors. `ClassNames` must have the same data type as `Y`.

If `ClassNames` is a character array, then each element must correspond to one *row* of the array.

Use `ClassNames` to:

- Order the classes during training.
- Specify the order of any input or output argument dimension that corresponds to the class order. For example, use `ClassNames` to specify the order of the dimensions of `Cost` or the column order of classification scores returned by `predict`.
- Select a subset of classes for training. For example, suppose that the set of all distinct class names in `Y` is `{'a','b','c'}`. To train the model using observations from classes `'a'` and `'c'` only, specify `'ClassNames',{'a','c'}`.

The default value for `ClassNames` is the set of all distinct class names in `Y`.

Example: `'ClassNames', {'b', 'g'}`

Data Types: `categorical | char | string | logical | single | double | cell`

Cost — Cost of misclassification

`square matrix | structure`

Cost of misclassification of a point, specified as the comma-separated pair consisting of `'Cost'` and one of the following:

- Square matrix, where `Cost(i, j)` is the cost of classifying a point into class `j` if its true class is `i` (i.e., the rows correspond to the true class and the columns correspond to the predicted class). To specify the class order for the corresponding rows and columns of `Cost`, additionally specify the `ClassNames` name-value pair argument.
- Structure `S` having two fields: `S.ClassNames` containing the group names as a variable of the same type as `Y`, and `S.ClassificationCosts` containing the cost matrix.

The default is `Cost(i, j)=1` if `i~≠j`, and `Cost(i, j)=0` if `i=j`.

Example: `'Cost', struct('ClassNames', {'b', 'g'}, 'ClassificationCosts', [0 0.5; 1 0])`

Data Types: `single | double | struct`

PredictorNames — Predictor variable names

`string array of unique names | cell array of unique character vectors`

Predictor variable names, specified as the comma-separated pair consisting of `'PredictorNames'` and a string array of unique names or cell array of unique character vectors. The functionality of `'PredictorNames'` depends on the way you supply the training data.

- If you supply `X` and `Y`, then you can use `'PredictorNames'` to give the predictor variables in `X` names.
 - The order of the names in `PredictorNames` must correspond to the column order of `X`. That is, `PredictorNames{1}` is the name of `X(:, 1)`, `PredictorNames{2}` is the name of `X(:, 2)`, and so on. Also, `size(X, 2)` and `numel(PredictorNames)` must be equal.
 - By default, `PredictorNames` is `{'x1', 'x2', ...}`.

- If you supply `Tbl`, then you can use `'PredictorNames'` to choose which predictor variables to use in training. That is, `fitcnb` uses only the predictor variables in `PredictorNames` and the response variable in training.
 - `PredictorNames` must be a subset of `Tbl.Properties.VariableNames` and cannot include the name of the response variable.
 - By default, `PredictorNames` contains the names of all predictor variables.
 - It is a good practice to specify the predictors for training using either `'PredictorNames'` or formula only.

Example: `'PredictorNames'`,
`{'SepalLength','SepalWidth','PetalLength','PetalWidth'}`

Data Types: `string` | `cell`

Prior — Prior probabilities

`'empirical'` (default) | `'uniform'` | vector of scalar values | structure

Prior probabilities for each class, specified as the comma-separated pair consisting of `'Prior'` and a value in this table.

Value	Description
<code>'empirical'</code>	The class prior probabilities are the class relative frequencies in <code>Y</code> .
<code>'uniform'</code>	All class prior probabilities are equal to $1/K$, where K is the number of classes.
numeric vector	Each element is a class prior probability. Order the elements according to <code>Mdl.ClassNames</code> or specify the order using the <code>ClassNames</code> name-value pair argument. The software normalizes the elements such that they sum to 1.

Value	Description
structure	<p>A structure <code>S</code> with two fields:</p> <ul style="list-style-type: none"> • <code>S.ClassNames</code> contains the class names as a variable of the same type as <code>Y</code>. • <code>S.ClassProbs</code> contains a vector of corresponding prior probabilities. The software normalizes the elements such that they sum to 1.

If you set values for both `Weights` and `Prior`, the weights are renormalized to add up to the value of the prior probability in the respective class.

Example: `'Prior', 'uniform'`

Data Types: `char | string | single | double | struct`

ResponseName — Response variable name

`'Y'` (default) | character vector | string scalar

Response variable name, specified as the comma-separated pair consisting of `'ResponseName'` and a character vector or string scalar.

- If you supply `Y`, then you can use `'ResponseName'` to specify a name for the response variable.
- If you supply `ResponseVarName` or `formula`, then you cannot use `'ResponseName'`.

Example: `'ResponseName', 'response'`

Data Types: `char | string`

ScoreTransform — Score transformation

`'none'` (default) | `'doublelogit'` | `'invlogit'` | `'ismax'` | `'logit'` | function handle | ...

Score transformation, specified as the comma-separated pair consisting of `'ScoreTransform'` and a character vector, string scalar, or function handle.

This table summarizes the available character vectors and string scalars.

Value	Description
'doublelogit'	$1/(1 + e^{-2x})$
'invlogit'	$\log(x / (1 - x))$
'ismax'	Sets the score for the class with the largest score to 1, and sets the scores for all other classes to 0
'logit'	$1/(1 + e^{-x})$
'none' or 'identity'	x (no transformation)
'sign'	-1 for $x < 0$ 0 for $x = 0$ 1 for $x > 0$
'symmetric'	$2x - 1$
'symmetricismax'	Sets the score for the class with the largest score to 1, and sets the scores for all other classes to -1
'symmetriclogit'	$2/(1 + e^{-x}) - 1$

For a MATLAB function or a function you define, use its function handle for score transform. The function handle must accept a matrix (the original scores) and return a matrix of the same size (the transformed scores).

Example: 'ScoreTransform', 'logit'

Data Types: char | string | function_handle

Weights — Observation weights

numeric vector of positive values | name of variable in Tbl

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a numeric vector of positive values or name of a variable in Tbl. The software weighs the observations in each row of X or Tbl with the corresponding value in Weights. The size of Weights must equal the number of rows of X or Tbl.

If you specify the input data as a table Tbl, then Weights can be the name of a variable in Tbl that contains a numeric vector. In this case, you must specify Weights as a character vector or string scalar. For example, if the weights vector W is stored as Tbl.W, then specify it as 'W'. Otherwise, the software treats all columns of Tbl, including W, as predictors or the response when training the model.

The software normalizes `Weights` to sum up to the value of the prior probability in the respective class.

By default, `Weights` is `ones(n, 1)`, where n is the number of observations in `X` or `Tbl`.

Data Types: `double` | `single` | `char` | `string`

Hyperparameter Optimization

OptimizeHyperparameters — Parameters to optimize

'none' (default) | 'auto' | 'all' | string array or cell array of eligible parameter names | vector of `optimizableVariable` objects

Parameters to optimize, specified as the comma-separated pair consisting of 'OptimizeHyperparameters' and one of the following:

- 'none' — Do not optimize.
- 'auto' — Use {'DistributionNames', 'Width'}.
- 'all' — Optimize all eligible parameters.
- String array or cell array of eligible parameter names.
- Vector of `optimizableVariable` objects, typically the output of `hyperparameters`.

The optimization attempts to minimize the cross-validation loss (error) for `fitcnb` by varying the parameters. For information about cross-validation loss (albeit in a different context), see “Classification Loss” on page 32-3352. To control the cross-validation type and other aspects of the optimization, use the `HyperparameterOptimizationOptions` name-value pair.

Note 'OptimizeHyperparameters' values override any values you set using other name-value pair arguments. For example, setting 'OptimizeHyperparameters' to 'auto' causes the 'auto' values to apply.

The eligible parameters for `fitcnb` are:

- `DistributionNames` — `fitcnb` searches among 'normal' and 'kernel'.
- `Width` — `fitcnb` searches among real values, by default log-scaled in the range `[MinPredictorDiff/4, max(MaxPredictorRange, MinPredictorDiff)]`.
- `Kernel` — `fitcnb` searches among 'normal', 'box', 'epanechnikov', and 'triangle'.

Set nondefault parameters by passing a vector of `optimizableVariable` objects that have nondefault values. For example,

```
load fisheriris
params = hyperparameters('fitcnb',meas,species);
params(2).Range = [1e-2,1e2];
```

Pass `params` as the value of `OptimizeHyperparameters`.

By default, iterative display appears at the command line, and plots appear according to the number of hyperparameters in the optimization. For the optimization and plots, the objective function is $\log(1 + \text{cross-validation loss})$ for regression and the misclassification rate for classification. To control the iterative display, set the `Verbose` field of the `'HyperparameterOptimizationOptions'` name-value pair argument. To control the plots, set the `ShowPlots` field of the `'HyperparameterOptimizationOptions'` name-value pair argument.

For an example, see “Optimize Naive Bayes Classifier” on page 32-2020.

Example: 'auto'

HyperparameterOptimizationOptions — Options for optimization structure

Options for optimization, specified as the comma-separated pair consisting of `'HyperparameterOptimizationOptions'` and a structure. This argument modifies the effect of the `OptimizeHyperparameters` name-value pair argument. All fields in the structure are optional.

Field Name	Values	Default
Optimizer	<ul style="list-style-type: none"> • 'bayesopt' — Use Bayesian optimization. Internally, this setting calls bayesopt. • 'gridsearch' — Use grid search with NumGridDivisions values per dimension. • 'randomsearch' — Search at random among MaxObjectiveEvaluations points. <p>'gridsearch' searches in a random order, using uniform sampling without replacement from the grid. After optimization, you can get a table in grid order by using the command <code>sortrows(Mdl.HyperparameterOptimizationResults)</code>.</p>	'bayesopt'
AcquisitionFunctionName	<ul style="list-style-type: none"> • 'expected-improvement-per-second-plus' • 'expected-improvement' • 'expected-improvement-plus' • 'expected-improvement-per-second' • 'lower-confidence-bound' • 'probability-of-improvement' <p>Acquisition functions whose names include <code>per-second</code> do not yield reproducible results because the optimization depends on the runtime of the objective function. Acquisition functions whose names include <code>plus</code> modify their behavior when they are overexploiting an area. For more details, see “Acquisition Function Types” on page 10-4.</p>	'expected-improvement-per-second-plus'

Field Name	Values	Default
MaxObjectiveEvaluations	Maximum number of objective function evaluations.	30 for 'bayesopt' or 'randomsearch', and the entire grid for 'gridsearch'
MaxTime	Time limit, specified as a positive real. The time limit is in seconds, as measured by tic and toc. Run time can exceed MaxTime because MaxTime does not interrupt function evaluations.	Inf
NumGridDivisions	For 'gridsearch', the number of values in each dimension. The value can be a vector of positive integers giving the number of values for each dimension, or a scalar that applies to all dimensions. This field is ignored for categorical variables.	10
ShowPlots	Logical value indicating whether to show plots. If true, this field plots the best objective function value against the iteration number. If there are one or two optimization parameters, and if Optimizer is 'bayesopt', then ShowPlots also plots a model of the objective function against the parameters.	true
SaveIntermediateResults	Logical value indicating whether to save results when Optimizer is 'bayesopt'. If true, this field overwrites a workspace variable named 'BayesoptResults' at each iteration. The variable is a BayesianOptimization object.	false

Field Name	Values	Default
Verbose	Display to the command line. <ul style="list-style-type: none"> • 0 — No iterative display • 1 — Iterative display • 2 — Iterative display with extra information For details, see the <code>bayesopt</code> <code>Verbose</code> name-value pair argument.	1
UseParallel	Logical value indicating whether to run Bayesian optimization in parallel, which requires Parallel Computing Toolbox. For details, see “Parallel Bayesian Optimization” on page 10-8.	false
Repartition	Logical value indicating whether to repartition the cross-validation at every iteration. If <code>false</code> , the optimizer uses a single partition for the optimization. <code>true</code> usually gives the most robust results because this setting takes partitioning noise into account. However, for good results, <code>true</code> requires at least twice as many function evaluations.	false
Use no more than one of the following three field names.		
CVPartition	A <code>cvpartition</code> object, as created by <code>cvpartition</code> .	'Kfold', 5 if you do not specify any cross-validation field
Holdout	A scalar in the range (0, 1) representing the holdout fraction.	
Kfold	An integer greater than 1.	

Example:

```
'HyperparameterOptimizationOptions', struct('MaxObjectiveEvaluations', 60)
```

Data Types: struct

Output Arguments

Mdl — Trained naive Bayes classification model

ClassificationNaiveBayes model object | ClassificationPartitionedModel
cross-validated model object

Trained naive Bayes classification model, returned as a `ClassificationNaiveBayes` model object or a `ClassificationPartitionedModel` cross-validated model object.

If you set any of the name-value pair arguments `KFold`, `Holdout`, `CrossVal`, or `CVPartition`, then `Mdl` is a `ClassificationPartitionedModel` cross-validated model object. Otherwise, `Mdl` is a `ClassificationNaiveBayes` model object.

To reference properties of `Mdl`, use dot notation. For example, to access the estimated distribution parameters, enter `Mdl.DistributionParameters`.

Definitions

Bag-of-Tokens Model

In the bag-of-tokens model, the value of predictor j is the nonnegative number of occurrences of token j in this observation. The number of categories (bins) in this multinomial model is the number of distinct tokens, that is, the number of predictors.

Naive Bayes

Naive Bayes is a classification algorithm that applies density estimation to the data.

The algorithm leverages Bayes theorem, and (naively) assumes that the predictors are conditionally independent, given the class. Though the assumption is usually violated in practice, naive Bayes classifiers tend to yield posterior distributions that are robust to biased class density estimates, particularly where the posterior is 0.5 (the decision boundary) [1].

Naive Bayes classifiers assign observations to the most probable class (in other words, the maximum a posteriori decision rule). Explicitly, the algorithm:

- 1 Estimates the densities of the predictors within each class.

- 2 Models posterior probabilities according to Bayes rule. That is, for all $k = 1, \dots, K$,

$$\widehat{P}(Y = k | X_1, \dots, X_P) = \frac{\pi(Y = k) \prod_{j=1}^P P(X_j | Y = k)}{\sum_{k=1}^K \pi(Y = k) \prod_{j=1}^P P(X_j | Y = k)},$$

where:

- Y is the random variable corresponding to the class index of an observation.
 - X_1, \dots, X_P are the random predictors of an observation.
 - $\pi(Y = k)$ is the prior probability that a class index is k .
- 3 Classifies an observation by estimating the posterior probability for each class, and then assigns the observation to the class yielding the maximum posterior probability.

If the predictors compose a multinomial distribution, then the posterior probability $\widehat{P}(Y = k | X_1, \dots, X_P) \propto \pi(Y = k) P_{mn}(X_1, \dots, X_P | Y = k)$, where $P_{mn}(X_1, \dots, X_P | Y = k)$ is the probability mass function of a multinomial distribution.

Tips

- For classifying count-based data, such as the bag-of-tokens model on page 32-2043, use the multinomial distribution (e.g., set 'DistributionNames', 'mn').
- After training a model, you can generate C/C++ code that predicts labels for new data. Generating C/C++ code requires MATLAB Coder. For details, see “Introduction to Code Generation” on page 31-2.

Algorithms

- If you specify 'DistributionNames', 'mn' when training Mdl using fitcnb, then the software fits a multinomial distribution using the bag-of-tokens model on page 32-2043. The software stores the probability that token j appears in class k in the property DistributionParameters{ k, j }. Using additive smoothing [2], the estimated probability is

$$P(\text{token } j \mid \text{class } k) = \frac{1 + c_{j|k}}{P + c_k},$$

where:

- $$c_{j|k} = n_k \frac{\sum_{i: y_i \in \text{class } k} x_{ij} w_i}{\sum_{i: y_i \in \text{class } k} w_i};$$
 which is the weighted number of occurrences of token j in class k .
- n_k is the number of observations in class k .
- w_i is the weight for observation i . The software normalizes weights within a class such that they sum to the prior probability for that class.
- $c_k = \sum_{j=1}^P c_{j|k}$; which is the total weighted number of occurrences of all tokens in class k .
- If you specify 'DistributionNames', 'mvnm' when training Mdl using fitcnb, then:
 - 1 For each predictor, the software collects a list of the unique levels, stores the sorted list in `CategoricalLevels`, and considers each level a bin. Each predictor/class combination is a separate, independent multinomial random variable.
 - 2 For predictor j in class k , the software counts instances of each categorical level using the list stored in `CategoricalLevels{j}`.
 - 3 The software stores the probability that predictor j , in class k , has level L in the property `DistributionParameters{k, j}`, for all levels in `CategoricalLevels{j}`. Using additive smoothing [2], the estimated probability is

$$P(\text{predictor } j = L | \text{class } k) = \frac{1 + m_{j|k}(L)}{m_j + m_k},$$

where:

- $$m_{j|k}(L) = n_k \frac{\sum_{i: y_i \in \text{class } k} I\{x_{ij} = L\} w_i}{\sum_{i: y_i \in \text{class } k} w_i};$$
 which is the weighted number of observations for which predictor j equals L in class k .

- n_k is the number of observations in class k .
- $I\{x_{ij} = L\} = 1$ if $x_{ij} = L$, 0 otherwise.
- w_i is the weight for observation i . The software normalizes weights within a class such that they sum to the prior probability for that class.
- m_j is the number of distinct levels in predictor j .
- m_k is the weighted number of observations in class k .

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function supports tall arrays with the limitations:

- Supported syntaxes are:
 - `Mdl = fitcnb(Tbl,Y)`
 - `Mdl = fitcnb(X,Y)`
 - `Mdl = fitcnb(__,Name,Value)`
- Options related to kernel densities, cross-validation, and hyperparameter optimization are not supported. The supported name-value pair arguments are:
 - 'DistributionNames' — 'kernel' value is not supported.
 - 'CategoricalPredictors'
 - 'Cost'

- 'PredictorNames'
- 'Prior'
- 'ResponseName'
- 'ScoreTransform'
- 'Weights' — Value must be a tall array.

For more information, see “Tall Arrays” (MATLAB).

Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the 'UseParallel' option to true.

To perform parallel hyperparameter optimization, use the 'HyperparameterOptions', struct('UseParallel', true) name-value pair argument in the call to this function.

For more information on parallel hyperparameter optimization, see “Parallel Bayesian Optimization” on page 10-8.

For more general information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

Introduced in R2014b

fitcsvm

Train support vector machine (SVM) classifier for one-class and binary classification

`fitcsvm` trains or cross-validates a support vector machine (SVM) model for one-class and two-class (binary) classification on a low-dimensional or moderate-dimensional predictor data set. `fitcsvm` supports mapping the predictor data using kernel functions, and supports sequential minimal optimization (SMO), iterative single data algorithm (ISDA), or $L1$ soft-margin minimization via quadratic programming for objective-function minimization.

To train a linear SVM model for binary classification on a high-dimensional data set, that is, a data set that includes many predictor variables, use `fitclinear` instead.

For multiclass learning with combined binary SVM models, use error-correcting output codes (ECOC). For more details, see `fitcecoc`.

To train an SVM regression model, see `fitrsvm` for low-dimensional and moderate-dimensional predictor data sets, or `fitrlinear` for high-dimensional data sets.

Syntax

```
Mdl = fitcsvm(Tbl,ResponseVarName)
```

```
Mdl = fitcsvm(Tbl,formula)
```

```
Mdl = fitcsvm(Tbl,Y)
```

```
Mdl = fitcsvm(X,Y)
```

```
Mdl = fitcsvm(___,Name,Value)
```

Description

`Mdl = fitcsvm(Tbl,ResponseVarName)` returns a support vector machine (SVM) classifier on page 32-2089 `Mdl` trained using the sample data contained in the table `Tbl`. `ResponseVarName` is the name of the variable in `Tbl` that contains the class labels for one-class or two-class classification.

`Mdl = fitcsvm(Tbl, formula)` returns an SVM classifier trained using the sample data contained in the table `Tbl`. `formula` is an explanatory model of the response and a subset of the predictor variables in `Tbl` used to fit `Mdl`.

`Mdl = fitcsvm(Tbl, Y)` returns an SVM classifier trained using the predictor variables in the table `Tbl` and the class labels in vector `Y`.

`Mdl = fitcsvm(X, Y)` returns an SVM classifier trained using the predictors in the matrix `X` and the class labels in vector `Y` for one-class or two-class classification.

`Mdl = fitcsvm(____, Name, Value)` specifies options using one or more name-value pair arguments in addition to the input arguments in previous syntaxes. For example, you can specify the type of cross-validation, the cost for misclassification, and the type of score transformation function.

Examples

Train SVM Classifier

Load Fisher's iris data set. Remove the sepal lengths and widths and all observed setosa irises.

```
load fisheriris
inds = ~strcmp(species, 'setosa');
X = meas(inds, 3:4);
y = species(inds);
```

Train an SVM classifier using the processed data set.

```
SVModel = fitcsvm(X, y)

SVModel =
  ClassificationSVM
      ResponseName: 'Y'
  CategoricalPredictors: []
      ClassNames: {'versicolor' 'virginica'}
      ScoreTransform: 'none'
  NumObservations: 100
          Alpha: [24x1 double]
          Bias: -14.4149
  KernelParameters: [1x1 struct]
```

```
BoxConstraints: [100x1 double]
ConvergenceInfo: [1x1 struct]
IsSupportVector: [100x1 logical]
Solver: 'SMO'
```

Properties, Methods

`SVMModel` is a trained `ClassificationSVM` classifier. Display the properties of `SVMModel`. For example, to determine the class order, use dot notation.

```
classOrder = SVMModel.ClassNames
```

```
classOrder = 2x1 cell array
    {'versicolor'}
    {'virginica' }
```

The first class ('versicolor') is the negative class, and the second ('virginica') is the positive class. You can change the class order during training by using the 'ClassNames' name-value pair argument.

Plot a scatter diagram of the data and circle the support vectors.

```
sv = SVMModel.SupportVectors;
figure
gscatter(X(:,1),X(:,2),y)
hold on
plot(sv(:,1),sv(:,2),'ko','MarkerSize',10)
legend('versicolor','virginica','Support Vector')
hold off
```

The support vectors are observations that occur on or beyond their estimated class boundaries.

You can adjust the boundaries (and, therefore, the number of support vectors) by setting a box constraint during training using the 'BoxConstraint' name-value pair argument.

Train and Cross-Validate SVM Classifier

Load the ionosphere data set.

```
load ionosphere
rng(1); % For reproducibility
```

Train an SVM classifier using the radial basis kernel. Let the software find a scale value for the kernel function. Standardize the predictors.

```
SVMMModel = fitcsvm(X,Y,'Standardize',true,'KernelFunction','RBF',...  
    'KernelScale','auto');
```

SVMMModel is a trained `ClassificationSVM` classifier.

Cross-validate the SVM classifier. By default, the software uses 10-fold cross-validation.

```
CVSVMMModel = crossval(SVMMModel);
```

CVSVMMModel is a `ClassificationPartitionedModel` cross-validated classifier.

Estimate the out-of-sample misclassification rate.

```
classLoss = kfoldLoss(CVSVMMModel)  
  
classLoss = 0.0484
```

The generalization rate is approximately 5%.

Detect Outliers Using SVM and One-Class Learning

Modify Fisher's iris data set by assigning all the irises to the same class. Detect outliers in the modified data set, and confirm the expected proportion of the observations that are outliers.

Load Fisher's iris data set. Remove the petal lengths and widths. Treat all irises as coming from the same class.

```
load fisheriris  
X = meas(:,1:2);  
y = ones(size(X,1),1);
```

Train an SVM classifier using the modified data set. Assume that 5% of the observations are outliers. Standardize the predictors.

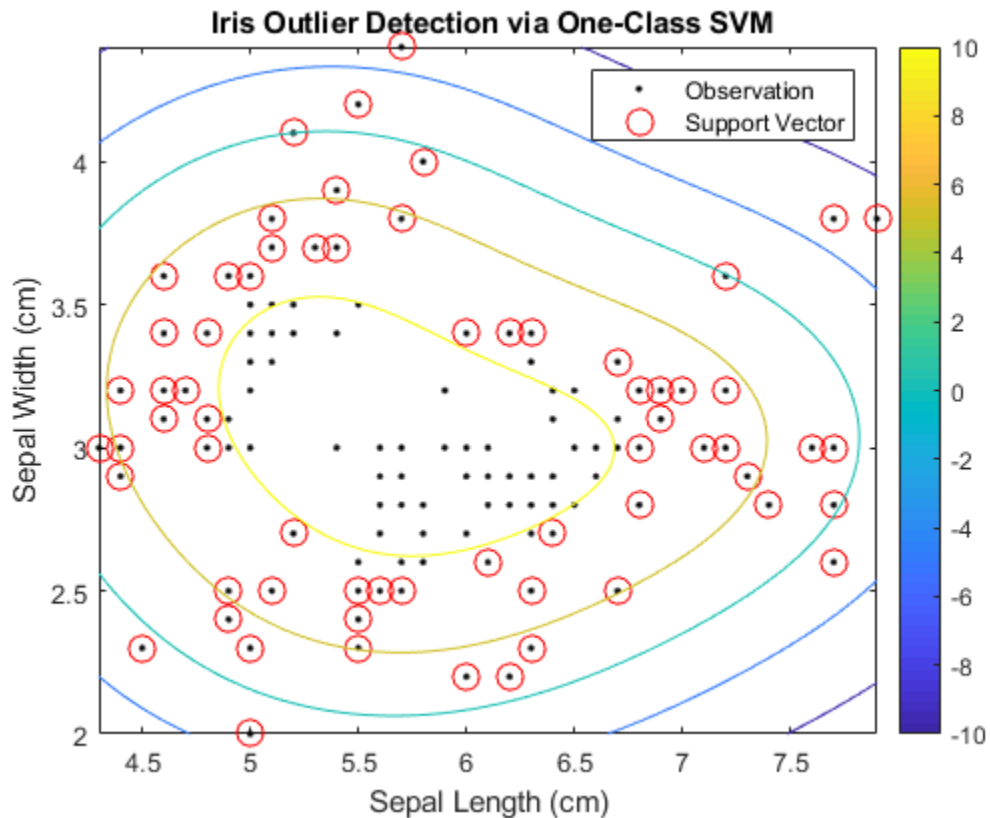

```
rng(1);  
SVMMModel = fitcsvm(X,y,'KernelScale','auto','Standardize',true,...  
    'OutlierFraction',0.05);
```

SVMModel is a trained ClassificationSVM classifier. By default, the software uses the Gaussian kernel for one-class learning.

Plot the observations and the decision boundary. Flag the support vectors and potential outliers.

```
svInd = SVMModel.IsSupportVector;
h = 0.02; % Mesh grid step size
[X1,X2] = meshgrid(min(X(:,1)):h:max(X(:,1)),...
    min(X(:,2)):h:max(X(:,2)));
[~,score] = predict(SVMModel,[X1(:),X2(:)]);
scoreGrid = reshape(score,size(X1,1),size(X2,2));

figure
plot(X(:,1),X(:,2),'k.')
hold on
plot(X(svInd,1),X(svInd,2),'ro','MarkerSize',10)
contour(X1,X2,scoreGrid)
colorbar;
title('{\bf Iris Outlier Detection via One-Class SVM}')
xlabel('Sepal Length (cm)')
ylabel('Sepal Width (cm)')
legend('Observation','Support Vector')
hold off
```

The boundary separating the outliers from the rest of the data occurs where the contour value is 0.

Verify that the fraction of observations with negative scores in the cross-validated data is close to 5%.

```
CVSVMModel = crossval(SVMModel);
[~,scorePred] = kfoldPredict(CVSVMModel);
outlierRate = mean(scorePred<0)
```

```
outlierRate = 0.0467
```

Find Multiple Class Boundaries Using Binary SVM

Create a scatter plot of the `fisheriris` data set. Treat coordinates of a grid within the plot as new observations from the distribution of the data set, and find class boundaries by assigning the coordinates to one of the three classes in the data set.

Load Fisher's iris data set. Use the petal lengths and widths as the predictors.

```
load fisheriris
X = meas(:,3:4);
Y = species;
```

Examine a scatter plot of the data.

```
figure
gscatter(X(:,1),X(:,2),Y);
h = gca;
lims = [h.XLim h.YLim]; % Extract the x and y axis limits
title('\bf Scatter Diagram of Iris Measurements');
xlabel('Petal Length (cm)');
ylabel('Petal Width (cm)');
legend('Location', 'Northwest');
```

The data contains three classes, one of which is linearly separable from the others.

For each class:

- 1 Create a logical vector (`indx`) indicating whether an observation is a member of the class.
- 2 Train an SVM classifier using the predictor data and `indx`.
- 3 Store the classifier in a cell of a cell array.

Define the class order.

```
SVMModels = cell(3,1);  
classes = unique(Y);
```

```

rng(1); % For reproducibility

for j = 1:numel(classes)
    indx = strcmp(Y,classes(j)); % Create binary classes for each classifier
    SVMModels{j} = fitcsvm(X,indx,'ClassNames',[false true],'Standardize',true,...
        'KernelFunction','rbf','BoxConstraint',1);
end

```

SVMModels is a 3-by-1 cell array, with each cell containing a ClassificationSVM classifier. For each cell, the positive class is setosa, versicolor, and virginica, respectively.

Define a fine grid within the plot, and treat the coordinates as new observations from the distribution of the training data. Estimate the score of the new observations using each classifier.

```

d = 0.02;
[x1Grid,x2Grid] = meshgrid(min(X(:,1)):d:max(X(:,1)),...
    min(X(:,2)):d:max(X(:,2)));
xGrid = [x1Grid(:),x2Grid(:)];
N = size(xGrid,1);
Scores = zeros(N,numel(classes));

for j = 1:numel(classes)
    [~,score] = predict(SVMModels{j},xGrid);
    Scores(:,j) = score(:,2); % Second column contains positive-class scores
end

```

Each row of Scores contains three scores. The index of the element with the largest score is the index of the class to which the new class observation most likely belongs.

Associate each new observation with the classifier that gives it the maximum score.

```

[~,maxScore] = max(Scores,[],2);

```

Color in the regions of the plot based on the class to which the corresponding new observation belongs.

```

figure
h(1:3) = gscatter(xGrid(:,1),xGrid(:,2),maxScore,...
    [0.1 0.5 0.5; 0.5 0.1 0.5; 0.5 0.5 0.1]);
hold on
h(4:6) = gscatter(X(:,1),X(:,2),Y);
title('\bf Iris Classification Regions');
xlabel('Petal Length (cm)');

```

```

ylabel('Petal Width (cm)');
legend(h,{'setosa region','versicolor region','virginica region',...
         'observed setosa','observed versicolor','observed virginica'},...
       'Location','Northwest');
axis tight
hold off

```

Optimize SVM Classifier

Optimize hyperparameters automatically using `fitcsvm`.

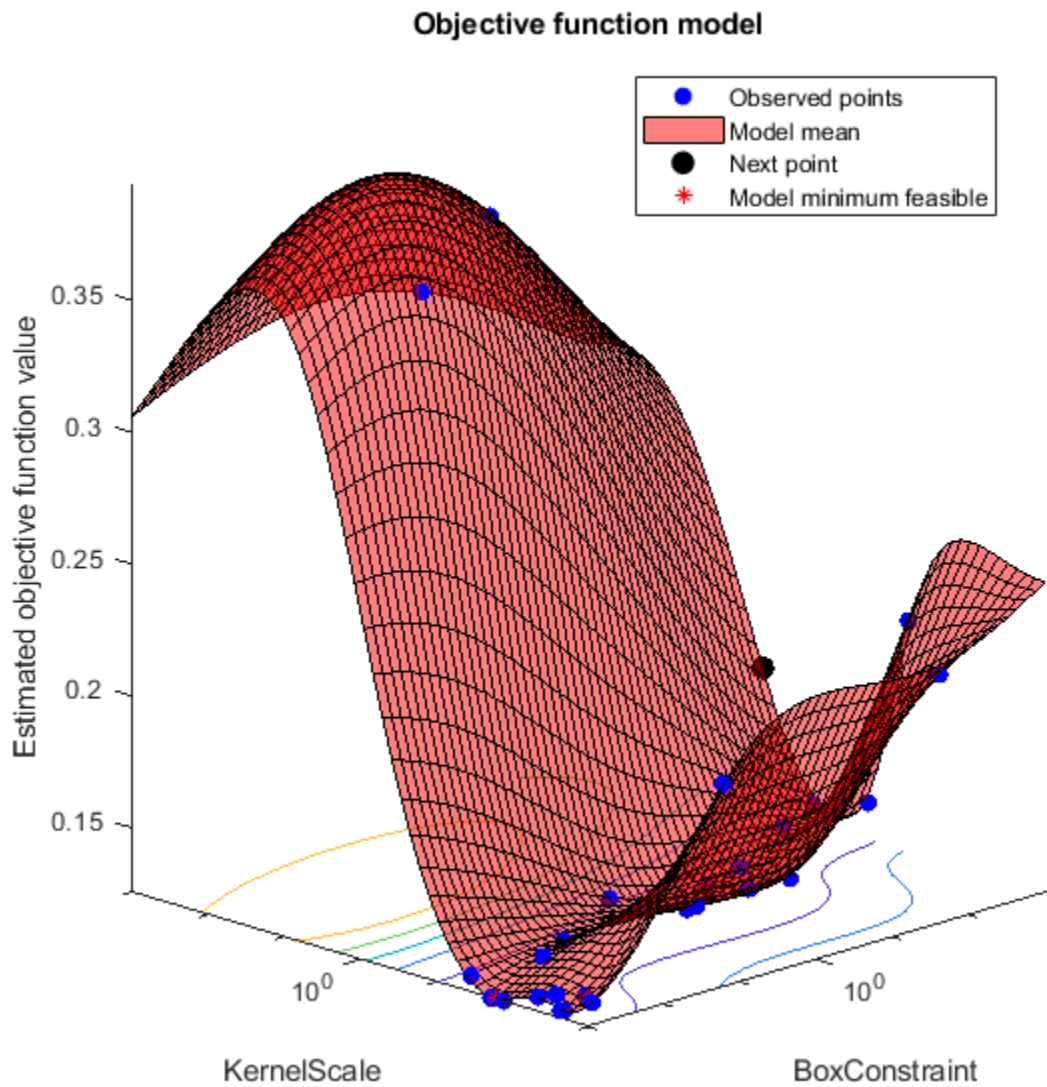

Load the `ionosphere` data set.

```
load ionosphere
```

Find hyperparameters that minimize five-fold cross-validation loss by using automatic hyperparameter optimization. For reproducibility, set the random seed and use the 'expected-improvement-plus' acquisition function.

```
rng default
Mdl = fitcsvm(X,Y,'OptimizeHyperparameters','auto',...
    'HyperparameterOptimizationOptions',struct('AcquisitionFunctionName',...
    'expected-improvement-plus'))
```

Properties, Methods

Input Arguments

Tbl — Sample data

table

Sample data used to train the model, specified as a table. Each row of `Tbl` corresponds to one observation, and each column corresponds to one predictor variable. Optionally, `Tbl` can contain one additional column for the response variable. Multicolumn variables and cell arrays other than cell arrays of character vectors are not allowed.

If `Tbl` contains the response variable, and you want to use all remaining variables in `Tbl` as predictors, then specify the response variable by using `ResponseVarName`.

If `Tbl` contains the response variable, and you want to use only a subset of the remaining variables in `Tbl` as predictors, then specify a formula by using `formula`.

If `Tbl` does not contain the response variable, then specify a response variable by using `Y`. The length of the response variable and the number of rows in `Tbl` must be equal.

Data Types: `table`

ResponseVarName — Response variable name

name of variable in `Tbl`

Response variable name, specified as the name of a variable in `Tbl`.

You must specify `ResponseVarName` as a character vector or string scalar. For example, if the response variable `Y` is stored as `Tbl.Y`, then specify it as `'Y'`. Otherwise, the software treats all columns of `Tbl`, including `Y`, as predictors when training the model.

The response variable must be a categorical, character, or string array, logical or numeric vector, or cell array of character vectors. If `Y` is a character array, then each element of the response variable must correspond to one row of the array.

It is a good practice to specify the order of the classes by using the `ClassNames` name-value pair argument.

Data Types: `char` | `string`

formula — Explanatory model of response and subset of predictor variables

character vector | string scalar

Explanatory model of the response and a subset of the predictor variables, specified as a character vector or string scalar in the form `'Y~X1+X2+X3'`. In this form, `Y` represents

the response variable, and `X1`, `X2`, and `X3` represent the predictor variables. The variables must be variable names in `Tbl` (`Tbl.Properties.VariableNames`).

To specify a subset of variables in `Tbl` as predictors for training the model, use a formula. If you specify a formula, then the software does not use any variables in `Tbl` that do not appear in `formula`.

Data Types: `char` | `string`

Y — Class labels

categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Class labels to which the SVM model is trained, specified as a categorical, character, or string array, logical or numeric vector, or cell array of character vectors.

- `Y` must contain at most two distinct classes. For multiclass learning, see `fitcecoc`.
- If `Y` is a character array, then each element of the class labels must correspond to one row of the array.
- The length of `Y` and the number of rows in `Tbl` or `X` must be equal.
- It is a good practice to specify the class order by using the `ClassNames` name-value pair argument.

Data Types: `categorical` | `char` | `string` | `logical` | `single` | `double` | `cell`

X — Predictor data

matrix of numeric values

Predictor data to which the SVM classifier is trained, specified as a matrix of numeric values.

Each row of `X` corresponds to one observation (also known as an instance or example), and each column corresponds to one predictor (also known as a feature).

The length of `Y` and the number of rows in `X` must be equal.

To specify the names of the predictors in the order of their appearance in `X`, use the `'PredictorNames'` name-value pair argument.

Data Types: `double` | `single`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `fitcsvm(X,Y,'KFold',10,'Cost',[0 2;1 0], 'ScoreTransform','sign')` performs 10-fold cross-validation, applies double the penalty to false positives compared to false negatives, and transforms scores using the `sign` function.

SVM Options

BoxConstraint — Box constraint

1 (default) | positive scalar

Box constraint on page 32-2087, specified as the comma-separated pair consisting of `'BoxConstraint'` and a positive scalar.

For one-class learning, the software always sets the box constraint to 1.

For more details on the relationships and algorithmic behavior of `BoxConstraint`, `Cost`, `Prior`, `Standardize`, and `Weights`, see “Algorithms” on page 32-2092.

Example: `'BoxConstraint',100`

Data Types: `double` | `single`

KernelFunction — Kernel function

`'linear'` (default) | `'gaussian'` | `'rbf'` | `'polynomial'` | function name

Kernel function used to compute the elements of the Gram matrix on page 32-2088, specified as the comma-separated pair consisting of `'KernelFunction'` and a kernel function name. Suppose $G(x_j, x_k)$ is element (j,k) of the Gram matrix, where x_j and x_k are p -dimensional vectors representing observations j and k in X . This table describes supported kernel function names and their functional forms.

Kernel Function Name	Description	Formula
'gaussian' or 'rbf'	Gaussian or Radial Basis Function (RBF) kernel, default for one-class learning	$G(x_j, x_k) = \exp(-\ x_j - x_k\ ^2)$
'linear'	Linear kernel, default for two-class learning	$G(x_j, x_k) = x_j'x_k$
'polynomial'	Polynomial kernel. Use 'PolynomialOrder', q to specify a polynomial kernel of order q .	$G(x_j, x_k) = (1 + x_j'x_k)^q$

You can set your own kernel function, for example, `kernel`, by setting 'KernelFunction', 'kernel'. The value `kernel` must have this form.

```
function G = kernel(U,V)
```

where:

- U is an m -by- p matrix. Columns correspond to predictor variables, and rows correspond to observations.
- V is an n -by- p matrix. Columns correspond to predictor variables, and rows correspond to observations.
- G is an m -by- n Gram matrix on page 32-2088 of the rows of U and V .

`kernel.m` must be on the MATLAB path.

It is a good practice to avoid using generic names for kernel functions. For example, call a sigmoid kernel function 'mysigmoid' rather than 'sigmoid'.

Example: 'KernelFunction', 'gaussian'

Data Types: char | string

KernelScale — Kernel scale parameter

1 (default) | 'auto' | positive scalar

Kernel scale parameter, specified as the comma-separated pair consisting of 'KernelScale' and 'auto' or a positive scalar. The software divides all elements of the predictor matrix X by the value of `KernelScale`. Then, the software applies the appropriate kernel norm to compute the Gram matrix.

- If you specify 'auto', then the software selects an appropriate scale factor using a heuristic procedure. This heuristic procedure uses subsampling, so estimates can vary from one call to another. Therefore, to reproduce results, set a random number seed using rng before training.
- If you specify KernelScale and your own kernel function, for example, 'KernelFunction', 'kernel', then the software throws an error. You must apply scaling within kernel.

Example: 'KernelScale', 'auto'

Data Types: double | single | char | string

PolynomialOrder — Polynomial kernel function order

3 (default) | positive integer

Polynomial kernel function order, specified as the comma-separated pair consisting of 'PolynomialOrder' and a positive integer.

If you set 'PolynomialOrder' and KernelFunction is not 'polynomial', then the software throws an error.

Example: 'PolynomialOrder', 2

Data Types: double | single

KernelOffset — Kernel offset parameter

nonnegative scalar

Kernel offset parameter, specified as the comma-separated pair consisting of 'KernelOffset' and a nonnegative scalar.

The software adds KernelOffset to each element of the Gram matrix.

The defaults are:

- 0 if the solver is SMO (that is, you set 'Solver', 'SMO')
- 0.1 if the solver is ISDA (that is, you set 'Solver', 'ISDA')

Example: 'KernelOffset', 0

Data Types: double | single

Standardize — Flag to standardize predictor data

false (default) | true

Flag to standardize the predictor data, specified as the comma-separated pair consisting of 'Standardize' and true (1) or false (0).

If you set 'Standardize', true:

- The software centers and scales each predictor variable (X or Tbl) by the corresponding weighted column mean and standard deviation. For details on weighted standardizing, see “Algorithms” on page 32-2092. MATLAB does not standardize the data contained in the dummy variable columns generated for categorical predictors.
- The software trains the classifier using the standardized predictors, but stores the unstandardized predictors as a matrix or table in the classifier property X.

Example: 'Standardize', true

Data Types: logical

Solver — Optimization routine

'ISDA' | 'L1QP' | 'SMO'

Optimization routine, specified as the comma-separated pair consisting of 'Solver' and a value in this table.

Value	Description
'ISDA'	Iterative Single Data Algorithm (see [30])
'L1QP'	Uses <code>quadprog</code> to implement $L1$ soft-margin minimization by quadratic programming. This option requires an Optimization Toolbox license. For more details, see “Quadratic Programming Definition” (Optimization Toolbox).
'SMO'	Sequential Minimal Optimization (see [17])

The default value is 'ISDA' for two-class learning or if you set 'OutlierFraction' to a positive value, and 'SMO' otherwise.

Example: 'Solver', 'ISDA'

Alpha — Initial estimates of alpha coefficients

numeric vector of nonnegative values

Initial estimates of alpha coefficients, specified as the comma-separated pair consisting of 'Alpha' and a numeric vector of nonnegative values. The length of Alpha must be equal to the number of rows in X.

- Each element of 'Alpha' corresponds to an observation in X.
- 'Alpha' cannot contain any NaNs.
- If you specify 'Alpha' and any one of the cross-validation name-value pair arguments ('CrossVal', 'CVPartition', 'Holdout', 'KFold', or 'Leaveout'), then the software returns an error.

If Y contains any missing values, then remove all rows of Y, X, and 'Alpha' that correspond to the missing values. That is, enter:

```
idx = ~isundefined(categorical(Y));
Y = Y(idx,:);
X = X(idx,:);
alpha = alpha(idx);
```

Then pass Y, X, and alpha as the response, predictors, and initial alpha estimates, respectively.

The default values are:

- `0.5*ones(size(X,1),1)` for one-class learning
- `zeros(size(X,1),1)` for two-class learning

Example: 'Alpha', `0.1*ones(size(X,1),1)`

Data Types: double | single

CacheSize — Cache size

1000 (default) | 'maximal' | positive scalar

Cache size, specified as the comma-separated pair consisting of 'CacheSize' and 'maximal' or a positive scalar.

If CacheSize is 'maximal', then the software reserves enough memory to hold the entire n -by- n Gram matrix on page 32-2088.

If CacheSize is a positive scalar, then the software reserves CacheSize megabytes of memory for training the model.

Example: 'CacheSize', 'maximal'

Data Types: double | single | char | string

ClipAlphas — Flag to clip alpha coefficients

true (default) | false

Flag to clip alpha coefficients, specified as the comma-separated pair consisting of 'ClipAlphas' and either true or false.

Suppose that the alpha coefficient for observation j is α_j and the box constraint of observation j is $C_j, j = 1, \dots, n$, where n is the training sample size.

Value	Description
true	At each iteration, if α_j is near 0 or near C_j , then MATLAB sets α_j to 0 or to C_j , respectively.
false	MATLAB does not change the alpha coefficients during optimization.

MATLAB stores the final values of α in the Alpha property of the trained SVM model object.

ClipAlphas can affect SMO and ISDA convergence.

Example: 'ClipAlphas', false

Data Types: logical

Nu — ν parameter for one-class learning

0.5 (default) | positive scalar

ν parameter for “One-Class Learning” on page 32-2088, specified as the comma-separated pair consisting of 'Nu' and a positive scalar. Nu must be greater than 0 and at most 1.

Set Nu to control the tradeoff between ensuring that most training examples are in the positive class and minimizing the weights in the score function.

Example: 'Nu', 0.25

Data Types: double | single

NumPrint — Number of iterations between optimization diagnostic message output

1000 (default) | nonnegative integer

Number of iterations between optimization diagnostic message output, specified as the comma-separated pair consisting of 'NumPrint' and a nonnegative integer.

If you specify 'Verbose',1 and 'NumPrint',numprint, then the software displays all optimization diagnostic messages from SMO and ISDA every numprint iterations in the Command Window.

Example: 'NumPrint',500

Data Types: double | single

OutlierFraction — Expected proportion of outliers in training data

0 (default) | numeric scalar in the interval [0,1)

Expected proportion of outliers in the training data, specified as the comma-separated pair consisting of 'OutlierFraction' and a numeric scalar in the interval [0,1).

Suppose that you set 'OutlierFraction',outlierfraction, where outlierfraction is a value greater than 0.

- For two-class learning, the software implements robust learning. In other words, the software attempts to remove 100*outlierfraction% of the observations when the optimization algorithm converges. The removed observations correspond to gradients that are large in magnitude.
- For one-class learning, the software finds an appropriate bias term such that outlierfraction of the observations in the training set have negative scores.

Example: 'OutlierFraction',0.01

Data Types: double | single

RemoveDuplicates — Flag to replace duplicate observations with single observations

false (default) | true

Flag to replace duplicate observations with single observations in the training data, specified as the comma-separated pair consisting of 'RemoveDuplicates' and true or false.

If RemoveDuplicates is true, then fitcsvm replaces duplicate observations in the training data with a single observation of the same value. The weight of the single observation is equal to the sum of the weights of the corresponding removed duplicates (see Weights).

Tip If your data set contains many duplicate observations, then specifying 'RemoveDuplicates', true can decrease convergence time considerably.

Data Types: logical

Verbose — Verbosity level

0 (default) | 1 | 2

Verbosity level, specified as the comma-separated pair consisting of 'Verbose' and 0, 1, or 2. The value of Verbose controls the amount of optimization information that the software displays in the Command Window and saves the information as a structure to `Mdl.ConvergenceInfo.History`.

This table summarizes the available verbosity level options.

Value	Description
0	The software does not display or save convergence information.
1	The software displays diagnostic messages and saves convergence criteria every <code>numprint</code> iterations, where <code>numprint</code> is the value of the name-value pair argument 'NumPrint'.
2	The software displays diagnostic messages and saves convergence criteria at every iteration.

Example: 'Verbose', 1

Data Types: double | single

Other Classification Options

CategoricalPredictors — Categorical predictors list

vector of positive integers | logical vector | character matrix | string array | cell array of character vectors | 'all'

Categorical predictors list, specified as the comma-separated pair consisting of 'CategoricalPredictors' and one of the values in this table.

Value	Description
Vector of positive integers	An entry in the vector is the index value corresponding to the column of the predictor data (<code>X</code> or <code>Tbl</code>) that contains a categorical variable.
Logical vector	A <code>true</code> entry means that the corresponding column of predictor data (<code>X</code> or <code>Tbl</code>) is a categorical variable.

Value	Description
Character matrix	Each row of the matrix is the name of a predictor variable. The names must match the entries in <code>PredictorNames</code> . Pad the names with extra blanks so each row of the character matrix has the same length.
String array or cell array of character vectors	Each element in the array is the name of a predictor variable. The names must match the entries in <code>PredictorNames</code> .
'all'	All predictors are categorical.

By default, if the predictor data is in a table (`Tbl`), `fitcsvm` assumes that a variable is categorical if it contains logical values, categorical values, a string array, or a cell array of character vectors. If the predictor data is a matrix (`X`), `fitcsvm` assumes all predictors are continuous. To identify any categorical predictors when the data is a matrix, use the `'CategoricalPredictors'` name-value pair argument.

Example: `'CategoricalPredictors','all'`

Data Types: `single` | `double` | `logical` | `char` | `string` | `cell`

ClassNames — Names of classes to use for training

categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Names of classes to use for training, specified as the comma-separated pair consisting of `'ClassNames'` and a categorical, character, or string array, a logical or numeric vector, or a cell array of character vectors. `ClassNames` must have the same data type as `Y`.

If `ClassNames` is a character array, then each element must correspond to one *row* of the array.

Use `ClassNames` to:

- Order the classes during training.
- Specify the order of any input or output argument dimension that corresponds to the class order. For example, use `ClassNames` to specify the order of the dimensions of `Cost` or the column order of classification scores returned by `predict`.
- Select a subset of classes for training. For example, suppose that the set of all distinct class names in `Y` is `{'a','b','c'}`. To train the model using observations from classes `'a'` and `'c'` only, specify `'ClassNames',{'a','c'}`.

The default value for `ClassNames` is the set of all distinct class names in `Y`.

Example: `'ClassNames', {'b', 'g'}`

Data Types: `categorical` | `char` | `string` | `logical` | `single` | `double` | `cell`

Cost — Misclassification cost

square matrix | structure array

Misclassification cost specified as the comma-separated pair consisting of `'Cost'` and a square matrix or structure array.

- If you specify the square matrix `Cost` and the true class of an observation is `i`, then `Cost(i, j)` is the cost of classifying a point into class `j`. That is, rows correspond to the true classes and columns correspond to predicted classes. To specify the class order for the corresponding rows and columns of `Cost`, also specify the `ClassNames` name-value pair argument.
- If you specify the structure `S`, then it must have two fields:
 - `S.ClassNames`, which contains the class names as a variable of the same data type as `Y`
 - `S.ClassificationCosts`, which contains the cost matrix with rows and columns ordered as in `S.ClassNames`

For two-class learning, if you specify a cost matrix, then the software updates the prior probabilities by incorporating the penalties described in the cost matrix. Consequently, the cost matrix resets to the default. For more details on the relationships and algorithmic behavior of `BoxConstraint`, `Cost`, `Prior`, `Standardize`, and `Weights`, see “Algorithms” on page 32-2092.

The default values are:

- `Cost = 0` for one-class learning
- `Cost(i, j) = 1` if `i ~= j` and `Cost(i, j) = 0` if `i = j` for two-class learning

Example: `'Cost', [0, 1; 2, 0]`

Data Types: `double` | `single` | `struct`

PredictorNames — Predictor variable names

string array of unique names | cell array of unique character vectors

Predictor variable names, specified as the comma-separated pair consisting of `'PredictorNames'` and a string array of unique names or cell array of unique character

vectors. The functionality of 'PredictorNames' depends on the way you supply the training data.

- If you supply X and Y, then you can use 'PredictorNames' to give the predictor variables in X names.
 - The order of the names in PredictorNames must correspond to the column order of X. That is, PredictorNames{1} is the name of X(:,1), PredictorNames{2} is the name of X(:,2), and so on. Also, size(X,2) and numel(PredictorNames) must be equal.
 - By default, PredictorNames is {'x1', 'x2', ...}.
- If you supply Tbl, then you can use 'PredictorNames' to choose which predictor variables to use in training. That is, fitcsvm uses only the predictor variables in PredictorNames and the response variable in training.
 - PredictorNames must be a subset of Tbl.Properties.VariableNames and cannot include the name of the response variable.
 - By default, PredictorNames contains the names of all predictor variables.
 - It is a good practice to specify the predictors for training using either 'PredictorNames' or formula only.

Example: 'PredictorNames',
{'SepalLength', 'SepalWidth', 'PetalLength', 'PetalWidth'}

Data Types: string | cell

Prior — Prior probabilities

'empirical' (default) | 'uniform' | numeric vector | structure array

Prior probabilities for each class, specified as the comma-separated pair consisting of 'Prior' and a value in this table.

Value	Description
'empirical'	The class prior probabilities are the class relative frequencies in Y.
'uniform'	All class prior probabilities are equal to $1/K$, where K is the number of classes.

Value	Description
numeric vector	Each element in the vector is a class prior probability. Order the elements according to <code>Mdl.ClassNames</code> or specify the order using the <code>ClassNames</code> name-value pair argument. The software normalizes the elements to sum to 1.
structure	A structure <code>S</code> with two fields: <ul style="list-style-type: none"> <code>S.ClassNames</code> contains the class names as a variable of the same type as <code>Y</code>. <code>S.ClassProbs</code> contains a vector of corresponding prior probabilities. The software normalizes the elements of the vector to sum to 1.

For two-class learning, if you specify a cost matrix, then the software updates the prior probabilities by incorporating the penalties described in the cost matrix. For more details on the relationships and algorithmic behavior of `BoxConstraint`, `Cost`, `Prior`, `Standardize`, and `Weights`, see “Algorithms” on page 32-2092.

Example: `struct('ClassNames',
{'setosa','versicolor','virginica'}), 'ClassProbs',1:3)`

Data Types: `char` | `string` | `double` | `single` | `struct`

ResponseName — Response variable name

`'Y'` (default) | character vector | string scalar

Response variable name, specified as the comma-separated pair consisting of `'ResponseName'` and a character vector or string scalar.

- If you supply `Y`, then you can use `'ResponseName'` to specify a name for the response variable.
- If you supply `ResponseVarName` or `formula`, then you cannot use `'ResponseName'`.

Example: `'ResponseName','response'`

Data Types: `char` | `string`

ScoreTransform — Score transformation

`'none'` (default) | `'doublelogit'` | `'invlogit'` | `'ismax'` | `'logit'` | function handle | ...

Score transformation, specified as the comma-separated pair consisting of 'ScoreTransform' and a character vector, string scalar, or function handle.

This table summarizes the available character vectors and string scalars.

Value	Description
'doublelogit'	$1/(1 + e^{-2x})$
'invlogit'	$\log(x / (1 - x))$
'ismax'	Sets the score for the class with the largest score to 1, and sets the scores for all other classes to 0
'logit'	$1/(1 + e^{-x})$
'none' or 'identity'	x (no transformation)
'sign'	-1 for $x < 0$ 0 for $x = 0$ 1 for $x > 0$
'symmetric'	$2x - 1$
'symmetricismax'	Sets the score for the class with the largest score to 1, and sets the scores for all other classes to -1
'symmetriclogit'	$2/(1 + e^{-x}) - 1$

For a MATLAB function or a function you define, use its function handle for score transform. The function handle must accept a matrix (the original scores) and return a matrix of the same size (the transformed scores).

Example: 'ScoreTransform', 'logit'

Data Types: char | string | function_handle

Weights — Observation weights

numeric vector | name of variable in Tbl

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a numeric vector of positive values or the name of a variable in Tbl. The software weighs the observations in each row of X or Tbl with the corresponding value in Weights. The size of Weights must equal the number of rows in X or Tbl.

If you specify the input data as a table Tbl, then Weights can be the name of a variable in Tbl that contains a numeric vector. In this case, you must specify Weights as a

character vector or string scalar. For example, if the weights vector W is stored as `Tbl.W`, then specify it as `'W'`. Otherwise, the software treats all columns of `Tbl`, including W , as predictors or the response variable when training the model.

By default, `Weights` is `ones(n, 1)`, where n is the number of observations in X or `Tbl`.

The software normalizes `Weights` to sum up to the value of the prior probability in the respective class. For more details on the relationships and algorithmic behavior of `BoxConstraint`, `Cost`, `Prior`, `Standardize`, and `Weights`, see “Algorithms” on page 32-2092.

Data Types: `double` | `single` | `char` | `string`

Note You cannot use any cross-validation name-value pair argument along with the `'OptimizeHyperparameters'` name-value pair argument. You can modify the cross-validation for `'OptimizeHyperparameters'` only by using the `'HyperparameterOptimizationOptions'` name-value pair argument.

Cross-Validation Options

CrossVal — Flag to train cross-validated classifier

`'off'` (default) | `'on'`

Flag to train a cross-validated classifier, specified as the comma-separated pair consisting of `'Crossval'` and `'on'` or `'off'`.

If you specify `'on'`, then the software trains a cross-validated classifier with 10 folds.

You can override this cross-validation setting using the `CVPartition`, `Holdout`, `KFold`, or `Leaveout` name-value pair argument. You can use only one cross-validation name-value pair argument at a time to create a cross-validated model.

Alternatively, cross-validate later by passing `Mdl` to `crossval`.

Example: `'Crossval', 'on'`

CVPartition — Cross-validation partition

`[]` (default) | `cvpartition` partition object

Cross-validation partition, specified as the comma-separated pair consisting of `'CVPartition'` and a `cvpartition` partition object created by `cvpartition`. The

partition object specifies the type of cross-validation and the indexing for the training and validation sets.

To create a cross-validated model, you can use one of these four name-value pair arguments only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: Suppose you create a random partition for 5-fold cross-validation on 500 observations by using `cvp = cvpartition(500, 'KFold', 5)`. Then, you can specify the cross-validated model by using `'CVPartition', cvp`.

Holdout — Fraction of data for holdout validation

scalar value in the range (0,1)

Fraction of the data used for holdout validation, specified as the comma-separated pair consisting of `'Holdout'` and a scalar value in the range (0,1). If you specify `'Holdout', p`, then the software completes these steps:

- 1 Randomly select and reserve $p \times 100\%$ of the data as validation data, and train the model using the rest of the data.
- 2 Store the compact, trained model in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: `'Holdout', 0.1`

Data Types: `double` | `single`

KFold — Number of folds

10 (default) | positive integer value greater than 1

Number of folds to use in a cross-validated model, specified as the comma-separated pair consisting of `'KFold'` and a positive integer value greater than 1. If you specify `'KFold', k`, then the software completes these steps:

- 1 Randomly partition the data into k sets.
- 2 For each set, reserve the set as validation data, and train the model using the other $k - 1$ sets.
- 3 Store the k compact, trained models in the cells of a k -by-1 cell vector in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: `'KFold',5`

Data Types: `single` | `double`

Leaveout — Leave-one-out cross-validation flag

`'off'` (default) | `'on'`

Leave-one-out cross-validation flag, specified as the comma-separated pair consisting of `'Leaveout'` and `'on'` or `'off'`. If you specify `'Leaveout'`, `'on'`, then, for each of the n observations (where n is the number of observations excluding missing observations, specified in the `NumObservations` property of the model), the software completes these steps:

- 1 Reserve the observation as validation data, and train the model using the other $n - 1$ observations.
- 2 Store the n compact, trained models in the cells of an n -by-1 cell vector in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: `'Leaveout','on'`

Convergence Control Options

DeltaGradientTolerance — Tolerance for gradient difference

nonnegative scalar

Tolerance for the gradient difference between upper and lower violators obtained by Sequential Minimal Optimization (SMO) or Iterative Single Data Algorithm (ISDA), specified as the comma-separated pair consisting of `'DeltaGradientTolerance'` and a nonnegative scalar.

If `DeltaGradientTolerance` is `0`, then the software does not use the tolerance for the gradient difference to check for optimization convergence.

The default values are:

- `1e-3` if the solver is SMO (for example, you set `'Solver','SMO'`)
- `0` if the solver is ISDA (for example, you set `'Solver','ISDA'`)

Example: 'DeltaGradientTolerance',1e-2

Data Types: double | single

GapTolerance — Feasibility gap tolerance

0 (default) | nonnegative scalar

Feasibility gap tolerance obtained by SMO or ISDA, specified as the comma-separated pair consisting of 'GapTolerance' and a nonnegative scalar.

If `GapTolerance` is 0, then the software does not use the feasibility gap tolerance to check for optimization convergence.

Example: 'GapTolerance',1e-2

Data Types: double | single

IterationLimit — Maximal number of numerical optimization iterations

1e6 (default) | positive integer

Maximal number of numerical optimization iterations, specified as the comma-separated pair consisting of 'IterationLimit' and a positive integer.

The software returns a trained model regardless of whether the optimization routine successfully converges. `Mdl.ConvergenceInfo` contains convergence information.

Example: 'IterationLimit',1e8

Data Types: double | single

KKTTolerance — Karush-Kuhn-Tucker complementarity conditions violation tolerance

nonnegative scalar

Karush-Kuhn-Tucker (KKT) complementarity conditions on page 32-2088 violation tolerance, specified as the comma-separated pair consisting of 'KKTTolerance' and a nonnegative scalar.

If `KKTTolerance` is 0, then the software does not use the KKT complementarity conditions violation tolerance to check for optimization convergence.

The default values are:

- 0 if the solver is SMO (for example, you set 'Solver', 'SMO')

- `1e-3` if the solver is ISDA (for example, you set `'Solver', 'ISDA'`)

Example: `'KKTolerance', 1e-2`

Data Types: `double | single`

ShrinkagePeriod — Number of iterations between reductions of active set

`0` (default) | nonnegative integer

Number of iterations between reductions of the active set, specified as the comma-separated pair consisting of `'ShrinkagePeriod'` and a nonnegative integer.

If you set `'ShrinkagePeriod', 0`, then the software does not shrink the active set.

Example: `'ShrinkagePeriod', 1000`

Data Types: `double | single`

Hyperparameter Optimization Options

OptimizeHyperparameters — Parameters to optimize

`'none'` (default) | `'auto'` | `'all'` | string array or cell array of eligible parameter names | vector of `optimizableVariable` objects

Parameters to optimize, specified as the comma-separated pair consisting of `'OptimizeHyperparameters'` and one of these values:

- `'none'` — Do not optimize.
- `'auto'` — Use `{'BoxConstraint', 'KernelScale'}`.
- `'all'` — Optimize all eligible parameters.
- String array or cell array of eligible parameter names.
- Vector of `optimizableVariable` objects, typically the output of hyperparameters.

The optimization attempts to minimize the cross-validation loss (error) for `fitcsvm` by varying the parameters. For information about cross-validation loss see “Classification Loss” on page 32-3352. To control the cross-validation type and other aspects of the optimization, use the `HyperparameterOptimizationOptions` name-value pair argument.

Note `'OptimizeHyperparameters'` values override any values you set using other name-value pair arguments. For example, setting `'OptimizeHyperparameters'` to `'auto'` causes the `'auto'` values to apply.

The eligible parameters for `fitcsvm` are:

- `BoxConstraint` — `fitcsvm` searches among positive values, by default log-scaled in the range `[1e-3,1e3]`.
- `KernelScale` — `fitcsvm` searches among positive values, by default log-scaled in the range `[1e-3,1e3]`.
- `KernelFunction` — `fitcsvm` searches among 'gaussian', 'linear', and 'polynomial'.
- `PolynomialOrder` — `fitcsvm` searches among integers in the range `[2,4]`.
- `Standardize` — `fitcsvm` searches among 'true' and 'false'.

Set nondefault parameters by passing a vector of `optimizableVariable` objects that have nondefault values. For example:

```
load fisheriris
params = hyperparameters('fitcsvm',meas,species);
params(1).Range = [1e-4,1e6];
```

Pass `params` as the value of `OptimizeHyperparameters`.

By default, iterative display appears at the command line, and plots appear according to the number of hyperparameters in the optimization. For the optimization and plots, the objective function is $\log(1 + \text{cross-validation loss})$ for regression and the misclassification rate for classification. To control the iterative display, set the `Verbose` field of the 'HyperparameterOptimizationOptions' name-value pair argument. To control the plots, set the `ShowPlots` field of the 'HyperparameterOptimizationOptions' name-value pair argument.

For an example, see “Optimize SVM Classifier” on page 32-2058.

Example: 'auto'

HyperparameterOptimizationOptions — Options for optimization

structure

Options for optimization, specified as the comma-separated pair consisting of 'HyperparameterOptimizationOptions' and a structure. This argument modifies the effect of the `OptimizeHyperparameters` name-value pair argument. All fields in the structure are optional.

Field Name	Values	Default
Optimizer	<ul style="list-style-type: none"> • 'bayesopt' — Use Bayesian optimization. Internally, this setting calls bayesopt. • 'gridsearch' — Use grid search with NumGridDivisions values per dimension. • 'randomsearch' — Search at random among MaxObjectiveEvaluations points. <p>'gridsearch' searches in a random order, using uniform sampling without replacement from the grid. After optimization, you can get a table in grid order by using the command <code>sortrows(Mdl.HyperparameterOptimizationResults)</code>.</p>	'bayesopt'
AcquisitionFunctionName	<ul style="list-style-type: none"> • 'expected-improvement-per-second-plus' • 'expected-improvement' • 'expected-improvement-plus' • 'expected-improvement-per-second' • 'lower-confidence-bound' • 'probability-of-improvement' <p>Acquisition functions whose names include <code>per-second</code> do not yield reproducible results because the optimization depends on the runtime of the objective function. Acquisition functions whose names include <code>plus</code> modify their behavior when they are overexploiting an area. For more details, see “Acquisition Function Types” on page 10-4.</p>	'expected-improvement-per-second-plus'

Field Name	Values	Default
MaxObjectiveEvaluations	Maximum number of objective function evaluations.	30 for 'bayesopt' or 'randomsearch', and the entire grid for 'gridsearch'
MaxTime	Time limit, specified as a positive real. The time limit is in seconds, as measured by tic and toc. Run time can exceed MaxTime because MaxTime does not interrupt function evaluations.	Inf
NumGridDivisions	For 'gridsearch', the number of values in each dimension. The value can be a vector of positive integers giving the number of values for each dimension, or a scalar that applies to all dimensions. This field is ignored for categorical variables.	10
ShowPlots	Logical value indicating whether to show plots. If true, this field plots the best objective function value against the iteration number. If there are one or two optimization parameters, and if Optimizer is 'bayesopt', then ShowPlots also plots a model of the objective function against the parameters.	true
SaveIntermediateResults	Logical value indicating whether to save results when Optimizer is 'bayesopt'. If true, this field overwrites a workspace variable named 'BayesoptResults' at each iteration. The variable is a BayesianOptimization object.	false

Field Name	Values	Default
Verbose	<p>Display to the command line.</p> <ul style="list-style-type: none"> • 0 — No iterative display • 1 — Iterative display • 2 — Iterative display with extra information <p>For details, see the <code>bayesopt</code> <code>Verbose</code> name-value pair argument.</p>	1
UseParallel	<p>Logical value indicating whether to run Bayesian optimization in parallel, which requires Parallel Computing Toolbox. For details, see “Parallel Bayesian Optimization” on page 10-8.</p>	false
Repartition	<p>Logical value indicating whether to repartition the cross-validation at every iteration. If <code>false</code>, the optimizer uses a single partition for the optimization.</p> <p><code>true</code> usually gives the most robust results because this setting takes partitioning noise into account. However, for good results, <code>true</code> requires at least twice as many function evaluations.</p>	false
Use no more than one of the following three field names.		
CVPartition	A <code>cvpartition</code> object, as created by <code>cvpartition</code> .	'Kfold', 5 if you do not specify any cross-validation field
Holdout	A scalar in the range (0, 1) representing the holdout fraction.	
Kfold	An integer greater than 1.	

Example:

```
'HyperparameterOptimizationOptions', struct('MaxObjectiveEvaluations', 60)
```

Data Types: struct

Output Arguments

Mdl — Trained SVM classification model

`ClassificationSVM` model object | `ClassificationPartitionedModel` cross-validated model object

Trained SVM classification model, returned as a `ClassificationSVM` model object or `ClassificationPartitionedModel` cross-validated model object.

If you set any of the name-value pair arguments `KFold`, `Holdout`, `Leaveout`, `CrossVal`, or `CVPartition`, then `Mdl` is a `ClassificationPartitionedModel` cross-validated classifier. Otherwise, `Mdl` is a `ClassificationSVM` classifier.

To reference properties of `Mdl`, use dot notation. For example, enter `Mdl.Alpha` in the Command Window to display the trained Lagrange multipliers.

Limitations

- `fitcsvm` trains SVM classifiers for one-class or two-class learning applications. To train SVM classifiers using data with more than two classes, use `fitcecoc`.
- `fitcsvm` supports low-dimensional and moderate-dimensional data sets. For high-dimensional data sets, use `fitclinear` instead.

Definitions

Box Constraint

A box constraint is a parameter that controls the maximum penalty imposed on margin-violating observations, which helps to prevent overfitting (regularization).

If you increase the box constraint, then the SVM classifier assigns fewer support vectors. However, increasing the box constraint can lead to longer training times.

Gram Matrix

The Gram matrix of a set of n vectors $\{x_1, \dots, x_n; x_j \in R^p\}$ is an n -by- n matrix with element (j, k) defined as $G(x_j, x_k) = \langle \phi(x_j), \phi(x_k) \rangle$, an inner product of the transformed predictors using the kernel function ϕ .

For nonlinear SVM, the algorithm forms a Gram matrix using the rows of the predictor data X . The dual formalization replaces the inner product of the observations in X with corresponding elements of the resulting Gram matrix (called the “kernel trick”). Consequently, nonlinear SVM operates in the transformed predictor space to find a separating hyperplane.

Karush-Kuhn-Tucker (KKT) Complementarity Conditions

KKT complementarity conditions are optimization constraints required for optimal nonlinear programming solutions.

In SVM, the KKT complementarity conditions are

$$\begin{cases} \alpha_j [y_j f(x_j) - 1 + \xi_j] = 0 \\ \xi_j (C - \alpha_j) = 0 \end{cases}$$

for all $j = 1, \dots, n$, where $f(x_j) = \phi(x_j)' \beta + b$, ϕ is a kernel function (see Gram matrix on page 32-2088), and ξ_j is a slack variable. If the classes are perfectly separable, then $\xi_j = 0$ for all $j = 1, \dots, n$.

One-Class Learning

One-class learning, or unsupervised SVM, aims to separate data from the origin in the high-dimensional predictor space (not the original predictor space), and is an algorithm used for outlier detection.

The algorithm resembles that of SVM for binary classification on page 32-2089. The objective is to minimize the dual expression

$$0.5 \sum_{j,k} \alpha_j \alpha_k G(x_j, x_k)$$

with respect to $\alpha_1, \dots, \alpha_n$, subject to

$$\sum \alpha_j = n\nu$$

and $0 \leq \alpha_j \leq 1$ for all $j = 1, \dots, n$. The value of $G(x_j, x_k)$ is in element (j, k) of the Gram matrix on page 32-2088.

A small value of ν leads to fewer support vectors and, therefore, a smooth, crude decision boundary. A large value of ν leads to more support vectors and, therefore, a curvy, flexible decision boundary. The optimal value of ν should be large enough to capture the data complexity and small enough to avoid overtraining. Also, $0 < \nu \leq 1$.

For more details, see [5].

Support Vector

Support vectors are observations corresponding to strictly positive estimates of $\alpha_1, \dots, \alpha_n$.

SVM classifiers that yield fewer support vectors for a given training set are preferred.

Support Vector Machines for Binary Classification

The SVM binary classification algorithm searches for an optimal hyperplane that separates the data into two classes. For separable classes, the optimal hyperplane maximizes a margin (space that does not contain any observations) surrounding itself, which creates boundaries for the positive and negative classes. For inseparable classes, the objective is the same, but the algorithm imposes a penalty on the length of the margin for every observation that is on the wrong side of its class boundary.

The linear SVM score function is

$$f(x) = x'\beta + b,$$

where:

- x is an observation (corresponding to a row of X).
- The vector β contains the coefficients that define an orthogonal vector to the hyperplane (corresponding to `Mdl.Beta`). For separable data, the optimal margin length is $2/\|\beta\|$.
- b is the bias term (corresponding to `Mdl.Bias`).

The root of $f(x)$ for particular coefficients defines a hyperplane. For a particular hyperplane, $f(z)$ is the distance from point z to the hyperplane.

The algorithm searches for the maximum margin length, while keeping observations in the positive ($y = 1$) and negative ($y = -1$) classes separate.

- For separable classes, the objective is to minimize $\|\beta\|$ with respect to the β and b subject to $y_j f(x_j) \geq 1$, for all $j = 1, \dots, n$. This is the primal formalization for separable classes.
- For inseparable classes, the algorithm uses slack variables (ξ_j) to penalize the objective function for observations that cross the margin boundary for their class. $\xi_j = 0$ for observations that do not cross the margin boundary for their class, otherwise $\xi_j \geq 0$.

The objective is to minimize $0.5\|\beta\|^2 + C\sum \xi_j$ with respect to the β , b , and ξ_j subject to $y_j f(x_j) \geq 1 - \xi_j$ and $\xi_j \geq 0$ for all $j = 1, \dots, n$, and for a positive scalar box constraint on page 32-2087 C . This is the primal formalization for inseparable classes.

The algorithm uses the Lagrange multipliers method to optimize the objective, which introduces n coefficients $\alpha_1, \dots, \alpha_n$ (corresponding to `Mdl.Alpha`). The dual formalizations for linear SVM are as follows:

- For separable classes, minimize

$$0.5 \sum_{j=1}^n \sum_{k=1}^n \alpha_j \alpha_k y_j y_k x_j' x_k - \sum_{j=1}^n \alpha_j$$

with respect to $\alpha_1, \dots, \alpha_n$, subject to $\sum \alpha_j y_j = 0$, $\alpha_j \geq 0$ for all $j = 1, \dots, n$, and Karush-Kuhn-Tucker (KKT) complementarity conditions on page 32-2088.

- For inseparable classes, the objective is the same as for separable classes, except for the additional condition $0 \leq \alpha_j \leq C$ for all $j = 1, \dots, n$.

The resulting score function is

$$\widehat{f}(x) = \sum_{j=1}^n \widehat{\alpha}_j y_j x' x_j + \widehat{b}.$$

\widehat{b} is the estimate of the bias and $\widehat{\alpha}_j$ is the j th estimate of the vector $\widehat{\alpha}$, $j = 1, \dots, n$. Written this way, the score function is free of the estimate of β as a result of the primal formalization.

The SVM algorithm classifies a new observation z using $\text{sign}(\widehat{f}(z))$.

In some cases, a nonlinear boundary separates the classes. Nonlinear SVM works in a transformed predictor space to find an optimal, separating hyperplane.

The dual formalization for nonlinear SVM is

$$0.5 \sum_{j=1}^n \sum_{k=1}^n \alpha_j \alpha_k y_j y_k G(x_j, x_k) - \sum_{j=1}^n \alpha_j$$

with respect to $\alpha_1, \dots, \alpha_n$, subject to $\sum \alpha_j y_j = 0$, $0 \leq \alpha_j \leq C$ for all $j = 1, \dots, n$, and the KKT complementarity conditions. $G(x_k, x_j)$ are elements of the Gram matrix on page 32-2088. The resulting score function is

$$\widehat{f}(x) = \sum_{j=1}^n \widehat{\alpha}_j y_j G(x, x_j) + \widehat{b}.$$

For more details, see Understanding Support Vector Machines on page 18-189, [1], and [3].

Tips

- Unless your data set is large, always try to standardize the predictors (see `Standardize`). Standardization makes predictors insensitive to the scales on which they are measured.
- It is a good practice to cross-validate using the `KFold` name-value pair argument. The cross-validation results determine how well the SVM classifier generalizes.
- For one-class learning:
 - The default setting for the name-value pair argument `Alpha` can lead to long training times. To speed up training, set `Alpha` to a vector mostly composed of 0s.
 - Set the name-value pair argument `Nu` to a value closer to 0 to yield fewer support vectors and, therefore, a smoother but crude decision boundary.
- Sparsity in support vectors is a desirable property of an SVM classifier. To decrease the number of support vectors, set `BoxConstraint` to a large value. This action increases the training time.

- For optimal training time, set `CacheSize` as high as the memory limit your computer allows.
- If you expect many fewer support vectors than observations in the training set, then you can significantly speed up convergence by shrinking the active set using the name-value pair argument `'ShrinkagePeriod'`. It is a good practice to specify `'ShrinkagePeriod', 1000`.
- Duplicate observations that are far from the decision boundary do not affect convergence. However, just a few duplicate observations that occur near the decision boundary can slow down convergence considerably. To speed up convergence, specify `'RemoveDuplicates', true` if:
 - Your data set contains many duplicate observations.
 - You suspect that a few duplicate observations fall near the decision boundary.

To maintain the original data set during training, `fitcsvm` must temporarily store separate data sets: the original and one without the duplicate observations. Therefore, if you specify `true` for data sets containing few duplicates, then `fitcsvm` consumes close to double the memory of the original data.

- After training a model, you can generate C/C++ code that predicts labels for new data. Generating C/C++ code requires MATLAB Coder. For details, see “Introduction to Code Generation” on page 31-2.

Algorithms

- For the mathematical formulation of the SVM binary classification algorithm, see “Support Vector Machines for Binary Classification” on page 32-2089 and “Understanding Support Vector Machines” on page 18-189.
- `NaN`, `<undefined>`, empty character vector (`' '`), empty string (`''`), and `<missing>` values indicate missing values. `fitcsvm` removes entire rows of data corresponding to a missing response. When computing total weights (see the next bullets), `fitcsvm` ignores any weight corresponding to an observation with at least one missing predictor. This action can lead to unbalanced prior probabilities in balanced-class problems. Consequently, observation box constraints might not equal `BoxConstraint`.
- `fitcsvm` removes observations that have zero weight or prior probability.
- For two-class learning, if you specify the cost matrix `C` (see `Cost`), then the software updates the class prior probabilities p (see `Prior`) to p_c by incorporating the penalties described in `C`.

Specifically, `fitcsvm` completes these steps:

- 1 Compute $p_c^* = p'C$.
- 2 Normalize p_c^* so that the updated prior probabilities sum to 1.

$$p_c = \frac{1}{\sum_{j=1}^K p_{c,j}^*} p_c^*.$$

K is the number of classes.

- 3 Reset the cost matrix to the default

$$C = \begin{bmatrix} 0 & 1 \\ 1 & 0 \end{bmatrix}.$$

- 4 Remove observations from the training data corresponding to classes with zero prior probability.
- For two-class learning, `fitcsvm` normalizes all observation weights (see `Weights`) to sum to 1. The function then renormalizes the normalized weights to sum up to the updated prior probability of the class to which the observation belongs. That is, the total weight for observation j in class k is

$$w_j^* = \frac{w_j}{\sum_{\forall j \in \text{Class } k} w_j} p_{c,k}.$$

w_j is the normalized weight for observation j ; $p_{c,k}$ is the updated prior probability of class k (see previous bullet).

- For two-class learning, `fitcsvm` assigns a box constraint to each observation in the training data. The formula for the box constraint of observation j is

$$C_j = nC_0w_j^*.$$

n is the training sample size, C_0 is the initial box constraint (see the `'BoxConstraint'` name-value pair argument), and w_j^* is the total weight of observation j (see previous bullet).

- If you set `'Standardize', true` and the `'Cost'`, `'Prior'`, or `'Weights'` name-value pair argument, then `fitcsvm` standardizes the predictors using their corresponding weighted means and weighted standard deviations. That is, `fitcsvm` standardizes predictor j (x_j) using

$$x_j^* = \frac{x_j - \mu_j^*}{\sigma_j^*}.$$

$$\mu_j^* = \frac{1}{\sum_k w_k^*} \sum_k w_k^* x_{jk}.$$

x_{jk} is observation k (row) of predictor j (column).

$$(\sigma_j^*)^2 = \frac{v_1}{v_1^2 - v_2} \sum_k w_k^* (x_{jk} - \mu_j^*)^2.$$

$$v_1 = \sum_j w_j^*.$$

$$v_2 = \sum_j (w_j^*)^2.$$

- Assume that p is the proportion of outliers that you expect in the training data, and that you set 'OutlierFraction', p .
 - For one-class learning, the software trains the bias term such that 100 p % of the observations in the training data have negative scores.
 - The software implements robust learning for two-class learning. In other words, the software attempts to remove 100 p % of the observations when the optimization algorithm converges. The removed observations correspond to gradients that are large in magnitude.
- If your predictor data contains categorical variables, then the software generally uses full dummy encoding for these variables. The software creates one dummy variable for each level of each categorical variable.
 - The `PredictorNames` property stores one element for each of the original predictor variable names. For example, assume that there are three predictors, one of which is a categorical variable with three levels. Then `PredictorNames` is a 1-by-3 cell array of character vectors containing the original names of the predictor variables.
 - The `ExpandedPredictorNames` property stores one element for each of the predictor variables, including the dummy variables. For example, assume that there are three predictors, one of which is a categorical variable with three levels.

Then `ExpandedPredictorNames` is a 1-by-5 cell array of character vectors containing the names of the predictor variables and the new dummy variables.

- Similarly, the `Beta` property stores one beta coefficient for each predictor, including the dummy variables.
- The `SupportVectors` property stores the predictor values for the support vectors, including the dummy variables. For example, assume that there are m support vectors and three predictors, one of which is a categorical variable with three levels. Then `SupportVectors` is an n -by-5 matrix.
- The `X` property stores the training data as originally input and does not include the dummy variables. When the input is a table, `X` contains only the columns used as predictors.
- For predictors specified in a table, if any of the variables contain ordered (ordinal) categories, the software uses ordinal encoding for these variables.
 - For a variable with k ordered levels, the software creates $k - 1$ dummy variables. The j th dummy variable is -1 for levels up to j , and $+1$ for levels $j + 1$ through k .
 - The names of the dummy variables stored in the `ExpandedPredictorNames` property indicate the first level with the value $+1$. The software stores $k - 1$ additional predictor names for the dummy variables, including the names of levels 2, 3, ..., k .
- All solvers implement $L1$ soft-margin minimization.
- For one-class learning, the software estimates the Lagrange multipliers, $\alpha_1, \dots, \alpha_n$, such that

$$\sum_{j=1}^n \alpha_j = nv.$$

Extended Capabilities

Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the 'UseParallel' option to true.

To perform parallel hyperparameter optimization, use the 'HyperparameterOptions', struct('UseParallel', true) name-value pair argument in the call to this function.

For more information on parallel hyperparameter optimization, see "Parallel Bayesian Optimization" on page 10-8.

For more general information about parallel computing, see "Run MATLAB Functions with Automatic Parallel Support" (Parallel Computing Toolbox).

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Usage notes and limitations:

- The 'KernelFunction' option must not specify a custom kernel.
- The 'Solver' option can be set to only 'SMO'.
- The 'OutlierFraction' option is not supported.
- The 'Alpha' option must specify a feasible starting point.
- The 'OptimizeHyperparameters' option is not supported.
- One-class classification is not supported. The labels must contain two different classes.

For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

Introduced in R2014a

fitctree

Fit binary decision tree for multiclass classification

Syntax

```
tree = fitctree(Tbl,ResponseVarName)
tree = fitctree(Tbl,formula)
tree = fitctree(Tbl,Y)

tree = fitctree(X,Y)

tree = fitctree( ____,Name,Value)
```

Description

`tree = fitctree(Tbl,ResponseVarName)` returns a fitted binary classification decision tree based on the input variables (also known as predictors, features, or attributes) contained in the table `Tbl` and output (response or labels) contained in `ResponseVarName`. The returned binary tree splits branching nodes based on the values of a column of `Tbl`.

`tree = fitctree(Tbl,formula)` returns a fitted binary classification decision tree based on the input variables contained in the table `Tbl`. `formula` is an explanatory model of the response and a subset of predictor variables in `Tbl` used to fit `tree`.

`tree = fitctree(Tbl,Y)` returns a fitted binary classification decision tree based on the input variables contained in the table `Tbl` and output in vector `Y`.

`tree = fitctree(X,Y)` returns a fitted binary classification decision tree based on the input variables contained in matrix `X` and output `Y`. The returned binary tree splits branching nodes based on the values of a column of `X`.

`tree = fitctree(____,Name,Value)` fits a tree with additional options specified by one or more name-value pair arguments, using any of the previous syntaxes. For example, you can specify the algorithm used to find the best split on a categorical predictor, grow a cross-validated tree, or hold out a fraction of the input data for validation.

Examples

Grow a Classification Tree

Grow a classification tree using the `ionosphere` data set.

```
load ionosphere
tc = fitctree(X,Y)

tc =
  ClassificationTree
      ResponseName: 'Y'
      CategoricalPredictors: []
          ClassNames: {'b' 'g'}
      ScoreTransform: 'none'
      NumObservations: 351
```

Properties, Methods

Control Tree Depth

You can control the depth of the trees using the `MaxNumSplits`, `MinLeafSize`, or `MinParentSize` name-value pair parameters. `fitctree` grows deep decision trees by default. You can grow shallower trees to reduce model complexity or computation time.

Load the `ionosphere` data set.

```
load ionosphere
```

The default values of the tree depth controllers for growing classification trees are:

- `n - 1` for `MaxNumSplits`. `n` is the training sample size.
- `1` for `MinLeafSize`.
- `10` for `MinParentSize`.

These default values tend to grow deep trees for large training sample sizes.

Train a classification tree using the default values for tree depth control. Cross-validate the model by using 10-fold cross-validation.

```
rng(1); % For reproducibility
mdlDefault = fitctree(X,Y,'CrossVal','on');
```

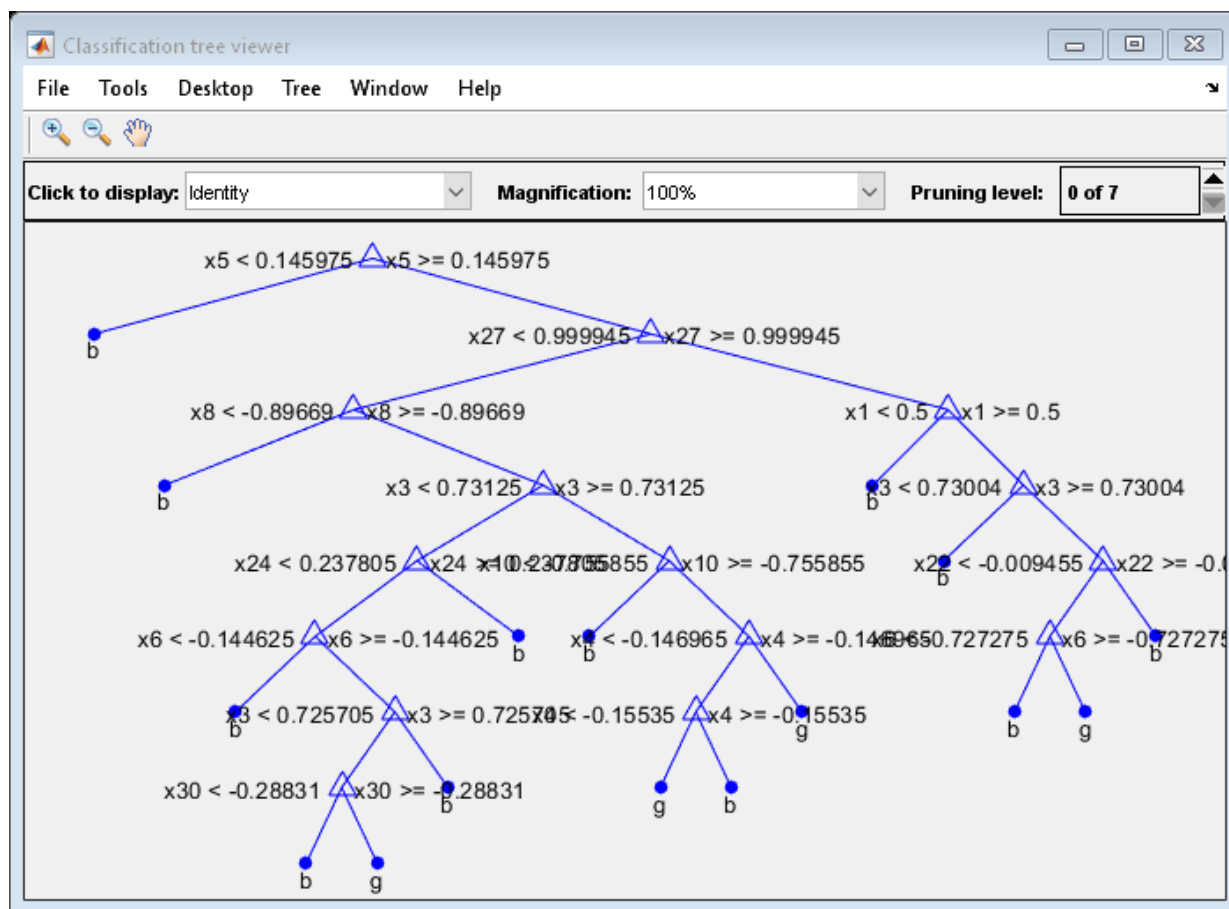

Draw a histogram of the number of imposed splits on the trees. Also, view one of the trees.

```
numBranches = @(x)sum(x.IsBranch);
mdlDefaultNumSplits = cellfun(numBranches, mdlDefault.Trained);

figure;
histogram(mdlDefaultNumSplits)
```

```
view(MdlDefault.Trained{1}, 'Mode', 'graph')
```

The average number of splits is around 15.

Suppose that you want a classification tree that is not as complex (deep) as the ones trained using the default number of splits. Train another classification tree, but set the maximum number of splits at 7, which is about half the mean number of splits from the default classification tree. Cross-validate the model by using 10-fold cross-validation.

```
Mdl7 = fitctree(X,Y, 'MaxNumSplits',7, 'CrossVal', 'on');
view(Mdl7.Trained{1}, 'Mode', 'graph')
```

Compare the cross-validation classification errors of the models.

```
classErrorDefault = kfoldLoss(MdlDefault)
```

```
classErrorDefault = 0.1140
```

```
classError7 = kfoldLoss(Mdl7)
```

```
classError7 = 0.1254
```

Mdl7 is much less complex and performs only slightly worse than MdlDefault.

Optimize Classification Tree

This example shows how to optimize hyperparameters automatically using `fitctree`. The example uses Fisher's iris data.

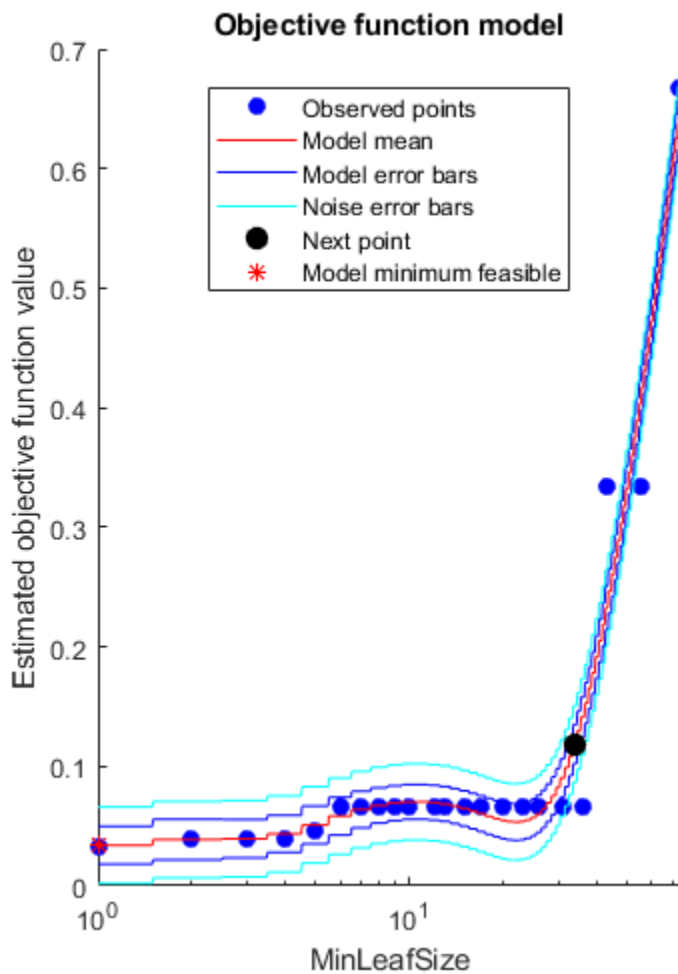

Load Fisher's iris data.

```
load fisheriris
```

Optimize the cross-validation loss of the classifier, using the data in `meas` to predict the response in `species`.

```
X = meas;  
Y = species;  
Mdl = fitctree(X,Y,'OptimizeHyperparameters','auto')
```

Properties, Methods

Unbiased Predictor Importance Estimates

Load the census1994 data set. Consider a model that predicts a person's salary category given their age, working class, education level, marital status, race, sex, capital gain and loss, and number of working hours per week.

```

load census1994
X = adultdata(:, {'age', 'workClass', 'education_num', 'marital_status', 'race', ...
    'sex', 'capital_gain', 'capital_loss', 'hours_per_week', 'salary'});

```

Display the number of categories represented in the categorical variables using `summary`.

```

summary(X)

```

Variables:

age: 32561x1 double

Values:

Min	17
Median	37
Max	90

workClass: 32561x1 categorical

Values:

Federal-gov	960
Local-gov	2093
Never-worked	7
Private	22696
Self-emp-inc	1116
Self-emp-not-inc	2541
State-gov	1298
Without-pay	14
NumMissing	1836

education_num: 32561x1 double

Values:

Min	1
Median	10
Max	16

marital_status: 32561x1 categorical

Values:

Divorced	4443
Married-AF-spouse	23
Married-civ-spouse	14976
Married-spouse-absent	418
Never-married	10683
Separated	1025
Widowed	993

race: 32561x1 categorical

Values:

Amer-Indian-Eskimo	311
Asian-Pac-Islander	1039
Black	3124
Other	271
White	27816

sex: 32561x1 categorical

Values:

Female	10771
Male	21790

capital_gain: 32561x1 double

Values:

Min	0
Median	0
Max	99999

capital_loss: 32561x1 double

Values:

Min	0
Median	0
Max	4356

hours_per_week: 32561x1 double

Values:

Min	1
Median	40
Max	99

salary: 32561x1 categorical

Values:

<=50K	24720
>50K	7841

Because there are few categories represented in the categorical variables compared to levels in the continuous variables, the standard CART, predictor-splitting algorithm prefers splitting a continuous predictor over the categorical variables.

Train a classification tree using the entire data set. To grow unbiased trees, specify usage of the curvature test for splitting predictors. Because there are missing observations in the data, specify usage of surrogate splits.

```
Mdl = fitctree(X, 'salary', 'PredictorSelection', 'curvature', ...  
             'Surrogate', 'on');
```

Estimate predictor importance values by summing changes in the risk due to splits on every predictor and dividing the sum by the number of branch nodes. Compare the estimates using a bar graph.

```
imp = predictorImportance(Mdl);  
  
figure;  
bar(imp);  
title('Predictor Importance Estimates');  
ylabel('Estimates');  
xlabel('Predictors');  
h = gca;  
h.XTickLabel = Mdl.PredictorNames;  
h.XTickLabelRotation = 45;  
h.TickLabelInterpreter = 'none';
```

In this case, `capital_gain` is the most important predictor, followed by `education_num`.

Optimize Classification Tree on Tall Array

This example shows how to optimize hyperparameters of a classification tree automatically using a tall array. The sample data set `airlinesmall.csv` is a large data set that contains a tabular file of airline flight data. This example creates a tall table containing the data and uses it to run the optimization procedure.

Create a datastore that references the folder location with the data. Select a subset of the variables to work with, and treat 'NA' values as missing data so that `datastore` replaces them with NaN values. Create a tall table that contains the data in the datastore.

```
ds = datastore('airlinesmall.csv');
ds.SelectedVariableNames = {'Month', 'DayofMonth', 'DayOfWeek', ...
    'DepTime', 'ArrDelay', 'Distance', 'DepDelay'};
ds.TreatAsMissing = 'NA';
tt = tall(ds) % Tall table
```

Starting parallel pool (parpool) using the 'local' profile ...
 Connected to the parallel pool (number of workers: 6).

```
tt =
```

M×7 tall table

Month	DayofMonth	DayOfWeek	DepTime	ArrDelay	Distance	DepDelay
10	21	3	642	8	308	12
10	26	1	1021	8	296	1
10	23	5	2055	21	480	20
10	23	5	1332	13	296	12
10	22	4	629	4	373	-1
10	28	3	1446	59	308	63
10	8	4	928	3	447	-2
10	10	6	859	11	954	-1

When you execute calculations on tall arrays, the default execution environment uses either the local MATLAB session or a local parallel pool (if you have Parallel Computing Toolbox™). You can use the `mapreducer` function to change the execution environment.

Determine the flights that are late by 10 minutes or more by defining a logical variable that is true for a late flight. This variable contains the class labels. A preview of this variable includes the first few rows.

```
Y = tt.DepDelay > 10 % Class labels
```

```
Y =

```

Remove rows in X and Y that contain missing data.

```
R = rmmissing([X Y]); % Data with missing entries removed
X = R(:,1:end-1);
Y = R(:,end);
```

Standardize the predictor variables.

```
Z = zscore(X);
```

Optimize hyperparameters automatically using the 'OptimizeHyperparameters' name-value pair argument. Find the optimal 'MinLeafSize' value that minimizes holdout cross-validation loss. (Specifying 'auto' uses 'MinLeafSize'.) For reproducibility, use the 'expected-improvement-plus' acquisition function and set the seeds of the random number generators using `rng` and `tallrng`. The results can vary depending on the number of workers and the execution environment for the tall arrays. For details, see “Control Where Your Code Runs” (MATLAB).

```
rng('default')
tallrng('default')
[Mdl,FitInfo,HyperparameterOptimizationResults] = fitctree(Z,Y,...
    'OptimizeHyperparameters','auto',...
    'HyperparameterOptimizationOptions',struct('Holdout',0.3,...
    'AcquisitionFunctionName','expected-improvement-plus'))
```

Input Arguments

Tbl — Sample data

table

Sample data used to train the model, specified as a table. Each row of `Tbl` corresponds to one observation, and each column corresponds to one predictor variable. Optionally, `Tbl` can contain one additional column for the response variable. Multicolumn variables and cell arrays other than cell arrays of character vectors are not allowed.

If `Tbl` contains the response variable, and you want to use all remaining variables in `Tbl` as predictors, then specify the response variable by using `ResponseVarName`.

If `Tbl` contains the response variable, and you want to use only a subset of the remaining variables in `Tbl` as predictors, then specify a formula by using `formula`.

If `Tbl` does not contain the response variable, then specify a response variable by using `Y`. The length of the response variable and the number of rows in `Tbl` must be equal.

Data Types: `table`

ResponseVarName — Response variable name

name of variable in `Tbl`

Response variable name, specified as the name of a variable in `Tbl`.

You must specify `ResponseVarName` as a character vector or string scalar. For example, if the response variable `Y` is stored as `Tbl.Y`, then specify it as `'Y'`. Otherwise, the software treats all columns of `Tbl`, including `Y`, as predictors when training the model.

The response variable must be a categorical, character, or string array, logical or numeric vector, or cell array of character vectors. If `Y` is a character array, then each element of the response variable must correspond to one row of the array.

It is a good practice to specify the order of the classes by using the `ClassNames` name-value pair argument.

Data Types: `char` | `string`

formula — Explanatory model of response and subset of predictor variables

character vector | string scalar

Explanatory model of the response and a subset of the predictor variables, specified as a character vector or string scalar in the form `'Y~X1+X2+X3'`. In this form, `Y` represents

the response variable, and `X1`, `X2`, and `X3` represent the predictor variables. The variables must be variable names in `Tbl` (`Tbl.Properties.VariableNames`).

To specify a subset of variables in `Tbl` as predictors for training the model, use a formula. If you specify a formula, then the software does not use any variables in `Tbl` that do not appear in `formula`.

Data Types: `char` | `string`

Y — Class labels

numeric vector | categorical vector | logical vector | character array | string array | cell array of character vectors

Class labels, specified as a numeric vector, categorical vector, logical vector, character array, string array, or cell array of character vectors. Each row of `Y` represents the classification of the corresponding row of `X`.

When fitting the tree, `fitctree` considers `NaN`, `' '` (empty character vector), `""` (empty string), `<missing>`, and `<undefined>` values in `Y` to be missing values. `fitctree` does not use observations with missing values for `Y` in the fit.

For numeric `Y`, consider fitting a regression tree using `fitrtree` instead.

Data Types: `single` | `double` | `categorical` | `logical` | `char` | `string` | `cell`

X — Predictor data

numeric matrix

Predictor data, specified as a numeric matrix. Each row of `X` corresponds to one observation, and each column corresponds to one predictor variable.

`fitctree` considers `NaN` values in `X` as missing values. `fitctree` does not use observations with all missing values for `X` in the fit. `fitctree` uses observations with some missing values for `X` to find splits on variables for which these observations have valid values.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes.

You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Note You cannot use any cross-validation name-value pair argument along with the `'OptimizeHyperparameters'` name-value pair argument. You can modify the cross-validation for `'OptimizeHyperparameters'` only by using the `'HyperparameterOptimizationOptions'` name-value pair argument.

Example: `'CrossVal', 'on', 'MinLeafSize', 40` specifies a cross-validated classification tree with a minimum of 40 observations per leaf.

Model Parameters

AlgorithmForCategorical — Algorithm for best categorical predictor split
`'Exact' | 'PullLeft' | 'PCA' | 'OVBbyClass'`

Algorithm to find the best split on a categorical predictor with C categories for data and $K \geq 3$ classes, specified as the comma-separated pair consisting of `'AlgorithmForCategorical'` and one of the following values.

Value	Description
<code>'Exact'</code>	Consider all $2^{C-1} - 1$ combinations.
<code>'PullLeft'</code>	Start with all C categories on the right branch. Consider moving each category to the left branch as it achieves the minimum impurity for the K classes among the remaining categories. From this sequence, choose the split that has the lowest impurity.
<code>'PCA'</code>	Compute a score for each category using the inner product between the first principal component of a weighted covariance matrix (of the centered class probability matrix) and the vector of class probabilities for that category. Sort the scores in ascending order, and consider all $C - 1$ splits.

Value	Description
'OVAbyClass'	Start with all C categories on the right branch. For each class, order the categories based on their probability for that class. For the first class, consider moving each category to the left branch in order, recording the impurity criterion at each move. Repeat for the remaining classes. From this sequence, choose the split that has the minimum impurity.

`fitctree` automatically selects the optimal subset of algorithms for each split using the known number of classes and levels of a categorical predictor. For $K = 2$ classes, `fitctree` always performs the exact search. To specify a particular algorithm, use the 'AlgorithmForCategorical' name-value pair argument.

For more details, see “Splitting Categorical Predictors in Classification Trees” on page 19-31.

Example: 'AlgorithmForCategorical', 'PCA'

CategoricalPredictors – Categorical predictors list

vector of positive integers | logical vector | character matrix | string array | cell array of character vectors | 'all'

Categorical predictors list, specified as the comma-separated pair consisting of 'CategoricalPredictors' and one of the values in this table.

Value	Description
Vector of positive integers	An entry in the vector is the index value corresponding to the column of the predictor data (X or Tbl) that contains a categorical variable.
Logical vector	A <code>true</code> entry means that the corresponding column of predictor data (X or Tbl) is a categorical variable.
Character matrix	Each row of the matrix is the name of a predictor variable. The names must match the entries in <code>PredictorNames</code> . Pad the names with extra blanks so each row of the character matrix has the same length.

Value	Description
String array or cell array of character vectors	Each element in the array is the name of a predictor variable. The names must match the entries in <code>PredictorNames</code> .
'all'	All predictors are categorical.

By default, if the predictor data is in a table (`Tbl`), `fitctree` assumes that a variable is categorical if it contains logical values, categorical values, a string array, or a cell array of character vectors. If the predictor data is a matrix (`X`), `fitctree` assumes all predictors are continuous. To identify any categorical predictors when the data is a matrix, use the `'CategoricalPredictors'` name-value pair argument.

Example: `'CategoricalPredictors','all'`

Data Types: `single` | `double` | `logical` | `char` | `string` | `cell`

ClassNames — Names of classes to use for training

categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Names of classes to use for training, specified as the comma-separated pair consisting of `'ClassNames'` and a categorical, character, or string array, a logical or numeric vector, or a cell array of character vectors. `ClassNames` must have the same data type as `Y`.

If `ClassNames` is a character array, then each element must correspond to one *row* of the array.

Use `ClassNames` to:

- Order the classes during training.
- Specify the order of any input or output argument dimension that corresponds to the class order. For example, use `ClassNames` to specify the order of the dimensions of `Cost` or the column order of classification scores returned by `predict`.
- Select a subset of classes for training. For example, suppose that the set of all distinct class names in `Y` is `{'a','b','c'}`. To train the model using observations from classes `'a'` and `'c'` only, specify `'ClassNames',{'a','c'}`.

The default value for `ClassNames` is the set of all distinct class names in `Y`.

Example: `'ClassNames',{'b','g'}`

Data Types: `categorical` | `char` | `string` | `logical` | `single` | `double` | `cell`

Cost — Cost of misclassification

square matrix | structure

Cost of misclassification of a point, specified as the comma-separated pair consisting of 'Cost' and one of the following:

- Square matrix, where $\text{Cost}(i, j)$ is the cost of classifying a point into class j if its true class is i (i.e., the rows correspond to the true class and the columns correspond to the predicted class). To specify the class order for the corresponding rows and columns of **Cost**, also specify the **ClassNames** name-value pair argument.
- Structure **S** having two fields: **S.ClassNames** containing the group names as a variable of the same data type as **Y**, and **S.ClassificationCosts** containing the cost matrix.

The default is $\text{Cost}(i, j)=1$ if $i \neq j$, and $\text{Cost}(i, j)=0$ if $i=j$.

Data Types: single | double | struct

MaxDepth — Maximum tree depth

positive integer

Maximum tree depth, specified as the comma-separated pair consisting of 'MaxDepth' and a positive integer. Specify a value for this argument to return a tree that has fewer levels and requires fewer passes through the tall array to compute. Generally, the algorithm of `fitctree` takes one pass through the data and an additional pass for each tree level. The function does not set a maximum tree depth, by default.

Note This option applies only when you use `fitctree` on tall arrays. See Tall Arrays on page 32-2181 for more information.

MaxNumCategories — Maximum category levels

10 (default) | nonnegative scalar value

Maximum category levels, specified as the comma-separated pair consisting of 'MaxNumCategories' and a nonnegative scalar value. `fitctree` splits a categorical predictor using the exact search algorithm if the predictor has at most **MaxNumCategories** levels in the split node. Otherwise, `fitctree` finds the best categorical split using one of the inexact algorithms.

Passing a small value can lead to loss of accuracy and passing a large value can increase computation time and memory overload.

Example: 'MaxNumCategories',8

MergeLeaves — Leaf merge flag

'on' (default) | 'off'

Leaf merge flag, specified as the comma-separated pair consisting of 'MergeLeaves' and 'on' or 'off'.

If MergeLeaves is 'on', then `fitctree`:

- Merges leaves that originate from the same parent node, and that yields a sum of risk values greater or equal to the risk associated with the parent node
- Estimates the optimal sequence of pruned subtrees, but does not prune the classification tree

Otherwise, `fitctree` does not merge leaves.

Example: 'MergeLeaves', 'off'

MinParentSize — Minimum number of branch node observations

10 (default) | positive integer value

Minimum number of branch node observations, specified as the comma-separated pair consisting of 'MinParentSize' and a positive integer value. Each branch node in the tree has at least `MinParentSize` observations. If you supply both `MinParentSize` and `MinLeafSize`, `fitctree` uses the setting that gives larger leaves: `MinParentSize = max(MinParentSize, 2*MinLeafSize)`.

Example: 'MinParentSize',8

Data Types: `single` | `double`

NumBins — Number of bins for numeric predictors

[] (empty) (default) | positive integer scalar

Number of bins for numeric predictors, specified as the comma-separated pair consisting of 'NumBins' and a positive integer scalar.

- If the 'NumBins' value is empty (default), then the software does not bin any predictors.
- If you specify the 'NumBins' value as a positive integer scalar, then the software bins every numeric predictor into a specified number of equiprobable bins, and then grows trees on the bin indices instead of the original data.

- If the 'NumBins' value exceeds the number (u) of unique values for a predictor, then `fitctree` bins the predictor into u bins.
- `fitctree` does not bin categorical predictors.

When you use a large training data set, this binning option speeds up training but causes a potential decrease in accuracy. You can try 'NumBins', 50 first, and then change the 'NumBins' value depending on the accuracy and training speed.

A trained model stores the bin edges in the `BinEdges` property.

Example: 'NumBins', 50

Data Types: `single` | `double`

PredictorNames — Predictor variable names

string array of unique names | cell array of unique character vectors

Predictor variable names, specified as the comma-separated pair consisting of 'PredictorNames' and a string array of unique names or cell array of unique character vectors. The functionality of 'PredictorNames' depends on the way you supply the training data.

- If you supply `X` and `Y`, then you can use 'PredictorNames' to give the predictor variables in `X` names.
 - The order of the names in `PredictorNames` must correspond to the column order of `X`. That is, `PredictorNames{1}` is the name of `X(:,1)`, `PredictorNames{2}` is the name of `X(:,2)`, and so on. Also, `size(X,2)` and `numel(PredictorNames)` must be equal.
 - By default, `PredictorNames` is `{'x1', 'x2', ...}`.
- If you supply `Tbl`, then you can use 'PredictorNames' to choose which predictor variables to use in training. That is, `fitctree` uses only the predictor variables in `PredictorNames` and the response variable in training.
 - `PredictorNames` must be a subset of `Tbl.Properties.VariableNames` and cannot include the name of the response variable.
 - By default, `PredictorNames` contains the names of all predictor variables.
 - It is a good practice to specify the predictors for training using either 'PredictorNames' or formula only.

Example: 'PredictorNames',
{'SepalLength', 'SepalWidth', 'PetalLength', 'PetalWidth'}

Data Types: string | cell

PredictorSelection — Algorithm used to select the best split predictor

'allsplits' (default) | 'curvature' | 'interaction-curvature'

Algorithm used to select the best split predictor at each node, specified as the comma-separated pair consisting of 'PredictorSelection' and a value in this table.

Value	Description
'allsplits'	Standard CART — Selects the split predictor that maximizes the split-criterion gain over all possible splits of all predictors [1].
'curvature'	Curvature test on page 32-2173 — Selects the split predictor that minimizes the p -value of chi-square tests of independence between each predictor and the response [4]. Training speed is similar to standard CART.
'interaction-curvature'	Interaction test on page 32-2175 — Chooses the split predictor that minimizes the p -value of chi-square tests of independence between each predictor and the response, and that minimizes the p -value of a chi-square test of independence between each pair of predictors and response [3]. Training speed can be slower than standard CART.

For 'curvature' and 'interaction-curvature', if all tests yield p -values greater than 0.05, then `fitctree` stops splitting nodes.

Tip

- Standard CART tends to select split predictors containing many distinct values, e.g., continuous variables, over those containing few distinct values, e.g., categorical variables [4]. Consider specifying the curvature or interaction test if any of the following are true:
 - If there are predictors that have relatively fewer distinct values than other predictors, for example, if the predictor data set is heterogeneous.
 - If an analysis of predictor importance is your goal. For more on predictor importance estimation, see `predictorImportance`.
- Trees grown using standard CART are not sensitive to predictor variable interactions. Also, such trees are less likely to identify important variables in the presence of many

irrelevant predictors than the application of the interaction test. Therefore, to account for predictor interactions and identify importance variables in the presence of many irrelevant variables, specify the interaction test [3].

- Prediction speed is unaffected by the value of 'PredictorSelection'.

For details on how `fitctree` selects split predictors, see “Node Splitting Rules” on page 32-2177 and “Choose Split Predictor Selection Technique” on page 19-19.

Example: 'PredictorSelection', 'curvature'

Prior — Prior probabilities

'empirical' (default) | 'uniform' | vector of scalar values | structure

Prior probabilities for each class, specified as the comma-separated pair consisting of 'Prior' and one of the following.

- A character vector or string scalar:
 - 'empirical' determines class probabilities from class frequencies in Y. If you pass observation weights, `fitctree` uses the weights to compute the class probabilities.
 - 'uniform' sets all class probabilities equal.
- A vector (one scalar value for each class). To specify the class order for the corresponding elements of `Prior`, also specify the `ClassNames` name-value pair argument.
- A structure `S` with two fields:
 - `S.ClassNames` containing the class names as a variable of the same type as `Y`
 - `S.ClassProbs` containing a vector of corresponding probabilities

If you set values for both `weights` and `prior`, the weights are renormalized to add up to the value of the prior probability in the respective class.

Example: 'Prior', 'uniform'

Data Types: char | string | single | double | struct

Prune — Flag to estimate optimal sequence of pruned subtrees

'on' (default) | 'off'

Flag to estimate the optimal sequence of pruned subtrees, specified as the comma-separated pair consisting of 'Prune' and 'on' or 'off'.

If Prune is 'on', then `fitctree` grows the classification tree without pruning it, but estimates the optimal sequence of pruned subtrees. Otherwise, `fitctree` grows the classification tree without estimating the optimal sequence of pruned subtrees.

To prune a trained `ClassificationTree` model, pass it to `prune`.

Example: 'Prune', 'off'

PruneCriterion — Pruning criterion

'error' (default) | 'impurity'

Pruning criterion, specified as the comma-separated pair consisting of 'PruneCriterion' and 'error' or 'impurity'.

If you specify 'impurity', then `fitctree` uses the impurity measure specified by the 'SplitCriterion' name-value pair argument.

For details, see “Impurity and Node Error” on page 32-2174.

Example: 'PruneCriterion', 'impurity'

Reproducible — Flag to enforce reproducibility

false (logical 0) (default) | true (logical 1)

Flag to enforce reproducibility over repeated runs of training a model, specified as the comma-separated pair consisting of 'Reproducible' and either false or true.

If 'NumVariablesToSample' is not 'all', then the software selects predictors at random for each split. To reproduce the random selections, you must specify 'Reproducible', true and set the seed of the random number generator by using `rng`. Note that setting 'Reproducible' to true can slow down training.

Example: 'Reproducible', true

Data Types: logical

ResponseName — Response variable name

'Y' (default) | character vector | string scalar

Response variable name, specified as the comma-separated pair consisting of 'ResponseName' and a character vector or string scalar representing the name of the response variable.

This name-value pair is not valid when using the ResponseVarName or formula input arguments.

Example: 'ResponseName', 'IrisType'

Data Types: char | string

ScoreTransform – Score transformation

'none' (default) | 'doublelogit' | 'invlogit' | 'ismax' | 'logit' | function handle | ...

Score transformation, specified as the comma-separated pair consisting of 'ScoreTransform' and a character vector, string scalar, or function handle.

This table summarizes the available character vectors and string scalars.

Value	Description
'doublelogit'	$1/(1 + e^{-2x})$
'invlogit'	$\log(x / (1 - x))$
'ismax'	Sets the score for the class with the largest score to 1, and sets the scores for all other classes to 0
'logit'	$1/(1 + e^{-x})$
'none' or 'identity'	x (no transformation)
'sign'	-1 for $x < 0$ 0 for $x = 0$ 1 for $x > 0$
'symmetric'	$2x - 1$
'symmetricismax'	Sets the score for the class with the largest score to 1, and sets the scores for all other classes to -1
'symmetriclogit'	$2/(1 + e^{-x}) - 1$

For a MATLAB function or a function you define, use its function handle for score transform. The function handle must accept a matrix (the original scores) and return a matrix of the same size (the transformed scores).

Example: 'ScoreTransform', 'logit'

Data Types: char | string | function_handle

Surrogate — Surrogate decision splits flag

'off' (default) | 'on' | 'all' | positive integer value

Surrogate decision splits on page 32-2176 flag, specified as the comma-separated pair consisting of 'Surrogate' and 'on', 'off', 'all', or a positive integer value.

- When set to 'on', `fitctree` finds at most 10 surrogate splits at each branch node.
- When set to 'all', `fitctree` finds all surrogate splits at each branch node. The 'all' setting can use considerable time and memory.
- When set to a positive integer value, `fitctree` finds at most the specified number of surrogate splits at each branch node.

Use surrogate splits to improve the accuracy of predictions for data with missing values. The setting also lets you compute measures of predictive association between predictors. For more details, see “Node Splitting Rules” on page 32-2177.

Example: 'Surrogate', 'on'

Data Types: single | double | char | string

Weights — Observation weights

`ones(size(x,1),1)` (default) | vector of scalar values | name of variable in `Tbl`

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a vector of scalar values or the name of a variable in `Tbl`. The software weights the observations in each row of `X` or `Tbl` with the corresponding value in `Weights`. The size of `Weights` must equal the number of rows in `X` or `Tbl`.

If you specify the input data as a table `Tbl`, then `Weights` can be the name of a variable in `Tbl` that contains a numeric vector. In this case, you must specify `Weights` as a character vector or string scalar. For example, if weights vector `W` is stored as `Tbl.W`, then specify it as 'W'. Otherwise, the software treats all columns of `Tbl`, including `W`, as predictors when training the model.

`fitctree` normalizes the weights in each class to add up to the value of the prior probability of the class.

Data Types: single | double | char | string

Cross-Validation**CrossVal — Flag to grow cross-validated decision tree**

'off' (default) | 'on'

Flag to grow a cross-validated decision tree, specified as the comma-separated pair consisting of 'CrossVal' and 'on' or 'off'.

If 'on', `fitctree` grows a cross-validated decision tree with 10 folds. You can override this cross-validation setting using one of the 'KFold', 'Holdout', 'Leaveout', or 'CVPartition' name-value pair arguments. You can only use one of these four arguments at a time when creating a cross-validated tree.

Alternatively, cross-validate `tree` later using the `crossval` method.

Example: 'CrossVal', 'on'

CVPartition — Partition for cross-validated tree

`cvpartition` object

Partition to use in a cross-validated tree, specified as the comma-separated pair consisting of 'CVPartition' and an object created using `cvpartition`.

If you use 'CVPartition', you cannot use any of the 'KFold', 'Holdout', or 'Leaveout' name-value pair arguments.

Holdout — Fraction of data for holdout validation

0 (default) | scalar value in the range [0, 1]

Fraction of data used for holdout validation, specified as the comma-separated pair consisting of 'Holdout' and a scalar value in the range [0, 1]. Holdout validation tests the specified fraction of the data, and uses the rest of the data for training.

If you use 'Holdout', you cannot use any of the 'CVPartition', 'KFold', or 'Leaveout' name-value pair arguments.

Example: 'Holdout', 0.1

Data Types: `single` | `double`

KFold — Number of folds

10 (default) | positive integer value greater than 1

Number of folds to use in a cross-validated classifier, specified as the comma-separated pair consisting of 'KFold' and a positive integer value greater than 1. If you specify, e.g., 'KFold', k , then the software:

- 1 Randomly partitions the data into k sets

- 2 For each set, reserves the set as validation data, and trains the model using the other $k - 1$ sets
- 3 Stores the k compact, trained models in the cells of a k -by-1 cell vector in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can use one of these four options only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: `'KFold',8`

Data Types: `single` | `double`

Leaveout — Leave-one-out cross-validation flag

`'off'` (default) | `'on'`

Leave-one-out cross-validation flag, specified as the comma-separated pair consisting of `'Leaveout'` and `'on'` or `'off'`. Specify `'on'` to use leave-one-out cross-validation.

If you use `'Leaveout'`, you cannot use any of the `'CVPartition'`, `'Holdout'`, or `'KFold'` name-value pair arguments.

Example: `'Leaveout','on'`

Hyperparameters

MaxNumSplits — Maximal number of decision splits

`size(X,1) - 1` (default) | positive integer

Maximal number of decision splits (or branch nodes), specified as the comma-separated pair consisting of `'MaxNumSplits'` and a positive integer. `fitctree` splits `MaxNumSplits` or fewer branch nodes. For more details on splitting behavior, see Algorithms on page 32-2177.

Example: `'MaxNumSplits',5`

Data Types: `single` | `double`

MinLeafSize — Minimum number of leaf node observations

1 (default) | positive integer value

Minimum number of leaf node observations, specified as the comma-separated pair consisting of `'MinLeafSize'` and a positive integer value. Each leaf has at least `MinLeafSize` observations per tree leaf. If you supply both `MinParentSize` and `MinLeafSize`, `fitctree` uses the setting that gives larger leaves: `MinParentSize = max(MinParentSize,2*MinLeafSize)`.

Example: `'MinLeafSize',3`

Data Types: `single` | `double`

NumVariablesToSample — Number of predictors to select at random for each split

`'all'` (default) | positive integer value

Number of predictors to select at random for each split, specified as the comma-separated pair consisting of `'NumVariablesToSample'` and a positive integer value. Alternatively, you can specify `'all'` to use all available predictors.

If the training data includes many predictors and you want to analyze predictor importance, then specify `'NumVariablesToSample'` as `'all'`. Otherwise, the software might not select some predictors, underestimating their importance.

To reproduce the random selections, you must set the seed of the random number generator by using `rng` and specify `'Reproducible',true`.

Example: `'NumVariablesToSample',3`

Data Types: `char` | `string` | `single` | `double`

SplitCriterion — Split criterion

`'gdi'` (default) | `'twoing'` | `'deviance'`

Split criterion, specified as the comma-separated pair consisting of `'SplitCriterion'` and `'gdi'` (Gini's diversity index), `'twoing'` for the twoing rule, or `'deviance'` for maximum deviance reduction (also known as cross entropy).

For details, see “Impurity and Node Error” on page 32-2174.

Example: `'SplitCriterion','deviance'`

Hyperparameter Optimization

OptimizeHyperparameters — Parameters to optimize

`'none'` (default) | `'auto'` | `'all'` | string array or cell array of eligible parameter names | vector of `optimizableVariable` objects

Parameters to optimize, specified as the comma-separated pair consisting of `'OptimizeHyperparameters'` and one of the following:

- `'none'` — Do not optimize.

- 'auto' — Use {'MinLeafSize'}
- 'all' — Optimize all eligible parameters.
- String array or cell array of eligible parameter names
- Vector of `optimizableVariable` objects, typically the output of hyperparameters

The optimization attempts to minimize the cross-validation loss (error) for `fitctree` by varying the parameters. For information about cross-validation loss (albeit in a different context), see “Classification Loss” on page 32-3352. To control the cross-validation type and other aspects of the optimization, use the `HyperparameterOptimizationOptions` name-value pair.

Note 'OptimizeHyperparameters' values override any values you set using other name-value pair arguments. For example, setting 'OptimizeHyperparameters' to 'auto' causes the 'auto' values to apply.

The eligible parameters for `fitctree` are:

- `MaxNumSplits` — `fitctree` searches among integers, by default log-scaled in the range `[1,max(2,NumObservations-1)]`.
- `MinLeafSize` — `fitctree` searches among integers, by default log-scaled in the range `[1,max(2,floor(NumObservations/2))]`.
- `SplitCriterion` — For two classes, `fitctree` searches among 'gdi' and 'deviance'. For three or more classes, `fitctree` also searches among 'twoing'.
- `NumVariablesToSample` — `fitctree` does not optimize over this hyperparameter. If you pass `NumVariablesToSample` as a parameter name, `fitctree` simply uses the full number of predictors. However, `fitcensemble` does optimize over this hyperparameter.

Set nondefault parameters by passing a vector of `optimizableVariable` objects that have nondefault values. For example,

```
load fisheriris
params = hyperparameters('fitctree',meas,species);
params(1).Range = [1,30];
```

Pass `params` as the value of `OptimizeHyperparameters`.

By default, iterative display appears at the command line, and plots appear according to the number of hyperparameters in the optimization. For the optimization and plots, the

objective function is $\log(1 + \text{cross-validation loss})$ for regression and the misclassification rate for classification. To control the iterative display, set the `Verbose` field of the `'HyperparameterOptimizationOptions'` name-value pair argument. To control the plots, set the `ShowPlots` field of the `'HyperparameterOptimizationOptions'` name-value pair argument.

For an example, see “Optimize Classification Tree” on page 32-2103.

Example: `'auto'`

HyperparameterOptimizationOptions — Options for optimization structure

Options for optimization, specified as the comma-separated pair consisting of `'HyperparameterOptimizationOptions'` and a structure. This argument modifies the effect of the `OptimizeHyperparameters` name-value pair argument. All fields in the structure are optional.

Field Name	Values	Default
Optimizer	<ul style="list-style-type: none"> 'bayesopt' — Use Bayesian optimization. Internally, this setting calls <code>bayesopt</code>. 'gridsearch' — Use grid search with <code>NumGridDivisions</code> values per dimension. 'randomsearch' — Search at random among <code>MaxObjectiveEvaluations</code> points. <p>'gridsearch' searches in a random order, using uniform sampling without replacement from the grid. After optimization, you can get a table in grid order by using the command <code>sortrows(Mdl.HyperparameterOptimizationResults)</code>.</p>	'bayesopt'

Field Name	Values	Default
AcquisitionFunctionName	<ul style="list-style-type: none"> • 'expected-improvement-per-second-plus' • 'expected-improvement' • 'expected-improvement-plus' • 'expected-improvement-per-second' • 'lower-confidence-bound' • 'probability-of-improvement' <p>Acquisition functions whose names include <code>per-second</code> do not yield reproducible results because the optimization depends on the runtime of the objective function. Acquisition functions whose names include <code>plus</code> modify their behavior when they are overexploiting an area. For more details, see “Acquisition Function Types” on page 10-4.</p>	'expected-improvement-per-second-plus'
MaxObjectiveEvaluations	Maximum number of objective function evaluations.	30 for 'bayesopt' or 'randomsearch', and the entire grid for 'gridsearch'
MaxTime	Time limit, specified as a positive real. The time limit is in seconds, as measured by <code>tic</code> and <code>toc</code> . Run time can exceed <code>MaxTime</code> because <code>MaxTime</code> does not interrupt function evaluations.	Inf
NumGridDivisions	For 'gridsearch', the number of values in each dimension. The value can be a vector of positive integers giving the number of values for each dimension, or a scalar that applies to all dimensions. This field is ignored for categorical variables.	10

Field Name	Values	Default
ShowPlots	Logical value indicating whether to show plots. If <code>true</code> , this field plots the best objective function value against the iteration number. If there are one or two optimization parameters, and if <code>Optimizer</code> is <code>'bayesopt'</code> , then <code>ShowPlots</code> also plots a model of the objective function against the parameters.	<code>true</code>
SaveIntermediateResults	Logical value indicating whether to save results when <code>Optimizer</code> is <code>'bayesopt'</code> . If <code>true</code> , this field overwrites a workspace variable named <code>'BayesoptResults'</code> at each iteration. The variable is a <code>BayesianOptimization</code> object.	<code>false</code>
Verbose	Display to the command line. <ul style="list-style-type: none"> • 0 — No iterative display • 1 — Iterative display • 2 — Iterative display with extra information For details, see the <code>bayesopt</code> <code>Verbose</code> name-value pair argument.	1
UseParallel	Logical value indicating whether to run Bayesian optimization in parallel, which requires Parallel Computing Toolbox. For details, see “Parallel Bayesian Optimization” on page 10-8.	<code>false</code>

Field Name	Values	Default
Repartition	Logical value indicating whether to repartition the cross-validation at every iteration. If <code>false</code> , the optimizer uses a single partition for the optimization. <code>true</code> usually gives the most robust results because this setting takes partitioning noise into account. However, for good results, <code>true</code> requires at least twice as many function evaluations.	<code>false</code>
Use no more than one of the following three field names.		
CVPartition	A <code>cvpartition</code> object, as created by <code>cvpartition</code> .	'Kfold', 5 if you do not specify any cross-validation field
Holdout	A scalar in the range (0, 1) representing the holdout fraction.	
Kfold	An integer greater than 1.	

Example:

```
'HyperparameterOptimizationOptions', struct('MaxObjectiveEvaluations', 60)
```

Data Types: `struct`

Output Arguments

tree — Classification tree

classification tree object

Classification tree, returned as a classification tree object.

Using the `'CrossVal'`, `'KFold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'` options results in a tree of class `ClassificationPartitionedModel`. You cannot use a partitioned tree for prediction, so this kind of tree does not have a `predict` method. Instead, use `kfoldPredict` to predict responses for observations not used for training.

Otherwise, `tree` is of class `ClassificationTree`, and you can use the `predict` method to make predictions.

Definitions

Curvature Test

The curvature test is a statistical test assessing the null hypothesis that two variables are unassociated.

The curvature test between predictor variable x and y is conducted using this process.

- 1 If x is continuous, then partition it into its quartiles. Create a nominal variable that bins observations according to which section of the partition they occupy. If there are missing values, then create an extra bin for them.
- 2 For each level in the partitioned predictor $j = 1 \dots J$ and class in the response $k = 1, \dots, K$, compute the weighted proportion of observations in class k

$$\hat{\pi}_{jk} = \sum_{i=1}^n I\{y_i = k\} w_i.$$

w_i is the weight of observation i , $\sum w_i = 1$, I is the indicator function, and n is the sample size. If all observations have the same weight, then $\hat{\pi}_{jk} = \frac{n_{jk}}{n}$, where n_{jk} is the number of observations in level j of the predictor that are in class k .

- 3 Compute the test statistic

$$t = n \sum_{k=1}^K \sum_{j=1}^J \frac{(\hat{\pi}_{jk} - \hat{\pi}_{j+} \hat{\pi}_{+k})^2}{\hat{\pi}_{j+} \hat{\pi}_{+k}}$$

$\hat{\pi}_{j+} = \sum_k \hat{\pi}_{jk}$, that is, the marginal probability of observing the predictor at level j .

$\hat{\pi}_{+k} = \sum_j \hat{\pi}_{jk}$, that is the marginal probability of observing class k . If n is large

enough, then t is distributed as a χ^2 with $(K - 1)(J - 1)$ degrees of freedom.

- 4 If the p -value for the test is less than 0.05, then reject the null hypothesis that there is no association between x and y .

When determining the best split predictor at each node, the standard CART algorithm prefers to select continuous predictors that have many levels. Sometimes, such a selection can be spurious and can also mask more important predictors that have fewer levels, such as categorical predictors.

The curvature test can be applied instead of standard CART to determine the best split predictor at each node. In that case, the best split predictor variable is the one that minimizes the significant p -values (those less than 0.05) of curvature tests between each predictor and the response variable. Such a selection is robust to the number of levels in individual predictors.

Note If levels of a predictor are pure for a particular class, then `fitctree` merges those levels. Therefore, in step 3 of the algorithm, J can be less than the actual number of levels in the predictor. For example, if x has 4 levels, and all observations in bins 1 and 2 belong to class 1, then those levels are pure for class 1. Consequently, `fitctree` merges the observations in bins 1 and 2, and J reduces to 3.

For more details on how the curvature test applies to growing classification trees, see “Node Splitting Rules” on page 32-2177 and [4].

Impurity and Node Error

`ClassificationTree` splits nodes based on either impurity or node error.

Impurity means one of several things, depending on your choice of the `SplitCriterion` name-value pair argument:

- Gini's Diversity Index (`gdi`) — The Gini index of a node is

$$1 - \sum_i p^2(i),$$

where the sum is over the classes i at the node, and $p(i)$ is the observed fraction of classes with class i that reach the node. A node with just one class (a pure node) has Gini index 0; otherwise the Gini index is positive. So the Gini index is a measure of node impurity.

- Deviance ('deviance') — With $p(i)$ defined the same as for the Gini index, the deviance of a node is

$$- \sum_i p(i) \log_2 p(i).$$

A pure node has deviance 0; otherwise, the deviance is positive.

- Twoing rule ('twoing') — Twoing is not a purity measure of a node, but is a different measure for deciding how to split a node. Let $L(i)$ denote the fraction of members of

class i in the left child node after a split, and $R(i)$ denote the fraction of members of class i in the right child node after a split. Choose the split criterion to maximize

$$P(L)P(R)\left(\sum_i |L(i) - R(i)|\right)^2,$$

where $P(L)$ and $P(R)$ are the fractions of observations that split to the left and right respectively. If the expression is large, the split made each child node purer. Similarly, if the expression is small, the split made each child node similar to each other, and therefore similar to the parent node. The split did not increase node purity.

- Node error — The node error is the fraction of misclassified classes at a node. If j is the class with the largest number of training samples at a node, the node error is

$$1 - p(j).$$

Interaction Test

The interaction test is a statistical test that assesses the null hypothesis that there is no interaction between a pair of predictor variables and the response variable.

The interaction test assessing the association between predictor variables x_1 and x_2 with respect to y is conducted using this process.

- 1 If x_1 or x_2 is continuous, then partition that variable into its quartiles. Create a nominal variable that bins observations according to which section of the partition they occupy. If there are missing values, then create an extra bin for them.
- 2 Create the nominal variable z with $J = J_1 J_2$ levels that assigns an index to observation i according to which levels of x_1 and x_2 it belongs. Remove any levels of z that do not correspond to any observations.
- 3 Conduct a curvature test on page 32-2173 between z and y .

When growing decision trees, if there are important interactions between pairs of predictors, but there are also many other less important predictors in the data, then standard CART tends to miss the important interactions. However, conducting curvature and interaction tests for predictor selection instead can improve detection of important interactions, which can yield more accurate decision trees.

For more details on how the interaction test applies to growing decision trees, see “Curvature Test” on page 32-2173, “Node Splitting Rules” on page 32-2177 and [3].

Predictive Measure of Association

The predictive measure of association is a value that indicates the similarity between decision rules that split observations. Among all possible decision splits that are compared to the optimal split (found by growing the tree), the best surrogate decision split on page 32-2176 yields the maximum predictive measure of association. The second-best surrogate split has the second-largest predictive measure of association.

Suppose x_j and x_k are predictor variables j and k , respectively, and $j \neq k$. At node t , the predictive measure of association between the optimal split $x_j < u$ and a surrogate split $x_k < v$ is

$$\lambda_{jk} = \frac{\min(P_L, P_R) - (1 - P_{L_j L_k} - P_{R_j R_k})}{\min(P_L, P_R)}.$$

- P_L is the proportion of observations in node t , such that $x_j < u$. The subscript L stands for the left child of node t .
- P_R is the proportion of observations in node t , such that $x_j \geq u$. The subscript R stands for the right child of node t .
- $P_{L_j L_k}$ is the proportion of observations at node t , such that $x_j < u$ and $x_k < v$.
- $P_{R_j R_k}$ is the proportion of observations at node t , such that $x_j \geq u$ and $x_k \geq v$.
- Observations with missing values for x_j or x_k do not contribute to the proportion calculations.

λ_{jk} is a value in $(-\infty, 1]$. If $\lambda_{jk} > 0$, then $x_k < v$ is a worthwhile surrogate split for $x_j < u$.

Surrogate Decision Splits

A surrogate decision split is an alternative to the optimal decision split at a given node in a decision tree. The optimal split is found by growing the tree; the surrogate split uses a similar or correlated predictor variable and split criterion.

When the value of the optimal split predictor for an observation is missing, the observation is sent to the left or right child node using the best surrogate predictor. When the value of the best surrogate split predictor for the observation is also missing, the observation is sent to the left or right child node using the second-best surrogate predictor, and so on. Candidate splits are sorted in descending order by their predictive measure of association on page 32-2680.

Tip

- By default, Prune is 'on'. However, this specification does not prune the classification tree. To prune a trained classification tree, pass the classification tree to `prune`.
- After training a model, you can generate C/C++ code that predicts labels for new data. Generating C/C++ code requires MATLAB Coder. For details, see “Introduction to Code Generation” on page 31-2.

Algorithms

Node Splitting Rules

`fitctree` uses these processes to determine how to split node t .

- For standard CART (that is, if `PredictorSelection` is 'allpairs') and for all predictors x_i , $i = 1, \dots, p$:
 - 1 `fitctree` computes the weighted impurity of node t , i_t . For supported impurity measures, see `SplitCriterion`.
 - 2 `fitctree` estimates the probability that an observation is in node t using

$$P(T) = \sum_{j \in T} w_j.$$

w_j is the weight of observation j , and T is the set of all observation indices in node t . If you do not specify `Prior` or `Weights`, then $w_j = 1/n$, where n is the sample size.

- 3 `fitctree` sorts x_i in ascending order. Each element of the sorted predictor is a splitting candidate or cut point. `fitctree` stores any indices corresponding to missing values in the set T_U , which is the unsplit set.
- 4 `fitctree` determines the best way to split node t using x_i by maximizing the impurity gain (ΔI) over all splitting candidates. That is, for all splitting candidates in x_i :
 - a `fitctree` splits the observations in node t into left and right child nodes (t_L and t_R , respectively).

- b** `fitctree` computes ΔI . Suppose that for a particular splitting candidate, t_L and t_R contain observation indices in the sets T_L and T_R , respectively.

- If x_i does not contain any missing values, then the impurity gain for the current splitting candidate is

$$\Delta I = P(T)t - P(T_L)t_{t_L} - P(T_R)t_{t_R}.$$

- If x_i contains missing values then, assuming that the observations are missing at random, the impurity gain is

$$\Delta I_U = P(T - T_U)t - P(T_L)t_{t_L} - P(T_R)t_{t_R}.$$

$T - T_U$ is the set of all observation indices in node t that are not missing.

- If you use surrogate decision splits on page 32-2176, then:
 - `fitctree` computes the predictive measures of association on page 32-2176 between the decision split $x_j < u$ and all possible decision splits $x_k < v$, $j \neq k$.
 - `fitctree` sorts the possible alternative decision splits in descending order by their predictive measure of association with the optimal split. The surrogate split is the decision split yielding the largest measure.
 - `fitctree` decides the child node assignments for observations with a missing value for x_i using the surrogate split. If the surrogate predictor also contains a missing value, then `fitctree` uses the decision split with the second largest measure, and so on, until there are no other surrogates. It is possible for `fitctree` to split two different observations at node t using two different surrogate splits. For example, suppose the predictors x_1 and x_2 are the best and second best surrogates, respectively, for the predictor x_i , $i \notin \{1,2\}$, at node t . If observation m of predictor x_i is missing (i.e., x_{mi} is missing), but x_{m1} is not missing, then x_1 is the surrogate predictor for observation x_{mi} . If observations $x_{(m+1),i}$ and $x_{(m+1),1}$ are missing, but $x_{(m+1),2}$ is not missing, then x_2 is the surrogate predictor for observation $m+1$.
 - `fitctree` uses the appropriate impurity gain formula. That is, if `fitctree` fails to assign all missing observations in node t to children nodes using surrogate splits, then the impurity gain is ΔI_U . Otherwise, `fitctree` uses ΔI for the impurity gain.
- c** `fitctree` chooses the candidate that yields the largest impurity gain.

`fitctree` splits the predictor variable at the cut point that maximizes the impurity gain.

- For the curvature test (that is, if `PredictorSelection` is `'curvature'`):
 - 1 `fitctree` conducts curvature tests on page 32-2173 between each predictor and the response for observations in node t .
 - If all p -values are at least 0.05, then `fitctree` does not split node t .
 - If there is a minimal p -value, then `fitctree` chooses the corresponding predictor to split node t .
 - If more than one p -value is zero due to underflow, then `fitctree` applies standard CART to the corresponding predictors to choose the split predictor.
 - 2 If `fitctree` chooses a split predictor, then it uses standard CART to choose the cut point (see step 4 in the standard CART process).
- For the interaction test (that is, if `PredictorSelection` is `'interaction-curvature'`):
 - 1 For observations in node t , `fitctree` conducts curvature tests on page 32-2173 between each predictor and the response and interaction tests on page 32-2175 between each pair of predictors and the response.
 - If all p -values are at least 0.05, then `fitctree` does not split node t .
 - If there is a minimal p -value and it is the result of a curvature test, then `fitctree` chooses the corresponding predictor to split node t .
 - If there is a minimal p -value and it is the result of an interaction test, then `fitctree` chooses the split predictor using standard CART on the corresponding pair of predictors.
 - If more than one p -value is zero due to underflow, then `fitctree` applies standard CART to the corresponding predictors to choose the split predictor.
 - 2 If `fitctree` chooses a split predictor, then it uses standard CART to choose the cut point (see step 4 in the standard CART process).

Tree Depth Control

- If `MergeLeaves` is `'on'` and `PruneCriterion` is `'error'` (which are the default values for these name-value pair arguments), then the software applies pruning only to the leaves and by using classification error. This specification amounts to merging leaves that share the most popular class per leaf.

- To accommodate `MaxNumSplits`, `fitctree` splits all nodes in the current layer, and then counts the number of branch nodes. A layer is the set of nodes that are equidistant from the root node. If the number of branch nodes exceeds `MaxNumSplits`, `fitctree` follows this procedure:
 - 1 Determine how many branch nodes in the current layer must be unsplit so that there are at most `MaxNumSplits` branch nodes.
 - 2 Sort the branch nodes by their impurity gains.
 - 3 Unsplit the number of least successful branches.
 - 4 Return the decision tree grown so far.

This procedure produces maximally balanced trees.

- The software splits branch nodes layer by layer until at least one of these events occurs:
 - There are `MaxNumSplits` branch nodes.
 - A proposed split causes the number of observations in at least one branch node to be fewer than `MinParentSize`.
 - A proposed split causes the number of observations in at least one leaf node to be fewer than `MinLeafSize`.
 - The algorithm cannot find a good split within a layer (i.e., the pruning criterion (see `PruneCriterion`), does not improve for all proposed splits in a layer). A special case is when all nodes are pure (i.e., all observations in the node have the same class).
 - For values `'curvature'` or `'interaction-curvature'` of `PredictorSelection`, all tests yield *p*-values greater than 0.05.

`MaxNumSplits` and `MinLeafSize` do not affect splitting at their default values. Therefore, if you set `'MaxNumSplits'`, splitting might stop due to the value of `MinParentSize`, before `MaxNumSplits` splits occur.

Parallelization

For dual-core systems and above, `fitctree` parallelizes training decision trees using Intel Threading Building Blocks (TBB). For details on Intel TBB, see <https://software.intel.com/en-us/intel-tbb>.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

Usage notes and limitations:

- Supported syntaxes are:
 - `tree = fitctree(Tbl,Y)`
 - `tree = fitctree(X,Y)`
 - `tree = fitctree(__,Name,Value)`
 - `[tree,FitInfo,HyperparameterOptimizationResults] = fitctree(__,Name,Value)` — `fitctree` returns the additional output arguments `FitInfo` and `HyperparameterOptimizationResults` when you specify the 'OptimizeHyperparameters' name-value pair argument.
- The `FitInfo` output argument is an empty structure array currently reserved for possible future use.
- The `HyperparameterOptimizationResults` output argument is a `BayesianOptimization` object or a table of hyperparameters with associated values that describe the cross-validation optimization of hyperparameters.

'HyperparameterOptimizationResults' is nonempty when the 'OptimizeHyperparameters' name-value pair argument is nonempty at the time you create the model. The values in 'HyperparameterOptimizationResults' depend on the value you specify for the 'HyperparameterOptimizationOptions' name-value pair argument when you create the model.

- If you specify 'bayesopt' (default), then HyperparameterOptimizationResults is an object of class BayesianOptimization.
- If you specify 'gridsearch' or 'randomsearch', then HyperparameterOptimizationResults is a table of the hyperparameters used, observed objective function values (cross-validation loss), and rank of observations from lowest (best) to highest (worst).
- Supported name-value pair arguments, and any differences, are:
 - 'AlgorithmForCategorical'
 - 'CategoricalPredictors'
 - 'ClassNames'
 - 'Cost'
 - 'HyperparameterOptimizationOptions' — For cross-validation, tall optimization supports only 'Holdout' validation. For example, you can specify `fitctree(X,Y,'OptimizeHyperparameters','auto','HyperparameterOptimizationOptions',struct('Holdout',0.2))`.
 - 'MaxNumCategories'
 - 'MaxNumSplits' — for tall optimization, `fitctree` searches among integers, by default log-scaled in the range `[1,max(2,min(10000,NumObservations-1))]`.
 - 'MergeLeaves'
 - 'MinLeafSize'
 - 'MinParentSize'
 - 'NumVariablesToSample'
 - 'OptimizeHyperparameters'
 - 'PredictorNames'
 - 'Prior'
 - 'ResponseName'
 - 'ScoreTransform'

- 'SplitCriterion'
- 'Weights'
- This additional name-value pair argument is specific to tall arrays:
 - 'MaxDepth' — A positive integer specifying the maximum depth of the output tree. Specify a value for this argument to return a tree that has fewer levels and requires fewer passes through the tall array to compute. Generally, the algorithm of `fitctree` takes one pass through the data and an additional pass for each tree level. The function does not set a maximum tree depth, by default.

For more information, see “Tall Arrays” (MATLAB).

Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the 'UseParallel' option to `true`.

To perform parallel hyperparameter optimization, use the 'HyperparameterOptions', `struct('UseParallel', true)` name-value pair argument in the call to this function.

For more information on parallel hyperparameter optimization, see “Parallel Bayesian Optimization” on page 10-8.

For more general information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

Introduced in R2014a

fitglm

Create generalized linear regression model

Syntax

```
mdl = fitglm(tbl)
mdl = fitglm(X,y)
mdl = fitglm( ____,modelspec)
mdl = fitglm( ____,Name,Value)
```

Description

`mdl = fitglm(tbl)` returns a generalized linear model fit to variables in the table or dataset array `tbl`. By default, `fitglm` takes the last variable as the response variable.

`mdl = fitglm(X,y)` returns a generalized linear model of the responses `y`, fit to the data matrix `X`.

`mdl = fitglm(____,modelspec)` returns a generalized linear model of the type you specify in `modelspec`.

`mdl = fitglm(____,Name,Value)` returns a generalized linear model with additional options specified by one or more `Name,Value` pair arguments.

For example, you can specify which variables are categorical, the distribution of the response variable, and the link function to use.

Examples

Fit a Logistic Regression Model

Make a logistic binomial model of the probability of smoking as a function of age, weight, and sex, using a two-way interactions model.

Load the hospital dataset array.

```
load hospital
dsa = hospital;
```

Specify the model using a formula that allows up to two-way interactions between the variables age, weight, and sex. Smoker is the response variable.

```
modelspec = 'Smoker ~ Age*Weight*Sex - Age:Weight:Sex';
```

Fit a logistic binomial model.

```
mdl = fitglm(dsa,modelspec,'Distribution','binomial')
```

```
mdl =
```

Generalized linear regression model:

```
logit(Smoker) ~ 1 + Sex*Age + Sex*Weight + Age*Weight
Distribution = Binomial
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	-6.0492	19.749	-0.3063	0.75938
Sex_Male	-2.2859	12.424	-0.18399	0.85402
Age	0.11691	0.50977	0.22934	0.81861
Weight	0.031109	0.15208	0.20455	0.83792
Sex_Male:Age	0.020734	0.20681	0.10025	0.92014
Sex_Male:Weight	0.01216	0.053168	0.22871	0.8191
Age:Weight	-0.00071959	0.0038964	-0.18468	0.85348

100 observations, 93 error degrees of freedom

Dispersion: 1

Chi²-statistic vs. constant model: 5.07, p-value = 0.535

All of the p-values (under pValue) are large. This means none of the coefficients are significant. The large *p*-value for the test of the model, 0.535, indicates that this model might not differ statistically from a constant model.

GLM for Poisson Response

Create sample data with 20 predictors, and Poisson response using just three of the predictors, plus a constant.

```
rng('default') % for reproducibility
X = randn(100,7);
mu = exp(X(:, [1 3 6]) * [.4; .2; .3] + 1);
y = poissrnd(mu);
```

Fit a generalized linear model using the Poisson distribution.

```
mdl = fitglm(X,y,'linear','Distribution','poisson')
```

```
mdl =
Generalized linear regression model:
log(y) ~ 1 + x1 + x2 + x3 + x4 + x5 + x6 + x7
Distribution = Poisson
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	0.88723	0.070969	12.502	7.3149e-36
x1	0.44413	0.052337	8.4858	2.1416e-17
x2	0.0083388	0.056527	0.14752	0.88272
x3	0.21518	0.063416	3.3932	0.00069087
x4	-0.058386	0.065503	-0.89135	0.37274
x5	-0.060824	0.073441	-0.8282	0.40756
x6	0.34267	0.056778	6.0352	1.5878e-09
x7	0.04316	0.06146	0.70225	0.48252

100 observations, 92 error degrees of freedom

Dispersion: 1

Chi²-statistic vs. constant model: 119, p-value = 1.55e-22

The p-values of 2.14e-17, 0.00069, and 1.58e-09 indicate that the coefficients of the variables x1, x3, and x6 are statistically significant.

Input Arguments

tbl — Input data

table | dataset array

Input data, specified as a table or dataset array. When `modelspec` is a formula, the formula specifies the predictor and response variables. Otherwise, if you do not specify the predictor and response variables, the last variable in `tbl` is the response variable and the others are the predictor variables by default.

The predictor variables and response variable can be numeric, logical, categorical, character, or string. The response variable can have a data type other than numeric only if 'Distribution' is 'binomial'.

To set a different column as the response variable, use the `ResponseVar` name-value pair argument. To use a subset of the columns as predictors, use the `PredictorVars` name-value pair argument.

X — Predictor variables

matrix

Predictor variables, specified as an n -by- p matrix, where n is the number of observations and p is the number of predictor variables. Each column of `X` represents one variable, and each row represents one observation.

By default, there is a constant term in the model, unless you explicitly remove it, so do not include a column of 1s in `X`.

Data Types: `single` | `double`

y — Response variable

vector

Response variable, specified as an n -by-1 vector, where n is the number of observations. Each entry in `y` is the response for the corresponding row of `X`.

Data Types: `single` | `double` | `logical` | `categorical`

modelspec — Model specification

character vector or string scalar specifying the model | t -by- $(p+1)$ terms matrix | character vector or string scalar of the form 'Y ~ terms'

Model specification, which is the starting model for `stepwiseglm`, specified as one of the following:

- A character vector or string scalar naming the model.

Value	Model Type
'constant'	Model contains only a constant (intercept) term.
'linear'	Model contains an intercept and linear term for each predictor.
'interactions'	Model contains an intercept, linear term for each predictor, and all products of pairs of distinct predictors (no squared terms).
'purequadratic'	Model contains an intercept term and linear and squared terms for each predictor.
'quadratic'	Model contains an intercept term, linear and squared terms for each predictor, and all products of pairs of distinct predictors.
'polyijk'	Model is a polynomial with all terms up to degree i in the first predictor, degree j in the second predictor, and so on. Specify the maximum degree for each predictor by using numerals 0 through 9. The model contains interaction terms, but the degree of each interaction term does not exceed the maximum value of the specified degrees. For example, 'poly13' has an intercept and x_1 , x_2 , x_2^2 , x_2^3 , x_1*x_2 , and $x_1*x_2^2$ terms, where x_1 and x_2 are the first and second predictors, respectively.

- A t -by- $(p + 1)$ matrix, or a “Terms Matrix” on page 32-2195, specifying terms in the model, where t is the number of terms and p is the number of predictor variables, and +1 accounts for the response variable. A terms matrix is convenient when the number of predictors is large and you want to generate the terms programmatically.
- A character vector or string scalar representing a “Formula” on page 32-2195 in the form
`'Y ~ terms'`,
 where the terms are in “Wilkinson Notation” on page 32-2196.

Example: 'quadratic'

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'Distribution', 'normal', 'link', 'probit', 'Exclude', [23,59]` specifies that the distribution of the response is normal, and instructs `fitglm` to use the probit link function and exclude the 23rd and 59th observations from the fit.

BinomialSize — Number of trials for binomial distribution

1 (default) | scalar value | vector

Number of trials for binomial distribution, that is the sample size, specified as the comma-separated pair consisting of a scalar value or a vector of the same length as the response. This is the parameter `n` for the fitted binomial distribution. `BinomialSize` applies only when the `Distribution` parameter is `'binomial'`.

If `BinomialSize` is a scalar value, that means all observations have the same number of trials.

As an alternative to `BinomialSize`, you can specify the response as a two-column vector with counts in column 1 and `BinomialSize` in column 2.

Data Types: `single` | `double`

CategoricalVars — Categorical variable list

string array | cell array of character vectors | logical or numeric index vector

Categorical variable list, specified as the comma-separated pair consisting of `'CategoricalVars'` and either a string array or cell array of character vectors containing categorical variable names in the table or dataset array `tbl`, or a logical or numeric index vector indicating which columns are categorical.

- If data is in a table or dataset array `tbl`, then, by default, `fitglm` treats all categorical values, logical values, character arrays, string arrays, and cell arrays of character vectors as categorical variables.
- If data is in matrix `X`, then the default value of `'CategoricalVars'` is an empty matrix `[]`. That is, no variable is categorical unless you specify it as categorical.

For example, you can specify the observations 2 and 3 out of 6 as categorical using either of the following examples.

Example: 'CategoricalVars',[2,3]

Example: 'CategoricalVars',logical([0 1 1 0 0 0])

Data Types: single | double | logical | string | cell

DispersionFlag — Indicator to compute dispersion parameter

false for 'binomial' and 'poisson' distributions (default) | true

Indicator to compute dispersion parameter for 'binomial' and 'poisson' distributions, specified as the comma-separated pair consisting of 'DispersionFlag' and one of the following.

true	Estimate a dispersion parameter when computing standard errors
false	Default. Use the theoretical value when computing standard errors

The fitting function always estimates the dispersion for other distributions.

Example: 'DispersionFlag',true

Distribution — Distribution of the response variable

'normal' (default) | 'binomial' | 'poisson' | 'gamma' | 'inverse gaussian'

Distribution of the response variable, specified as the comma-separated pair consisting of 'Distribution' and one of the following.

'normal'	Normal distribution
'binomial'	Binomial distribution
'poisson'	Poisson distribution
'gamma'	Gamma distribution
'inverse gaussian'	Inverse Gaussian distribution

Example: 'Distribution','gamma'

Exclude — Observations to exclude

logical or numeric index vector

Observations to exclude from the fit, specified as the comma-separated pair consisting of 'Exclude' and a logical or numeric index vector indicating which observations to exclude from the fit.

For example, you can exclude observations 2 and 3 out of 6 using either of the following examples.

Example: 'Exclude', [2,3]

Example: 'Exclude', logical([0 1 1 0 0 0])

Data Types: single | double | logical

Intercept — Indicator for constant term

true (default) | false

Indicator for the constant term (intercept) in the fit, specified as the comma-separated pair consisting of 'Intercept' and either true to include or false to remove the constant term from the model.

Use 'Intercept' only when specifying the model using a character vector or string scalar, not a formula or matrix.

Example: 'Intercept', false

Link — Link function

canonical link function (default) | scalar value | structure

Link function to use in place of the canonical link function, specified as the comma-separated pair consisting of 'Link' and one of the following.

Link Function Name	Link Function	Mean (Inverse) Function
'identity'	$f(\mu) = \mu$	$\mu = Xb$
'log'	$f(\mu) = \log(\mu)$	$\mu = \exp(Xb)$
'logit'	$f(\mu) = \log(\mu/(1-\mu))$	$\mu = \exp(Xb) / (1 + \exp(Xb))$
'probit'	$f(\mu) = \Phi^{-1}(\mu)$	$\mu = \Phi(Xb)$
'comploglog'	$f(\mu) = \log(-\log(1 - \mu))$	$\mu = 1 - \exp(-\exp(Xb))$
'reciprocal'	$f(\mu) = 1/\mu$	$\mu = 1/(Xb)$
p (a number)	$f(\mu) = \mu^p$	$\mu = Xb^{1/p}$

Link Function Name	Link Function	Mean (Inverse) Function
<p>S (a structure) with three fields. Each field holds a function handle that accepts a vector of inputs and returns a vector of the same size:</p> <ul style="list-style-type: none"> • S.Link — The link function • S.Inverse — The inverse link function • S.Derivative — The derivative of the link function 	$f(\mu) = S.Link(\mu)$	$\mu = S.Inverse(Xb)$

The link function defines the relationship $f(\mu) = X*b$ between the mean response μ and the linear combination of predictors $X*b$.

For more information on the canonical link functions, see “Canonical Link Function” on page 32-2197.

Example: 'Link', 'probit'

Data Types: char | string | single | double | struct

Offset — Offset variable

[] (default) | vector | character vector | string scalar

Offset variable in the fit, specified as the comma-separated pair consisting of 'Offset' and a vector or name of a variable with the same length as the response.

fitglm uses Offset as an additional predictor, with a coefficient value fixed at 1.0. In other words, the formula for fitting is

$$f(\mu) \sim \text{Offset} + (\text{terms involving real predictors})$$

with the Offset predictor having coefficient 1.

For example, consider a Poisson regression model. Suppose the number of counts is known for theoretical reasons to be proportional to a predictor A. By using the log link

function and by specifying $\log(A)$ as an offset, you can force the model to satisfy this theoretical constraint.

Data Types: `single` | `double` | `char` | `string`

PredictorVars — Predictor variables

string array | cell array of character vectors | logical or numeric index vector

Predictor variables to use in the fit, specified as the comma-separated pair consisting of 'PredictorVars' and either a string array or cell array of character vectors of the variable names in the table or dataset array `tbl`, or a logical or numeric index vector indicating which columns are predictor variables.

The string values or character vectors should be among the names in `tbl`, or the names you specify using the 'VarNames' name-value pair argument.

The default is all variables in X , or all variables in `tbl` except for `ResponseVar`.

For example, you can specify the second and third variables as the predictor variables using either of the following examples.

Example: `'PredictorVars',[2,3]`

Example: `'PredictorVars',logical([0 1 1 0 0 0])`

Data Types: `single` | `double` | `logical` | `string` | `cell`

ResponseVar — Response variable

last column in `tbl` (default) | character vector or string scalar containing variable name | logical or numeric index vector

Response variable to use in the fit, specified as the comma-separated pair consisting of 'ResponseVar' and either a character vector or string scalar containing the variable name in the table or dataset array `tbl`, or a logical or numeric index vector indicating which column is the response variable. You typically need to use 'ResponseVar' when fitting a table or dataset array `tbl`.

For example, you can specify the fourth variable, say `yield`, as the response out of six variables, in one of the following ways.

Example: `'ResponseVar','yield'`

Example: `'ResponseVar',[4]`

Example: `'ResponseVar',logical([0 0 0 1 0 0])`

Data Types: `single` | `double` | `logical` | `char` | `string`

VarNames — Names of variables

`{'x1', 'x2', ..., 'xn', 'y'}` (default) | string array | cell array of character vectors

Names of variables, specified as the comma-separated pair consisting of 'VarNames' and a string array or cell array of character vectors including the names for the columns of *X* first, and the name for the response variable *y* last.

'VarNames' is not applicable to variables in a table or dataset array, because those variables already have names.

For example, if in your data, horsepower, acceleration, and model year of the cars are the predictor variables, and miles per gallon (MPG) is the response variable, then you can name the variables as follows.

Example: `'VarNames', {'Horsepower', 'Acceleration', 'Model_Year', 'MPG'}`

Data Types: `string` | `cell`

Weights — Observation weights

`ones(n, 1)` (default) | *n*-by-1 vector of nonnegative scalar values

Observation weights, specified as the comma-separated pair consisting of 'Weights' and an *n*-by-1 vector of nonnegative scalar values, where *n* is the number of observations.

Data Types: `single` | `double`

Output Arguments

mdl — Generalized linear model

`GeneralizedLinearModel` object

Generalized linear model representing a least-squares fit of the link of the response to the data, returned as a `GeneralizedLinearModel` object.

For properties and methods of the generalized linear model object, `mdl`, see the `GeneralizedLinearModel` class page.

Definitions

Terms Matrix

A terms matrix T is a t -by- $(p + 1)$ matrix specifying terms in a model, where t is the number of terms, p is the number of predictor variables, and $+1$ accounts for the response variable. The value of $T(i, j)$ is the exponent of variable j in term i .

For example, suppose that an input includes three predictor variables A , B , and C and the response variable Y in the order A , B , C , and Y . Each row of T represents one term:

- $[0 \ 0 \ 0 \ 0]$ — Constant term or intercept
- $[0 \ 1 \ 0 \ 0]$ — B ; equivalently, $A^0 * B^1 * C^0$
- $[1 \ 0 \ 1 \ 0]$ — $A * C$
- $[2 \ 0 \ 0 \ 0]$ — A^2
- $[0 \ 1 \ 2 \ 0]$ — $B * (C^2)$

The 0 at the end of each term represents the response variable. In general, a column vector of zeros in a terms matrix represents the position of the response variable. If you have the predictor and response variables in a matrix and column vector, then you must include 0 for the response variable in the last column of each row.

Formula

A formula for model specification is a character vector or string scalar of the form ' $Y \sim terms$ '.

- Y is the response name.
- $terms$ represents the predictor terms in a model using Wilkinson notation.

For example:

- ' $Y \sim A + B + C$ ' specifies a three-variable linear model with intercept.
- ' $Y \sim A + B + C - 1$ ' specifies a three-variable linear model without intercept. Note that formulas include a constant (intercept) term by default. To exclude a constant term from the model, you must include -1 in the formula.

Wilkinson Notation

Wilkinson notation describes the terms present in a model. The notation relates to the terms present in a model, not to the multipliers (coefficients) of those terms.

Wilkinson notation uses these symbols:

- $+$ means include the next variable.
- $-$ means do not include the next variable.
- $:$ defines an interaction, which is a product of terms.
- $*$ defines an interaction and all lower-order terms.
- $^$ raises the predictor to a power, exactly as in $*$ repeated, so $^$ includes lower-order terms as well.
- $()$ groups terms.

This table shows typical examples of Wilkinson notation.

Wilkinson Notation	Term in Standard Notation
1	Constant (intercept) term
A^k , where k is a positive integer	A, A^2, \dots, A^k
$A + B$	A, B
$A*B$	$A, B, A*B$
$A:B$	$A*B$ only
$-B$	Do not include B
$A*B + C$	$A, B, C, A*B$
$A + B + C + A:B$	$A, B, C, A*B$
$A*B*C - A:B:C$	$A, B, C, A*B, A*C, B*C$
$A*(B + C)$	$A, B, C, A*B, A*C$

Statistics and Machine Learning Toolbox notation always includes a constant term unless you explicitly remove the term using -1 .

For more details, see “Wilkinson Notation” on page 11-117.

Canonical Link Function

The default link function for a generalized linear model is the canonical link function.

Canonical Link Functions for Generalized Linear Models

Distribution	Link Function Name	Link Function	Mean (Inverse) Function
'normal'	'identity'	$f(\mu) = \mu$	$\mu = Xb$
'binomial'	'logit'	$f(\mu) = \log(\mu/(1-\mu))$	$\mu = \exp(Xb) / (1 + \exp(Xb))$
'poisson'	'log'	$f(\mu) = \log(\mu)$	$\mu = \exp(Xb)$
'gamma'	-1	$f(\mu) = 1/\mu$	$\mu = 1/(Xb)$
'inverse gaussian'	-2	$f(\mu) = 1/\mu^2$	$\mu = (Xb)^{-1/2}$

Tips

- The generalized linear model mdl is a standard linear model unless you specify otherwise with the Distribution name-value pair.
- For methods such as plotResiduals or devianceTest, or properties of the GeneralizedLinearModel object, see GeneralizedLinearModel.
- After training a model, you can generate C/C++ code that predicts responses for new data. Generating C/C++ code requires MATLAB Coder. For details, see “Introduction to Code Generation” on page 31-2.

Algorithms

- fitglm treats a categorical predictor as follows:
 - A model with a categorical predictor that has L levels (categories) includes $L - 1$ indicator variables. The model uses the first category as a reference level, so it does not include the indicator variable for the reference level. If the data type of the categorical predictor is categorical, then you can check the order of categories by using categories and reorder the categories by using reordercats to customize the reference level.
 - fitglm treats the group of $L - 1$ indicator variables as a single variable. If you want to treat the indicator variables as distinct predictor variables, create indicator

variables manually by using `dummyvar`. Then use the indicator variables, except the one corresponding to the reference level of the categorical variable, when you fit a model. For the categorical predictor X , if you specify all columns of `dummyvar(X)` and an intercept term as predictors, then the design matrix becomes rank deficient.

- Interaction terms between a continuous predictor and a categorical predictor with L levels consist of the element-wise product of the $L - 1$ indicator variables with the continuous predictor.
- Interaction terms between two categorical predictors with L and M levels consist of the $(L - 1)*(M - 1)$ indicator variables to include all possible combinations of the two categorical predictor levels.
- You cannot specify higher-order terms for a categorical predictor because the square of an indicator is equal to itself.
- `fitglm` considers NaN, '' (empty character vector), "" (empty string), <missing>, and <undefined> values in `tbl`, X , and Y to be missing values. `fitglm` does not use observations with missing values in the fit. The `ObservationInfo` property of a fitted model indicates whether or not `fitglm` uses each observation in the fit.

Alternative Functionality

- Use `stepwiseglm` to select a model specification automatically. Use `step`, `addTerms`, or `removeTerms` to adjust a fitted model.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function supports tall arrays for out-of-memory data with some limitations.

- If any input argument to `fitglm` is a tall array, then all of the other inputs must be tall arrays as well. This includes nonempty variables supplied with the `'Weights'`, `'Exclude'`, `'Offset'`, and `'BinomialSize'` name-value pairs.
- The default number of iterations is 5. You can change the number of iterations using the `'Options'` name-value pair to pass in an options structure. Create an options structure using `statset` to specify a different value for `MaxIter`.
- For tall data, `fitglm` returns a `CompactGeneralizedLinearModel` object that contains most of the same properties as a `GeneralizedLinearModel` object. The main difference is that the compact object is sensitive to memory requirements. The compact object does not include properties that include the data, or that include an array of the same size as the data. The compact object does not contain these `GeneralizedLinearModel` properties:
 - `Diagnostics`
 - `Fitted`
 - `Offset`
 - `ObservationInfo`
 - `ObservationNames`
 - `Residuals`
 - `Steps`
 - `Variables`

You can compute the residuals directly from the compact object returned by `GLM = fitglm(X,Y)` using

```
RES = Y - predict(GLM,X);  
S = sqrt(GLM.SSE/GLM.DFE);  
histogram(RES,linspace(-3*S,3*S,51))
```

For more information, see “Tall Arrays” (MATLAB).

“Generalized Linear Models” on page 12-12

Introduced in R2013b

fitglme

Fit generalized linear mixed-effects model

Syntax

```
glme = fitglme(tbl, formula)
glme = fitglme(tbl, formula, Name, Value)
```

Description

`glme = fitglme(tbl, formula)` returns a generalized linear mixed-effects model, `glme`. The model is specified by `formula` and fitted to the predictor variables in the table or dataset array, `tbl`.

`glme = fitglme(tbl, formula, Name, Value)` returns a generalized linear mixed-effects model using additional options specified by one or more `Name, Value` pair arguments. For example, you can specify the distribution of the response, the link function, or the covariance pattern of the random-effects terms.

Examples

Fit a Generalized Linear Mixed-Effects Model

Load the sample data.

```
load mfr
```

This simulated data is from a manufacturing company that operates 50 factories across the world, with each factory running a batch process to create a finished product. The company wants to decrease the number of defects in each batch, so it developed a new manufacturing process. To test the effectiveness of the new process, the company selected 20 of its factories at random to participate in an experiment: Ten factories implemented the new process, while the other ten continued to run the old process. In

each of the 20 factories, the company ran five batches (for a total of 100 batches) and recorded the following data:

- Flag to indicate whether the batch used the new process (`newprocess`)
- Processing time for each batch, in hours (`time`)
- Temperature of the batch, in degrees Celsius (`temp`)
- Categorical variable indicating the supplier of the chemical used in the batch (`supplier`)
- Number of defects in the batch (`defects`)

The data also includes `time_dev` and `temp_dev`, which represent the absolute deviation of time and temperature, respectively, from the process standard of 3 hours at 20 degrees Celsius.

Fit a generalized linear mixed-effects model using `newprocess`, `time_dev`, `temp_dev`, and `supplier` as fixed-effects predictors. Include a random-effects term for intercept grouped by `factory`, to account for quality differences that might exist due to factory-specific variations. The response variable `defects` has a Poisson distribution, and the appropriate link function for this model is log. Use the Laplace fit method to estimate the coefficients. Specify the dummy variable encoding as `'effects'`, so the dummy variable coefficients sum to 0.

The number of defects can be modeled using a Poisson distribution

$$\text{defects}_{ij} \sim \text{Poisson}(\mu_{ij}).$$

This corresponds to the generalized linear mixed-effects model

$$\begin{aligned} \log(\mu_{ij}) = & \beta_0 + \beta_1 \text{newprocess}_{ij} + \beta_2 \text{time_dev}_{ij} + \beta_3 \text{temp_dev}_{ij} + \beta_4 \text{supplier_C}_{ij} \\ & + \beta_5 \text{supplier_B}_{ij} + b_i, \end{aligned}$$

where

- defects_{ij} is the number of defects observed in the batch produced by factory i during batch j .
- μ_{ij} is the mean number of defects corresponding to factory i (where $i = 1, 2, \dots, 20$) during batch j (where $j = 1, 2, \dots, 5$).

- newprocess_{ij} , time_dev_{ij} , and temp_dev_{ij} are the measurements for each variable that correspond to factory i during batch j . For example, newprocess_{ij} indicates whether the batch produced by factory i during batch j used the new process.
- supplier_C_{ij} and supplier_B_{ij} are dummy variables that use effects (sum-to-zero) coding to indicate whether company C or B, respectively, supplied the process chemicals for the batch produced by factory i during batch j .
- $b_i \sim N(0, \sigma_b^2)$ is a random-effects intercept for each factory i that accounts for factory-specific variation in quality.

```
glme = fitglme(mfr, 'defects ~ 1 + newprocess + time_dev + temp_dev + supplier + (1|factory)
  'Distribution', 'Poisson', 'Link', 'log', 'FitMethod', 'Laplace', ...
  'DummyVarCoding', 'effects');
```

Display the model.

```
disp(glme)
```

Generalized linear mixed-effects model fit by ML

Model information:

Number of observations	100
Fixed effects coefficients	6
Random effects coefficients	20
Covariance parameters	1
Distribution	Poisson
Link	Log
FitMethod	Laplace

Formula:

```
defects ~ 1 + newprocess + time_dev + temp_dev + supplier + (1 | factory)
```

Model fit statistics:

AIC	BIC	LogLikelihood	Deviance
416.35	434.58	-201.17	402.35

Fixed effects coefficients (95% CIs):

Name	Estimate	SE	tStat	DF	pValue
'(Intercept)'	1.4689	0.15988	9.1875	94	9.8194e-15
'newprocess'	-0.36766	0.17755	-2.0708	94	0.041122
'time_dev'	-0.094521	0.82849	-0.11409	94	0.90941
'temp_dev'	-0.28317	0.9617	-0.29444	94	0.76907
'supplier_C'	-0.071868	0.078024	-0.9211	94	0.35936
'supplier_B'	0.071072	0.07739	0.91836	94	0.36078

Lower	Upper
1.1515	1.7864
-0.72019	-0.015134
-1.7395	1.5505
-2.1926	1.6263
-0.22679	0.083051
-0.082588	0.22473

Random effects covariance parameters:

Group: factory (20 Levels)

Name1	Name2	Type	Estimate
'(Intercept)'	'(Intercept)'	'std'	0.31381

Group: Error

Name	Estimate
'sqrt(Dispersion)'	1

The `Model information` table displays the total number of observations in the sample data (100), the number of fixed- and random-effects coefficients (6 and 20, respectively), and the number of covariance parameters (1). It also indicates that the response variable has a Poisson distribution, the link function is Log, and the fit method is Laplace.

`Formula` indicates the model specification using Wilkinson's notation.

The `Model fit statistics` table displays statistics used to assess the goodness of fit of the model. This includes the Akaike information criterion (AIC), Bayesian information criterion (BIC) values, log likelihood (LogLikelihood), and deviance (Deviance) values.

The `Fixed effects coefficients` table indicates that `fitglm` returned 95% confidence intervals. It contains one row for each fixed-effects predictor, and each column contains statistics corresponding to that predictor. Column 1 (`Name`) contains the name of each fixed-effects coefficient, column 2 (`Estimate`) contains its estimated value, and column 3 (`SE`) contains the standard error of the coefficient. Column 4 (`tStat`) contains the *t*-statistic for a hypothesis test that the coefficient is equal to 0. Column 5 (`DF`) and column 6 (`pValue`) contain the degrees of freedom and *p*-value that correspond to the *t*-statistic, respectively. The last two columns (`Lower` and `Upper`) display the lower and upper limits, respectively, of the 95% confidence interval for each fixed-effects coefficient.

`Random effects covariance parameters` displays a table for each grouping variable (here, only `factory`), including its total number of levels (20), and the type and estimate of the covariance parameter. Here, `std` indicates that `fitglm` returns the

standard deviation of the random effect associated with the factory predictor, which has an estimated value of 0.31381. It also displays a table containing the error parameter type (here, the square root of the dispersion parameter), and its estimated value of 1.

The standard display generated by `fitglm` does not provide confidence intervals for the random-effects parameters. To compute and display these values, use `covarianceParameters`.

Input Arguments

tbl — Input data

table | dataset array

Input data, which includes the response variable, predictor variables, and grouping variables, specified as a table or dataset array. The predictor variables can be continuous or grouping variables (see “Grouping Variables” on page 2-57). You must specify the model for the variables using `formula`.

formula — Formula for model specification

character vector or string scalar of the form `'y ~ fixed + (random1|grouping1) + ... + (randomR|groupingR)'`

Formula for model specification, specified as a character vector or string scalar of the form `'y ~ fixed + (random1|grouping1) + ... + (randomR|groupingR)'`. The formula is case sensitive. For a full description, see “Formula” on page 32-2218.

Example: `'y ~ treatment + (1|block)'`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example:

`'Distribution', 'Poisson', 'Link', 'log', 'FitMethod', 'Laplace', 'DummyVariableCoding', 'effects'` specifies the response variable distribution as Poisson, the link function as log, the fit method as Laplace, and dummy variable coding where the coefficients sum to 0.

BinomialSize — Number of trials for binomial distribution

1 (default) | scalar value | vector | variable name

Number of trials for binomial distribution, that is the sample size, specified as the comma-separated pair consisting of a scalar value, a vector of the same length as the response, or the name of a variable in the input table. If you specify the name of a variable, then the variable must be of the same length as the response. `BinomialSize` applies only when the `Distribution` parameter is 'binomial'.

If `BinomialSize` is a scalar value, that means all observations have the same number of trials.

Data Types: `single` | `double`

CheckHessian — Indicator to check positive definiteness of Hessian`false` (default) | `true`

Indicator to check the positive definiteness of the Hessian of the objective function with respect to unconstrained parameters at convergence, specified as the comma-separated pair consisting of 'CheckHessian' and either `false` or `true`. Default is `false`.

Specify 'CheckHessian' as `true` to verify optimality of the solution or to determine if the model is overparameterized in the number of covariance parameters.

If you specify 'FitMethod' as 'MPL' or 'REML', then the covariance of the fixed effects and the covariance parameters is based on the fitted linear mixed-effects model from the final pseudo likelihood iteration.

Example: 'CheckHessian',`true`

CovarianceMethod — Method to compute covariance of estimated parameters`'conditional'` (default) | `'JointHessian'`

Method to compute covariance of estimated parameters, specified as the comma-separated pair consisting of 'CovarianceMethod' and either 'conditional' or 'JointHessian'. If you specify 'conditional', then `fitglme` computes a fast approximation to the covariance of fixed effects given the estimated covariance parameters. It does not compute the covariance of covariance parameters. If you specify 'JointHessian', then `fitglme` computes the joint covariance of fixed effects and covariance parameters via the observed information matrix using the Laplacian loglikelihood.

If you specify 'FitMethod' as 'MPL' or 'REML', then the covariance of the fixed effects and the covariance parameters is based on the fitted linear mixed-effects model from the final pseudo likelihood iteration.

Example: 'CovarianceMethod', 'JointHessian'

CovariancePattern — Pattern of covariance matrix

'FullCholesky' | 'Isotropic' | 'Full' | 'Diagonal' | 'CompSymm' | square symmetric logical matrix | string array | cell array of character vectors or logical matrices

Pattern of the covariance matrix of the random effects, specified as the comma-separated pair consisting of 'CovariancePattern' and 'FullCholesky', 'Isotropic', 'Full', 'Diagonal', 'CompSymm', a square symmetric logical matrix, a string array, or a cell array containing character vectors or logical matrices.

If there are R random-effects terms, then the value of 'CovariancePattern' must be a string array or cell array of length R , where each element r of the array specifies the pattern of the covariance matrix of the random-effects vector associated with the r th random-effects term. The options for each element follow.

Value	Description
'FullCholesky'	Full covariance matrix using the Cholesky parameterization. fitglme estimates all elements of the covariance matrix.
'Isotropic'	Diagonal covariance matrix with equal variances. That is, off-diagonal elements of the covariance matrix are constrained to be 0, and the diagonal elements are constrained to be equal. For example, if there are three random-effects terms with an isotropic covariance structure, this covariance matrix looks like $\begin{pmatrix} \sigma_b^2 & 0 & 0 \\ 0 & \sigma_b^2 & 0 \\ 0 & 0 & \sigma_b^2 \end{pmatrix}$ where σ_b^2 is the common variance of the random-effects terms.

Value	Description
'Full'	Full covariance matrix, using the log-Cholesky parameterization. <code>fitlme</code> estimates all elements of the covariance matrix.
'Diagonal'	Diagonal covariance matrix. That is, off-diagonal elements of the covariance matrix are constrained to be 0. $\begin{pmatrix} \sigma_{b1}^2 & 0 & 0 \\ 0 & \sigma_{b2}^2 & 0 \\ 0 & 0 & \sigma_{b3}^2 \end{pmatrix}$
'CompSymm'	Compound symmetry structure. That is, common variance along diagonals and equal correlation between all random effects. For example, if there are three random-effects terms with a covariance matrix having a compound symmetry structure, this covariance matrix looks like $\begin{pmatrix} \sigma_{b1}^2 & \sigma_{b1,b2} & \sigma_{b1,b2} \\ \sigma_{b1,b2} & \sigma_{b1}^2 & \sigma_{b1,b2} \\ \sigma_{b1,b2} & \sigma_{b1,b2} & \sigma_{b1}^2 \end{pmatrix}$ where σ_{b1}^2 is the common variance of the random-effects terms and $\sigma_{b1,b2}$ is the common covariance between any two random-effects term .
PAT	Square symmetric logical matrix. If 'CovariancePattern' is defined by the matrix PAT, and if <code>PAT(a,b) = false</code> , then the (a,b) element of the corresponding covariance matrix is constrained to be 0.

For scalar random-effects terms, the default is 'Isotropic'. Otherwise, the default is 'FullCholesky'.

Example: 'CovariancePattern', 'Diagonal'

Example: 'CovariancePattern', {'Full', 'Diagonal'}

Data Types: char | string | logical | cell

DispersionFlag – Indicator to compute dispersion parameter

false for 'binomial' and 'poisson' distributions (default) | true

Indicator to compute dispersion parameter for 'binomial' and 'poisson' distributions, specified as the comma-separated pair consisting of 'DispersionFlag' and one of the following.

Value	Description
true	Estimate a dispersion parameter when computing standard errors
false	Use the theoretical value of 1.0 when computing standard errors

'DispersionFlag' only applies if 'FitMethod' is 'MPL' or 'REML'.

The fitting function always estimates the dispersion for other distributions.

Example: 'DispersionFlag', true

Distribution – Distribution of the response variable

'Normal' (default) | 'Binomial' | 'Poisson' | 'Gamma' | 'InverseGaussian'

Distribution of the response variable, specified as the comma-separated pair consisting of 'Distribution' and one of the following.

Value	Description
'Normal'	Normal distribution
'Binomial'	Binomial distribution
'Poisson'	Poisson distribution
'Gamma'	Gamma distribution
'InverseGaussian'	Inverse Gaussian distribution

Example: `'Distribution','Binomial'`

DummyVarCoding — Coding to use for dummy variables

`'reference'` (default) | `'effects'` | `'full'`

Coding to use for dummy variables created from the categorical variables, specified as the comma-separated pair consisting of `'DummyVarCoding'` and one of the following.

Value	Description
<code>'reference'</code>	Default. Coefficient for first category set to 0.
<code>'effects'</code>	Coefficients sum to 0.
<code>'full'</code>	One dummy variable for each category.

Example: `'DummyVarCoding','effects'`

EBMethod — Method used to approximate empirical Bayes estimates of random effects

`'Auto'` (default) | `'LineSearchNewton'` | `'TrustRegion2D'` | `'fsolve'`

Method used to approximate empirical Bayes estimates of random effects, specified as the comma-separated pair consisting of `'EBMethod'` and one of the following.

- `'Auto'`
- `'LineSearchNewton'`
- `'TrustRegion2D'`
- `'fsolve'`

`'Auto'` is similar to `'LineSearchNewton'` but uses a different convergence criterion and does not display iterative progress. `'Auto'` and `'LineSearchNewton'` may fail for non-canonical link functions. For non-canonical link functions, `'TrustRegion2D'` or `'fsolve'` are recommended. You must have Optimization Toolbox to use `'fsolve'`.

Example: `'EBMethod','LineSearchNewton'`

EBOptions — Options for empirical Bayes optimization

structure

Options for empirical Bayes optimization, specified as the comma-separated pair consisting of `'EBOptions'` and a structure containing the following.

Value	Description
'TolFun'	Relative tolerance on the gradient norm. Default is 1e-6.
'TolX'	Absolute tolerance on the step size. Default is 1e-8.
'MaxIter'	Maximum number of iterations. Default is 100.
'Display'	'off', 'iter', or 'final'. Default is 'off'.

If `EBMethod` is 'Auto' and `FitMethod` is 'Laplace', `TolFun` is the relative tolerance on the linear predictor of the model, and the `Display` option does not apply.

If `EBMethod` is 'fsolve', then `EBOptions` must be specified as an object created by `optimoptions('fsolve')`.

Data Types: `struct`

Exclude — Indices for rows to exclude

use all rows without NaNs (default) | vector of integer or logical values

Indices for rows to exclude from the generalized linear mixed-effects model in the data, specified as the comma-separated pair consisting of 'Exclude' and a vector of integer or logical values.

For example, you can exclude the 13th and 67th rows from the fit as follows.

Example: 'Exclude', [13,67]

Data Types: `single` | `double` | `logical`

FitMethod — Method for estimating model parameters

'MPL' (default) | 'REML' | 'Laplace' | 'ApproximateLaplace

Method for estimating model parameters, specified as the comma-separated pair consisting of `FitMethod` and one of the following.

- 'MPL' — Maximum pseudo likelihood
- 'REML' — Restricted maximum pseudo likelihood
- 'Laplace' — Maximum likelihood using Laplace approximation

- `'ApproximateLaplace'` — Maximum likelihood using approximate Laplace approximation with fixed effects profiled out

Example: `'FitMethod', 'REML'`

InitPLIterations — Initial number of pseudo likelihood iterations

10 (default) | integer value in the range $[1, \infty)$

Initial number of pseudo likelihood iterations used to initialize parameters for `ApproximateLaplace` and `Laplace` fit methods, specified as the comma-separated pair consisting of `'InitPLIterations'` and an integer value greater than or equal to 1.

Data Types: `single` | `double`

Link — Link function

`'identity'` | `'log'` | `'logit'` | `'probit'` | `'comploglog'` | `'reciprocal'` | scalar value | structure

Link function, specified as the comma-separated pair consisting of `'Link'` and one of the following.

Value	Description
<code>'identity'</code>	$g(\mu) = \mu$ This is the default for the normal distribution.
<code>'log'</code>	$g(\mu) = \log(\mu)$ This is the default for the Poisson distribution.
<code>'logit'</code>	$g(\mu) = \log(\mu/(1-\mu))$ This is the default for the binomial distribution.
<code>'loglog'</code>	$g(\mu) = \log(-\log(\mu))$
<code>'probit'</code>	$g(\mu) = \text{norminv}(\mu)$
<code>'comploglog'</code>	$g(\mu) = \log(-\log(1-\mu))$
<code>'reciprocal'</code>	$g(\mu) = \mu.^{-1}$

Value	Description
Scalar value P	$g(\mu) = \mu.^P$
Structure S	<p>A structure containing four fields whose values are function handles with the following names:</p> <ul style="list-style-type: none"> • S.Link — Link function • S.Derivative — Derivative • S.SecondDerivative — Second derivative • S.Inverse — Inverse of link <p>Specification of S.SecondDerivative can be omitted if FitMethod is MPL or REMPL, or if S is the canonical link for the specified distribution.</p>

The default link function used by `fitglm` is the canonical link that depends on the distribution of the response.

Response Distribution	Canonical Link Function
'Normal'	'identity'
'Binomial'	'logit'
'Poisson'	'log'
'Gamma'	-1
'InverseGaussian'	-2

Example: 'Link', 'log'

Data Types: char | string | single | double | struct

MuStart — Starting value for conditional mean

scalar value

Starting value for conditional mean, specified as the comma-separated pair consisting of 'MuStart' and a scalar value. Valid values are as follows.

Response Distribution	Valid Values
'Normal'	(-Inf, Inf)
'Binomial'	(0, 1)
'Poisson'	(0, Inf)
'Gamma'	(0, Inf)
'InverseGaussian'	(0, Inf)

Data Types: single | double

Offset — Offset

`zeros(n, 1)` (default) | n -by-1 vector of scalar values

Offset, specified as the comma-separated pair consisting of 'Offset' and an n -by-1 vector of scalar values, where n is the length of the response vector. You can also specify the variable name of an n -by-1 vector of scalar values. 'Offset' is used as an additional predictor that has a coefficient value fixed at 1.0.

Data Types: single | double

Optimizer — Optimization algorithm

'quasinevton' (default) | 'fminsearch' | 'fminunc'

Optimization algorithm, specified as the comma-separated pair consisting of 'Optimizer' and either of the following.

Value	Description
'quasinevton'	Uses a trust region based quasi-Newton optimizer. You can change the options of the algorithm using <code>statset('fitglm')</code> . If you do not specify the options, then <code>fitglm</code> uses the default options of <code>statset('fitglm')</code> .

Value	Description
'fminsearch'	Uses a derivative-free Nelder-Mead method. You can change the options of the algorithm using <code>optimset('fminsearch')</code> . If you do not specify the options, then <code>fitglme</code> uses the default options of <code>optimset('fminsearch')</code> .
'fminunc'	Uses a line search-based quasi-Newton method. You must have Optimization Toolbox to specify this option. You can change the options of the algorithm using <code>optimoptions('fminunc')</code> . If you do not specify the options, then <code>fitglme</code> uses the default options of <code>optimoptions('fminunc')</code> with 'Algorithm' set to 'quasi-newton'.

Example: 'Optimizer', 'fminsearch'

OptimizerOptions — Options for optimization algorithm

structure returned by `statset` | structure returned by `optimset` | object returned by `optimoptions`

Options for the optimization algorithm, specified as the comma-separated pair consisting of 'OptimizerOptions' and a structure returned by `statset('fitglme')`, a structure created by `optimset('fminsearch')`, or an object returned by `optimoptions('fminunc')`.

- If 'Optimizer' is 'fminsearch', then use `optimset('fminsearch')` to change the options of the algorithm. If 'Optimizer' is 'fminsearch' and you do not supply 'OptimizerOptions', then the defaults used in `fitglme` are the default options created by `optimset('fminsearch')`.
- If 'Optimizer' is 'fminunc', then use `optimoptions('fminunc')` to change the options of the optimization algorithm. See `optimoptions` for the options 'fminunc' uses. If 'Optimizer' is 'fminunc' and you do not supply 'OptimizerOptions', then the defaults used in `fitglme` are the default options created by `optimoptions('fminunc')` with 'Algorithm' set to 'quasi-newton'.

- If 'Optimizer' is 'quasnewton', then use `statset('fitglme')` to change the optimization parameters. If 'Optimizer' is 'quasnewton' and you do not change the optimization parameters using `statset`, then `fitglme` uses the default options created by `statset('fitglme')`.

The 'quasnewton' optimizer uses the following fields in the structure created by `statset('fitglme')`.

ToIFun — Relative tolerance on gradient of objective function

1e-6 (default) | positive scalar value

Relative tolerance on the gradient of the objective function, specified as a positive scalar value.

ToIX — Absolute tolerance on step size

1e-12 (default) | positive scalar value

Absolute tolerance on the step size, specified as a positive scalar value.

MaxIter — Maximum number of iterations allowed

10000 (default) | positive scalar value

Maximum number of iterations allowed, specified as a positive scalar value.

Display — Level of display

'off' (default) | 'iter' | 'final'

Level of display, specified as one of 'off', 'iter', or 'final'.

PLIterations — Maximum number of pseudo likelihood iterations

100 (default) | positive integer value

Maximum number of pseudo likelihood (PL) iterations, specified as the comma-separated pair consisting of 'PLIterations' and a positive integer value. PL is used for fitting the model if 'FitMethod' is 'MPL' or 'REMP'. For other 'FitMethod' values, PL iterations are used to initialize parameters for subsequent optimization.

Example: 'PLIterations',200

Data Types: single | double

PLTolerance — Relative tolerance factor for pseudo likelihood iterations

1e-08 (default) | positive scalar value

Relative tolerance factor for pseudo likelihood iterations, specified as the comma-separated pair consisting of 'PLTolerance' and a positive scalar value.

Example: 'PLTolerance', 1e-06

Data Types: single | double

StartMethod — Method to start iterative optimization

'default' (default) | 'random'

Method to start iterative optimization, specified as the comma-separated pair consisting of 'StartMethod' and either of the following.

Value	Description
'default'	An internally defined default value
'random'	A random initial value

Example: 'StartMethod', 'random'

UseSequentialFitting — Initial fitting type

false (default) | true

, specified as the comma-separated pair consisting of 'UseSequentialFitting' and either false or true. If 'UseSequentialFitting' is false, all maximum likelihood methods are initialized using one or more pseudo likelihood iterations. If 'UseSequentialFitting' is true, the initial values from pseudo likelihood iterations are refined using 'ApproximateLaplace' for 'Laplace' fitting.

Example: 'UseSequentialFitting', true

Verbose — Indicator to display optimization process on screen

0 (default) | 1 | 2

Indicator to display the optimization process on screen, specified as the comma-separated pair consisting of 'Verbose' and 0, 1, or 2. If 'Verbose' is specified as 1 or 2, then fitglm displays the progress of the iterative model-fitting process. Specifying 'Verbose' as 2 displays iterative optimization information from the individual pseudo likelihood iterations. Specifying 'Verbose' as 1 omits this display.

The setting for 'Verbose' overrides the field 'Display' in 'OptimizerOptions'.

Example: 'Verbose', 1

Weights — Observation weights

vector of nonnegative scalar values

Observation weights, specified as the comma-separated pair consisting of 'Weights' and an n -by-1 vector of nonnegative scalar values, where n is the number of observations. If the response distribution is binomial or Poisson, then 'Weights' must be a vector of positive integers.

Data Types: `single` | `double`

Output Arguments

g_lme — Generalized linear mixed-effects model

`GeneralizedLinearMixedModel` object

Generalized linear mixed-effects model, specified as a `GeneralizedLinearMixedModel` object. For properties and methods of this object, see `GeneralizedLinearMixedModel`.

Definitions

Formula

In general, a formula for model specification is a character vector or string scalar of the form 'y ~ terms'. For the generalized linear mixed-effects models, this formula is in the form 'y ~ fixed + (random₁|grouping₁) + ... + (random_R|grouping_R)', where `fixed` and `random` contain the fixed-effects and the random-effects terms.

Suppose a table `tbl` contains the following:

- A response variable, y
- Predictor variables, X_j , which can be continuous or grouping variables
- Grouping variables, g_1, g_2, \dots, g_R ,

where the grouping variables in X_j and g_r can be categorical, logical, character arrays, string arrays, or cell arrays of character vectors.

Then, in a formula of the form, 'y ~ fixed + (random₁|g₁) + ... + (random_R|g_R)', the term `fixed` corresponds to a specification of the fixed-effects design matrix X ,

random_1 is a specification of the random-effects design matrix Z_1 corresponding to grouping variable g_1 , and similarly random_R is a specification of the random-effects design matrix Z_R corresponding to grouping variable g_R . You can express the fixed and random terms using Wilkinson notation.

Wilkinson notation describes the factors present in models. The notation relates to factors present in models, not to the multipliers (coefficients) of those factors.

Wilkinson Notation	Factors in Standard Notation
1	Constant (intercept) term
X^k , where k is a positive integer	X, X^2, \dots, X^k
$X1 + X2$	$X1, X2$
$X1 * X2$	$X1, X2, X1.*X2$ (elementwise multiplication of $X1$ and $X2$)
$X1 : X2$	$X1.*X2$ only
$- X2$	Do not include $X2$
$X1 * X2 + X3$	$X1, X2, X3, X1 * X2$
$X1 + X2 + X3 + X1 : X2$	$X1, X2, X3, X1 * X2$
$X1 * X2 * X3 - X1 : X2 : X3$	$X1, X2, X3, X1 * X2, X1 * X3, X2 * X3$
$X1 * (X2 + X3)$	$X1, X2, X3, X1 * X2, X1 * X3$

Statistics and Machine Learning Toolbox notation always includes a constant term unless you explicitly remove the term using -1 . Here are some examples for generalized linear mixed-effects model specification.

Examples:

Formula	Description
'y ~ X1 + X2'	Fixed effects for the intercept, $X1$ and $X2$. This is equivalent to 'y ~ 1 + X1 + X2'.
'y ~ -1 + X1 + X2'	No intercept and fixed effects for $X1$ and $X2$. The implicit intercept term is suppressed by including -1 .

Formula	Description
'y ~ 1 + (1 g1)'	Fixed effects for the intercept plus random effect for the intercept for each level of the grouping variable g1.
'y ~ X1 + (1 g1)'	Random intercept model with a fixed slope.
'y ~ X1 + (X1 g1)'	Random intercept and slope, with possible correlation between them. This is equivalent to 'y ~ 1 + X1 + (1 + X1 g1)'
'y ~ X1 + (1 g1) + (-1 + X1 g1)'	Independent random effects terms for intercept and slope.
'y ~ 1 + (1 g1) + (1 g2) + (1 g1:g2)'	Random intercept model with independent main effects for g1 and g2, plus an independent interaction effect.

Introduced in R2014b

fitgmdist

Fit Gaussian mixture model to data

Syntax

```
GMMModel = fitgmdist(X,k)  
GMMModel = fitgmdist(X,k,Name,Value)
```

Description

`GMMModel = fitgmdist(X,k)` returns a Gaussian mixture distribution model (`GMMModel`) with `k` components fitted to data (`X`).

`GMMModel = fitgmdist(X,k,Name,Value)` returns a Gaussian mixture distribution model with additional options specified by one or more `Name, Value` pair arguments.

For example, you can specify a regularization value or the covariance type.

Examples

Cluster Data Using a Gaussian Mixture Model

Generate data from a mixture of two bivariate Gaussian distributions.

```
mu1 = [1 2];  
Sigma1 = [2 0; 0 0.5];  
mu2 = [-3 -5];  
Sigma2 = [1 0; 0 1];  
rng(1); % For reproducibility  
X = [mvnrnd(mu1,Sigma1,1000);mvnrnd(mu2,Sigma2,1000)];
```

Fit a Gaussian mixture model. Specify that there are two components.

```
GMMModel = fitgmdist(X,2);
```

Plot the data over the fitted Gaussian mixture model contours.

```
figure
y = [zeros(1000,1);ones(1000,1)];
h = gscatter(X(:,1),X(:,2),y);
hold on
gmPDF = @(x1,x2)reshape(pdf(GMMModel,[x1(:) x2(:)]),size(x1));
g = gca;
fcontour(gmPDF,[g.XLim g.YLim])
title('\bf Scatter Plot and Fitted Gaussian Mixture Contours')
legend(h,'Model 0','Model1')
hold off
```

Regularize Gaussian Mixture Model Estimation

Generate data from a mixture of two bivariate Gaussian distributions. Create a third predictor that is the sum of the first and second predictors.

```
mu1 = [1 2];
Sigma1 = [1 0; 0 1];
mu2 = [3 4];
Sigma2 = [0.5 0; 0 0.5];
rng(3); % For reproducibility
X1 = [mvnrnd(mu1,Sigma1,100);mvnrnd(mu2,Sigma2,100)];
X = [X1,X1(:,1)+X1(:,2)];
```

The columns of X are linearly dependent. This can cause ill-conditioned covariance estimates.

Fit a Gaussian mixture model to the data. You can use try / catch statements to help manage error messages.

```
rng(1); % Reset seed for common start values
try
    GMMModel = fitgmdist(X,2)
catch exception
    disp('There was an error fitting the Gaussian mixture model')
    error = exception.message
end
```

There was an error fitting the Gaussian mixture model

```
error =
'Ill-conditioned covariance created at iteration 2.'
```

The covariance estimates are ill-conditioned. Consequently, optimization stops and an error appears.

Fit a Gaussian mixture model again, but use regularization.

```
rng(3); % Reset seed for common start values
GMMModel = fitgmdist(X,2,'RegularizationValue',0.1)
```

```
GMMModel =
```

```
Gaussian mixture distribution with 2 components in 3 dimensions
```

```
Component 1:  
Mixing proportion: 0.536725  
Mean:      2.8831   3.9506   6.8338
```

```
Component 2:  
Mixing proportion: 0.463275  
Mean:      0.8813   1.9758   2.8571
```

In this case, the algorithm converges to a solution due to regularization.

Select the Number of Gaussian Mixture Model Components Using PCA

Gaussian mixture models require that you specify a number of components before being fit to data. For many applications, it might be difficult to know the appropriate number of components. This example shows how to explore the data, and try to get an initial guess at the number of components using principal component analysis.

Load Fisher's iris data set.

```
load fisheriris  
classes = unique(species)  
  
classes = 3x1 cell array  
    {'setosa'   }  
    {'versicolor'}  
    {'virginica' }
```

The data set contains three classes of iris species. The analysis proceeds as if this is unknown.

Use principal component analysis to reduce the dimension of the data to two dimensions for visualization.

```
[~,score] = pca(meas, 'NumComponents',2);
```

Fit three Gaussian mixture models to the data by specifying 1, 2, and 3 components. Increase the number of optimization iterations to 1000. Use dot notation to store the final parameter estimates. By default, the software fits full and different covariances for each component.

```

GMModels = cell(3,1); % Preallocation
options = statset('MaxIter',1000);
rng(1); % For reproducibility

for j = 1:3
    GMModels{j} = fitgmdist(score,j,'Options',options);
    fprintf('\n GM Mean for %i Component(s)\n',j)
    Mu = GMModels{j}.mu
end

```

```
GM Mean for 1 Component(s)
```

```
Mu = 1×2
10-14 ×
```

```
-0.2743    -0.0870
```

```
GM Mean for 2 Component(s)
```

```
Mu = 2×2
```

```
1.3212    -0.0954
-2.6424    0.1909
```

```
GM Mean for 3 Component(s)
```

```
Mu = 3×2
```

```
0.4856    -0.1287
1.4484    -0.0904
-2.6424    0.1909
```

`GMModels` is a cell array containing three, fitted `gmdistribution` models. The means in the three component models are different, suggesting that the model distinguishes among the three iris species.

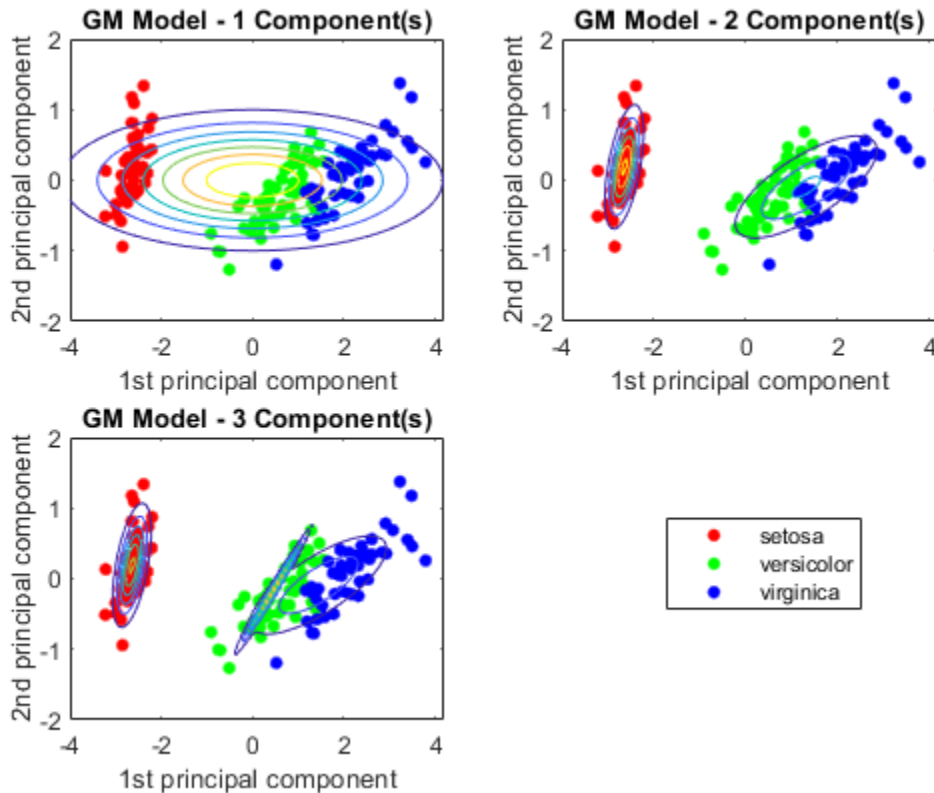

Plot the scores over the fitted Gaussian mixture model contours. Since the data set includes labels, use `gscatter` to distinguish between the true number of components.

```

figure
for j = 1:3
    subplot(2,2,j)

```

```
h1 = gscatter(score(:,1),score(:,2),species);
h = gca;
hold on
gmPDF = @(x1,x2)reshape(pdf(GMModels{j}],[x1(:) x2(:)]),size(x1));
fcontour(gmPDF,[h.XLim h.YLim],'MeshDensity',100)
title(sprintf('GM Model - %i Component(s)',j));
xlabel('1st principal component');
ylabel('2nd principal component');
if(j ~= 3)
    legend off;
end
hold off
end
g = legend(h1);
g.Position = [0.7 0.25 0.1 0.1];
```

The three-component Gaussian mixture model, in conjunction with PCA, looks like it distinguishes between the three iris species.

There are other options you can use to help select the appropriate number of components for a Gaussian mixture model. For example,

- Compare multiple models with varying numbers of components using information criteria, e.g., AIC or BIC.
- Estimate the number of clusters using `evalclusters`, which supports, the Calinski-Harabasz criterion and the gap statistic, or other criteria.

Determine the Best Gaussian Mixture Fit Using AIC

Gaussian mixture models require that you specify a number of components before being fit to data. For many applications, it might be difficult to know the appropriate number of components. This example uses the AIC fit statistic to help you choose the best fitting Gaussian mixture model over varying numbers of components.

Generate data from a mixture of two bivariate Gaussian distributions.

```
mu1 = [1 1];
Sigma1 = [0.5 0; 0 0.5];
mu2 = [2 4];
Sigma2 = [0.2 0; 0 0.2];
rng(1);
X = [mvnrnd(mu1,Sigma1,1000);mvnrnd(mu2,Sigma2,1000)];

plot(X(:,1),X(:,2),'ko')
title('Scatter Plot')
xlim([min(X(:)) max(X(:))]) % Make axes have the same scale
ylim([min(X(:)) max(X(:))])
```

Supposing that you do not know the underlying parameter values, the scatter plots suggests:

- There are two components.
- The variances between the clusters are different.
- The variance within the clusters is the same.
- There is no covariance within the clusters.

Fit a two-component Gaussian mixture model. Based on the scatter plot inspection, specify that the covariance matrices are diagonal. Print the final iteration and loglikelihood statistic to the Command Window by passing a `statset` structure as the value of the `Options` name-value pair argument.

```
options = statset('Display','final');
GMMModel = fitgmdist(X,2,'CovarianceType','diagonal','Options',options);
```

```
11 iterations, log-likelihood = -4787.38
```

GMMModel is a fitted gmdistribution model.

Examine the AIC over varying numbers of components.

```
AIC = zeros(1,4);
GMMModels = cell(1,4);
options = statset('MaxIter',500);
for k = 1:4
    GMMModels{k} = fitgmdist(X,k,'Options',options,'CovarianceType','diagonal');
    AIC(k) = GMMModels{k}.AIC;
end
```

```
[minAIC,numComponents] = min(AIC);
numComponents
```

```
numComponents = 2
```

```
BestModel = GMMModels{numComponents}
```

```
BestModel =
```

```
Gaussian mixture distribution with 2 components in 2 dimensions
```

```
Component 1:
```

```
Mixing proportion: 0.501719
```

```
Mean:    1.9824    4.0013
```

```
Component 2:
```

```
Mixing proportion: 0.498281
```

```
Mean:    0.9880    1.0511
```

The smallest AIC occurs when the software fits the two-component Gaussian mixture model.

Set Initial Values When Fitting Gaussian Mixture Models

Gaussian mixture model parameter estimates might vary with different initial values. This example shows how to control initial values when you fit Gaussian mixture models using `fitgmdist`.

Load Fisher's iris data set. Use the petal lengths and widths as predictors.

```
load fisheriris
X = meas(:,3:4);
```

Fit a Gaussian mixture model to the data using default initial values. There are three iris species, so specify $k = 3$ components.

```
rng(10); % For reproducibility
GMMModel1 = fitgmdist(X,3);
```

By default, the software:

- 1 Implements the “k-means++ Algorithm for Initialization” on page 32-2240 to choose $k = 3$ initial cluster centers.
- 2 Sets the initial covariance matrices as diagonal, where element (j, j) is the variance of $X(:, j)$.
- 3 Treats the initial mixing proportions as uniform.

Fit a Gaussian mixture model by connecting each observation to its label.

```
y = ones(size(X,1),1);
y(strcmp(species,'setosa')) = 2;
y(strcmp(species,'virginica')) = 3;

GMMModel2 = fitgmdist(X,3,'Start',y);
```

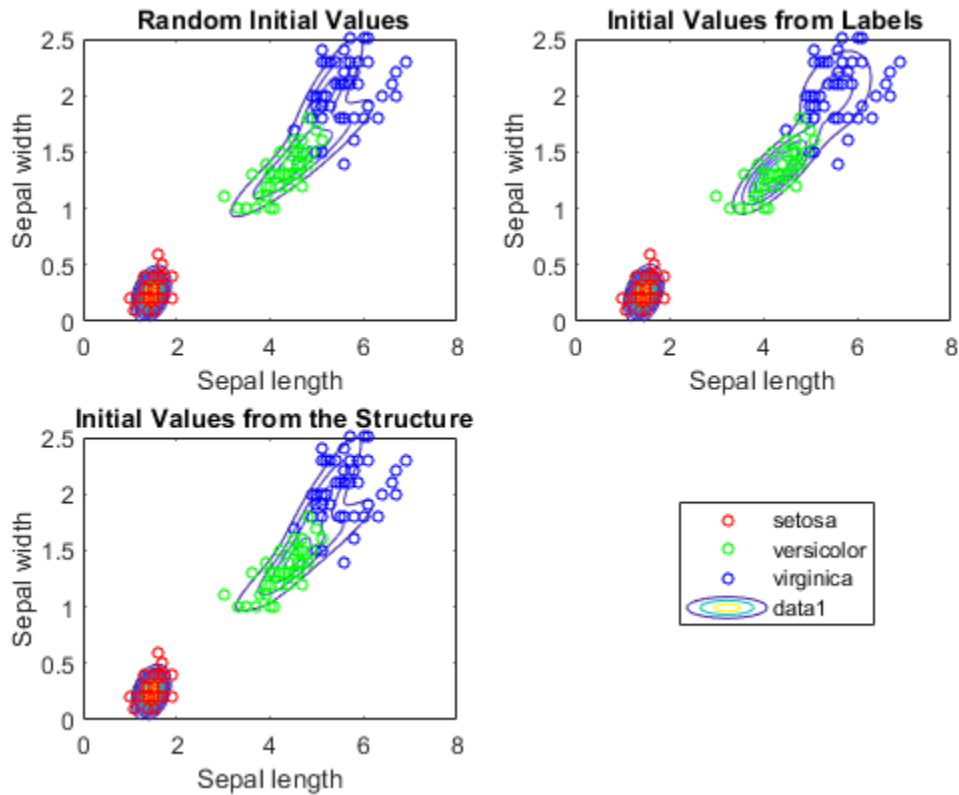

Fit a Gaussian mixture model by explicitly specifying the initial means, covariance matrices, and mixing proportions.

```
Mu = [1 1; 2 2; 3 3];
Sigma(:,:,1) = [1 1; 1 2];
Sigma(:,:,2) = 2*[1 1; 1 2];
Sigma(:,:,3) = 3*[1 1; 1 2];
PComponents = [1/2,1/4,1/4];
S = struct('mu',Mu,'Sigma',Sigma,'ComponentProportion',PComponents);

GMMModel3 = fitgmdist(X,3,'Start',S);
```

Use `gscatter` to plot a scatter diagram that distinguishes between the iris species. For each model, plot the fitted Gaussian mixture model contours.

```
figure
subplot(2,2,1)
h = gscatter(X(:,1),X(:,2),species,[], 'o',4);
haxis = gca;
xlim = haxis.XLim;
ylim = haxis.YLim;
d = (max([xlim ylim])-min([xlim ylim]))/1000;
[X1Grid,X2Grid] = meshgrid(xlim(1):d:xlim(2),ylim(1):d:ylim(2));
hold on
contour(X1Grid,X2Grid,reshape(pdf(GMModel1,[X1Grid(:) X2Grid(:)]),...
    size(X1Grid,1),size(X1Grid,2)),20)
uistack(h,'top')
title('{\bf Random Initial Values}');
xlabel('Sepal length');
ylabel('Sepal width');
legend off;
hold off
subplot(2,2,2)
h = gscatter(X(:,1),X(:,2),species,[], 'o',4);
hold on
contour(X1Grid,X2Grid,reshape(pdf(GMModel2,[X1Grid(:) X2Grid(:)]),...
    size(X1Grid,1),size(X1Grid,2)),20)
uistack(h,'top')
title('{\bf Initial Values from Labels}');
xlabel('Sepal length');
ylabel('Sepal width');
legend off
hold off
subplot(2,2,3)
h = gscatter(X(:,1),X(:,2),species,[], 'o',4);
hold on
contour(X1Grid,X2Grid,reshape(pdf(GMModel3,[X1Grid(:) X2Grid(:)]),...
    size(X1Grid,1),size(X1Grid,2)),20)
uistack(h,'top')
title('{\bf Initial Values from the Structure}');
xlabel('Sepal length');
ylabel('Sepal width');
legend('Location',[0.7,0.25,0.1,0.1]);
hold off
```

According to the contours, GMMModel2 seems to suggest a slight trimodality, while the others suggest bimodal distributions.

Display the estimated component means.

```
table(GMMModel1.mu, GMMModel2.mu, GMMModel3.mu, 'VariableNames', ...
      {'Model1', 'Model2', 'Model3'})
```

```
ans=3x3 table
      Model1      Model2      Model3
-----
5.2115    2.0119    4.2857    1.3339    1.4604    0.2429
1.461     0.24423    1.462     0.246     4.7509    1.4629
```

4.6829 1.4429 5.5507 2.0316 5.0158 1.8592

`GMMModel2` seems to distinguish between the iris species the best.

Input Arguments

X — Data

numeric matrix

Data to which the Gaussian mixture model is fit, specified as a numeric matrix.

The rows of `X` correspond to observations, and the columns of `X` correspond to variables. The number of observations must be larger than each of the following: the number of variables and the number of components.

`NaN`s indicate missing values. The software removes rows of `X` containing at least one `NaN` before fitting, which decreases the effective sample size.

Data Types: `single` | `double`

k — Number of components

positive integer

Number of components to use when fitting Gaussian mixture model, specified as a positive integer. For example, if you specify `k = 3`, then the software fits a Gaussian mixture model with three distinct means, covariances matrices, and component proportions to the data (`X`).

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'RegularizationValue', 0.1, 'CovarianceType', 'diagonal'` specifies a regularization parameter value of 0.1 and to fit diagonal covariance matrices.

CovarianceType — Type of covariance matrix`'full' (default) | 'diagonal'`

Type of covariance matrix to fit to the data, specified as the comma-separated pair consisting of `'CovarianceType'` and either `'diagonal'` or `'full'`.

If you set `'diagonal'`, then the software fits diagonal covariance matrices. In this case, the software estimates $k*d$ covariance parameters, where d is the number of columns in X (i.e., $d = \text{size}(X,2)$).

Otherwise, the software fits full covariance matrices. In this case, the software estimates $k*d*(d+1)/2$ covariance parameters.

Example: `'CovarianceType','diagonal'`

Options — Iterative EM algorithm optimization options`statset options structure`

Iterative EM algorithm optimization options, specified as the comma-separated pair consisting of `'Options'` and a `statset options structure`.

This table describes the available name-value pair arguments.

Name	Value
<code>'Display'</code>	<p><code>'final'</code>: Display the final output.</p> <p><code>'iter'</code>: Display iterative output to the Command Window for some functions; otherwise display the final output.</p> <p><code>'off'</code>: Do not display optimization information.</p>
<code>'MaxIter'</code>	Positive integer indicating the maximum number of iterations allowed. The default is 100
<code>'TolFun'</code>	Positive scalar indicating the termination tolerance for the loglikelihood function value. The default is 1e-6 .

Example:

```
'Options',statset('Display','final','MaxIter',1500,'TolFun',1e-5)
```

ProbabilityTolerance — Tolerance for posterior probabilities

1e-8 (default) | nonnegative scalar value in range [0, 1e-6]

Tolerance for posterior probabilities, specified as the comma-separated pair consisting of `ProbabilityTolerance` and a nonnegative scalar value in the range [0, 1e-6].

In each iteration, after the estimation of posterior probabilities, `fitgmdist` sets any posterior probability that is not larger than the tolerance value to zero. Using a nonzero tolerance might speed up `fitgmdist`.

Example: `'ProbabilityTolerance', 0.0000025`

Data Types: `single` | `double`

RegularizationValue — Regularization parameter value

0 (default) | nonnegative scalar

Regularization parameter value, specified as the comma-separated pair consisting of `'RegularizationValue'` and a nonnegative scalar.

Set `RegularizationValue` to a small positive scalar to ensure that the estimated covariance matrices are positive definite.

Example: `'RegularizationValue', 0.01`

Data Types: `single` | `double`

Replicates — Number of times to repeat EM algorithm

1 (default) | positive integer

Number of times to repeat the EM algorithm using a new set of initial values, specified as the comma-separated pair consisting of `'Replicates'` and a positive integer.

If `Replicates` is greater than 1, then:

- The name-value pair argument `Start` must be `plus` (the default) or `randSample`.
- `GMMModel` is the fit with the largest loglikelihood.

Example: `'Replicates', 10`

Data Types: `single` | `double`

SharedCovariance — Flag indicating whether all covariance matrices are identical

logical false (default) | logical true

Flag indicating whether all covariance matrices are identical (i.e., fit a pooled estimate), specified as the comma-separated pair consisting of 'SharedCovariance' and either logical value `false` or `true`.

If `SharedCovariance` is `true`, then all k covariance matrices are equal, and the number of covariance parameters is scaled down by a factor of k .

Start — Initial value setting method

'plus' (default) | 'randSample' | vector of integers | structure array

Initial value setting method, specified as the comma-separated pair consisting of 'Start' and 'randSample', 'plus', a vector of integers, or a structure array.

The value of `Start` determines the initial values required by the optimization routine for each Gaussian component parameter — mean, covariance, and mixing proportion. This table summarizes the available options.

Value	Description
'randSample'	The software selects k observations from X at random as initial component means. The mixing proportions are uniform. The initial covariance matrices for all components are diagonal, where the element j on the diagonal is the variance of $X(:, j)$.
'plus'	The software selects k observations from X using the <code>kmeans++</code> algorithm on page 32-2240. The initial mixing proportions are uniform. The initial covariance matrices for all components are diagonal, where the element j on the diagonal is the variance of $X(:, j)$.
Vector of integers	A vector of length n (the number of observations) containing an initial guess of the component index for each point. That is, each element is an integer from 1 to k , which corresponds to a component. The software collects all observations corresponding to the same component, computes means, covariances, and mixing proportions for each, and sets the initial values to these statistics.

Value	Description
Structure array	<p>Suppose that there are d variables (i.e., $d = \text{size}(X,2)$). The structure array, e.g., S, must have three fields:</p> <ul style="list-style-type: none"> • $S.\mu$: A k-by-d matrix specifying the initial mean of each component • $S.\text{Sigma}$: A numeric array specifying the covariance matrix of each component. Sigma is one of the following: <ul style="list-style-type: none"> • A d-by-d-by-k array. $\text{Sigma}(:, :, j)$ is the initial covariance matrix of component j. • A 1-by-d-by-k array. $\text{diag}(\text{Sigma}(:, :, j))$ is the initial covariance matrix of component j. • A d-by-d matrix. Sigma is the initial covariance matrix for all components. • A 1-by-d vector. $\text{diag}(\text{Sigma})$ is the initial covariance matrix for all components. • $S.\text{ComponentProportion}$: A 1-by-k vector of scalars specifying the initial mixing proportions of each component. The default is uniform.

Example: `'Start', ones(n,1)`

Data Types: `single | double | char | string | struct`

Output Arguments

GMMModel — Fitted Gaussian mixture model

`gmdistribution model`

Fitted Gaussian mixture model, returned as a `gmdistribution` model.

Access properties of `GMMModel` using dot notation. For example, display the AIC by entering `GMMModel.AIC`.

Tips

`fitgmdist` might:

- Converge to a solution where one or more of the components has an ill-conditioned or singular covariance matrix.

The following issues might result in an ill-conditioned covariance matrix:

- The number of dimensions of your data is relatively high and there are not enough observations.
- Some of the predictors (variables) of your data are highly correlated.
- Some or all the features are discrete.
- You tried to fit the data to too many components.

In general, you can avoid getting ill-conditioned covariance matrices by using one of the following precautions:

- Preprocess your data to remove correlated features.
 - Set `'SharedCovariance'` to `true` to use an equal covariance matrix for every component.
 - Set `'CovarianceType'` to `'diagonal'`.
 - Use `'RegularizationValue'` to add a very small positive number to the diagonal of every covariance matrix.
 - Try another set of initial values.
- Pass through an intermediate step where one or more of the components has an ill-conditioned covariance matrix. Try another set of initial values to avoid this issue without altering your data or model.

Algorithms

Gaussian Mixture Model Likelihood Optimization

The software optimizes the Gaussian mixture model likelihood using the iterative Expectation-Maximization (EM) algorithm.

`fitgmdist` fits GMMs to data using the iterative Expectation-Maximization (EM) algorithm. Using initial values for component means, covariance matrices, and mixing proportions, the EM algorithm proceeds using these steps.

- 1 For each observation, the algorithm computes posterior probabilities of component memberships. You can think of the result as an n -by- k matrix, where element (i,j)

contains the posterior probability that observation i is from component j . This is the E-step of the EM algorithm.

- 2 Using the component-membership posterior probabilities as weights, the algorithm estimates the component means, covariance matrices, and mixing proportions by applying maximum likelihood. This is the M-step of the EM algorithm.

The algorithm iterates over these steps until convergence. The likelihood surface is complex, and the algorithm might converge to a local optimum. Also, the resulting local optimum might depend on the initial conditions. `fitgmdist` has several options for choosing initial conditions, including random component assignments for the observations and the k -means ++ algorithm.

k -means++ Algorithm for Initialization

The k -means++ algorithm uses an heuristic to find centroid seeds for k -means clustering. `fitgmdist` can apply the same principle to initialize the EM algorithm by using the k -means++ algorithm to select the initial parameter values for a fitted Gaussian mixture model.

The k -means++ algorithm assumes the number of clusters is k and chooses the initial parameter values as follows.

- 1 Select the component mixture probability to be the uniform probability $p_i = \frac{1}{k}$, where $i = 1, \dots, k$.
- 2 Select the covariance matrices to be diagonal and identical, where $\sigma_i = \text{diag}(a_1, a_2, \dots, a_k)$ and $a_j = \text{var}(X_j)$.
- 3 Select the first initial component center μ_1 uniformly from all data points in X .
- 4 To choose center j :
 - a Compute the Mahalanobis distances from each observation to each centroid, and assign each observation to its closest centroid.
 - b For $m = 1, \dots, n$ and $p = 1, \dots, j - 1$, select centroid j at random from X with probability

$$\frac{d^2(x_m, \mu_p)}{\sum_{h; x_h \in M_p} d^2(x_h, \mu_p)}$$

where $d(x_m, \mu_p)$ is the distance between observation m and μ_p , and M_p is the set of all observations closest to centroid μ_p and x_m belongs to M_p .

That is, select each subsequent center with a probability proportional to the distance from itself to the closest center that you already chose.

- 5 Repeat step 4 until k centroids are chosen.

Introduced in R2014a

fitlm

Fit linear regression model

Syntax

```
mdl = fitlm(tbl)
mdl = fitlm(X,y)
mdl = fitlm( ____,modelspec)
mdl = fitlm( ____,Name,Value)
```

Description

`mdl = fitlm(tbl)` returns a linear regression model fit to variables in the table or dataset array `tbl`. By default, `fitlm` takes the last variable as the response variable.

`mdl = fitlm(X,y)` returns a linear regression model of the responses `y`, fit to the data matrix `X`.

`mdl = fitlm(____,modelspec)` defines the model specification using any of the input argument combinations in the previous syntaxes.

`mdl = fitlm(____,Name,Value)` specifies additional options using one or more name-value pair arguments. For example, you can specify which variables are categorical, perform robust regression, or use observation weights.

Examples

Fit Linear Regression Using Data in Matrix

Fit a linear regression model using a matrix input data set.

Load the `carsmall` data set, a matrix input data set.

```
load carsmall
X = [Weight,Horsepower,Acceleration];
```

Fit a linear regression model by using fitlm.

```
mdl = fitlm(X,MPG)
```

```
mdl =
Linear regression model:
y ~ 1 + x1 + x2 + x3
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	47.977	3.8785	12.37	4.8957e-21
x1	-0.0065416	0.0011274	-5.8023	9.8742e-08
x2	-0.042943	0.024313	-1.7663	0.08078
x3	-0.011583	0.19333	-0.059913	0.95236

Number of observations: 93, Error degrees of freedom: 89

Root Mean Squared Error: 4.09

R-squared: 0.752, Adjusted R-Squared: 0.744

F-statistic vs. constant model: 90, p-value = 7.38e-27

The model display includes the model formula, estimated coefficients, and model summary statistics.

The model formula in the display, $y \sim 1 + x1 + x2 + x3$, corresponds to $y = \beta_0 + \beta_1 X_1 + \beta_2 X_2 + \beta_3 X_3 + \epsilon$.

The model display also shows the estimated coefficient information, which is stored in the Coefficients property. Display the Coefficients property.

```
mdl.Coefficients
```

```
ans=4x4 table
```

	Estimate	SE	tStat	pValue
(Intercept)	47.977	3.8785	12.37	4.8957e-21
x1	-0.0065416	0.0011274	-5.8023	9.8742e-08
x2	-0.042943	0.024313	-1.7663	0.08078

x3 -0.011583 0.19333 -0.059913 0.95236

The `Coefficient` property includes these columns:

- `Estimate` — Coefficient estimates for each corresponding term in the model. For example, the estimate for the constant term (`intercept`) is 47.977.
- `SE` — Standard error of the coefficients.
- `tStat` — t -statistic for each coefficient to test the null hypothesis that the corresponding coefficient is zero against the alternative that it is different from zero, given the other predictors in the model. Note that $tStat = Estimate/SE$. For example, the t -statistic for the intercept is $47.977/3.8785 = 12.37$.
- `pValue` — p -value for the t -statistic of the hypothesis test that the corresponding coefficient is equal to zero or not. For example, the p -value of the t -statistic for `x2` is greater than 0.05, so this term is not significant at the 5% significance level given the other terms in the model.

The summary statistics of the model are:

- `Number of observations` — Number of rows without any `NaN` values. For example, `Number of observations` is 93 because the `MPG` data vector has six `NaN` values and the `Horsepower` data vector has one `NaN` value for a different observation, where the number of rows in `X` and `MPG` is 100.
- `Error degrees of freedom` — $n - p$, where n is the number of observations, and p is the number of coefficients in the model, including the intercept. For example, the model has four predictors, so the `Error degrees of freedom` is $93 - 4 = 89$.
- `Root mean squared error` — Square root of the mean squared error, which estimates the standard deviation of the error distribution.
- `R-squared` and `Adjusted R-squared` — Coefficient of determination and adjusted coefficient of determination, respectively. For example, the `R-squared` value suggests that the model explains approximately 75% of the variability in the response variable `MPG`.
- `F-statistic vs. constant model` — Test statistic for the F -test on the regression model, which tests whether the model fits significantly better than a degenerate model consisting of only a constant term.
- `p-value` — p -value for the F -test on the model. For example, the model is significant with a p -value of $7.3816e-27$.

You can find these statistics in the model properties (NumObservations, DFE, RMSE, and Rsquared) and by using the anova function.

```
anova mdl, 'summary'
```

```
ans=3x5 table
```

	SumSq	DF	MeanSq	F	pValue
Total	6004.8	92	65.269		
Model	4516	3	1505.3	89.987	7.3816e-27
Residual	1488.8	89	16.728		

Fit Linear Regression Using Data in Table

Load the sample data.

```
load carsmall
```

Store the variables in a table.

```
tbl = table(Weight,Acceleration,MPG,'VariableNames',{'Weight','Acceleration','MPG'});
```

Display the first five rows of the table.

```
tbl(1:5,:)
```

```
ans=5x3 table
```

Weight	Acceleration	MPG
3504	12	18
3693	11.5	15
3436	11	18
3433	12	16
3449	10.5	17

Fit a linear regression model for miles per gallon (MPG). Specify the model formula by using Wilkinson notation.

```
lm = fitlm(tbl,'MPG~Weight+Acceleration')
```

```
lm =  
Linear regression model:  
MPG ~ 1 + Weight + Acceleration
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	45.155	3.4659	13.028	1.6266e-22
Weight	-0.0082475	0.00059836	-13.783	5.3165e-24
Acceleration	0.19694	0.14743	1.3359	0.18493

```
Number of observations: 94, Error degrees of freedom: 91  
Root Mean Squared Error: 4.12  
R-squared: 0.743, Adjusted R-Squared: 0.738  
F-statistic vs. constant model: 132, p-value = 1.38e-27
```

The model 'MPG~Weight+Acceleration' in this example is equivalent to set the model specification as 'linear'. For example,

```
lm2 = fitlm(tbl, 'linear');
```

If you use a character vector for model specification and you do not specify the response variable, then `fitlm` accepts the last variable in `tbl` as the response variable and the other variables as the predictor variables.

Fit Linear Regression Using Specified Model Formula

Fit a linear regression model using a model formula specified by Wilkinson notation.

Load the sample data.

```
load carsmall
```

Store the variables in a table.

```
tbl = table(Weight, Acceleration, Model_Year, MPG, 'VariableNames', {'Weight', 'Acceleration
```

Fit a linear regression model for miles per gallon (MPG) with weight and acceleration as the predictor variables.

```
lm = fitlm(tbl, 'MPG~Weight+Acceleration')
```

```
lm =
Linear regression model:
MPG ~ 1 + Weight + Acceleration
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	45.155	3.4659	13.028	1.6266e-22
Weight	-0.0082475	0.00059836	-13.783	5.3165e-24
Acceleration	0.19694	0.14743	1.3359	0.18493

Number of observations: 94, Error degrees of freedom: 91
 Root Mean Squared Error: 4.12
 R-squared: 0.743, Adjusted R-Squared: 0.738
 F-statistic vs. constant model: 132, p-value = 1.38e-27

The *p*-value of 0.18493 indicates that **Acceleration** does not have a significant impact on **MPG**.

Remove **Acceleration** from the model, and try improving the model by adding the predictor variable **Model_Year**. First define **Model_Year** as a categorical variable.

```
tbl.Model_Year = categorical(tbl.Model_Year);
lm = fitlm(tbl, 'MPG~Weight+Model_Year')
```

```
lm =
Linear regression model:
MPG ~ 1 + Weight + Model_Year
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	40.11	1.5418	26.016	1.2024e-43
Weight	-0.0066475	0.00042802	-15.531	3.3639e-27
Model_Year_76	1.9291	0.74761	2.5804	0.011488
Model_Year_82	7.9093	0.84975	9.3078	7.8681e-15

Number of observations: 94, Error degrees of freedom: 90
 Root Mean Squared Error: 2.92

```
R-squared: 0.873, Adjusted R-Squared: 0.868  
F-statistic vs. constant model: 206, p-value = 3.83e-40
```

Specifying `modelspec` using Wilkinson notation enables you to update the model without having to change the design matrix. `fitlm` uses only the variables that are specified in the formula. It also creates the necessary two dummy indicator variables for the categorical variable `Model_Year`.

Fit Linear Regression Using Terms Matrix

Fit a linear regression model using a terms matrix.

Terms Matrix for Table Input

If the model variables are in a table, then a column of 0s in a terms matrix represents the position of the response variable.

Load the `hospital` data set.

```
load hospital
```

Store the variables in a table.

```
t = table(hospital.Sex,hospital.BloodPressure(:,1),hospital.Age,hospital.Smoker, ...  
         'VariableNames',{'Sex','BloodPressure','Age','Smoker'});
```

Represent the linear model `'BloodPressure ~ 1 + Sex + Age + Smoker'` using a terms matrix. The response variable is in the second column of the table, so the second column of the terms matrix must be a column of 0s for the response variable.

```
T = [0 0 0 0;1 0 0 0;0 0 1 0;0 0 0 1]
```

```
T = 4x4
```

```
0    0    0    0  
1    0    0    0  
0    0    1    0  
0    0    0    1
```

Fit a linear model.

```
mdl1 = fitlm(t,T)
```

```
mdl1 =
```

```
Linear regression model:
```

```
BloodPressure ~ 1 + Sex + Age + Smoker
```

```
Estimated Coefficients:
```

	Estimate	SE	tStat	pValue
(Intercept)	116.14	2.6107	44.485	7.1287e-66
Sex_Male	0.050106	0.98364	0.050939	0.95948
Age	0.085276	0.066945	1.2738	0.2058
Smoker_1	9.87	1.0346	9.5395	1.4516e-15

```
Number of observations: 100, Error degrees of freedom: 96
```

```
Root Mean Squared Error: 4.78
```

```
R-squared: 0.507, Adjusted R-Squared: 0.492
```

```
F-statistic vs. constant model: 33, p-value = 9.91e-15
```

Terms Matrix for Matrix Input

If the predictor and response variables are in a matrix and column vector, then you must include 0 for the response variable at the end of each row in a terms matrix.

Load the `carsmall` data set and define the matrix of predictors.

```
load carsmall
```

```
X = [Acceleration,Weight];
```

Specify the model 'MPG ~ Acceleration + Weight + Acceleration:Weight + Weight^2' using a terms matrix. This model includes the main effect and two-way interaction terms for the variables `Acceleration` and `Weight`, and a second-order term for the variable `Weight`.

```
T = [0 0 0;1 0 0;0 1 0;1 1 0;0 2 0]
```

```
T = 5×3
```

```
0 0 0
1 0 0
0 1 0
1 1 0
```

```
0 2 0
```

Fit a linear model.

```
mdl2 = fitlm(X,MPG,T)
```

```
mdl2 =  
Linear regression model:  
y ~ 1 + x1*x2 + x2^2
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	48.906	12.589	3.8847	0.00019665
x1	0.54418	0.57125	0.95261	0.34337
x2	-0.012781	0.0060312	-2.1192	0.036857
x1:x2	-0.00010892	0.00017925	-0.6076	0.545
x2^2	9.7518e-07	7.5389e-07	1.2935	0.19917

Number of observations: 94, Error degrees of freedom: 89

Root Mean Squared Error: 4.1

R-squared: 0.751, Adjusted R-Squared: 0.739

F-statistic vs. constant model: 67, p-value = 4.99e-26

Only the intercept and x2 term, which corresponds to the `Weight` variable, are significant at the 5% significance level.

Linear Regression with Categorical Predictor

Fit a linear regression model that contains a categorical predictor. Reorder the categories of the categorical predictor to control the reference level in the model. Then, use `anova` to test the significance of the categorical variable.

Model with Categorical Predictor

Load the `carsmall` data set and create a linear regression model of `MPG` as a function of `Model_Year`. To treat the numeric vector `Model_Year` as a categorical variable, identify the predictor using the `'CategoricalVars'` name-value pair argument.

```
load carsmall
mdl = fitlm(Model_Year,MPG,'CategoricalVars',1,'VarNames',{'Model_Year','MPG'})
```

```
mdl =
Linear regression model:
    MPG ~ 1 + Model_Year
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	17.69	1.0328	17.127	3.2371e-30
Model_Year_76	3.8839	1.4059	2.7625	0.0069402
Model_Year_82	14.02	1.4369	9.7571	8.2164e-16

```
Number of observations: 94, Error degrees of freedom: 91
Root Mean Squared Error: 5.56
R-squared: 0.531, Adjusted R-Squared: 0.521
F-statistic vs. constant model: 51.6, p-value = 1.07e-15
```

The model formula in the display, $MPG \sim 1 + Model_Year$, corresponds to

$$MPG = \beta_0 + \beta_1 I_{Year = 76} + \beta_2 I_{Year = 82} + \epsilon,$$

where $I_{Year = 76}$ and $I_{Year = 82}$ are indicator variables whose value is one if the value of `Model_Year` is 76 and 82, respectively. The `Model_Year` variable includes three distinct values, which you can check by using the `unique` function.

```
unique(Model_Year)
```

```
ans = 3×1
```

```
70
76
82
```

`fitlm` chooses the smallest value in `Model_Year` as a reference level ('70') and creates two indicator variables $I_{Year = 76}$ and $I_{Year = 82}$. The model includes only two indicator variables because the design matrix becomes rank deficient if the model includes three indicator variables (one for each level) and an intercept term.

Model with Full Indicator Variables

You can interpret the model formula of `mdl` as a model that has three indicator variables without an intercept term:

$$y = \beta_0 I_{x_1} = 70 + (\beta_0 + \beta_1) I_{x_1} = 76 + (\beta_0 + \beta_2) I_{x_2} = 82 + \epsilon.$$

Alternatively, you can create a model that has three indicator variables without an intercept term by manually creating indicator variables and specifying the model formula.

```
temp_Year = dummyvar(categorical(Model_Year));
Model_Year_70 = temp_Year(:,1);
Model_Year_76 = temp_Year(:,2);
Model_Year_82 = temp_Year(:,3);
tbl = table(Model_Year_70,Model_Year_76,Model_Year_82,MPG);
mdl = fitlm(tbl,'MPG ~ Model_Year_70 + Model_Year_76 + Model_Year_82 - 1')
```

```
mdl =
Linear regression model:
    MPG ~ Model_Year_70 + Model_Year_76 + Model_Year_82
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
Model_Year_70	17.69	1.0328	17.127	3.2371e-30
Model_Year_76	21.574	0.95387	22.617	4.0156e-39
Model_Year_82	31.71	0.99896	31.743	5.2234e-51

```
Number of observations: 94, Error degrees of freedom: 91
Root Mean Squared Error: 5.56
```

Choose Reference Level in Model

You can choose a reference level by modifying the order of categories in a categorical variable. First, create a categorical variable `Year`.

```
Year = categorical(Model_Year);
```

Check the order of categories by using the `categories` function.

```
categories(Year)
ans = 3x1 cell array
    {'70'}
```

```
{'76'}
{'82'}
```

If you use `Year` as a predictor variable, then `fitlm` chooses the first category `'70'` as a reference level. Reorder `Year` by using the `reordercats` function.

```
Year_reordered = reordercats(Year,{'76','70','82'});
categories(Year_reordered)
```

```
ans = 3x1 cell array
    {'76'}
    {'70'}
    {'82'}
```

The first category of `Year_reordered` is `'76'`. Create a linear regression model of `MPG` as a function of `Year_reordered`.

```
mdl2 = fitlm(Year_reordered,MPG,'VarNames',{'Model_Year','MPG'})
```

```
mdl2 =
Linear regression model:
    MPG ~ 1 + Model_Year
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	21.574	0.95387	22.617	4.0156e-39
Model_Year_70	-3.8839	1.4059	-2.7625	0.0069402
Model_Year_82	10.136	1.3812	7.3385	8.7634e-11

Number of observations: 94, Error degrees of freedom: 91

Root Mean Squared Error: 5.56

R-squared: 0.531, Adjusted R-Squared: 0.521

F-statistic vs. constant model: 51.6, p-value = 1.07e-15

`mdl2` uses `'76'` as a reference level and includes two indicator variables $I_{\text{Year} = 70}$ and $I_{\text{Year} = 82}$.

Evaluate Categorical Predictor

The model display of `mdl2` includes a p -value of each term to test whether or not the corresponding coefficient is equal to zero. Each p -value examines each indicator variable. To examine the categorical variable `Model_Year` as a group of indicator variables, use `anova`. Specify `'components'` to return a component ANOVA table that includes ANOVA statistics for each variable in the model except the constant term.

```
anova(mdl2, 'components')
```

```
ans=2x5 table
```

	SumSq	DF	MeanSq	F	pValue
	-----	---	-----	-----	-----
Model_Year	3190.1	2	1595.1	51.56	1.0694e-15
Error	2815.2	91	30.936		

The component ANOVA table includes the p -value of the `Model_Year` variable, which is smaller than the p -values of the indicator variables.

Specify Response and Predictor Variables for Linear Model

Fit a linear regression model to sample data. Specify the response and predictor variables, and include only pairwise interaction terms in the model.

Load sample data.

```
load hospital
```

Fit a linear model with interaction terms to the data. Specify `weight` as the response variable, and `sex`, `age`, and `smoking status` as the predictor variables. Also, specify that `sex` and `smoking status` are categorical variables.

```
mdl = fitlm(hospital, 'interactions', 'ResponseVar', 'Weight', ...  
            'PredictorVars', {'Sex', 'Age', 'Smoker'}, ...  
            'CategoricalVar', {'Sex', 'Smoker'})
```

```
mdl =
```

```
Linear regression model:
```

```
Weight ~ 1 + Sex*Age + Sex*Smoker + Age*Smoker
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	118.7	7.0718	16.785	6.821e-30
Sex_Male	68.336	9.7153	7.0339	3.3386e-10
Age	0.31068	0.18531	1.6765	0.096991
Smoker_1	3.0425	10.446	0.29127	0.77149
Sex_Male:Age	-0.49094	0.24764	-1.9825	0.050377
Sex_Male:Smoker_1	0.9509	3.8031	0.25003	0.80312
Age:Smoker_1	-0.07288	0.26275	-0.27737	0.78211

Number of observations: 100, Error degrees of freedom: 93

Root Mean Squared Error: 8.75

R-squared: 0.898, Adjusted R-Squared: 0.892

F-statistic vs. constant model: 137, p-value = 6.91e-44

The weight of the patients do not seem to differ significantly according to age, or the status of smoking, or interaction of these factors with patient sex at the 5% significance level.

Fit Robust Linear Regression Model

Load the `hald` data set, which measures the effect of cement composition on its hardening heat.

```
load hald
```

This data set includes the variables `ingredients` and `heat`. The matrix `ingredients` contains the percent composition of four chemicals present in the cement. The vector `heat` contains the values for the heat hardening after 180 days for each cement sample.

Fit a robust linear regression model to the data.

```
mdl = fitlm(ingredients,heat,'RobustOpts','on')
```

```
mdl =
```

```
Linear regression model (robust fit):
```

```
    y ~ 1 + x1 + x2 + x3 + x4
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	60.09	75.818	0.79256	0.4509
x1	1.5753	0.80585	1.9548	0.086346
x2	0.5322	0.78315	0.67957	0.51596
x3	0.13346	0.8166	0.16343	0.87424
x4	-0.12052	0.7672	-0.15709	0.87906

Number of observations: 13, Error degrees of freedom: 8
Root Mean Squared Error: 2.65
R-squared: 0.979, Adjusted R-Squared: 0.969
F-statistic vs. constant model: 94.6, p-value = 9.03e-07

For more details, see the topic “Robust Regression — Reduce Outlier Effects” on page 11-132, which compares the results of a robust fit to a standard least-squares fit.

Input Arguments

tbl — Input data

table | dataset array

Input data, specified as a table or dataset array. When `modelspec` is a formula, the formula specifies the predictor and response variables. Otherwise, if you do not specify the predictor and response variables, the last variable in `tbl` is the response variable and the others are the predictor variables by default.

The predictor variables can be numeric, logical, categorical, character, or string. The response variable must be numeric or logical.

To set a different column as the response variable, use the `ResponseVar` name-value pair argument. To use a subset of the columns as predictors, use the `PredictorVars` name-value pair argument.

X — Predictor variables

matrix

Predictor variables, specified as an n -by- p matrix, where n is the number of observations and p is the number of predictor variables. Each column of `X` represents one variable, and each row represents one observation.

By default, there is a constant term in the model, unless you explicitly remove it, so do not include a column of 1s in X .

Data Types: `single` | `double`

y — Response variable

vector

Response variable, specified as an n -by-1 vector, where n is the number of observations. Each entry in y is the response for the corresponding row of X .

Data Types: `single` | `double` | `logical`

modelspec — Model specification

'linear' (default) | 'constant' | 'interactions' | t -by- $(p + 1)$ terms matrix | character vector or string scalar of the form 'Y ~ terms' | ...

Model specification, specified as one of these values.

- A character vector or string scalar naming the model.

Value	Model Type
'constant'	Model contains only a constant (intercept) term.
'linear'	Model contains an intercept and linear term for each predictor.
'interactions'	Model contains an intercept, linear term for each predictor, and all products of pairs of distinct predictors (no squared terms).
'purequadratic'	Model contains an intercept term and linear and squared terms for each predictor.
'quadratic'	Model contains an intercept term, linear and squared terms for each predictor, and all products of pairs of distinct predictors.

Value	Model Type
'polyijk'	Model is a polynomial with all terms up to degree i in the first predictor, degree j in the second predictor, and so on. Specify the maximum degree for each predictor by using numerals 0 through 9. The model contains interaction terms, but the degree of each interaction term does not exceed the maximum value of the specified degrees. For example, 'poly13' has an intercept and x_1 , x_2 , x_2^2 , x_2^3 , x_1*x_2 , and $x_1*x_2^2$ terms, where x_1 and x_2 are the first and second predictors, respectively.

- A t -by- $(p + 1)$ matrix, or a “Terms Matrix” on page 32-2263, specifying terms in the model, where t is the number of terms and p is the number of predictor variables, and +1 accounts for the response variable. A terms matrix is convenient when the number of predictors is large and you want to generate the terms programmatically.
- A character vector or string scalar representing a “Formula” on page 32-2264 in the form
`'Y ~ terms'`,
where the terms are in “Wilkinson Notation” on page 32-2264.

Example: `'quadratic'`

Example: `'y ~ X1 + X2^2 + X1:X2'`

Data Types: `single | double | char | string`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example: `'Intercept', false, 'PredictorVars', [1,3], 'ResponseVar', 5, 'RobustOpts', 'logistic'` specifies a robust regression model with no constant term, where the algorithm uses the logistic weighting function with the default tuning constant, first and third variables are the predictor variables, and fifth variable is the response variable.

CategoricalVars — Categorical variable list

string array | cell array of character vectors | logical or numeric index vector

Categorical variable list, specified as the comma-separated pair consisting of 'CategoricalVars' and either a string array or cell array of character vectors containing categorical variable names in the table or dataset array `tbl`, or a logical or numeric index vector indicating which columns are categorical.

- If data is in a table or dataset array `tbl`, then, by default, `fitlm` treats all categorical values, logical values, character arrays, string arrays, and cell arrays of character vectors as categorical variables.
- If data is in matrix `X`, then the default value of 'CategoricalVars' is an empty matrix `[]`. That is, no variable is categorical unless you specify it as categorical.

For example, you can specify the observations 2 and 3 out of 6 as categorical using either of the following examples.

Example: 'CategoricalVars', [2,3]

Example: 'CategoricalVars', logical([0 1 1 0 0 0])

Data Types: single | double | logical | string | cell

Exclude — Observations to exclude

logical or numeric index vector

Observations to exclude from the fit, specified as the comma-separated pair consisting of 'Exclude' and a logical or numeric index vector indicating which observations to exclude from the fit.

For example, you can exclude observations 2 and 3 out of 6 using either of the following examples.

Example: 'Exclude', [2,3]

Example: 'Exclude', logical([0 1 1 0 0 0])

Data Types: single | double | logical

Intercept — Indicator for constant term

true (default) | false

Indicator for the constant term (intercept) in the fit, specified as the comma-separated pair consisting of 'Intercept' and either `true` to include or `false` to remove the constant term from the model.

Use 'Intercept' only when specifying the model using a character vector or string scalar, not a formula or matrix.

Example: `'Intercept', false`

PredictorVars — Predictor variables

string array | cell array of character vectors | logical or numeric index vector

Predictor variables to use in the fit, specified as the comma-separated pair consisting of `'PredictorVars'` and either a string array or cell array of character vectors of the variable names in the table or dataset array `tbl`, or a logical or numeric index vector indicating which columns are predictor variables.

The string values or character vectors should be among the names in `tbl`, or the names you specify using the `'VarNames'` name-value pair argument.

The default is all variables in `X`, or all variables in `tbl` except for `ResponseVar`.

For example, you can specify the second and third variables as the predictor variables using either of the following examples.

Example: `'PredictorVars', [2,3]`

Example: `'PredictorVars', logical([0 1 1 0 0 0])`

Data Types: `single` | `double` | `logical` | `string` | `cell`

ResponseVar — Response variable

last column in `tbl` (default) | character vector or string scalar containing variable name | logical or numeric index vector

Response variable to use in the fit, specified as the comma-separated pair consisting of `'ResponseVar'` and either a character vector or string scalar containing the variable name in the table or dataset array `tbl`, or a logical or numeric index vector indicating which column is the response variable. You typically need to use `'ResponseVar'` when fitting a table or dataset array `tbl`.

For example, you can specify the fourth variable, say `yield`, as the response out of six variables, in one of the following ways.

Example: `'ResponseVar', 'yield'`

Example: `'ResponseVar', [4]`

Example: `'ResponseVar', logical([0 0 0 1 0 0])`

Data Types: `single` | `double` | `logical` | `char` | `string`

RobustOpts — Indicator of robust fitting type

'off' (default) | 'on' | character vector | string scalar | structure

Indicator of the robust fitting type to use, specified as the comma-separated pair consisting of 'RobustOpts' and one of these values.

- 'off' — No robust fitting. `fitlm` uses ordinary least squares.
- 'on' — Robust fitting using the 'bisquare' weight function with the default tuning constant.
- Character vector or string scalar — Name of a robust fitting weight function from the following table. `fitlm` uses the corresponding default tuning constant specified in the table.
- Structure with the two fields `RobustWgtFun` and `Tune`.
 - The `RobustWgtFun` field contains the name of a robust fitting weight function from the following table or a function handle of a custom weight function.
 - The `Tune` field contains a tuning constant. If you do not set the `Tune` field, `fitlm` uses the corresponding default tuning constant.

Weight Function	Description	Default Tuning Constant
'andrews'	$w = (\text{abs}(r) < \pi) .* \sin(r) ./ r$	1.339
'bisquare'	$w = (\text{abs}(r) < 1) .* (1 - r.^2).^2$ (also called biweight)	4.685
'cauchy'	$w = 1 ./ (1 + r.^2)$	2.385
'fair'	$w = 1 ./ (1 + \text{abs}(r))$	1.400
'huber'	$w = 1 ./ \max(1, \text{abs}(r))$	1.345
'logistic'	$w = \tanh(r) ./ r$	1.205
'ols'	Ordinary least squares (no weighting function)	None
'talwar'	$w = 1 * (\text{abs}(r) < 1)$	2.795
'welsch'	$w = \exp(-(r.^2))$	2.985
function handle	Custom weight function that accepts a vector <code>r</code> of scaled residuals, and returns a vector of weights the same size as <code>r</code>	1

- The default tuning constants of built-in weight functions give coefficient estimates that are approximately 95% as statistically efficient as the ordinary least-squares estimates, provided the response has a normal distribution with no outliers. Decreasing the tuning constant increases the downweight assigned to large residuals; increasing the tuning constant decreases the downweight assigned to large residuals.
- The value r in the weight functions is

$$r = \text{resid}/(\text{tune}*s*\text{sqrt}(1-h)),$$

where `resid` is the vector of residuals from the previous iteration, `tune` is the tuning constant, `h` is the vector of leverage values from a least-squares fit, and `s` is an estimate of the standard deviation of the error term given by

$$s = \text{MAD}/0.6745.$$

MAD is the median absolute deviation of the residuals from their median. The constant 0.6745 makes the estimate unbiased for the normal distribution. If X has p columns, the software excludes the smallest p absolute deviations when computing the median.

For robust fitting, `fitlm` uses M-estimation to formulate estimating equations and solves them using the method of iterative reweighted least squares (IRLS).

Example: `'RobustOpts', 'andrews'`

VarNames — Names of variables

`{'x1', 'x2', ..., 'xn', 'y'}` (default) | string array | cell array of character vectors

Names of variables, specified as the comma-separated pair consisting of `'VarNames'` and a string array or cell array of character vectors including the names for the columns of X first, and the name for the response variable y last.

`'VarNames'` is not applicable to variables in a table or dataset array, because those variables already have names.

For example, if in your data, horsepower, acceleration, and model year of the cars are the predictor variables, and miles per gallon (MPG) is the response variable, then you can name the variables as follows.

Example: `'VarNames', {'Horsepower', 'Acceleration', 'Model_Year', 'MPG'}`

Data Types: string | cell

Weights — Observation weights

`ones(n,1)` (default) | n -by-1 vector of nonnegative scalar values

Observation weights, specified as the comma-separated pair consisting of 'Weights' and an n -by-1 vector of nonnegative scalar values, where n is the number of observations.

Data Types: `single` | `double`

Output Arguments

mdl — Linear model

`LinearModel` object

Linear model representing a least-squares fit of the response to the data, returned as a `LinearModel` object.

If the value of the 'RobustOpts' name-value pair is not `[]` or 'ols', the model is not a least-squares fit, but uses the robust fitting function.

Definitions

Terms Matrix

A terms matrix T is a t -by- $(p + 1)$ matrix specifying terms in a model, where t is the number of terms, p is the number of predictor variables, and $+1$ accounts for the response variable. The value of $T(i, j)$ is the exponent of variable j in term i .

For example, suppose that an input includes three predictor variables A, B, and C and the response variable Y in the order A, B, C, and Y. Each row of T represents one term:

- $[0 \ 0 \ 0 \ 0]$ — Constant term or intercept
- $[0 \ 1 \ 0 \ 0]$ — B; equivalently, $A^0 * B^1 * C^0$
- $[1 \ 0 \ 1 \ 0]$ — $A * C$
- $[2 \ 0 \ 0 \ 0]$ — A^2
- $[0 \ 1 \ 2 \ 0]$ — $B * (C^2)$

The 0 at the end of each term represents the response variable. In general, a column vector of zeros in a terms matrix represents the position of the response variable. If you

have the predictor and response variables in a matrix and column vector, then you must include θ for the response variable in the last column of each row.

Formula

A formula for model specification is a character vector or string scalar of the form ' $Y \sim terms$ '.

- Y is the response name.
- $terms$ represents the predictor terms in a model using Wilkinson notation.

For example:

- ' $Y \sim A + B + C$ ' specifies a three-variable linear model with intercept.
- ' $Y \sim A + B + C - 1$ ' specifies a three-variable linear model without intercept. Note that formulas include a constant (intercept) term by default. To exclude a constant term from the model, you must include -1 in the formula.

Wilkinson Notation

Wilkinson notation describes the terms present in a model. The notation relates to the terms present in a model, not to the multipliers (coefficients) of those terms.

Wilkinson notation uses these symbols:

- $+$ means include the next variable.
- $-$ means do not include the next variable.
- $:$ defines an interaction, which is a product of terms.
- $*$ defines an interaction and all lower-order terms.
- $^$ raises the predictor to a power, exactly as in $*$ repeated, so $^$ includes lower-order terms as well.
- $()$ groups terms.

This table shows typical examples of Wilkinson notation.

Wilkinson Notation	Term in Standard Notation
1	Constant (intercept) term

Wilkinson Notation	Term in Standard Notation
A^k , where k is a positive integer	A, A^2, \dots, A^k
$A + B$	A, B
$A*B$	$A, B, A*B$
$A:B$	$A*B$ only
$-B$	Do not include B
$A*B + C$	$A, B, C, A*B$
$A + B + C + A:B$	$A, B, C, A*B$
$A*B*C - A:B:C$	$A, B, C, A*B, A*C, B*C$
$A*(B + C)$	$A, B, C, A*B, A*C$

Statistics and Machine Learning Toolbox notation always includes a constant term unless you explicitly remove the term using -1 .

For more details, see “Wilkinson Notation” on page 11-117.

Tips

- To access the model properties of the `LinearModel` object `mdl`, you can use dot notation. For example, `mdl.Residuals` returns a table of the raw, Pearson, Studentized, and standardized residual values for the model.
- After training a model, you can generate C/C++ code that predicts responses for new data. Generating C/C++ code requires MATLAB Coder. For details, see “Introduction to Code Generation” on page 31-2.

Algorithms

- The main fitting algorithm is QR decomposition. For robust fitting, `fitlm` uses M-estimation to formulate estimating equations and solves them using the method of iterative reweighted least squares (IRLS).
- `fitlm` treats a categorical predictor as follows:
 - A model with a categorical predictor that has L levels (categories) includes $L - 1$ indicator variables. The model uses the first category as a reference level, so it

does not include the indicator variable for the reference level. If the data type of the categorical predictor is `categorical`, then you can check the order of categories by using `categories` and reorder the categories by using `reordercats` to customize the reference level.

- `fitlm` treats the group of $L - 1$ indicator variables as a single variable. If you want to treat the indicator variables as distinct predictor variables, create indicator variables manually by using `dummyvar`. Then use the indicator variables, except the one corresponding to the reference level of the categorical variable, when you fit a model. For the categorical predictor X , if you specify all columns of `dummyvar(X)` and an intercept term as predictors, then the design matrix becomes rank deficient.
- Interaction terms between a continuous predictor and a categorical predictor with L levels consist of the element-wise product of the $L - 1$ indicator variables with the continuous predictor.
- Interaction terms between two categorical predictors with L and M levels consist of the $(L - 1)*(M - 1)$ indicator variables to include all possible combinations of the two categorical predictor levels.
- You cannot specify higher-order terms for a categorical predictor because the square of an indicator is equal to itself.
- `fitlm` considers `NaN`, `' '` (empty character vector), `""` (empty string), `<missing>`, and `<undefined>` values in `tbl`, X , and Y to be missing values. `fitlm` does not use observations with missing values in the fit. The `ObservationInfo` property of a fitted model indicates whether or not `fitlm` uses each observation in the fit.

Alternative Functionality

- For reduced computation time on high-dimensional data sets, fit a linear regression model using the `fitrlinear` function.
- To regularize a regression, use `fitrlinear`, `lasso`, `ridge`, or `plsregress`.
 - `fitrlinear` regularizes a regression for high-dimensional data sets using lasso or ridge regression.
 - `lasso` removes redundant predictors in linear regression using lasso or elastic net.
 - `ridge` regularizes a regression with correlated terms using ridge regression.
 - `plsregress` regularizes a regression with correlated terms using partial least squares.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function supports tall arrays for out-of-memory data with some limitations.

- If any input argument to `fitlm` is a tall array, then all of the other inputs must be tall arrays as well. This includes nonempty variables supplied with the 'Weights' and 'Exclude' name-value pairs.
- The 'RobustOpts' name-value pair is not supported with tall arrays.
- For tall data, `fitlm` returns a `CompactLinearModel` object that contains most of the same properties as a `LinearModel` object. The main difference is that the compact object is sensitive to memory requirements. The compact object does not include properties that include the data, or that include an array of the same size as the data. The compact object does not contain these `LinearModel` properties:
 - `Diagnostics`
 - `Fitted`

- `ObservationInfo`
- `ObservationNames`
- `Residuals`
- `Steps`
- `Variables`

You can compute the residuals directly from the compact object returned by `LM = fitlm(X,Y)` using

```
RES = Y - predict(LM,X);  
S = LM.RMSE;  
histogram(RES,linspace(-3*S,3*S,51))
```

- If the `CompactLinearModel` object is missing lower order terms that include categorical factors:
 - The `plotEffects` and `plotInteraction` methods are not supported.
 - The `anova` method with the `'components'` option is not supported.

For more information, see “Tall Arrays” (MATLAB).

fitlme

Fit linear mixed-effects model

Syntax

```
lme = fitlme(tbl,formula)
lme = fitlme(tbl,formula,Name,Value)
```

Description

`lme = fitlme(tbl,formula)` returns a linear mixed-effects model, specified by `formula`, fitted to the variables in the table or dataset array `tbl`.

`lme = fitlme(tbl,formula,Name,Value)` returns a linear mixed-effects model with additional options specified by one or more `Name,Value` pair arguments.

For example, you can specify the covariance pattern of the random-effects terms, the method to use in estimating the parameters, or options for the optimization algorithm.

Examples

Fit Linear Mixed-Effects Model

Load the sample data.

```
load imports-85
```

Store the variables in a table.

```
tbl = table(X(:,12),X(:,14),X(:,24),'VariableNames',{ 'Horsepower', 'CityMPG', 'EngineType
```

Display the first five rows of the table.

```
tbl(1:5,:)
```

```
ans=5x3 table
  Horsepower  CityMPG  EngineType
  _____  _____  _____
      111         21         13
      111         21         13
      154         19         37
      102         24         35
      115         18         35
```

Fit a linear mixed-effects model for miles per gallon in the city, with fixed effects for horsepower, and uncorrelated random effect for intercept and horsepower grouped by the engine type.

```
lme = fitlme(tbl, 'CityMPG~Horsepower+(1|EngineType)+(Horsepower-1|EngineType)');
```

In this model, `CityMPG` is the response variable, `horsepower` is the predictor variable, and engine type is the grouping variable. The fixed-effects portion of the model corresponds to `1 + Horsepower`, because the intercept is included by default.

Since the random-effect terms for intercept and horsepower are uncorrelated, these terms are specified separately. Because the second random-effect term is only for horsepower, you must include a `-1` to eliminate the intercept from the second random-effect term.

Display the model.

```
lme
```

```
lme =
Linear mixed-effects model fit by ML

'(Intercept)' '(Intercept)' 'std'      5.7338      2.3773

Upper
13.829

Group: EngineType (7 Levels)
Name1      Name2      Type      Estimate    Lower
'Horsepower' 'Horsepower' 'std'      0.050357    0.02307

Upper
0.10992

Group: Error
Name      Estimate    Lower    Upper
'Res Std' 3.226      2.9078   3.5789

```

Note that the random-effects covariance parameters for intercept and horsepower are separate in the display.

Now, fit a linear mixed-effects model for miles per gallon in the city, with the same fixed-effects term and potentially correlated random effect for intercept and horsepower grouped by the engine type.

```
lme2 = fitlme(tbl, 'CityMPG~Horsepower+(Horsepower|EngineType)');
```

Because the random-effect term includes the intercept by default, you do not have to add 1, the random effect term is equivalent to (1 + Horsepower|EngineType).

Display the model.

```

Note that the random effects covariance parameters for intercept and horsepower are together in the display, and it includes the correlation ('corr') between the intercept and horsepower.

Fit Random Intercept LME Model

Load the sample data.

```
load flu
```

The `flu` dataset array has a `Date` variable, and 10 variables containing estimated influenza rates (in 9 different regions, estimated from Google® searches, plus a nationwide estimate from the Centers for Disease Control and Prevention, CDC).

To fit a linear-mixed effects model, your data must be in a properly formatted dataset array. To fit a linear mixed-effects model with the influenza rates as the responses, combine the nine columns corresponding to the regions into an array. The new dataset array, `flu2`, must have the new response variable `FluRate`, the nominal variable `Region` that shows which region each estimate is from, the nationwide estimate `WtdILI`, and the grouping variable `Date`.

```
flu2 = stack(flu,2:10,'NewDataVarName','FluRate', ...
            'IndVarName','Region');
flu2.Date = nominal(flu2.Date);
```

Display the first six rows of `flu2`.

```
flu2(1:6,:)
```

```
ans =
    Date          WtdILI      Region      FluRate
    10/9/2005     1.182      NE          0.97
    10/9/2005     1.182      MidAtl     1.025
    10/9/2005     1.182      ENCentral  1.232
    10/9/2005     1.182      WNCentral  1.286
    10/9/2005     1.182      SAtl      1.082
    10/9/2005     1.182      ESCentral  1.457
```

Fit a linear mixed-effects model with a fixed-effects term for the nationwide estimate, `WtdILI`, and a random intercept that varies by `Date`. The model corresponds to

$$y_{im} = \beta_0 + \beta_1 \text{WtdILI}_{im} + b_{0m} + \varepsilon_{im}, \quad i = 1, 2, \dots, 468, \quad m = 1, 2, \dots, 52,$$

where y_{im} is the observation i for level m of grouping variable `Date`, b_{0m} is the random effect for level m of the grouping variable `Date`, and ε_{im} is the observation error for observation i . The random effect has the prior distribution,

$$b_{0m} \sim N(0, \sigma_b^2),$$

and the error term has the distribution,

$$\varepsilon_{im} \sim N(0, \sigma^2).$$

```
lme = fitlme(flu2, 'FluRate ~ 1 + WtdILI + (1|Date)')
```

```
lme =
```

```

Random effects covariance parameters (95% CIs):

Group: Date (52 Levels)

Name1	Name2	Type	Estimate	Lower
'(Intercept)'	'(Intercept)'	'std'	0.17146	0.13227
Upper				
0.22226				

Group: Error

Name	Estimate	Lower	Upper
'Res Std'	0.30201	0.28217	0.32324

Estimated covariance parameters are displayed in the section titled "Random effects covariance parameters". The estimated value of σ_b is 0.17146 and its 95% confidence interval is [0.13227, 0.22226]. Since this interval does not include 0, the random-effects term is significant. You can formally test the significance of any random-effects term using a likelihood ratio test via the `compare` method.

The estimated response at an observation is the sum of the fixed effects and the random-effect value at the grouping variable level corresponding to that observation. For example, the estimated flu rate for observation 28 is

$$\begin{aligned}\hat{y}_{28} &= \hat{\beta}_0 + \hat{\beta}_1 \text{WtdILI}_{28} + \hat{b}_{10/30/2005} \\ &= 0.1639 + 0.7236 * (1.343) + 0.3318 \\ &= 1.46749,\end{aligned}$$

where \hat{b} is the estimated best linear unbiased predictor (BLUP) of the random effects for the intercept. You can compute this value as follows.

```
beta = fixedEffects(lme);
[~,~,STATS] = randomEffects(lme); % Compute the random-effects statistics (STATS)
STATS.Level = nominal(STATS.Level);
y_hat = beta(1) + beta(2)*flu2.WtdILI(28) + STATS.Estimate(STATS.Level=='10/30/2005')
y_hat = 1.4674
```

You can display the fitted value using the `fitted` method.

```
F = fitted(lme);
F(28)
```

```
ans = 1.4674
```

LME Model for Randomized Block Design

Load the sample data.

```
load(fullfile(matlabroot, 'examples', 'stats', 'shift.mat'))
```

The data shows the absolute deviations from the target quality characteristic measured from the products each of five operators manufacture during three shifts: morning, evening, and night. This is a randomized block design, where the operators are the blocks. The experiment is designed to study the impact of the time of shift on the performance. The performance measure is the absolute deviations of the quality characteristics from the target value. This is simulated data.

Fit a linear mixed-effects model with a random intercept grouped by operator to assess if performance significantly differs according to the time of the shift. Use the restricted maximum likelihood method and 'effects' contrasts.

'effects' contrasts mean that the coefficients sum to 0, and `fitlme` creates a matrix called a *fixed effects design matrix* to describe the effect of shift. This matrix has two columns, `Shift_Evening` and `Shift_Morning`, where

$$\text{Shift_Evening} = \begin{cases} 0, & \text{if Morning} \\ 1, & \text{if Evening} \\ -1, & \text{if Night} \end{cases}$$

$$\text{Shift_Morning} = \begin{cases} 1, & \text{if Morning} \\ 0, & \text{if Evening} \\ -1, & \text{if Night} \end{cases}$$

The model corresponds to

$$\text{Morning Shift: } \text{QCDev}_{im} = \beta_0 + \beta_2 \text{Shift_Morning}_i + b_{0m} + \epsilon_{im},$$

$$\text{Evening Shift: } \text{QCDev}_{im} = \beta_0 + \beta_1 \text{Shift_Evening}_i + b_{0m} + \epsilon_{im},$$

$$\text{Night Shift: } \text{QCDev}_{im} = \beta_0 - \beta_1 \text{Shift_Evening}_i - \beta_2 \text{Shift_Morning}_i + b_{0m} + \epsilon_{im},$$

where i represents the observations, and m represents the operators, $i = 1, 2, \dots, 15$, and $m = 1, 2, \dots, 5$. The random effects and the observation error have the following distributions:

$$b_{0m} \sim N(0, \sigma_b^2)$$

and

$$\varepsilon_{im} \sim N(0, \sigma^2).$$

```
lme = fitlme(shift, 'QCDev ~ Shift + (1|Operator)', ...
'FitMethod', 'REML', 'DummyVarCoding', 'effects')
```

Compute the best linear unbiased predictor (BLUP) estimates of random effects.

```
B = randomEffects(lme)
```

```
B = 5×1
```

```
 0.5775  
 1.1757  
-2.1715  
 2.3655  
-1.9472
```

The estimated absolute deviation from the target quality characteristics for the third operator working the evening shift is

$$\begin{aligned}\hat{Y}_{\text{Evening, Operator3}} &= \hat{\beta}_0 + \hat{\beta}_1 \text{Shift_Evening} + \hat{b}_{03} \\ &= 3.6525 - 0.53293 - 2.1715 \\ &= 0.94807.\end{aligned}$$

You can also display this value as follows.

```
F = fitted(lme);  
F(shift.Shift=='Evening' & shift.Operator=='3')  
ans = 0.9481
```

Similarly, you can calculate the estimated absolute deviation from the target quality characteristics for the third operator working the morning shift as

$$\begin{aligned}\hat{Y}_{\text{Morning, Operator3}} &= \hat{\beta}_0 + \hat{\beta}_2 \text{Shift_Morning} + \hat{b}_{03} \\ &= 3.6525 - 0.91973 - 2.1715 \\ &= 0.56127.\end{aligned}$$

You can also display this value as follows.

```
F(shift.Shift=='Morning' & shift.Operator=='3')
ans = 0.5613
```

The operator tends to make a smaller magnitude of error during the morning shift.

LME Model for Split-Plot Experiment

Load the sample data.

```
load(fullfile(matlabroot, 'examples', 'stats', 'fertilizer.mat'))
```

The dataset array includes data from a split-plot experiment, where soil is divided into three blocks based on the soil type: sandy, silty, and loamy. Each block is divided into five plots, where five types of tomato plants (cherry, heirloom, grape, vine, and plum) are randomly assigned to these plots. The tomato plants in the plots are then divided into subplots, where each subplot is treated by one of four fertilizers. This is simulated data.

Store the data in a dataset array called `ds`, and define `Tomato`, `Soil`, and `Fertilizer` as categorical variables.

```
ds = fertilizer;
ds.Tomato = nominal(ds.Tomato);
ds.Soil = nominal(ds.Soil);
ds.Fertilizer = nominal(ds.Fertilizer);
```

Fit a linear mixed-effects model, where `Fertilizer` and `Tomato` are the fixed-effects variables, and the mean yield varies by the block (soil type) and the plots within blocks (tomato types within soil types) independently.

This model corresponds to

$$y_{imjk} = \beta_0 + \sum_{m=2}^4 \beta_{1m} I[F]_{im} + \sum_{j=2}^5 \beta_{2j} I[T]_{ij} + \sum_{j=2}^5 \sum_{m=2}^4 \beta_{3mj} I[F]_{im} I[T]_{ij} + b_{0k} S_k + b_{0jk} (S * T)_{jk} + \varepsilon_{imjk},$$

where $i = 1, 2, \dots, 60$, index m corresponds to the fertilizer types, j corresponds to the tomato types, and $k = 1, 2, 3$ corresponds to the blocks (soil). S_k represents the k th soil

type, and $(S*T)_{jk}$ represents the j th tomato type nested in the k th soil type. $I[F]_{im}$ is the dummy variable representing level m of the fertilizer. Similarly, $I[T]_{ij}$ is the dummy variable representing level j of the tomato type.

The random effects and observation error have these prior distributions: $b_{0k} \sim N(0, \sigma_S^2)$, $b_{0jk} \sim N(0, \sigma_{S*T}^2)$, and $\epsilon_{imjk} \sim N(0, \sigma^2)$.

```
lme = fitlme(ds, 'Yield ~ Fertilizer * Tomato + (1|Soil) + (1|Soil:Tomato)')
```

```
lme =  
Linear mixed-effects model fit by ML

```

The p -values corresponding to the last 12 rows in the fixed-effects coefficients display (0.82701 to 0.47881) indicate that interaction coefficients between the tomato and fertilizer types are not significant. To test for the overall interaction between tomato and fertilizer, use the `anova` method after refitting the model using 'effects' contrasts.

The confidence interval for the standard deviations of the random-effects terms (σ_S^2), where the intercept is grouped by soil, is very large. This term does not appear significant.

Refit the model after removing the interaction term `Tomato:Fertilizer` and the random-effects term (`1 | Soil`).

You can compare the two models using the `compare` method with the simulated likelihood ratio test since both a fixed-effect and a random-effect term are tested.

Longitudinal Study with a Covariate

Load the sample data.

```
load(fullfile(matlabroot, 'examples', 'stats', 'weight.mat'))
```

`weight` contains data from a longitudinal study, where 20 subjects are randomly assigned to 4 exercise programs (A, B, C, D), and their weight loss is recorded over six 2-week time periods. This is simulated data.

Store the data in a table. Define `Subject` and `Program` as categorical variables.

```
tbl = table(InitialWeight,Program,Subject,Week,y);
tbl.Subject = nominal(tbl.Subject);
tbl.Program = nominal(tbl.Program);
```

Fit a linear mixed-effects model where the initial weight, type of program, week, and the interaction between the week and type of program are the fixed effects. The intercept and week vary by subject.

`fitlme` uses program A as a reference and creates the necessary dummy variables $I[\cdot]$. Since the model already has an intercept, `fitlme` only creates dummy variables for programs B, C, and D. This is also known as the 'reference' method of coding dummy variables.

This model corresponds to

$$y_{im} = \beta_0 + \beta_1 IW_i + \beta_2 \text{Week}_i + \beta_3 I[\text{PB}]_i + \beta_4 I[\text{PC}]_i + \beta_5 I[\text{PD}]_i \\ + \beta_6 (\text{Week}_i * I[\text{PB}]_i) + \beta_7 (\text{Week}_i * I[\text{PC}]_i) + \beta_8 (\text{Week}_i * I[\text{PD}]_i) \\ + b_{0m} + b_{1m} \text{Week}_{im} + \varepsilon_{im},$$

where $i = 1, 2, \dots, 120$, and $m = 1, 2, \dots, 20$. β_j are the fixed-effects coefficients, $j = 0, 1, \dots, 8$, and b_{0m} and b_{1m} are random effects. IW stands for initial weight and $I[\cdot]$ is a dummy variable representing a type of program. For example, $I[\text{PB}]_i$ is the dummy variable representing program type B. The random effects and observation error have the following prior distributions:

$$b_{0m} \sim N(0, \sigma_0^2)$$

$$b_{1m} \sim N(0, \sigma_1^2)$$

$$\varepsilon_{im} \sim N(0, \sigma^2).$$

```
lme = fitlme(tbl, 'y ~ InitialWeight + Program*Week + (Week|Subject)')
```

```
lme =  
Linear mixed-effects model fit by ML
```

```
Model information:
```

Number of observations	120

0.20537

Group: Error			
Name	Estimate	Lower	Upper
'Res Std'	0.10261	0.087882	0.11981

The p -values 0.022863 and 0.011567 indicate significant effects of subject initial weights and time in the amount of weight lost. The weight loss of subjects who are in program B is significantly different relative to the weight loss of subjects who are in program A. The lower and upper limits of the covariance parameters for the random effects do not include 0, thus they are significant. You can also test the significance of the random effects using the `compare` method.

Input Arguments

tbl — Input data

table | dataset array

Input data, which includes the response variable, predictor variables, and grouping variables, specified as a table or dataset array. The predictor variables can be continuous or grouping variables (see “Grouping Variables” on page 2-57). You must specify the model for the variables using `formula`.

Data Types: table

formula — Formula for model specification

character vector or string scalar of the form `'y ~ fixed + (random1|grouping1) + ... + (randomR|groupingR)'`

Formula for model specification, specified as a character vector or string scalar of the form `'y ~ fixed + (random1|grouping1) + ... + (randomR|groupingR)'`. The formula is case sensitive. For a full description, see “Formula” on page 32-2293.

Example: `'y ~ treatment + (1|block)'`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes.

You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example:

`'CovariancePattern', 'Diagonal', 'Optimizer', 'fminunc', 'OptimizerOptions'`, `opt` specifies a model, where the random-effects terms have a diagonal covariance matrix structure, and `fitlme` uses the `fminunc` optimization algorithm with the custom optimization parameters defined in variable `opt`.

CovariancePattern — Pattern of covariance matrix

`'FullCholesky'` (default) | character vector | string scalar | square symmetric logical matrix | string array | cell array of character vectors or logical matrices

Pattern of the covariance matrix of the random effects, specified as the comma-separated pair consisting of `'CovariancePattern'` and a character vector, a string scalar, a square symmetric logical matrix, a string array, or a cell array of character vectors or logical matrices.

If there are R random-effects terms, then the value of `'CovariancePattern'` must be a string array or cell array of length R , where each element r of the array specifies the pattern of the covariance matrix of the random-effects vector associated with the r th random-effects term. The options for each element follow.

<code>'FullCholesky'</code>	Default. Full covariance matrix using the Cholesky parameterization. <code>fitlme</code> estimates all elements of the covariance matrix.
<code>'Full'</code>	Full covariance matrix, using the log-Cholesky parameterization. <code>fitlme</code> estimates all elements of the covariance matrix.
<code>'Diagonal'</code>	Diagonal covariance matrix. That is, off-diagonal elements of the covariance matrix are constrained to be 0.

$$\begin{pmatrix} \sigma_{b_1}^2 & 0 & 0 \\ 0 & \sigma_{b_2}^2 & 0 \\ 0 & 0 & \sigma_{b_3}^2 \end{pmatrix}$$

'Isotropic'

Diagonal covariance matrix with equal variances. That is, off-diagonal elements of the covariance matrix are constrained to be 0, and the diagonal elements are constrained to be equal. For example, if there are three random-effects terms with an isotropic covariance structure, this covariance matrix looks like

$$\begin{pmatrix} \sigma_b^2 & 0 & 0 \\ 0 & \sigma_b^2 & 0 \\ 0 & 0 & \sigma_b^2 \end{pmatrix}$$

where σ_b^2 is the common variance of the random-effects terms.

'CompSymm'

Compound symmetry structure. That is, common variance along diagonals and equal correlation between all random effects. For example, if there are three random-effects terms with a covariance matrix having a compound symmetry structure, this covariance matrix looks like

$$\begin{pmatrix} \sigma_{b1}^2 & \sigma_{b1,b2} & \sigma_{b1,b2} \\ \sigma_{b1,b2} & \sigma_{b1}^2 & \sigma_{b1,b2} \\ \sigma_{b1,b2} & \sigma_{b1,b2} & \sigma_{b1}^2 \end{pmatrix}$$

where σ_{b1}^2 is the common variance of the random-effects terms and $\sigma_{b1,b2}$ is the common covariance between any two random-effects term .

PAT Square symmetric logical matrix. If 'CovariancePattern' is defined by the matrix PAT, and if $PAT(a,b) = \text{false}$, then the (a,b) element of the corresponding covariance matrix is constrained to be 0.

Example: 'CovariancePattern', 'Diagonal'

Example: 'CovariancePattern', {'Full', 'Diagonal'}

Data Types: char | string | logical | cell

FitMethod — Method for estimating parameters

'ML' (default) | 'REML'

Method for estimating parameters of the linear mixed-effects model, specified as the comma-separated pair consisting of 'FitMethod' and either of the following.

'ML'	Default. Maximum likelihood estimation
'REML'	Restricted maximum likelihood estimation

Example: 'FitMethod', 'REML'

Weights — Observation weights

vector of scalar values

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a vector of length n , where n is the number of observations.

Data Types: single | double

Exclude — Indices for rows to exclude

use all rows without NaNs (default) | vector of integer or logical values

Indices for rows to exclude from the linear mixed-effects model in the data, specified as the comma-separated pair consisting of 'Exclude' and a vector of integer or logical values.

For example, you can exclude the 13th and 67th rows from the fit as follows.

Example: 'Exclude', [13,67]

Data Types: single | double | logical

DummyVarCoding — Coding to use for dummy variables`'reference' (default) | 'effects' | 'full'`

Coding to use for dummy variables created from the categorical variables, specified as the comma-separated pair consisting of `'DummyVarCoding'` and one of the following.

Value	Description
<code>'reference'</code>	Default. Coefficient for first category set to 0.
<code>'effects'</code>	Coefficients sum to 0.
<code>'full'</code>	One dummy variable for each category.

Example: `'DummyVarCoding','effects'`

Optimizer — Optimization algorithm`'quasinevton' (default) | 'fminunc'`

Optimization algorithm, specified as the comma-separated pair consisting of `'Optimizer'` and either of the following.

<code>'quasinevton'</code>	Default. Uses a trust region based quasi-Newton optimizer. Change the options of the algorithm using <code>statset('LinearMixedModel')</code> . If you don't specify the options, then <code>LinearMixedModel</code> uses the default options of <code>statset('LinearMixedModel')</code> .
<code>'fminunc'</code>	You must have Optimization Toolbox to specify this option. Change the options of the algorithm using <code>optimoptions('fminunc')</code> . If you don't specify the options, then <code>LinearMixedModel</code> uses the default options of <code>optimoptions('fminunc')</code> with <code>'Algorithm'</code> set to <code>'quasinevton'</code> .

Example: `'Optimizer','fminunc'`

OptimizerOptions — Options for optimization algorithm

structure returned by `statset` | object returned by `optimoptions`

Options for the optimization algorithm, specified as the comma-separated pair consisting of `'OptimizerOptions'` and a structure returned by `statset('LinearMixedModel')` or an object returned by `optimoptions('fminunc')`.

- If `'Optimizer'` is `'fminunc'`, then use `optimoptions('fminunc')` to change the options of the optimization algorithm. See `optimoptions` for the options `'fminunc'` uses. If `'Optimizer'` is `'fminunc'` and you do not supply `'OptimizerOptions'`, then the default for `LinearMixedModel` is the default options created by `optimoptions('fminunc')` with `'Algorithm'` set to `'quasi-newton'`.
- If `'Optimizer'` is `'quasinevton'`, then use `statset('LinearMixedModel')` to change the optimization parameters. If you don't change the optimization parameters, then `LinearMixedModel` uses the default options created by `statset('LinearMixedModel')`:

The `'quasinevton'` optimizer uses the following fields in the structure created by `statset('LinearMixedModel')`.

ToIFun — Relative tolerance on gradient of objective function

1e-6 (default) | positive scalar value

Relative tolerance on the gradient of the objective function, specified as a positive scalar value.

ToIX — Absolute tolerance on step size

1e-12 (default) | positive scalar value

Absolute tolerance on the step size, specified as a positive scalar value.

MaxIter — Maximum number of iterations allowed

10000 (default) | positive scalar value

Maximum number of iterations allowed, specified as a positive scalar value.

Display — Level of display

'off' (default) | 'iter' | 'final'

Level of display, specified as one of `'off'`, `'iter'`, or `'final'`.

StartMethod — Method to start iterative optimization`'default' (default) | 'random'`

Method to start iterative optimization, specified as the comma-separated pair consisting of `'StartMethod'` and either of the following.

Value	Description
<code>'default'</code>	An internally defined default value
<code>'random'</code>	A random initial value

Example: `'StartMethod', 'random'`

Verbose — Indicator to display optimization process on screen`false (default) | true`

Indicator to display the optimization process on screen, specified as the comma-separated pair consisting of `'Verbose'` and either `false` or `true`. Default is `false`.

The setting for `'Verbose'` overrides the field `'Display'` in `'OptimizerOptions'`.

Example: `'Verbose', true`

CheckHessian — Indicator to check positive definiteness of Hessian`false (default) | true`

Indicator to check the positive definiteness of the Hessian of the objective function with respect to unconstrained parameters at convergence, specified as the comma-separated pair consisting of `'CheckHessian'` and either `false` or `true`. Default is `false`.

Specify `'CheckHessian'` as `true` to verify optimality of the solution or to determine if the model is overparameterized in the number of covariance parameters.

Example: `'CheckHessian', true`

Output Arguments

lme — Linear mixed-effects model`LinearMixedModel` object

Linear mixed-effects model, returned as a `LinearMixedModel` object.

Definitions

Formula

In general, a formula for model specification is a character vector or string scalar of the form 'y ~ terms'. For the linear mixed-effects models, this formula is in the form 'y ~ fixed + (random1|grouping1) + ... + (randomR|groupingR)', where `fixed` and `random` contain the fixed-effects and the random-effects terms.

Suppose a table `tbl` contains the following:

- A response variable, `y`
- Predictor variables, `Xj`, which can be continuous or grouping variables
- Grouping variables, `g1`, `g2`, ..., `gR`,

where the grouping variables in `Xj` and `gr` can be categorical, logical, character arrays, string arrays, or cell arrays of character vectors.

Then, in a formula of the form, 'y ~ fixed + (random₁|g₁) + ... + (random_R|g_R)', the term `fixed` corresponds to a specification of the fixed-effects design matrix `X`, `random1` is a specification of the random-effects design matrix `Z1` corresponding to grouping variable `g1`, and similarly `randomR` is a specification of the random-effects design matrix `ZR` corresponding to grouping variable `gR`. You can express the `fixed` and `random` terms using Wilkinson notation.

Wilkinson notation describes the factors present in models. The notation relates to factors present in models, not to the multipliers (coefficients) of those factors.

Wilkinson Notation	Factors in Standard Notation
1	Constant (intercept) term
X ^k , where k is a positive integer	X, X ² , ..., X ^k
X1 + X2	X1, X2
X1*X2	X1, X2, X1.*X2 (elementwise multiplication of X1 and X2)
X1:X2	X1.*X2 only
- X2	Do not include X2

Wilkinson Notation	Factors in Standard Notation
$X1 * X2 + X3$	X1, X2, X3, X1*X2
$X1 + X2 + X3 + X1 : X2$	X1, X2, X3, X1*X2
$X1 * X2 * X3 - X1 : X2 : X3$	X1, X2, X3, X1*X2, X1*X3, X2*X3
$X1 * (X2 + X3)$	X1, X2, X3, X1*X2, X1*X3

Statistics and Machine Learning Toolbox notation always includes a constant term unless you explicitly remove the term using -1. Here are some examples for linear mixed-effects model specification.

Examples:

Formula	Description
'y ~ X1 + X2'	Fixed effects for the intercept, X1 and X2. This is equivalent to 'y ~ 1 + X1 + X2'.
'y ~ -1 + X1 + X2'	No intercept and fixed effects for X1 and X2. The implicit intercept term is suppressed by including -1.
'y ~ 1 + (1 g1)'	Fixed effects for the intercept plus random effect for the intercept for each level of the grouping variable g1.
'y ~ X1 + (1 g1)'	Random intercept model with a fixed slope.
'y ~ X1 + (X1 g1)'	Random intercept and slope, with possible correlation between them. This is equivalent to 'y ~ 1 + X1 + (1 + X1 g1)'.
'y ~ X1 + (1 g1) + (-1 + X1 g1)'	Independent random effects terms for intercept and slope.
'y ~ 1 + (1 g1) + (1 g2) + (1 g1:g2)'	Random intercept model with independent main effects for g1 and g2, plus an independent interaction effect.

Cholesky Parameterization

One of the assumptions of linear mixed-effects models is that the random effects have the following prior distribution.

$$b \sim N(0, \sigma^2 D(\theta)),$$

where D is a q -by- q symmetric and positive semidefinite matrix, parameterized by a variance component vector θ , q is the number of variables in the random-effects term, and σ^2 is the observation error variance. Since the covariance matrix of the random effects, D , is symmetric, it has $q(q+1)/2$ free parameters. Suppose L is the lower triangular Cholesky factor of $D(\theta)$ such that

$$D(\theta) = L(\theta)L(\theta)^T,$$

then the $q^*(q+1)/2$ -by-1 unconstrained parameter vector θ is formed from elements in the lower triangular part of L .

For example, if

$$L = \begin{bmatrix} L_{11} & 0 & 0 \\ L_{21} & L_{22} & 0 \\ L_{31} & L_{32} & L_{33} \end{bmatrix},$$

then

$$\theta = \begin{bmatrix} L_{11} \\ L_{21} \\ L_{31} \\ L_{22} \\ L_{32} \\ L_{33} \end{bmatrix}.$$

Log-Cholesky Parameterization

When the diagonal elements of L in Cholesky parameterization are constrained to be positive, then the solution for L is unique. Log-Cholesky parameterization is the same as Cholesky parameterization except that the logarithm of the diagonal elements of L are used to guarantee unique parameterization.

For example, for the 3-by-3 example in Cholesky parameterization, enforcing $L_{ii} \geq 0$,

$$\theta = \begin{bmatrix} \log(L_{11}) \\ L_{21} \\ L_{31} \\ \log(L_{22}) \\ L_{32} \\ \log(L_{33}) \end{bmatrix}.$$

Alternatives

If your model is not easily described using a formula, you can create matrices to define the fixed and random effects, and fit the model using `fitlmematrix(X,y,Z,G)`.

fitlmematrix

Fit linear mixed-effects model

Syntax

```
lme = fitlmematrix(X,y,Z,[])  
lme = fitlmematrix(X,y,Z,G)  
lme = fitlmematrix( ____,Name,Value)
```

Description

`lme = fitlmematrix(X,y,Z,[])` creates a linear mixed-effects model of the responses `y` using the fixed-effects design matrix `X` and random-effects design matrix or matrices in `Z`.

`[]` implies that there is one group. That is, the grouping variable `G` is `ones(n,1)`, where `n` is the number of observations. Using `fitlmematrix(X,Y,Z,[])` without a specified covariance pattern most likely results in a nonidentifiable model. This syntax is recommended only if you build the grouping information into the random effects design `Z` and specify a covariance pattern for the random effects using the 'CovariancePattern' name-value pair argument.

`lme = fitlmematrix(X,y,Z,G)` creates a linear mixed-effects model of the responses `y` using the fixed-effects design matrix `X` and random-effects design matrix `Z` or matrices in `Z`, and the grouping variable or variables in `G`.

`lme = fitlmematrix(____,Name,Value)` also creates a linear mixed-effects model with additional options specified by one or more `Name,Value` pair arguments, using any of the previous input arguments.

For example, you can specify the names of the response, predictor, and grouping variables. You can also specify the covariance pattern, fitting method, or the optimization algorithm.

Examples

No Grouping Variable Specified

Load the sample data.

```
load carsmall
```

Fit a linear mixed-effects model, where miles per gallon (MPG) is the response, weight is the predictor variable, and the intercept varies by model year. First, define the design matrices. Then, fit the model using the specified design matrices.

```
y = MPG;  
X = [ones(size(Weight)), Weight];  
Z = ones(size(y));  
lme = fitlmematrix(X,y,Z,Model_Year)
```

```
lme =  
Linear mixed-effects model fit by ML
```

Model information:

Number of observations	94

Longitudinal Study with a Covariate

Load the sample data.

```
load(fullfile(matlabroot, 'examples', 'stats', 'weight.mat'));
```

`weight` contains data from a longitudinal study, where 20 subjects are randomly assigned 4 exercise programs (A, B, C, D) and their weight loss is recorded over six 2-week time periods. This is simulated data.

Define `Subject` and `Program` as categorical variables. Create the design matrices for a linear mixed-effects model, with the initial weight, type of program, week, and the interaction between the week and type of program as the fixed effects. The intercept and coefficient of week vary by subject.

This model corresponds to

$$\begin{aligned} y_{im} = & \beta_0 + \beta_1 IW_i + \beta_2 \text{Week}_i + \beta_3 I[\text{PB}]_i + \beta_4 I[\text{PC}]_i + \beta_5 I[\text{PD}]_i \\ & + \beta_6 (\text{Week}_i * I[\text{PB}]_i) + \beta_7 (\text{Week}_i * I[\text{PC}]_i) + \beta_8 (\text{Week}_i * I[\text{PD}]_i) \\ & + b_{0m} + b_{1m} \text{Week}_{im} + \varepsilon_{im}, \end{aligned}$$

where $i = 1, 2, \dots, 120$, and $m = 1, 2, \dots, 20$. β_j are the fixed-effects coefficients, $j = 0, 1, \dots, 8$, and b_{0m} and b_{1m} are random effects. `IW` stands for initial weight and $I[\cdot]$ is a dummy variable representing a type of program. For example, $I[\text{PB}]_i$ is the dummy variable representing program type B. The random effects and observation error have the following prior distributions:

$$b_{0m} \sim N(0, \sigma_0^2)$$

$$b_{1m} \sim N(0, \sigma_1^2)$$

$$\varepsilon_{im} \sim N(0, \sigma^2).$$

```

Subject = nominal(Subject);
Program = nominal(Program);
D = dummyvar(Program); % Create dummy variables for Program
X = [ones(120,1), InitialWeight, D(:,2:4), Week, ...
     D(:,2).*Week, D(:,3).*Week, D(:,4).*Week];
Z = [ones(120,1), Week];
G = Subject;

```

Since the model has an intercept, you only need the dummy variables for programs B, C, and D. This is also known as the 'reference' method of coding dummy variables.

Fit the model using `fitlmematrix` with the defined design matrices and grouping variables.

```

lme = fitlmematrix(X,y,Z,G,'FixedEffectPredictors',...
{'Intercept','InitWeight','PrgB','PrgC','PrgD','Week','Week_PrgB','Week_PrgC','Week_PrgD',
'RandomEffectPredictors',{{'Intercept','Week'}},'RandomEffectGroups',{'Subject'})

```

```

Examine the fixed effects coefficients table. The row labeled 'InitWeight' has a *p*-value of 0.0228, and the row labeled 'Week' has a *p*-value of 0.0115. These *p*-values indicate significant effects of the initial weights of the subjects and the time factor in the amount of weight lost. The weight loss of subjects who are in program B is significantly different relative to the weight loss of subjects who are in program A. The lower and upper limits of the covariance parameters for the random effects do not include zero, thus they seem significant. You can also test the significance of the random-effects using the compare method.

Random Intercept Model

Load the sample data.

```
load flu
```

The `flu` dataset array has a `Date` variable, and 10 variables for estimated influenza rates (in 9 different regions, estimated from Google® searches, plus a nationwide estimate from the Centers for Disease Control and Prevention, CDC).

To fit a linear-mixed effects model, where the influenza rates are the responses, combine the nine columns corresponding to the regions into an array that has a single response variable, `FluRate`, and a nominal variable, `Region`, the nationwide estimate `WtdILI`, that shows which region each estimate is from, and the grouping variable `Date`.

```
flu2 = stack(flu,2:10, 'NewDataVarName', 'FluRate', ...
            'IndVarName', 'Region');
flu2.Date = nominal(flu2.Date);
```

Define the design matrices for a random-intercept linear mixed-effects model, where the intercept varies by `Date`. The corresponding model is

$$y_{im} = \beta_0 + \beta_1 \text{WtdILI}_{im} + b_{0m} + \varepsilon_{im}, \quad i = 1, 2, \dots, 468, \quad m = 1, 2, \dots, 52,$$

where y_{im} is the observation i for level m of grouping variable `Date`, b_{0m} is the random effect for level m of the grouping variable `Date`, and ε_{im} is the observation error for observation i . The random effect has the prior distribution,

$$b_{0m} \sim N(0, \sigma_b^2),$$

and the error term has the distribution,

$$\varepsilon_{im} \sim N(0, \sigma^2).$$

```
y = flu2.FluRate;
X = [ones(468,1) flu2.WtdILI];
Z = [ones(468,1)];
G = flu2.Date;
```

Fit the linear mixed-effects model.

```
lme = fitlmematrix(X,y,Z,G, 'FixedEffectPredictors', {'Intercept', 'NationalRate'}, ...
                  'RandomEffectPredictors', {'Intercept'}, 'RandomEffectGroups', {'Date'})
```

```

lme =
Linear mixed-effects model fit by ML

Model information:
  Number of observations      468
  Fixed effects coefficients    2
  Random effects coefficients  52
  Covariance parameters       2

Formula:
  y ~ Intercept + NationalRate + (Intercept | Date)

Model fit statistics:
  AIC      BIC      LogLikelihood  Deviance
  286.24   302.83   -139.12      278.24

  'NationalRate'    0.7236    0.032219   22.459   466     3.0502e-76

  Lower      Upper
  0.050813   0.27689
  0.66028    0.78691

Random effects covariance parameters (95% CIs):
Group: Date (52 Levels)
  Name1          Name2          Type          Estimate    Lower
  'Intercept'    'Intercept'    'std'         0.17146     0.13227

  Upper
  0.22226

Group: Error
  Name          Estimate    Lower    Upper
  'Res Std'     0.30201    0.28217  0.32324

```

The confidence limits of the standard deviation of the random-effects term σ_b , do not include zero (0.13227, 0.22226), which indicates that the random-effects term is significant. You can also test the significance of the random-effects using `compare` method.

The estimated value of an observation is the sum of the fixed-effects values and value of the random effect at the grouping variable level corresponding to that observation. For example, the estimated flu rate for observation 28

$$\begin{aligned}\hat{y}_{28} &= \hat{\beta}_0 + \hat{\beta}_1 \text{WtdILI}_{28} + \hat{b}_{10/30/2005} \\ &= 0.1639 + 0.7236 * (1.343) + 0.3318 \\ &= 1.46749,\end{aligned}$$

where \hat{b} is the best linear unbiased predictor (BLUP) of the random effects for the intercept. You can compute this value as follows.

```
beta = fixedEffects(lme);
[~,~,STATS] = randomEffects(lme); % compute the random effects statistics STATS
STATS.Level = nominal(STATS.Level);
y_hat = beta(1) + beta(2)*flu2.WtdILI(28) + STATS.Estimate(STATS.Level=='10/30/2005')
y_hat = 1.4674
```

You can simply display the fitted value using the `fitted(lme)` method.

```
F = fitted(lme);
F(28)
ans = 1.4674
```

Randomized Block Design

Load the sample data.

```
load(fullfile(matlabroot,'examples','stats','shift.mat'));
```

The data shows the deviations from the target quality characteristic measured from the products that five operators manufacture during three shifts: morning, evening, and night. This is a randomized block design, where the operators are the blocks. The experiment is designed to study the impact of the time of shift on the performance. The performance measure is the deviations of the quality characteristics from the target value. This is simulated data.

Define the design matrices for a linear mixed-effects model with a random intercept grouped by operator, and shift as the fixed effects. Use the 'effects' contrasts.

'effects' contrasts mean that the coefficients sum to 0. You need to create two contrast coded variables in the fixed-effects design matrix, X1 and X2, where

$$\text{Shift_Evening} = \begin{cases} 0, & \text{if Morning} \\ 1, & \text{if Evening} \\ -1, & \text{if Night} \end{cases}$$

$$\text{Shift_Morning} = \begin{cases} 1, & \text{if Morning} \\ 0, & \text{if Evening} \\ -1, & \text{if Night} \end{cases}$$

The model corresponds to

$$\text{Morning Shift: } \text{QCDev}_{im} = \beta_0 + \beta_2 \text{Shift_Morning}_i + b_{0m} + \epsilon_{im},$$

$$\text{Evening Shift: } \text{QCDev}_{im} = \beta_0 + \beta_1 \text{Shift_Evening}_i + b_{0m} + \epsilon_{im},$$

$$\text{Night Shift: } \text{QCDev}_{im} = \beta_0 - \beta_1 \text{Shift_Evening}_i - \beta_2 \text{Shift_Morning}_i + b_{0m} + \epsilon_{im},$$

where i represents the observations, and m represents the operators, $i = 1, 2, \dots, 15$, and $m = 1, 2, \dots, 5$. The random effects and the observation error have the following distributions:

$$b_{0m} \sim N(0, \sigma_b^2)$$

and

$$\epsilon_{im} \sim N(0, \sigma^2).$$

```
S = shift.Shift;
X1 = (S=='Morning') - (S=='Night');
X2 = (S=='Evening') - (S=='Night');
X = [ones(15,1), X1, X2];
y = shift.QCDev;
Z = ones(15,1);
G = shift.Operator;
```

Fit a linear mixed-effects model using the specified design matrices and restricted maximum likelihood method.

```
lme = fitlmematrix(X,y,Z,G,'FitMethod','REML','FixedEffectPredictors',...
{'Intercept','S_Morning','S_Evening'},'RandomEffectPredictors',{{'Intercept'}},...
'RandomEffectGroups',{'Operator'},'DummyVarCoding','effects')
```

```

The estimated deviation from the target quality characteristics for the third operator working the evening shift is

$$\begin{aligned}\hat{y}_{\text{Evening, Operator3}} &= \hat{\beta}_0 + \hat{\beta}_1 \text{Shift_Evening} + \hat{b}_{03} \\ &= 3.6525 - 0.53293 - 2.1715 \\ &= 0.94807.\end{aligned}$$

You can also display this value as follows.

```
F = fitted(lme);
F(shift.Shift=='Evening' & shift.Operator=='3')
ans = 0.9481
```

Correlated and Uncorrelated Random-Effects Terms

Load the sample data.

```
load carbig
```

Fit a linear mixed-effects model for miles per gallon (MPG), with fixed effects for acceleration and horsepower, and uncorrelated random effect for intercept and acceleration grouped by the model year. This model corresponds to

$$\text{MPG}_{im} = \beta_0 + \beta_1 \text{Acc}_i + \beta_2 \text{HP} + b_{0m} + b_{1m} \text{Acc}_{im} + \varepsilon_{im}, \quad m = 1, 2, 3,$$

with the random-effects terms having the following prior distributions:

$$b_{0m} \sim N(0, \sigma_0^2),$$

$$b_{1m} \sim N(0, \sigma_1^2),$$

where m represents the model year.

First, prepare the design matrices for fitting the linear mixed-effects model.

```
X = [ones(406,1) Acceleration Horsepower];
Z = {ones(406,1),Acceleration};
G = {Model_Year,Model_Year};
Model_Year = nominal(Model_Year);
```

Now, fit the model using `fitlmematrix` with the defined design matrices and grouping variables.

```
lme = fitlmematrix(X,MPG,Z,G,'FixedEffectPredictors',...
{'Intercept','Acceleration','Horsepower'},'RandomEffectPredictors',...
{'Intercept'},{'Acceleration'}},'RandomEffectGroups',{'Model_Year','Model_Year'})

lme =
Linear mixed-effects model fit by ML
```

Model information:

Number of observations	392
Fixed effects coefficients	3
Random effects coefficients	26
Covariance parameters	3

Formula:

Linear Mixed Formula with 4 predictors.

Model fit statistics:

AIC	BIC	LogLikelihood	Deviance
2194.5	2218.3	-1091.3	2182.5

Fixed effects coefficients (95% CIs):

Name	Estimate	SE	tStat	DF	pValue
'Intercept'	49.839	2.0518	24.291	389	5.6168e-80
'Acceleration'	-0.58565	0.10846	-5.3995	389	1.1652e-07
'Horsepower'	-0.16534	0.0071227	-23.213	389	1.9755e-75

Lower	Upper
45.806	53.873
-0.7989	-0.3724
-0.17934	-0.15133

Random effects covariance parameters (95% CIs):

```

Group: Model_Year (13 Levels)
  Name1          Name2          Type          Estimate      Lower
  'Intercept'    'Intercept'    'std'         8.928e-07     NaN

  Upper
  NaN

Group: Model_Year (13 Levels)
  Name1          Name2          Type          Estimate      Lower
  'Acceleration' 'Acceleration' 'std'         0.18783      0.12523

  Upper
  0.28172

  Name          Estimate      Lower      Upper
  'Res Std'     3.7258      3.4698    4.0007

```

Note that the random effects covariance parameters for intercept and acceleration are separate in the display. The standard deviation of the random effect for the intercept does not seem significant.

Refit the model with potentially correlated random effects for intercept and acceleration. In this case, the random-effects terms has this prior distribution

$$b_m = \begin{pmatrix} b_{0m} \\ b_{1m} \end{pmatrix} \sim N\left(0, \begin{pmatrix} \sigma_0^2 & \sigma_{0,1} \\ \sigma_{0,1} & \sigma_1^2 \end{pmatrix}\right),$$

where m represents the model year.

First, prepare the random-effects design matrix and grouping variable.

```

Z = [ones(406,1) Acceleration];
G = Model_Year;

lme = fitlmematrix(X,MPG,Z,G,'FixedEffectPredictors',...
{'Intercept','Acceleration','Horsepower'},'RandomEffectPredictors',...
{{'Intercept','Acceleration'}},'RandomEffectGroups',{'Model_Year'})

lme =
Linear mixed-effects model fit by ML

```

Model information:

Number of observations	392
Fixed effects coefficients	3
Random effects coefficients	26
Covariance parameters	4

Formula:

Linear Mixed Formula with 4 predictors.

Model fit statistics:

AIC	BIC	LogLikelihood	Deviance

0.1825	0.62558

Group: Error

Name	Estimate	Lower	Upper
'Res Std'	3.6874	3.4298	3.9644

Note that the random effects covariance parameters for intercept and acceleration are together in the display, with an addition of the correlation between the intercept and acceleration. The confidence intervals for the standard deviations and the correlation between the random effects for intercept and acceleration do not include 0s, hence they seem significant. You can compare these two models using the `compare` method.

Specify the Covariance Pattern

Load the sample data.

```
load(fullfile(matlabroot, 'examples', 'stats', 'weight.mat'));
```

`weight` contains data from a longitudinal study, where 20 subjects are randomly assigned 4 exercise programs, and their weight loss is recorded over six 2-week time periods. This is simulated data.

Define `Subject` and `Program` as categorical variables.

```
Subject = nominal(Subject);  
Program = nominal(Program);
```

Create the design matrices for a linear mixed-effects model, with the initial weight, type of program, and week as the fixed effects.

```
D = dummyvar(Program);  
X = [ones(120,1), InitialWeight, D(:,2:4), Week];  
Z = [ones(120,1) Week];  
G = Subject;
```

This model corresponds to

$$\begin{aligned} y_{im} = & \beta_0 + \beta_1 IW_i + \beta_2 \text{Week}_i + \beta_3 I[\text{PB}]_i + \beta_4 I[\text{PC}]_i + \beta_5 I[\text{PD}]_i \\ & + b_{0m} + b_{1m} \text{Week}_{2im} + b_{2m} \text{Week}_{4im} + b_{3m} \text{Week}_{6im} + b_{4m} \text{Week}_{8im} \\ & + b_{5m} \text{Week}_{10im} + b_{6m} \text{Week}_{12im} + \varepsilon_{im}, \end{aligned}$$

where $i = 1, 2, \dots, 120$, and $m = 1, 2, \dots, 20$.

β_j are the fixed-effects coefficients, $j = 0, 1, \dots, 8$, and b_{0m} and b_{1m} are random effects. `IW` stands for initial weight and $I[\cdot]$ is a dummy variable representing a type of program. For

example, $I[\text{PB}]_i$ is the dummy variable representing program type B. The random effects and observation error have the following prior distributions:

$$b_{0m} \sim N(0, \sigma_0^2)$$

$$b_{1m} \sim N(0, \sigma_1^2)$$

$$\varepsilon_{im} \sim N(0, \sigma^2).$$

Fit the model using `fitlmematrix` with the defined design matrices and grouping variables. Assume the repeated observations collected on a subject have common variance along diagonals.

```
lme = fitlmematrix(X,y,Z,G,'FixedEffectPredictors',...
{'Intercept','InitWeight','PrgB','PrgC','PrgD','Week'},...
'RandomEffectPredictors',{{'Intercept','Week'}},...
'RandomEffectGroups',{'Subject'},'CovariancePattern','Isotropic')
```

```
lme =
Linear mixed-effects model fit by ML
```

Input Arguments

X — Fixed-effects design matrix

n-by-*p* matrix

Fixed-effects design matrix, specified as an *n*-by-*p* matrix, where *n* is the number of observations, and *p* is the number of fixed-effects predictor variables. Each row of **X** corresponds to one observation, and each column of **X** corresponds to one variable.

Data Types: single | double

y — Response values

n-by-1 vector

Response values, specified as an *n*-by-1 vector, where *n* is the number of observations.

Data Types: single | double

Z — Random-effects design

n-by-*q* matrix | cell array of *R* *n*-by-*q*(*r*) matrices, *r* = 1, 2, ..., *R*

Random-effects design, specified as either of the following.

- If there is one random-effects term in the model, then Z must be an n -by- q matrix, where n is the number of observations and q is the number of variables in the random-effects term.
- If there are R random-effects terms, then Z must be a cell array of length R . Each cell of Z contains an n -by- $q(r)$ design matrix $Z\{r\}$, $r = 1, 2, \dots, R$, corresponding to each random-effects term. Here, $q(r)$ is the number of random effects term in the r th random effects design matrix, $Z\{r\}$.

Data Types: `single` | `double` | `cell`

G — Grouping variable or variables

n -by-1 vector | cell array of R n -by-1 vectors

Grouping variable or variables on page 2-57, specified as either of the following.

- If there is one random-effects term, then G must be an n -by-1 vector corresponding to a single grouping variable with M levels or groups.

G can be a categorical vector, logical vector, numeric vector, character array, string array, or cell array of character vectors.

- If there are multiple random-effects terms, then G must be a cell array of length R . Each cell of G contains a grouping variable $G\{r\}$, $r = 1, 2, \dots, R$, with $M(r)$ levels.

$G\{r\}$ can be a categorical vector, logical vector, numeric vector, character array, string array, or cell array of character vectors.

Data Types: `categorical` | `logical` | `single` | `double` | `char` | `string` | `cell`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example:

`'CovariancePattern', 'Diagonal', 'DummyVarCoding', 'full', 'Optimizer', 'fminunc'` specifies a random-effects covariance pattern with zero off-diagonal elements, creates a dummy variable for each level of a categorical variable, and uses the `fminunc` optimization algorithm.

FixedEffectPredictors — Names of columns in fixed-effects design matrix`{'x1', 'x2', ..., 'xP'}` (default) | string array or cell array of length p

Names of columns in the fixed-effects design matrix X , specified as the comma-separated pair consisting of 'FixedEffectPredictors' and a string array or cell array of length p .

For example, if you have a constant term and two predictors, say `TimeSpent` and `Gender`, where `Female` is the reference level for `Gender`, as the fixed effects, then you can specify the names of your fixed effects in the following way. `Gender_Male` represents the dummy variable you must create for category `Male`. You can choose different names for these variables.

Example: 'FixedEffectPredictors',
{'Intercept', 'TimeSpent', 'Gender_Male'},

Data Types: string | cell

RandomEffectPredictors — Names of columns in random-effects design matrix or cell array`string array or cell array of length q | cell array of length R with elements of length $q(r)$, $r = 1, 2, \dots, R$`

Names of columns in the random-effects design matrix or cell array Z , specified as the comma-separated pair consisting of 'RandomEffectPredictors' and either of the following:

- A string array or cell array of length q when Z is an n -by- q design matrix. In this case, the default is {'z1', 'z2', ..., 'zQ'}.
- A cell array of length R , when Z is a cell array of length R with each element $Z\{r\}$ of length $q(r)$, $r = 1, 2, \dots, R$. In this case, the default is {'z11', 'z12', ..., 'z1Q(1)'}, ..., {'zr1', 'zr2', ..., 'zrQ(r)'}

For example, suppose you have correlated random effects for intercept and a variable named `Acceleration`. Then, you can specify the random-effects predictor names as follows.

Example: 'RandomEffectPredictors', {'Intercept', 'Acceleration'}

If you have two random effects terms, one for the intercept and the variable `Acceleration` grouped by variable `g1`, and the second for the intercept, grouped by the variable `g2`, then you specify the random-effects predictor names as follows.

Example: 'RandomEffectPredictors',{{'Intercept','Acceleration'},
'Intercept'}}

Data Types: string | cell

ResponseVarName — Name of response variable

'y' (default) | character vector | string scalar

Name of response variable, specified as the comma-separated pair consisting of 'ResponseVarName' and a character vector or string scalar.

For example, if your response variable name is `score`, then you can specify it as follows.

Example: 'ResponseVarName', 'score'

Data Types: char | string

RandomEffectGroups — Names of random effects grouping variables

'g' or {'g1','g2',...,'gR'} (default) | character vector | string scalar | string array
| cell array of character vectors

Names of random effects grouping variables, specified as the comma-separated pair 'RandomEffectGroups' and either of the following:

- Character vector or string scalar — If there is only one random-effects term, that is, if G is a vector, then the value of 'RandomEffectGroups' is the name for the grouping variable G . The default is 'g'.
- String array or cell array of character vectors — If there are multiple random-effects terms, that is, if G is a cell array of length R , then the value of 'RandomEffectGroups' is a string array or cell array of length R , where each element is the name for the grouping variable $G\{r\}$. The default is {'g1','g2',...,'gR'}.

For example, if you have two random-effects terms, `z1` and `z2`, grouped by the grouping variables `sex` and `subject`, then you can specify the names of your grouping variables as follows.

Example: 'RandomEffectGroups',{'sex','subject'}

Data Types: char | string | cell

CovariancePattern — Pattern of covariance matrix

'FullCholesky' (default) | character vector | string scalar | square symmetric logical matrix | string array | cell array of character vectors or logical matrices

Pattern of the covariance matrix of the random effects, specified as the comma-separated pair consisting of 'CovariancePattern' and a character vector, a string scalar, a square symmetric logical matrix, a string array, or a cell array of character vectors or logical matrices.

If there are R random-effects terms, then the value of 'CovariancePattern' must be a string array or cell array of length R , where each element r of the array specifies the pattern of the covariance matrix of the random-effects vector associated with the r th random-effects term. The options for each element follow.

'FullCholesky'

Default. Full covariance matrix using the Cholesky parameterization. `fitlme` estimates all elements of the covariance matrix.

'Full'

Full covariance matrix, using the log-Cholesky parameterization. `fitlme` estimates all elements of the covariance matrix.

'Diagonal'

Diagonal covariance matrix. That is, off-diagonal elements of the covariance matrix are constrained to be 0.

$$\begin{pmatrix} \sigma_{b1}^2 & 0 & 0 \\ 0 & \sigma_{b2}^2 & 0 \\ 0 & 0 & \sigma_{b3}^2 \end{pmatrix}$$

'Isotropic'

Diagonal covariance matrix with equal variances. That is, off-diagonal elements of the covariance matrix are constrained to be 0, and the diagonal elements are constrained to be equal. For example, if there are three random-effects terms with an isotropic covariance structure, this covariance matrix looks like

$$\begin{pmatrix} \sigma_b^2 & 0 & 0 \\ 0 & \sigma_b^2 & 0 \\ 0 & 0 & \sigma_b^2 \end{pmatrix}$$

where σ_b^2 is the common variance of the random-effects terms.

'CompSymm'

Compound symmetry structure. That is, common variance along diagonals and equal correlation between all random effects. For example, if there are three random-effects terms with a covariance matrix having a compound symmetry structure, this covariance matrix looks like

$$\begin{pmatrix} \sigma_{b1}^2 & \sigma_{b1,b2} & \sigma_{b1,b2} \\ \sigma_{b1,b2} & \sigma_{b1}^2 & \sigma_{b1,b2} \\ \sigma_{b1,b2} & \sigma_{b1,b2} & \sigma_{b1}^2 \end{pmatrix}$$

where σ_{b1}^2 is the common variance of the random-effects terms and $\sigma_{b1,b2}$ is the common covariance between any two random-effects term .

PAT

Square symmetric logical matrix. If 'CovariancePattern' is defined by the matrix PAT, and if $PAT(a,b) = false$, then the (a,b) element of the corresponding covariance matrix is constrained to be 0.

Example: 'CovariancePattern', 'Diagonal'

Example: 'CovariancePattern', {'Full', 'Diagonal'}

Data Types: char | string | logical | cell

FitMethod — Method for estimating parameters

'ML' (default) | 'REML'

Method for estimating parameters of the linear mixed-effects model, specified as the comma-separated pair consisting of 'FitMethod' and either of the following.

'ML'

Default. Maximum likelihood estimation

'REML'

Restricted maximum likelihood estimation

Example: 'FitMethod', 'REML'

Weights — Observation weights

vector of scalar values

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a vector of length n , where n is the number of observations.

Data Types: single | double

Exclude — Indices for rows to exclude

use all rows without NaNs (default) | vector of integer or logical values

Indices for rows to exclude from the linear mixed-effects model in the data, specified as the comma-separated pair consisting of 'Exclude' and a vector of integer or logical values.

For example, you can exclude the 13th and 67th rows from the fit as follows.

Example: 'Exclude', [13,67]

Data Types: single | double | logical

DummyVarCoding — Coding to use for dummy variables

'reference' (default) | 'effects' | 'full'

Coding to use for dummy variables created from the categorical variables, specified as the comma-separated pair consisting of 'DummyVarCoding' and one of the following.

Value	Description
'reference'	Default. Coefficient for first category set to 0.
'effects'	Coefficients sum to 0.
'full'	One dummy variable for each category.

Example: 'DummyVarCoding','effects'

Optimizer — Optimization algorithm

'quasinevton' (default) | 'fminunc'

Optimization algorithm, specified as the comma-separated pair consisting of 'Optimizer' and either of the following.

'quasinevton'	Default. Uses a trust region based quasi-Newton optimizer. Change the options of the algorithm using <code>statset('LinearMixedModel')</code> . If you don't specify the options, then <code>LinearMixedModel</code> uses the default options of <code>statset('LinearMixedModel')</code> .
'fminunc'	You must have Optimization Toolbox to specify this option. Change the options of the algorithm using <code>optimoptions('fminunc')</code> . If you don't specify the options, then <code>LinearMixedModel</code> uses the default options of <code>optimoptions('fminunc')</code> with 'Algorithm' set to 'quasi-newton'.

Example: 'Optimizer','fminunc'

OptimizerOptions — Options for optimization algorithmstructure returned by `statset` | object returned by `optimoptions`

Options for the optimization algorithm, specified as the comma-separated pair consisting of `'OptimizerOptions'` and a structure returned by `statset('LinearMixedModel')` or an object returned by `optimoptions('fminunc')`.

- If `'Optimizer'` is `'fminunc'`, then use `optimoptions('fminunc')` to change the options of the optimization algorithm. See `optimoptions` for the options `'fminunc'` uses. If `'Optimizer'` is `'fminunc'` and you do not supply `'OptimizerOptions'`, then the default for `LinearMixedModel` is the default options created by `optimoptions('fminunc')` with `'Algorithm'` set to `'quasi-newton'`.
- If `'Optimizer'` is `'quasinevton'`, then use `statset('LinearMixedModel')` to change the optimization parameters. If you don't change the optimization parameters, then `LinearMixedModel` uses the default options created by `statset('LinearMixedModel')`:

The `'quasinevton'` optimizer uses the following fields in the structure created by `statset('LinearMixedModel')`.

TolFun — Relative tolerance on gradient of objective function

1e-6 (default) | positive scalar value

Relative tolerance on the gradient of the objective function, specified as a positive scalar value.

TolX — Absolute tolerance on step size

1e-12 (default) | positive scalar value

Absolute tolerance on the step size, specified as a positive scalar value.

MaxIter — Maximum number of iterations allowed

10000 (default) | positive scalar value

Maximum number of iterations allowed, specified as a positive scalar value.

Display — Level of display

'off' (default) | 'iter' | 'final'

Level of display, specified as one of `'off'`, `'iter'`, or `'final'`.

StartMethod — Method to start iterative optimization`'default'` (default) | `'random'`

Method to start iterative optimization, specified as the comma-separated pair consisting of `'StartMethod'` and either of the following.

Value	Description
<code>'default'</code>	An internally defined default value
<code>'random'</code>	A random initial value

Example: `'StartMethod', 'random'`

Verbose — Indicator to display optimization process on screen`false` (default) | `true`

Indicator to display the optimization process on screen, specified as the comma-separated pair consisting of `'Verbose'` and either `false` or `true`. Default is `false`.

The setting for `'Verbose'` overrides the field `'Display'` in `'OptimizerOptions'`.

Example: `'Verbose', true`

CheckHessian — Indicator to check positive definiteness of Hessian`false` (default) | `true`

Indicator to check the positive definiteness of the Hessian of the objective function with respect to unconstrained parameters at convergence, specified as the comma-separated pair consisting of `'CheckHessian'` and either `false` or `true`. Default is `false`.

Specify `'CheckHessian'` as `true` to verify optimality of the solution or to determine if the model is overparameterized in the number of covariance parameters.

Example: `'CheckHessian', true`

Output Arguments

lme — Linear mixed-effects model`LinearMixedModel` object

Linear mixed-effects model, returned as a `LinearMixedModel` object.

Definitions

Cholesky Parameterization

One of the assumptions of linear mixed-effects models is that the random effects have the following prior distribution.

$$b \sim N(0, \sigma^2 D(\theta)),$$

where D is a q -by- q symmetric and positive semidefinite matrix, parameterized by a variance component vector θ , q is the number of variables in the random-effects term, and σ^2 is the observation error variance. Since the covariance matrix of the random effects, D , is symmetric, it has $q(q+1)/2$ free parameters. Suppose L is the lower triangular Cholesky factor of $D(\theta)$ such that

$$D(\theta) = L(\theta)L(\theta)^T,$$

then the $q*(q+1)/2$ -by-1 unconstrained parameter vector θ is formed from elements in the lower triangular part of L .

For example, if

$$L = \begin{bmatrix} L_{11} & 0 & 0 \\ L_{21} & L_{22} & 0 \\ L_{31} & L_{32} & L_{33} \end{bmatrix},$$

then

$$\theta = \begin{bmatrix} L_{11} \\ L_{21} \\ L_{31} \\ L_{22} \\ L_{32} \\ L_{33} \end{bmatrix}.$$

Log-Cholesky Parameterization

When the diagonal elements of L in Cholesky parameterization are constrained to be positive, then the solution for L is unique. Log-Cholesky parameterization is the same as Cholesky parameterization except that the logarithm of the diagonal elements of L are used to guarantee unique parameterization.

For example, for the 3-by-3 example in Cholesky parameterization, enforcing $L_{ii} \geq 0$,

$$\theta = \begin{bmatrix} \log(L_{11}) \\ L_{21} \\ L_{31} \\ \log(L_{22}) \\ L_{32} \\ \log(L_{33}) \end{bmatrix}.$$

Alternative Functionality

You can also fit a linear mixed-effects model using `fitlme(tbl, formula)`, where `tbl` is a table or dataset array containing the response y , the predictor variables X , and the grouping variables, and `formula` is of the form ' $y \sim \text{fixed} + (\text{random}_1 | g_1) + \dots + (\text{random}_R | g_R)$ '.

`LinearMixedModel` | `compare` | `fitlme`

Introduced in R2013b

fitrgp

Fit a Gaussian process regression (GPR) model

Syntax

```
gprMdl = fitrgp(tbl,ResponseVarName)
gprMdl = fitrgp(tbl,formula)
gprMdl = fitrgp(tbl,y)

gprMdl = fitrgp(X,y)

gprMdl = fitrgp( ____,Name,Value)
```

Description

`gprMdl = fitrgp(tbl,ResponseVarName)` returns a Gaussian process regression (GPR) model trained using the sample data in `tbl`, where `ResponseVarName` is the name of the response variable in `tbl`.

`gprMdl = fitrgp(tbl,formula)` returns a Gaussian process regression (GPR) model, trained using the sample data in `tbl`, for the predictor variables and response variables identified by `formula`.

`gprMdl = fitrgp(tbl,y)` returns a GPR model for the predictors in table `tbl` and continuous response vector `y`.

`gprMdl = fitrgp(X,y)` returns a GPR model for predictors `X` and continuous response vector `y`.

`gprMdl = fitrgp(____,Name,Value)` returns a GPR model for any of the input arguments in the previous syntaxes, with additional options specified by one or more `Name,Value` pair arguments.

For example, you can specify the fitting method, the prediction method, the covariance function, or the active set selection method. You can also train a cross-validated model.

`gprMdl` is a `RegressionGP` object. For methods and properties of this class, see `RegressionGP` class page.

If you train a cross-validated model, then `gprMdl` is a `RegressionPartitionedModel` object. For further analysis on the cross-validated object, use the methods of `RegressionPartitionedModel` class. For the methods of this class, see the `RegressionPartitionedModel` class page.

Examples

Train GPR Model Using Data in Table

This example uses the abalone data [1], [2], from the UCI Machine Learning Repository [3]. Download the data and save it in your current folder with the name 'abalone.data'.

Store the data into a table. Display the first seven rows.

```
tbl = readtable('abalone.data', 'Filetype', 'text', ...
    'ReadVariableNames', false);
tbl.Properties.VariableNames = {'Sex', 'Length', 'Diameter', 'Height', ...
    'WWeight', 'SWeight', 'VWeight', 'ShWeight', 'NoShellRings'};
tbl(1:7, :)
```

ans =

Sex	Length	Diameter	Height	WWeight	SWeight	VWeight	ShWeight
'M'	0.455	0.365	0.095	0.514	0.2245	0.101	0.15
'M'	0.35	0.265	0.09	0.2255	0.0995	0.0485	0.07
'F'	0.53	0.42	0.135	0.677	0.2565	0.1415	0.21
'M'	0.44	0.365	0.125	0.516	0.2155	0.114	0.155
'I'	0.33	0.255	0.08	0.205	0.0895	0.0395	0.055
'I'	0.425	0.3	0.095	0.3515	0.141	0.0775	0.12
'F'	0.53	0.415	0.15	0.7775	0.237	0.1415	0.33

The dataset has 4177 observations. The goal is to predict the age of abalone from eight physical measurements. The last variable, number of shell rings shows the age of the abalone. The first predictor is a categorical variable. The last variable in the table is the response variable.

Fit a GPR model using the subset of regressors method for parameter estimation and fully independent conditional method for prediction. Standardize the predictors.

```
gprMdl = fitrgp(tbl,'NoShellRings','KernelFunction','ardsquaredexponential',...  
              'FitMethod','sr','PredictMethod','fic','Standardize',1)
```

```
grMdl =
```

```
RegressionGP  
  PredictorNames: {1x8 cell}  
  ResponseName: 'Var9'  
  ResponseTransform: 'none'  
  NumObservations: 4177  
  KernelFunction: 'ARDSquaredExponential'  
  KernelInformation: [1x1 struct]  
    BasisFunction: 'Constant'

  BCDInformation: []
```

Predict the responses using the trained model.

```
ypred = resubPredict(gprMdl);
```

Plot the true response and the predicted responses.

```
figure();  
plot(tbl.NoShellRings,'r.');
```

```
hold on  
plot(ypred,'b');  
xlabel('x');  
ylabel('y');  
legend({'data','predictions'},'Location','Best');
```

```
axis([0 4300 0 30]);
hold off;
```

Compute the regression loss on the training data (resubstitution loss) for the trained model.

```
L = resubLoss(gprMdl)
```

```
L =
```

```
4.0064
```

Train GPR Model and Plot Predictions

Generate sample data.

```
rng(0, 'twister'); % For reproducibility
n = 1000;
```

```
x = linspace(-10,10,n)';  
y = 1 + x*5e-2 + sin(x)./x + 0.2*randn(n,1);
```

Fit a GPR model using a linear basis function and the exact fitting method to estimate the parameters. Also use the exact prediction method.

```
gprMdl = fitrgp(x,y,'Basis','linear',...  
               'FitMethod','exact','PredictMethod','exact');
```

Predict the response corresponding to the rows of x (resubstitution predictions) using the trained model.

```
ypred = resubPredict(gprMdl);
```

Plot the true response with the predicted values.

```
plot(x,y,'b. ');  
hold on;  
plot(x,ypred,'r','LineWidth',1.5);  
xlabel('x');  
ylabel('y');  
legend('Data','GPR predictions');  
hold off
```

Impact of Specifying Initial Kernel Parameter Values

Load the sample data.

```
load(fullfile(matlabroot,'examples','stats','gprdata2.mat'))
```

The data has one predictor variable and continuous response. This is simulated data.

Fit a GPR model using the squared exponential kernel function with default kernel parameters.

```
gprMdl1 = fitrgp(x,y,'KernelFunction','squareexponential');
```

Now, fit a second model, where you specify the initial values for the kernel parameters.

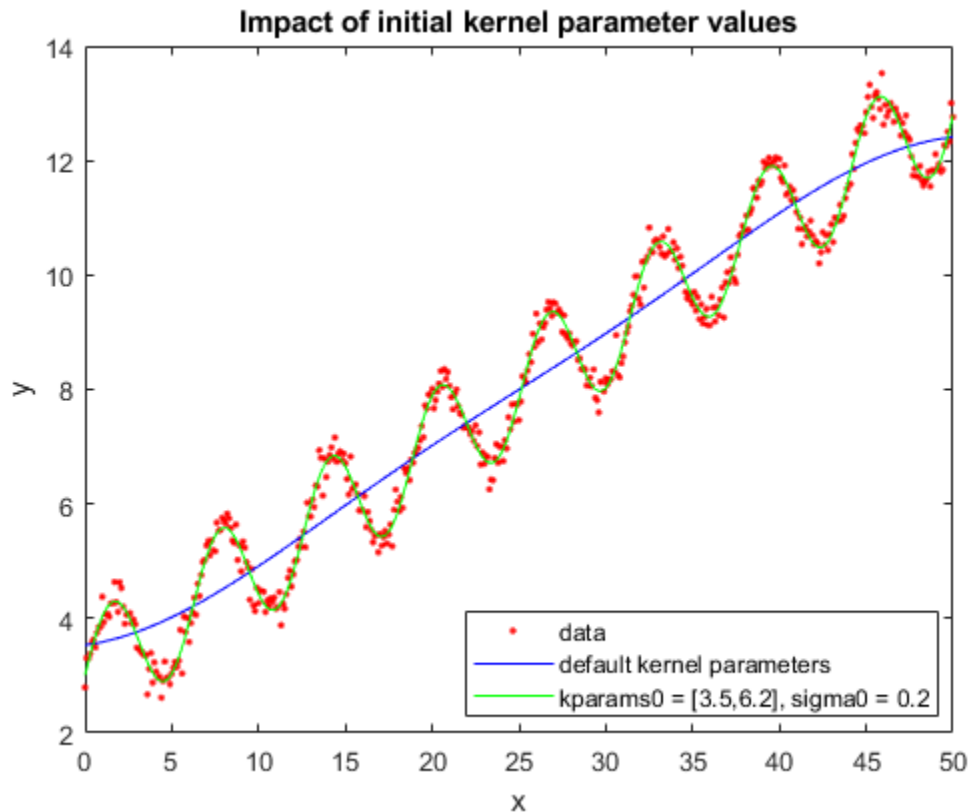

```
sigma0 = 0.2;
kparams0 = [3.5, 6.2];
gprMdl2 = fitrgp(x,y,'KernelFunction','squareexponential',...
    'KernelParameters',kparams0,'Sigma',sigma0);
```

Compute the resubstitution predictions from both models.

```
ypred1 = resubPredict(gprMdl1);
ypred2 = resubPredict(gprMdl2);
```

Plot the response predictions from both models and the responses in training data.

```
figure();
plot(x,y,'r. ');
hold on
plot(x,ypred1,'b');
plot(x,ypred2,'g');
xlabel('x');
ylabel('y');
legend({'data','default kernel parameters',...
    'kparams0 = [3.5,6.2], sigma0 = 0.2'},...
    'Location','Best');
title('Impact of initial kernel parameter values');
hold off
```

The marginal log likelihood that `fitrgp` maximizes to estimate GPR parameters has multiple local solutions; the solution that it converges to depends on the initial point. Each local solution corresponds to a particular interpretation of the data. In this example, the solution with the default initial kernel parameters corresponds to a low frequency signal with high noise whereas the second solution with custom initial kernel parameters corresponds to a high frequency signal with low noise.

Use Separate Length Scales for Predictors

Load the sample data.

```
load(fullfile(matlabroot, 'examples', 'stats', 'gprdata.mat'))
```

There are six continuous predictor variables. There are 500 observations in the training data set and 100 observations in the test data set. This is simulated data.

Fit a GPR model using the squared exponential kernel function with a separate length scale for each predictor. This covariance function is defined as:

$$k(x_i, x_j | \theta) = \sigma_f^2 \exp \left[-\frac{1}{2} \sum_{m=1}^d \frac{(x_{im} - x_{jm})^2}{\sigma_m^2} \right].$$

where σ_m represents the length scale for predictor m , $m = 1, 2, \dots, d$ and σ_f is the signal standard deviation. The unconstrained parametrization θ is

$$\begin{aligned} \theta_m &= \log \sigma_m, \quad \text{for } m = 1, 2, \dots, d \\ \theta_{d+1} &= \log \sigma_f. \end{aligned}$$

Initialize length scales of the kernel function at 10 and signal and noise standard deviations at the standard deviation of the response.

```
sigma0 = std(ytrain);
sigmaF0 = sigma0;
d = size(Xtrain,2);
sigmaM0 = 10*ones(d,1);
```

Fit the GPR model using the initial kernel parameter values. Standardize the predictors in the training data. Use the exact fitting and prediction methods.

```
gprMdl = fitrgp(Xtrain,ytrain,'Basis','constant','FitMethod','exact',...
'PredictMethod','exact','KernelFunction','ardsquaredexponential',...
'KernelParameters',[sigmaM0;sigmaF0],'Sigma',sigma0,'Standardize',1);
```

Compute the regression loss on the test data.

```
L = loss(gprMdl,Xtest,ytest)
```

```
L = 0.6919
```

Access the kernel information.

```
gprMdl.KernelInformation
```

```
ans = struct with fields:
        Name: 'ARDSquaredExponential'
```

```
KernelParameters: [7x1 double]
KernelParameterNames: {7x1 cell}
```

Display the kernel parameter names.

```
gprMdl.KernelInformation.KernelParameterNames
```

```
ans = 7x1 cell array
    {'LengthScale1'}
    {'LengthScale2'}
    {'LengthScale3'}
    {'LengthScale4'}
    {'LengthScale5'}
    {'LengthScale6'}
    {'SigmaF'      }
```

Display the kernel parameters.

```
sigmaM = gprMdl.KernelInformation.KernelParameters(1:end-1,1)
```

```
sigmaM = 6x1
104 ×
```

```
0.0004
0.0007
0.0004
4.1731
0.1018
0.0056
```

```
sigmaF = gprMdl.KernelInformation.KernelParameters(end)
```

```
sigmaF = 28.1718
```

```
sigma = gprMdl.Sigma
```

```
sigma = 0.8162
```

Plot the log of learned length scales.

```
figure()
plot((1:d)',log(sigmaM),'ro-');
xlabel('Length scale number');
ylabel('Log of length scale');
```

The log of length scale for the 4th and 5th predictor variables are high relative to the others. These predictor variables do not seem to be as influential on the response as the other predictor variables.

Fit the GPR model without using the 4th and 5th variables as the predictor variables.

```
X = [Xtrain(:,1:3) Xtrain(:,6)];  
sigma0 = std(ytrain);  
sigmaF0 = sigma0;  
d = size(X,2);  
sigmaM0 = 10*ones(d,1);  
  
gprMdl = fitrgp(X,ytrain,'Basis','constant','FitMethod','exact',...
```

```
'PredictMethod','exact','KernelFunction','ardsquaredexponential',...  
'KernelParameters',[sigmaM0;sigmaF0],'Sigma',sigma0,'Standardize',1);
```

Compute the regression error on the test data.

```
xtest = [Xtest(:,1:3) Xtest(:,6)];  
L = loss(gprMdl,xtest,ytest)
```

```
L = 0.6928
```

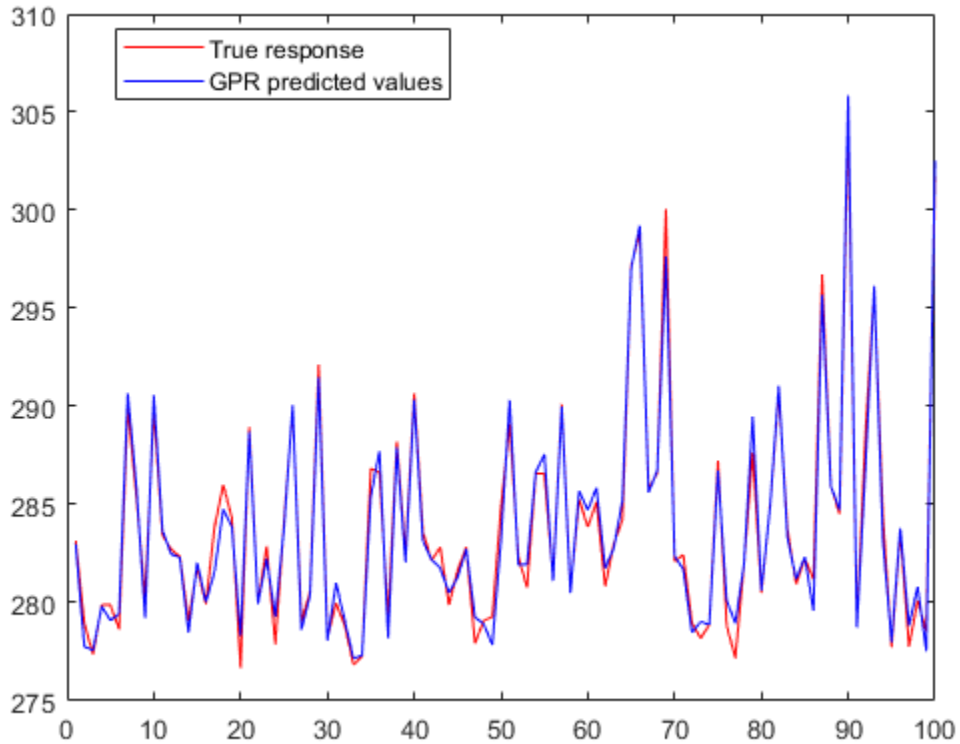

The loss is similar to the one when all variables are used as predictor variables.

Compute the predicted response for the test data.

```
ypred = predict(gprMdl,xtest);
```

Plot the original response along with the fitted values.

```
figure;  
plot(ytest,'r');  
hold on;  
plot(ypred,'b');  
legend('True response','GPR predicted values','Location','Best');  
hold off
```

Optimize GPR Regression

This example shows how to optimize hyperparameters automatically using `fitrgp`. The example uses the `gprdata2` data that ships with your software.

Load the data.

```
load(fullfile(matlabroot, 'examples', 'stats', 'gprdata2.mat'))
```

The data has one predictor variable and continuous response. This is simulated data.

Fit a GPR model using the squared exponential kernel function with default kernel parameters.

```
gprMdl1 = fitrgp(x,y,'KernelFunction','squaredexponential');
```

Find hyperparameters that minimize five-fold cross-validation loss by using automatic hyperparameter optimization.

For reproducibility, set the random seed and use the 'expected-improvement-plus' acquisition function.

```
rng default
gprMdl2 = fitrgp(x,y,'KernelFunction','squaredexponential',...
    'OptimizeHyperparameters','auto','HyperparameterOptimizationOptions',...
    struct('AcquisitionFunctionName','expected-improvement-plus'));
```

Train GPR Model Using Cross-Validation

This example uses the abalone data [1], [2], from the UCI Machine Learning Repository [3]. Download the data and save it in your current folder with the name 'abalone.data'.

Store the data into a table. Display the first seven rows.

```
tbl = readtable('abalone.data', 'Filetype', 'text', 'ReadVariableNames', false);tbl.Properties.VariableNames = {'Sex', 'Length', 'Diameter', 'Height', 'WWeight', 'SWeight', 'VWeight', 'ShWeight'};tbl(1:7,:)
```

```
ans =
```

Sex	Length	Diameter	Height	WWeight	SWeight	VWeight	ShWeight
'M'	0.455	0.365	0.095	0.514	0.2245	0.101	0.15
'M'	0.35	0.265	0.09	0.2255	0.0995	0.0485	0.07
'F'	0.53	0.42	0.135	0.677	0.2565	0.1415	0.21
'M'	0.44	0.365	0.125	0.516	0.2155	0.114	0.155
'I'	0.33	0.255	0.08	0.205	0.0895	0.0395	0.055
'I'	0.425	0.3	0.095	0.3515	0.141	0.0775	0.12
'F'	0.53	0.415	0.15	0.7775	0.237	0.1415	0.33

The dataset has 4177 observations. The goal is to predict the age of abalone from eight physical measurements. The last variable, number of shell rings shows the age of the abalone. The first predictor is a categorical variable. The last variable in the table is the response variable.

Train a cross-validated GPR model using the 25% of the data for validation.

```
rng('default') % For reproducibility
cvgprMdl = fitrgp(tbl, 'NoShellRings', 'Standardize', 1, 'Holdout', 0.25);
```

Compute the average loss on folds using models trained on out-of-fold observations.

```
kfoldLoss(cvgprMdl)
```

```
ans =
    4.6409
```

Predict the responses for out-of-fold data.

```
ypred = kfoldPredict(cvgprMdl);
```

Plot the true responses used for testing and the predictions.

```
figure();  
plot(ypred(cvgprMdl.Partition.test));  
hold on;  
y = table2array(tbl(:,end));  
plot(y(cvgprMdl.Partition.test), 'r.');
```

```
axis([0 1050 0 30]);  
xlabel('x')  
ylabel('y')  
hold off;
```

Fit GPR Model Using Custom Kernel Function

Generate the sample data.

```
rng(0, 'twister'); % For reproducibility
n = 1000;
x = linspace(-10,10,n)';
y = 1 + x*5e-2 + sin(x)./x + 0.2*randn(n,1);
```

Define the squared exponential kernel function as a custom kernel function.

You can compute the squared exponential kernel function as

$$k(x_i, x_j | \theta) = \sigma_f^2 \exp\left(-\frac{1}{2} \frac{(x_i - x_j)^T (x_i - x_j)}{\sigma_l^2}\right),$$

where σ_f is the signal standard deviation, σ_l is the length scale. Both σ_f and σ_l must be greater than zero. This condition can be enforced by the unconstrained parametrization, $\sigma_l = \exp(\theta(1))$ and $\sigma_f = \exp(\theta(2))$, for some unconstrained parametrization vector θ .

Hence, you can define the squared exponential kernel function as a custom kernel function as follows:

```
kfcn = @(XN,XM,theta) (exp(theta(2))^2)*exp(-(pdist2(XN,XM).^2)/(2*exp(theta(1))^2));
```

Here `pdist2(XN,XM).^2` computes the distance matrix.

Fit a GPR model using the custom kernel function, `kfcn`. Specify the initial values of the kernel parameters (Because you use a custom kernel function, you must provide initial values for the unconstrained parametrization vector, `theta`).

```
theta0 = [1.5,0.2];
gprMdl = fitrgp(x,y,'KernelFunction',kfcn,'KernelParameters',theta0);
```

`fitrgp` uses analytical derivatives to estimate parameters when using a built-in kernel function, whereas when using a custom kernel function it uses numerical derivatives.

Compute the resubstitution loss for this model.

```
L = resubLoss(gprMdl)
```

```
L = 0.0391
```

Fit the GPR model using the built-in squared exponential kernel function option. Specify the initial values of the kernel parameters (Because you use the built-in custom kernel function and specifying initial parameter values, you must provide the initial values for the signal standard deviation and length scale(s) directly).

```
sigmaL0 = exp(1.5);
sigmaF0 = exp(0.2);
gprMdl2 = fitrgp(x,y,'KernelFunction','squareexponential','KernelParameters',[sigmaL0
```

Compute the resubstitution loss for this model.

```
L2 = resubLoss(gprMdl2)
```

```
L2 = 0.0391
```

The two loss values are the same as expected.

Specify Initial Step Size for LBFGS Optimization

Train a GPR model on generated data with many predictors. Specify the initial step size for the LBFGS optimizer.

Set the seed and type of the random number generator for reproducibility of the results.

```
rng(0, 'twister'); % For reproducibility
```

Generate sample data with 300 observations and 3000 predictors, where the response variable depends on the 4th, 7th, and 13th predictors.

```
N = 300;  
P = 3000;  
X = rand(N,P);  
y = cos(X(:,7)) + sin(X(:,4).*X(:,13)) + 0.1*randn(N,1);
```

Set initial values for the kernel parameters.

```
sigmaL0 = sqrt(P)*ones(P,1); % Length scale for predictors  
sigmaF0 = 1; % Signal standard deviation
```

Set initial noise standard deviation to 1.

```
sigmaN0 = 1;
```

Specify $1e-2$ as the termination tolerance for the relative gradient norm.

```
opts = statset('fitrgp');  
opts.TolFun = 1e-2;
```

Fit a GPR model using the initial kernel parameter values, initial noise standard deviation, and an automatic relevance determination (ARD) squared exponential kernel function.

Specify the initial step size as 1 for determining the initial Hessian approximation for an LBFGS optimizer.

```
gpr = fitrgp(X,y,'KernelFunction','ardsquaredexponential','Verbose',1, ...  
            'Optimizer','lbfgs','OptimizerOptions',opts, ...  
            'KernelParameters',[sigmaL0;sigmaF0],'Sigma',sigmaN0,'InitialStepSize',1);
```

```
o Parameter estimation: FitMethod = Exact, Optimizer = lbfgs
```

o Solver = LBFGS, HessianHistorySize = 15, LineSearchMethod = weakwolfe

```

Infinity norm of the final gradient = 1.546e+00
Two norm of the final step = 8.142e-01, TolX = 1.000e-12
Relative infinity norm of the final gradient = 6.016e-03, TolFun = 1.000e-02
EXIT: Local minimum found.

```

```
o Alpha estimation: PredictMethod = Exact
```

Because the GPR model uses an ARD kernel with many predictors, using an LBFGS approximation to the Hessian is more memory efficient than storing the full Hessian matrix. Also, using the initial step size to determine the initial Hessian approximation may help speed up optimization.

Find the predictor weights by taking the exponential of the negative learned length scales. Normalize the weights.

```

sigmaL = gpr.KernelInformation.KernelParameters(1:end-1); % Learned length scales
weights = exp(-sigmaL); % Predictor weights
weights = weights/sum(weights); % Normalized predictor weights

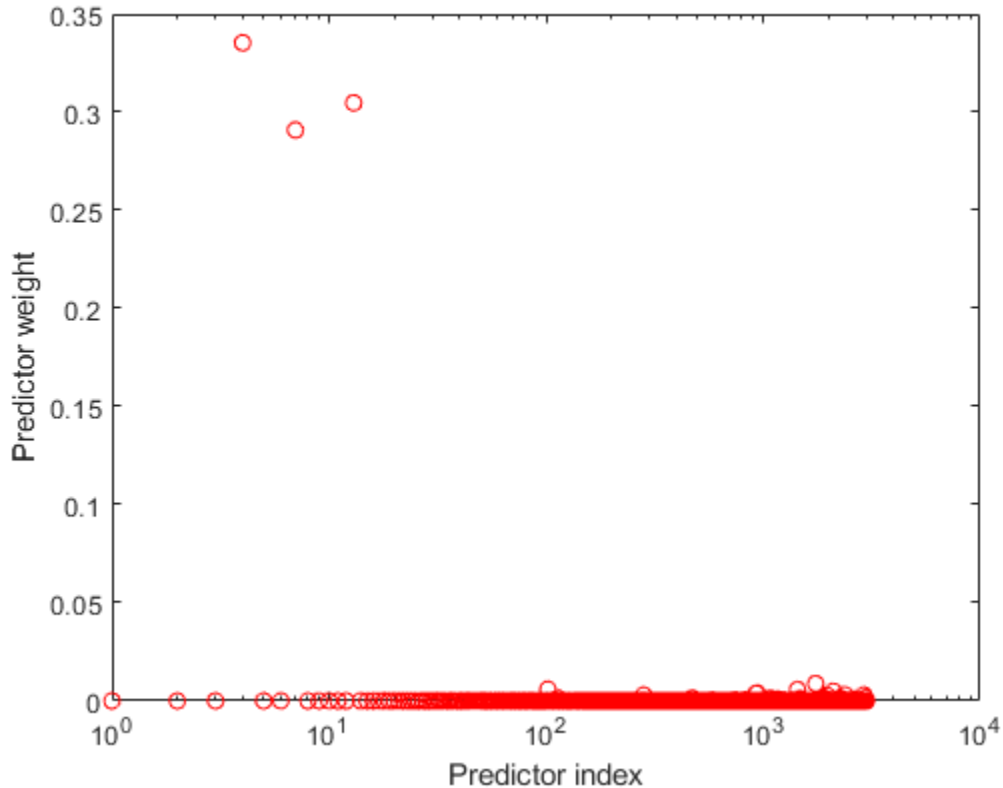

```

Plot the normalized predictor weights.

```

figure;
semilogx(weights,'ro');
xlabel('Predictor index');
ylabel('Predictor weight');

```

The trained GPR model assigns the largest weights to the 4th, 7th, and 13th predictors. The irrelevant predictors have weights close to zero.

Input Arguments

tbl — Sample data

table

Sample data used to train the model, specified as a `table`. Each row of `tbl` corresponds to one observation, and each column corresponds to one variable. `tbl` contains the predictor variables, and optionally it can also contain one column for the response

variable. Multi-column variables and cell arrays other than cell arrays of character vectors are not allowed.

- If `tbl` contains the response variable, and you want to use all the remaining variables as predictors, then specify the response variable using `ResponseVarName`.
- If `tbl` contains the response variable, and you want to use only a subset of the predictors in training the model, then specify the response variable and the predictor variables using `formula`.
- If `tbl` does not contain the response variable, then specify a response variable using `y`. The length of the response variable and the number of rows in `tbl` must be equal.

For more information on the `table` data type, please see `table`.

If your predictor data contains categorical variables, then the software uses full dummy coding for these variables. The software creates one dummy variable for each level of the categorical variable.

Data Types: `table`

ResponseVarName — Response variable name

name of a variable in `tbl`

Response variable name, specified as the name of a variable in `tbl`. You must specify `ResponseVarName` as a character vector or string scalar. For example, if the response variable `y` is stored in `tbl` (as `tbl.y`), then specify it as `'y'`. Otherwise, the software treats all the columns of `tbl`, including `y`, as predictors when training the model.

Data Types: `char` | `string`

formula — Response and predictor variables to use in model training

character vector or string scalar in the form of `'y~x1+x2+x3'`

Response and predictor variables to use in model training, specified as a character vector or string scalar in the form of `'y~x1+x2+x3'`. In this form, `y` represents the response variable; `x1`, `x2`, `x3` represent the predictor variables to use in training the model.

Use a formula if you want to specify a subset of variables in `tbl` as predictors to use when training the model. If you specify a formula, then any variables that do not appear in `formula` are not used to train the model.

The formula does not indicate the form of the `BasisFunction`.

Example: `'PetalLength~PetalWidth+Species'` identifies the variable `PetalLength` as the response variable, and `PetalWidth` and `Species` as the predictor variables.

Data Types: `char` | `string`

X — Predictor data for the GPR model

n-by-*d* matrix

Predictor data for the GPR model, specified as an *n*-by-*d* matrix. *n* is the number of observations (rows), and *d* is the number of predictors (columns).

The length of *y* and the number of rows of *X* must be equal.

To specify the names of the predictors in the order of their appearance in *X*, use the `PredictorNames` name-value pair argument.

Data Types: `double`

y — Response data for the GPR model

n-by-1 vector

Response data for the GPR model, specified as an *n*-by-1 vector. You can omit *y* if you provide the `tbl` training data that also includes *y*. In that case, use `ResponseVarName` to identify the response variable or use `formula` to identify the response and predictor variables.

Data Types: `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Note You cannot use any cross-validation name-value pair argument along with the `'OptimizeHyperparameters'` name-value pair argument. You can modify the cross-validation for `'OptimizeHyperparameters'` only by using the `'HyperparameterOptimizationOptions'` name-value pair argument.

Example:

```
'FitMethod','sr','BasisFunction','linear','ActiveSetMethod','sgma','
```

PredictMethod', 'fic' trains the GPR model using the subset of regressors approximation method for parameter estimation, uses a linear basis function, uses sparse greedy matrix approximation for active selection, and fully independent conditional approximation method for prediction.

Fitting

FitMethod — Method to estimate parameters of the GPR model

'none' | 'exact' | 'sd' | 'sr' | 'fic'

Method to estimate parameters of the GPR model, specified as the comma-separated pair consisting of 'FitMethod' and one of the following.

Fit Method	Description
'none'	No estimation, use the initial parameter values as the known parameter values.
'exact'	Exact Gaussian process regression. Default if $n \leq 2000$, where n is the number of observations.
'sd'	Subset of data points approximation. Default if $n > 2000$, where n is the number of observations.
'sr'	Subset of regressors approximation.
'fic'	Fully independent conditional approximation.

Example: 'FitMethod', 'fic'

BasisFunction — Explicit basis in the GPR model

'constant' (default) | 'none' | 'linear' | 'pureQuadratic' | function handle

Explicit basis in the GPR model, specified as the comma-separated pair consisting of 'BasisFunction' and one of the following. If n is the number of observations, the basis function adds the term $\mathbf{H}*\boldsymbol{\beta}$ to the model, where \mathbf{H} is the basis matrix and $\boldsymbol{\beta}$ is a p -by-1 vector of basis coefficients.

Explicit Basis	Basis Matrix
'none'	Empty matrix.

Explicit Basis	Basis Matrix
'constant'	$H = 1$ (n -by-1 vector of 1s, where n is the number of observations)
'linear'	$H = [1, X]$
'pureQuadratic'	$H = [1, X, X_2]$, where $X_2 = \begin{bmatrix} x_{11}^2 & x_{12}^2 & \dots & x_{1d}^2 \\ x_{21}^2 & x_{22}^2 & \dots & x_{2d}^2 \\ \vdots & \vdots & \vdots & \vdots \\ x_{n1}^2 & x_{n2}^2 & \dots & x_{nd}^2 \end{bmatrix}.$
Function handle	Function handle, <code>hfcn</code> , that <code>fitrgp</code> calls as: $H = hfcn(X)$, where X is an n -by- d matrix of predictors and H is an n -by- p matrix of basis functions.

Example: 'BasisFunction', 'pureQuadratic'

Data Types: char | string | function_handle

Beta – Initial value of the coefficients

p -by-1 vector

Initial value of the coefficients for the explicit basis, specified as the comma-separated pair consisting of 'Beta' and p -by-1 vector, where p is the number of columns in the basis matrix H .

The basis matrix depends on the choice of the explicit basis function as follows (also see `BasisFunction`).

`fitrgp` uses the coefficient initial values as the known coefficient values, only when `FitMethod` is 'none'.

Data Types: double

Sigma — Initial value for the noise standard deviation of the Gaussian process model`std(y)/sqrt(2) (default) | positive scalar value`

Initial value for the noise standard deviation of the Gaussian process model, specified as the comma-separated pair consisting of 'Sigma' and a positive scalar value.

Example: 'Sigma',2

Data Types: double

ConstantSigma — Constant value of Sigma for the noise standard deviation of the Gaussian process model`false (default) | true`

Constant value of Sigma for the noise standard deviation of the Gaussian process model, specified as a logical scalar. When ConstantSigma is true, fitrgp does not optimize the value of Sigma, but instead takes the initial value as the value throughout its computations.

Example: 'ConstantSigma',true

Data Types: logical

SigmaLowerBound — Lower bound on the noise standard deviation`1e-2*std(y) (default) | positive scalar value`

Lower bound on the noise standard deviation, specified as the comma-separated pair consisting of 'SigmaLowerBound' and a positive scalar value.

Example: 'SigmaLowerBound',0.02

Data Types: double

CategoricalPredictors — Categorical predictors list`vector of positive integers | logical vector | character matrix | string array | cell array of character vectors | 'all'`

Categorical predictors list, specified as the comma-separated pair consisting of 'CategoricalPredictors' and one of these values:

Value	Description
Vector of positive integers	An entry in the vector is the index value corresponding to the column of the predictor data (<code>X</code> or <code>tbl</code>) that contains a categorical variable.
Logical vector	A <code>true</code> entry means that the corresponding column of predictor data (<code>X</code> or <code>tbl</code>) is a categorical variable.
Character matrix	Each row of the matrix is the name of a predictor variable. The names must match the entries in <code>PredictorNames</code> . Pad the names with extra blanks so each row of the character matrix has the same length.
String array or cell array of character vectors	Each element in the array is the name of a predictor variable. The names must match the entries in <code>PredictorNames</code> .
'all'	All predictors are categorical.

By default, if the predictor data is in a table (`tbl`), `fitrgp` assumes that a variable is categorical if it contains logical values, categorical values, a string array, or a cell array of character vectors. If the predictor data is a matrix (`X`), `fitrgp` assumes all predictors are continuous. To identify any categorical predictors when the data is a matrix, use the `'CategoricalPredictors'` name-value pair argument.

Example: `'CategoricalPredictors','all'`

Data Types: `single` | `double` | `logical` | `char` | `string` | `cell`

Standardize — Indicator to standardize data

0 (false) (default) | logical value

Indicator to standardize data, specified as the comma-separated pair consisting of `'Standardize'` and a logical value.

If you set `'Standardize',1`, then the software centers and scales each column of the predictor data, by the column mean and standard deviation, respectively. The software does not standardize the data contained in the dummy variable columns that it generates for categorical predictors.

Example: `'Standardize',1`

Example: `'Standardize',true`

Data Types: `logical`

Regularization — Regularization standard deviation

`1e-2*std(y)` (default) | positive scalar value

Regularization standard deviation for sparse methods subset of regressors ('sr') and fully independent conditional ('fic'), specified as the comma-separated pair consisting of 'Regularization' and a positive scalar value.

Example: 'Regularization',0.2

Data Types: double

ComputationMethod — Method for computing log likelihood and gradient

'qr' (default) | 'v'

Method for computing the log likelihood and gradient for parameter estimation using subset of regressors ('sr') and fully independent conditional ('fic') approximation methods, specified as the comma-separated pair consisting of 'ComputationMethod' and one of the following.

- 'qr' — Use QR factorization based approach, this option provides better accuracy.
- 'v' — Use V-method-based approach. This option provides faster computation of log likelihood gradients.

Example: 'ComputationMethod','v'

Kernel (Covariance) Function**KernelFunction — Form of the covariance function**

'squarexponential' (default) | 'exponential' | 'matern32' | 'matern52' | 'rationalquadratic' | 'ardsquarexponential' | 'ardexponential' | 'ardmatern32' | 'ardmatern52' | 'ardrationalquadratic' | function handle

Form of the covariance function, specified as the comma-separated pair consisting of 'KernelFunction' and one of the following.

Function	Description
'exponential'	Exponential kernel.
'squarexponential'	Squared exponential kernel.
'matern32'	Matern kernel with parameter 3/2.
'matern52'	Matern kernel with parameter 5/2.

Function	Description
'rationalquadratic'	Rational quadratic kernel.
'ardexponential'	Exponential kernel with a separate length scale per predictor.
'ardsquaredexponential'	Squared exponential kernel with a separate length scale per predictor.
'ardmatern32'	Matern kernel with parameter 3/2 and a separate length scale per predictor.
'ardmatern52'	Matern kernel with parameter 5/2 and a separate length scale per predictor.
'ardrationalquadratic'	Rational quadratic kernel with a separate length scale per predictor.
Function handle	A function handle that can be called like this: $K_{mn} = \text{kfcn}(X_m, X_n, \theta)$ where X_m is an m -by- d matrix, X_n is an n -by- d matrix and K_{mn} is an m -by- n matrix of kernel products such that $K_{mn}(i,j)$ is the kernel product between $X_m(i,:)$ and $X_n(j,:)$. θ is the r -by-1 unconstrained parameter vector for kfcn .

For more information on the kernel functions, see “Kernel (Covariance) Function Options” on page 6-6.

Example: 'KernelFunction', 'matern32'

Data Types: char | string | function_handle

KernelParameters – Initial values for the kernel parameters

vector

Initial values for the kernel parameters, specified as the comma-separated pair consisting of 'KernelParameters' and a vector. The size of the vector and the values depend on the form of the covariance function, specified by the KernelFunction name-value pair argument.

'KernelFunction'	'KernelParameters'
'exponential' or 'squarexponential' or 'matern32' or 'matern52'	<p>2-by-1 vector phi, where phi(1) contains the length scale and phi(2) contains the signal standard deviation.</p> <p>Default initial value of the length scale parameter is the mean of standard deviations of the predictors, and the signal standard deviation is the standard deviation of the responses divided by square root of 2. That is,</p> $\text{phi} = [\text{mean}(\text{std}(X)); \text{std}(y) / \text{sqrt}(2)]$
'rationalquadratic'	<p>3-by-1 vector phi, where phi(1) contains the length scale, phi(2) contains the scale-mixture parameter, and phi(3) contains the signal standard deviation.</p> <p>Default initial value of the length scale parameter is the mean of standard deviations of the predictors, and the signal standard deviation is the standard deviation of the responses divided by square root of 2. Default initial value for the scale-mixture parameter is 1. That is,</p> $\text{phi} = [\text{mean}(\text{std}(X)); 1; \text{std}(y) / \text{sqrt}(2)]$
'ardexponential' or 'ardsquarexponential' or 'ardmatern32' or 'ardmatern52'	<p>(d+1)-by-1 vector phi, where phi(i) contains the length scale for predictor i and phi(d+1) contains the signal standard deviation. d is the number of predictor variables.</p> <p>Default initial value of the length scale parameters are the standard deviations of the predictors and the signal standard deviation is the standard deviation of the responses divided by square root of 2. That is,</p> $\text{phi} = [\text{std}(X)'; \text{std}(y) / \text{sqrt}(2)]$

'KernelFunction'	'KernelParameters'
'ardrationalquadratic'	<p>$(d+2)$-by-1 vector ϕ, where $\phi(i)$ contains the length scale for predictor i, $\phi(d+1)$ contains the scale-mixture parameter, and $\phi(d+2)$ contains signal standard deviation.</p> <p>Default initial value of the length scale parameters are the standard deviations of the predictors and the signal standard deviation is the standard deviation of the responses divided by square root of 2. Default initial value for the scale-mixture parameter is 1. That is,</p> $\phi = [\text{std}(X)'; 1; \text{std}(y)/\text{sqrt}(2)]$
Function handle	<p>r-by-1 vector as the initial value of the unconstrained parameter vector ϕ for the custom kernel function $kfcn$.</p> <p>When <code>KernelFunction</code> is a function handle, you must supply initial values for the kernel parameters.</p>

For more information on the kernel functions, see “Kernel (Covariance) Function Options” on page 6-6.

Example: 'KernelParameters', theta

Data Types: double

DistanceMethod — Method for computing inter-point distances

'fast' (default) | 'accurate'

Method for computing inter-point distances to evaluate built-in kernel functions, specified as the comma-separated pair consisting of 'DistanceMethod' and either 'fast' or 'accurate'. `fitrgp` computes $(x - y)^2$ as $x^2 + y^2 - 2*x*y$ when you choose the `fast` option and as $(x - y)^2$ when you choose the `accurate` option.

Example: 'DistanceMethod', 'accurate'

Active Set Selection**ActiveSet — Observations in the active set**

[] (default) | m -by-1 vector of integers ranging from 1 to n ($m \leq n$) | logical vector of length n

Observations in the active set, specified as the comma-separated pair consisting of 'ActiveSet' and an m -by-1 vector of integers ranging from 1 to n ($m \leq n$) or a logical vector of length n with at least one true element. n is the total number of observations in the training data.

fitrgp uses the observations indicated by ActiveSet to train the GPR model. The active set cannot have duplicate elements.

If you supply ActiveSet, then:

- fitrgp does not use ActiveSetSize and ActiveSetMethod.
- You cannot perform cross-validation on this model.

Data Types: double | logical

ActiveSetSize — Size of the active set for sparse methods

an integer m ($1 \leq m \leq n$)

Size of the active set for sparse methods ('sd', 'sr', 'fic'), specified as the comma-separated pair consisting of 'ActiveSetSize' and an integer m , $1 \leq m \leq n$, where n is the number of observations.

Default is $\min(1000, n)$ when FitMethod is 'sr' or 'fic', and $\min(2000, n)$, otherwise.

Example: 'ActiveSetSize', 100

Data Types: double

ActiveSetMethod — Active set selection method

'random' (default) | 'sgma' | 'entropy' | 'likelihood'

Active set selection method, specified as the comma-separated pair consisting of 'ActiveSetMethod' and one of the following.

Method	Description
'random'	Random selection

Method	Description
'sgma'	Sparse greedy matrix approximation
'entropy'	Differential entropy-based selection
'likelihood'	Subset of regressors log likelihood-based selection

All active set selection methods (except 'random') require the storage of an n -by- m matrix, where m is the size of the active set and n is the number of observations.

Example: 'ActiveSetMethod', 'entropy'

RandomSearchSetSize — Random search set size

59 (default) | integer value

Random search set size per greedy inclusion for active set selection, specified as the comma-separated pair consisting of 'RandomSearchSetSize' and an integer value.

Example: 'RandomSearchSetSize', 30

Data Types: double

ToleranceActiveSet — Relative tolerance for terminating active set selection

1e-06 (default) | positive scalar

Relative tolerance for terminating active set selection, specified as the comma-separated pair consisting of 'ToleranceActiveSet' and a positive scalar value.

Example: 'ToleranceActiveSet', 0.0002

Data Types: double

NumActiveSetRepeats — Number of repetitions

3 (default) | integer value

Number of repetitions for interleaved active set selection and parameter estimation on page 32-2377 when ActiveSetMethod is not 'random', specified as the comma-separated pair consisting of 'NumActiveSetRepeats' and an integer value.

Example: 'NumActiveSetRepeats', 5

Data Types: double

Prediction**PredictMethod — Method used to make predictions**`'exact' | 'bcd' | 'sd' | 'sr' | 'fic'`

Method used to make predictions from a Gaussian process model given the parameters, specified as the comma-separated pair consisting of 'PredictMethod' and one of the following.

Method	Description
'exact'	Exact Gaussian process regression method. Default, if $n \leq 10000$.
'bcd'	Block Coordinate Descent. Default, if $n > 10000$.
'sd'	Subset of Datapoints approximation.
'sr'	Subset of Regressors approximation.
'fic'	Fully Independent Conditional approximation.

Example: 'PredictMethod', 'bcd'

BlockSizeBCD — Block size

minimum of 1000 or n (default) | integer in the range from 1 to n

Block size for block coordinate descent method ('bcd'), specified as the comma-separated pair consisting of 'BlockSizeBCD' and an integer in the range from 1 to n , where n is the number of observations.

Example: 'BlockSizeBCD', 1500

Data Types: double

NumGreedyBCD — Number of greedy selections

minimum of 100 and BlockSizeBCD (default) | integer value in the range from 1 to BlockSizeBCD

Number of greedy selections for block coordinate descent method ('bcd'), specified as the comma-separated pair consisting of 'NumGreedyBCD' and an integer in the range from 1 to BlockSizeBCD.

Example: 'NumGreedyBCD', 150

Data Types: double

ToleranceBCD — Relative tolerance on gradient norm

1e-3 (default) | positive scalar

Relative tolerance on gradient norm for terminating block coordinate descent method ('bcd') iterations, specified as the comma-separated pair consisting of 'ToleranceBCD' and a positive scalar.

Example: 'ToleranceBCD',0.002

Data Types: double

StepToleranceBCD — Absolute tolerance on step size

1e-3 (default) | positive scalar

Absolute tolerance on step size for terminating block coordinate descent method ('bcd') iterations, specified as the comma-separated pair consisting of 'StepToleranceBCD' and a positive scalar.

Example: 'StepToleranceBCD',0.002

Data Types: double

IterationLimitBCD — Maximum number of BCD iterations

1000000 (default) | integer value

Maximum number of block coordinate descent method ('bcd') iterations, specified as the comma-separated pair consisting of 'IterationLimitBCD' and an integer value.

Example: 'IterationLimitBCD',10000

Data Types: double

Optimization

Optimizer — Optimizer to use for parameter estimation

'quasnewton' (default) | 'lbfgs' | 'fminsearch' | 'fminunc' | 'fmincon'

Optimizer to use for parameter estimation, specified as the comma-separated pair consisting of 'Optimizer' and one of the values in this table.

Value	Description
'quasnewton'	Dense, symmetric rank-1-based, quasi-Newton approximation to the Hessian
'lbfgs'	LBFGS-based quasi-Newton approximation to the Hessian
'fminsearch'	Unconstrained nonlinear optimization using the simplex search method of Lagarias et al. [5]
'fminunc'	Unconstrained nonlinear optimization (requires an Optimization Toolbox license)
'fmincon'	Constrained nonlinear optimization (requires an Optimization Toolbox license)

For more information on the optimizers, see Algorithms on page 32-2378.

Example: 'Optimizer', 'fmincon'

OptimizerOptions — Options for the optimizer

structure | object

Options for the optimizer you choose using the `Optimizer` name-value pair argument, specified as the comma-separated pair consisting of 'OptimizerOptions' and a structure or object created by `optimset`, `statset('fitrgp')`, or `optimoptions`.

Optimizer	Create Optimizer Options Using
'fminsearch'	<code>optimset</code> (structure)
'quasnewton' or 'lbfgs'	<code>statset('fitrgp')</code> (structure)
'fminunc' or 'fmincon'	<code>optimoptions</code> (object)

The default options depend on the type of optimizer.

Example: 'OptimizerOptions', `opt`

InitialStepSize — Initial step size

[] (default) | real positive scalar | 'auto'

Initial step size, specified as the comma-separated pair consisting of 'InitialStepSize' and a real positive scalar or 'auto'.

'InitialStepSize' is the approximate maximum absolute value of the first optimization step when the optimizer is 'quasinewton' or 'lbfgs'. The initial step size can determine the initial Hessian approximation during optimization.

By default, `fitrgp` does not use the initial step size to determine the initial Hessian approximation. To use the initial step size, set a value for the 'InitialStepSize' name-value pair argument, or specify 'InitialStepSize', 'auto' to have `fitrgp` determine a value automatically. For more information on 'auto', see Algorithms on page 32-2378.

Example: 'InitialStepSize', 'auto'

Cross-Validation

CrossVal — Indicator for cross-validation

'off' (default) | 'on'

Indicator for cross-validation, specified as the comma-separated pair consisting of 'CrossVal' and either 'off' or 'on'. If it is 'on', then `fitrgp` returns a GPR model cross-validated with 10 folds.

You can use one of the `KFold`, `Holdout`, `Leaveout` or `CVPartition` name-value pair arguments to change the default cross-validation settings. You can use only one of these name-value pairs at a time.

As an alternative, you can use the `crossval` method for your model.

Example: 'CrossVal', 'on'

CVPartition — Random partition for a stratified *k*-fold cross-validation

`cvpartition` object

Random partition for a stratified *k*-fold cross-validation, specified as the comma-separated pair consisting of 'CVPartition' and a `cvpartition` object.

Example: 'CVPartition', `cvp` uses the random partition defined by `cvp`.

If you specify `CVPartition`, then you cannot specify `Holdout`, `KFold`, or `Leaveout`.

Holdout — Fraction of data to use for testing

scalar value in the range from 0 to 1

Fraction of the data to use for testing in holdout validation, specified as the comma-separated pair consisting of 'Holdout' and a scalar value in the range from 0 to 1. If you specify 'Holdout', p , then the software:

1. Randomly reserves around $p*100\%$ of the data as validation data, and trains the model using the rest of the data
2. Stores the compact, trained model in `cvgprMdl.Trained`.

Example: 'Holdout', 0.3 uses 30% of the data for testing and 70% of the data for training.

If you specify `Holdout`, then you cannot specify `CVPartition`, `KFold`, or `Leaveout`.

Data Types: double

KFold — Number of folds

10 (default) | positive integer value

Number of folds to use in cross-validated GPR model, specified as the comma-separated pair consisting of 'KFold' and a positive integer value. `KFold` must be greater than 1. If you specify 'KFold', k then the software:

1. Randomly partitions the data into k sets.
2. For each set, reserves the set as test data, and trains the model using the other $k - 1$ sets.
3. Stores the k compact, trained models in the cells of a k -by-1 cell array in `cvgprMdl.Trained`.

Example: 'KFold', 5 uses 5 folds in cross-validation. That is, for each fold, uses that fold as test data, and trains the model on the remaining 4 folds.

If you specify `KFold`, then you cannot specify `CVPartition`, `Holdout`, or `Leaveout`.

Data Types: double

Leaveout — Indicator for leave-one-out cross-validation

'off' (default) | 'on'

Indicator for leave-one-out cross-validation, specified as the comma-separated pair consisting of 'Leaveout' and either 'off' or 'on'.

If you specify 'Leaveout', 'on', then, for each of the n observations, the software:

1. Reserves the observation as test data, and trains the model using the other $n - 1$ observations.
2. Stores the compact, trained model in a cell in the n -by-1 cell array `cvgprMdl.Trained`.

Example: 'Leaveout', 'on'

If you specify Leaveout, then you cannot specify CVPartition, Holdout, or KFold.

Hyperparameter Optimization

OptimizeHyperparameters — Parameters to optimize

'none' (default) | 'auto' | 'all' | string array or cell array of eligible parameter names | vector of optimizableVariable objects

Parameters to optimize, specified as the comma-separated pair consisting of 'OptimizeHyperparameters' and one of the following:

- 'none' — Do not optimize.
- 'auto' — Use {'Sigma'}.
- 'all' — Optimize all eligible parameters, equivalent to{'BasisFunction', 'KernelFunction', 'KernelScale', 'Sigma', 'Standardize'}.
- String array or cell array of eligible parameter names.
- Vector of optimizableVariable objects, typically the output of hyperparameters.

The optimization attempts to minimize the cross-validation loss (error) for fitrgp by varying the parameters. For information about cross-validation loss (albeit in a different context), see “Classification Loss” on page 32-3352. To control the cross-validation type and other aspects of the optimization, use the HyperparameterOptimizationOptions name-value pair.

Note 'OptimizeHyperparameters' values override any values you set using other name-value pair arguments. For example, setting 'OptimizeHyperparameters' to 'auto' causes the 'auto' values to apply.

The eligible parameters for fitrgp are:

- BasisFunction — fitrgp searches among 'constant', 'none', 'linear', and 'pureQuadratic'.
- KernelFunction — fitrgp searches among 'ardexponential', 'ardmatern32', 'ardmatern52', 'ardrationalquadratic', 'ardsquaredexponential', 'exponential', 'matern32', 'matern52', 'rationalquadratic', and 'squaredexponential'.

- **KernelScale** — `fitrgp` uses the `KernelParameters` argument to specify the value of the kernel scale parameter, which is held constant during fitting. In this case, all input dimensions are constrained to have the same `KernelScale` value. `fitrgp` searches among real value in the range $[1e-3 * \text{MaxPredictorRange}, \text{MaxPredictorRange}]$, where

$$\text{MaxPredictorRange} = \max(\max(X) - \min(X)).$$

`KernelScale` cannot be optimized for any of the ARD kernels.

- **Sigma** — `fitrgp` searches among real value in the range $[1e-4, \max(1e-3, 10 * \text{ResponseStd})]$, where

$$\text{ResponseStd} = \text{std}(y).$$

Internally, `fitrgp` sets the `ConstantSigma` name-value pair to `true` so the value of `Sigma` is constant during the fitting.

- **Standardize** — `fitrgp` searches among `true` and `false`.

Set nondefault parameters by passing a vector of `optimizableVariable` objects that have nondefault values. For example,

```
load fisheriris
params = hyperparameters('fitrgp',meas,species);
params(1).Range = [1e-4,1e6];
```

Pass `params` as the value of `OptimizeHyperparameters`.

By default, iterative display appears at the command line, and plots appear according to the number of hyperparameters in the optimization. For the optimization and plots, the objective function is $\log(1 + \text{cross-validation loss})$ for regression and the misclassification rate for classification. To control the iterative display, set the `Verbose` field of the `'HyperparameterOptimizationOptions'` name-value pair argument. To control the plots, set the `ShowPlots` field of the `'HyperparameterOptimizationOptions'` name-value pair argument.

For an example, see “Optimize GPR Regression” on page 32-2338.

Example: `'auto'`

HyperparameterOptimizationOptions — Options for optimization structure

Options for optimization, specified as the comma-separated pair consisting of 'HyperparameterOptimizationOptions' and a structure. This argument modifies the effect of the `OptimizeHyperparameters` name-value pair argument. All fields in the structure are optional.

Field Name	Values	Default
Optimizer	<ul style="list-style-type: none"> • 'bayesopt' — Use Bayesian optimization. Internally, this setting calls <code>bayesopt</code>. • 'gridsearch' — Use grid search with <code>NumGridDivisions</code> values per dimension. • 'randomsearch' — Search at random among <code>MaxObjectiveEvaluations</code> points. <p>'gridsearch' searches in a random order, using uniform sampling without replacement from the grid. After optimization, you can get a table in grid order by using the command <code>sortrows(Mdl.HyperparameterOptimizationResults)</code>.</p>	'bayesopt'

Field Name	Values	Default
AcquisitionFunctionName	<ul style="list-style-type: none"> • 'expected-improvement-per-second-plus' • 'expected-improvement' • 'expected-improvement-plus' • 'expected-improvement-per-second' • 'lower-confidence-bound' • 'probability-of-improvement' <p>Acquisition functions whose names include <code>per-second</code> do not yield reproducible results because the optimization depends on the runtime of the objective function. Acquisition functions whose names include <code>plus</code> modify their behavior when they are overexploiting an area. For more details, see “Acquisition Function Types” on page 10-4.</p>	'expected-improvement-per-second-plus'
MaxObjectiveEvaluations	Maximum number of objective function evaluations.	30 for 'bayesopt' or 'randomsearch', and the entire grid for 'gridsearch'
MaxTime	Time limit, specified as a positive real. The time limit is in seconds, as measured by <code>tic</code> and <code>toc</code> . Run time can exceed <code>MaxTime</code> because <code>MaxTime</code> does not interrupt function evaluations.	Inf
NumGridDivisions	For 'gridsearch', the number of values in each dimension. The value can be a vector of positive integers giving the number of values for each dimension, or a scalar that applies to all dimensions. This field is ignored for categorical variables.	10

Field Name	Values	Default
ShowPlots	Logical value indicating whether to show plots. If <code>true</code> , this field plots the best objective function value against the iteration number. If there are one or two optimization parameters, and if <code>Optimizer</code> is <code>'bayesopt'</code> , then <code>ShowPlots</code> also plots a model of the objective function against the parameters.	<code>true</code>
SaveIntermediateResults	Logical value indicating whether to save results when <code>Optimizer</code> is <code>'bayesopt'</code> . If <code>true</code> , this field overwrites a workspace variable named <code>'BayesoptResults'</code> at each iteration. The variable is a <code>BayesianOptimization</code> object.	<code>false</code>
Verbose	Display to the command line. <ul style="list-style-type: none"> • 0 — No iterative display • 1 — Iterative display • 2 — Iterative display with extra information For details, see the <code>bayesopt</code> <code>Verbose</code> name-value pair argument.	1
UseParallel	Logical value indicating whether to run Bayesian optimization in parallel, which requires Parallel Computing Toolbox. For details, see “Parallel Bayesian Optimization” on page 10-8.	<code>false</code>

Field Name	Values	Default
Repartition	Logical value indicating whether to repartition the cross-validation at every iteration. If <code>false</code> , the optimizer uses a single partition for the optimization. <code>true</code> usually gives the most robust results because this setting takes partitioning noise into account. However, for good results, <code>true</code> requires at least twice as many function evaluations.	<code>false</code>
Use no more than one of the following three field names.		
CVPartition	A <code>cvpartition</code> object, as created by <code>cvpartition</code> .	'Kfold', 5 if you do not specify any cross-validation field
Holdout	A scalar in the range (0, 1) representing the holdout fraction.	
Kfold	An integer greater than 1.	

Example:

```
'HyperparameterOptimizationOptions', struct('MaxObjectiveEvaluations', 60)
```

Data Types: `struct`

Other

PredictorNames — Predictor variable names

string array of unique names | cell array of unique character vectors

Predictor variable names, specified as the comma-separated pair consisting of 'PredictorNames' and a string array of unique names or a cell array of unique character vectors. The functionality of 'PredictorNames' depends on the way you supply the training data.

- If you supply `X` and `y`, then you can use 'PredictorNames' to give the predictor variables in `X` names.
- The order of the names in `PredictorNames` must correspond to the column order of `X`. That is, `PredictorNames{1}` is the name of `X(:, 1)`, `PredictorNames{2}`

is the name of $X(:,2)$, and so on. Also, `size(X,2)` and `numel(PredictorNames)` must be equal.

- By default, `PredictorNames` is `{'x1', 'x2', ...}`.
- If you supply `tbl`, then you can use `'PredictorNames'` to choose which predictor variables to use in training. That is, `fitrgp` uses the predictor variables in `PredictorNames` and the response only in training.
 - `PredictorNames` must be a subset of `tbl.Properties.VariableNames` and cannot include the name of the response variable.
 - By default, `PredictorNames` contains the names of all predictor variables.
 - It good practice to specify the predictors for training using one of `'PredictorNames'` or `formula` only.

Example: `'PredictorNames', {'PedalLength', 'PedalWidth'}`

Data Types: `string` | `cell`

ResponseName — Response variable name

`'Y'` (default) | character vector | string scalar

Response variable name, specified as the comma-separated pair consisting of `'ResponseName'` and a character vector or string scalar.

- If you supply `Y`, then you can use `'ResponseName'` to specify a name for the response variable.
- If you supply `ResponseVarName` or `formula`, then you cannot use `'ResponseName'`.

Example: `'ResponseName', 'response'`

Data Types: `char` | `string`

Verbose — Verbosity level

0 (default) | 1

Verbosity level, specified as the comma-separated pair consisting of `'Verbose'` and one of the following.

- 0 — `fitrgp` suppresses diagnostic messages related to active set selection and block coordinate descent but displays the messages related to parameter estimation, depending on the value of `'Display'` in `OptimizerOptions`.
- 1 — `fitrgp` displays the iterative diagnostic messages related to parameter estimation, active set selection, and block coordinate descent.

Example: `'Verbose',1`

CacheSize — Cache size in megabytes

1000 MB (default) | positive scalar

Cache size in megabytes (MB), specified as the comma-separated pair consisting of `'CacheSize'` and a positive scalar. Cache size is the extra memory that is available in addition to that required for fitting and active set selection. `fitrgp` uses `CacheSize` to:

- Decide whether interpoint distances should be cached when estimating parameters.
- Decide how matrix vector products should be computed for block coordinate descent method and for making predictions.

Example: `'CacheSize',2000`

Data Types: `double`

Output Arguments

gprMdl — Gaussian process regression model

`RegressionGP` object | `RegressionPartitionedModel` object

Gaussian process regression model, returned as a `RegressionGP` or a `RegressionPartitionedModel` object.

- If you cross-validate, that is, if you use one of the `'Crossval'`, `'KFold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'` name-value pairs, then `gprMdl` is a `RegressionPartitionedModel` object. You cannot use a `RegressionPartitionedModel` object to make predictions using `predict`. For more information on the methods and properties of this object, see `RegressionPartitionedModel`.
- If you do not cross-validate, then `gprMdl` is a `RegressionGP` object. You can use this object for predictions using the `predict` method. For more information on the methods and properties of this object, see `RegressionGP`.

Definitions

Active Set Selection and Parameter Estimation

For subset of data, subset of regressors, or fully independent conditional approximation fitting methods (FitMethod equal to 'sd', 'sr', or 'fic'), if you do not provide the active set, `fitrgp` selects the active set and computes the parameter estimates in a series of iterations.

In the first iteration, the software uses the initial parameter values in vector $\eta_0 = [\beta_0, \sigma_0, \theta_0]$ to select an active set A_1 . It maximizes the GPR marginal log likelihood or its approximation using η_0 as the initial values and A_1 to compute the new parameter estimates η_1 . Next, it computes the new log likelihood L_1 using η_1 and A_1 .

In the second iteration, the software selects the active set A_2 using the parameter values in η_1 . Then, using η_1 as the initial values and A_2 , it maximizes the GPR marginal log likelihood or its approximation and estimates the new parameter values η_2 . Then using η_2 and A_2 , computes the new log likelihood value L_2 .

The following table summarizes the iterations and what is computed at each iteration.

Iteration Number	Active Set	Parameter Vector	Log Likelihood
1	A_1	η_1	L_1
2	A_2	η_2	L_2
3	A_3	η_3	L_3
...

The software iterates similarly for a specified number of repetitions. You can specify the number of replications for active set selection using the `NumActiveSetRepeats` name-value pair argument.

Tips

- `fitrgp` accepts any combination of fitting, prediction, and active set selection methods. In some cases it might not be possible to compute the standard deviations of the predicted responses, hence the prediction intervals. See `predict`. And in some cases, using the exact method might be expensive due to the size of the training data.

- The `PredictorNames` property stores one element for each of the original predictor variable names. For example, if there are three predictors, one of which is a categorical variable with three levels, `PredictorNames` is a 1-by-3 cell array of character vectors.
- The `ExpandedPredictorNames` property stores one element for each of the predictor variables, including the dummy variables. For example, if there are three predictors, one of which is a categorical variable with three levels, then `ExpandedPredictorNames` is a 1-by-5 cell array of character vectors.
- Similarly, the `Beta` property stores one beta coefficient for each predictor, including the dummy variables.
- The `X` property stores the training data as originally input. It does not include the dummy variables.
- The default approach to initializing the Hessian approximation in `fitrgp` can be slow when you have a GPR model with many kernel parameters, such as when using an ARD kernel with many predictors. In this case, consider specifying `'auto'` or a value for the initial step size.

You can set `'Verbose', 1` for display of iterative diagnostic messages, and begin training a GPR model using an LBFGS or quasi-Newton optimizer with the default `fitrgp` optimization. If the iterative diagnostic messages are not displayed after a few seconds, it is possible that initialization of the Hessian approximation is taking too long. In this case, consider restarting training and using the initial step size to speed up optimization.

- After training a model, you can generate C/C++ code that predicts responses for new data. Generating C/C++ code requires MATLAB Coder. For details, see “Introduction to Code Generation” on page 31-2..

Algorithms

- Fitting a GPR model involves estimating the following model parameters from the data:
 - Covariance function $k(x_i, x_j | \theta)$ parameterized in terms of kernel parameters in vector θ (see “Kernel (Covariance) Function Options” on page 6-6)
 - Noise variance, σ^2
 - Coefficient vector of fixed basis functions, β

The value of the 'KernelParameters' name-value pair argument is a vector that consists of initial values for the signal standard deviation σ_f and the characteristic length scales σ_l . The `fitrgp` function uses these values to determine the kernel parameters. Similarly, the 'Sigma' name-value pair argument contains the initial value for the noise standard deviation σ .

- During optimization, `fitrgp` creates a vector of unconstrained initial parameter values η_0 by using the initial values for the noise standard deviation and the kernel parameters.
- `fitrgp` analytically determines the explicit basis coefficients β , specified by the 'Beta' name-value pair argument, from estimated values of θ and σ^2 . Therefore, β does not appear in the η_0 vector when `fitrgp` initializes numerical optimization.

Note If you specify no estimation of parameters for the GPR model, `fitrgp` uses the value of the 'Beta' name-value pair argument and other initial parameter values as the known GPR parameter values (see `Beta`). In all other cases, the value of the 'Beta' argument is optimized analytically from the objective function.

- The quasi-Newton optimizer uses a trust-region method with a dense, symmetric rank-1-based (SR1), quasi-Newton approximation to the Hessian, while the LBFGS optimizer uses a standard line-search method with a limited-memory Broyden-Fletcher-Goldfarb-Shanno (LBFGS) quasi-Newton approximation to the Hessian. See Nocedal and Wright [6].
- If you set the 'InitialStepSize' name-value pair argument to 'auto', `fitrgp` determines the initial step size, $\|s_0\|_\infty$, by using $\|s_0\|_\infty = 0.5\|\eta_0\|_\infty + 0.1$.

s_0 is the initial step vector, and η_0 is the vector of unconstrained initial parameter values.

- During optimization, `fitrgp` uses the initial step size, $\|s_0\|_\infty$, as follows:

If you use 'Optimizer', 'quasinewton' with the initial step size, then the initial

Hessian approximation is $\frac{\|g_0\|_\infty}{\|s_0\|_\infty}I$.

If you use 'Optimizer', 'lbfgs' with the initial step size, then the initial inverse-

Hessian approximation is $\frac{\|s_0\|_\infty}{\|g_0\|_\infty}I$.

g_0 is the initial gradient vector, and I is the identity matrix.

Extended Capabilities

Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the 'UseParallel' option to true.

To perform parallel hyperparameter optimization, use the 'HyperparameterOptions', struct('UseParallel', true) name-value pair argument in the call to this function.

For more information on parallel hyperparameter optimization, see "Parallel Bayesian Optimization" on page 10-8.

For more general information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

Introduced in R2015b

fitrlinear

Fit linear regression model to high-dimensional data

`fitrlinear` efficiently trains linear regression models with high-dimensional, full or sparse predictor data. Available linear regression models include regularized support vector machines (SVM) and least-squares regression methods. `fitrlinear` minimizes the objective function using techniques that reduce computing time (e.g., stochastic gradient descent).

For reduced computation time on a high-dimensional data set that includes many predictor variables, train a linear regression model by using `fitrlinear`. For low-through medium-dimensional predictor data sets, see “Alternatives for Lower-Dimensional Data” on page 32-2421.

Syntax

```
Mdl = fitrlinear(X,Y)
Mdl = fitrlinear(X,Y,Name,Value)
[Mdl,FitInfo] = fitrlinear(____)
[Mdl,FitInfo,HyperparameterOptimizationResults] = fitrlinear(____)
```

Description

`Mdl = fitrlinear(X,Y)` returns a trained regression model object that contains the results of fitting a support vector machine regression model to the predictors `X` and response `Y`.

`Mdl = fitrlinear(X,Y,Name,Value)` returns a trained linear regression model with additional options specified by one or more `Name,Value` pair arguments. For example, you can specify implement least-squares regression, specify to cross-validate, or specify the type of regularization. It is good practice to cross-validate using the `Kfold` `Name,Value` pair argument. The cross-validation results determine how well the model generalizes.

`[Mdl,FitInfo] = fitrlinear(____)` also returns optimization details using any of the previous syntaxes. You cannot request `FitInfo` for cross-validated models.

[Mdl,FitInfo,HyperparameterOptimizationResults] = fitrlinear(____) also returns hyperparameter optimization details when you pass an OptimizeHyperparameters name-value pair.

Examples

Train Linear Regression Model

Train a linear regression model using SVM, dual SGD, and ridge regularization.

Simulate 10000 observations from this model

$$y = x_{100} + 2x_{200} + e.$$

- $X = x_1, \dots, x_{1000}$ is a 10000-by-1000 sparse matrix with 10% nonzero standard normal elements.
- e is random normal error with mean 0 and standard deviation 0.3.

```
rng(1) % For reproducibility
n = 1e4;
d = 1e3;
nz = 0.1;
X = sprandn(n,d,nz);
Y = X(:,100) + 2*X(:,200) + 0.3*randn(n,1);
```

Train a linear regression model. By default, `fitrlinear` uses support vector machines with a ridge penalty, and optimizes using dual SGD for SVM. Determine how well the optimization algorithm fit the model to the data by extracting a fit summary.

```
[Mdl,FitInfo] = fitrlinear(X,Y)
```

```
Mdl =
  RegressionLinear
    ResponseName: 'Y'
  ResponseTransform: 'none'
           Beta: [1000x1 double]
           Bias: -0.0056
           Lambda: 1.0000e-04
           Learner: 'svm'
```

Properties, Methods

```
FitInfo = struct with fields:
    Lambda: 1.0000e-04
    Objective: 0.2725
    PassLimit: 10
    NumPasses: 10
    BatchLimit: []
    NumIterations: 100000
    GradientNorm: NaN
    GradientTolerance: 0
    RelativeChangeInBeta: 0.4907
    BetaTolerance: 1.0000e-04
    DeltaGradient: 1.5816
    DeltaGradientTolerance: 0.1000
    TerminationCode: 0
    TerminationStatus: {'Iteration limit exceeded.'}
    Alpha: [10000x1 double]
    History: []
    FitTime: 0.0912
    Solver: {'dual'}
```

`Mdl` is a `RegressionLinear` model. You can pass `Mdl` and the training or new data to `loss` to inspect the in-sample mean-squared error. Or, you can pass `Mdl` and new predictor data to `predict` to predict responses for new observations.

`FitInfo` is a structure array containing, among other things, the termination status (`TerminationStatus`) and how long the solver took to fit the model to the data (`FitTime`). It is good practice to use `FitInfo` to determine whether optimization-termination measurements are satisfactory. In this case, `fitrlinear` reached the maximum number of iterations. Because training time is fast, you can retrain the model, but increase the number of passes through the data. Or, try another solver, such as `LBFGS`.

Find Good Lasso Penalty Using Cross-Validation

To determine a good lasso-penalty strength for a linear regression model that uses least squares, implement 5-fold cross-validation.

Simulate 10000 observations from this model

$$y = x_{100} + 2x_{200} + e.$$

- $X = \{x_1, \dots, x_{1000}\}$ is a 10000-by-1000 sparse matrix with 10% nonzero standard normal elements.
- e is random normal error with mean 0 and standard deviation 0.3.

```
rng(1) % For reproducibility
n = 1e4;
d = 1e3;
nz = 0.1;
X = sprandn(n,d,nz);
Y = X(:,100) + 2*X(:,200) + 0.3*randn(n,1);
```

Create a set of 15 logarithmically-spaced regularization strengths from 10^{-5} through 10^{-1} .

```
Lambda = logspace(-5,-1,15);
```

Cross-validate the models. To increase execution speed, transpose the predictor data and specify that the observations are in columns. Optimize the objective function using SpARSA.

```
X = X';
CVMdl = fitrlinear(X,Y,'ObservationsIn','columns','KFold',5,'Lambda',Lambda,...
    'Learner','leastsquares','Solver','sparsa','Regularization','lasso');
```

```
numCLModels = numel(CVMdl.Trained)
```

```
numCLModels = 5
```

CVMdl is a `RegressionPartitionedLinear` model. Because `fitrlinear` implements 5-fold cross-validation, CVMdl contains 5 `RegressionLinear` models that the software trains on each fold.

Display the first trained linear regression model.

```
Mdl1 = CVMdl.Trained{1}
```

```
Mdl1 =
    RegressionLinear
        ResponseName: 'Y'
```

```
ResponseTransform: 'none'  
    Beta: [1000x15 double]  
    Bias: [1x15 double]  
    Lambda: [1x15 double]  
Learner: 'leastsquares'
```

Properties, Methods

Mdl1 is a `RegressionLinear` model object. `fitrlinear` constructed Mdl1 by training on the first four folds. Because `Lambda` is a sequence of regularization strengths, you can think of Mdl1 as 15 models, one for each regularization strength in `Lambda`.

Estimate the cross-validated MSE.

```
mse = kfoldLoss(CVMdl);
```

Higher values of `Lambda` lead to predictor variable sparsity, which is a good quality of a regression model. For each regularization strength, train a linear regression model using the entire data set and the same options as when you cross-validated the models. Determine the number of nonzero coefficients per model.

```
Mdl = fitrlinear(X,Y,'ObservationsIn','columns','Lambda',Lambda,...  
    'Learner','leastsquares','Solver','sparsa','Regularization','lasso');  
numNZCoeff = sum(Mdl.Beta~=0);
```

In the same figure, plot the cross-validated MSE and frequency of nonzero coefficients for each regularization strength. Plot all variables on the log scale.

```
figure  
[h,hL1,hL2] = plotyy(log10(Lambda),log10(mse),...  
    log10(Lambda),log10(numNZCoeff));  
hL1.Marker = 'o';  
hL2.Marker = 'o';  
ylabel(h(1),'log10 MSE')  
ylabel(h(2),'log10 nonzero-coefficient frequency')  
xlabel('log10 Lambda')  
hold off
```

Choose the index of the regularization strength that balances predictor variable sparsity and low MSE (for example, $\text{Lambda}(10)$).

```
idxFinal = 10;
```

Extract the model with corresponding to the minimal MSE.

```
MdlFinal = selectModels(Mdl,idxFinal)
```

```
MdlFinal =
  RegressionLinear
    ResponseName: 'Y'
    ResponseTransform: 'none'
    Beta: [1000x1 double]
```

```
Bias: -0.0050  
Lambda: 0.0037  
Learner: 'leastsquares'
```

Properties, Methods

```
idxNZCoeff = find(MdlFinal.Beta~=0)
```

```
idxNZCoeff = 2×1
```

```
100  
200
```

```
EstCoeff = Mdl.Beta(idxNZCoeff)
```

```
EstCoeff = 2×1
```

```
1.0051  
1.9965
```

`MdlFinal` is a `RegressionLinear` model with one regularization strength. The nonzero coefficients `EstCoeff` are close to the coefficients that simulated the data.

Optimize a Linear Regression

This example shows how to optimize hyperparameters automatically using `fitrlinear`. The example uses artificial (simulated) data for the model

$$y = x_{100} + 2x_{200} + e.$$

- $X = \{x_1, \dots, x_{1000}\}$ is a 10000-by-1000 sparse matrix with 10% nonzero standard normal elements.
- e is random normal error with mean 0 and standard deviation 0.3.

```
rng(1) % For reproducibility  
n = 1e4;  
d = 1e3;  
nz = 0.1;
```

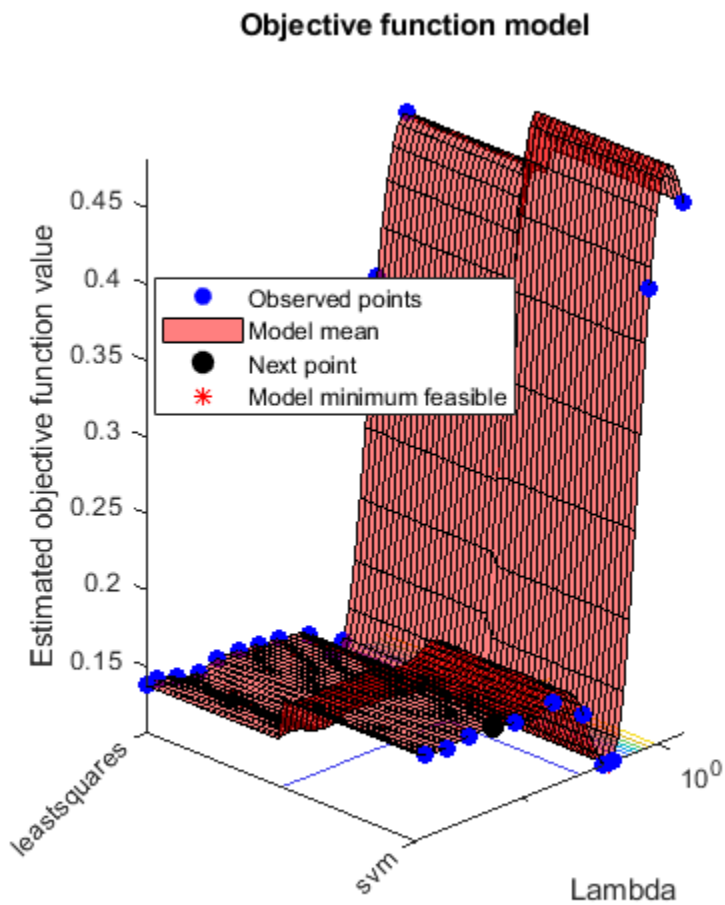

```
X = sprandn(n,d,nz);  
Y = X(:,100) + 2*X(:,200) + 0.3*randn(n,1);
```

Find hyperparameters that minimize five-fold cross validation loss by using automatic hyperparameter optimization.

For reproducibility, use the 'expected-improvement-plus' acquisition function.

```
hyperopts = struct('AcquisitionFunctionName','expected-improvement-plus');  
[Mdl,FitInfo,HyperparameterOptimizationResults] = fitrlinear(X,Y,...  
    'OptimizeHyperparameters','auto',...  
    'HyperparameterOptimizationOptions',hyperopts)
```

This optimization technique is simpler than that shown in “Find Good Lasso Penalty Using Cross-Validation” on page 32-2384, but does not allow you to trade off model complexity and cross-validation loss.

Input Arguments

X — Predictor data

full matrix | sparse matrix

Predictor data, specified as an n -by- p full or sparse matrix.

The length of Y and the number of observations in X must be equal.

Note If you orient your predictor matrix so that observations correspond to columns and specify 'ObservationsIn', 'columns', then you might experience a significant reduction in optimization-execution time.

Data Types: `single` | `double`

Y — Response data

numeric vector

Response data, specified as an n -dimensional numeric vector. The length of Y and the number of observations in X must be equal.

Data Types: `single` | `double`

Note `fitrlinear` removes missing observations, that is, observations with any of these characteristics:

- NaN elements in the response (Y or `ValidationData{2}`)
- At least one NaN value in a predictor observation (row in X or `ValidationData{1}`)
- NaN value or 0 weight (`Weights` or `ValidationData{3}`)

For memory-usage economy, it is best practice to remove observations containing missing values from your training data manually before training.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Note You cannot use any cross-validation name-value pair argument along with the 'OptimizeHyperparameters' name-value pair argument. You can modify the cross-validation for 'OptimizeHyperparameters' only by using the 'HyperparameterOptimizationOptions' name-value pair argument.

Example: `Mdl = fitrlinear(X,Y,'Learner','leastsquares','CrossVal','on','Regularization','lasso')` specifies to implement least-squares regression, implement 10-fold cross-validation, and specifies to include a lasso regularization term.

Linear Regression Options

Epsilon — Half the width of epsilon-insensitive band

`iqr(Y)/13.49` (default) | nonnegative scalar value

Half the width of the epsilon-insensitive band, specified as the comma-separated pair consisting of 'Epsilon' and a nonnegative scalar value. 'Epsilon' applies to SVM learners only.

The default Epsilon value is `iqr(Y)/13.49`, which is an estimate of standard deviation using the interquartile range of the response variable Y . If `iqr(Y)` is equal to zero, then the default Epsilon value is 0.1.

Example: `'Epsilon',0.3`

Data Types: `single` | `double`

Lambda — Regularization term strength

'auto' (default) | nonnegative scalar | vector of nonnegative values

Regularization term strength, specified as the comma-separated pair consisting of 'Lambda' and 'auto', a nonnegative scalar, or a vector of nonnegative values.

- For 'auto', $\text{Lambda} = 1/n$.
 - If you specify a cross-validation, name-value pair argument (e.g., `CrossVal`), then n is the number of in-fold observations.
 - Otherwise, n is the training sample size.
- For a vector of nonnegative values, the software sequentially optimizes the objective function for each distinct value in `Lambda` in ascending order.
 - If `Solver` is 'sgd' or 'asgd' and `Regularization` is 'lasso', then the software does not use the previous coefficient estimates as a warm start on page 32-2002 for the next optimization iteration. Otherwise, the software uses warm starts.
 - If `Regularization` is 'lasso', then any coefficient estimate of 0 retains its value when the software optimizes using subsequent values in `Lambda`.

Returns coefficient estimates for all optimization iterations.

Example: 'Lambda', 10.^(-(10:-2:2))

Data Types: char | string | double | single

Learner — Linear regression model type

'svm' (default) | 'leastsquares'

Linear regression model type, specified as the comma-separated pair consisting of 'Learner' and 'svm' or 'leastsquares'.

In this table, $f(x) = x\beta + b$.

- β is a vector of p coefficients.
- x is an observation from p predictor variables.
- b is the scalar bias.

Value	Algorithm	Response range	Loss function
'leastsquares'	Linear regression via ordinary least squares	$y \in (-\infty, \infty)$	Mean squared error (MSE): $\ell[y, f(x)]$ $= \frac{1}{2}[y - f(x)]^2$
'svm'	Support vector machine regression	Same as 'leastsquares'	Epsilon-insensitive: $\ell[y, f(x)] = \max$ $[0, y - f(x) - \varepsilon]$

Example: 'Learner', 'leastsquares'

ObservationsIn — Predictor data observation dimension

'rows' (default) | 'columns'

Predictor data observation dimension, specified as the comma-separated pair consisting of 'ObservationsIn' and 'columns' or 'rows'.

Note If you orient your predictor matrix so that observations correspond to columns and specify 'ObservationsIn', 'columns', then you might experience a significant reduction in optimization-execution time.

Regularization — Complexity penalty type

'lasso' | 'ridge'

Complexity penalty type, specified as the comma-separated pair consisting of 'Regularization' and 'lasso' or 'ridge'.

The software composes the objective function for minimization from the sum of the average loss function (see Learner) and the regularization term in this table.

Value	Description
'lasso'	Lasso (L1) penalty: $\lambda \sum_{j=1}^p \beta_j $
'ridge'	Ridge (L2) penalty: $\frac{\lambda}{2} \sum_{j=1}^p \beta_j^2$

To specify the regularization term strength, which is λ in the expressions, use Lambda.

The software excludes the bias term (β_0) from the regularization penalty.

If Solver is 'sparsa', then the default value of Regularization is 'lasso'. Otherwise, the default is 'ridge'.

Tip

- For predictor variable selection, specify 'lasso'.
- For optimization accuracy, specify 'ridge'.

Example: 'Regularization', 'lasso'

Solver — Objective function minimization technique

'sgd' | 'asgd' | 'dual' | 'bfgs' | 'lbfgs' | 'sparsa' | string array | cell array of character vectors

Objective function minimization technique, specified as the comma-separated pair consisting of 'Solver' and a character vector or string scalar, a string array, or a cell array of character vectors with values from this table.

Value	Description	Restrictions
'sgd'	Stochastic gradient descent (SGD) [5][3]	
'asgd'	Average stochastic gradient descent (ASGD) [8]	
'dual'	Dual SGD for SVM [2][7]	Regularization must be 'ridge' and Learner must be 'svm'.
'bfgs'	Broyden-Fletcher-Goldfarb-Shanno quasi-Newton algorithm (BFGS) [4]	Inefficient if X is very high-dimensional.
'lbfgs'	Limited-memory BFGS (LBFGS) [4]	Regularization must be 'ridge'.
'sparsa'	Sparse Reconstruction by Separable Approximation (SpaRSA) [6]	Regularization must be 'lasso'.

If you specify:

- A ridge penalty (see Regularization) and $\text{size}(X,1) \leq 100$ (100 or fewer predictor variables), then the default solver is 'bfgs'.
- An SVM regression model (see Learner), a ridge penalty, and $\text{size}(X,1) > 100$ (more than 100 predictor variables), then the default solver is 'dual'.
- A lasso penalty and X contains 100 or fewer predictor variables, then the default solver is 'sparsa'.

Otherwise, the default solver is 'sgd'.

If you specify a string array or cell array of solver names, then the software uses all solvers in the specified order for each Lambda.

For more details on which solver to choose, see “Tips” on page 32-2422.

Example: 'Solver',{'sgd','lbfgs'}

Beta — Initial linear coefficient estimates

`zeros(p,1)` (default) | numeric vector | numeric matrix

Initial linear coefficient estimates (β), specified as the comma-separated pair consisting of 'Beta' and a p -dimensional numeric vector or a p -by- L numeric matrix. p is the number of predictor variables in X and L is the number of regularization-strength values (for more details, see Lambda).

- If you specify a p -dimensional vector, then the software optimizes the objective function L times using this process.
 - 1 The software optimizes using Beta as the initial value and the minimum value of Lambda as the regularization strength.
 - 2 The software optimizes again using the resulting estimate from the previous optimization as a warm start on page 32-2002, and the next smallest value in Lambda as the regularization strength.
 - 3 The software implements step 2 until it exhausts all values in Lambda.
- If you specify a p -by- L matrix, then the software optimizes the objective function L times. At iteration j , the software uses Beta(:, j) as the initial value and, after it sorts Lambda in ascending order, uses Lambda(j) as the regularization strength.

If you set 'Solver', 'dual', then the software ignores Beta.

Data Types: single | double

Bias — Initial intercept estimate

numeric scalar | numeric vector

Initial intercept estimate (b), specified as the comma-separated pair consisting of 'Bias' and a numeric scalar or an L -dimensional numeric vector. L is the number of regularization-strength values (for more details, see Lambda).

- If you specify a scalar, then the software optimizes the objective function L times using this process.
 - 1 The software optimizes using Bias as the initial value and the minimum value of Lambda as the regularization strength.
 - 2 The uses the resulting estimate as a warm start on page 32-2421 to the next optimization iteration, and uses the next smallest value in Lambda as the regularization strength.
 - 3 The software implements step 2 until it exhausts all values in Lambda.
- If you specify an L -dimensional vector, then the software optimizes the objective function L times. At iteration j , the software uses Bias(j) as the initial value and,

after it sorts Lambda in ascending order, uses $\text{Lambda}(j)$ as the regularization strength.

- By default:
 - If `Learner` is `'leastsquares'`, then `Bias` is the weighted average of `Y` for training or, for cross-validation, in-fold responses.
 - If `Learner` is `'svm'`, then `Bias` is the weighted median of `Y` for all training or, for cross-validation, in-fold observations that are greater than `Epsilon`.

Data Types: `single` | `double`

FitBias — Linear model intercept inclusion flag

`true` (default) | `false`

Linear model intercept inclusion flag, specified as the comma-separated pair consisting of `'FitBias'` and `true` or `false`.

Value	Description
<code>true</code>	The software includes the bias term b in the linear model, and then estimates it.
<code>false</code>	The software sets $b = 0$ during estimation.

Example: `'FitBias', false`

Data Types: `logical`

PostFitBias — Flag to fit linear model intercept after optimization

`false` (default) | `true`

Flag to fit the linear model intercept after optimization, specified as the comma-separated pair consisting of `'PostFitBias'` and `true` or `false`.

Value	Description
<code>false</code>	The software estimates the bias term b and the coefficients β during optimization.

Value	Description
true	To estimate b , the software: <ol style="list-style-type: none"> 1 Estimates β and b using the model. 2 Computes residuals. 3 Refits b. For least squares, b is the weighted average of the residuals. For SVM regression, b is the weighted median between all residuals with magnitude greater than <code>Epsilon</code>.

If you specify `true`, then `FitBias` must be `true`.

Example: `'PostFitBias', true`

Data Types: `logical`

Verbose — Verbosity level

0 (default) | nonnegative integer

Verbosity level, specified as the comma-separated pair consisting of `'Verbose'` and a nonnegative integer. `Verbose` controls the amount of diagnostic information `fitrlinear` displays at the command line.

Value	Description
0	<code>fitrlinear</code> does not display diagnostic information.
1	<code>fitrlinear</code> periodically displays and stores the value of the objective function, gradient magnitude, and other diagnostic information. <code>FitInfo.History</code> contains the diagnostic information.
Any other positive integer	<code>fitrlinear</code> displays and stores diagnostic information at each optimization iteration. <code>FitInfo.History</code> contains the diagnostic information.

Example: `'Verbose', 1`

Data Types: `double` | `single`

SGD and ASGD Solver Options**BatchSize — Mini-batch size**

positive integer

Mini-batch size, specified as the comma-separated pair consisting of 'BatchSize' and a positive integer. At each iteration, the software estimates the subgradient using BatchSize observations from the training data.

- If X is a numeric matrix, then the default value is 10.
- If X is a sparse matrix, then the default value is $\max([10, \text{ceil}(\text{sqrt}(\text{ff}))])$, where $\text{ff} = \text{numel}(X)/\text{nnz}(X)$ (the fullness factor of X).

Example: 'BatchSize', 100

Data Types: single | double

LearnRate — Learning rate

positive scalar

Learning rate, specified as the comma-separated pair consisting of 'LearnRate' and a positive scalar. LearnRate specifies how many steps to take per iteration. At each iteration, the gradient specifies the direction and magnitude of each step.

- If Regularization is 'ridge', then LearnRate specifies the initial learning rate γ_0 . The software determines the learning rate for iteration t , γ_t , using

$$\gamma_t = \frac{\gamma_0}{(1 + \lambda \gamma_0 t)^c}.$$

- λ is the value of Lambda.
- If Solver is 'sgd', then $c = 1$.
- If Solver is 'asgd', then c is:
 - 2/3 if Learner is 'leastsquares'
 - 3/4 if Learner is 'svm' [8]
- If Regularization is 'lasso', then, for all iterations, LearnRate is constant.

By default, LearnRate is $1/\text{sqrt}(1 + \max((\text{sum}(X.^2, \text{obsDim}))))$, where obsDim is 1 if the observations compose the columns of X , and 2 otherwise.

Example: 'LearnRate', 0.01

Data Types: single | double

OptimizeLearnRate — Flag to decrease learning rate

true (default) | false

Flag to decrease the learning rate when the software detects divergence (that is, overstepping the minimum), specified as the comma-separated pair consisting of 'OptimizeLearnRate' and true or false.

If `OptimizeLearnRate` is 'true', then:

- 1 For the few optimization iterations, the software starts optimization using `LearnRate` as the learning rate.
- 2 If the value of the objective function increases, then the software restarts and uses half of the current value of the learning rate.
- 3 The software iterates step 2 until the objective function decreases.

Example: 'OptimizeLearnRate', true

Data Types: logical

TruncationPeriod — Number of mini-batches between lasso truncation runs

10 (default) | positive integer

Number of mini-batches between lasso truncation runs, specified as the comma-separated pair consisting of 'TruncationPeriod' and a positive integer.

After a truncation run, the software applies a soft threshold to the linear coefficients. That is, after processing $k = \text{TruncationPeriod}$ mini-batches, the software truncates the estimated coefficient j using

$$\widehat{\beta}_j^* = \begin{cases} \widehat{\beta}_j - u_t & \text{if } \widehat{\beta}_j > u_t, \\ 0 & \text{if } |\widehat{\beta}_j| \leq u_t, \\ \widehat{\beta}_j + u_t & \text{if } \widehat{\beta}_j < -u_t. \end{cases}$$

- For SGD, $\widehat{\beta}_j$ is the estimate of coefficient j after processing k mini-batches. $u_t = k\gamma_t\lambda$. γ_t is the learning rate at iteration t . λ is the value of Lambda.
- For ASGD, $\widehat{\beta}_j$ is the averaged estimate coefficient j after processing k mini-batches, $u_t = k\lambda$.

If `Regularization` is `'ridge'`, then the software ignores `TruncationPeriod`.

Example: `'TruncationPeriod', 100`

Data Types: `single` | `double`

Other Regression Options

Weights — Observation weights

`ones(n, 1)/n` (default) | numeric vector of positive values

Observation weights, specified as the comma-separated pair consisting of `'Weights'` and a numeric vector of positive values. `fitrlinear` weighs the observations in `X` with the corresponding value in `Weights`. The size of `Weights` must equal `n`, the number of observations in `X`.

`fitrlinear` normalizes `Weights` to sum to 1.

Data Types: `double` | `single`

ResponseName — Response variable name

`'Y'` (default) | character vector | string scalar

Response variable name, specified as the comma-separated pair consisting of `'ResponseName'` and a character vector or string scalar.

- If you supply `Y`, then you can use `'ResponseName'` to specify a name for the response variable.
- If you supply `ResponseVarName` or `formula`, then you cannot use `'ResponseName'`.

Example: `'ResponseName', 'response'`

Data Types: `char` | `string`

ResponseTransform — Response transformation

`'none'` (default) | function handle

Response transformation, specified as the comma-separated pair consisting of `'ResponseTransform'` and either `'none'` or a function handle. The default is `'none'`, which means $@(y)y$, or no transformation. For a MATLAB function or a function you define, use its function handle. The function handle must accept a vector (the original response values) and return a vector of the same size (the transformed response values).

Example: Suppose you create a function handle that applies an exponential transformation to an input vector by using `myfunction = @(y)exp(y)`. Then, you can specify the response transformation as `'ResponseTransform',myfunction`.

Data Types: `char` | `string` | `function_handle`

Cross-Validation Options

CrossVal — Cross-validation flag

`'off'` (default) | `'on'`

Cross-validation flag, specified as the comma-separated pair consisting of `'Crossval'` and `'on'` or `'off'`.

If you specify `'on'`, then the software implements 10-fold cross-validation.

To override this cross-validation setting, use one of these name-value pair arguments: `CVPartition`, `Holdout`, or `KFold`. To create a cross-validated model, you can use one cross-validation name-value pair argument at a time only.

Example: `'Crossval','on'`

CVPartition — Cross-validation partition

`[]` (default) | `cvpartition` partition object

Cross-validation partition, specified as the comma-separated pair consisting of `'CVPartition'` and a `cvpartition` partition object as created by `cvpartition`. The partition object specifies the type of cross-validation, and also the indexing for training and validation sets.

To create a cross-validated model, you can use one of these four options only: `'CVPartition'`, `'Holdout'`, or `'KFold'`.

Holdout — Fraction of data for holdout validation

scalar value in the range (0,1)

Fraction of data used for holdout validation, specified as the comma-separated pair consisting of `'Holdout'` and a scalar value in the range (0,1). If you specify `'Holdout',p`, then the software:

- 1 Randomly reserves $p*100\%$ of the data as validation data, and trains the model using the rest of the data

- 2 Stores the compact, trained model in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can use one of these four options only: `'CVPartition'`, `'Holdout'`, or `'KFold'`.

Example: `'Holdout',0.1`

Data Types: `double` | `single`

KFold — Number of folds

10 (default) | positive integer value greater than 1

Number of folds to use in a cross-validated classifier, specified as the comma-separated pair consisting of `'KFold'` and a positive integer value greater than 1. If you specify, e.g., `'KFold',k`, then the software:

- 1 Randomly partitions the data into k sets
- 2 For each set, reserves the set as validation data, and trains the model using the other $k - 1$ sets
- 3 Stores the k compact, trained models in the cells of a k -by-1 cell vector in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can use one of these four options only: `'CVPartition'`, `'Holdout'`, or `'KFold'`.

Example: `'KFold',8`

Data Types: `single` | `double`

SGD and ASGD Convergence Controls

BatchLimit — Maximal number of batches

positive integer

Maximal number of batches to process, specified as the comma-separated pair consisting of `'BatchLimit'` and a positive integer. When the software processes `BatchLimit` batches, it terminates optimization.

- By default:
 - The software passes through the data `PassLimit` times.

- If you specify multiple solvers, and use (A)SGD to get an initial approximation for the next solver, then the default value is `ceil(1e6/BatchSize)`. `BatchSize` is the value of the 'BatchSize' name-value pair argument.
- If you specify 'BatchLimit' and 'PassLimit', then the software chooses the argument that results in processing the fewest observations.
- If you specify 'BatchLimit' but not 'PassLimit', then the software processes enough batches to complete up to one entire pass through the data.

Example: 'BatchLimit',100

Data Types: single | double

BetaTolerance — Relative tolerance on linear coefficients and bias term

1e-4 (default) | nonnegative scalar

Relative tolerance on the linear coefficients and the bias term (intercept), specified as the comma-separated pair consisting of 'BetaTolerance' and a nonnegative scalar.

Let $B_t = [\beta_t' \ b_t]$, that is, the vector of the coefficients and the bias term at optimization iteration t . If $\left\| \frac{B_t - B_{t-1}}{B_t} \right\|_2 < \text{BetaTolerance}$, then optimization terminates.

If the software converges for the last solver specified in `Solver`, then optimization terminates. Otherwise, the software uses the next solver specified in `Solver`.

Example: 'BetaTolerance',1e-6

Data Types: single | double

NumCheckConvergence — Number of batches to process before next convergence check

positive integer

Number of batches to process before next convergence check, specified as the comma-separated pair consisting of 'NumCheckConvergence' and a positive integer.

To specify the batch size, see `BatchSize`.

The software checks for convergence about 10 times per pass through the entire data set by default.

Example: 'NumCheckConvergence',100

Data Types: `single` | `double`

PassLimit — Maximal number of passes

1 (default) | positive integer

Maximal number of passes through the data, specified as the comma-separated pair consisting of 'PassLimit' and a positive integer.

`fitrlinear` processes all observations when it completes one pass through the data.

When `fitrlinear` passes through the data `PassLimit` times, it terminates optimization.

If you specify 'BatchLimit' and `PassLimit`, then `fitrlinear` chooses the argument that results in processing the fewest observations. For more details, see “Algorithms” on page 32-2424.

Example: 'PassLimit',5

Data Types: `single` | `double`

ValidationData — Validation data for optimization convergence detection

cell array

Data for optimization convergence detection, specified as the comma-separated pair consisting of 'ValidationData' and a cell array.

During optimization, the software periodically estimates the loss of `ValidationData`. If the validation-data loss increases, then the software terminates optimization. For more details, see “Algorithms” on page 32-2424. To optimize hyperparameters using cross-validation, see cross-validation options such as `CrossVal`.

- `ValidationData(1)` must contain an m -by- p or p -by- m full or sparse matrix of predictor data that has the same orientation as `X`. The predictor variables in the training data `X` and `ValidationData{1}` must correspond. The number of observations in both sets can vary.
- `ValidationData(2)` must contain an array of m responses with length corresponding to the number of observations in `ValidationData{1}`.
- Optionally, `ValidationData(3)` can contain an m -dimensional numeric vector of observation weights. The software normalizes the weights with the validation data so that they sum to 1.

If you specify `ValidationData`, then, to display validation loss at the command line, specify a value larger than 0 for `Verbose`.

If the software converges for the last solver specified in `Solver`, then optimization terminates. Otherwise, the software uses the next solver specified in `Solver`.

By default, the software does not detect convergence by monitoring validation-data loss.

GradientTolerance — Absolute gradient tolerance

1e-6 (default) | nonnegative scalar

Absolute gradient tolerance, specified as the comma-separated pair consisting of 'GradientTolerance' and a nonnegative scalar. `GradientTolerance` applies to these values of `Solver`: 'bfgs', 'lbfgs', and 'sparsa'.

Let $\nabla \mathcal{L}_t$ be the gradient vector of the objective function with respect to the coefficients and bias term at optimization iteration t . If $\|\nabla \mathcal{L}_t\|_\infty = \max|\nabla \mathcal{L}_t| < \text{GradientTolerance}$, then optimization terminates.

If you also specify `BetaTolerance`, then optimization terminates when `fitrlinear` satisfies either stopping criterion.

If `fitrlinear` converges for the last solver specified in `Solver`, then optimization terminates. Otherwise, `fitrlinear` uses the next solver specified in `Solver`.

Example: 'GradientTolerance',eps

Data Types: single | double

IterationLimit — Maximal number of optimization iterations

1000 (default) | positive integer

Maximal number of optimization iterations, specified as the comma-separated pair consisting of 'IterationLimit' and a positive integer. `IterationLimit` applies to these values of `Solver`: 'bfgs', 'lbfgs', and 'sparsa'.

Example: 'IterationLimit',1e7

Data Types: single | double

Dual SGD Optimization Convergence Controls

BetaTolerance — Relative tolerance on linear coefficients and bias term

1e-4 (default) | nonnegative scalar

Relative tolerance on the linear coefficients and the bias term (intercept), specified as the comma-separated pair consisting of 'BetaTolerance' and a nonnegative scalar.

Let $B_t = [\beta_t' \ b_t]$, that is, the vector of the coefficients and the bias term at optimization iteration t . If $\left\| \frac{B_t - B_{t-1}}{B_t} \right\|_2 < \text{BetaTolerance}$, then optimization terminates.

If you also specify DeltaGradientTolerance, then optimization terminates when the software satisfies either stopping criterion.

If the software converges for the last solver specified in Solver, then optimization terminates. Otherwise, the software uses the next solver specified in Solver.

Example: 'BetaTolerance', 1e-6

Data Types: single | double

DeltaGradientTolerance — Gradient-difference tolerance

0.1 (default) | nonnegative scalar

Gradient-difference tolerance between upper and lower pool Karush-Kuhn-Tucker (KKT) complementarity conditions on page 32-2088 violators, specified as the comma-separated pair consisting of 'DeltaGradientTolerance' and a nonnegative scalar.

DeltaGradientTolerance applies to the 'dual' value of Solver only.

- If the magnitude of the KKT violators is less than DeltaGradientTolerance, then fitrlinear terminates optimization.
- If fitrlinear converges for the last solver specified in Solver, then optimization terminates. Otherwise, fitrlinear uses the next solver specified in Solver.

Example: 'DeltaGapTolerance', 1e-2

Data Types: double | single

NumCheckConvergence — Number of passes through entire data set to process before next convergence check

5 (default) | positive integer

Number of passes through entire data set to process before next convergence check, specified as the comma-separated pair consisting of 'NumCheckConvergence' and a positive integer.

Example: 'NumCheckConvergence', 100

Data Types: `single` | `double`

PassLimit — Maximal number of passes

10 (default) | positive integer

Maximal number of passes through the data, specified as the comma-separated pair consisting of 'PassLimit' and a positive integer.

When the software completes one pass through the data, it has processed all observations.

When the software passes through the data `PassLimit` times, it terminates optimization.

Example: 'PassLimit',5

Data Types: `single` | `double`

ValidationData — Validation data for optimization convergence detection

cell array

Data for optimization convergence detection, specified as the comma-separated pair consisting of 'ValidationData' and a cell array.

During optimization, the software periodically estimates the loss of `ValidationData`. If the validation-data loss increases, then the software terminates optimization. For more details, see “Algorithms” on page 32-2424. To optimize hyperparameters using cross-validation, see cross-validation options such as `CrossVal`.

- `ValidationData(1)` must contain an m -by- p or p -by- m full or sparse matrix of predictor data that has the same orientation as `X`. The predictor variables in the training data `X` and `ValidationData{1}` must correspond. The number of observations in both sets can vary.
- `ValidationData(2)` must contain an array of m responses with length corresponding to the number of observations in `ValidationData{1}`.
- Optionally, `ValidationData(3)` can contain an m -dimensional numeric vector of observation weights. The software normalizes the weights with the validation data so that they sum to 1.

If you specify `ValidationData`, then, to display validation loss at the command line, specify a value larger than 0 for `Verbose`.

If the software converges for the last solver specified in `Solver`, then optimization terminates. Otherwise, the software uses the next solver specified in `Solver`.

By default, the software does not detect convergence by monitoring validation-data loss.

BFGS, LBFGS, and SpARSA Convergence Controls

BetaTolerance — Relative tolerance on linear coefficients and bias term

1e-4 (default) | nonnegative scalar

Relative tolerance on the linear coefficients and the bias term (intercept), specified as the comma-separated pair consisting of 'BetaTolerance' and a nonnegative scalar.

Let $B_t = [\beta_t' \ b_t]$, that is, the vector of the coefficients and the bias term at optimization iteration t . If $\left\| \frac{B_t - B_{t-1}}{B_t} \right\|_2 < \text{BetaTolerance}$, then optimization terminates.

If you also specify GradientTolerance, then optimization terminates when the software satisfies either stopping criterion.

If the software converges for the last solver specified in Solver, then optimization terminates. Otherwise, the software uses the next solver specified in Solver.

Example: 'BetaTolerance', 1e-6

Data Types: single | double

GradientTolerance — Absolute gradient tolerance

1e-6 (default) | nonnegative scalar

Absolute gradient tolerance, specified as the comma-separated pair consisting of 'GradientTolerance' and a nonnegative scalar.

Let $\nabla \mathcal{L}_t$ be the gradient vector of the objective function with respect to the coefficients and bias term at optimization iteration t . If $\|\nabla \mathcal{L}_t\|_\infty = \max|\nabla \mathcal{L}_t| < \text{GradientTolerance}$, then optimization terminates.

If you also specify BetaTolerance, then optimization terminates when the software satisfies either stopping criterion.

If the software converges for the last solver specified in the software, then optimization terminates. Otherwise, the software uses the next solver specified in Solver.

Example: 'GradientTolerance', 1e-5

Data Types: single | double

HessianHistorySize — Size of history buffer for Hessian approximation

15 (default) | positive integer

Size of history buffer for Hessian approximation, specified as the comma-separated pair consisting of 'HessianHistorySize' and a positive integer. That is, at each iteration, the software composes the Hessian using statistics from the latest HessianHistorySize iterations.

The software does not support 'HessianHistorySize' for SpaRSA.

Example: 'HessianHistorySize',10

Data Types: single | double

IterationLimit — Maximal number of optimization iterations

1000 (default) | positive integer

Maximal number of optimization iterations, specified as the comma-separated pair consisting of 'IterationLimit' and a positive integer. IterationLimit applies to these values of Solver: 'bfgs', 'lbfgs', and 'sparsa'.

Example: 'IterationLimit',500

Data Types: single | double

ValidationData — Validation data for optimization convergence detection

cell array

Data for optimization convergence detection, specified as the comma-separated pair consisting of 'ValidationData' and a cell array.

During optimization, the software periodically estimates the loss of ValidationData. If the validation-data loss increases, then the software terminates optimization. For more details, see “Algorithms” on page 32-2424. To optimize hyperparameters using cross-validation, see cross-validation options such as CrossVal.

- `ValidationData(1)` must contain an m -by- p or p -by- m full or sparse matrix of predictor data that has the same orientation as X . The predictor variables in the training data X and `ValidationData{1}` must correspond. The number of observations in both sets can vary.
- `ValidationData(2)` must contain an array of m responses with length corresponding to the number of observations in `ValidationData{1}`.

- Optionally, `ValidationData(3)` can contain an m -dimensional numeric vector of observation weights. The software normalizes the weights with the validation data so that they sum to 1.

If you specify `ValidationData`, then, to display validation loss at the command line, specify a value larger than 0 for `Verbose`.

If the software converges for the last solver specified in `Solver`, then optimization terminates. Otherwise, the software uses the next solver specified in `Solver`.

By default, the software does not detect convergence by monitoring validation-data loss.

Hyperparameter Optimization

OptimizeHyperparameters — Parameters to optimize

'none' (default) | 'auto' | 'all' | string array or cell array of eligible parameter names | vector of `optimizableVariable` objects

Parameters to optimize, specified as the comma-separated pair consisting of 'OptimizeHyperparameters' and one of the following:

- 'none' — Do not optimize.
- 'auto' — Use {'Lambda', 'Learner'}.
- 'all' — Optimize all eligible parameters.
- String array or cell array of eligible parameter names.
- Vector of `optimizableVariable` objects, typically the output of hyperparameters.

The optimization attempts to minimize the cross-validation loss (error) for `fitrlinear` by varying the parameters. To control the cross-validation type and other aspects of the optimization, use the `HyperparameterOptimizationOptions` name-value pair.

Note 'OptimizeHyperparameters' values override any values you set using other name-value pair arguments. For example, setting 'OptimizeHyperparameters' to 'auto' causes the 'auto' values to apply.

The eligible parameters for `fitrlinear` are:

- `Lambda` — `fitrlinear` searches among positive values, by default log-scaled in the range $[1e-5/\text{NumObservations}, 1e5/\text{NumObservations}]$.

- **Learner** — fitrlinear searches among 'svm' and 'leastsquares'.
- **Regularization** — fitrlinear searches among 'ridge' and 'lasso'.

Set nondefault parameters by passing a vector of `optimizableVariable` objects that have nondefault values. For example,

```
load carsmall
params = hyperparameters('fitrlinear',[Horsepower,Weight],MPG);
params(1).Range = [1e-3,2e4];
```

Pass `params` as the value of `OptimizeHyperparameters`.

By default, iterative display appears at the command line, and plots appear according to the number of hyperparameters in the optimization. For the optimization and plots, the objective function is $\log(1 + \text{cross-validation loss})$ for regression and the misclassification rate for classification. To control the iterative display, set the `Verbose` field of the `'HyperparameterOptimizationOptions'` name-value pair argument. To control the plots, set the `ShowPlots` field of the `'HyperparameterOptimizationOptions'` name-value pair argument.

For an example, see “Optimize a Linear Regression” on page 32-2388.

Example: `'OptimizeHyperparameters','auto'`

HyperparameterOptimizationOptions — Options for optimization

structure

Options for optimization, specified as the comma-separated pair consisting of `'HyperparameterOptimizationOptions'` and a structure. This argument modifies the effect of the `OptimizeHyperparameters` name-value pair argument. All fields in the structure are optional.

Field Name	Values	Default
Optimizer	<ul style="list-style-type: none"> • 'bayesopt' — Use Bayesian optimization. Internally, this setting calls bayesopt. • 'gridsearch' — Use grid search with NumGridDivisions values per dimension. • 'randomsearch' — Search at random among MaxObjectiveEvaluations points. <p>'gridsearch' searches in a random order, using uniform sampling without replacement from the grid. After optimization, you can get a table in grid order by using the command <code>sortrows(Mdl.HyperparameterOptimizationResults)</code>.</p>	'bayesopt'
AcquisitionFunctionName	<ul style="list-style-type: none"> • 'expected-improvement-per-second-plus' • 'expected-improvement' • 'expected-improvement-plus' • 'expected-improvement-per-second' • 'lower-confidence-bound' • 'probability-of-improvement' <p>Acquisition functions whose names include <code>per-second</code> do not yield reproducible results because the optimization depends on the runtime of the objective function. Acquisition functions whose names include <code>plus</code> modify their behavior when they are overexploiting an area. For more details, see “Acquisition Function Types” on page 10-4.</p>	'expected-improvement-per-second-plus'

Field Name	Values	Default
MaxObjectiveEvaluations	Maximum number of objective function evaluations.	30 for 'bayesopt' or 'randomsearch', and the entire grid for 'gridsearch'
MaxTime	Time limit, specified as a positive real. The time limit is in seconds, as measured by tic and toc. Run time can exceed MaxTime because MaxTime does not interrupt function evaluations.	Inf
NumGridDivisions	For 'gridsearch', the number of values in each dimension. The value can be a vector of positive integers giving the number of values for each dimension, or a scalar that applies to all dimensions. This field is ignored for categorical variables.	10
ShowPlots	Logical value indicating whether to show plots. If true, this field plots the best objective function value against the iteration number. If there are one or two optimization parameters, and if Optimizer is 'bayesopt', then ShowPlots also plots a model of the objective function against the parameters.	true
SaveIntermediateResults	Logical value indicating whether to save results when Optimizer is 'bayesopt'. If true, this field overwrites a workspace variable named 'BayesoptResults' at each iteration. The variable is a BayesianOptimization object.	false

Field Name	Values	Default
Verbose	Display to the command line. <ul style="list-style-type: none"> • 0 — No iterative display • 1 — Iterative display • 2 — Iterative display with extra information For details, see the <code>bayesopt</code> <code>Verbose</code> name-value pair argument.	1
UseParallel	Logical value indicating whether to run Bayesian optimization in parallel, which requires Parallel Computing Toolbox. For details, see “Parallel Bayesian Optimization” on page 10-8.	false
Repartition	Logical value indicating whether to repartition the cross-validation at every iteration. If <code>false</code> , the optimizer uses a single partition for the optimization. <code>true</code> usually gives the most robust results because this setting takes partitioning noise into account. However, for good results, <code>true</code> requires at least twice as many function evaluations.	false
Use no more than one of the following three field names.		
CVPartition	A <code>cvpartition</code> object, as created by <code>cvpartition</code> .	'Kfold', 5 if you do not specify any cross-validation field
Holdout	A scalar in the range (0, 1) representing the holdout fraction.	
Kfold	An integer greater than 1.	

Example:

```
'HyperparameterOptimizationOptions', struct('MaxObjectiveEvaluations', 60)
```

Data Types: struct

Output Arguments

Mdl — Trained linear regression model

RegressionLinear model object | RegressionPartitionedLinear cross-validated model object

Trained linear regression model, returned as a RegressionLinear model object or RegressionPartitionedLinear cross-validated model object.

If you set any of the name-value pair arguments KFold, Holdout, CrossVal, or CVPartition, then Mdl is a RegressionPartitionedLinear cross-validated model object. Otherwise, Mdl is a RegressionLinear model object.

To reference properties of Mdl, use dot notation. For example, enter Mdl.Beta in the Command Window to display the vector or matrix of estimated coefficients.

Note Unlike other regression models, and for economical memory usage, RegressionLinear and RegressionPartitionedLinear model objects do not store the training data or optimization details (for example, convergence history).

FitInfo — Optimization details

structure array

Optimization details, returned as a structure array.

Fields specify final values or name-value pair argument specifications, for example, Objective is the value of the objective function when optimization terminates. Rows of multidimensional fields correspond to values of Lambda and columns correspond to values of Solver.

This table describes some notable fields.

Field	Description
TerminationStatus	<ul style="list-style-type: none"> Reason for optimization termination Corresponds to a value in TerminationCode
FitTime	Elapsed, wall-clock time in seconds

Field	Description	
History	A structure array of optimization information for each iteration. The field <code>Solver</code> stores solver types using integer coding.	
	Integer	Solver
	1	SGD
	2	ASGD
	3	Dual SGD for SVM
	4	LBFGS
	5	BFGS
	6	SpaRSA

To access fields, use dot notation. For example, to access the vector of objective function values for each iteration, enter `FitInfo.History.Objective`.

It is good practice to examine `FitInfo` to assess whether convergence is satisfactory.

HyperparameterOptimizationResults — Cross-validation optimization of hyperparameters

BayesianOptimization object | table of hyperparameters and associated values

Cross-validation optimization of hyperparameters, returned as a BayesianOptimization object or a table of hyperparameters and associated values. The output is nonempty when the value of `'OptimizeHyperparameters'` is not `'none'`. The output value depends on the `Optimizer` field value of the `'HyperparameterOptimizationOptions'` name-value pair argument:

Value of Optimizer Field	Value of HyperparameterOptimizationResults
<code>'bayesopt'</code> (default)	Object of class BayesianOptimization
<code>'gridsearch'</code> or <code>'randomsearch'</code>	Table of hyperparameters used, observed objective function values (cross-validation loss), and rank of observations from lowest (best) to highest (worst)

Note If Learner is 'leastquares', then the loss term in the objective function is half of the MSE. `loss` returns the MSE by default. Therefore, if you use `loss` to check the resubstitution, or training, error then there is a discrepancy between the MSE returned by `loss` and optimization results in `FitInfo` or returned to the command line by setting a positive verbosity level using `Verbose`.

Definitions

Warm Start

A warm start is initial estimates of the beta coefficients and bias term supplied to an optimization routine for quicker convergence.

Alternatives for Lower-Dimensional Data

High-dimensional linear classification and regression models minimize objective functions relatively quickly, but at the cost of some accuracy, the numeric-only predictor variables restriction, and the model must be linear with respect to the parameters. If your predictor data set is low- through medium-dimensional, or contains heterogeneous variables, then you should use the appropriate classification or regression fitting function. To help you decide which fitting function is appropriate for your low-dimensional data set, use this table.

Model to Fit	Function	Notable Algorithmic Differences
SVM	<ul style="list-style-type: none"> Binary classification: <code>fitcsvm</code> Multiclass classification: <code>fitcecoc</code> Regression: <code>fitrsvm</code> 	<ul style="list-style-type: none"> Computes the Gram matrix of the predictor variables, which is convenient for nonlinear kernel transformations. Solves dual problem using SMO, ISDA, or $L1$ minimization via quadratic programming using <code>quadprog</code>.

Model to Fit	Function	Notable Algorithmic Differences
Linear regression	<ul style="list-style-type: none"> Least-squares without regularization: <code>fitlm</code> Regularized least-squares using a lasso penalty: <code>lasso</code> Ridge regression: <code>ridge</code> or <code>lasso</code> 	<ul style="list-style-type: none"> <code>lasso</code> implements cyclic coordinate descent.
Logistic regression	<ul style="list-style-type: none"> Logistic regression without regularization: <code>fitglm</code>. Regularized logistic regression using a lasso penalty: <code>lassoglm</code> 	<ul style="list-style-type: none"> <code>fitglm</code> implements iteratively reweighted least squares. <code>lassoglm</code> implements cyclic coordinate descent.

Tips

- It is a best practice to orient your predictor matrix so that observations correspond to columns and to specify `'ObservationsIn'`, `'columns'`. As a result, you can experience a significant reduction in optimization-execution time.
- For better optimization accuracy if X is high-dimensional and `Regularization` is `'ridge'`, set any of these combinations for `Solver`:
 - `'sgd'`
 - `'asgd'`
 - `'dual'` if `Learner` is `'svm'`
 - `{'sgd','lbfgs'}`
 - `{'asgd','lbfgs'}`
 - `{'dual','lbfgs'}` if `Learner` is `'svm'`

Other combinations can result in poor optimization accuracy.

- For better optimization accuracy if X is moderate- through low-dimensional and `Regularization` is `'ridge'`, set `Solver` to `'bfgs'`.

- If Regularization is 'lasso', set any of these combinations for Solver:
 - 'sgd'
 - 'asgd'
 - 'sparsa'
 - {'sgd', 'sparsa'}
 - {'asgd', 'sparsa'}
- When choosing between SGD and ASGD, consider that:
 - SGD takes less time per iteration, but requires more iterations to converge.
 - ASGD requires fewer iterations to converge, but takes more time per iteration.
- If X has few observations, but many predictor variables, then:
 - Specify 'PostFitBias', true.
 - For SGD or ASGD solvers, set PassLimit to a positive integer that is greater than 1, for example, 5 or 10. This setting often results in better accuracy.
- For SGD and ASGD solvers, BatchSize affects the rate of convergence.
 - If BatchSize is too small, then fitrlinear achieves the minimum in many iterations, but computes the gradient per iteration quickly.
 - If BatchSize is too large, then fitrlinear achieves the minimum in fewer iterations, but computes the gradient per iteration slowly.
- Large learning rates (see LearnRate) speed up convergence to the minimum, but can lead to divergence (that is, over-stepping the minimum). Small learning rates ensure convergence to the minimum, but can lead to slow termination.
- When using lasso penalties, experiment with various values of TruncationPeriod. For example, set TruncationPeriod to 1, 10, and then 100.
- For efficiency, fitrlinear does not standardize predictor data. To standardize X, enter

```
X = bsxfun(@rdivide,bsxfun(@minus,X,mean(X,2)),std(X,0,2));
```

The code requires that you orient the predictors and observations as the rows and columns of X, respectively. Also, for memory-usage economy, the code replaces the original predictor data the standardized data.

- After training a model, you can generate C/C++ code that predicts responses for new data. Generating C/C++ code requires MATLAB Coder. For details, see “Introduction to Code Generation” on page 31-2.

Algorithms

- If you specify `ValidationData`, then, during objective-function optimization:
 - `fitrlinear` estimates the validation loss of `ValidationData` periodically using the current model, and tracks the minimal estimate.
 - When `fitrlinear` estimates a validation loss, it compares the estimate to the minimal estimate.
 - When subsequent, validation loss estimates exceed the minimal estimate five times, `fitrlinear` terminates optimization.
- If you specify `ValidationData` and to implement a cross-validation routine (`CrossVal`, `CVPartition`, `Holdout`, or `KFold`), then:
 - 1** `fitrlinear` randomly partitions X and Y according to the cross-validation routine that you choose.
 - 2** `fitrlinear` trains the model using the training-data partition. During objective-function optimization, `fitrlinear` uses `ValidationData` as another possible way to terminate optimization (for details, see the previous bullet).
 - 3** Once `fitrlinear` satisfies a stopping criterion, it constructs a trained model based on the optimized linear coefficients and intercept.
 - a** If you implement *k*-fold cross-validation, and `fitrlinear` has not exhausted all training-set folds, then `fitrlinear` returns to Step 2 to train using the next training-set fold.
 - b** Otherwise, `fitrlinear` terminates training, and then returns the cross-validated model.
 - 4** You can determine the quality of the cross-validated model. For example:
 - To determine the validation loss using the holdout or out-of-fold data from step 1, pass the cross-validated model to `kfoldLoss`.
 - To predict observations on the holdout or out-of-fold data from step 1, pass the cross-validated model to `kfoldPredict`.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

Usage notes and limitations:

- Some name-value pair arguments have different defaults and values compared to the in-memory `fitrlinear` function. Supported name-value pair arguments, and any differences, are:
 - 'Epsilon'
 - 'ObservationsIn' — Supports only 'rows'.
 - 'Lambda' — Can be 'auto' (default) or a scalar.
 - 'Learner'
 - 'Regularization' — Supports only 'ridge'.
 - 'Solver' — Supports only 'lbfgs'.
 - 'Verbose' — Default value is 1
 - 'Beta'
 - 'Bias'
 - 'FitBias' — Supports only true.
 - 'Weights' — Value must be a tall array.
 - 'HessianHistorySize'
 - 'BetaTolerance' — Default value is relaxed to 1e-3.
 - 'GradientTolerance' — Default value is relaxed to 1e-3.
 - 'IterationLimit' — Default value is relaxed to 20.
 - 'OptimizeHyperparameters' — Value of 'Regularization' parameter must be 'ridge'.
 - 'HyperparameterOptimizationOptions' — For cross-validation, tall optimization supports only 'Holdout' validation. For example, you can specify `fitrlinear(X,Y,'OptimizeHyperparameters','auto','HyperparameterOptimizationOptions',struct('Holdout',0.2))`.
- For tall arrays `fitrlinear` implements LBFGS by distributing the calculation of the loss and the gradient among different parts of the tall array at each iteration. Other solvers are not available for tall arrays.

When initial values for `Beta` and `Bias` are not given, `fitrlinear` first refines the initial estimates of the parameters by fitting the model locally to parts of the data and combining the coefficients by averaging.

For more information, see “Tall Arrays” (MATLAB).

Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the 'UseParallel' option to true.

To perform parallel hyperparameter optimization, use the 'HyperparameterOptions', struct('UseParallel',true) name-value pair argument in the call to this function.

For more information on parallel hyperparameter optimization, see “Parallel Bayesian Optimization” on page 10-8.

For more general information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

Introduced in R2016a

fitrm

Fit repeated measures model

Syntax

```
rm = fitrm(t,modelspec)
rm = fitrm(t,modelspec,Name,Value)
```

Description

`rm = fitrm(t,modelspec)` returns a repeated measures model, specified by `modelspec`, fitted to the variables in the table or dataset array `t`.

`rm = fitrm(t,modelspec,Name,Value)` returns a repeated measures model, with additional options specified by one or more `Name, Value` pair arguments.

For example, you can specify the hypothesis for the within-subject factors.

Examples

Fit a Repeated Measures Model

Load the sample data.

```
load fisheriris
```

The column vector `species` consists of iris flowers of three different species: `setosa`, `versicolor`, and `virginica`. The double matrix `meas` consists of four types of measurements on the flowers: the length and width of sepals and petals in centimeters, respectively.

Store the data in a table array.

```
t = table(species,meas(:,1),meas(:,2),meas(:,3),meas(:,4),...
'VariableNames',{'species','meas1','meas2','meas3','meas4'});
Meas = table([1 2 3 4]','VariableNames',{'Measurements'});
```

Fit a repeated measures model, where the measurements are the responses and the species is the predictor variable.

```
rm = fitrm(t, 'meas1-meas4~species', 'WithinDesign', Meas)
rm =
  RepeatedMeasuresModel with properties:

  Between Subjects:
    BetweenDesign: [150x5 table]
    ResponseNames: {'meas1' 'meas2' 'meas3' 'meas4'}
    BetweenFactorNames: {'species'}
    BetweenModel: '1 + species'

  Within Subjects:
    WithinDesign: [4x1 table]
    WithinFactorNames: {'Measurements'}
    WithinModel: 'separatemeans'

  Estimates:
    Coefficients: [3x4 table]
    Covariance: [4x4 table]
```

Display the coefficients.

```
rm.Coefficients
```

```
ans=3x4 table
```

	meas1	meas2	meas3	meas4
(Intercept)	5.8433	3.0573	3.758	1.1993
species_setosa	-0.83733	0.37067	-2.296	-0.95333
species_versicolor	0.092667	-0.28733	0.502	0.12667

fitrm uses the 'effects' contrasts which means that the coefficients sum to 0. The rm.DesignMatrix has one column of 1s for the intercept, and two other columns species_setosa and species_versicolor, which are as follows:

$$\text{species_setosa} = \begin{cases} 1 & \text{if setosa} \\ 0 & \text{if versicolor} \\ -1 & \text{if virginica} \end{cases} \quad \text{and} \quad \text{species_versicolor} = \begin{cases} 0 & \text{if setosa} \\ 1 & \text{if versicolor} \\ -1 & \text{if virginica} \end{cases}$$

Display the covariance matrix.

```
rm.Covariance
```

```
ans=4x4 table
```

	meas1	meas2	meas3	meas4
meas1	0.26501	0.092721	0.16751	0.038401
meas2	0.092721	0.11539	0.055244	0.03271
meas3	0.16751	0.055244	0.18519	0.042665
meas4	0.038401	0.03271	0.042665	0.041882

Specify the Within-Subject Hypothesis

Load the sample data.

```
load(fullfile(matlabroot, 'examples', 'stats', 'longitudinalData.mat'));
```

The matrix *Y* contains response data for 16 individuals. The response is the blood level of a drug measured at five time points (time = 0, 2, 4, 6, and 8). Each row of *Y* corresponds to an individual, and each column corresponds to a time point. The first eight subjects are female, and the second eight subjects are male. This is simulated data.

Define a variable that stores gender information.

```
Gender = ['F' 'F' 'F' 'F' 'F' 'F' 'F' 'F' 'M' 'M' 'M' 'M' 'M' 'M' 'M'];
```

Store the data in a proper table array format to conduct repeated measures analysis.

```
t = table(Gender, Y(:,1), Y(:,2), Y(:,3), Y(:,4), Y(:,5), ...  
 'VariableNames', {'Gender', 't0', 't2', 't4', 't6', 't8'});
```

Define the within-subjects variable.

```
Time = [0 2 4 6 8]';
```

Fit a repeated measures model, where blood levels are the responses and gender is the predictor variable. Also define the hypothesis for within-subject factors.

```
rm = fitrm(t, 't0-t8 ~ Gender', 'WithinDesign', Time, 'WithinModel', 'orthogonalcontrasts')
```

```

rm =
  RepeatedMeasuresModel with properties:

  Between Subjects:
    BetweenDesign: [16x6 table]
    ResponseNames: {'t0' 't2' 't4' 't6' 't8'}
    BetweenFactorNames: {'Gender'}
    BetweenModel: '1 + Gender'

  Within Subjects:
    WithinDesign: [5x1 table]
    WithinFactorNames: {'Time'}
    WithinModel: 'orthogonalcontrasts'

  Estimates:
    Coefficients: [2x5 table]
    Covariance: [5x5 table]

```

Fit a Model with Covariates

Load the sample data.

```
load repeatedmeas
```

The table `between` includes the eight repeated measurements, `y1` through `y8`, as responses and the between-subject factors `Group`, `Gender`, `IQ`, and `Age`. `IQ` and `Age` as continuous variables. The table `within` includes the within-subject factors `w1` and `w2`.

Fit a repeated measures model, where age, IQ, and group, gender are the predictor variables, and the model includes the interaction effect of group and gender. Also define the within-subject factors.

```
rm = fitrm(between, 'y1-y8 ~ Group*Gender+Age+IQ', 'WithinDesign', within)
```

```

rm =
  RepeatedMeasuresModel with properties:

  Between Subjects:
    BetweenDesign: [30x12 table]
    ResponseNames: {'y1' 'y2' 'y3' 'y4' 'y5' 'y6' 'y7' 'y8'}
    BetweenFactorNames: {'Age' 'IQ' 'Group' 'Gender'}

```

```

BetweenModel: '1 + Age + IQ + Group*Gender'

Within Subjects:
  WithinDesign: [8x2 table]
  WithinFactorNames: {'w1' 'w2'}
  WithinModel: 'separatemeans'

Estimates:
  Coefficients: [8x8 table]
  Covariance: [8x8 table]

```

Display the coefficients.

```
rm.Coefficients
```

```
ans=8x8 table
```

	y1	y2	y3	y4	y5
(Intercept)	141.38	195.25	9.8663	-49.154	157.77
Age	0.32042	-4.7672	-1.2748	0.6216	-1.0621
IQ	-1.2671	-1.1653	0.05862	0.4288	-1.4518
Group_A	-1.2195	-9.6186	22.532	15.303	12.602
Group_B	2.5186	1.417	-2.2501	0.50181	8.0907
Gender_Female	5.3957	-3.9719	8.5225	9.3403	6.0909
Group_A:Gender_Female	4.1046	10.064	-7.3053	-3.3085	4.6751
Group_B:Gender_Female	-0.48486	-2.9202	1.1222	0.69715	-0.065945

The display shows the coefficients for fitting the repeated measures as a function of the terms in the between-subjects model.

Input Arguments

t — Input data

table

Input data, which includes the values of the response variables and the between-subject factors to use as predictors in the repeated measures model, specified as a table.

Data Types: table

modelspec — Formula for model specification

character vector or string scalar of the form 'y1-yk ~ terms'

Formula for model specification, specified as a character vector or string scalar of the form 'y1-yk ~ terms'. The responses and terms are specified using Wilkinson notation on page 32-2435. `fitrm` treats the variables used in model terms as categorical if they are categorical (nominal or ordinal), logical, character arrays, string arrays, or cell arrays of character vectors.

For example, if you have four repeated measures as responses and the factors `x1`, `x2`, and `x3` as the predictor variables, then you can define a repeated measures model as follows.

Example: 'y1-y4 ~ x1 + x2 * x3'

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: 'WithinDesign', 'W', 'WithinModel', 'w1+w2' specifies the matrix `w` as the design matrix for within-subject factors, and the model for within-subject factors `w1` and `w2` is 'w1+w2'.

WithinDesign — Design for within-subject factors

numeric vector of length `r` (default) | `r`-by-`k` numeric matrix | `r`-by-`k` table

Design for within-subject factors, specified as the comma-separated pair consisting of 'WithinDesign' and one of the following:

- Numeric vector of length `r`, where `r` is the number of repeated measures.
In this case, `fitrm` treats the values in the vector as continuous, and these are typically time values.
- `r`-by-`k` numeric matrix of the values of the `k` within-subject factors, `w1`, `w2`, ..., `wk`.
In this case, `fitrm` treats all `k` variables as continuous.
- `r`-by-`k` table that contains the values of the `k` within-subject factors.

In this case, `fitrm` treats all numeric variables as continuous, and all categorical variables as categorical.

For example, if the table `weeks` contains the values of the within-subject factors, then you can define the design table as follows.

Example: `'WithinDesign', weeks`

Data Types: `single | double | table`

WithinModel — Model specifying within-subject hypothesis test

`'separatemeans'` (default) | `'orthogonalcontrasts'` | character vector or string scalar that defines a model

Model specifying the within-subject hypothesis test, specified as the comma-separated pair consisting of `'WithinModel'` and one of the following:

- `'separatemeans'` — Compute a separate mean for each group.
- `'orthogonalcontrasts'` — This is valid only when the within-subject model has a single numeric factor T . Responses are the average, the slope of centered T , and, in general, all orthogonal contrasts for a polynomial up to $T^{(p-1)}$, where p is the number of rows in the within-subject model.
- A character vector or string scalar that defines a model specification in the within-subject factors. You can define the model based on the rules for the terms in `modelspec`.

For example, if there are three within-subject factors `w1`, `w2`, and `w3`, then you can specify a model for the within-subject factors as follows.

Example: `'WithinModel', 'w1+w2+w2*w3'`

Data Types: `char | string`

Output Arguments

rm — Repeated measures model

`RepeatedMeasuresModel` object

Repeated measures model, returned as a `RepeatedMeasuresModel` object.

For properties and methods of this object, see `RepeatedMeasuresModel`.

Definitions

Model Specification Using Wilkinson Notation

Wilkinson notation describes the factors present in models. It does not describe the multipliers (coefficients) of those factors.

The following rules specify the responses in `modelspec`.

Wilkinson Notation	Meaning
Y1, Y2, Y3	Specific list of variables
Y1-Y5	All table variables from Y1 through Y5

The following rules specify terms in `modelspec`.

Wilkinson notation	Factors in Standard Notation
1	Constant (intercept) term
X^k , where k is a positive integer	X, X^2, \dots, X^k
$X1 + X2$	$X1, X2$
$X1 * X2$	$X1, X2, X1 * X2$
$X1 : X2$	$X1 * X2$ only
$-X2$	Do not include $X2$
$X1 * X2 + X3$	$X1, X2, X3, X1 * X2$
$X1 + X2 + X3 + X1 : X2$	$X1, X2, X3, X1 * X2$
$X1 * X2 * X3 - X1 : X2 : X3$	$X1, X2, X3, X1 * X2, X1 * X3, X2 * X3$
$X1 * (X2 + X3)$	$X1, X2, X3, X1 * X2, X1 * X3$

Statistics and Machine Learning Toolbox notation always includes a constant term unless you explicitly remove the term using `-1`.

`RepeatedMeasuresModel`

Introduced in R2014a

fitdist

Fit probability distribution object to data

Syntax

```
pd = fitdist(x,distname)
pd = fitdist(x,distname,Name,Value)

[pdca,gn,gl] = fitdist(x,distname,'By',groupvar)
[pdca,gn,gl] = fitdist(x,distname,'By',groupvar,Name,Value)
```

Description

`pd = fitdist(x,distname)` creates a probability distribution object by fitting the distribution specified by `distname` to the data in column vector `x`.

`pd = fitdist(x,distname,Name,Value)` creates the probability distribution object with additional options specified by one or more name-value pair arguments. For example, you can indicate censored data or specify control parameters for the iterative fitting algorithm.

`[pdca,gn,gl] = fitdist(x,distname,'By',groupvar)` creates probability distribution objects by fitting the distribution specified by `distname` to the data in `x` based on the grouping variable `groupvar`. It returns a cell array of fitted probability distribution objects, `pdca`, a cell array of group labels, `gn`, and a cell array of grouping variable levels, `gl`.

`[pdca,gn,gl] = fitdist(x,distname,'By',groupvar,Name,Value)` returns the above output arguments using additional options specified by one or more name-value pair arguments. For example, you can indicate censored data or specify control parameters for the iterative fitting algorithm.

Examples

Fit a Normal Distribution to Data

Load the sample data. Create a vector containing the patients' weight data.

```
load hospital
x = hospital.Weight;
```

Create a normal distribution object by fitting it to the data.

```
pd = fitdist(x, 'Normal')

pd =
  NormalDistribution

  Normal distribution
      mu =      154   [148.728, 159.272]
      sigma = 26.5714 [23.3299, 30.8674]
```

The intervals next to the parameter estimates are the 95% confidence intervals for the distribution parameters.

Plot the pdf of the distribution.

```
x_values = 50:1:250;
y = pdf(pd,x_values);
plot(x_values,y, 'LineWidth',2)
```

Fit a Kernel Distribution to Data

Load the sample data. Create a vector containing the patients' weight data.

```
load hospital
x = hospital.Weight;
```

Create a kernel distribution object by fitting it to the data. Use the Epanechnikov kernel function.

```
pd = fitdist(x, 'Kernel', 'Kernel', 'epanechnikov')
```

```
pd =  
  KernelDistribution  
  
  Kernel = epanechnikov  
  Bandwidth = 14.3792  
  Support = unbounded
```

Plot the pdf of the distribution.

```
x_values = 50:1:250;  
y = pdf(pd,x_values);  
plot(x_values,y)
```

Fit Normal Distributions to Grouped Data

Load the sample data. Create a vector containing the patients' weight data.

```
load hospital
x = hospital.Weight;
```

Create normal distribution objects by fitting them to the data, grouped by patient gender.

```
gender = hospital.Sex;
[pdca,gn,gl] = fitdist(x,'Normal','By',gender)

pdca = 1x2 cell array
      {1x1 prob.NormalDistribution}    {1x1 prob.NormalDistribution}

gn = 2x1 cell array
     {'Female'}
     {'Male'  }

gl = 2x1 cell array
     {'Female'}
     {'Male'  }
```

The cell array `pdca` contains two probability distribution objects, one for each gender group. The cell array `gn` contains two group labels. The cell array `gl` contains two group levels.

View each distribution in the cell array `pdca` to compare the mean, `mu`, and the standard deviation, `sigma`, grouped by patient gender.

```
female = pdca{1} % Distribution for females

female =
  NormalDistribution

  Normal distribution
      mu = 130.472    [128.183, 132.76]
      sigma = 8.30339    [6.96947, 10.2736]

male = pdca{2} % Distribution for males
```

```
male =  
    NormalDistribution  
  
    Normal distribution  
        mu = 180.532    [177.833, 183.231]  
        sigma = 9.19322    [7.63933, 11.5466]
```

Compute the pdf of each distribution.

```
x_values = 50:1:250;  
femalepdf = pdf(female,x_values);  
malepdf = pdf(male,x_values);
```

Plot the pdfs for a visual comparison of weight distribution by gender.

```
figure  
plot(x_values,femalepdf,'LineWidth',2)  
hold on  
plot(x_values,malepdf,'Color','r','LineStyle',':','LineWidth',2)  
legend(gn,'Location','NorthEast')  
hold off
```

Fit Kernel Distributions to Grouped Data

Load the sample data. Create a vector containing the patients' weight data.

```
load hospital
x = hospital.Weight;
```

Create kernel distribution objects by fitting them to the data, grouped by patient gender. Use a triangular kernel function.

```
gender = hospital.Sex;
[pdca,gn,gl] = fitdist(x,'Kernel','By',gender,'Kernel','triangle');
```

View each distribution in the cell array `pdca` to see the kernel distributions for each gender.

```
female = pdca{1} % Distribution for females
```

```
female =  
  KernelDistribution  
  
  Kernel = triangle  
  Bandwidth = 4.25894  
  Support = unbounded
```

```
male = pdca{2} % Distribution for males
```

```
male =  
  KernelDistribution  
  
  Kernel = triangle  
  Bandwidth = 5.08961  
  Support = unbounded
```

Compute the pdf of each distribution.

```
x_values = 50:1:250;  
femalepdf = pdf(female,x_values);  
malepdf = pdf(male,x_values);
```

Plot the pdfs for a visual comparison of weight distribution by gender.

```
figure  
plot(x_values,femalepdf,'LineWidth',2)  
hold on  
plot(x_values,malepdf,'Color','r','LineStyle',':','LineWidth',2)  
legend(gn,'Location','NorthEast')  
hold off
```

Input Arguments

x — Input data

column vector

Input data, specified as a column vector. `fitdist` ignores NaN values in `x`. Additionally, any NaN values in the censoring vector or frequency vector cause `fitdist` to ignore the corresponding values in `x`.

Data Types: double

distname — Distribution name

character vector | string scalar

Distribution name, specified as one of the following character vectors or string scalars. The distribution specified by `distname` determines the type of the returned probability distribution object.

Distribution Name	Description	Distribution Object
'Beta'	Beta distribution	BetaDistribution
'Binomial'	Binomial distribution	BinomialDistribution
'BirnbaumSaunders'	Birnbaum-Saunders distribution	BirnbaumSaundersDistribution
'Burr'	Burr distribution	BurrDistribution
'Exponential'	Exponential distribution	ExponentialDistribution
'ExtremeValue'	Extreme Value distribution	ExtremeValueDistribution
'Gamma'	Gamma distribution	GammaDistribution
'GeneralizedExtremeValue'	Generalized Extreme Value distribution	GeneralizedExtremeValueDistribution
'GeneralizedPareto'	Generalized Pareto distribution	GeneralizedParetoDistribution
'HalfNormal'	Half-normal distribution	HalfNormalDistribution
'InverseGaussian'	Inverse Gaussian distribution	InverseGaussianDistribution
'Kernel'	Kernel distribution	KernelDistribution
'Logistic'	Logistic distribution	LogisticDistribution
'Loglogistic'	Loglogistic distribution	LoglogisticDistribution
'Lognormal'	Lognormal distribution	LognormalDistribution
'Nakagami'	Nakagami distribution	NakagamiDistribution

Distribution Name	Description	Distribution Object
'NegativeBinomial'	Negative Binomial distribution	NegativeBinomialDistribution
'Normal'	Normal distribution	NormalDistribution
'Poisson'	Poisson distribution	PoissonDistribution
'Rayleigh'	Rayleigh distribution	RayleighDistribution
'Rician'	Rician distribution	RicianDistribution
'Stable'	Stable distribution	StableDistribution
'tLocationScale'	<i>t</i> Location-Scale distribution	tLocationScaleDistribution
'Weibull'	Weibull distribution	WeibullDistribution

groupvar — Grouping variable

categorical array | logical or numeric vector | character array | string array | cell array of character vectors

Grouping variable, specified as a categorical array, logical or numeric vector, character array, string array, or cell array of character vectors. Each unique value in a grouping variable defines a group.

For example, if `Gender` is a cell array of character vectors with values 'Male' and 'Female', you can use `Gender` as a grouping variable to fit a distribution to your data by gender.

More than one grouping variable can be used by specifying a cell array of grouping variables. Observations are placed in the same group if they have common values of all specified grouping variables.

For example, if `Smoker` is a logical vector with values 0 for nonsmokers and 1 for smokers, then specifying the cell array `{Gender, Smoker}` divides observations into four groups: Male Smoker, Male Nonsmoker, Female Smoker, and Female Nonsmoker.

Example: `{Gender, Smoker}`

Data Types: categorical | logical | single | double | char | string | cell

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example: `fitdist(x, 'Kernel', 'Kernel', 'triangle')` fits a kernel distribution object to the data in `x` using a triangular kernel function.

Censoring — Logical flag for censored data

0 (default) | vector of logical values

Logical flag for censored data, specified as the comma-separated pair consisting of `'Censoring'` and a vector of logical values that is the same size as input vector `x`. The value is 1 when the corresponding element in `x` is a right-censored observation and 0 when the corresponding element is an exact observation. The default is a vector of 0s, indicating that all observations are exact.

`fitdist` ignores any NaN values in this censoring vector. Additionally, any NaN values in `x` or the frequency vector cause `fitdist` to ignore the corresponding values in the censoring vector.

This argument is valid only if `distname` is `'BirnbaumSaunders'`, `'Burr'`, `'Exponential'`, `'ExtremeValue'`, `'Gamma'`, `'InverseGaussian'`, `'Kernel'`, `'Logistic'`, `'Loglogistic'`, `'Lognormal'`, `'Nakagami'`, `'Normal'`, `'Rician'`, `'tLocationScale'`, or `'Weibull'`.

Data Types: `logical`

Frequency — Observation frequency

1 (default) | vector of nonnegative integer values

Observation frequency, specified as the comma-separated pair consisting of `'Frequency'` and a vector of nonnegative integer values that is the same size as input vector `x`. Each element of the frequency vector specifies the frequencies for the corresponding elements in `x`. The default is a vector of 1s, indicating that each value in `x` only appears once.

`fitdist` ignores any NaN values in this frequency vector. Additionally, any NaN values in `x` or the censoring vector cause `fitdist` to ignore the corresponding values in the frequency vector.

Data Types: `single` | `double`

Options — Control parameters

structure

Control parameters for the iterative fitting algorithm, specified as the comma-separated pair consisting of 'Options' and a structure you create using `statset`.

Data Types: `struct`

NTrials — Number of trials

positive integer value

Number of trials for the binomial distribution, specified as the comma-separated pair consisting of 'NTrials' and a positive integer value. You must specify `distname` as 'Binomial' to use this option.

Data Types: `single` | `double`

Theta — Threshold parameter

0 (default) | scalar value

Threshold parameter for the generalized Pareto distribution, specified as the comma-separated pair consisting of 'Theta' and a scalar value. You must specify `distname` as 'GeneralizedPareto' to use this option.

Data Types: `single` | `double`

mu — Location parameter

0 (default) | scalar value

Location parameter for the half-normal distribution, specified as the comma-separated pair consisting of 'mu' and a scalar value. You must specify `distname` as 'HalfNormal' to use this option.

Data Types: `single` | `double`

Kernel — Kernel smoother type

'normal' (default) | 'box' | 'triangle' | 'epanechnikov'

Kernel smoother type, specified as the comma-separated pair consisting of 'Kernel' and one of the following:

- 'normal'

- 'box'
- 'triangle'
- 'epanechnikov'

You must specify `distname` as 'Kernel' to use this option.

Support — Kernel density support

'unbounded' (default) | 'positive' | two-element vector

Kernel density support, specified as the comma-separated pair consisting of 'Support' and 'unbounded', 'positive', or a two-element vector.

'unbounded'	Density can extend over the whole real line.
'positive'	Density is restricted to positive values.

Alternatively, you can specify a two-element vector giving finite lower and upper limits for the support of the density.

You must specify `distname` as 'Kernel' to use this option.

Data Types: `single` | `double` | `char` | `string`

Width — Bandwidth of kernel smoothing window

scalar value

Bandwidth of the kernel smoothing window, specified as the comma-separated pair consisting of 'Width' and a scalar value. The default value used by `fitdist` is optimal for estimating normal densities, but you might want to choose a smaller value to reveal features such as multiple modes. You must specify `distname` as 'Kernel' to use this option.

Data Types: `single` | `double`

Output Arguments

pd — Probability distribution

probability distribution object

Probability distribution, returned as a probability distribution object. The distribution specified by `distname` determines the class type of the returned probability distribution object.

pdca — Probability distribution objects

cell array

Probability distribution objects of the type specified by `distname`, returned as a cell array.

gn — Group labels

cell array of character vectors

Group labels, returned as a cell array of character vectors.

gl — Grouping variable levels

cell array of character vectors

Grouping variable levels, returned as a cell array of character vectors containing one column for each grouping variable.

Algorithms

The `fitdist` function fits most distributions using maximum likelihood estimation. Two exceptions are the normal and lognormal distributions with uncensored data.

- For the uncensored normal distribution, the estimated value of the sigma parameter is the square root of the unbiased estimate of the variance.
- For the uncensored lognormal distribution, the estimated value of the sigma parameter is the square root of the unbiased estimate of the variance of the log of the data.

Alternative Functionality

App

The **Distribution Fitter** app opens a graphical user interface for you to import data from the workspace and interactively fit a probability distribution to that data. You can then save the distribution to the workspace as a probability distribution object. Open the Distribution Fitter app using `distributionFitter`, or click Distribution Fitter on the Apps tab.

Introduced in R2009a

fitensemble

Fit ensemble of learners for classification and regression

`fitensemble` can boost or bag decision tree learners or discriminant analysis classifiers. The function can also train random subspace ensembles of KNN or discriminant analysis classifiers.

For simpler interfaces that fit classification and regression ensembles, instead use `fitcensemble` and `fitrensemble`, respectively. Also, `fitcensemble` and `fitrensemble` provide options for Bayesian optimization.

Syntax

```
Mdl = fitensemble(Tbl,ResponseVarName,Method,NLearn,Learners)
```

```
Mdl = fitensemble(Tbl,formula,Method,NLearn,Learners)
```

```
Mdl = fitensemble(Tbl,Y,Method,NLearn,Learners)
```

```
Mdl = fitensemble(X,Y,Method,NLearn,Learners)
```

```
Mdl = fitensemble(___,Name,Value)
```

Description

`Mdl = fitensemble(Tbl,ResponseVarName,Method,NLearn,Learners)` returns a trained ensemble model object that contains the results of fitting an ensemble of `NLearn` classification or regression learners (`Learners`) to all variables in the table `Tbl`.

`ResponseVarName` is the name of the response variable in `Tbl`. `Method` is the ensemble-aggregation method.

`Mdl = fitensemble(Tbl,formula,Method,NLearn,Learners)` fits the model specified by `formula`.

`Mdl = fitensemble(Tbl,Y,Method,NLearn,Learners)` treats all variables in `Tbl` as predictor variables. `Y` is the response variable that is not in `Tbl`.

`Mdl = fitensemble(X,Y,Method,NLearn,Learners)` trains an ensemble using the predictor data in `X` and response data in `Y`.

`Mdl = fitensemble(___,Name,Value)` trains an ensemble using additional options specified by one or more `Name,Value` pair arguments and any of the previous syntaxes. For example, you can specify the class order, to implement 10-fold cross-validation, or the learning rate.

Examples

Estimate the Resubstitution Loss of a Boosting Ensemble

Estimate the resubstitution loss of a trained, boosting classification ensemble of decision trees.

Load the `ionosphere` data set.

```
load ionosphere;
```

Train a decision tree ensemble using `AdaBoostM1`, 100 learning cycles, and the entire data set.

```
ClassTreeEns = fitensemble(X,Y,'AdaBoostM1',100,'Tree');
```

`ClassTreeEns` is a trained `ClassificationEnsemble` ensemble classifier.

Determine the cumulative resubstitution losses (i.e., the cumulative misclassification error of the labels in the training data).

```
rsLoss = resubLoss(ClassTreeEns,'Mode','Cumulative');
```

`rsLoss` is a 100-by-1 vector, where element k contains the resubstitution loss after the first k learning cycles.

Plot the cumulative resubstitution loss over the number of learning cycles.

```
plot(rsLoss);  
xlabel('Number of Learning Cycles');  
ylabel('Resubstitution Loss');
```

In general, as the number of decision trees in the trained classification ensemble increases, the resubstitution loss decreases.

A decrease in resubstitution loss might indicate that the software trained the ensemble sensibly. However, you cannot infer the predictive power of the ensemble by this decrease. To measure the predictive power of an ensemble, estimate the generalization error by:

- 1 Randomly partitioning the data into training and cross-validation sets. Do this by specifying 'holdout', `holdoutProportion` when you train the ensemble using `fitensemble`.
- 2 Passing the trained ensemble to `kfoldLoss`, which estimates the generalization error.

Train Regression Ensemble

Use a trained, boosted regression tree ensemble to predict the fuel economy of a car. Choose the number of cylinders, volume displaced by the cylinders, horsepower, and weight as predictors. Then, train an ensemble using fewer predictors and compare its in-sample predictive accuracy against the first ensemble.

Load the `carsmall` data set. Store the training data in a table.

```
load carsmall
Tbl = table(Cylinders,Displacement,Horsepower,Weight,MPG);
```

Specify a regression tree template that uses surrogate splits to improve predictive accuracy in the presence of NaN values.

```
t = templateTree('Surrogate','On');
```

Train the regression tree ensemble using LSBoost and 100 learning cycles.

```
Mdl1 = fitensemble(Tbl,'MPG','LSBoost',100,t);
```

`Mdl1` is a trained `RegressionEnsemble` regression ensemble. Because `MPG` is a variable in the MATLAB® Workspace, you can obtain the same result by entering

```
Mdl1 = fitensemble(Tbl,MPG,'LSBoost',100,t);
```

Use the trained regression ensemble to predict the fuel economy for a four-cylinder car with a 200-cubic inch displacement, 150 horsepower, and weighing 3000 lbs.

```
predMPG = predict(Mdl1,[4 200 150 3000])
```

```
predMPG = 22.8462
```

The average fuel economy of a car with these specifications is 21.78 mpg.

Train a new ensemble using all predictors in `Tbl` except `Displacement`.

```
formula = 'MPG ~ Cylinders + Horsepower + Weight';
Mdl2 = fitensemble(Tbl,formula,'LSBoost',100,t);
```

Compare the resubstitution MSEs between `Mdl1` and `Mdl2`.

```
mse1 = resubLoss(Mdl1)
mse1 = 6.4721
mse2 = resubLoss(Mdl2)
mse2 = 7.8599
```

The in-sample MSE for the ensemble that trains on all predictors is lower.

Estimate the Generalization Error of a Boosting Ensemble

Estimate the generalization error of a trained, boosting classification ensemble of decision trees.

Load the `ionosphere` data set.

```
load ionosphere;
```

Train a decision tree ensemble using `AdaBoostM1`, 100 learning cycles, and half of the data chosen randomly. The software validates the algorithm using the remaining half.

```
rng(2); % For reproducibility
ClassTreeEns = fitensemble(X,Y,'AdaBoostM1',100,'Tree',...
    'Holdout',0.5);
```

`ClassTreeEns` is a trained `ClassificationEnsemble` ensemble classifier.

Determine the cumulative generalization error, i.e., the cumulative misclassification error of the labels in the validation data).

```
genError = kfoldLoss(ClassTreeEns,'Mode','Cumulative');
```

`genError` is a 100-by-1 vector, where element k contains the generalization error after the first k learning cycles.

Plot the generalization error over the number of learning cycles.

```
plot(genError);
xlabel('Number of Learning Cycles');
ylabel('Generalization Error');
```

The cumulative generalization error decreases to approximately 7% when 25 weak learners compose the ensemble classifier.

Find the Optimal Number of Splits and Trees for an Ensemble

You can control the depth of the trees in an ensemble of decision trees. You can also control the tree depth in an ECOC model containing decision tree binary learners using the `MaxNumSplits`, `MinLeafSize`, or `MinParentSize` name-value pair parameters.

- When bagging decision trees, `fitensemble` grows deep decision trees by default. You can grow shallower trees to reduce model complexity or computation time.

- When boosting decision trees, `fitensemble` grows stumps (a tree with one split) by default. You can grow deeper trees for better accuracy.

Load the `carsmall` data set. Specify the variables `Acceleration`, `Displacement`, `Horsepower`, and `Weight` as predictors, and `MPG` as the response.

```
load carsmall
X = [Acceleration Displacement Horsepower Weight];
Y = MPG;
```

The default values of the tree depth controllers for boosting regression trees are:

- 1 for `MaxNumSplits`. This option grows stumps.
- 5 for `MinLeafSize`
- 10 for `MinParentSize`

To search for the optimal number of splits:

- 1 Train a set of ensembles. Exponentially increase the maximum number of splits for subsequent ensembles from stump to at most $n - 1$ splits, where n is the training sample size. Also, decrease the learning rate for each ensemble from 1 to 0.1.
- 2 Cross validate the ensembles.
- 3 Estimate the cross-validated mean-squared error (MSE) for each ensemble.
- 4 Compare the cross-validated MSEs. The ensemble with the lowest one performs the best, and indicates the optimal maximum number of splits, number of trees, and learning rate for the data set.

Grow and cross validate a deep regression tree and a stump. Specify to use surrogate splits because the data contains missing values. These serve as benchmarks.

```
MdlDeep = fitrtree(X,Y,'CrossVal','on','MergeLeaves','off',...
    'MinParentSize',1,'Surrogate','on');
MdlStump = fitrtree(X,Y,'MaxNumSplits',1,'CrossVal','on','Surrogate','on');
```

Train the boosting ensembles using 150 regression trees. Cross validate the ensemble using 5-fold cross validation. Vary the maximum number of splits using the values in the sequence $\{2^0, 2^1, \dots, 2^m\}$, where m is such that 2^m is no greater than $n - 1$, where n is the training sample size. For each variant, adjust the learning rate to each value in the set $\{0.1, 0.25, 0.5, 1\}$;

```
n = size(X,1);
m = floor(log2(n - 1));
```

```

lr = [0.1 0.25 0.5 1];
maxNumSplits = 2.^(0:m);
numTrees = 150;
Mdl = cell(numel(maxNumSplits),numel(lr));
rng(1); % For reproducibility
for k = 1:numel(lr);
    for j = 1:numel(maxNumSplits);
        t = templateTree('MaxNumSplits',maxNumSplits(j),'Surrogate','on');
        Mdl{j,k} = fitensemble(X,Y,'LSBoost',numTrees,t,...
            'Type','regression','KFold',5,'LearnRate',lr(k));
    end;
end;

```

Compute the cross-validated MSE for each ensemble.

```

kflAll = @(x)kfoldLoss(x,'Mode','cumulative');
errorCell = cellfun(kflAll,Mdl,'Uniform',false);
error = reshape(cell2mat(errorCell),[numTrees numel(maxNumSplits) numel(lr)]);
errorDeep = kfoldLoss(MdlDeep);
errorStump = kfoldLoss(MdlStump);

```

Plot how the cross-validated MSE behaves as the number of trees in the ensemble increases for a few of the ensembles, the deep tree, and the stump. Plot the curves with respect to learning rate in the same plot, and plot separate plots for varying tree complexities. Choose a subset of tree complexity levels.

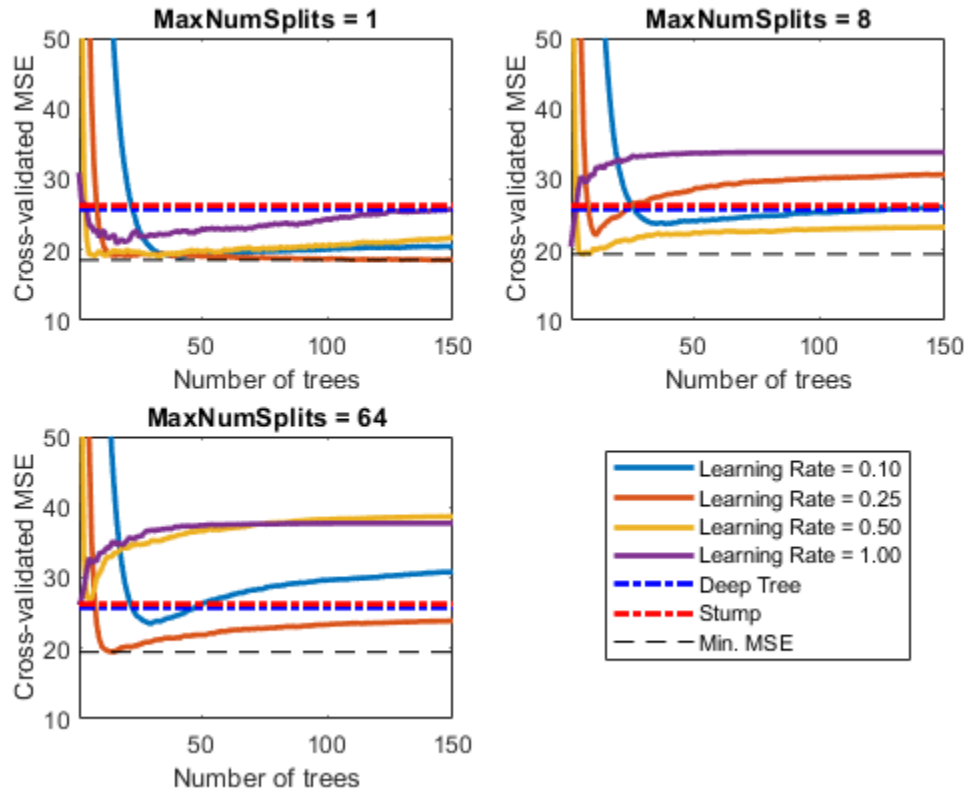

```

mnsPlot = [1 round(numel(maxNumSplits)/2) numel(maxNumSplits)];
figure;
for k = 1:3;
    subplot(2,2,k);
    plot(squeeze(error(:,mnsPlot(k),:)), 'LineWidth',2);
    axis tight;
    hold on;
    h = gca;
    plot(h.XLim,[errorDeep errorDeep], '-.b', 'LineWidth',2);
    plot(h.XLim,[errorStump errorStump], '-.r', 'LineWidth',2);
    plot(h.XLim,min(min(error(:,mnsPlot(k),:))).*[1 1], '--k');
    h.YLim = [10 50];
    xlabel 'Number of trees';
    ylabel 'Cross-validated MSE';
    title(sprintf('MaxNumSplits = %0.3g', maxNumSplits(mnsPlot(k))));
    hold off;
end;
hL = legend([cellstr(num2str(lr),'Learning Rate = %0.2f'));...

```

```
'Deep Tree';'Stump';'Min. MSE']]);
hL.Position(1) = 0.6;
```

Each curve contains a minimum cross-validated MSE occurring at the optimal number of trees in the ensemble.

Identify the maximum number of splits, number of trees, and learning rate that yields the lowest MSE overall.

```
[minErr,minErrIdxLin] = min(error(:));
[idxNumTrees,idxMNS,idxLR] = ind2sub(size(error),minErrIdxLin);
```

```
fprintf('\nMin. MSE = %0.5f',minErr)
```

```
Min. MSE = 18.50574
```

```
fprintf('\nOptimal Parameter Values:\nNum. Trees = %d',idxNumTrees);
```

```
Optimal Parameter Values:  
Num. Trees = 12
```

```
fprintf('\nMaxNumSplits = %d\nLearning Rate = %0.2f\n',...  
      maxNumSplits(idxMNS),lr(idxLR))
```

```
MaxNumSplits = 4  
Learning Rate = 0.25
```

For a different approach to optimizing this ensemble, see “Optimize a Boosted Regression Ensemble” on page 10-77.

Input Arguments

Tbl — Sample data

table

Sample data used to train the model, specified as a table. Each row of **Tbl** corresponds to one observation, and each column corresponds to one predictor variable. **Tbl** can contain one additional column for the response variable. Multi-column variables and cell arrays other than cell arrays of character vectors are not allowed.

- If **Tbl** contains the response variable and you want to use all remaining variables as predictors, then specify the response variable using **ResponseVarName**.
- If **Tbl** contains the response variable, and you want to use a subset of the remaining variables only as predictors, then specify a formula using **formula**.
- If **Tbl** does not contain the response variable, then specify the response data using **Y**. The length of response variable and the number of rows of **Tbl** must be equal.

Note To save memory and execution time, supply **X** and **Y** instead of **Tbl**.

Data Types: table

ResponseVarName — Response variable name

name of response variable in **Tbl**

Response variable name, specified as the name of the response variable in **Tbl**.

You must specify `ResponseVarName` as a character vector or string scalar. For example, if `Tbl.Y` is the response variable, then specify `ResponseVarName` as `'Y'`. Otherwise, `fitensemble` treats all columns of `Tbl` as predictor variables.

The response variable must be a categorical, character, or string array, logical or numeric vector, or cell array of character vectors. If the response variable is a character array, then each element must correspond to one row of the array.

For classification, you can specify the order of the classes using the `ClassNames` name-value pair argument. Otherwise, `fitensemble` determines the class order, and stores it in the `Mdl.ClassNames`.

Data Types: `char` | `string`

formula — Explanatory model of response and subset of predictor variables

character vector | string scalar

Explanatory model of the response and a subset of the predictor variables, specified as a character vector or string scalar in the form `'Y~X1+X2+X3'`. In this form, `Y` represents the response variable, and `X1`, `X2`, and `X3` represent the predictor variables. The variables must be variable names in `Tbl` (`Tbl.Properties.VariableNames`).

To specify a subset of variables in `Tbl` as predictors for training the model, use a formula. If you specify a formula, then the software does not use any variables in `Tbl` that do not appear in `formula`.

Data Types: `char` | `string`

X — Predictor data

numeric matrix

Predictor data, specified as numeric matrix.

Each row corresponds to one observation, and each column corresponds to one predictor variable.

The length of `Y` and the number of rows of `X` must be equal.

To specify the names of the predictors in the order of their appearance in `X`, use the `PredictorNames` name-value pair argument.

Data Types: `single` | `double`

Y — Response data

categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Response data, specified as a categorical, character, or string array, a logical or numeric vector, or a cell array of character vectors. Each entry in `Y` is the response to or label for the observation in the corresponding row of `X` or `Tbl`. The length of `Y` and the number of rows of `X` or `Tbl` must be equal. If the response variable is a character array, then each element must correspond to one row of the array.

- For classification, `Y` can be any of the supported data types. You can specify the order of the classes using the `ClassNames` name-value pair argument. Otherwise, `fitensemble` determines the class order, and stores it in the `Mdl.ClassNames`.
- For regression, `Y` must be a numeric column vector.

Data Types: categorical | char | string | logical | single | double | cell

Method — Ensemble aggregation method

'AdaBoostM1' | 'LogitBoost' | 'GentleBoost' | 'RUSBoost' | 'Subspace' | 'Bag' | 'AdaBoostM2' | 'LSBoost' | ...

Ensemble aggregation method, specified as one of the method names in this list.

- For classification with two classes:
 - 'AdaBoostM1'
 - 'LogitBoost'
 - 'GentleBoost'
 - 'RobustBoost' (requires Optimization Toolbox)
 - 'LPBoost' (requires Optimization Toolbox)
 - 'TotalBoost' (requires Optimization Toolbox)
 - 'RUSBoost'
 - 'Subspace'
 - 'Bag'
- For classification with three or more classes:
 - 'AdaBoostM2'
 - 'LPBoost' (requires Optimization Toolbox)

- 'TotalBoost' (requires Optimization Toolbox)
- 'RUSBoost'
- 'Subspace'
- 'Bag'
- For regression:
 - 'LSBoost'
 - 'Bag'

If you specify 'Method', 'Bag', then specify the problem type using the `Type` name-value pair argument, because you can specify 'Bag' for classification and regression problems.

For details about ensemble aggregation algorithms and examples, see “Ensemble Algorithms” on page 18-50 and “Choose an Applicable Ensemble Aggregation Method” on page 18-42.

NLearn — Number of ensemble learning cycles

positive integer | 'AllPredictorCombinations'

Number of ensemble learning cycles, specified as a positive integer or 'AllPredictorCombinations'.

- If you specify a positive integer, then, at every learning cycle, the software trains one weak learner for every template object in `Learners`. Consequently, the software trains `NLearn* numel(Learners)` learners.
- If you specify 'AllPredictorCombinations', then set `Method` to 'Subspace' and specify one learner only in `Learners`. With these settings, the software trains learners for all possible combinations of predictors taken `NPredToSample` at a time. Consequently, the software trains `nchoosek(size(X,2),NPredToSample)` learners.

The software composes the ensemble using all trained learners and stores them in `Mdl.Trained`.

For more details, see “Tips” on page 32-2479.

Data Types: `single` | `double` | `char` | `string`

Learners — Weak learners to use in ensemble

weak-learner name | weak-learner template object | cell vector of weak-learner template objects

Weak learners to use in the ensemble, specified as a weak-learner name, weak-learner template object, or cell array of weak-learner template objects.

Weak Learner	Weak-Learner Name	Template Object Creation Function	Method Settings
Discriminant analysis	'Discriminant'	templateDiscriminant	Recommended for 'Subspace'
<i>k</i> nearest neighbors	'KNN'	templateKNN	For 'Subspace' only
Decision tree	'Tree'	templateTree	All methods except 'Subspace'

For more details, see `NLearn` and “Tips” on page 32-2479.

Example: For an ensemble composed of two types of classification trees, supply `{t1 t2}`, where `t1` and `t2` are classification tree templates.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'CrossVal', 'on', 'LearnRate', 0.05` specifies to implement 10-fold cross-validation and to use `0.05` as the learning rate.

General Ensemble Options

`CategoricalPredictors` — Categorical predictors list

vector of positive integers | logical vector | character matrix | string array | cell array of character vectors | 'all'

Categorical predictors list, specified as the comma-separated pair consisting of `'CategoricalPredictors'` and one of the values in this table.

Value	Description
Vector of positive integers	An entry in the vector is the index value corresponding to the column of the predictor data (<code>X</code> or <code>Tbl</code>) that contains a categorical variable.
Logical vector	A <code>true</code> entry means that the corresponding column of predictor data (<code>X</code> or <code>Tbl</code>) is a categorical variable.
Character matrix	Each row of the matrix is the name of a predictor variable. The names must match the entries in <code>PredictorNames</code> . Pad the names with extra blanks so each row of the character matrix has the same length.
String array or cell array of character vectors	Each element in the array is the name of a predictor variable. The names must match the entries in <code>PredictorNames</code> .
'all'	All predictors are categorical.

Specification of `CategoricalPredictors` is appropriate if:

- 'Learners' is 'tree'.
- 'Learners' is 'knn' when all predictors are categorical.

By default, if the predictor data is in a table (`Tbl`), `fitensemble` assumes that a variable is categorical if it contains logical values, categorical values, a string array, or a cell array of character vectors. If the predictor data is a matrix (`X`), `fitensemble` assumes all predictors are continuous. To identify any categorical predictors when the data is a matrix, use the '`CategoricalPredictors`' name-value pair argument.

Example: '`CategoricalPredictors`', 'all'

Data Types: `single` | `double` | `logical` | `char` | `string` | `cell`

NPrint — Printout frequency

'off' (default) | positive integer

Printout frequency, specified as the comma-separated pair consisting of '`NPrint`' and a positive integer or 'off'.

To track the number of *weak learners* or *folds* that `fitensemble` trained so far, specify a positive integer. That is, if you specify the positive integer m :

- Without also specifying any cross-validation option (for example, `CrossVal`), then `fitensemble` displays a message to the command line every time it completes training m weak learners.
- And a cross-validation option, then `fitensemble` displays a message to the command line every time it finishes training m folds.

If you specify 'off', then `fitensemble` does not display a message when it completes training weak learners.

Tip When training an ensemble of many weak learners on a large data set, specify a positive integer for `NPrint`.

Example: 'NPrint',5

Data Types: `single` | `double` | `char` | `string`

PredictorNames — Predictor variable names

string array of unique names | cell array of unique character vectors

Predictor variable names, specified as the comma-separated pair consisting of 'PredictorNames' and a string array of unique names or cell array of unique character vectors. The functionality of 'PredictorNames' depends on the way you supply the training data.

- If you supply X and Y , then you can use 'PredictorNames' to give the predictor variables in X names.
 - The order of the names in `PredictorNames` must correspond to the column order of X . That is, `PredictorNames{1}` is the name of $X(:,1)$, `PredictorNames{2}` is the name of $X(:,2)$, and so on. Also, `size(X,2)` and `numel(PredictorNames)` must be equal.
 - By default, `PredictorNames` is `{'x1', 'x2', ...}`.
- If you supply `Tbl`, then you can use 'PredictorNames' to choose which predictor variables to use in training. That is, `fitensemble` uses only the predictor variables in `PredictorNames` and the response variable in training.
 - `PredictorNames` must be a subset of `Tbl.Properties.VariableNames` and cannot include the name of the response variable.
 - By default, `PredictorNames` contains the names of all predictor variables.

- It is a good practice to specify the predictors for training using either 'PredictorNames' or formula only.

Example: 'PredictorNames',
{'SepalLength', 'SepalWidth', 'PetalLength', 'PetalWidth'}

Data Types: string | cell

ResponseName — Response variable name

'Y' (default) | character vector | string scalar

Response variable name, specified as the comma-separated pair consisting of 'ResponseName' and a character vector or string scalar.

- If you supply Y, then you can use 'ResponseName' to specify a name for the response variable.
- If you supply ResponseVarName or formula, then you cannot use 'ResponseName'.

Example: 'ResponseName', 'response'

Data Types: char | string

Type — Supervised learning type

'classification' | 'regression'

Supervised learning type, specified as the comma-separated pair consisting of 'Type' and 'classification' or 'regression'.

- If Method is 'bag', then the supervised learning type is ambiguous. Therefore, specify Type when bagging.
- Otherwise, the value of Method determines the supervised learning type.

Example: 'Type', 'classification'

Cross-Validation Options

CrossVal — Cross-validation flag

'off' (default) | 'on'

Cross-validation flag, specified as the comma-separated pair consisting of 'Crossval' and 'on' or 'off'.

If you specify 'on', then the software implements 10-fold cross-validation.

To override this cross-validation setting, use one of these name-value pair arguments: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`. To create a cross-validated model, you can use one cross-validation name-value pair argument at a time only.

Alternatively, cross-validate later by passing `Mdl` to `crossval` or `crossval`.

Example: `'Crossval', 'on'`

CVPartition — Cross-validation partition

`[]` (default) | `cvpartition` partition object

Cross-validation partition, specified as the comma-separated pair consisting of `'CVPartition'` and a `cvpartition` partition object created by `cvpartition`. The partition object specifies the type of cross-validation and the indexing for the training and validation sets.

To create a cross-validated model, you can use one of these four name-value pair arguments only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: Suppose you create a random partition for 5-fold cross-validation on 500 observations by using `cvp = cvpartition(500, 'KFold', 5)`. Then, you can specify the cross-validated model by using `'CVPartition', cvp`.

Holdout — Fraction of data for holdout validation

scalar value in the range (0,1)

Fraction of the data used for holdout validation, specified as the comma-separated pair consisting of `'Holdout'` and a scalar value in the range (0,1). If you specify `'Holdout', p`, then the software completes these steps:

- 1 Randomly select and reserve $p \times 100\%$ of the data as validation data, and train the model using the rest of the data.
- 2 Store the compact, trained model in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: `'Holdout', 0.1`

Data Types: `double` | `single`

KFold — Number of folds

10 (default) | positive integer value greater than 1

Number of folds to use in a cross-validated model, specified as the comma-separated pair consisting of 'KFold' and a positive integer value greater than 1. If you specify 'KFold', k , then the software completes these steps:

- 1 Randomly partition the data into k sets.
- 2 For each set, reserve the set as validation data, and train the model using the other $k - 1$ sets.
- 3 Store the k compact, trained models in the cells of a k -by-1 cell vector in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: 'KFold',5

Data Types: single | double

Leaveout — Leave-one-out cross-validation flag

'off' (default) | 'on'

Leave-one-out cross-validation flag, specified as the comma-separated pair consisting of 'Leaveout' and 'on' or 'off'. If you specify 'Leaveout', 'on', then, for each of the n observations (where n is the number of observations excluding missing observations, specified in the `NumObservations` property of the model), the software completes these steps:

- 1 Reserve the observation as validation data, and train the model using the other $n - 1$ observations.
- 2 Store the n compact, trained models in the cells of an n -by-1 cell vector in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: 'Leaveout', 'on'

Other Classification or Regression Options

ClassNames — Names of classes to use for training

categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Names of classes to use for training, specified as the comma-separated pair consisting of 'ClassNames' and a categorical, character, or string array, a logical or numeric vector, or a cell array of character vectors. ClassNames must have the same data type as Y.

If ClassNames is a character array, then each element must correspond to one *row* of the array.

Use ClassNames to:

- Order the classes during training.
- Specify the order of any input or output argument dimension that corresponds to the class order. For example, use ClassNames to specify the order of the dimensions of Cost or the column order of classification scores returned by predict.
- Select a subset of classes for training. For example, suppose that the set of all distinct class names in Y is {'a', 'b', 'c'}. To train the model using observations from classes 'a' and 'c' only, specify 'ClassNames', {'a', 'c'}.

The default value for ClassNames is the set of all distinct class names in Y.

Example: 'ClassNames', {'b', 'g'}

Data Types: categorical | char | string | logical | single | double | cell

Cost — Misclassification cost

square matrix | structure array

Misclassification cost, specified as the comma-separated pair consisting of 'Cost' and a square matrix or structure. If you specify:

- The square matrix Cost, then Cost(i, j) is the cost of classifying a point into class j if its true class is i. That is, the rows correspond to the true class and the columns correspond to the predicted class. To specify the class order for the corresponding rows and columns of Cost, also specify the ClassNames name-value pair argument.
- The structure S, then it must have two fields:
 - S.ClassNames, which contains the class names as a variable of the same data type as Y
 - S.ClassificationCosts, which contains the cost matrix with rows and columns ordered as in S.ClassNames

The default is ones(K) - eye(K), where K is the number of distinct classes.

Note `fitensemble` uses `Cost` to adjust the prior class probabilities specified in `Prior`. Then, `fitensemble` uses the adjusted prior probabilities for training and resets the cost matrix to its default.

Example: `'Cost',[0 1 2 ; 1 0 2; 2 2 0]`

Data Types: `double | single | struct`

Prior — Prior probabilities

`'empirical'` (default) | `'uniform'` | numeric vector | structure array

Prior probabilities for each class, specified as the comma-separated pair consisting of `'Prior'` and a value in this table.

Value	Description
<code>'empirical'</code>	The class prior probabilities are the class relative frequencies in <code>Y</code> .
<code>'uniform'</code>	All class prior probabilities are equal to $1/K$, where K is the number of classes.
numeric vector	Each element is a class prior probability. Order the elements according to <code>Mdl.ClassNames</code> or specify the order using the <code>ClassNames</code> name-value pair argument. The software normalizes the elements such that they sum to 1.
structure array	A structure <code>S</code> with two fields: <ul style="list-style-type: none"> <code>S.ClassNames</code> contains the class names as a variable of the same type as <code>Y</code>. <code>S.ClassProbs</code> contains a vector of corresponding prior probabilities. The software normalizes the elements such that they sum to 1.

`fitensemble` normalizes the prior probabilities in `Prior` to sum to 1.

Example: `struct('ClassNames',
{'setosa','versicolor','virginica'}),'ClassProbs',1:3)`

Data Types: `char` | `string` | `double` | `single` | `struct`

Weights — Observation weights

numeric vector of positive values | name of variable in `Tbl`

Observation weights, specified as the comma-separated pair consisting of `'Weights'` and a numeric vector of positive values or name of a variable in `Tbl`. The software weighs the observations in each row of `X` or `Tbl` with the corresponding value in `Weights`. The size of `Weights` must equal the number of rows of `X` or `Tbl`.

If you specify the input data as a table `Tbl`, then `Weights` can be the name of a variable in `Tbl` that contains a numeric vector. In this case, you must specify `Weights` as a character vector or string scalar. For example, if the weights vector `W` is stored as `Tbl.W`, then specify it as `'W'`. Otherwise, the software treats all columns of `Tbl`, including `W`, as predictors or the response when training the model.

The software normalizes `Weights` to sum up to the value of the prior probability in the respective class.

By default, `Weights` is `ones(n, 1)`, where n is the number of observations in `X` or `Tbl`.

Data Types: `double` | `single` | `char` | `string`

Sampling Options for Boosting Methods and Bagging

FResample — Fraction of training set to resample

1 (default) | positive scalar in $(0,1]$

Fraction of the training set to resample for every weak learner, specified as the comma-separated pair consisting of `'FResample'` and a positive scalar in $(0,1]$.

To use `'FResample'`, specify `'bag'` for `Method` or set `Resample` to `'on'`.

Example: `'FResample', 0.75`

Data Types: `single` | `double`

Replace — Flag indicating to sample with replacement

`'on'` (default) | `'off'`

Flag indicating sampling with replacement, specified as the comma-separated pair consisting of `'Replace'` and `'off'` or `'on'`.

- For 'on', the software samples the training observations with replacement.
- For 'off', the software samples the training observations without replacement. If you set `Resample` to 'on', then the software samples training observations assuming uniform weights. If you also specify a boosting method, then the software boosts by reweighting observations.

Unless you set `Method` to 'bag' or set `Resample` to 'on', `Replace` has no effect.

Example: 'Replace', 'off'

Resample — Flag indicating to resample

'off' | 'on'

Flag indicating to resample, specified as the comma-separated pair consisting of 'Resample' and 'off' or 'on'.

- If `Method` is a boosting method, then:
 - 'Resample', 'on' specifies to sample training observations using updated weights as the multinomial sampling probabilities.
 - 'Resample', 'off' (default) specifies to reweight observations at every learning iteration.
- If `Method` is 'bag', then 'Resample' must be 'on'. The software resamples a fraction of the training observations (see `FResample`) with or without replacement (see `Replace`).

If you specify to resample using `Resample`, then it is good practice to resample to entire data set. That is, use the default setting of 1 for `FResample`.

AdaBoostM1, AdaBoostM2, LogitBoost, GentleBoost, and LSBoost Method Options

LearnRate — Learning rate for shrinkage

1 (default) | numeric scalar in (0,1]

Learning rate for shrinkage, specified as the comma-separated pair consisting of a numeric scalar in the interval (0,1].

To train an ensemble using shrinkage, set `LearnRate` to a value less than 1, for example, 0.1 is a popular choice. Training an ensemble using shrinkage requires more learning iterations, but often achieves better accuracy.

Example: 'LearnRate', 0.1

Data Types: `single` | `double`

RUSBoost Method Options

LearnRate — Learning rate for shrinkage

1 (default) | numeric scalar in (0,1]

Learning rate for shrinkage, specified as the comma-separated pair consisting of a numeric scalar in the interval (0,1].

To train an ensemble using shrinkage, set `LearnRate` to a value less than 1, for example, 0.1 is a popular choice. Training an ensemble using shrinkage requires more learning iterations, but often achieves better accuracy.

Example: `'LearnRate', 0.1`

Data Types: `single` | `double`

RatioToSmallest — Sampling proportion with respect to lowest-represented class

positive numeric scalar | numeric vector of positive values

Sampling proportion with respect to the lowest-represented class, specified as the comma-separated pair consisting of `'RatioToSmallest'` and a numeric scalar or numeric vector of positive values with length equal to the number of distinct classes in the training data.

Suppose that there are K classes in the training data and the lowest-represented class has m observations in the training data.

- If you specify the positive numeric scalar s , then `fitensemble` samples $s*m$ observations from each class, that is, it uses the same sampling proportion for each class. For more details, see “Algorithms” on page 32-2481.
- If you specify the numeric vector $[s_1, s_2, \dots, s_K]$, then `fitensemble` samples s_i*m observations from class i , $i = 1, \dots, K$. The elements of `RatioToSmallest` correspond to the order of the class names specified using `ClassNames` (see “Tips” on page 32-2479).

The default value is `ones(K, 1)`, which specifies to sample m observations from each class.

Example: `'RatioToSmallest', [2, 1]`

Data Types: `single` | `double`

LPBoost and TotalBoost Method Options

MarginPrecision — Margin precision to control convergence speed

0.1 (default) | numeric scalar in [0,1]

Margin precision to control convergence speed, specified as the comma-separated pair consisting of 'MarginPrecision' and a numeric scalar in the interval [0,1]. MarginPrecision affects the number of boosting iterations required for convergence.

Tip To train an ensemble using many learners, specify a small value for MarginPrecision. For training using a few learners, specify a large value.

Example: 'MarginPrecision',0.5

Data Types: single | double

RobustBoost Method Options

RobustErrorGoal — Target classification error

0.1 (default) | nonnegative numeric scalar

Target classification error, specified as the comma-separated pair consisting of 'RobustErrorGoal' and a nonnegative numeric scalar. The upper bound on possible values depends on the values of RobustMarginSigma and RobustMaxMargin. However, the upper bound cannot exceed 1.

Tip For a particular training set, usually there is an optimal range for RobustErrorGoal. If you set it too low or too high, then the software can produce a model with poor classification accuracy. Try cross-validating to search for the appropriate value.

Example: 'RobustErrorGoal',0.05

Data Types: single | double

RobustMarginSigma — Classification margin distribution spread

0.1 (default) | positive numeric scalar

Classification margin distribution spread over the training data, specified as the comma-separated pair consisting of 'RobustMarginSigma' and a positive numeric scalar.

Before specifying `RobustMarginSigma`, consult the literature on `RobustBoost`, for example, [19].

Example: `'RobustMarginSigma', 0.5`

Data Types: `single` | `double`

RobustMaxMargin — Maximal classification margin

`0` (default) | nonnegative numeric scalar

Maximal classification margin in the training data, specified as the comma-separated pair consisting of `'RobustMaxMargin'` and a nonnegative numeric scalar. The software minimizes the number of observations in the training data having classification margins below `RobustMaxMargin`.

Example: `'RobustMaxMargin', 1`

Data Types: `single` | `double`

Random Subspace Method Options

NPredToSample — Number of predictors to sample

`1` (default) | positive integer

Number of predictors to sample for each random subspace learner, specified as the comma-separated pair consisting of `'NPredToSample'` and a positive integer in the interval $1, \dots, p$, where p is the number of predictor variables (`size(X, 2)` or `size(Tbl, 2)`).

Data Types: `single` | `double`

Output Arguments

Mdl — Trained ensemble model

`ClassificationBaggedEnsemble` model object | `ClassificationEnsemble` model object | `ClassificationPartitionedEnsemble` cross-validated model object | `RegressionBaggedEnsemble` model object | `RegressionEnsemble` model object | `RegressionPartitionedEnsemble` cross-validated model object

Trained ensemble model, returned as one of the model objects in this table.

Model Object	Type Setting	Specify Any Cross-Validation Options?	Method Setting	Resample Setting
ClassificationBaggedEnsemble	'classification'	No	'Bag'	'on'
ClassificationEnsemble	'classification'	No	Any ensemble-aggregation method for classification	'off'
ClassificationPartitionedEnsemble	'classification'	Yes	Any classification ensemble-aggregation method	'off' or 'on'
RegressionBaggedEnsemble	'regression'	No	'Bag'	'on'
RegressionEnsemble	'regression'	No	'LSBoost'	'off'
RegressionPartitionedEnsemble	'regression'	Yes	'LSBoost' or 'Bag'	'off' or 'on'

The name-value pair arguments that control cross-validation are `CrossVal`, `Holdout`, `KFold`, `Leaveout`, and `CVPartition`.

To reference properties of `Mdl`, use dot notation. For example, to access or display the cell vector of weak learner model objects for an ensemble that has not been cross-validated, enter `Mdl.Trained` at the command line.

Tips

- `NLearn` can vary from a few dozen to a few thousand. Usually, an ensemble with good predictive power requires from a few hundred to a few thousand weak learners. However, you do not have to train an ensemble for that many cycles at once. You can start by growing a few dozen learners, inspect the ensemble performance and then, if necessary, train more weak learners using `resume` for classification problems, or `resume` for regression problems.

- Ensemble performance depends on the ensemble setting and the setting of the weak learners. That is, if you specify weak learners with default parameters, then the ensemble can perform poorly. Therefore, like ensemble settings, it is good practice to adjust the parameters of the weak learners using templates, and to choose values that minimize generalization error.
- If you specify to resample using `Resample`, then it is good practice to resample to entire data set. That is, use the default setting of 1 for `FResample`.
- In classification problems (that is, `Type` is 'classification'):
 - If the ensemble-aggregation method (`Method`) is 'bag' and:
 - The misclassification cost (`Cost`) is highly imbalanced, then, for in-bag samples, the software oversamples unique observations from the class that has a large penalty.
 - The class prior probabilities (`Prior`) are highly skewed, the software oversamples unique observations from the class that has a large prior probability.

For smaller sample sizes, these combinations can result in a low relative frequency of out-of-bag observations from the class that has a large penalty or prior probability. Consequently, the estimated out-of-bag error is highly variable and it can be difficult to interpret. To avoid large estimated out-of-bag error variances, particularly for small sample sizes, set a more balanced misclassification cost matrix using `Cost` or a less skewed prior probability vector using `Prior`.

- Because the order of some input and output arguments correspond to the distinct classes in the training data, it is good practice to specify the class order using the `ClassNames` name-value pair argument.
 - To determine the class order quickly, remove all observations from the training data that are unclassified (that is, have a missing label), obtain and display an array of all the distinct classes, and then specify the array for `ClassNames`. For example, suppose the response variable (`Y`) is a cell array of labels. This code specifies the class order in the variable `classNames`.

```
Ycat = categorical(Y);  
classNames = categories(Ycat)
```

`categorical` assigns `<undefined>` to unclassified observations and `categories` excludes `<undefined>` from its output. Therefore, if you use this code for cell arrays of labels or similar code for categorical arrays, then you do

not have to remove observations with missing labels to obtain a list of the distinct classes.

- To specify that the class order from lowest-represented label to most-represented, then quickly determine the class order (as in the previous bullet), but arrange the classes in the list by frequency before passing the list to `ClassNames`. Following from the previous example, this code specifies the class order from lowest- to most-represented in `classNamesLH`.

```
Ycat = categorical(Y);
classNames = categories(Ycat);
freq = countcats(Ycat);
[~,idx] = sort(freq);
classNamesLH = classNames(idx);
```

Algorithms

- For details of ensemble-aggregation algorithms, see “Ensemble Algorithms” on page 18-50.
- If you specify `Method` to be a boosting algorithm and `Learners` to be decision trees, then the software grows stumps by default. A decision stump is one root node connected to two terminal, leaf nodes. You can adjust tree depth by specifying the `MaxNumSplits`, `MinLeafSize`, and `MinParentSize` name-value pair arguments using `templateTree`.
- `fitensemble` generates in-bag samples by oversampling classes with large misclassification costs and undersampling classes with small misclassification costs. Consequently, out-of-bag samples have fewer observations from classes with large misclassification costs and more observations from classes with small misclassification costs. If you train a classification ensemble using a small data set and a highly skewed cost matrix, then the number of out-of-bag observations per class can be low. Therefore, the estimated out-of-bag error can have a large variance and can be difficult to interpret. The same phenomenon can occur for classes with large prior probabilities.
- For the RUSBoost ensemble-aggregation method (`Method`), the name-value pair argument `RatioToSmallest` specifies the sampling proportion for each class with respect to the lowest-represented class. For example, suppose that there are two classes in the training data: *A* and *B*. *A* have 100 observations and *B* have 10 observations. and that the lowest-represented class has *m* observations in the training data.

- If you set 'RatioToSmallest', 2, then $s*m = 2*10 = 20$. Consequently, `fitensemble` trains every learner using 20 observations from class A and 20 observations from class B. If you set 'RatioToSmallest', [2 2], then you obtain the same result.
- If you set 'RatioToSmallest', [2, 1], then $s1*m = 2*10 = 20$ and $s2*m = 1*10 = 10$. Consequently, `fitensemble` trains every learner using 20 observations from class A and 10 observations from class B.
- For ensembles of decision trees, and for dual-core systems and above, `fitensemble` parallelizes training using Intel Threading Building Blocks (TBB). For details on Intel TBB, see <https://software.intel.com/en-us/intel-tbb>.

Introduced in R2011a

fitnlm

Fit nonlinear regression model

Syntax

```
mdl = fitnlm(tbl,modelfun,beta0)
mdl = fitnlm(X,y,modelfun,beta0)
mdl = fitnlm( ____,modelfun,beta0,Name,Value)
```

Description

`mdl = fitnlm(tbl,modelfun,beta0)` fits the model specified by `modelfun` to variables in the table or dataset array `tbl`, and returns the nonlinear model `mdl`.

`fitnlm` estimates model coefficients using an iterative procedure starting from the initial values in `beta0`.

`mdl = fitnlm(X,y,modelfun,beta0)` fits a nonlinear regression model using the column vector `y` as a response variable and the columns of the matrix `X` as predictor variables.

`mdl = fitnlm(____,modelfun,beta0,Name,Value)` fits a nonlinear regression model with additional options specified by one or more `Name, Value` pair arguments.

Examples

Nonlinear Model from Table

Create a nonlinear model for auto mileage based on the `carbig` data.

Load the data and create a nonlinear model.

```
load carbig
tbl = table(Horsepower,Weight,MPG);
```

```

modelfun = @(b,x)b(1) + b(2)*x(:,1).^b(3) + ...
           b(4)*x(:,2).^b(5);
beta0 = [-50 500 -1 500 -1];
mdl = fitnlm(tbl,modelfun,beta0)

```

```

mdl =
Nonlinear regression model:
MPG ~ b1 + b2*Horsepower^b3 + b4*Weight^b5

```

Estimated	Coefficients:			
	Estimate	SE	tStat	pValue
	-----	-----	-----	-----
b1	-49.383	119.97	-0.41164	0.68083
b2	376.43	567.05	0.66384	0.50719
b3	-0.78193	0.47168	-1.6578	0.098177
b4	422.37	776.02	0.54428	0.58656
b5	-0.24127	0.48325	-0.49926	0.61788

```

Number of observations: 392, Error degrees of freedom: 387
Root Mean Squared Error: 3.96
R-Squared: 0.745, Adjusted R-Squared 0.743
F-statistic vs. constant model: 283, p-value = 1.79e-113

```

Nonlinear Model from Matrix Data

Create a nonlinear model for auto mileage based on the carbig data.

Load the data and create a nonlinear model.

```

load carbig
X = [Horsepower,Weight];
y = MPG;
modelfun = @(b,x)b(1) + b(2)*x(:,1).^b(3) + ...
           b(4)*x(:,2).^b(5);
beta0 = [-50 500 -1 500 -1];
mdl = fitnlm(X,y,modelfun,beta0)

mdl =
Nonlinear regression model:
y ~ b1 + b2*x1^b3 + b4*x2^b5

```

Estimated	Coefficients:			
	Estimate	SE	tStat	pValue
b1	-49.383	119.97	-0.41164	0.68083
b2	376.43	567.05	0.66384	0.50719
b3	-0.78193	0.47168	-1.6578	0.098177
b4	422.37	776.02	0.54428	0.58656
b5	-0.24127	0.48325	-0.49926	0.61788

Number of observations: 392, Error degrees of freedom: 387
 Root Mean Squared Error: 3.96
 R-Squared: 0.745, Adjusted R-Squared 0.743
 F-statistic vs. constant model: 283, p-value = 1.79e-113

Adjust Fitting Options in Nonlinear Model

Create a nonlinear model for auto mileage based on the `carbig` data. Strive for more accuracy by lowering the `TolFun` option, and observe the iterations by setting the `Display` option.

Load the data and create a nonlinear model.

```
load carbig
X = [Horsepower,Weight];
y = MPG;
modelfun = @(b,x)b(1) + b(2)*x(:,1).^b(3) + ...
    b(4)*x(:,2).^b(5);
beta0 = [-50 500 -1 500 -1];
```

Create options to lower `TolFun` and to report iterative display, and create a model using the options.

```
opts = statset('Display','iter','TolFun',1e-10);
mdl = fitnlm(X,y,modelfun,beta0,'Options',opts);
```

Iteration	SSE	Norm of Gradient	Norm of Step

Specify Nonlinear Regression Using Model Name Syntax

Specify a nonlinear regression model for estimation using a function handle or model syntax.

Load sample data.

```
S = load('reaction');
X = S.reactants;
y = S.rate;
beta0 = S.beta;
```

Use a function handle to specify the Hougen-Watson model for the rate data.

```
mdl = fitnlm(X,y,@hougen,beta0)
```

```
mdl =
Nonlinear regression model:
y ~ hougen(b,X)
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
b1	1.2526	0.86701	1.4447	0.18654
b2	0.062776	0.043561	1.4411	0.18753
b3	0.040048	0.030885	1.2967	0.23089
b4	0.11242	0.075157	1.4957	0.17309
b5	1.1914	0.83671	1.4239	0.1923

Number of observations: 13, Error degrees of freedom: 8

Root Mean Squared Error: 0.193

R-Squared: 0.999, Adjusted R-Squared 0.998

F-statistic vs. zero model: 3.91e+03, p-value = 2.54e-13

Alternatively, you can use an expression to specify the Hougen-Watson model for the rate data.

```
myfun = 'y~(b1*x2-x3/b5)/(1+b2*x1+b3*x2+b4*x3)';
mdl2 = fitnlm(X,y,myfun,beta0)
```

```
mdl2 =
Nonlinear regression model:
y ~ (b1*x2 - x3/b5)/(1 + b2*x1 + b3*x2 + b4*x3)
```

Estimated	Coefficients:			
	Estimate	SE	tStat	pValue
	-----	-----	-----	-----
b1	1.2526	0.86701	1.4447	0.18654
b2	0.062776	0.043561	1.4411	0.18753
b3	0.040048	0.030885	1.2967	0.23089
b4	0.11242	0.075157	1.4957	0.17309
b5	1.1914	0.83671	1.4239	0.1923

Number of observations: 13, Error degrees of freedom: 8
 Root Mean Squared Error: 0.193
 R-Squared: 0.999, Adjusted R-Squared 0.998
 F-statistic vs. zero model: 3.91e+03, p-value = 2.54e-13

Estimate Nonlinear Regression Using Robust Fitting Options

Generate sample data from the nonlinear regression model

$$y = b_1 + b_2 \exp(-b_3 x) + \varepsilon,$$

where b_1 , b_2 , and b_3 are coefficients, and the error term is normally distributed with mean 0 and standard deviation 0.5.

```
modelfun = @(b,x)(b(1)+b(2)*exp(-b(3)*x));
```

```
rng('default') % for reproducibility
b = [1;3;2];
x = exprnd(2,100,1);
y = modelfun(b,x) + normrnd(0,0.5,100,1);
```

Set robust fitting options.

```
opts = statset('nlinfit');
opts.RobustWgtFun = 'bisquare';
```

Fit the nonlinear model using the robust fitting options. Here, use an expression to specify the model.

```
b0 = [2;2;2];
modelstr = 'y ~ b1 + b2*exp(-b3*x)';
```

```
mdl = fitnlm(x,y,modelstr,b0,'Options',opts)
```

```
mdl =  
Nonlinear regression model (robust fit):  
y ~ b1 + b2*exp( - b3*x)
```

Estimated	Coefficients:			
	Estimate	SE	tStat	pValue
b1	1.0218	0.07202	14.188	2.1344e-25
b2	3.6619	0.25429	14.401	7.974e-26
b3	2.9732	0.38496	7.7232	1.0346e-11

```
Number of observations: 100, Error degrees of freedom: 97  
Root Mean Squared Error: 0.501  
R-Squared: 0.807, Adjusted R-Squared 0.803  
F-statistic vs. constant model: 203, p-value = 2.34e-35
```

Fit Nonlinear Regression Model Using Weights Function Handle

Load sample data.

```
S = load('reaction');  
X = S.reactants;  
y = S.rate;  
beta0 = S.beta;
```

Specify a function handle for observation weights. The function accepts the model fitted values as input, and returns a vector of weights.

```
a = 1; b = 1;  
weights = @(yhat) 1./((a + b*abs(yhat)).^2);
```

Fit the Hougen-Watson model to the rate data using the specified observation weights function.

```
mdl = fitnlm(X,y,@hougen,beta0,'Weights',weights)  
  
mdl =  
Nonlinear regression model:
```

$y \sim \text{hougen}(b,X)$

Estimated	Coefficients:			
	Estimate	SE	tStat	pValue
b1	0.83085	0.58224	1.427	0.19142
b2	0.04095	0.029663	1.3805	0.20477
b3	0.025063	0.019673	1.274	0.23842
b4	0.080053	0.057812	1.3847	0.20353
b5	1.8261	1.281	1.4256	0.19183

Number of observations: 13, Error degrees of freedom: 8
 Root Mean Squared Error: 0.037
 R-Squared: 0.998, Adjusted R-Squared 0.998
 F-statistic vs. zero model: 1.14e+03, p-value = 3.49e-11

Nonlinear Regression Model Using Nonconstant Error Model

Load sample data.

```
S = load('reaction');
X = S.reactants;
y = S.rate;
beta0 = S.beta;
```

Fit the Hougen-Watson model to the rate data using the combined error variance model.

```
mdl = fitnlm(X,y,@hougen,beta0,'ErrorModel','combined')
```

```
mdl =
Nonlinear regression model:
y ~ hougen(b,X)
```

Estimated	Coefficients:			
	Estimate	SE	tStat	pValue
b1	1.2526	0.86702	1.4447	0.18654
b2	0.062776	0.043561	1.4411	0.18753
b3	0.040048	0.030885	1.2967	0.23089

b4	0.11242	0.075158	1.4957	0.17309
b5	1.1914	0.83671	1.4239	0.1923

Number of observations: 13, Error degrees of freedom: 8
Root Mean Squared Error: 1.27
R-Squared: 0.999, Adjusted R-Squared 0.998
F-statistic vs. zero model: 3.91e+03, p-value = 2.54e-13

Input Arguments

tbl — Input data

table | dataset array

Input data, specified as a table or dataset array. If you do not specify the predictor and response variables, the last variable is the response variable and the others are the predictor variables by default.

Predictor variables and response variable must be numeric.

You specify the response and predictor names in your model specification. If you do not specify a model, you can set a different column as the response variable by using the `ResponseVar` name-value pair argument. You can select a subset of the columns as predictors by using the `PredictorVars` name-value pair argument.

Data Types: table

X — Predictor variables

matrix

Predictor variables, specified as an n -by- p matrix, where n is the number of observations and p is the number of predictor variables. Each column of X represents one variable, and each row represents one observation.

Data Types: single | double

y — Response variable

vector

Response variable, specified as an n -by-1 vector, where n is the number of observations. Each entry in y is the response for the corresponding row of X .

Data Types: `single` | `double`

modelfun — Functional form of the model

function handle | character vector or string scalar of the form ' $y \sim f(b_1, b_2, \dots, b_j, x_1, x_2, \dots, x_k)$ '

Functional form of the model, specified as either of the following.

- Function handle `@modelfun` or `@(b,x)modelfun`, where
 - `b` is a coefficient vector with the same number of elements as `beta0`.
 - `x` is a matrix with the same number of columns as `X` or the number of predictor variable columns of `tbl`.

`modelfun(b,x)` returns a column vector that contains the same number of rows as `x`. Each row of the vector is the result of evaluating `modelfun` on the corresponding row of `x`. In other words, `modelfun` is a vectorized function, one that operates on all data rows and returns all evaluations in one function call. `modelfun` should return real numbers to obtain meaningful coefficients.

- Character vector or string scalar of the form ' $y \sim f(b_1, b_2, \dots, b_j, x_1, x_2, \dots, x_k)$ ', where `f` represents a scalar function of the scalar coefficient variables `b1,...,bj` and the scalar data variables `x1,...,xk`.

Data Types: `function_handle` | `char` | `string`

beta0 — Coefficients

numeric vector

Coefficients for the nonlinear model, specified as a numeric vector. `NonLinearModel` starts its search for optimal coefficients from `beta0`.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: 'ErrorModel', 'combined', 'Exclude', 2, 'Options', opt specifies the error model as the combined model, excludes the second observation from the fit, and uses the options defined in the structure opt to control the iterative fitting procedure.

CoefficientNames — Names of the model coefficients

{ 'b1', 'b2', ..., 'bk' } (default) | string array | cell array of character vectors

Names of the model coefficients, specified as a string array or cell array of character vectors.

Data Types: string | cell

ErrorModel — Form of the error variance model

'constant' (default) | 'proportional' | 'combined'

Form of the error variance model, specified as one of the following. Each model defines the error using a standard mean-zero and unit-variance variable e in combination with independent components: the function value f , and one or two parameters a and b

'constant' (default)	$y = f + ae$
'proportional'	$y = f + bfe$
'combined'	$y = f + (a + b f)e$

The only allowed error model when using `Weights` is 'constant'.

Note `options.RobustWgtFun` must have value `[]` when using an error model other than 'constant'.

Example: 'ErrorModel', 'proportional'

ErrorParameters — Initial estimates of the error model parameters

numeric array

Initial estimates of the error model parameters for the chosen `ErrorModel`, specified as a numeric array.

Error Model	Parameters	Default Values
'constant'	a	1

Error Model	Parameters	Default Values
'proportional'	b	1
'combined'	a, b	[1,1]

You can only use the 'constant' error model when using `Weights`.

Note `options.RobustWgtFun` must have value `[]` when using an error model other than 'constant'.

For example, if `ErrorModel` has the value 'combined', you can specify the starting value 1 for a and the starting value 2 for b as follows.

Example: `'ErrorParameters',[1,2]`

Data Types: `single` | `double`

Exclude — Observations to exclude

logical or numeric index vector

Observations to exclude from the fit, specified as the comma-separated pair consisting of 'Exclude' and a logical or numeric index vector indicating which observations to exclude from the fit.

For example, you can exclude observations 2 and 3 out of 6 using either of the following examples.

Example: `'Exclude',[2,3]`

Example: `'Exclude',logical([0 1 1 0 0 0])`

Data Types: `single` | `double` | `logical`

Options — Options for controlling the iterative fitting procedure

`[]` (default) | structure

Options for controlling the iterative fitting procedure, specified as a structure created by `statset`. The relevant fields are the nonempty fields in the structure returned by the call `statset('fitnlm')`.

Option	Meaning	Default
DerivStep	Relative difference used in finite difference derivative calculations. A positive scalar, or a vector of positive scalars the same size as the vector of parameters estimated by the Statistics and Machine Learning Toolbox function using the options structure.	$\text{eps}^{(1/3)}$
Display	Amount of information displayed by the fitting algorithm. <ul style="list-style-type: none"> 'off' — Displays no information. 'final' — Displays the final output. 'iter' — Displays iterative output to the Command Window. 	'off'
FunValCheck	Character vector or string scalar indicating to check for invalid values, such as NaN or Inf, from the model function.	'on'
MaxIter	Maximum number of iterations allowed. Positive integer.	200
RobustWgtFun	Weight function for robust fitting. Can also be a function handle that accepts a normalized residual as input and returns the robust weights as output. If you use a function handle, give a Tune constant. See “Robust Options” on page 32-2501	[]
Tune	Tuning constant used in robust fitting to normalize the residuals before applying the weight function. A positive scalar. Required if the weight function is specified as a function handle.	See “Robust Options” on page 32-2501 for the default, which depends on RobustWgtFun.
TolFun	Termination tolerance for the objective function value. Positive scalar.	1e-8
TolX	Termination tolerance for the parameters. Positive scalar.	1e-8

Data Types: struct

PredictorVars — Predictor variables

string array | cell array of character vectors | logical or numeric index vector

Predictor variables to use in the fit, specified as the comma-separated pair consisting of 'PredictorVars' and either a string array or cell array of character vectors of the variable names in the table or dataset array `tbl`, or a logical or numeric index vector indicating which columns are predictor variables.

The string values or character vectors should be among the names in `tbl`, or the names you specify using the 'VarNames' name-value pair argument.

The default is all variables in X , or all variables in `tbl` except for `ResponseVar`.

For example, you can specify the second and third variables as the predictor variables using either of the following examples.

Example: 'PredictorVars',[2,3]

Example: 'PredictorVars',logical([0 1 1 0 0 0])

Data Types: single | double | logical | string | cell

ResponseVar — Response variable

last column of `tbl` (default) | variable name | logical or numeric index vector

Response variable to use in the fit, specified as the comma-separated pair consisting of 'ResponseVar' and either a variable name in the table or dataset array `tbl`, or a logical or numeric index vector indicating which column is the response variable.

If you specify a model, it specifies the response variable. Otherwise, when fitting a table or dataset array, 'ResponseVar' indicates which variable `fitnlm` should use as the response.

For example, you can specify the fourth variable, say `yield`, as the response out of six variables, in one of the following ways.

Example: 'ResponseVar','yield'

Example: 'ResponseVar',[4]

Example: 'ResponseVar',logical([0 0 0 1 0 0])

Data Types: single | double | logical | char | string

VarNames — Names of variables

{'x1','x2',..., 'xn','y'} (default) | string array | cell array of character vectors

Names of variables, specified as the comma-separated pair consisting of 'VarNames' and a string array or cell array of character vectors including the names for the columns of X first, and the name for the response variable y last.

'VarNames' is not applicable to variables in a table or dataset array, because those variables already have names.

For example, if in your data, horsepower, acceleration, and model year of the cars are the predictor variables, and miles per gallon (MPG) is the response variable, then you can name the variables as follows.

Example: 'VarNames', {'Horsepower', 'Acceleration', 'Model_Year', 'MPG'}

Data Types: string | cell

Weights — Observation weights

ones(n,1) (default) | vector of nonnegative scalar values | function handle

Observation weights, specified as a vector of nonnegative scalar values or function handle.

- If you specify a vector, then it must have n elements, where n is the number of rows in `tbl` or `y`.
- If you specify a function handle, then the function must accept a vector of predicted response values as input, and return a vector of real positive weights as output.

Given weights, W , `NonLinearModel` estimates the error variance at observation i by $MSE*(1/W(i))$, where MSE is the mean squared error.

Data Types: single | double | function_handle

Output Arguments

mdl — Nonlinear model

`NonLinearModel` object

Nonlinear model representing a least-squares fit of the response to the data, returned as a `NonLinearModel` object.

If the `Options` structure contains a nonempty `RobustWgtFun` field, the model is not a least-squares fit, but uses the `RobustWgtFun` robust fitting function.

For properties and methods of the nonlinear model object, `mdl`, see the `NonLinearModel` class page.

Definitions

Robust Options

Weight Function	Equation	Default Tuning Constant
'andrews'	$w = (\text{abs}(r) < \pi) .* \sin(r) ./ r$	1.339
'bisquare' (default)	$w = (\text{abs}(r) < 1) .* (1 - r.^2).^2$	4.685
'cauchy'	$w = 1 ./ (1 + r.^2)$	2.385
'fair'	$w = 1 ./ (1 + \text{abs}(r))$	1.400
'huber'	$w = 1 ./ \max(1, \text{abs}(r))$	1.345
'logistic'	$w = \tanh(r) ./ r$	1.205
'talwar'	$w = 1 * (\text{abs}(r) < 1)$	2.795
'welsch'	$w = \exp(-(r.^2))$	2.985
[]	No robust fitting	—

Algorithms

`fitnlm` uses the same fitting algorithm as `nlinfit`.

LinearMixedModel.fitmatrix

Class: LinearMixedModel

Fit linear mixed-effects model using design matrices

Note `LinearMixedModel.fitmatrix` will be removed in a future release. Use `fitlmematrix` instead.

Syntax

```
lme = LinearMixedModel.fitmatrix(X,y,Z,[])  
lme = LinearMixedModel.fitmatrix(X,y,Z,G)  
lme = LinearMixedModel.fitmatrix( ____,Name,Value)
```

Description

`lme = LinearMixedModel.fitmatrix(X,y,Z,[])` creates a linear mixed-effects model of the responses `y` using the fixed-effects design matrix `X` and random-effects design matrix or matrices in `Z`.

`[]` implies that there is one group. That is, the grouping variable `G` is `ones(n,1)`, where `n` is the number of observations. Using `LinearMixedModel.fitmatrix(X,Y,Z,[])` without a specified covariance pattern most likely will result in a non-identifiable model. This syntax is recommended only if you build the grouping information into the random effects design `Z` and specify a covariance pattern for the random effects using 'CovariancePattern' name-value pair argument.

`lme = LinearMixedModel.fitmatrix(X,y,Z,G)` creates a linear mixed-effects model of the responses `y` using the fixed-effects design matrix `X` and random-effects design matrix `Z` or matrices in `Z`, and the grouping variable or variables in `G`.

`lme = LinearMixedModel.fitmatrix(____,Name,Value)` also creates a linear mixed-effects model with additional options specified by one or more `Name,Value` pair arguments, using any of the previous input arguments.

For example, you can specify the names of the response, predictor, and grouping variables. You can also specify the covariance pattern, fitting method, or the optimization algorithm.

Input Arguments

X — Fixed-effects design matrix

n-by-*p* matrix

Fixed-effects design matrix, specified as an *n*-by-*p* matrix, where *n* is the number of observations, and *p* is the number of fixed-effects predictor variables. Each row of *X* corresponds to one observation, and each column of *X* corresponds to one variable.

Data Types: `single` | `double`

y — Response values

n-by-1 vector

Response values, specified as an *n*-by-1 vector, where *n* is the number of observations.

Data Types: `single` | `double`

Z — Random-effects design

n-by-*q* matrix | cell array of *R* *n*-by-*q*(*r*) matrices, *r* = 1, 2, ..., *R*

Random-effects design, specified as either of the following.

- If there is one random-effects term in the model, then *Z* must be an *n*-by-*q* matrix, where *n* is the number of observations and *q* is the number of variables in the random-effects term.
- If there are *R* random-effects terms, then *Z* must be a cell array of length *R*. Each cell of *Z* contains an *n*-by-*q*(*r*) design matrix *Z*{*r*}, *r* = 1, 2, ..., *R*, corresponding to each random-effects term. Here, *q*(*r*) is the number of random effects term in the *r*th random effects design matrix, *Z*{*r*}.

Data Types: `single` | `double` | `cell`

G — Grouping variable or variables

n-by-1 vector | cell array of *R* *n*-by-1 vectors

Grouping variable or variables on page 2-57, specified as either of the following.

- If there is one random-effects term, then `G` must be an n -by-1 vector corresponding to a single grouping variable with M levels or groups.

`G` can be a categorical vector, logical vector, numeric vector, character array, string array, or cell array of character vectors.

- If there are multiple random-effects terms, then `G` must be a cell array of length R . Each cell of `G` contains a grouping variable `G{r}`, $r = 1, 2, \dots, R$, with $M(r)$ levels.

`G{r}` can be a categorical vector, logical vector, numeric vector, character array, string array, or cell array of character vectors.

Data Types: `categorical` | `logical` | `single` | `double` | `char` | `string` | `cell`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, \dots, NameN, ValueN`.

FixedEffectPredictors — Names of columns in fixed-effects design matrix

`{'x1', 'x2', \dots, 'xP'}` (default) | string array or cell array of length p

Names of columns in the fixed-effects design matrix `X`, specified as the comma-separated pair consisting of `'FixedEffectPredictors'` and a string array or cell array of length p .

For example, if you have a constant term and two predictors, say `TimeSpent` and `Gender`, where `Female` is the reference level for `Gender`, as the fixed effects, then you can specify the names of your fixed effects in the following way. `Gender_Male` represents the dummy variable you must create for category `Male`. You can choose different names for these variables.

Example: `'FixedEffectPredictors', {'Intercept', 'TimeSpent', 'Gender_Male'}`,

Data Types: `string` | `cell`

RandomEffectPredictors — Names of columns in random-effects design matrix or cell array

string array or cell array of length q | cell array of length R with elements of length $q(r)$, $r = 1, 2, \dots, R$

Names of columns in the random-effects design matrix or cell array `Z`, specified as the comma-separated pair consisting of `'RandomEffectPredictors'` and either of the following:

- A string array or cell array of length q when `Z` is an n -by- q design matrix. In this case, the default is `{'z1', 'z2', ..., 'zQ'}`.
- A cell array of length R , when `Z` is a cell array of length R with each element `Z{r}` of length $q(r)$, $r = 1, 2, \dots, R$. In this case, the default is `{'z11', 'z12', ..., 'z1Q(1)'}, ..., {'zr1', 'zr2', ..., 'zrQ(r)'}`.

For example, suppose you have correlated random effects for intercept and a variable named `Acceleration`. Then, you can specify the random-effects predictor names as follows.

Example: `'RandomEffectPredictors', {'Intercept', 'Acceleration'}`

If you have two random effects terms, one for the intercept and the variable `Acceleration` grouped by variable `g1`, and the second for the intercept, grouped by the variable `g2`, then you specify the random-effects predictor names as follows.

Example: `'RandomEffectPredictors', {'Intercept', 'Acceleration'}, {'Intercept'}`

Data Types: `string` | `cell`

ResponseVarName — Name of response variable

`'y'` (default) | character vector | string scalar

Name of response variable, specified as the comma-separated pair consisting of `'ResponseVarName'` and a character vector or string scalar.

For example, if your response variable name is `score`, then you can specify it as follows.

Example: `'ResponseVarName', 'score'`

Data Types: `char` | `string`

RandomEffectGroups — Names of random effects grouping variables

`'g'` or `{'g1', 'g2', ..., 'gR'}` (default) | character vector | string scalar | string array | cell array of character vectors

Names of random effects grouping variables, specified as the comma-separated pair `'RandomEffectGroups'` and either of the following:

- Character vector or string scalar — If there is only one random-effects term, that is, if G is a vector, then the value of 'RandomEffectGroups' is the name for the grouping variable G . The default is 'g'.
- String array or cell array of character vectors — If there are multiple random-effects terms, that is, if G is a cell array of length R , then the value of 'RandomEffectGroups' is a string array or cell array of length R , where each element is the name for the grouping variable $G\{r\}$. The default is {'g1', 'g2', ..., 'gR'}.

For example, if you have two random-effects terms, z_1 and z_2 , grouped by the grouping variables `sex` and `subject`, then you can specify the names of your grouping variables as follows.

Example: 'RandomEffectGroups', {'sex', 'subject'}

Data Types: char | string | cell

CovariancePattern — Pattern of covariance matrix

'FullCholesky' (default) | character vector | string scalar | square symmetric logical matrix | string array | cell array of character vectors or logical matrices

Pattern of the covariance matrix of the random effects, specified as the comma-separated pair consisting of 'CovariancePattern' and a character vector, a string scalar, a square symmetric logical matrix, a string array, or a cell array of character vectors or logical matrices.

If there are R random-effects terms, then the value of 'CovariancePattern' must be a string array or cell array of length R , where each element r of the array specifies the pattern of the covariance matrix of the random-effects vector associated with the r th random-effects term. The options for each element follow.

'FullCholesky'	Default. Full covariance matrix using the Cholesky parameterization. <code>fitlme</code> estimates all elements of the covariance matrix.
'Full'	Full covariance matrix, using the log-Cholesky parameterization. <code>fitlme</code> estimates all elements of the covariance matrix.

'Diagonal'

Diagonal covariance matrix. That is, off-diagonal elements of the covariance matrix are constrained to be 0.

$$\begin{pmatrix} \sigma_{b1}^2 & 0 & 0 \\ 0 & \sigma_{b2}^2 & 0 \\ 0 & 0 & \sigma_{b3}^2 \end{pmatrix}$$

'Isotropic'

Diagonal covariance matrix with equal variances. That is, off-diagonal elements of the covariance matrix are constrained to be 0, and the diagonal elements are constrained to be equal. For example, if there are three random-effects terms with an isotropic covariance structure, this covariance matrix looks like

$$\begin{pmatrix} \sigma_b^2 & 0 & 0 \\ 0 & \sigma_b^2 & 0 \\ 0 & 0 & \sigma_b^2 \end{pmatrix}$$

where σ_b^2 is the common variance of the random-effects terms.

`'CompSymm'`

Compound symmetry structure. That is, common variance along diagonals and equal correlation between all random effects. For example, if there are three random-effects terms with a covariance matrix having a compound symmetry structure, this covariance matrix looks like

$$\begin{pmatrix} \sigma_{b_1}^2 & \sigma_{b_1,b_2} & \sigma_{b_1,b_2} \\ \sigma_{b_1,b_2} & \sigma_{b_1}^2 & \sigma_{b_1,b_2} \\ \sigma_{b_1,b_2} & \sigma_{b_1,b_2} & \sigma_{b_1}^2 \end{pmatrix}$$

where $\sigma_{b_1}^2$ is the common variance of the random-effects terms and σ_{b_1,b_2} is the common covariance between any two random-effects term .

`PAT`

Square symmetric logical matrix. If `'CovariancePattern'` is defined by the matrix `PAT`, and if `PAT(a,b) = false`, then the `(a,b)` element of the corresponding covariance matrix is constrained to be 0.

Example: `'CovariancePattern', 'Diagonal'`

Example: `'CovariancePattern', {'Full', 'Diagonal'}`

Data Types: `char | string | logical | cell`

FitMethod — Method for estimating parameters

`'ML'` (default) | `'REML'`

Method for estimating parameters of the linear mixed-effects model, specified as the comma-separated pair consisting of `'FitMethod'` and either of the following.

`'ML'`

Default. Maximum likelihood estimation

`'REML'`

Restricted maximum likelihood estimation

Example: `'FitMethod', 'REML'`

Weights — Observation weights

vector of scalar values

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a vector of length n , where n is the number of observations.

Data Types: single | double

Exclude — Indices for rows to exclude

use all rows without NaNs (default) | vector of integer or logical values

Indices for rows to exclude from the linear mixed-effects model in the data, specified as the comma-separated pair consisting of 'Exclude' and a vector of integer or logical values.

For example, you can exclude the 13th and 67th rows from the fit as follows.

Example: 'Exclude', [13,67]

Data Types: single | double | logical

DummyVarCoding — Coding to use for dummy variables

'reference' (default) | 'effects' | 'full'

Coding to use for dummy variables created from the categorical variables, specified as the comma-separated pair consisting of 'DummyVarCoding' and one of the following.

Value	Description
'reference'	Default. Coefficient for first category set to 0.
'effects'	Coefficients sum to 0.
'full'	One dummy variable for each category.

Example: 'DummyVarCoding', 'effects'

Optimizer — Optimization algorithm

'quasinewton' (default) | 'fminunc'

Optimization algorithm, specified as the comma-separated pair consisting of 'Optimizer' and either of the following.

'quasinevton'	Default. Uses a trust region based quasi-Newton optimizer. Change the options of the algorithm using <code>statset('LinearMixedModel')</code> . If you don't specify the options, then <code>LinearMixedModel</code> uses the default options of <code>statset('LinearMixedModel')</code> .
'fminunc'	You must have Optimization Toolbox to specify this option. Change the options of the algorithm using <code>optimoptions('fminunc')</code> . If you don't specify the options, then <code>LinearMixedModel</code> uses the default options of <code>optimoptions('fminunc')</code> with 'Algorithm' set to 'quasi-newton'.

Example: 'Optimizer', 'fminunc'

OptimizerOptions — Options for optimization algorithm

structure returned by `statset` | object returned by `optimoptions`

Options for the optimization algorithm, specified as the comma-separated pair consisting of 'OptimizerOptions' and a structure returned by `statset('LinearMixedModel')` or an object returned by `optimoptions('fminunc')`.

- If 'Optimizer' is 'fminunc', then use `optimoptions('fminunc')` to change the options of the optimization algorithm. See `optimoptions` for the options 'fminunc' uses. If 'Optimizer' is 'fminunc' and you do not supply 'OptimizerOptions', then the default for `LinearMixedModel` is the default options created by `optimoptions('fminunc')` with 'Algorithm' set to 'quasi-newton'.
- If 'Optimizer' is 'quasinevton', then use `statset('LinearMixedModel')` to change the optimization parameters. If you don't change the optimization parameters, then `LinearMixedModel` uses the default options created by `statset('LinearMixedModel')`:

The 'quasinevton' optimizer uses the following fields in the structure created by `statset('LinearMixedModel')`.

ToIFun — Relative tolerance on gradient of objective function

1e-6 (default) | positive scalar value

Relative tolerance on the gradient of the objective function, specified as a positive scalar value.

ToIX — Absolute tolerance on step size

1e-12 (default) | positive scalar value

Absolute tolerance on the step size, specified as a positive scalar value.

MaxIter — Maximum number of iterations allowed

10000 (default) | positive scalar value

Maximum number of iterations allowed, specified as a positive scalar value.

Display — Level of display

'off' (default) | 'iter' | 'final'

Level of display, specified as one of 'off', 'iter', or 'final'.

StartMethod — Method to start iterative optimization

'default' (default) | 'random'

Method to start iterative optimization, specified as the comma-separated pair consisting of 'StartMethod' and either of the following.

Value	Description
'default'	An internally defined default value
'random'	A random initial value

Example: 'StartMethod', 'random'

Verbose — Indicator to display optimization process on screen

false (default) | true

Indicator to display the optimization process on screen, specified as the comma-separated pair consisting of 'Verbose' and either false or true. Default is false.

The setting for 'Verbose' overrides the field 'Display' in 'OptimizerOptions'.

Example: 'Verbose', true

CheckHessian — Indicator to check positive definiteness of Hessian`false (default) | true`

Indicator to check the positive definiteness of the Hessian of the objective function with respect to unconstrained parameters at convergence, specified as the comma-separated pair consisting of 'CheckHessian' and either `false` or `true`. Default is `false`.

Specify 'CheckHessian' as `true` to verify optimality of the solution or to determine if the model is overparameterized in the number of covariance parameters.

Example: 'CheckHessian',true

Output Arguments

lme — Linear mixed-effects model`LinearMixedModel` object

Linear mixed-effects model, returned as a `LinearMixedModel` object.

Examples

No Grouping Variable Specified

Load the sample data.

```
load carsmall
```

Fit a linear mixed-effects model, where MPG is the response, weight is the predictor variable, and the intercept varies by model year. First, define the design matrices. Then, fit the model using the specified design matrices.

```
y = MPG;
X = [ones(size(Weight)), Weight];
Z = ones(size(y));
lme = LinearMixedModel.fitmatrix(X,y,Z,Model_Year)
```

```
lme =
Linear mixed-effects model fit by ML
```

```
Model information:

Longitudinal Study with Covariate

Load the sample data.

```
load(fullfile(matlabroot, 'examples', 'stats', 'weight.mat'));
```

`weight` contains data from a longitudinal study, where 20 subjects are randomly assigned 4 exercise programs (A, B, C, D) and their weight loss is recorded over six two-week time periods. This is simulated data.

Define `Subject` and `Program` as categorical variables. Create the design matrices for a linear mixed-effects model, with the initial weight, type of program, week, and the

interaction between the week and type of program as the fixed effects. The intercept and coefficient of week vary by subject.

This model corresponds to

$$\begin{aligned}
 y_{im} = & \beta_0 + \beta_1 IW_i + \beta_2 \text{Week}_i + \beta_3 I[\text{PB}]_i + \beta_4 I[\text{PC}]_i + \beta_5 I[\text{PD}]_i \\
 & + \beta_6 (\text{Week}_i * I[\text{PB}]_i) + \beta_7 (\text{Week}_i * I[\text{PC}]_i) + \beta_8 (\text{Week}_i * I[\text{PD}]_i) \\
 & + b_{0m} + b_{1m} \text{Week}_{im} + \varepsilon_{im},
 \end{aligned}$$

where $i = 1, 2, \dots, 120$, and $m = 1, 2, \dots, 20$. β_j are the fixed-effects coefficients, $j = 0, 1, \dots, 8$, and b_{0m} and b_{1m} are random effects. IW stands for initial weight and $I[\cdot]$ is a dummy variable representing a type of program. For example, $I[\text{PB}]_i$ is the dummy variable representing program type B. The random effects and observation error have the following prior distributions:

$$b_{0m} \sim N(0, \sigma_0^2)$$

$$b_{1m} \sim N(0, \sigma_1^2)$$

$$\varepsilon_{im} \sim N(0, \sigma^2).$$

```

Subject = nominal(Subject);
Program = nominal(Program);
D = dummyvar(Program); % Create dummy variables for Program
X = [ones(120,1), InitialWeight, D(:,2:4), Week, ...
     D(:,2).*Week, D(:,3).*Week, D(:,4).*Week];
Z = [ones(120,1), Week];
G = Subject;

```

Since the model has an intercept, you only need the dummy variables for programs B, C, and D. This is also known as the 'reference' method of coding dummy variables.

Fit the model using `LinearMixedModel.fitmatrix` with the defined design matrices and grouping variables.

```

lme = LinearMixedModel.fitmatrix(X,y,Z,G,'FixedEffectPredictors',...
{'Intercept','InitWeight','PrgB','PrgC','PrgD','Week','Week_PrgB','Week_PrgC','Week_PrgD',
'RandomEffectPredictors',{{'Intercept','Week'}},'RandomEffectGroups',{'Subject'})

lme =
Linear mixed-effects model fit by ML

```

The p -values 0.0228 and 0.0115 indicate significant effects of the initial weights of the subjects and the time factor in the amount of weight lost. The weight loss of subjects that are in program B is significantly different relative to the weight loss of subjects that are in program A. The lower and upper limits of the covariance parameters for the random effects do not include zero, thus they seem significant. You can also test the significance of the random-effects using the `compare` method.

Random-Intercept Model

Load the sample data.

```
load flu
```

`flu` dataset array has a `Date` variable, and 10 variables for estimated influenza rates (in 9 different regions, estimated from Google® searches, plus a nationwide estimate from the CDC).

To fit a linear-mixed effects model, where the influenza rates are the responses, combine the nine columns corresponding to the regions into an array that has a single response variable, `FluRate`, and a nominal variable, `Region`, the nationwide estimate `WtdILLI`, that shows which region each estimate is from, and the grouping variable `Date`.

```
flu2 = stack(flu,2:10,'NewDataVarName','FluRate',...  
            'IndVarName','Region');  
flu2.Date = nominal(flu2.Date);
```

Define the design matrices for a random-intercept linear mixed-effects model, where the intercept varies by `Date`. The corresponding model is

$$y_{im} = \beta_0 + \beta_1 \text{WtdILI}_{im} + b_{0m} + \varepsilon_{im}, \quad i = 1, 2, \dots, 468, \quad m = 1, 2, \dots, 52,$$

where y_{im} is the observation i for level m of grouping variable Date, b_{0m} is the random effect for level m of the grouping variable Date, and ε_{im} is the observation error for observation i . The random effect has the prior distribution,

$$b_{0m} \sim N(0, \sigma_b^2),$$

and the error term has the distribution,

$$\varepsilon_{im} \sim N(0, \sigma^2).$$

```
y = flu2.FluRate;
X = [ones(468,1) flu2.WtdILI];
Z = [ones(468,1)];
G = flu2.Date;
```

Fit the linear mixed-effects model.

```
lme = LinearMixedModel.fitmatrix(X,y,Z,G, 'FixedEffectPredictors', {'Intercept', 'NationalRate'},
'RandomEffectPredictors', {'Intercept'}, 'RandomEffectGroups', {'Date'})
```

```
lme =
Linear mixed-effects model fit by ML
```

Model information:

Number of observations	468

Random effects covariance parameters (95% CIs):

Group: Date (52 Levels)

Name1	Name2	Type	Estimate	Lower
'Intercept'	'Intercept'	'std'	0.17146	0.13227

Upper
0.22226

Group: Error

Name	Estimate	Lower	Upper
'Res Std'	0.30201	0.28217	0.32324

The confidence limits of the standard deviation of the random-effects term σ_b do not include zero (0.13227, 0.22226), which indicates that the random-effects term is significant. You can also test the significance of the random-effects using `compare` method.

The estimated value of an observation is the sum of the fixed-effects values and value of the random effect at the grouping variable level corresponding to that observation. For example, the estimated flu rate for observation 28

$$\begin{aligned}\hat{y}_{28} &= \hat{\beta}_0 + \hat{\beta}_1 \text{WtdILI}_{28} + \hat{b}_{10/30/2005} \\ &= 0.1639 + 0.7236 * (1.343) + 0.3318 \\ &= 1.46749,\end{aligned}$$

where \hat{b} is the BLUP of the random effects for the intercept. You can compute this value in the following way.

```
beta = fixedEffects(lme);
[~,~,STATS] = randomEffects(lme); % compute the random effects statistics STATS
STATS.Level = nominal(STATS.Level1);
y_hat = beta(1) + beta(2)*flu2.WtdILI(28) + STATS.Estimate(STATS.Level=='10/30/2005')
y_hat = 1.4674
```

You can simply display the fitted value using the `fitted(lme)` method.

```
F = fitted(lme);
F(28)
```

```
ans = 1.4674
```

Randomized-Block Design

Load the sample data.

```
load(fullfile(matlabroot, 'examples', 'stats', 'shift.mat'));
```

The data set shows the deviations from the target quality characteristic measured from the products each of five operators manufacture over three different shifts, morning, evening, and night. This is a randomized block design, where the operators are the blocks. The experiment is designed to study the impact of the time of shift on the performance. The performance measure is the deviations of the quality characteristics from the target value. This is simulated data.

Define the design matrices for a linear mixed-effects model with a random intercept grouped by operator, and shift as the fixed effects. Use the 'effects' contrasts. 'effects' contrasts mean that the coefficients sum to zero. You need to create two contrast coded variables in the fixed-effects design matrix, X1 and X2, where

$$\text{Shift_Evening} = \begin{cases} 0, & \text{if Morning} \\ 1, & \text{if Evening} \\ -1, & \text{if Night} \end{cases}$$

$$\text{Shift_Morning} = \begin{cases} 1, & \text{if Morning} \\ 0, & \text{if Evening} \\ -1, & \text{if Night} \end{cases}$$

The model corresponds to

$$\text{Morning Shift: } \text{QCDev}_{im} = \beta_0 + \beta_2 \text{Shift_Morning}_i + b_{0m} + \epsilon_{im},$$

$$\text{Evening Shift: } \text{QCDev}_{im} = \beta_0 + \beta_1 \text{Shift_Evening}_i + b_{0m} + \epsilon_{im},$$

$$\text{Night Shift: } \text{QCDev}_{im} = \beta_0 - \beta_1 \text{Shift_Evening}_i - \beta_2 \text{Shift_Morning}_i + b_{0m} + \epsilon_{im}.$$

where i represents the observations, and m represents the operators, $i = 1, 2, \dots, 15$, and $m = 1, 2, \dots, 5$. The random effects and the observation error have the following distributions:

$$b_{0m} \sim N(0, \sigma_b^2)$$

and

$$\varepsilon_{im} \sim N(0, \sigma^2).$$

```
S = shift.Shift;
X1 = (S=='Morning') - (S=='Night');
X2 = (S=='Evening') - (S=='Night');
X = [ones(15,1), X1, X2];
y = shift.QCDev;
Z = ones(15,1);
G = shift.Operator;
```

Fit a linear mixed-effects model using the specified design matrices and restricted maximum likelihood method.

```
lme = LinearMixedModel.fitmatrix(X,y,Z,G, 'FitMethod', 'REML', 'FixedEffectPredictors', ...
{'Intercept', 'S_Morning', 'S_Evening'}, 'RandomEffectPredictors', {'Intercept'}, ...
'RandomEffectGroups', {'Operator'}, 'DummyVarCoding', 'effects')
```

```
lme =
Linear mixed-effects model fit by REML
```

The estimated deviation from the target quality characteristics for the third operator working in the evening shift is

$$\begin{aligned}\hat{y}_{\text{Evening, Operator3}} &= \hat{\beta}_0 + \hat{\beta}_1 \text{Shift_Evening} + \hat{b}_{03} \\ &= 3.6525 - 0.53293 - 2.1715 \\ &= 0.94807.\end{aligned}$$

You can also display this value in the following way.

```
F = fitted(lme);
F(shift.Shift=='Evening' & shift.Operator=='3')

ans = 0.9481
```

Correlated and Uncorrelated Random-Effects Terms

Load the sample data.

```
load carbig
```

Fit a linear mixed-effects model for miles per gallon (MPG), with fixed effects for acceleration, horsepower and the cylinders, and uncorrelated random-effect for intercept and acceleration grouped by the model year. This model corresponds to

$$\text{MPG}_{im} = \beta_0 + \beta_1 \text{Acc}_i + \beta_2 \text{HP} + b_{0m} + b_{1m} \text{Acc}_{im} + \varepsilon_{im}, \quad m = 1, 2, 3,$$

with the random-effects terms having the following prior distributions:

$$b_{0m} \sim N(0, \sigma_0^2),$$

$$b_{1m} \sim N(0, \sigma_1^2),$$

where m represents the model year.

First, prepare the design matrices for fitting the linear mixed-effects model.

```
X = [ones(406,1) Acceleration Horsepower];
Z = {ones(406,1), Acceleration};
G = {Model_Year, Model_Year};
Model_Year = nominal(Model_Year);
```

Now, fit the model using `LinearMixedModel.fitmatrix` with the defined design matrices and grouping variables.

```
lme = LinearMixedModel.fitmatrix(X, MPG, Z, G, 'FixedEffectPredictors', ...
{'Intercept', 'Acceleration', 'Horsepower'}, 'RandomEffectPredictors', ...
{'Intercept'}, {'Acceleration'}}, 'RandomEffectGroups', {'Model_Year', 'Model_Year'})

lme =
Linear mixed-effects model fit by ML
```

Model information:

The confidence intervals for the standard deviations and the correlation between the random effects for intercept and acceleration do not include zeros, hence they seem significant. You can compare these two models using the `compare` method.

Specify the Covariance Pattern

Load the sample data.

```
load(fullfile(matlabroot, 'examples', 'stats', 'weight.mat'));
```

`weight` contains data from a longitudinal study, where 20 subjects are randomly assigned 4 exercise programs, and their weight loss is recorded over six two-week time periods. This is simulated data.

Define `Subject` and `Program` as categorical variables.

```
Subject = nominal(Subject);
Program = nominal(Program);
```

Create the design matrices for a linear mixed-effects model, with the initial weight, type of program, and week are the fixed effects.

```
D = dummyvar(Program);
X = [ones(120,1), InitialWeight, D(:,2:4), Week];
Z = [ones(120,1) Week];
G = Subject;
```

This model corresponds to

$$y_{im} = \beta_0 + \beta_1 IW_i + \beta_2 \text{Week}_i + \beta_3 I[\text{PB}]_i + \beta_4 I[\text{PC}]_i + \beta_5 I[\text{PD}]_i \\ + b_{0m} + b_{1m} \text{Week}_{2im} + b_{2m} \text{Week}_{4im} + b_{3m} \text{Week}_{6im} + b_{4m} \text{Week}_{8im} \\ + b_{5m} \text{Week}_{10im} + b_{6m} \text{Week}_{12im} + \varepsilon_{im},$$

where $i = 1, 2, \dots, 120$, and $m = 1, 2, \dots, 20$.

β_j are the fixed-effects coefficients, $j = 0, 1, \dots, 8$, and b_{0m} and b_{1m} are random effects. IW stands for initial weight and $I[.]$ is a dummy variable representing a type of program. For example, $I[\text{PB}]_i$ is the dummy variable representing program type B. The random effects and observation error have the following prior distributions:

$$b_{0m} \sim N(0, \sigma_0^2)$$

$$b_{1m} \sim N(0, \sigma_1^2)$$

$$\varepsilon_{im} \sim N(0, \sigma^2).$$

Fit the model using `LinearMixedModel.fitmatrix` with the defined design matrices and grouping variables. Assume the repeated observations collected on a subject have common variance along diagonals.

```
lme = LinearMixedModel.fitmatrix(X,y,Z,G,'FixedEffectPredictors',...
{'Intercept','InitWeight','PrgB','PrgC','PrgD','Week'},...
'RandomEffectPredictors',{{'Intercept','Week'}},...
'RandomEffectGroups',{'Subject'},'CovariancePattern','Isotropic')

lme =

Definitions

Cholesky Parameterization

One of the assumptions of linear mixed-effects models is that the random effects have the following prior distribution.

$$b \sim N(0, \sigma^2 D(\theta)),$$

where D is a q -by- q symmetric and positive semidefinite matrix, parameterized by a variance component vector θ , q is the number of variables in the random-effects term, and σ^2 is the observation error variance. Since the covariance matrix of the random effects, D , is symmetric, it has $q(q+1)/2$ free parameters. Suppose L is the lower triangular Cholesky factor of $D(\theta)$ such that

$$D(\theta) = L(\theta)L(\theta)^T,$$

then the $q^*(q+1)/2$ -by-1 unconstrained parameter vector θ is formed from elements in the lower triangular part of L .

For example, if

$$L = \begin{bmatrix} L_{11} & 0 & 0 \\ L_{21} & L_{22} & 0 \\ L_{31} & L_{32} & L_{33} \end{bmatrix},$$

then

$$\theta = \begin{bmatrix} L_{11} \\ L_{21} \\ L_{31} \\ L_{22} \\ L_{32} \\ L_{33} \end{bmatrix}.$$

Log-Cholesky Parameterization

When the diagonal elements of L in Cholesky parameterization are constrained to be positive, then the solution for L is unique. Log-Cholesky parameterization is the same as Cholesky parameterization except that the logarithm of the diagonal elements of L are used to guarantee unique parameterization.

For example, for the 3-by-3 example in Cholesky parameterization, enforcing $L_{ii} \geq 0$,

$$\theta = \begin{bmatrix} \log(L_{11}) \\ L_{21} \\ L_{31} \\ \log(L_{22}) \\ L_{32} \\ \log(L_{33}) \end{bmatrix}.$$

Tips

- If your model is not easily described using a formula, you can create matrices to define the fixed and random effects, and fit the model using `fitlmematrix`.

Alternatives

You can also fit a linear mixed-effects model using `fitlme(tbl, formula)`, where `tbl` is a table or dataset array containing the response y , the predictor variables X , and the grouping variables, and `formula` is of the form `'y ~ fixed + (random1|g1) + ... + (randomR|gR)'`.

If your model is not easily described using a formula, you can create matrices to define the fixed and random effects, and fit the model using `fitlmematrix(X,y,Z,G)`.

fitPosterior

Fit posterior probabilities for support vector machine (SVM) classifier

Syntax

```
ScoreSVMModel = fitPosterior(SVMModel)
[ScoreSVMModel,ScoreTransform] = fitPosterior(SVMModel)
[ScoreSVMModel,ScoreTransform] = fitPosterior(SVMModel,Name,Value)
```

Description

`ScoreSVMModel = fitPosterior(SVMModel)` returns a trained support vector machine (SVM) classifier `ScoreSVMModel` containing the optimal score-to-posterior-probability transformation function for two-class learning. For more details, see “Algorithms” on page 32-2543.

`[ScoreSVMModel,ScoreTransform] = fitPosterior(SVMModel)` additionally returns the optimal score-to-posterior-probability transformation function parameters.

`[ScoreSVMModel,ScoreTransform] = fitPosterior(SVMModel,Name,Value)` uses additional options specified by one or more name-value pair arguments. For example, you can specify the number of folds or the holdout sample proportion.

Examples

Estimate In-Sample Posterior Probabilities of SVM Classifiers

Load the ionosphere data set.

```
load ionosphere
```

Train an SVM classifier. Standardize the data and specify that 'g' is the positive class.

```
SVMModel = fitcsvm(X,Y,'ClassNames',{'b','g'},'Standardize',true);
```

SVMModel is a ClassificationSVM classifier.

Fit the optimal score-to-posterior-probability transformation function.

```
rng(1); % For reproducibility
ScoreSVMModel = fitPosterior(SVMModel)

ScoreSVMModel =
  ClassificationSVM
      ResponseName: 'Y'
  CategoricalPredictors: []
      ClassNames: {'b' 'g'}
  ScoreTransform: '@(S) sigmoid(S, -9.481802e-01, -1.218745e-01) '
  NumObservations: 351
      Alpha: [90x1 double]
      Bias: -0.1343
  KernelParameters: [1x1 struct]
      Mu: [1x34 double]
      Sigma: [1x34 double]
  BoxConstraints: [351x1 double]
  ConvergenceInfo: [1x1 struct]
  IsSupportVector: [351x1 logical]
      Solver: 'SMO'
```

Properties, Methods

Because the classes are inseparable, the score transformation function (ScoreSVMModel.ScoreTransform) is the sigmoid function.

Estimate scores and positive class posterior probabilities for the training data. Display the results for the first 10 observations.

```
[label,scores] = resubPredict(SVMModel);
[~,postProbs] = resubPredict(ScoreSVMModel);
table(Y(1:10),label(1:10),scores(1:10,2),postProbs(1:10,2),'VariableNames',...
      {'TrueLabel','PredictedLabel','Score','PosteriorProbability'})
```

```
ans=10x4 table
  TrueLabel PredictedLabel Score PosteriorProbability
  _____ _____
```

TrueLabel	PredictedLabel	Score	PosteriorProbability
'g'	'g'	1.4861	0.82215
'b'	'b'	-1.0004	0.30436

'g'	'g'	1.8685	0.86916

Plot Posterior Probability Contours for Multiple Classes

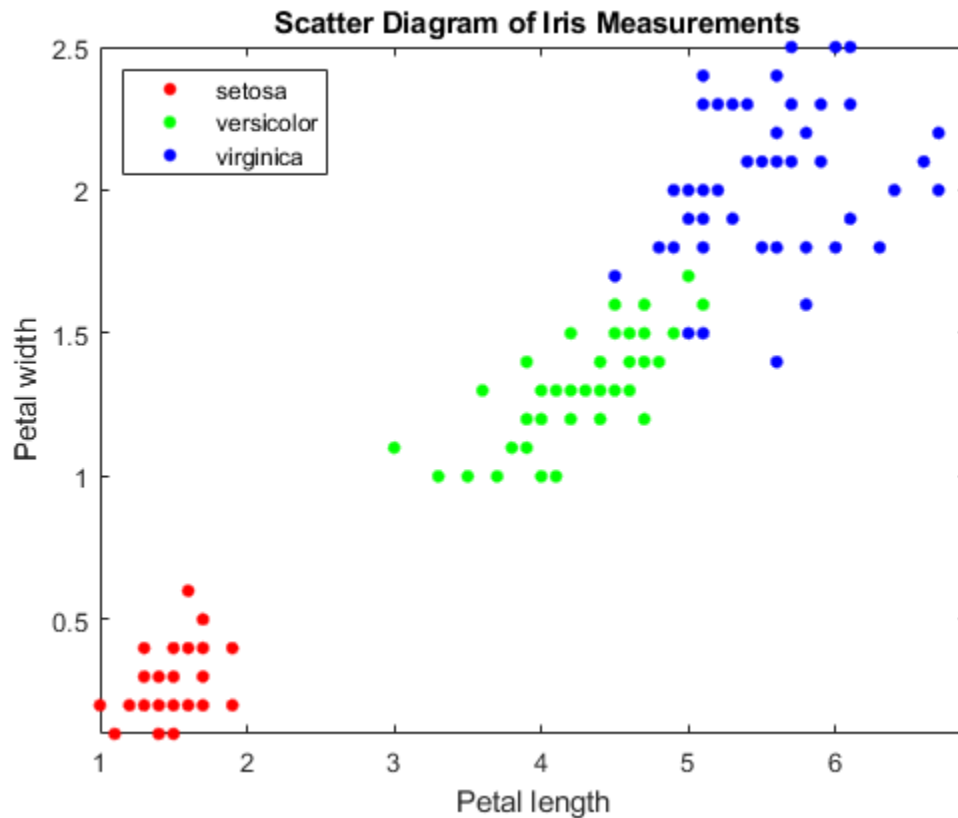

Train a multiclass SVM classifier through the process of one-versus-all (OVA) classification, and then plot probability contours for each class. To implement OVA directly, see `fitcecoc`.

Load Fisher's iris data set. Use the petal lengths and widths as the predictor data.

```
load fisheriris
X = meas(:,3:4);
Y = species;
```

Examine a scatter plot of the data.

```
figure
gscatter(X(:,1),X(:,2),Y);
title('\bf Scatter Diagram of Iris Measurements');
xlabel('Petal length');
ylabel('Petal width');
legend('Location','Northwest');
axis tight
```

Train three binary SVM classifiers that separate each type of iris from the others. Assume that a radial basis function is an appropriate kernel for each, and allow the algorithm to choose a kernel scale. Define the class order.

```

classNames = {'setosa'; 'virginica'; 'versicolor'};
numClasses = size(classNames,1);
inds = cell(3,1); % Preallocation
SVMModel = cell(3,1);

rng(1); % For reproducibility
for j = 1:numClasses
    inds{j} = strcmp(Y,classNames{j}); % OVA classification
    SVMModel{j} = fitcsvm(X,inds{j},'ClassNames',[false true],...

```

```
        'Standardize',true,'KernelFunction','rbf','KernelScale','auto');  
end
```

fitcsvm uses a heuristic procedure that involves subsampling to compute the value of the kernel scale.

Fit the optimal score-to-posterior-probability transformation function for each classifier.

```
for j = 1:numClasses  
    SVMModel{j} = fitPosterior(SVMModel{j});  
end
```

Warning: Classes are perfectly separated. The optimal score-to-posterior transformation

Define a grid to plot the posterior probability contours. Estimate the posterior probabilities over the grid for each classifier.

```
d = 0.02;  
[x1Grid,x2Grid] = meshgrid(min(X(:,1)):d:max(X(:,1)),...  
    min(X(:,2)):d:max(X(:,2)));  
xGrid = [x1Grid(:),x2Grid(:)];
```

```
posterior = cell(3,1);  
for j = 1:numClasses  
    [~,posterior{j}] = predict(SVMModel{j},xGrid);  
end
```

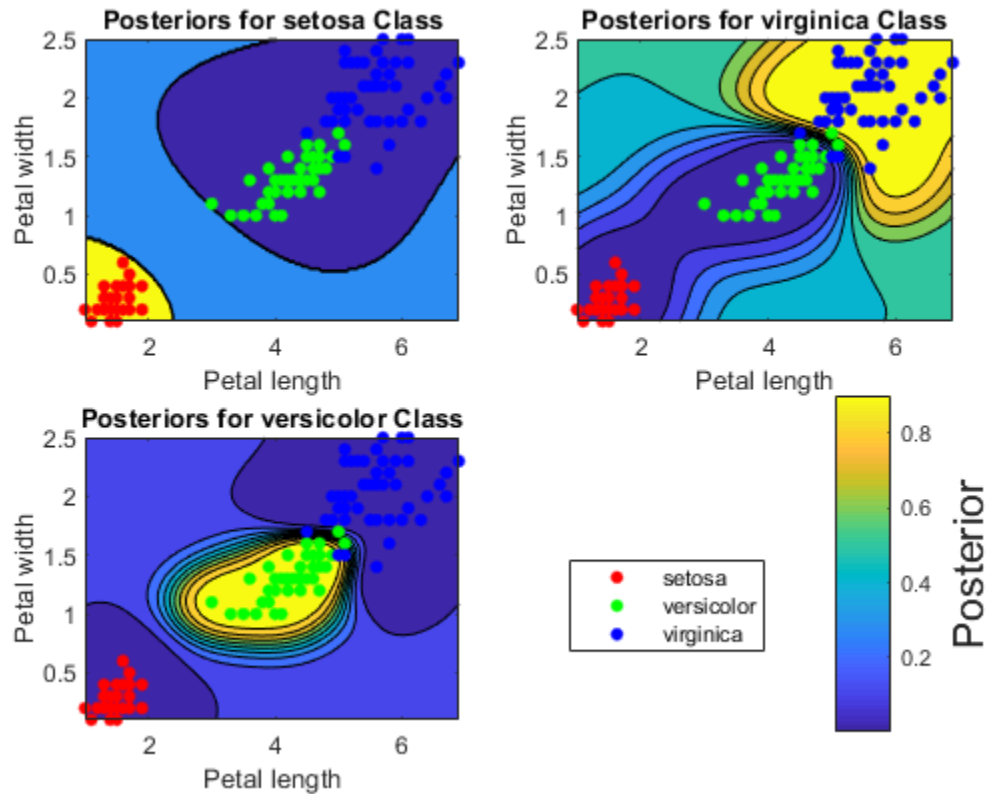

For each SVM classifier, plot the posterior probability contour under the scatter plot of the data.

```
figure  
h = zeros(numClasses + 1,1); % Preallocation for graphics handles  
for j = 1:numClasses  
    subplot(2,2,j)  
    contourf(x1Grid,x2Grid,reshape(posterior{j}(:,2),size(x1Grid,1),size(x1Grid,2)));  
    hold on  
    h(1:numClasses) = gscatter(X(:,1),X(:,2),Y);  
    title(sprintf('Posteriors for %s Class',classNames{j}));  
    xlabel('Petal length');  
    ylabel('Petal width');  
    legend off  
    axis tight  
    hold off  
end  
h(numClasses + 1) = colorbar('Location','EastOutside',...
```

```

'Position', [[0.8,0.1,0.05,0.4]]);
set(get(h(numClasses + 1), 'YLabel'), 'String', 'Posterior', 'FontSize', 16);
legend(h(1:numClasses), 'Location', [0.6,0.2,0.1,0.1]);

```

Fit Optimal Posterior Probability Function Using Holdout Cross-Validation

Estimate the score-to-posterior-probability transformation function after training an SVM classifier. Use cross-validation during the estimation to reduce bias, and compare the run times for 10-fold cross-validation and holdout cross-validation.

Load the ionosphere data set.

```
load ionosphere
```

Train an SVM classifier. Standardize the data and specify that 'g' is the positive class.

```
SVMMoDel = fitcsvm(X,Y,'ClassNames',{ 'b','g'},'Standardize',true);
```

SVMMoDel is a ClassificationSVM classifier.

Fit the optimal score-to-posterior-probability transformation function. Compare the run times from using 10-fold cross-validation (the default) and a 10% holdout test sample.

```
rng(1); % For reproducibility
tic;    % Start the stopwatch
SVMMoDel_10FCV = fitPosterior(SVMMoDel);
toc     % Stop the stopwatch and display the run time
```

```
Elapsed time is 0.820551 seconds.
```

```
tic;
SVMMoDel_H0 = fitPosterior(SVMMoDel,'Holdout',0.10);
toc
```

```
Elapsed time is 0.215839 seconds.
```

Although both run times are short because the data set is relatively small, SVMMoDel_H0 fits the score transformation function much faster than SVMMoDel_10FCV. You can specify holdout cross-validation (instead of the default 10-fold cross validation) to reduce run time for larger data sets.

Input Arguments

SVMMoDel — Full, trained SVM classifier

ClassificationSVM classifier

Full, trained SVM classifier, specified as a ClassificationSVM model trained with fitcsvm.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes.

You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `fitPosterior(SVMModel, 'KFold', 5)` uses five folds in a cross-validated model.

CVPartition — Cross-validation partition

`[]` (default) | `cvpartition` partition

Cross-validation partition used to compute the transformation function, specified as the comma-separated pair consisting of 'CVPartition' and a `cvpartition` partition object as created by `cvpartition`. You can use only one of these four options at a time for creating a cross-validated model: 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'.

The `crossval` name-value pair argument of `fitcsvm` splits the data into subsets using `cvpartition`.

Example: Suppose you create a random partition for 5-fold cross-validation on 500 observations by using `cvp = cvpartition(500, 'KFold', 5)`. Then, you can specify the cross-validated model by using 'CVPartition', `cvp`.

Holdout — Fraction of data for holdout validation

scalar value in the range (0,1)

Fraction of the data for holdout validation used to compute the transformation function, specified as the comma-separated pair consisting of 'Holdout' and a scalar value in the range (0,1). Holdout validation tests the specified fraction of the data and uses the remaining data for training.

You can use only one of these four options at a time for creating a cross-validated model: 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'.

Example: 'Holdout', 0.1

Data Types: `double` | `single`

KFold — Number of folds

10 (default) | positive integer value greater than 1

Number of folds to use when computing the transformation function, specified as the comma-separated pair consisting of 'KFold' and a positive integer value greater than 1.

You can use only one of these four options at a time for creating a cross-validated model: 'Kfold', 'holdout', 'leaveout', or 'cvpartition'.

Example: 'Kfold',8

Data Types: single | double

leaveout — Leave-one-out cross-validation flag

'off' (default) | 'on'

Leave-one-out cross-validation flag indicating whether to use leave-one-out cross-validation to compute the transformation function, specified as the comma-separated pair consisting of 'leaveout' and 'on' or 'off'. Use leave-one-out cross-validation by specifying 'leaveout', 'on'.

You can use only one of these four options at a time for creating a cross-validated model: 'Kfold', 'holdout', 'leaveout', or 'cvpartition'.

Example: 'leaveout', 'on'

Output Arguments

ScoreSVMModel — Trained SVM classifier

ClassificationSVM classifier

Trained SVM classifier, returned as a ClassificationSVM classifier. The trained classifier contains the estimated score-to-posterior-probability transformation function.

To estimate posterior probabilities for the training set observations, pass ScoreSVMModel to resubPredict.

To estimate posterior probabilities for new observations, pass the new observations and ScoreSVMModel to predict.

ScoreTransform — Optimal score-to-posterior-probability transformation function parameters

structure array

Optimal score-to-posterior-probability transformation function parameters, returned as a structure array.

- If the value of the `Type` field of `ScoreTransform` is `sigmoid`, then `ScoreTransform` also has these fields:
 - `Slope`: The value of A in the sigmoid function on page 32-2553
 - `Intercept`: The value of B in the sigmoid function
- If the value of the `Type` field of `ScoreTransform` is `step`, then `ScoreTransform` also has these fields:
 - `PositiveClassProbability`: The value of π in the step function on page 32-2553. This value represents the probability that an observation is in the positive class or the posterior probability that an observation is in the positive class given that its score is in the interval (`LowerBound`,`UpperBound`).
 - `LowerBound`: The value $\max_{y_n = -1} s_n$ in the step function. This value represents the lower bound of the score interval that assigns observations with scores in the interval the posterior probability of being in the positive class `PositiveClassProbability`. Any observation with a score less than `LowerBound` has the posterior probability of being in the positive class equal to 0.
 - `UpperBound`: The value $\min_{y_n = +1} s_n$ in the step function. This value represents the upper bound of the score interval that assigns observations with scores in the interval the posterior probability of being in the positive class `PositiveClassProbability`. Any observation with a score greater than `UpperBound` has the posterior probability of being in the positive class equal to 1.
- If the value of the `Type` field of `ScoreTransform` is `constant`, then `ScoreTransform.PredictedClass` contains the name of the class prediction.

This result is the same as `SVMModel.ClassNames`. The posterior probability of an observation being in `ScoreTransform.PredictedClass` is always 1.

Definitions

Sigmoid Function

The sigmoid function that maps score s_j corresponding to observation j to the positive class posterior probability is

$$P(s_j) = \frac{1}{1 + \exp(As_j + B)}.$$

If the value of the `Type` field of `ScoreTransform` is `sigmoid`, then parameters `A` and `B` correspond to the fields `Scale` and `Intercept` of `ScoreTransform`, respectively.

Step Function

The step function that maps score s_j corresponding to observation j to the positive class posterior probability is

$$P(s_j) = \begin{cases} 0; & s < \max_{y_k = -1} s_k \\ \pi; & \max_{y_k = -1} s_k \leq s_j \leq \min_{y_k = +1} s_k, \\ 1; & s_j > \min_{y_k = +1} s_k \end{cases}$$

where:

- s_j is the score of observation j .
- $+1$ and -1 denote the positive and negative classes, respectively.
- π is the prior probability that an observation is in the positive class.

If the value of the `Type` field of `ScoreTransform` is `step`, then the quantities $\max_{y_k = -1} s_k$ and $\min_{y_k = +1} s_k$ correspond to the fields `LowerBound` and `UpperBound` of `ScoreTransform`, respectively.

Constant Function

The constant function maps all scores in a sample to posterior probabilities 1 or 0.

If all observations have posterior probability 1, then they are expected to come from the positive class.

If all observations have posterior probability 0, then they are not expected to come from the positive class.

Tips

- This process describes one way to predict positive class posterior probabilities.
 - 1 Train an SVM classifier by passing the data to `fitcsvm`. The result is a trained SVM classifier, such as `SVMMODEL`, that stores the data. The software sets the score transformation function property (`SVMMODEL.ScoreTransformation`) to `none`.
 - 2 Pass the trained SVM classifier `SVMMODEL` to `fitSVMPosterior` or `fitPosterior`. The result, such as `ScoreSVMMODEL`, is the same trained SVM classifier as `SVMMODEL`, except the software sets `ScoreSVMMODEL.ScoreTransformation` to the optimal score transformation function.
 - 3 Pass the predictor data matrix and the trained SVM classifier containing the optimal score transformation function (`ScoreSVMMODEL`) to `predict`. The second column in the second output argument of `predict` stores the positive class posterior probabilities corresponding to each row of the predictor data matrix.

If you skip step 2, then `predict` returns the positive class score rather than the positive class posterior probability.

- After fitting posterior probabilities, you can generate C/C++ code that predicts labels for new data. Generating C/C++ code requires MATLAB Coder. For details, see “Introduction to Code Generation” on page 31-2.

Algorithms

The software fits the appropriate score-to-posterior-probability transformation function by using the SVM classifier `SVMMODEL` and by conducting 10-fold cross-validation using the stored predictor data (`SVMMODEL.X`) and the class labels (`SVMMODEL.Y`), as outlined in [1]. The transformation function computes the posterior probability that an observation is classified into the positive class (`SVMMODEL.Classnames(2)`).

- If the classes are inseparable, then the transformation function is the sigmoid function on page 32-2553.
- If the classes are perfectly separable, then the transformation function is the step function on page 32-2553.

- In two-class learning, if one of the two classes has a relative frequency of 0, then the transformation function is the constant function on page 32-2700. The `fitPosterior` function is not appropriate for one-class learning.
- The software stores the optimal score-to-posterior-probability transformation function in `ScoreSVMModel.ScoreTransform`.

If you re-estimate the score-to-posterior-probability transformation function, that is, if you pass an SVM classifier to `fitPosterior` or `fitSVMPosterior` and its `ScoreTransform` property is not none, then the software:

- Displays a warning
- Resets the original transformation function to 'none' before estimating the new one

Alternative Functionality

You can also fit the posterior probability function by using `fitSVMPosterior`. This function is similar to `fitPosterior`, except it is more broad because it accepts a wider range of SVM classifier types.

`ClassificationSVM` | `fitSVMPosterior` | `fitcsvm` | `predict`

Introduced in R2014a

fitPosterior

Package: classreg.learning.classif

Fit posterior probabilities for compact support vector machine (SVM) classifier

Syntax

```
ScoreSVMModel = fitPosterior(SVMModel,TBL,Y)
ScoreSVMModel = fitPosterior(SVMModel,X,Y)
[ScoreSVMModel,ScoreTransform] = fitPosterior( ___ )
```

Description

`ScoreSVMModel = fitPosterior(SVMModel,TBL,Y)` returns a trained support vector machine (SVM) classifier `ScoreSVMModel` containing the optimal score-to-posterior-probability transformation function for two-class learning. For more details, see “Algorithms” on page 32-2555. If you train `SVMModel` using a table, then you must use a table as input for `fitPosterior`.

`ScoreSVMModel = fitPosterior(SVMModel,X,Y)` returns a trained SVM classifier `ScoreSVMModel` containing the optimal score-to-posterior-probability transformation function for two-class learning. If you train `SVMModel` using a matrix, then you must use a matrix as input for `fitPosterior`.

`[ScoreSVMModel,ScoreTransform] = fitPosterior(___)` additionally returns the optimal score-to-posterior-probability transformation function parameters (`ScoreTransform`) for any of the input argument combinations in the previous syntaxes.

Examples

Estimate Posterior Probabilities for Data with Inseparable Classes

Load the `ionosphere` data set. Reserve 20 random observations of the data, and consider this set new data.

```
load ionosphere
n = size(X,1);
rng(1); % For reproducibility

indx = ~ismember([1:n],randsample(n,20)); % Indices for the training data
```

The classes of this data set are inseparable.

Train an SVM classifier using the training data. Standardize the data and specify that 'g' is the positive class.

```
SVMMModel = fitcsvm(X(indx,:),Y(indx),'ClassNames',{'b','g'},...
    'Standardize',true);
```

SVMMModel is a ClassificationSVM classifier.

Use the new data set to estimate the optimal score-to-posterior-probability transformation function for mapping scores to the posterior probability of an observation being classified as g. For efficiency, make a compact version of SVMMModel, and pass it and the new data to fitPosterior.

```
CompactSVMMModel = compact(SVMMModel);
[ScoreCSVMMModel,ScoreParameters] = fitPosterior(CompactSVMMModel,...
    X(~indx,:),Y(~indx));
```

```
ScoreTransform = ScoreCSVMMModel.ScoreTransform
```

```
ScoreTransform =
'@(S)sigmoid(S,-1.098922e+00,4.519963e-01)'
```

```
ScoreParameters
```

```
ScoreParameters = struct with fields:
    Type: 'sigmoid'
    Slope: -1.0989
    Intercept: 0.4520
```

ScoreTransform is the optimal score transformation function. ScoreParameters is a structure array with three fields: the score transformation function name (Type), the sigmoid slope (Slope), and the sigmoid intercept estimates (Intercept).

Alternatively, you can pass SVMMModel and the new data to fitSVMPosterior, but this process is not as efficient.

Estimate the posterior probabilities that the observations in the new data are in class g.

```
[labels,postProbs] = predict(ScoreCSVMModel,X(~indx,:));
table(Y(~indx),labels,postProbs(:,2),...
      'VariableNames',{'TrueLabel','PredictedLabel','PosteriorProbability'})
```

```
ans=20x3 table
      TrueLabel      PredictedLabel      PosteriorProbability
      _____      _____      _____
      'g'           'g'           0.78437
      'b'           'b'           0.024588
      'g'           'g'           0.82399
      'b'           'b'           0.0061637
      'b'           'b'           3.6118e-06
      'b'           'b'           0.15688
      'b'           'g'           0.9622
      'b'           'b'           6.1348e-09
      'b'           'b'           0.0019646
      'g'           'g'           0.7251
      'g'           'g'           0.70263
      'b'           'b'           0.075298
      'g'           'g'           0.90691
      'g'           'g'           0.82849
      'b'           'b'           0.051193
      'g'           'g'           0.95331
      :
```

Estimate Posterior Probabilities for Data with Separable Classes

Load Fisher's iris data set. Use the petal lengths and widths as the predictor data, and remove the virginica species from the data. Reserve 10 random observations of the data, and consider this set new data.

```
load fisheriris
classKeep = ~strcmp(species,'virginica');
X = meas(classKeep,3:4);
Y = species(classKeep);

rng(1); % For reproducibility
indx1 = 1:numel(species);
```

```
indx2 = indx1(classKeep);  
indx = ~ismember(indx2,randsample(indx2,10)); % Indices for the training data  
  
gscatter(X(indx,1),X(indx,2),Y(indx));  
title('Scatter Diagram of Iris Measurements')  
xlabel('Petal length')  
ylabel('Petal width')  
legend('Setosa','Versicolor')
```

The classes are perfectly separable. Therefore, the score-to-posterior-probability transformation function is a step function.

Train an SVM classifier. Standardize the data and specify that `versicolor` is the positive class.

```
SVMModel = fitcsvm(X(indx,:),Y(indx),...
    'ClassNames',{'setosa','versicolor'},'Standardize',true);
```

SVMModel is a ClassificationSVM classifier.

Use the new data set to estimate the optimal score-to-posterior-probability transformation function for mapping scores to the posterior probability of an observation being classified as versicolor. For efficiency, make a compact version SVMModel, and pass it and the new data to fitPosterior.

```
CompactSVMModel = compact(SVMModel);
[ScoreCSVMModel,ScoreParameters] = fitPosterior(CompactSVMModel,...
    X(~indx,:),Y(~indx));
```

Warning: Classes are perfectly separated. The optimal score-to-posterior transformation

```
ScoreTransform = ScoreCSVMModel.ScoreTransform
```

```
ScoreTransform =
 '@(S)step(S,-1.338450e+00,2.012495e+00,5.333333e-01)'
```

fitPosterior displays a warning whenever the classes are separable, and stores the step function in ScoreSVMModel.ScoreTransform.

Display the score function type and its estimated values.

```
ScoreParameters
```

```
ScoreParameters = struct with fields:
    Type: 'step'
    LowerBound: -1.3385
    UpperBound: 2.0125
    PositiveClassProbability: 0.5333
```

ScoreParameters is a structure array with four fields:

- Score transformation function type (Type)
- Score corresponding to the negative class boundary (LowerBound)
- Score corresponding to the positive class boundary (UpperBound)
- Positive class probability (PositiveClassProbability)

Alternatively, you can pass `SVMModel` and the new data to `fitSVMPosterior`, but this process is not as efficient.

Estimate the posterior probabilities that the observations in the new data are versicolor irises.

```
[labels,postProbs] = predict(ScoreCSVMModel,X(~indx,:));
table(Y(~indx),labels,postProbs(:,2),...
      'VariableNames',{'TrueLabel','PredictedLabel','PosteriorProbability'})
```

```
ans=10x3 table
      TrueLabel      PredictedLabel      PosteriorProbability
      _____      _____      _____
      'setosa'        'setosa'                0
      'setosa'        'setosa'                0
      'setosa'        'setosa'                0
      'setosa'        'setosa'                0
      'setosa'        'setosa'                0
      'setosa'        'setosa'                0
      'setosa'        'setosa'                0
      'setosa'        'setosa'                0
      'versicolor'    'versicolor'            1
      'versicolor'    'versicolor'            1
```

Because the classes are separable, the step function transforms the positive-class score to:

- 0 if the score is less than `ScoreParameters.LowerBound`
- 1 if the score is greater than `ScoreParameters.UpperBound`
- `ScoreParameters.PositiveClassProbability` if the score is in the interval `[ScoreParameters.LowerBound,ScoreParameters.LowerBound]`

Input Arguments

SVMModel — Trained, compact SVM classifier

CompactClassificationSVM classifier

Trained, compact SVM classifier, specified as a CompactClassificationSVM model returned by `compact`.

TBL — Sample data

table

Sample data, specified as a table. Each row of TBL corresponds to one observation, and each column corresponds to one predictor variable. TBL must contain all of the predictors used to train `SVMMODEL`. Optionally, TBL can contain an additional column for the response variable. Multicolumn variables and cell arrays other than cell arrays of character vectors are not allowed.

If TBL contains the response variable used to train `SVMMODEL`, then you do not need to specify Y. If TBL does not include the response variable, then the length of Y must be equal to the number of rows in TBL.

If the sample data used to train `SVMMODEL` is a table, then you must specify the input data for `fitPosterior` as a table.

If you set `'Standardize', true` in `fitcsvm` when training `SVMMODEL`, then the software fits the transformation function parameter estimates using standardized data.

Data Types: table

X — Predictor data

matrix

Predictor data used to estimate the score-to-posterior-probability transformation function, specified as a matrix.

Each row of X corresponds to one observation (also known as an instance or example), and each column corresponds to one variable (also known as a feature).

The length of Y and the number of rows in X must be equal.

If you set `'Standardize', true` in `fitcsvm` when training `SVMMODEL`, then the software fits the transformation function parameter estimates using standardized data.

Data Types: double | single

Y — Class labels

categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Class labels used to estimate the score-to-posterior-probability transformation function, specified as a categorical, character, or string array, a logical or numeric vector, or a cell array of character vectors.

If `Y` is a character array, then each element must correspond to one class label.

The length of `Y` and the number of rows in `X` must be equal.

Data Types: `categorical` | `char` | `string` | `logical` | `single` | `double` | `cell`

Output Arguments

ScoreSVMModel — Trained, compact SVM classifier

`CompactClassificationSVM` classifier

Trained, compact SVM classifier containing the estimated score-to-posterior-probability transformation function, returned as a `CompactClassificationSVM` classifier.

To estimate posterior probabilities for new observations, pass `ScoreSVMModel` and the new observations to `predict`.

ScoreTransform — Optimal score-to-posterior-probability transformation function parameters

structure array

Optimal score-to-posterior-probability transformation function parameters, returned as a structure array.

- If the value of the `Type` field of `ScoreTransform` is `sigmoid`, then `ScoreTransform` also has these fields:
 - **Slope:** The value of A in the sigmoid function on page 32-2553
 - **Intercept:** The value of B in the sigmoid function
- If the value of the `Type` field of `ScoreTransform` is `step`, then `ScoreTransform` also has these fields:
 - **PositiveClassProbability:** The value of π in the step function on page 32-2553. This value represents the probability that an observation is in the positive class or the posterior probability that an observation is in the positive class given that its score is in the interval (`LowerBound`,`UpperBound`).
 - **LowerBound:** The value $\max_{y_n = -1} s_n$ in the step function. This value represents the lower bound of the score interval that assigns observations with scores in the interval the posterior probability of being in the positive class

- PositiveClassProbability.** Any observation with a score less than `LowerBound` has the posterior probability of being in the positive class equal to `0`.
- **UpperBound:** The value $\min_{y_n = +1} s_n$ in the step function. This value represents the upper bound of the score interval that assigns observations with scores in the interval the posterior probability of being in the positive class **PositiveClassProbability**. Any observation with a score greater than `UpperBound` has the posterior probability of being in the positive class equal to `1`.
 - If the value of the `Type` field of `ScoreTransform` is constant, then `ScoreTransform.PredictedClass` contains the name of the class prediction.

This result is the same as `SVMModel.ClassNames`. The posterior probability of an observation being in `ScoreTransform.PredictedClass` is always `1`.

Definitions

Sigmoid Function

The sigmoid function that maps score s_j corresponding to observation j to the positive class posterior probability is

$$P(s_j) = \frac{1}{1 + \exp(As_j + B)}.$$

If the value of the `Type` field of `ScoreTransform` is `sigmoid`, then parameters A and B correspond to the fields `Scale` and `Intercept` of `ScoreTransform`, respectively.

Step Function

The step function that maps score s_j corresponding to observation j to the positive class posterior probability is

$$P(s_j) = \begin{cases} 0; & s < \max_{y_k = -1} s_k \\ \pi; & \max_{y_k = -1} s_k \leq s_j \leq \min_{y_k = +1} s_k \\ 1; & s_j > \min_{y_k = +1} s_k \end{cases},$$

where:

- s_j is the score of observation j .
- $+1$ and -1 denote the positive and negative classes, respectively.
- π is the prior probability that an observation is in the positive class.

If the value of the `Type` field of `ScoreTransform` is `step`, then the quantities $\max_{y_k = -1} s_k$ and $\min_{y_k = +1} s_k$ correspond to the fields `LowerBound` and `UpperBound` of `ScoreTransform`, respectively.

Constant Function

The constant function maps all scores in a sample to posterior probabilities 1 or 0.

If all observations have posterior probability 1, then they are expected to come from the positive class.

If all observations have posterior probability 0, then they are not expected to come from the positive class.

Tips

- This process describes one way to predict positive class posterior probabilities.
 - 1 Train an SVM classifier by passing the data to `fitcsvm`. The result is a trained SVM classifier, such as `SVMModel`, that stores the data. The software sets the score transformation function property (`SVMModel.ScoreTransformation`) to `none`.
 - 2 Pass the trained SVM classifier `SVMModel` to `fitSVMPosterior` or `fitPosterior`. The result, such as `ScoreSVMModel`, is the same trained SVM classifier as `SVMModel`, except the software sets `ScoreSVMModel.ScoreTransformation` to the optimal score transformation function.
 - 3 Pass the predictor data matrix and the trained SVM classifier containing the optimal score transformation function (`ScoreSVMModel`) to `predict`. The second column in the second output argument of `predict` stores the positive class posterior probabilities corresponding to each row of the predictor data matrix.

If you skip step 2, then `predict` returns the positive class score rather than the positive class posterior probability.

- After fitting posterior probabilities, you can generate C/C++ code that predicts labels for new data. Generating C/C++ code requires MATLAB Coder. For details, see “Introduction to Code Generation” on page 31-2.

Algorithms

The software fits the appropriate score-to-posterior-probability transformation function by using the SVM classifier `SVMMODEL` and by conducting 10-fold cross-validation using the stored predictor data (`SVMMODEL.X`) and the class labels (`SVMMODEL.Y`), as outlined in [1]. The transformation function computes the posterior probability that an observation is classified into the positive class (`SVMMODEL.Classnames(2)`).

- If the classes are inseparable, then the transformation function is the sigmoid function on page 32-2553.
- If the classes are perfectly separable, then the transformation function is the step function on page 32-2553.
- In two-class learning, if one of the two classes has a relative frequency of 0, then the transformation function is the constant function on page 32-2700. The `fitPosterior` function is not appropriate for one-class learning.
- The software stores the optimal score-to-posterior-probability transformation function in `ScoreSVMMODEL.ScoreTransform`.

If you re-estimate the score-to-posterior-probability transformation function, that is, if you pass an SVM classifier to `fitPosterior` or `fitSVMPosterior` and its `ScoreTransform` property is not `none`, then the software:

- Displays a warning
- Resets the original transformation function to 'none' before estimating the new one

Alternative Functionality

You can also fit the optimal score-to-posterior-probability function by using `fitSVMPosterior`. This function is similar to `fitPosterior`, except it is more broad because it accepts a wider range of SVM classifier types.

Introduced in R2014a

fitrensemble

Fit ensemble of learners for regression

Syntax

```
Mdl = fitrensemble(Tbl,ResponseVarName)
```

```
Mdl = fitrensemble(Tbl,formula)
```

```
Mdl = fitrensemble(Tbl,Y)
```

```
Mdl = fitrensemble(X,Y)
```

```
Mdl = fitrensemble( ____,Name,Value)
```

Description

`Mdl = fitrensemble(Tbl,ResponseVarName)` returns the trained regression ensemble model object (`Mdl`) that contains the results of boosting 100 regression trees using LSBoost and the predictor and response data in the table `Tbl`. `ResponseVarName` is the name of the response variable in `Tbl`.

`Mdl = fitrensemble(Tbl,formula)` applies `formula` to fit the model to the predictor and response data in the table `Tbl`. `formula` is an explanatory model of the response and a subset of predictor variables in `Tbl` used to fit `Mdl`. For example, `'Y~X1+X2+X3'` fits the response variable `Tbl.Y` as a function of the predictor variables `Tbl.X1`, `Tbl.X2`, and `Tbl.X3`.

`Mdl = fitrensemble(Tbl,Y)` treats all variables in the table `Tbl` as predictor variables. `Y` is the vector of responses that is not in `Tbl`.

`Mdl = fitrensemble(X,Y)` uses the predictor data in the matrix `X` and response data in the vector `Y`.

`Mdl = fitrensemble(____,Name,Value)` uses additional options specified by one or more `Name,Value` pair arguments and any of the input arguments in the previous syntaxes. For example, you can specify the number of learning cycles, the ensemble aggregation method, or to implement 10-fold cross-validation.

Examples

Train Regression Ensemble

Create a regression ensemble that predicts the fuel economy of a car given the number of cylinders, volume displaced by the cylinders, horsepower, and weight. Then, train another ensemble using fewer predictors. Compare the in-sample predictive accuracies of the ensembles.

Load the `carsmall` data set. Store the variables to be used in training in a table.

```
load carsmall
Tbl = table(Cylinders,Displacement,Horsepower,Weight,MPG);
```

Train a regression ensemble.

```
Mdl1 = fitensemble(Tbl,'MPG');
```

`Mdl1` is a `RegressionEnsemble` model. Some notable characteristics of `Mdl1` are:

- The ensemble aggregation algorithm is 'LSBoost'.
- Because the ensemble aggregation method is a boosting algorithm, regression trees that allow a maximum of 10 splits compose the ensemble.
- One hundred trees compose the ensemble.

Because `MPG` is a variable in the MATLAB® Workspace, you can obtain the same result by entering

```
Mdl1 = fitensemble(Tbl,MPG);
```

Use the trained regression ensemble to predict the fuel economy for a four-cylinder car with a 200-cubic inch displacement, 150 horsepower, and weighing 3000 lbs.

```
pMPG = predict(Mdl1,[4 200 150 3000])
```

```
pMPG = 25.6467
```

Train a new ensemble using all predictors in `Tbl` except `Displacement`.

```
formula = 'MPG ~ Cylinders + Horsepower + Weight';
Mdl2 = fitensemble(Tbl,formula);
```

Compare the resubstitution MSEs between Mdl1 and Mdl2.

```
mse1 = resubLoss(Mdl1)
mse1 = 0.3096
mse2 = resubLoss(Mdl2)
mse2 = 0.5861
```

The in-sample MSE for the ensemble that trains on all predictors is lower.

Speed Up Training by Binning Numeric Predictor Values

Train an ensemble of boosted regression trees by using `fitrensemble`. Reduce training time by specifying the `'NumBins'` name-value pair argument to bin numeric predictors. After training, you can reproduce binned predictor data by using the `BinEdges` property of the trained model and the `discretize` function.

Generate a sample data set.

```
rng('default') % For reproducibility
N = 1e6;
X1 = randi([-1,5],[N,1]);
X2 = randi([5,10],[N,1]);
X3 = randi([0,5],[N,1]);
X4 = randi([1,10],[N,1]);
X = [X1 X2 X3 X4];
y = X1 + X2 + X3 + X4 + normrnd(0,1,[N,1]);
```

Train an ensemble of boosted regression trees using least-squares boosting (LSBoost, the default value). Time the function for comparison purposes.

```
tic
Mdl1 = fitrensemble(X,y);
toc
```

Elapsed time is 78.662954 seconds.

Speed up training by using the `'NumBins'` name-value pair argument. If you specify the `'NumBins'` value as a positive integer scalar, then the software bins every numeric predictor into a specified number of equiprobable bins, and then grows trees on the bin indices instead of the original data. The software does not bin categorical predictors.

```
tic
Mdl2 = fitensemble(X,y,'NumBins',50);
toc
```

Elapsed time is 43.353208 seconds.

The process is about two times faster when you use binned data instead of the original data. Note that the elapsed time can vary depending on your operating system.

Compare the regression errors by resubstitution.

```
rsLoss = resubLoss(Mdl1)

rsLoss = 1.0134

rsLoss2 = resubLoss(Mdl2)

rsLoss2 = 1.0133
```

In this example, binning predictor values reduces training time without a significant loss of accuracy. In general, when you have a large data set like the one in this example, using the binning option speeds up training but causes a potential decrease in accuracy. If you want to reduce training time further, specify a smaller number of bins.

Reproduce binned predictor data by using the `BinEdges` property of the trained model and the `discretize` function.

```
X = Mdl2.X; % Predictor data
Xbinned = zeros(size(X));
edges = Mdl2.BinEdges;
% Find indices of binned predictors.
idxNumeric = find(~cellfun(@isempty,edges));
if iscolumn(idxNumeric)
    idxNumeric = idxNumeric';
end
for j = idxNumeric
    x = X(:,j);
    % Convert x to array if x is a table.
    if istable(x)
        x = table2array(x);
    end
    % Group x into bins by using the discretize function.
    xbinned = discretize(x,[-inf; edges{j}; inf]);
    Xbinned(:,j) = xbinned;
end
```

Xbinned contains the bin indices, ranging from 1 to the number of bins, for numeric predictors. Xbinned values are 0 for categorical predictors. If X contains NaNs, then the corresponding Xbinned values are NaNs.

Estimate Generalization Error of Boosting Ensemble

Estimate the generalization error of an ensemble of boosted regression trees.

Load the carsmall data set. Choose the number of cylinders, volume displaced by the cylinders, horsepower, and weight as predictors of fuel economy.

```
load carsmall
X = [Cylinders Displacement Horsepower Weight];
```

Cross-validate an ensemble of regression trees using 10-fold cross-validation. Using a decision tree template, specify that each tree should be a split once only.

```
rng(1); % For reproducibility
t = templateTree('MaxNumSplits',1);
Mdl = fitrensemble(X,MPG,'Learners',t,'CrossVal','on');
```

Mdl is a RegressionPartitionedEnsemble model.

Plot the cumulative, 10-fold cross-validated, mean-squared error (MSE). Display the estimated generalization error of the ensemble.

```
kflc = kfoldLoss(Mdl,'Mode','cumulative');
figure;
plot(kflc);
ylabel('10-fold cross-validated MSE');
xlabel('Learning cycle');
```

```
estGenError = kflc(end)
```

```
estGenError = 25.6818
```

`kfoldLoss` returns the generalization error by default. However, plotting the cumulative loss allows you to monitor how the loss changes as weak learners accumulate in the ensemble.

The ensemble achieves an MSE of around 23.5 after accumulating about 30 weak learners.

If you are satisfied with the generalization error of the ensemble, then, to create a predictive model, train the ensemble again using all of the settings except cross-

validation. However, it is good practice to tune hyperparameters such as the maximum number of decision splits per tree and the number of learning cycles..

Optimize Regression Ensemble

This example shows how to optimize hyperparameters automatically using `fitrensemble`. The example uses the `carsmall` data.

Load the data.

```
load carsmall
```

You can find hyperparameters that minimize five-fold cross-validation loss by using automatic hyperparameter optimization.

```
Mdl = fitrensemble([Horsepower,Weight],MPG,'OptimizeHyperparameters','auto')
```

In this example, for reproducibility, set the random seed and use the `'expected-improvement-plus'` acquisition function. Also, for reproducibility of random forest algorithm, specify the `'Reproducible'` name-value pair argument as `true` for tree learners.

```
rng('default')
t = templateTree('Reproducible',true);
Mdl = fitrensemble([Horsepower,Weight],MPG,'OptimizeHyperparameters','auto','Learners'
    'HyperparameterOptimizationOptions',struct('AcquisitionFunctionName','expected-imp
```

Properties, Methods

The optimization searched over the methods for regression (**Bag** and **LSBoost**), over **NumLearningCycles**, over the **LearnRate** for **LSBoost**, and over the tree learner **MinLeafSize**. The output is the ensemble regression with the minimum estimated cross-validation loss.

Optimize Regression Ensemble Using Cross-Validation

One way to create an ensemble of boosted regression trees that has satisfactory predictive performance is to tune the decision tree complexity level using cross-validation. While searching for an optimal complexity level, tune the learning rate to minimize the number of learning cycles as well.

This example manually finds optimal parameters by using the cross-validation option (the 'KFold' name-value pair argument) and the `kfoldLoss` function. Alternatively, you can use the 'OptimizeHyperparameters' name-value pair argument to optimize hyperparameters automatically. See “Optimize Regression Ensemble” on page 32-2563.

Load the `carsmall` data set. Choose the number of cylinders, volume displaced by the cylinders, horsepower, and weight as predictors of fuel economy.

```
load carsmall
Tbl = table(Cylinders,Displacement,Horsepower,Weight,MPG);
```

The default values of the tree depth controllers for boosting regression trees are:

- 10 for `MaxNumSplits`.
- 5 for `MinLeafSize`
- 10 for `MinParentSize`

To search for the optimal tree-complexity level:

- 1 Cross-validate a set of ensembles. Exponentially increase the tree-complexity level for subsequent ensembles from decision stump (one split) to at most $n - 1$ splits. n is the sample size. Also, vary the learning rate for each ensemble between 0.1 to 1.
- 2 Estimate the cross-validated mean-squared error (MSE) for each ensemble.
- 3 For tree-complexity level j , $j = 1 \dots J$, compare the cumulative, cross-validated MSE of the ensembles by plotting them against number of learning cycles. Plot separate curves for each learning rate on the same figure.
- 4 Choose the curve that achieves the minimal MSE, and note the corresponding learning cycle and learning rate.

Cross-validate a deep regression tree and a stump. Because the data contain missing values, use surrogate splits. These regression trees serve as benchmarks.

```
rng(1) % For reproducibility
MdlDeep = fitrtree(Tbl,'MPG','CrossVal','on','MergeLeaves','off', ...
    'MinParentSize',1,'Surrogate','on');
MdlStump = fitrtree(Tbl,'MPG','MaxNumSplits',1,'CrossVal','on', ...
    'Surrogate','on');
```

Cross-validate an ensemble of 150 boosted regression trees using 5-fold cross-validation. Using a tree template:

- Vary the maximum number of splits using the values in the sequence $\{2^0, 2^1, \dots, 2^m\}$. m is such that 2^m is no greater than $n - 1$.
- Turn on surrogate splits.

For each variant, adjust the learning rate using each value in the set $\{0.1, 0.25, 0.5, 1\}$.

```
n = size(Tbl,1);
m = floor(log2(n - 1));
learnRate = [0.1 0.25 0.5 1];
numLR = numel(learnRate);
maxNumSplits = 2.^(0:m);
numMNS = numel(maxNumSplits);
numTrees = 150;
Mdl = cell(numMNS,numLR);

for k = 1:numLR
    for j = 1:numMNS
        t = templateTree('MaxNumSplits',maxNumSplits(j),'Surrogate','on');
        Mdl{j,k} = fitrensemble(Tbl,'MPG','NumLearningCycles',numTrees, ...
            'Learners',t,'KFold',5,'LearnRate',learnRate(k));
    end
end
```

Estimate the cumulative, cross-validated MSE of each ensemble.

```
kf1All = @(x)kfoldLoss(x,'Mode','cumulative');
errorCell = cellfun(kf1All,Mdl,'Uniform',false);
error = reshape(cell2mat(errorCell),[numTrees numel(maxNumSplits) numel(learnRate)]);
errorDeep = kfoldLoss(MdlDeep);
errorStump = kfoldLoss(MdlStump);
```

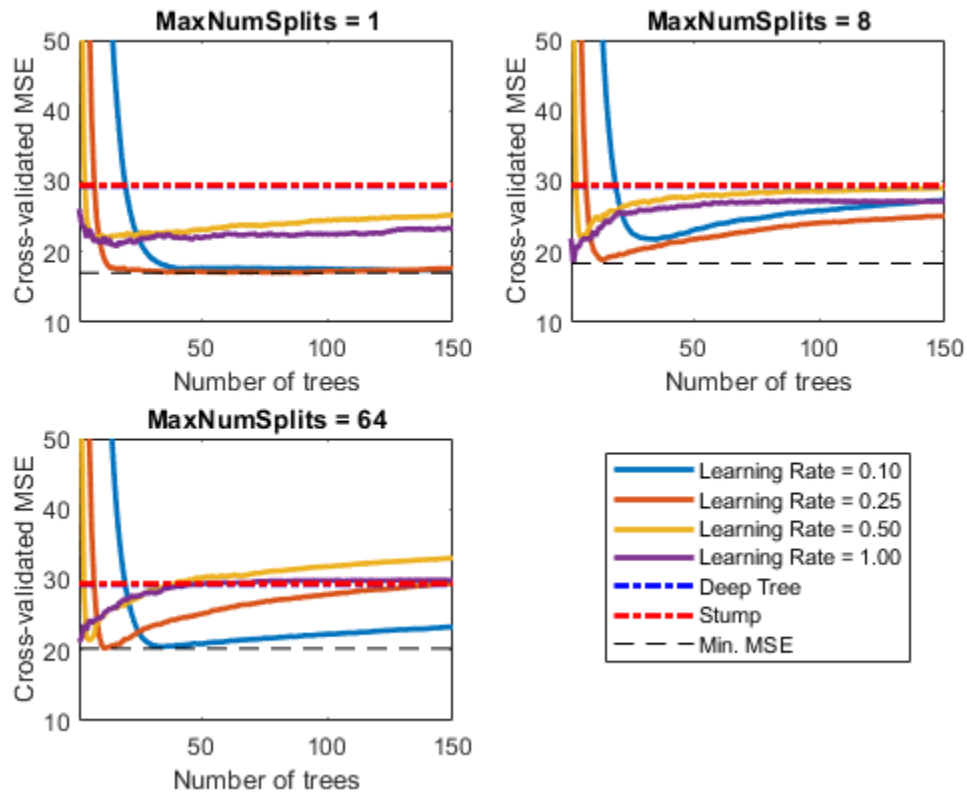

Plot how the cross-validated MSE behaves as the number of trees in the ensemble increases. Plot the curves with respect to learning rate on the same plot, and plot separate plots for varying tree-complexity levels. Choose a subset of tree complexity levels to plot.

```
mnsPlot = [1 round(numel(maxNumSplits)/2) numel(maxNumSplits)];
figure;
for k = 1:3
    subplot(2,2,k)
    plot(squeeze(error(:,mnsPlot(k),:)), 'LineWidth',2)
    axis tight
    hold on
```

```

h = gca;
plot(h.XLim,[errorDeep errorDeep],'--.b','LineWidth',2)
plot(h.XLim,[errorStump errorStump],'--.r','LineWidth',2)
plot(h.XLim,min(min(error(:,mnsPlot(k),:)).*[1 1]),'--.k')
h.YLim = [10 50];
xlabel('Number of trees')
ylabel('Cross-validated MSE')
title(sprintf('MaxNumSplits = %0.3g', maxNumSplits(mnsPlot(k))))
hold off
end
hL = legend([cellstr(num2str(learnRate','Learning Rate = %0.2f')); ...
            'Deep Tree';'Stump';'Min. MSE']);
hL.Position(1) = 0.6;

```

Each curve contains a minimum cross-validated MSE occurring at the optimal number of trees in the ensemble.

Identify the maximum number of splits, number of trees, and learning rate that yields the lowest MSE overall.

```
[minErr,minErrIdxLin] = min(error(:));  
[idxNumTrees,idxMNS,idxLR] = ind2sub(size(error),minErrIdxLin);  
fprintf('\nMin. MSE = %0.5f',minErr)
```

```
Min. MSE = 17.01148
```

```
fprintf('\nOptimal Parameter Values:\nNum. Trees = %d',idxNumTrees);
```

```
Optimal Parameter Values:  
Num. Trees = 38
```

```
fprintf('\nMaxNumSplits = %d\nLearning Rate = %0.2f\n',...  
        maxNumSplits(idxMNS),learnRate(idxLR))
```

```
MaxNumSplits = 4  
Learning Rate = 0.10
```

Create a predictive ensemble based on the optimal hyperparameters and the entire training set.

```
tFinal = templateTree('MaxNumSplits',maxNumSplits(idxMNS),'Surrogate','on');  
MdlFinal = fitensemble(Tbl,'MPG','NumLearningCycles',idxNumTrees, ...  
    'Learners',tFinal,'LearnRate',learnRate(idxLR))
```

```
MdlFinal =  
    classreg.learning.regr.RegressionEnsemble  
        PredictorNames: {'Cylinders' 'Displacement' 'Horsepower' 'Weight'}  
        ResponseName: 'MPG'  
    CategoricalPredictors: []  
        ResponseTransform: 'none'  
        NumObservations: 94  
        NumTrained: 38  
        Method: 'LSBoost'

        FitInfo: [38x1 double]  
    FitInfoDescription: {2x1 cell}  
        Regularization: []
```

Properties, Methods

`MdlFinal` is a `RegressionEnsemble`. To predict the fuel economy of a car given its number of cylinders, volume displaced by the cylinders, horsepower, and weight, you can pass the predictor data and `MdlFinal` to `predict`.

Instead of searching optimal values manually by using the cross-validation option (`'Kfold'`) and the `kfoldLoss` function, you can use the `'OptimizeHyperparameters'` name-value pair argument. When you specify `'OptimizeHyperparameters'`, the software finds optimal parameters automatically using Bayesian optimization. The optimal values obtained by using `'OptimizeHyperparameters'` can be different from those obtained using manual search.

```
t = templateTree('Surrogate','on');
mdl = fitrensemble(Tbl,'MPG','Learners',t, ...
    'OptimizeHyperparameters',{ 'NumLearningCycles', 'LearnRate', 'MaxNumSplits'})
```

Properties, Methods

Input Arguments

Tbl — Sample data

table

Sample data used to train the model, specified as a table. Each row of Tbl corresponds to one observation, and each column corresponds to one predictor variable. Tbl can contain one additional column for the response variable. Multi-column variables and cell arrays other than cell arrays of character vectors are not allowed.

- If Tbl contains the response variable and you want to use all remaining variables as predictors, then specify the response variable using ResponseVarName.
- If Tbl contains the response variable, and you want to use a subset of the remaining variables only as predictors, then specify a formula using formula.

- If `Tbl` does not contain the response variable, then specify the response data using `Y`. The length of response variable and the number of rows of `Tbl` must be equal.

Note To save memory and execution time, supply `X` and `Y` instead of `Tbl`.

Data Types: `table`

ResponseVarName — Response variable name

name of response variable in `Tbl`

Response variable name, specified as the name of the response variable in `Tbl`.

You must specify `ResponseVarName` as a character vector or string scalar. For example, if `Tbl.Y` is the response variable, then specify `ResponseVarName` as `'Y'`. Otherwise, `fitrensemble` treats all columns of `Tbl` as predictor variables.

Data Types: `char` | `string`

formula — Explanatory model of response and subset of predictor variables

character vector | string scalar

Explanatory model of the response and a subset of the predictor variables, specified as a character vector or string scalar in the form `'Y~X1+X2+X3'`. In this form, `Y` represents the response variable, and `X1`, `X2`, and `X3` represent the predictor variables. The variables must be variable names in `Tbl` (`Tbl.Properties.VariableNames`).

To specify a subset of variables in `Tbl` as predictors for training the model, use a formula. If you specify a formula, then the software does not use any variables in `Tbl` that do not appear in `formula`.

Data Types: `char` | `string`

X — Predictor data

numeric matrix

Predictor data, specified as numeric matrix.

Each row corresponds to one observation, and each column corresponds to one predictor variable.

The length of `Y` and the number of rows of `X` must be equal.

To specify the names of the predictors in the order of their appearance in X , use the `PredictorNames` name-value pair argument.

Data Types: `single` | `double`

Y — Response

numeric vector

Response, specified as a numeric vector. Each element in Y is the response to the observation in the corresponding row of X or `Tbl`. The length of Y and the number of rows of X or `Tbl` must be equal.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Note You cannot use any cross-validation name-value pair argument along with the `'OptimizeHyperparameters'` name-value pair argument. You can modify the cross-validation for `'OptimizeHyperparameters'` only by using the `'HyperparameterOptimizationOptions'` name-value pair argument.

Example:

```
'NumLearningCycles', 500, 'Method', 'Bag', 'Learners', templateTree(), 'CrossVal', 'on'
```

cross-validates an ensemble of 500 bagged regression trees using 10-fold cross-validation.

General Ensemble Options

Method — Ensemble aggregation method

`'LSBoost'` (default) | `'Bag'`

Ensemble aggregation method, specified as the comma-separated pair consisting of `'Method'` and `'LSBoost'` or `'Bag'`.

Value	Method	Notes
'LSBoost'	Least-squares boosting (LSBoost)	You can specify the learning rate for shrinkage by using the 'LearnRate' name-value pair argument.
'Bag'	Bootstrap aggregation (bagging, for example, random forest[2])	fitrensemble uses bagging with random predictor selections at each split (random forest) by default. To use bagging without the random selections, use tree learners whose 'NumVariablesToSample' value is 'all'.

For details about ensemble aggregation algorithms and examples, see “Algorithms” on page 32-2592, “Ensemble Algorithms” on page 18-50, and “Choose an Applicable Ensemble Aggregation Method” on page 18-42.

Example: 'Method', 'Bag'

NumLearningCycles — Number of ensemble learning cycles

100 (default) | positive integer

Number of ensemble learning cycles, specified as the comma-separated pair consisting of 'NumLearningCycles' and a positive integer. At every learning cycle, the software trains one weak learner for every template object in Learners. Consequently, the software trains NumLearningCycles* numel(Learners) learners.

The software composes the ensemble using all trained learners and stores them in Mdl.Trained.

For more details, see “Tips” on page 32-2592.

Example: 'NumLearningCycles', 500

Data Types: single | double

Learners — Weak learners to use in ensemble

'tree' (default) | tree template object | cell vector of tree template objects

Weak learners to use in the ensemble, specified as the comma-separated pair consisting of 'Learners' and 'tree', a tree template object, or a cell vector of tree template objects.

- 'tree' (default) — `fitrensemble` uses default regression tree learners, which is the same as using `templateTree()`. The default values of `templateTree()` depend on the value of 'Method'.
 - For bagged decision trees, the maximum number of decision splits ('`MaxNumSplits`') is $n-1$, where n is the number of observations. The number of predictors to select at random for each split ('`NumVariablesToSample`') is one third of the number of predictors. Therefore, `fitrensemble` grows deep decision trees. You can grow shallower trees to reduce model complexity or computation time.
 - For boosted decision trees, '`MaxNumSplits`' is 10 and '`NumVariablesToSample`' is 'all'. Therefore, `fitrensemble` grows shallow decision trees. You can grow deeper trees for better accuracy.

See `templateTree` for the default settings of a weak learner.

- Tree template object — `fitrensemble` uses the tree template object created by `templateTree`. Use the name-value pair arguments of `templateTree` to specify settings of the tree learners.
- Cell vector of m tree template objects — `fitrensemble` grows m regression trees per learning cycle (see `NumLearningCycles`). For example, for an ensemble composed of two types of regression trees, supply `{t1 t2}`, where `t1` and `t2` are regression tree template objects returned by `templateTree`.

For details on the number of learners to train, see `NumLearningCycles` and “Tips” on page 32-2592.

Example: `'Learners',templateTree('MaxNumSplits',5)`

NPrint — Printout frequency

'off' (default) | positive integer

Printout frequency, specified as the comma-separated pair consisting of 'NPrint' and a positive integer or 'off'.

To track the number of *weak learners* or *folds* that `fitrensemble` trained so far, specify a positive integer. That is, if you specify the positive integer m :

- Without also specifying any cross-validation option (for example, `CrossVal`), then `fitrensemble` displays a message to the command line every time it completes training m weak learners.
- And a cross-validation option, then `fitrensemble` displays a message to the command line every time it finishes training m folds.

If you specify `'off'`, then `fitrensemble` does not display a message when it completes training weak learners.

Tip When training an ensemble of many weak learners on a large data set, specify a positive integer for `NPrint`.

Example: `'NPrint',5`

Data Types: `single | double | char | string`

NumBins — Number of bins for numeric predictors

`[]` (empty) (default) | positive integer scalar

Number of bins for numeric predictors, specified as the comma-separated pair consisting of `'NumBins'` and a positive integer scalar.

- If the `'NumBins'` value is empty (default), then the software does not bin any predictors.
- If you specify the `'NumBins'` value as a positive integer scalar, then the software bins every numeric predictor into a specified number of equiprobable bins, and then grows trees on the bin indices instead of the original data.
 - If the `'NumBins'` value exceeds the number (u) of unique values for a predictor, then `fitrensemble` bins the predictor into u bins.
 - `fitrensemble` does not bin categorical predictors.

When you use a large training data set, this binning option speeds up training but causes a potential decrease in accuracy. You can try `'NumBins',50` first, and then change the `'NumBins'` value depending on the accuracy and training speed.

A trained model stores the bin edges in the `BinEdges` property.

Example: `'NumBins',50`

Data Types: `single | double`

CategoricalPredictors — Categorical predictors list

vector of positive integers | logical vector | character matrix | string array | cell array of character vectors | 'all'

Categorical predictors list, specified as the comma-separated pair consisting of 'CategoricalPredictors' and one of the values in this table.

Value	Description
Vector of positive integers	An entry in the vector is the index value corresponding to the column of the predictor data (<i>X</i> or <i>Tbl</i>) that contains a categorical variable.
Logical vector	A <code>true</code> entry means that the corresponding column of predictor data (<i>X</i> or <i>Tbl</i>) is a categorical variable.
Character matrix	Each row of the matrix is the name of a predictor variable. The names must match the entries in <code>PredictorNames</code> . Pad the names with extra blanks so each row of the character matrix has the same length.
String array or cell array of character vectors	Each element in the array is the name of a predictor variable. The names must match the entries in <code>PredictorNames</code> .
'all'	All predictors are categorical.

By default, if the predictor data is in a table (*Tbl*), `fitrensemble` assumes that a variable is categorical if it contains logical values, categorical values, a string array, or a cell array of character vectors. If the predictor data is a matrix (*X*), `fitrensemble` assumes all predictors are continuous. To identify any categorical predictors when the data is a matrix, use the 'CategoricalPredictors' name-value pair argument.

Example: 'CategoricalPredictors','all'

Data Types: `single` | `double` | `logical` | `char` | `string` | `cell`

PredictorNames — Predictor variable names

string array of unique names | cell array of unique character vectors

Predictor variable names, specified as the comma-separated pair consisting of 'PredictorNames' and a string array of unique names or cell array of unique character vectors. The functionality of 'PredictorNames' depends on the way you supply the training data.

- If you supply `X` and `Y`, then you can use `'PredictorNames'` to give the predictor variables in `X` names.
 - The order of the names in `PredictorNames` must correspond to the column order of `X`. That is, `PredictorNames{1}` is the name of `X(:,1)`, `PredictorNames{2}` is the name of `X(:,2)`, and so on. Also, `size(X,2)` and `numel(PredictorNames)` must be equal.
 - By default, `PredictorNames` is `{'x1', 'x2', ...}`.
- If you supply `Tbl`, then you can use `'PredictorNames'` to choose which predictor variables to use in training. That is, `fitrensemble` uses only the predictor variables in `PredictorNames` and the response variable in training.
 - `PredictorNames` must be a subset of `Tbl.Properties.VariableNames` and cannot include the name of the response variable.
 - By default, `PredictorNames` contains the names of all predictor variables.
 - It is a good practice to specify the predictors for training using either `'PredictorNames'` or `formula` only.

Example: `'PredictorNames',`
`{'SepalLength', 'SepalWidth', 'PetalLength', 'PetalWidth'}`

Data Types: `string` | `cell`

ResponseName — Response variable name

`'Y'` (default) | character vector | string scalar

Response variable name, specified as the comma-separated pair consisting of `'ResponseName'` and a character vector or string scalar.

- If you supply `Y`, then you can use `'ResponseName'` to specify a name for the response variable.
- If you supply `ResponseVarName` or `formula`, then you cannot use `'ResponseName'`.

Example: `'ResponseName', 'response'`

Data Types: `char` | `string`

ResponseTransform — Response transformation

`'none'` (default) | function handle

Response transformation, specified as the comma-separated pair consisting of `'ResponseTransform'` and either `'none'` or a function handle. The default is `'none'`,

which means $\phi(y)$, or no transformation. For a MATLAB function or a function you define, use its function handle. The function handle must accept a vector (the original response values) and return a vector of the same size (the transformed response values).

Example: Suppose you create a function handle that applies an exponential transformation to an input vector by using `myfunction = @(y)exp(y)`. Then, you can specify the response transformation as `'ResponseTransform',myfunction`.

Data Types: `char` | `string` | `function_handle`

Cross-Validation Options

CrossVal — Cross-validation flag

`'off'` (default) | `'on'`

Cross-validation flag, specified as the comma-separated pair consisting of `'Crossval'` and `'on'` or `'off'`.

If you specify `'on'`, then the software implements 10-fold cross-validation.

To override this cross-validation setting, use one of these name-value pair arguments: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`. To create a cross-validated model, you can use one cross-validation name-value pair argument at a time only.

Alternatively, cross-validate later by passing `Mdl` to `crossval` or `crossval`.

Example: `'Crossval','on'`

CVPartition — Cross-validation partition

`[]` (default) | `cvpartition` partition object

Cross-validation partition, specified as the comma-separated pair consisting of `'CVPartition'` and a `cvpartition` partition object created by `cvpartition`. The partition object specifies the type of cross-validation and the indexing for the training and validation sets.

To create a cross-validated model, you can use one of these four name-value pair arguments only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: Suppose you create a random partition for 5-fold cross-validation on 500 observations by using `cvp = cvpartition(500,'KFold',5)`. Then, you can specify the cross-validated model by using `'CVPartition',cvp`.

Holdout — Fraction of data for holdout validation

scalar value in the range (0,1)

Fraction of the data used for holdout validation, specified as the comma-separated pair consisting of 'Holdout' and a scalar value in the range (0,1). If you specify 'Holdout', p , then the software completes these steps:

- 1 Randomly select and reserve $p \times 100\%$ of the data as validation data, and train the model using the rest of the data.
- 2 Store the compact, trained model in the Trained property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: CVPartition, Holdout, KFold, or Leaveout.

Example: 'Holdout', 0.1

Data Types: double | single

KFold — Number of folds

10 (default) | positive integer value greater than 1

Number of folds to use in a cross-validated model, specified as the comma-separated pair consisting of 'KFold' and a positive integer value greater than 1. If you specify 'KFold', k , then the software completes these steps:

- 1 Randomly partition the data into k sets.
- 2 For each set, reserve the set as validation data, and train the model using the other $k - 1$ sets.
- 3 Store the k compact, trained models in the cells of a k -by-1 cell vector in the Trained property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: CVPartition, Holdout, KFold, or Leaveout.

Example: 'KFold', 5

Data Types: single | double

Leaveout — Leave-one-out cross-validation flag

'off' (default) | 'on'

Leave-one-out cross-validation flag, specified as the comma-separated pair consisting of 'Leaveout' and 'on' or 'off'. If you specify 'Leaveout', 'on', then, for each of the n observations (where n is the number of observations excluding missing observations,

specified in the `NumObservations` property of the model), the software completes these steps:

- 1 Reserve the observation as validation data, and train the model using the other $n - 1$ observations.
- 2 Store the n compact, trained models in the cells of an n -by-1 cell vector in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: `'Leaveout', 'on'`

Other Regression Options

Weights — Observation weights

numeric vector of positive values | name of variable in `Tbl`

Observation weights, specified as the comma-separated pair consisting of `'Weights'` and a numeric vector of positive values or name of a variable in `Tbl`. The software weighs the observations in each row of `X` or `Tbl` with the corresponding value in `Weights`. The size of `Weights` must equal the number of rows of `X` or `Tbl`.

If you specify the input data as a table `Tbl`, then `Weights` can be the name of a variable in `Tbl` that contains a numeric vector. In this case, you must specify `Weights` as a character vector or string scalar. For example, if the weights vector `W` is stored as `Tbl.W`, then specify it as `'W'`. Otherwise, the software treats all columns of `Tbl`, including `W`, as predictors or the response when training the model.

The software normalizes `Weights` to sum up to the value of the prior probability in the respective class.

By default, `Weights` is `ones(n, 1)`, where n is the number of observations in `X` or `Tbl`.

Data Types: `double` | `single` | `char` | `string`

Sampling Options

FResample — Fraction of training set to resample

1 (default) | positive scalar in (0,1]

Fraction of the training set to resample for every weak learner, specified as the comma-separated pair consisting of `'FResample'` and a positive scalar in (0,1].

To use 'FResample', specify 'bag' for Method or set Resample to 'on'.

Example: 'FResample',0.75

Data Types: single | double

Replace — Flag indicating to sample with replacement

'on' (default) | 'off'

Flag indicating sampling with replacement, specified as the comma-separated pair consisting of 'Replace' and 'off' or 'on'.

- For 'on', the software samples the training observations with replacement.
- For 'off', the software samples the training observations without replacement. If you set Resample to 'on', then the software samples training observations assuming uniform weights. If you also specify a boosting method, then the software boosts by reweighting observations.

Unless you set Method to 'bag' or set Resample to 'on', Replace has no effect.

Example: 'Replace','off'

Resample — Flag indicating to resample

'off' | 'on'

Flag indicating to resample, specified as the comma-separated pair consisting of 'Resample' and 'off' or 'on'.

- If Method is a boosting method, then:
 - 'Resample', 'on' specifies to sample training observations using updated weights as the multinomial sampling probabilities.
 - 'Resample', 'off' (default) specifies to reweight observations at every learning iteration.
- If Method is 'bag', then 'Resample' must be 'on'. The software resamples a fraction of the training observations (see FResample) with or without replacement (see Replace).

If you specify to resample using Resample, then it is good practice to resample to entire data set. That is, use the default setting of 1 for FResample.

LSBoost Method Options

LearnRate — Learning rate for shrinkage

1 (default) | numeric scalar in (0,1]

Learning rate for shrinkage, specified as the comma-separated pair consisting of a numeric scalar in the interval (0,1].

To train an ensemble using shrinkage, set `LearnRate` to a value less than 1, for example, 0.1 is a popular choice. Training an ensemble using shrinkage requires more learning iterations, but often achieves better accuracy.

Example: `'LearnRate',0.1`

Data Types: `single` | `double`

Hyperparameter Optimization

OptimizeHyperparameters — Parameters to optimize

'none' (default) | 'auto' | 'all' | string array or cell array of eligible parameter names | vector of `optimizableVariable` objects

Parameters to optimize, specified as the comma-separated pair consisting of `'OptimizeHyperparameters'` and one of the following:

- 'none' — Do not optimize.
- 'auto' — Use `{'Method','NumLearningCycles','LearnRate'}` along with the default parameters for the specified Learners:
 - `Learners = 'tree'` (default) — `{'MinLeafSize'}`

Note For hyperparameter optimization, `Learners` must be a single argument, not a string array or cell array.

- 'all' — Optimize all eligible parameters.
- String array or cell array of eligible parameter names
- Vector of `optimizableVariable` objects, typically the output of `hyperparameters`

The optimization attempts to minimize the cross-validation loss (error) for `fitensemble` by varying the parameters. To control the cross-validation type and other aspects of the optimization, use the `HyperparameterOptimizationOptions` name-value pair.

Note 'OptimizeHyperparameters' values override any values you set using other name-value pair arguments. For example, setting 'OptimizeHyperparameters' to 'auto' causes the 'auto' values to apply.

The eligible parameters for fitrensemble are:

- **Method** — Eligible methods are 'Bag' or 'LSBoost'.
- **NumLearningCycles** — fitrensemble searches among positive integers, by default log-scaled with range [10,500].
- **LearnRate** — fitrensemble searches among positive reals, by default log-scaled with range [1e-3,1].
- **MinLeafSize** — fitrensemble searches among integers log-scaled in the range [1,max(2,floor(NumObservations/2))].
- **MaxNumSplits** — fitrensemble searches among integers log-scaled in the range [1,max(2,NumObservations-1)].
- **NumVariablesToSample** — fitrensemble searches among integers in the range [1,max(2,NumPredictors)].

Set nondefault parameters by passing a vector of `optimizableVariable` objects that have nondefault values. For example,

```
load carsmall
params = hyperparameters('fitrensemble',[Horsepower,Weight],MPG,'Tree');
params(4).Range = [1,20];
```

Pass `params` as the value of `OptimizeHyperparameters`.

By default, iterative display appears at the command line, and plots appear according to the number of hyperparameters in the optimization. For the optimization and plots, the objective function is $\log(1 + \text{cross-validation loss})$ for regression and the misclassification rate for classification. To control the iterative display, set the `Verbose` field of the 'HyperparameterOptimizationOptions' name-value pair argument. To control the plots, set the `ShowPlots` field of the 'HyperparameterOptimizationOptions' name-value pair argument.

For an example, see “Optimize Regression Ensemble” on page 32-2563.

```
Example: 'OptimizeHyperparameters',
{'Method','NumLearningCycles','LearnRate','MinLeafSize','MaxNumSplits'}
```

HyperparameterOptimizationOptions — Options for optimization

structure

Options for optimization, specified as the comma-separated pair consisting of 'HyperparameterOptimizationOptions' and a structure. This argument modifies the effect of the `OptimizeHyperparameters` name-value pair argument. All fields in the structure are optional.

Field Name	Values	Default
Optimizer	<ul style="list-style-type: none"> 'bayesopt' — Use Bayesian optimization. Internally, this setting calls <code>bayesopt</code>. 'gridsearch' — Use grid search with <code>NumGridDivisions</code> values per dimension. 'randomsearch' — Search at random among <code>MaxObjectiveEvaluations</code> points. <p>'gridsearch' searches in a random order, using uniform sampling without replacement from the grid. After optimization, you can get a table in grid order by using the command <code>sortrows(Mdl.HyperparameterOptimizationResults)</code>.</p>	'bayesopt'

Field Name	Values	Default
AcquisitionFunctionName	<ul style="list-style-type: none"> • 'expected-improvement-per-second-plus' • 'expected-improvement' • 'expected-improvement-plus' • 'expected-improvement-per-second' • 'lower-confidence-bound' • 'probability-of-improvement' <p>Acquisition functions whose names include <code>per-second</code> do not yield reproducible results because the optimization depends on the runtime of the objective function. Acquisition functions whose names include <code>plus</code> modify their behavior when they are overexploiting an area. For more details, see “Acquisition Function Types” on page 10-4.</p>	'expected-improvement-per-second-plus'
MaxObjectiveEvaluations	Maximum number of objective function evaluations.	30 for 'bayesopt' or 'randomsearch', and the entire grid for 'gridsearch'
MaxTime	Time limit, specified as a positive real. The time limit is in seconds, as measured by <code>tic</code> and <code>toc</code> . Run time can exceed <code>MaxTime</code> because <code>MaxTime</code> does not interrupt function evaluations.	Inf
NumGridDivisions	For 'gridsearch', the number of values in each dimension. The value can be a vector of positive integers giving the number of values for each dimension, or a scalar that applies to all dimensions. This field is ignored for categorical variables.	10

Field Name	Values	Default
ShowPlots	Logical value indicating whether to show plots. If <code>true</code> , this field plots the best objective function value against the iteration number. If there are one or two optimization parameters, and if <code>Optimizer</code> is <code>'bayesopt'</code> , then <code>ShowPlots</code> also plots a model of the objective function against the parameters.	<code>true</code>
SaveIntermediateResults	Logical value indicating whether to save results when <code>Optimizer</code> is <code>'bayesopt'</code> . If <code>true</code> , this field overwrites a workspace variable named <code>'BayesoptResults'</code> at each iteration. The variable is a <code>BayesianOptimization</code> object.	<code>false</code>
Verbose	Display to the command line. <ul style="list-style-type: none"> • 0 — No iterative display • 1 — Iterative display • 2 — Iterative display with extra information For details, see the <code>bayesopt</code> <code>Verbose</code> name-value pair argument.	1
UseParallel	Logical value indicating whether to run Bayesian optimization in parallel, which requires Parallel Computing Toolbox. For details, see “Parallel Bayesian Optimization” on page 10-8.	<code>false</code>

Field Name	Values	Default
Repartition	Logical value indicating whether to repartition the cross-validation at every iteration. If <code>false</code> , the optimizer uses a single partition for the optimization. <code>true</code> usually gives the most robust results because this setting takes partitioning noise into account. However, for good results, <code>true</code> requires at least twice as many function evaluations.	<code>false</code>
Use no more than one of the following three field names.		
CVPartition	A <code>cvpartition</code> object, as created by <code>cvpartition</code> .	'Kfold', 5 if you do not specify any cross-validation field
Holdout	A scalar in the range (0, 1) representing the holdout fraction.	
Kfold	An integer greater than 1.	

Example:

```
'HyperparameterOptimizationOptions', struct('MaxObjectiveEvaluations', 60)
```

Data Types: `struct`

Output Arguments

Mdl — Trained regression ensemble model

RegressionBaggedEnsemble model object | RegressionEnsemble model object | RegressionPartitionedEnsemble cross-validated model object

Trained ensemble model, returned as one of the model objects in this table.

Model Object	Specify Any Cross-Validation Options?	Method Setting	Resample Setting
RegressionBaggedEnsemble	No	'Bag'	'on'

Model Object	Specify Any Cross-Validation Options?	Method Setting	Resample Setting
RegressionEnsemble	No	'LSBoost'	'off'
RegressionPartitionedEnsemble	Yes	'LSBoost' or 'Bag'	'off' or 'on'

The name-value pair arguments that control cross-validation are `CrossVal`, `Holdout`, `KFold`, `Leaveout`, and `CVPartition`.

To reference properties of `Mdl`, use dot notation. For example, to access or display the cell vector of weak learner model objects for an ensemble that has not been cross-validated, enter `Mdl.Trained` at the command line.

Tips

- `NumLearningCycles` can vary from a few dozen to a few thousand. Usually, an ensemble with good predictive power requires from a few hundred to a few thousand weak learners. However, you do not have to train an ensemble for that many cycles at once. You can start by growing a few dozen learners, inspect the ensemble performance and then, if necessary, train more weak learners using `resume`.
- Ensemble performance depends on the ensemble setting and the setting of the weak learners. That is, if you specify weak learners with default parameters, then the ensemble can perform poorly. Therefore, like ensemble settings, it is good practice to adjust the parameters of the weak learners using templates, and to choose values that minimize generalization error.
- If you specify to resample using `Resample`, then it is good practice to resample to entire data set. That is, use the default setting of 1 for `FResample`.
- After training a model, you can generate C/C++ code that predicts responses for new data. Generating C/C++ code requires MATLAB Coder. For details, see “Introduction to Code Generation” on page 31-2.

Algorithms

- For details of ensemble aggregation algorithms, see “Ensemble Algorithms” on page 18-50.

- If you specify 'Method', 'LSBoost', then the software grows shallow decision trees by default. You can adjust tree depth by specifying the MaxNumSplits, MinLeafSize, and MinParentSize name-value pair arguments using `templateTree`.
- For dual-core systems and above, `fitrensemble` parallelizes training using Intel Threading Building Blocks (TBB). For details on Intel TBB, see <https://software.intel.com/en-us/intel-tbb>.

Extended Capabilities

Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the 'UseParallel' option to `true`.

To perform parallel hyperparameter optimization, use the 'HyperparameterOptions', `struct('UseParallel', true)` name-value pair argument in the call to this function.

For more information on parallel hyperparameter optimization, see "Parallel Bayesian Optimization" on page 10-8.

For more general information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

Introduced in R2016b

fitrsvm

Fit a support vector machine regression model

`fitrsvm` trains or cross-validates a support vector machine (SVM) regression model on a low- through moderate-dimensional predictor data set. `fitrsvm` supports mapping the predictor data using kernel functions, and supports SMO, ISDA, or $L1$ soft-margin minimization via quadratic programming for objective-function minimization.

To train a linear SVM regression model on a high-dimensional data set, that is, data sets that include many predictor variables, use `fitrlinear` instead.

To train an SVM model for binary classification, see `fitcsvm` for low- through moderate-dimensional predictor data sets, or `fitclinear` for high-dimensional data sets.

Syntax

```
Mdl = fitrsvm(Tbl,ResponseVarName)
```

```
Mdl = fitrsvm(Tbl,formula)
```

```
Mdl = fitrsvm(Tbl,Y)
```

```
Mdl = fitrsvm(X,Y)
```

```
Mdl = fitrsvm( ____,Name,Value)
```

Description

`Mdl = fitrsvm(Tbl,ResponseVarName)` returns a full, trained support vector machine (SVM) regression model `Mdl` trained using the predictors values in the table `Tbl` and the response values in `Tbl.ResponseVarName`.

`Mdl = fitrsvm(Tbl,formula)` returns a full SVM regression model trained using the predictors values in the table `Tbl`. `formula` is an explanatory model of the response and a subset of predictor variables in `Tbl` used to fit `Mdl`.

`Mdl = fitrsvm(Tbl,Y)` returns a full, trained SVM regression model trained using the predictors values in the table `Tbl` and the response values in the vector `Y`.

`Mdl = fitrsvm(X,Y)` returns a full, trained SVM regression model trained using the predictors values in the matrix `X` and the response values in the vector `Y`.

`Mdl = fitrsvm(____, Name, Value)` returns an SVM regression model with additional options specified by one or more name-value pair arguments, using any of the previous syntaxes. For example, you can specify the kernel function or train a cross-validated model.

Examples

Train Linear Support Vector Machine Regression Model

Train a support vector machine (SVM) regression model using sample data stored in matrices.

Load the `carsmall` data set.

```
load carsmall
rng 'default' % For reproducibility
```

Specify Horsepower and Weight as the predictor variables (`X`) and MPG as the response variable (`Y`).

```
X = [Horsepower,Weight];
Y = MPG;
```

Train a default SVM regression model.

```
Mdl = fitrsvm(X,Y)

Mdl =
  RegressionSVM
      ResponseName: 'Y'
  CategoricalPredictors: []
      ResponseTransform: 'none'
              Alpha: [76x1 double]
              Bias: 43.1920
  KernelParameters: [1x1 struct]
  NumObservations: 93
      BoxConstraints: [93x1 double]
  ConvergenceInfo: [1x1 struct]
```

```

IsSupportVector: [93x1 logical]
Solver: 'SMO'

```

Properties, Methods

Mdl is a trained RegressionSVM model.

Check the model for convergence.

Mdl.ConvergenceInfo.Converged

```

ans = logical
      0

```

0 indicates that the model did not converge.

Retrain the model using standardized data.

```
MdlStd = fitrsvm(X,Y,'Standardize',true)
```

```

MdlStd =
  RegressionSVM
      ResponseName: 'Y'
  CategoricalPredictors: []
      ResponseTransform: 'none'
              Alpha: [77x1 double]
              Bias: 22.9131
  KernelParameters: [1x1 struct]
              Mu: [109.3441 2.9625e+03]
              Sigma: [45.3545 805.9668]
  NumObservations: 93
      BoxConstraints: [93x1 double]
  ConvergenceInfo: [1x1 struct]
  IsSupportVector: [93x1 logical]
      Solver: 'SMO'

```

Properties, Methods

Check the model for convergence.

MdlStd.ConvergenceInfo.Converged

```
ans = logical
     1
```

1 indicates that the model did converge.

Compute the resubstitution (in-sample) mean-squared error for the new model.

```
lStd = resubLoss(MdlStd)
```

```
lStd = 17.0256
```

Train Support Vector Machine Regression Model

Train a support vector machine regression model using the abalone data from the UCI Machine Learning Repository.

Download the data and save it in your current folder with the name 'abalone.csv'.

```
url = 'https://archive.ics.uci.edu/ml/machine-learning-databases/abalone/abalone.data';
websave('abalone.csv',url);
```

Read the data into a table. Specify the variable names.

```
varnames = {'Sex'; 'Length'; 'Diameter'; 'Height'; 'Whole_weight'; ...
            'Shucked_weight'; 'Viscera_weight'; 'Shell_weight'; 'Rings'};
Tbl = readtable('abalone.csv', 'Filetype', 'text', 'ReadVariableNames', false);
Tbl.Properties.VariableNames = varnames;
```

The sample data contains 4177 observations. All the predictor variables are continuous except for Sex, which is a categorical variable with possible values 'M' (for males), 'F' (for females), and 'I' (for infants). The goal is to predict the number of rings (stored in Rings) on the abalone and determine its age using physical measurements.

Train an SVM regression model, using a Gaussian kernel function with an automatic kernel scale. Standardize the data.

```
rng default % For reproducibility
Mdl = fitsvm(Tbl, 'Rings', 'KernelFunction', 'gaussian', 'KernelScale', 'auto', ...
            'Standardize', true)
```

```
Mdl =
```

```
RegressionSVM
  PredictorNames: {1x8 cell}
  ResponseName: 'Rings'
  CategoricalPredictors: 1
  ResponseTransform: 'none'
    Alpha: [3635x1 double]
    Bias: 10.8144
  KernelParameters: [1x1 struct]
    Mu: [1x10 double]
    Sigma: [1x10 double]
  NumObservations: 4177
  BoxConstraints: [4177x1 double]
  ConvergenceInfo: [1x1 struct]
  IsSupportVector: [4177x1 logical]
  Solver: 'SMO'
```

The Command Window shows that `Mdl` is a trained `RegressionSVM` model and displays a property list.

Display the properties of `Mdl` using dot notation. For example, check to confirm whether the model converged and how many iterations it completed.

```
conv = Mdl.ConvergenceInfo.Converged
iter = Mdl.NumIterations
```

```
conv =
    logical
     1

iter =
    2759
```

The returned results indicate that the model converged after 2759 iterations.

Cross-Validate SVM Regression Model

Load the `carsmall` data set.

```
load carsmall
rng 'default' % For reproducibility
```

Specify Horsepower and Weight as the predictor variables (X) and MPG as the response variable (Y).

```
X = [Horsepower Weight];
Y = MPG;
```

Cross-validate two SVM regression models using 5-fold cross-validation. For both models, specify to standardize the predictors. For one of the models, specify to train using the default linear kernel, and the Gaussian kernel for the other model.

```
MdlLin = fitrsvm(X,Y,'Standardize',true,'KFold',5)
```

```
MdlLin =
classreg.learning.partition.RegistrationPartitionedSVM
  CrossValidatedModel: 'SVM'
  PredictorNames: {'x1' 'x2'}
  ResponseName: 'Y'
  NumObservations: 94
  KFold: 5
  Partition: [1x1 cvpartition]
  ResponseTransform: 'none'
```

Properties, Methods

```
MdlGau = fitrsvm(X,Y,'Standardize',true,'KFold',5,'KernelFunction','gaussian')
```

```
MdlGau =
classreg.learning.partition.RegistrationPartitionedSVM
  CrossValidatedModel: 'SVM'
  PredictorNames: {'x1' 'x2'}
  ResponseName: 'Y'
  NumObservations: 94
  KFold: 5
  Partition: [1x1 cvpartition]
  ResponseTransform: 'none'
```

Properties, Methods

MdlLin.Trained

```
ans = 5x1 cell array
    {1x1 classreg.learning.regr.CompactRegressionSVM}
    {1x1 classreg.learning.regr.CompactRegressionSVM}
    {1x1 classreg.learning.regr.CompactRegressionSVM}
    {1x1 classreg.learning.regr.CompactRegressionSVM}
    {1x1 classreg.learning.regr.CompactRegressionSVM}
```

MdlLin and MdlGau are RegressionPartitionedSVM cross-validated models. The Trained property of each model is a 5-by-1 cell array of CompactRegressionSVM models. The models in the cell store the results of training on 4 folds of observations, and leaving one fold of observations out.

Compare the generalization error of the models. In this case, the generalization error is the out-of-sample mean-squared error.

```
mseLin = kfoldLoss(MdlLin)
```

```
mseLin = 17.4417
```

```
mseGau = kfoldLoss(MdlGau)
```

```
mseGau = 16.7333
```

The SVM regression model using the Gaussian kernel performs better than the one using the linear kernel.

Create a model suitable for making predictions by passing the entire data set to fitrsvm, and specify all name-value pair arguments that yielded the better-performing model. However, do not specify any cross-validation options.

```
MdlGau = fitrsvm(X,Y,'Standardize',true,'KernelFunction','gaussian');
```

To predict the MPG of a set of cars, pass Mdl and a table containing the horsepower and weight measurements of the cars to predict.

Optimize SVM Regression

This example shows how to optimize hyperparameters automatically using `fitrsvm`. The example uses the `carsmall` data.

Load the `carsmall` data set.

```
load carsmall
```

Specify Horsepower and Weight as the predictor variables (X) and MPG as the response variable (Y).

```
X = [Horsepower Weight];
Y = MPG;
```

Find hyperparameters that minimize five-fold cross-validation loss by using automatic hyperparameter optimization.

For reproducibility, set the random seed and use the 'expected-improvement-plus' acquisition function.

```
rng default
Mdl = fitrsvm(X,Y,'OptimizeHyperparameters','auto',...
    'HyperparameterOptimizationOptions',struct('AcquisitionFunctionName',...
    'expected-improvement-plus'))
```

      Solver: 'SMO'
```

Properties, Methods

The optimization searched over `BoxConstraint`, `KernelScale`, and `Epsilon`. The output is the regression with the minimum estimated cross-validation loss.

Input Arguments

Tbl — Predictor data

table

Sample data used to train the model, specified as a table. Each row of `Tbl` corresponds to one observation, and each column corresponds to one predictor variable. Optionally, `Tbl`

can contain one additional column for the response variable. Multi-column variables and cell arrays other than cell arrays of character vectors are not allowed.

If `Tbl` contains the response variable, and you want to use all remaining variables in `Tbl` as predictors, then specify the response variable using `ResponseVarName`.

If `Tbl` contains the response variable, and you want to use only a subset of the remaining variables in `Tbl` as predictors, then specify a formula using `formula`.

If `Tbl` does not contain the response variable, then specify a response variable using `Y`. The length of response variable and the number of rows of `Tbl` must be equal.

If a row of `Tbl` or an element of `Y` contains at least one `NaN`, then `fitrsvm` removes those rows and elements from both arguments when training the model.

To specify the names of the predictors in the order of their appearance in `Tbl`, use the `PredictorNames` name-value pair argument.

Data Types: `table`

ResponseVarName — Response variable name

name of variable in `Tbl`

Response variable name, specified as the name of a variable in `Tbl`. The response variable must be a numeric vector.

You must specify `ResponseVarName` as a character vector or string scalar. For example, if `Tbl` stores the response variable `Y` as `Tbl.Y`, then specify it as `'Y'`. Otherwise, the software treats all columns of `Tbl`, including `Y`, as predictors when training the model.

Data Types: `char` | `string`

formula — Explanatory model of response and subset of predictor variables

character vector | string scalar

Explanatory model of the response and a subset of the predictor variables, specified as a character vector or string scalar in the form `'Y~X1+X2+X3'`. In this form, `Y` represents the response variable, and `X1`, `X2`, and `X3` represent the predictor variables. The variables must be variable names in `Tbl` (`Tbl.Properties.VariableNames`).

To specify a subset of variables in `Tbl` as predictors for training the model, use a formula. If you specify a formula, then the software does not use any variables in `Tbl` that do not appear in `formula`.

Data Types: `char` | `string`

Y — Response data

numeric vector

Response data, specified as an n -by-1 numeric vector. The length of Y and the number of rows of `Tbl` or `X` must be equal.

If a row of `Tbl` or `X`, or an element of Y, contains at least one NaN, then `fitrsvm` removes those rows and elements from both arguments when training the model.

To specify the response variable name, use the `ResponseName` name-value pair argument.

Data Types: `single` | `double`

X — Predictor data

numeric matrix

Predictor data to which the SVM regression model is fit, specified as an n -by- p numeric matrix. n is the number of observations and p is the number of predictor variables.

The length of Y and the number of rows of X must be equal.

If a row of X or an element of Y contains at least one NaN, then `fitrsvm` removes those rows and elements from both arguments.

To specify the names of the predictors in the order of their appearance in X, use the `PredictorNames` name-value pair argument.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Note You cannot use any cross-validation name-value pair argument along with the `'OptimizeHyperparameters'` name-value pair argument. You can modify the cross-

validation for 'OptimizeHyperparameters' only by using the 'HyperparameterOptimizationOptions' name-value pair argument.

Example:

'KernelFunction','gaussian','Standardize',true,'CrossVal','on' trains a 10-fold cross-validated SVM regression model using a Gaussian kernel and standardized training data.

Support Vector Machine Options

BoxConstraint — Box constraint

positive scalar value

Box constraint for the alpha coefficients, specified as the comma-separated pair consisting of 'BoxConstraint' and a positive scalar value.

The absolute value of the Alpha coefficients cannot exceed the value of BoxConstraint.

The default BoxConstraint value for the 'gaussian' or 'rbf' kernel function is $\text{iqr}(Y)/1.349$, where $\text{iqr}(Y)$ is the interquartile range of response variable Y . For all other kernels, the default BoxConstraint value is 1.

Example: BoxConstraint,10

Data Types: single | double

KernelFunction — Kernel function

'linear' (default) | 'gaussian' | 'rbf' | 'polynomial' | function name

Kernel function used to compute the Gram matrix on page 32-2088, specified as the comma-separated pair consisting of 'KernelFunction' and a value in this table.

Value	Description	Formula
'gaussian' or 'rbf'	Gaussian or Radial Basis Function (RBF) kernel	$G(x_j, x_k) = \exp(-\ x_j - x_k\ ^2)$
'linear'	Linear kernel	$G(x_j, x_k) = x_j'x_k$

Value	Description	Formula
'polynomial'	Polynomial kernel. Use 'PolynomialOrder', p to specify a polynomial kernel of order p .	$G(x_j, x_k) = (1 + x_j'x_k)^q$

You can set your own kernel function, for example, `kernel`, by setting 'KernelFunction', 'kernel'. `kernel` must have the following form:

```
function G = kernel(U,V)
```

where:

- U is an m -by- p matrix.
- V is an n -by- p matrix.
- G is an m -by- n Gram matrix of the rows of U and V .

And `kernel.m` must be on the MATLAB path.

It is good practice to avoid using generic names for kernel functions. For example, call a sigmoid kernel function 'mysigmoid' rather than 'sigmoid'.

Example: 'KernelFunction', 'gaussian'

Data Types: char | string

KernelScale — Kernel scale parameter

1 (default) | 'auto' | positive scalar

Kernel scale parameter, specified as the comma-separated pair consisting of 'KernelScale' and 'auto' or a positive scalar. The software divides all elements of the predictor matrix X by the value of `KernelScale`. Then, the software applies the appropriate kernel norm to compute the Gram matrix.

- If you specify 'auto', then the software selects an appropriate scale factor using a heuristic procedure. This heuristic procedure uses subsampling, so estimates can vary from one call to another. Therefore, to reproduce results, set a random number seed using `rng` before training.
- If you specify `KernelScale` and your own kernel function, for example, 'KernelFunction', 'kernel', then the software throws an error. You must apply scaling within `kernel`.

Example: `'KernelScale','auto'`

Data Types: `double | single | char | string`

PolynomialOrder — Polynomial kernel function order

`3 (default) | positive integer`

Polynomial kernel function order, specified as the comma-separated pair consisting of `'PolynomialOrder'` and a positive integer.

If you set `'PolynomialOrder'` and `KernelFunction` is not `'polynomial'`, then the software throws an error.

Example: `'PolynomialOrder',2`

Data Types: `double | single`

KernelOffset — Kernel offset parameter

`nonnegative scalar`

Kernel offset parameter, specified as the comma-separated pair consisting of `'KernelOffset'` and a nonnegative scalar.

The software adds `KernelOffset` to each element of the Gram matrix.

The defaults are:

- `0` if the solver is SMO (that is, you set `'Solver','SMO'`)
- `0.1` if the solver is ISDA (that is, you set `'Solver','ISDA'`)

Example: `'KernelOffset',0`

Data Types: `double | single`

Epsilon — Half the width of epsilon-insensitive band

`iqr(Y)/13.49 (default) | nonnegative scalar value`

Half the width of the epsilon-insensitive band, specified as the comma-separated pair consisting of `'Epsilon'` and a nonnegative scalar value.

The default `Epsilon` value is `iqr(Y)/13.49`, which is an estimate of a tenth of the standard deviation using the interquartile range of the response variable `Y`. If `iqr(Y)` is equal to zero, then the default `Epsilon` value is `0.1`.

Example: `'Epsilon',0.3`

Data Types: `single` | `double`

Standardize — Flag to standardize predictor data

`false` (default) | `true`

Flag to standardize the predictor data, specified as the comma-separated pair consisting of 'Standardize' and `true` (1) or `false` (0).

If you set 'Standardize', `true`:

- The software centers and scales each column of the predictor data (X) by the weighted column mean and standard deviation, respectively (for details on weighted standardizing, see “Algorithms” on page 32-2092). MATLAB does not standardize the data contained in the dummy variable columns generated for categorical predictors.
- The software trains the model using the standardized predictor matrix, but stores the unstandardized data in the model property X.

Example: 'Standardize', `true`

Data Types: `logical`

Solver — Optimization routine

'ISDA' | 'L1QP' | 'SMO'

Optimization routine, specified as the comma-separated pair consisting of 'Solver' and a value in this table.

Value	Description
'ISDA'	Iterative Single Data Algorithm (see [30])
'L1QP'	Uses <code>quadprog</code> to implement $L1$ soft-margin minimization by quadratic programming. This option requires an Optimization Toolbox license. For more details, see “Quadratic Programming Definition” (Optimization Toolbox).
'SMO'	Sequential Minimal Optimization (see [17])

The defaults are:

- 'ISDA' if you set 'OutlierFraction' to a positive value

- 'SMO' otherwise

Example: 'Solver', 'ISDA'

Alpha — Initial estimates of alpha coefficients

numeric vector

Initial estimates of alpha coefficients, specified as the comma-separated pair consisting of 'Alpha' and a numeric vector. The length of Alpha must be equal to the number of rows of X.

- Each element of Alpha corresponds to an observation in X.
- Alpha cannot contain any NaNs.
- If you specify Alpha and any one of the cross-validation name-value pair arguments ('CrossVal', 'CVPartition', 'Holdout', 'KFold', or 'Leaveout'), then the software returns an error.

If Y contains any missing values, then remove all rows of Y, X, and Alpha that correspond to the missing values. That is, enter:

```
idx = ~isnan(Y);  
Y = Y(idx);  
X = X(idx,:);  
alpha = alpha(idx);
```

Then, pass Y, X, and alpha as the response, predictors, and initial alpha estimates, respectively.

The default is `zeros(size(Y,1))`.

Example: 'Alpha', 0.1*ones(size(X,1),1)

Data Types: single | double

CacheSize — Cache size

1000 (default) | 'maximal' | positive scalar

Cache size, specified as the comma-separated pair consisting of 'CacheSize' and 'maximal' or a positive scalar.

If CacheSize is 'maximal', then the software reserves enough memory to hold the entire n -by- n Gram matrix on page 32-2088.

If `CacheSize` is a positive scalar, then the software reserves `CacheSize` megabytes of memory for training the model.

Example: `'CacheSize', 'maximal'`

Data Types: `double` | `single` | `char` | `string`

ClipAlphas — Flag to clip alpha coefficients

`true` (default) | `false`

Flag to clip alpha coefficients, specified as the comma-separated pair consisting of `'ClipAlphas'` and either `true` or `false`.

Suppose that the alpha coefficient for observation j is α_j and the box constraint of observation j is C_j , $j = 1, \dots, n$, where n is the training sample size.

Value	Description
<code>true</code>	At each iteration, if α_j is near 0 or near C_j , then MATLAB sets α_j to 0 or to C_j , respectively.
<code>false</code>	MATLAB does not change the alpha coefficients during optimization.

MATLAB stores the final values of α in the `Alpha` property of the trained SVM model object.

`ClipAlphas` can affect SMO and ISDA convergence.

Example: `'ClipAlphas', false`

Data Types: `logical`

NumPrint — Number of iterations between optimization diagnostic message output

1000 (default) | nonnegative integer

Number of iterations between optimization diagnostic message output, specified as the comma-separated pair consisting of `'NumPrint'` and a nonnegative integer.

If you specify `'Verbose', 1` and `'NumPrint', numprint`, then the software displays all optimization diagnostic messages from SMO and ISDA every `numprint` iterations in the Command Window.

Example: `'NumPrint', 500`

Data Types: `double` | `single`

OutlierFraction — Expected proportion of outliers in training data

0 (default) | numeric scalar in the interval [0,1)

Expected proportion of outliers in training data, specified as the comma-separated pair consisting of 'OutlierFraction' and a numeric scalar in the interval [0,1). `fitrsvm` removes observations with large gradients, ensuring that `fitrsvm` removes the fraction of observations specified by `OutlierFraction` by the time convergence is reached. This name-value pair is only valid when 'Solver' is 'ISDA'.

Example: 'OutlierFraction',0.1

Data Types: `single` | `double`

RemoveDuplicates — Flag to replace duplicate observations with single observations

false (default) | true

Flag to replace duplicate observations with single observations in the training data, specified as the comma-separated pair consisting of 'RemoveDuplicates' and true or false.

If `RemoveDuplicates` is true, then `fitrsvm` replaces duplicate observations in the training data with a single observation of the same value. The weight of the single observation is equal to the sum of the weights of the corresponding removed duplicates (see `Weights`).

Tip If your data set contains many duplicate observations, then specifying 'RemoveDuplicates', true can decrease convergence time considerably.

Data Types: `logical`

Verbose — Verbosity level

0 (default) | 1 | 2

Verbosity level, specified as the comma-separated pair consisting of 'Verbose' and 0, 1, or 2. The value of `Verbose` controls the amount of optimization information that the software displays in the Command Window and saves the information as a structure to `Mdl.ConvergenceInfo.History`.

This table summarizes the available verbosity level options.

Value	Description
0	The software does not display or save convergence information.
1	The software displays diagnostic messages and saves convergence criteria every <code>numprint</code> iterations, where <code>numprint</code> is the value of the name-value pair argument <code>'NumPrint'</code> .
2	The software displays diagnostic messages and saves convergence criteria at every iteration.

Example: `'Verbose', 1`

Data Types: `double` | `single`

Other Regression Options

CategoricalPredictors – Categorical predictors list

vector of positive integers | logical vector | character matrix | string array | cell array of character vectors | `'all'`

Categorical predictors list, specified as the comma-separated pair consisting of `'CategoricalPredictors'` and one of the values in this table.

Value	Description
Vector of positive integers	An entry in the vector is the index value corresponding to the column of the predictor data (<code>X</code> or <code>Tbl</code>) that contains a categorical variable.
Logical vector	A <code>true</code> entry means that the corresponding column of predictor data (<code>X</code> or <code>Tbl</code>) is a categorical variable.
Character matrix	Each row of the matrix is the name of a predictor variable. The names must match the entries in <code>PredictorNames</code> . Pad the names with extra blanks so each row of the character matrix has the same length.
String array or cell array of character vectors	Each element in the array is the name of a predictor variable. The names must match the entries in <code>PredictorNames</code> .
<code>'all'</code>	All predictors are categorical.

By default, if the predictor data is in a table (`Tbl`), `fitrsvm` assumes that a variable is categorical if it contains logical values, categorical values, a string array, or a cell array of

character vectors. If the predictor data is a matrix (X), `fitrsvm` assumes all predictors are continuous. To identify any categorical predictors when the data is a matrix, use the `'CategoricalPredictors'` name-value pair argument.

Example: `'CategoricalPredictors','all'`

Data Types: `single` | `double` | `logical` | `char` | `string` | `cell`

PredictorNames — Predictor variable names

string array of unique names | cell array of unique character vectors

Predictor variable names, specified as the comma-separated pair consisting of `'PredictorNames'` and a string array of unique names or cell array of unique character vectors. The functionality of `'PredictorNames'` depends on the way you supply the training data.

- If you supply X and Y , then you can use `'PredictorNames'` to give the predictor variables in X names.
 - The order of the names in `PredictorNames` must correspond to the column order of X . That is, `PredictorNames{1}` is the name of $X(:,1)$, `PredictorNames{2}` is the name of $X(:,2)$, and so on. Also, `size(X,2)` and `numel(PredictorNames)` must be equal.
 - By default, `PredictorNames` is `{'x1','x2',...}`.
- If you supply `Tbl`, then you can use `'PredictorNames'` to choose which predictor variables to use in training. That is, `fitrsvm` uses only the predictor variables in `PredictorNames` and the response variable in training.
 - `PredictorNames` must be a subset of `Tbl.Properties.VariableNames` and cannot include the name of the response variable.
 - By default, `PredictorNames` contains the names of all predictor variables.
 - It is a good practice to specify the predictors for training using either `'PredictorNames'` or `formula` only.

Example: `'PredictorNames',
{'SepalLength','SepalWidth','PetalLength','PetalWidth'}`

Data Types: `string` | `cell`

ResponseName — Response variable name

`'Y'` (default) | character vector | string scalar

Response variable name, specified as the comma-separated pair consisting of 'ResponseName' and a character vector or string scalar.

- If you supply Y, then you can use 'ResponseName' to specify a name for the response variable.
- If you supply ResponseVarName or formula, then you cannot use 'ResponseName'.

Example: 'ResponseName', 'response'

Data Types: char | string

ResponseTransform — Response transformation

'none' (default) | function handle

Response transformation, specified as the comma-separated pair consisting of 'ResponseTransform' and either 'none' or a function handle. The default is 'none', which means $@(y)y$, or no transformation. For a MATLAB function or a function you define, use its function handle. The function handle must accept a vector (the original response values) and return a vector of the same size (the transformed response values).

Example: Suppose you create a function handle that applies an exponential transformation to an input vector by using `myfunction = @(y)exp(y)`. Then, you can specify the response transformation as 'ResponseTransform', myfunction.

Data Types: char | string | function_handle

Weights — Observation weights

`ones(size(X,1),1)` (default) | vector of numeric values

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a vector of numeric values. The size of Weights must equal the number of rows in X. fitrsvm normalizes the values of Weights to sum to 1.

Data Types: single | double

Cross-Validation Options

CrossVal — Cross-validation flag

'off' (default) | 'on'

Cross-validation flag, specified as the comma-separated pair consisting of 'CrossVal' and either 'on' or 'off'.

If you specify 'on', then the software implements 10-fold cross-validation.

To override this cross-validation setting, use one of these name-value pair arguments: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`. To create a cross-validated model, you can use one cross-validation name-value pair argument at a time only.

Alternatively, you can cross-validate the model later using the `crossval` method.

Example: `'CrossVal', 'on'`

CVPartition — Cross-validation partition

`[]` (default) | `cvpartition` partition object

Cross-validation partition, specified as the comma-separated pair consisting of `'CVPartition'` and a `cvpartition` partition object created by `cvpartition`. The partition object specifies the type of cross-validation and the indexing for the training and validation sets.

To create a cross-validated model, you can use one of these four name-value pair arguments only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: Suppose you create a random partition for 5-fold cross-validation on 500 observations by using `cvp = cvpartition(500, 'KFold', 5)`. Then, you can specify the cross-validated model by using `'CVPartition', cvp`.

Holdout — Fraction of data for holdout validation

scalar value in the range (0,1)

Fraction of the data used for holdout validation, specified as the comma-separated pair consisting of `'Holdout'` and a scalar value in the range (0,1). If you specify `'Holdout', p`, then the software completes these steps:

- 1 Randomly select and reserve $p \times 100\%$ of the data as validation data, and train the model using the rest of the data.
- 2 Store the compact, trained model in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: `'Holdout', 0.1`

Data Types: `double` | `single`

KFold — Number of folds

10 (default) | positive integer value greater than 1

Number of folds to use in a cross-validated model, specified as the comma-separated pair consisting of 'KFold' and a positive integer value greater than 1. If you specify 'KFold', k , then the software completes these steps:

- 1 Randomly partition the data into k sets.
- 2 For each set, reserve the set as validation data, and train the model using the other $k - 1$ sets.
- 3 Store the k compact, trained models in the cells of a k -by-1 cell vector in the Trained property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: CVPartition, Holdout, KFold, or Leaveout.

Example: 'KFold',5

Data Types: single | double

Leaveout — Leave-one-out cross-validation flag

'off' (default) | 'on'

Leave-one-out cross-validation flag, specified as the comma-separated pair consisting of 'Leaveout' and 'on' or 'off'. If you specify 'Leaveout', 'on', then, for each of the n observations (where n is the number of observations excluding missing observations, specified in the NumObservations property of the model), the software completes these steps:

- 1 Reserve the observation as validation data, and train the model using the other $n - 1$ observations.
- 2 Store the n compact, trained models in the cells of an n -by-1 cell vector in the Trained property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: CVPartition, Holdout, KFold, or Leaveout.

Example: 'Leaveout', 'on'

Convergence Controls

DeltaGradientTolerance — Tolerance for gradient difference

0 (default) | nonnegative scalar

Tolerance for gradient difference between upper and lower violators obtained by SMO or ISDA, specified as the comma-separated pair consisting of 'DeltaGradientTolerance' and a nonnegative scalar.

Example: 'DeltaGradientTolerance',1e-4

Data Types: single | double

GapTolerance — Feasibility gap tolerance

1e-3 (default) | nonnegative scalar

Feasibility gap tolerance obtained by SMO or ISDA, specified as the comma-separated pair consisting of 'GapTolerance' and a nonnegative scalar.

If `GapTolerance` is 0, then `fitrsvm` does not use this parameter to check convergence.

Example: 'GapTolerance',1e-4

Data Types: single | double

IterationLimit — Maximal number of numerical optimization iterations

1e6 (default) | positive integer

Maximal number of numerical optimization iterations, specified as the comma-separated pair consisting of 'IterationLimit' and a positive integer.

The software returns a trained model regardless of whether the optimization routine successfully converges. `Mdl.ConvergenceInfo` contains convergence information.

Example: 'IterationLimit',1e8

Data Types: double | single

KKTTolerance — Tolerance for KKT violation

0 | nonnegative scalar value

Tolerance for Karush-Kuhn-Tucker (KKT) violation, specified as the comma-separated pair consisting of 'KKTTolerance' and a nonnegative scalar value.

This name-value pair applies only if 'Solver' is 'SMO' or 'ISDA'.

If `KKTTolerance` is 0, then `fitrsvm` does not use this parameter to check convergence.

Example: 'KKTTolerance',1e-4

Data Types: single | double

ShrinkagePeriod — Number of iterations between reductions of active set

0 (default) | nonnegative integer

Number of iterations between reductions of the active set, specified as the comma-separated pair consisting of 'ShrinkagePeriod' and a nonnegative integer.

If you set 'ShrinkagePeriod', 0, then the software does not shrink the active set.

Example: 'ShrinkagePeriod', 1000

Data Types: double | single

Hyperparameter Optimization**OptimizeHyperparameters — Parameters to optimize**

'none' (default) | 'auto' | 'all' | string array or cell array of eligible parameter names | vector of `optimizableVariable` objects

Parameters to optimize, specified as the comma-separated pair consisting of 'OptimizeHyperparameters' and one of the following:

- 'none' — Do not optimize.
- 'auto' — Use {'BoxConstraint', 'KernelScale', 'Epsilon'}.
- 'all' — Optimize all eligible parameters.
- String array or cell array of eligible parameter names.
- Vector of `optimizableVariable` objects, typically the output of hyperparameters.

The optimization attempts to minimize the cross-validation loss (error) for `fitrsvm` by varying the parameters. To control the cross-validation type and other aspects of the optimization, use the `HyperparameterOptimizationOptions` name-value pair.

Note 'OptimizeHyperparameters' values override any values you set using other name-value pair arguments. For example, setting 'OptimizeHyperparameters' to 'auto' causes the 'auto' values to apply.

The eligible parameters for `fitrsvm` are:

- `BoxConstraint` — `fitrsvm` searches among positive values, by default log-scaled in the range [1e-3, 1e3].

- `KernelScale` — `fitrsvm` searches among positive values, by default log-scaled in the range `[1e-3,1e3]`.
- `Epsilon` — `fitrsvm` searches among positive values, by default log-scaled in the range `[1e-3,1e2]*iqr(Y)/1.349`.
- `KernelFunction` — `fitrsvm` searches among 'gaussian', 'linear', and 'polynomial'.
- `PolynomialOrder` — `fitrsvm` searches among integers in the range `[2,4]`.
- `Standardize` — `fitrsvm` searches among 'true' and 'false'.

Set nondefault parameters by passing a vector of `optimizableVariable` objects that have nondefault values. For example,

```
load carsmall
params = hyperparameters('fitrsvm',[Horsepower,Weight],MPG);
params(1).Range = [1e-4,1e6];
```

Pass `params` as the value of `OptimizeHyperparameters`.

By default, iterative display appears at the command line, and plots appear according to the number of hyperparameters in the optimization. For the optimization and plots, the objective function is $\log(1 + \text{cross-validation loss})$ for regression and the misclassification rate for classification. To control the iterative display, set the `Verbose` field of the 'HyperparameterOptimizationOptions' name-value pair argument. To control the plots, set the `ShowPlots` field of the 'HyperparameterOptimizationOptions' name-value pair argument.

For an example, see “Optimize SVM Regression” on page 32-2601.

Example: 'OptimizeHyperparameters','auto'

HyperparameterOptimizationOptions — Options for optimization

structure

Options for optimization, specified as the comma-separated pair consisting of 'HyperparameterOptimizationOptions' and a structure. This argument modifies the effect of the `OptimizeHyperparameters` name-value pair argument. All fields in the structure are optional.

Field Name	Values	Default
Optimizer	<ul style="list-style-type: none"> • 'bayesopt' — Use Bayesian optimization. Internally, this setting calls bayesopt. • 'gridsearch' — Use grid search with NumGridDivisions values per dimension. • 'randomsearch' — Search at random among MaxObjectiveEvaluations points. <p>'gridsearch' searches in a random order, using uniform sampling without replacement from the grid. After optimization, you can get a table in grid order by using the command <code>sortrows(Mdl.HyperparameterOptimizationResults)</code>.</p>	'bayesopt'
AcquisitionFunctionName	<ul style="list-style-type: none"> • 'expected-improvement-per-second-plus' • 'expected-improvement' • 'expected-improvement-plus' • 'expected-improvement-per-second' • 'lower-confidence-bound' • 'probability-of-improvement' <p>Acquisition functions whose names include <code>per-second</code> do not yield reproducible results because the optimization depends on the runtime of the objective function. Acquisition functions whose names include <code>plus</code> modify their behavior when they are overexploiting an area. For more details, see “Acquisition Function Types” on page 10-4.</p>	'expected-improvement-per-second-plus'

Field Name	Values	Default
MaxObjectiveEvaluations	Maximum number of objective function evaluations.	30 for 'bayesopt' or 'randomsearch', and the entire grid for 'gridsearch'
MaxTime	Time limit, specified as a positive real. The time limit is in seconds, as measured by tic and toc. Run time can exceed MaxTime because MaxTime does not interrupt function evaluations.	Inf
NumGridDivisions	For 'gridsearch', the number of values in each dimension. The value can be a vector of positive integers giving the number of values for each dimension, or a scalar that applies to all dimensions. This field is ignored for categorical variables.	10
ShowPlots	Logical value indicating whether to show plots. If true, this field plots the best objective function value against the iteration number. If there are one or two optimization parameters, and if Optimizer is 'bayesopt', then ShowPlots also plots a model of the objective function against the parameters.	true
SaveIntermediateResults	Logical value indicating whether to save results when Optimizer is 'bayesopt'. If true, this field overwrites a workspace variable named 'BayesoptResults' at each iteration. The variable is a BayesianOptimization object.	false

Field Name	Values	Default
Verbose	Display to the command line. <ul style="list-style-type: none"> • 0 — No iterative display • 1 — Iterative display • 2 — Iterative display with extra information For details, see the <code>bayesopt</code> <code>Verbose</code> name-value pair argument.	1
UseParallel	Logical value indicating whether to run Bayesian optimization in parallel, which requires Parallel Computing Toolbox. For details, see “Parallel Bayesian Optimization” on page 10-8.	false
Repartition	Logical value indicating whether to repartition the cross-validation at every iteration. If <code>false</code> , the optimizer uses a single partition for the optimization. <code>true</code> usually gives the most robust results because this setting takes partitioning noise into account. However, for good results, <code>true</code> requires at least twice as many function evaluations.	false
Use no more than one of the following three field names.		
CVPartition	A <code>cvpartition</code> object, as created by <code>cvpartition</code> .	'Kfold', 5 if you do not specify any cross-validation field
Holdout	A scalar in the range (0, 1) representing the holdout fraction.	
Kfold	An integer greater than 1.	

Example:

```
'HyperparameterOptimizationOptions', struct('MaxObjectiveEvaluations', 60)
```

Data Types: struct

Output Arguments

Mdl — Trained SVM regression model

RegressionSVM model | RegressionPartitionedSVM cross-validated model

Trained SVM regression model, returned as a RegressionSVM model or RegressionPartitionedSVM cross-validated model.

If you set any of the name-value pair arguments KFold, Holdout, Leaveout, CrossVal, or CVPartition, then Mdl is a RegressionPartitionedSVM cross-validated model. Otherwise, Mdl is a RegressionSVM model.

Limitations

fitrsvm supports low- through moderate-dimensional data sets. For high-dimensional data set, use fitrlinear instead.

Tips

- Unless your data set is large, always try to standardize the predictors (see Standardize). Standardization makes predictors insensitive to the scales on which they are measured.
- It is good practice to cross-validate using the KFold name-value pair argument. The cross-validation results determine how well the SVM model generalizes.
- Sparsity in support vectors is a desirable property of an SVM model. To decrease the number of support vectors, set the BoxConstraint name-value pair argument to a large value. This action also increases the training time.
- For optimal training time, set CacheSize as high as the memory limit on your computer allows.
- If you expect many fewer support vectors than observations in the training set, then you can significantly speed up convergence by shrinking the active-set using the name-value pair argument 'ShrinkagePeriod'. It is good practice to use 'ShrinkagePeriod', 1000.
- Duplicate observations that are far from the regression line do not affect convergence. However, just a few duplicate observations that occur near the regression line can

slow down convergence considerably. To speed up convergence, specify 'RemoveDuplicates', true if:

- Your data set contains many duplicate observations.
- You suspect that a few duplicate observations can fall near the regression line.

However, to maintain the original data set during training, `fittersvm` must temporarily store separate data sets: the original and one without the duplicate observations. Therefore, if you specify `true` for data sets containing few duplicates, then `fittersvm` consumes close to double the memory of the original data.

- After training a model, you can generate C/C++ code that predicts responses for new data. Generating C/C++ code requires MATLAB Coder. For details, see “Introduction to Code Generation” on page 31-2.

Algorithms

- For the mathematical formulation of linear and nonlinear SVM regression problems and the solver algorithms, see “Understanding Support Vector Machine Regression” on page 25-2.
- NaN, <undefined>, empty character vector (' '), empty string (""), and <missing> values indicate missing data values. `fittersvm` removes entire rows of data corresponding to a missing response. When normalizing weights, `fittersvm` ignores any weight corresponding to an observation with at least one missing predictor. Consequently, observation box constraints might not equal `BoxConstraint`.
- `fittersvm` removes observations that have zero weight.
- If you set 'Standardize', true and 'Weights', then `fittersvm` standardizes the predictors using their corresponding weighted means and weighted standard deviations. That is, `fittersvm` standardizes predictor j (x_j) using

$$x_j^* = \frac{x_j - \mu_j^*}{\sigma_j^*}.$$

- $$\mu_j^* = \frac{1}{\sum_k w_k} \sum_k w_k x_{jk}.$$

- x_{jk} is observation k (row) of predictor j (column).

- $(\sigma_j^*)^2 = \frac{v_1}{v_1^2 - v_2} \sum_k w_k (x_{jk} - \mu_j^*)^2$.
- $v_1 = \sum_j w_j$.
- $v_2 = \sum_j (w_j)^2$.
- If your predictor data contains categorical variables, then the software generally uses full dummy encoding for these variables. The software creates one dummy variable for each level of each categorical variable.
 - The `PredictorNames` property stores one element for each of the original predictor variable names. For example, assume that there are three predictors, one of which is a categorical variable with three levels. Then `PredictorNames` is a 1-by-3 cell array of character vectors containing the original names of the predictor variables.
 - The `ExpandedPredictorNames` property stores one element for each of the predictor variables, including the dummy variables. For example, assume that there are three predictors, one of which is a categorical variable with three levels. Then `ExpandedPredictorNames` is a 1-by-5 cell array of character vectors containing the names of the predictor variables and the new dummy variables.
 - Similarly, the `Beta` property stores one beta coefficient for each predictor, including the dummy variables.
 - The `SupportVectors` property stores the predictor values for the support vectors, including the dummy variables. For example, assume that there are m support vectors and three predictors, one of which is a categorical variable with three levels. Then `SupportVectors` is an m -by-5 matrix.
 - The `X` property stores the training data as originally input. It does not include the dummy variables. When the input is a table, `X` contains only the columns used as predictors.
- For predictors specified in a table, if any of the variables contain ordered (ordinal) categories, the software uses ordinal encoding for these variables.
 - For a variable having k ordered levels, the software creates $k - 1$ dummy variables. The j th dummy variable is -1 for levels up to j , and +1 for levels $j + 1$ through k .
 - The names of the dummy variables stored in the `ExpandedPredictorNames` property indicate the first level with the value +1. The software stores $k - 1$ additional predictor names for the dummy variables, including the names of levels 2, 3, ..., k .

- All solvers implement $L1$ soft-margin minimization.
- Let p be the proportion of outliers that you expect in the training data. If you set 'OutlierFraction', p , then the software implements robust learning. In other words, the software attempts to remove $100p\%$ of the observations when the optimization algorithm converges. The removed observations correspond to gradients that are large in magnitude.

Extended Capabilities

Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the `'UseParallel'` option to `true`.

To perform parallel hyperparameter optimization, use the `'HyperparameterOptions'`, `struct('UseParallel',true)` name-value pair argument in the call to this function.

For more information on parallel hyperparameter optimization, see “Parallel Bayesian Optimization” on page 10-8.

For more general information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

Topics

“Understanding Support Vector Machine Regression” on page 25-2

Introduced in R2015b

fitree

Fit binary decision tree for regression

Syntax

```
tree = fitree(Tbl,ResponseVarName)
tree = fitree(Tbl,formula)
tree = fitree(Tbl,Y)

tree = fitree(X,Y)

tree = fitree( ____,Name,Value)
```

Description

`tree = fitree(Tbl,ResponseVarName)` returns a regression tree based on the input variables (also known as predictors, features, or attributes) in the table `Tbl` and the output (response) contained in `Tbl.ResponseVarName`. The returned `tree` is a binary tree where each branching node is split based on the values of a column of `Tbl`.

`tree = fitree(Tbl,formula)` returns a regression tree based on the input variables contained in the table `Tbl`. The input `formula` is an explanatory model of the response and a subset of predictor variables in `Tbl` used to fit `tree`.

`tree = fitree(Tbl,Y)` returns a regression tree based on the input variables contained in the table `Tbl` and the output in vector `Y`.

`tree = fitree(X,Y)` returns a regression tree based on the input variables `X` and the output `Y`. The returned `tree` is a binary tree where each branching node is split based on the values of a column of `X`.

`tree = fitree(____,Name,Value)` specifies options using one or more name-value pair arguments in addition to any of the input argument combinations in previous syntaxes. For example, you can specify observation weights or train a cross-validated model.

Examples

Construct Regression Tree

Load the sample data.

```
load carsmall
```

Construct a regression tree using the sample data. The response variable is miles per gallon, MPG.

```
tree = fitrtree([Weight, Cylinders],MPG,...  
               'CategoricalPredictors',2,'MinParentSize',20,...  
               'PredictorNames',{'W','C'})
```

```
tree =  
  RegressionTree  
    PredictorNames: {'W' 'C'}  
    ResponseName: 'Y'  
  CategoricalPredictors: 2  
    ResponseTransform: 'none'  
    NumObservations: 94
```

Properties, Methods

Predict the mileage of 4,000-pound cars with 4, 6, and 8 cylinders.

```
MPG4Kpred = predict(tree,[4000 4; 4000 6; 4000 8])
```

```
MPG4Kpred = 3×1
```

```
19.2778  
19.2778  
14.3889
```

Control Regression Tree Depth

`fitrtree` grows deep decision trees by default. You can grow shallower trees to reduce model complexity or computation time. To control the depth of trees, use the 'MaxNumSplits', 'MinLeafSize', or 'MinParentSize' name-value pair arguments.

Load the `carsmall` data set. Consider Displacement, Horsepower, and Weight as predictors of the response MPG.

```
load carsmall
X = [Displacement Horsepower Weight];
```

The default values of the tree-depth controllers for growing regression trees are:

- `n - 1` for `MaxNumSplits`. `n` is the training sample size.
- `1` for `MinLeafSize`.
- `10` for `MinParentSize`.

These default values tend to grow deep trees for large training sample sizes.

Train a regression tree using the default values for tree-depth control. Cross-validate the model using 10-fold cross-validation.

```
rng(1); % For reproducibility
MdlDefault = fitrtree(X,MPG,'CrossVal','on');
```

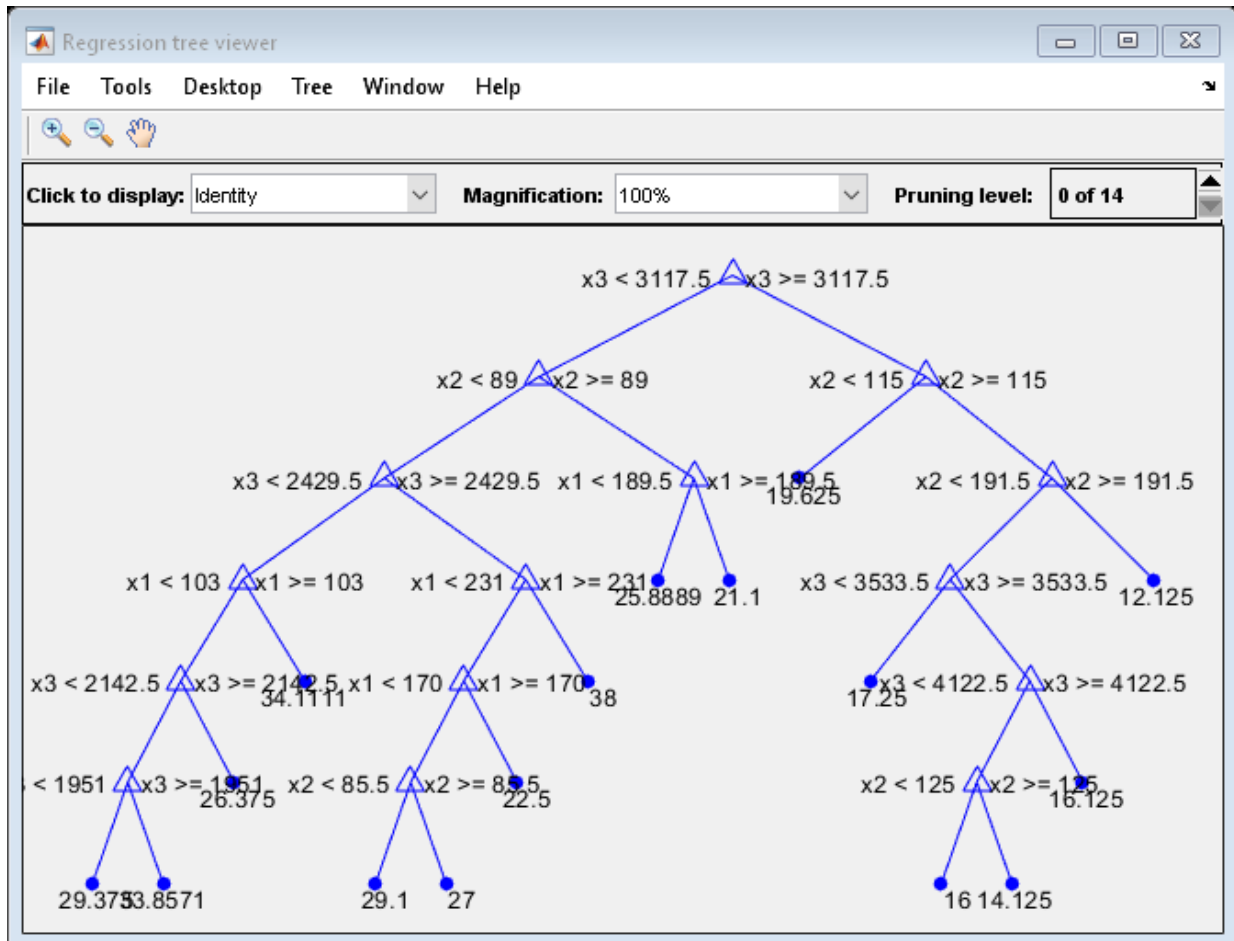

Draw a histogram of the number of imposed splits on the trees. The number of imposed splits is one less than the number of leaves. Also, view one of the trees.

```
numBranches = @(x)sum(x.IsBranch);
mdlDefaultNumSplits = cellfun(numBranches, MdlDefault.Trained);

figure;
histogram(mdlDefaultNumSplits)
```

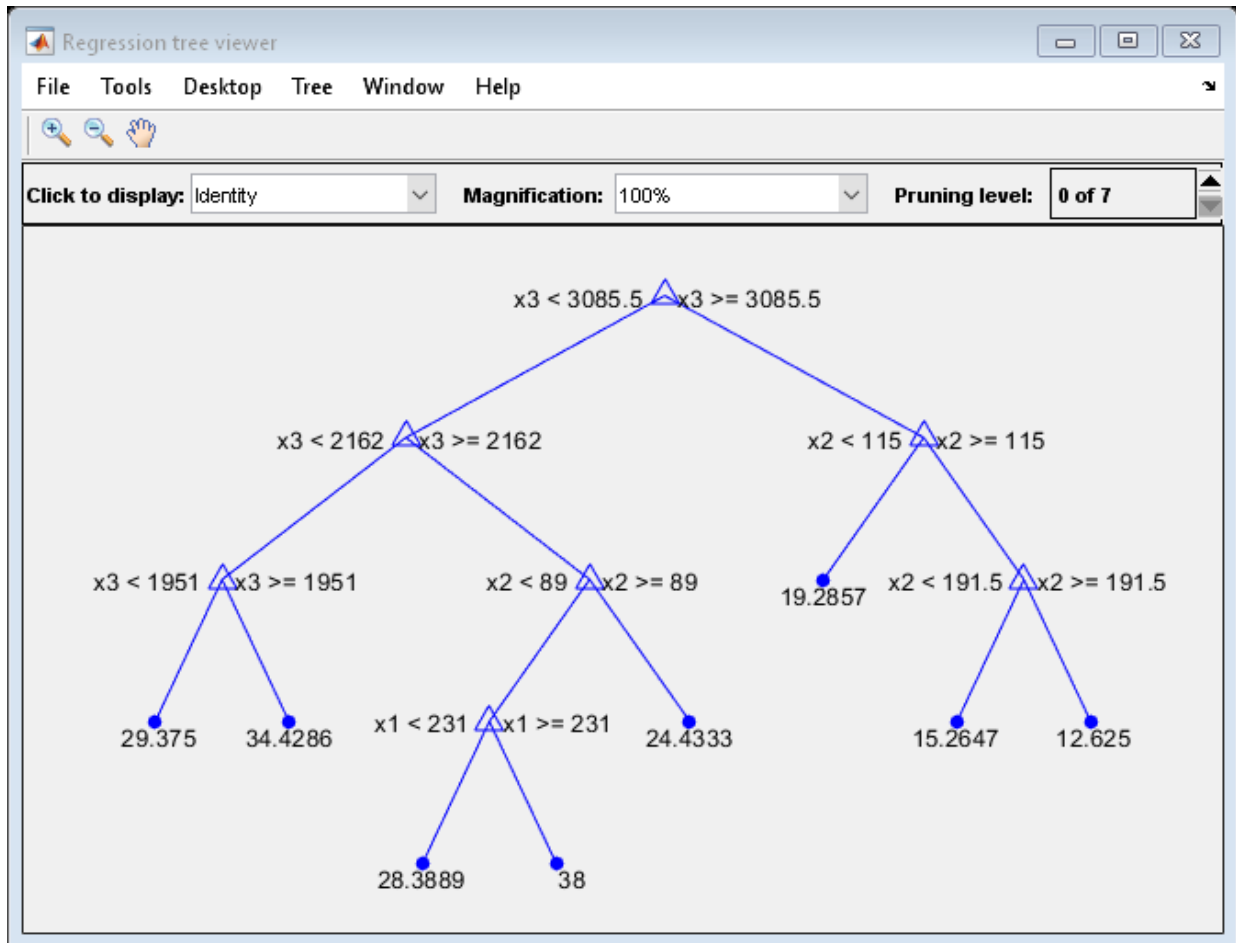

```
view(MdlDefault.Trained{1}, 'Mode', 'graph')
```

The average number of splits is between 14 and 15.

Suppose that you want a regression tree that is not as complex (deep) as the ones trained using the default number of splits. Train another regression tree, but set the maximum number of splits at 7, which is about half the mean number of splits from the default regression tree. Cross-validate the model using 10-fold cross-validation.

```
Mdl7 = fitree(X,MPG,'MaxNumSplits',7,'CrossVal','on');
view(Mdl7.Trained{1},'Mode','graph')
```

Compare the cross-validation mean squared errors (MSEs) of the models.

```
mseDefault = kfoldLoss(MdlDefault)
```

```
mseDefault = 25.7383
```

```
mse7 = kfoldLoss(Mdl7)
```

```
mse7 = 26.5031
```

`Mdl7` is much less complex and performs only slightly worse than `MdlDefault`.

Optimize Regression Tree

Optimize hyperparameters automatically using `fitrtree`.

Load the `carsmall` data set.

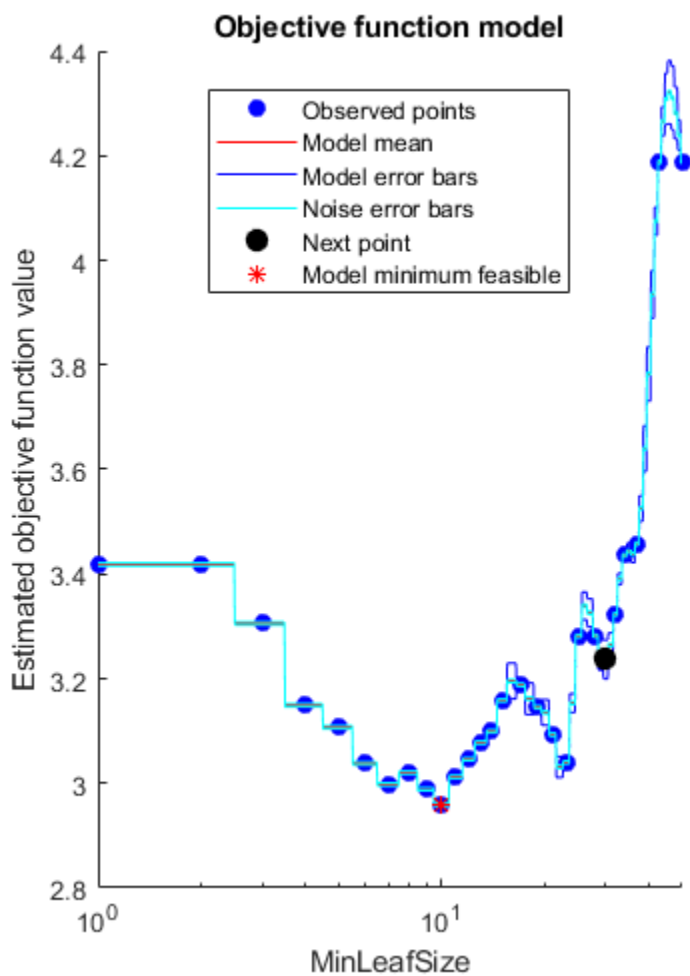

```
load carsmall
```

Use `Weight` and `Horsepower` as predictors for `MPG`. Find hyperparameters that minimize five-fold cross-validation loss by using automatic hyperparameter optimization.

For reproducibility, set the random seed and use the `'expected-improvement-plus'` acquisition function.

```
X = [Weight,Horsepower];  
Y = MPG;  
rng default  
Mdl = fitrtree(X,Y,'OptimizeHyperparameters','auto',...  
              'HyperparameterOptimizationOptions',struct('AcquisitionFunctionName',...  
                  'expected-improvement-plus'))
```

Iter	Eval result	Objective	Objective runtime	BestSoFar (observed)	BestSoFar (estim.)	MinLeafSize
1	Best	3.2818	0.37635	3.2818	3.2818	28
2	Accept	3.4183	0.15787	3.2818	3.2888	1

Unbiased Predictor Importance Estimates

Load the `carsmall` data set. Consider a model that predicts the mean fuel economy of a car given its acceleration, number of cylinders, engine displacement, horsepower, manufacturer, model year, and weight. Consider `Cylinders`, `Mfg`, and `Model_Year` as categorical variables.

```
load carsmall
Cylinders = categorical(Cylinders);
Mfg = categorical(cellstr(Mfg));
Model_Year = categorical(Model_Year);
X = table(Acceleration,Cylinders,Displacement,Horsepower,Mfg,...
          Model_Year,Weight,MPG);
```

Display the number of categories represented in the categorical variables.

```
numCylinders = numel(categories(Cylinders))
numCylinders = 3
numMfg = numel(categories(Mfg))
numMfg = 28
numModelYear = numel(categories(Model_Year))
numModelYear = 3
```

Because there are 3 categories only in `Cylinders` and `Model_Year`, the standard CART, predictor-splitting algorithm prefers splitting a continuous predictor over these two variables.

Train a regression tree using the entire data set. To grow unbiased trees, specify usage of the curvature test for splitting predictors. Because there are missing values in the data, specify usage of surrogate splits.

```
Mdl = fitrtree(X, 'MPG', 'PredictorSelection', 'curvature', 'Surrogate', 'on');
```

Estimate predictor importance values by summing changes in the risk due to splits on every predictor and dividing the sum by the number of branch nodes. Compare the estimates using a bar graph.

```
imp = predictorImportance(Mdl);

figure;
bar(imp);
title('Predictor Importance Estimates');
ylabel('Estimates');
xlabel('Predictors');
h = gca;
h.XTickLabel = Mdl.PredictorNames;
h.XTickLabelRotation = 45;
h.TickLabelInterpreter = 'none';
```

In this case, Displacement is the most important predictor, followed by Horsepower.

Control Maximum Tree Depth on Tall Array

`fitree` grows deep decision trees by default. Build a shallower tree that requires fewer passes through a tall array. Use the 'MaxDepth' name-value pair argument to control the maximum tree depth.

Load the `carsmall` data set. Consider Displacement, Horsepower, and Weight as predictors of the response MPG.

```
load carsmall
X = [Displacement Horsepower Weight];
```

Convert the in-memory arrays X and MPG to tall arrays.

```
tx = tall(X);
```

```
Starting parallel pool (parpool) using the 'local' profile ...
Connected to the parallel pool (number of workers: 6).
```

```
ty = tall(MPG);
```

When you execute calculations on tall arrays, the default execution environment uses either the local MATLAB session or a local parallel pool (if you have Parallel Computing Toolbox™). You can use the `mapreducer` function to change the execution environment. In this case, the example uses the default environment.

Grow a regression tree using all observations. Allow the tree to grow to the maximum possible depth.

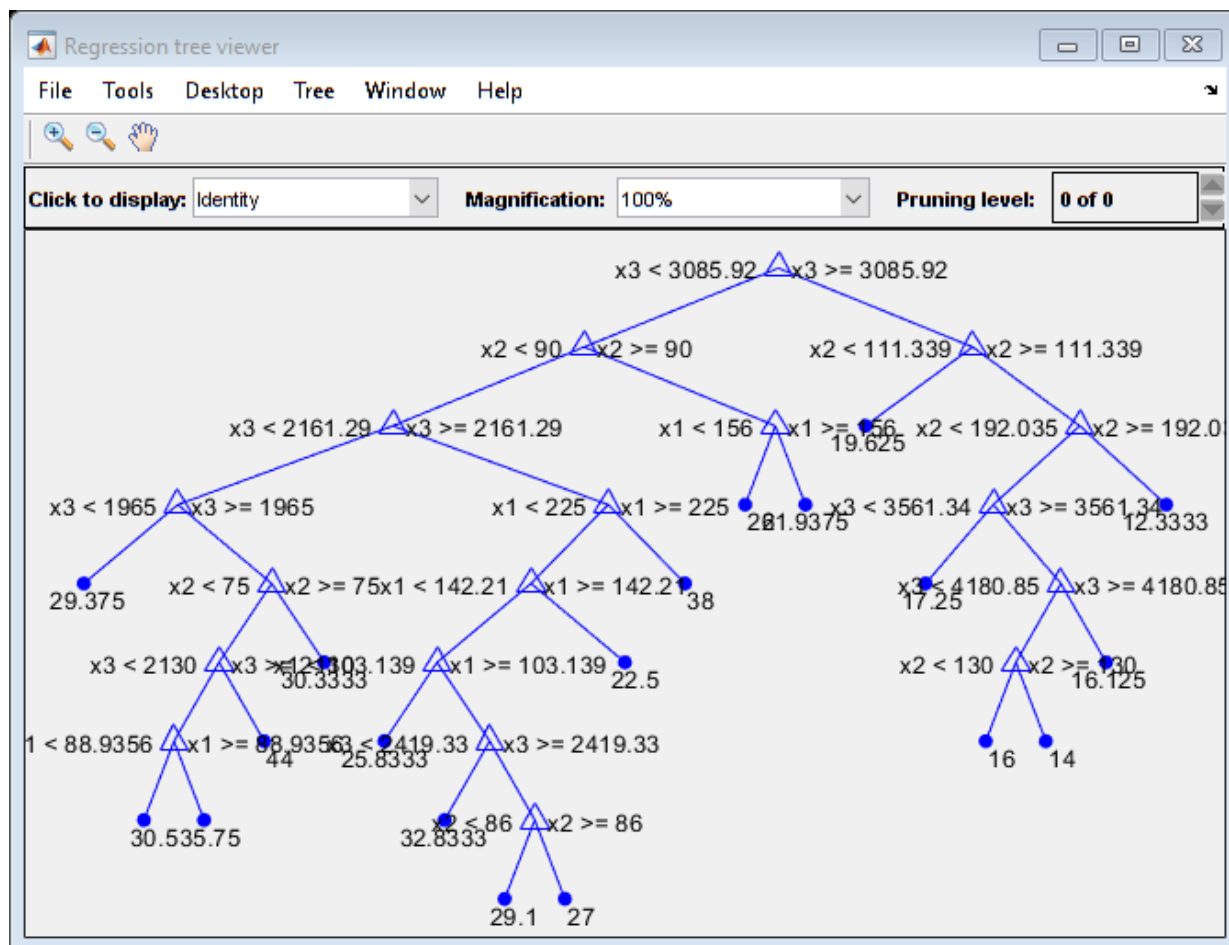

For reproducibility, set the seeds of the random number generators using `rng` and `tallrng`. The results can vary depending on the number of workers and the execution environment for the tall arrays. For details, see “Control Where Your Code Runs” (MATLAB).

```
rng('default')
tallrng('default')
Mdl = fitrtree(tx,ty);
```

```

```

View the trained tree Md1.

```
view(Md1, 'Mode', 'graph')
```

Md1 is a tree of depth 8.

Estimate the in-sample mean squared error.

```
MSE_Md1 = loss(Md1, tx, ty)
```

```
MSE_Md1 =
```

```
tall double
```

```
4.9078
```

Grow a regression tree using all observations. Limit the tree depth by specifying a maximum tree depth of 4.

```
Mdl2 = fitrtree(tx,ty, 'MaxDepth',4);
```

```
Evaluating tall expression using the Parallel Pool 'local':
```

```
Evaluation completed in 0.49 sec
```

```

```

```
Evaluating tall expression using the Parallel Pool 'local':
```

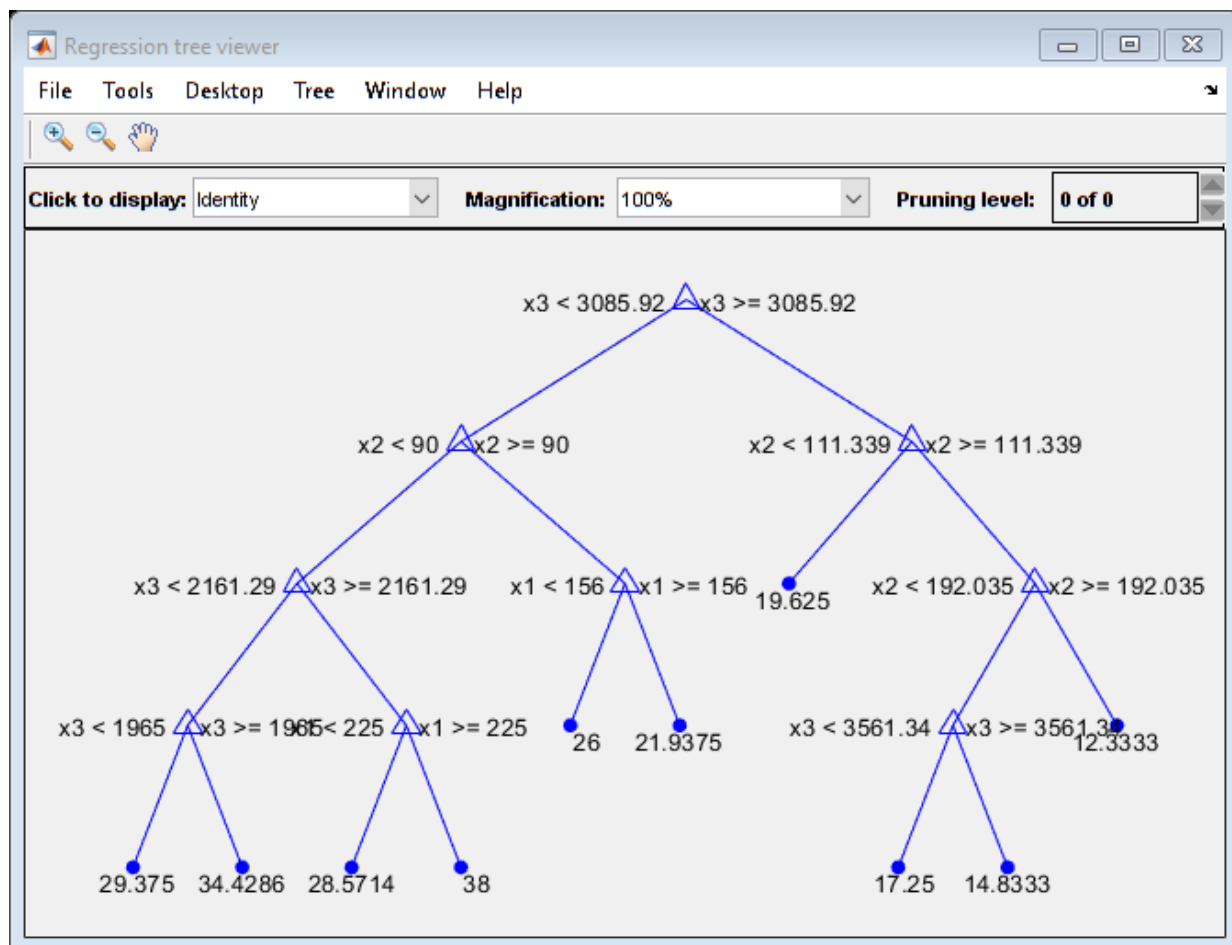

```
Evaluation completed in 0.47 sec
```

```
Evaluating tall expression using the Parallel Pool 'local':
```

```
Evaluation completed in 0.47 sec
```

View the trained tree Mdl2.

```
view(Mdl2, 'Mode', 'graph')
```

Estimate the in-sample mean squared error.

```
MSE_Mdl2 = loss(Mdl2, tx, ty)
```

```
MSE_Mdl2 =
```

```
    tall double
```

```
    9.3903
```

Mdl2 is a less complex tree with a depth of 4 and an in-sample mean squared error that is higher than the mean squared error of Mdl.

Optimize Regression Tree on Tall Array

Optimize hyperparameters of a regression tree automatically using a tall array. The sample data set is the `carsmall` data set. This example converts the data set to a tall array and uses it to run the optimization procedure.

Load the `carsmall` data set. Consider `Displacement`, `Horsepower`, and `Weight` as predictors of the response `MPG`.

```
load carsmall
X = [Displacement Horsepower Weight];
```

Convert the in-memory arrays `X` and `MPG` to tall arrays.

```
tx = tall(X);
```

```
Starting parallel pool (parpool) using the 'local' profile ...
Connected to the parallel pool (number of workers: 6).
```

```
ty = tall(MPG);
```

When you execute calculations on tall arrays, the default execution environment uses either the local MATLAB session or a local parallel pool (if you have Parallel Computing Toolbox™). You can use the `mapreducer` function to change the execution environment. In this case, the example uses the default environment.

Optimize hyperparameters automatically using the `'OptimizeHyperparameters'` name-value pair argument. Find the optimal `'MinLeafSize'` value that minimizes holdout cross-validation loss. (Specifying `'auto'` uses `'MinLeafSize'`.) For reproducibility, use the `'expected-improvement-plus'` acquisition function and set the seeds of the random number generators using `rng` and `tallrng`. The results can vary depending on the number of workers and the execution environment for the tall arrays. For details, see “Control Where Your Code Runs” (MATLAB).

```
rng('default')
tallrng('default')
[Mdl,FitInfo,HyperparameterOptimizationResults] = fitrtree(tx,ty,...
    'OptimizeHyperparameters','auto',...
```

```
'HyperparameterOptimizationOptions',struct('Holdout',0.3,...  
'AcquisitionFunctionName','expected-improvement-plus'))
```

Input Arguments

Tbl — Sample data

table

Sample data used to train the model, specified as a table. Each row of `Tbl` corresponds to one observation, and each column corresponds to one predictor variable. Optionally, `Tbl` can contain one additional column for the response variable. Multicolumn variables and cell arrays other than cell arrays of character vectors are not allowed.

If `Tbl` contains the response variable, and you want to use all remaining variables in `Tbl` as predictors, then specify the response variable by using `ResponseVarName`.

If `Tbl` contains the response variable, and you want to use only a subset of the remaining variables in `Tbl` as predictors, then specify a formula by using `formula`.

If `Tbl` does not contain the response variable, then specify a response variable by using `Y`. The length of the response variable and the number of rows in `Tbl` must be equal.

Data Types: `table`

ResponseVarName — Response variable name

name of variable in `Tbl`

Response variable name, specified as the name of a variable in `Tbl`. The response variable must be a numeric vector.

You must specify `ResponseVarName` as a character vector or string scalar. For example, if `Tbl` stores the response variable `Y` as `Tbl.Y`, then specify it as `'Y'`. Otherwise, the software treats all columns of `Tbl`, including `Y`, as predictors when training the model.

Data Types: `char` | `string`

formula — Explanatory model of response and subset of predictor variables

character vector | string scalar

Explanatory model of the response and a subset of the predictor variables, specified as a character vector or string scalar in the form `'Y~X1+X2+X3'`. In this form, `Y` represents the response variable, and `X1`, `X2`, and `X3` represent the predictor variables. The variables must be variable names in `Tbl` (`Tbl.Properties.VariableNames`).

To specify a subset of variables in `Tbl` as predictors for training the model, use a formula. If you specify a formula, then the software does not use any variables in `Tbl` that do not appear in `formula`.

Data Types: `char` | `string`

Y — Response data

numeric column vector

Response data, specified as a numeric column vector with the same number of rows as `X`. Each entry in `Y` is the response to the data in the corresponding row of `X`.

The software considers NaN values in `Y` to be missing values. `fitrtree` does not use observations with missing values for `Y` in the fit.

Data Types: `single` | `double`

X — Predictor data

numeric matrix

Predictor data, specified as a numeric matrix. Each column of `X` represents one variable, and each row represents one observation.

`fitrtree` considers NaN values in `X` as missing values. `fitrtree` does not use observations with all missing values for `X` in the fit. `fitrtree` uses observations with some missing values for `X` to find splits on variables for which these observations have valid values.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Note You cannot use any cross-validation name-value pair argument along with the `'OptimizeHyperparameters'` name-value pair argument. You can modify the cross-validation for `'OptimizeHyperparameters'` only by using the `'HyperparameterOptimizationOptions'` name-value pair argument.

Example: 'CrossVal', 'on', 'MinParentSize', 30 specifies a cross-validated regression tree with a minimum of 30 observations per branch node.

Model Parameters

CategoricalPredictors — Categorical predictors list

vector of positive integers | logical vector | character matrix | string array | cell array of character vectors | 'all'

Categorical predictors list, specified as the comma-separated pair consisting of 'CategoricalPredictors' and one of the values in this table.

Value	Description
Vector of positive integers	An entry in the vector is the index value corresponding to the column of the predictor data (<i>X</i> or <i>Tbl</i>) that contains a categorical variable.
Logical vector	A <code>true</code> entry means that the corresponding column of predictor data (<i>X</i> or <i>Tbl</i>) is a categorical variable.
Character matrix	Each row of the matrix is the name of a predictor variable. The names must match the entries in <code>PredictorNames</code> . Pad the names with extra blanks so each row of the character matrix has the same length.
String array or cell array of character vectors	Each element in the array is the name of a predictor variable. The names must match the entries in <code>PredictorNames</code> .
'all'	All predictors are categorical.

By default, if the predictor data is in a table (*Tbl*), `fitrtree` assumes that a variable is categorical if it contains logical values, categorical values, a string array, or a cell array of character vectors. If the predictor data is a matrix (*X*), `fitrtree` assumes all predictors are continuous. To identify any categorical predictors when the data is a matrix, use the 'CategoricalPredictors' name-value pair argument.

Example: 'CategoricalPredictors', 'all'

Data Types: `single` | `double` | `logical` | `char` | `string` | `cell`

MaxDepth — Maximum tree depth

positive integer

Maximum tree depth, specified as the comma-separated pair consisting of 'MaxDepth' and a positive integer. Specify a value for this argument to return a tree that has fewer levels and requires fewer passes through the tall array to compute. Generally, the algorithm of `fitrtree` takes one pass through the data and an additional pass for each tree level. The function does not set a maximum tree depth, by default.

Note This option applies only when you use `fitrtree` on tall arrays. See Tall Arrays on page 32-2686 for more information.

MergeLeaves — Leaf merge flag

'on' (default) | 'off'

Leaf merge flag, specified as the comma-separated pair consisting of 'MergeLeaves' and 'on' or 'off'.

If `MergeLeaves` is 'on', then `fitrtree`:

- Merges leaves that originate from the same parent node and yield a sum of risk values greater than or equal to the risk associated with the parent node
- Estimates the optimal sequence of pruned subtrees, but does not prune the regression tree

Otherwise, `fitrtree` does not merge leaves.

Example: 'MergeLeaves', 'off'

MinParentSize — Minimum number of branch node observations

10 (default) | positive integer value

Minimum number of branch node observations, specified as the comma-separated pair consisting of 'MinParentSize' and a positive integer value. Each branch node in the tree has at least `MinParentSize` observations. If you supply both `MinParentSize` and `MinLeafSize`, `fitrtree` uses the setting that gives larger leaves: `MinParentSize = max(MinParentSize, 2*MinLeafSize)`.

Example: 'MinParentSize', 8

Data Types: single | double

NumBins — Number of bins for numeric predictors

[] (empty) (default) | positive integer scalar

Number of bins for numeric predictors, specified as the comma-separated pair consisting of 'NumBins' and a positive integer scalar.

- If the 'NumBins' value is empty (default), then the software does not bin any predictors.
- If you specify the 'NumBins' value as a positive integer scalar, then the software bins every numeric predictor into a specified number of equiprobable bins, and then grows trees on the bin indices instead of the original data.
 - If the 'NumBins' value exceeds the number (u) of unique values for a predictor, then `fitrtree` bins the predictor into u bins.
 - `fitrtree` does not bin categorical predictors.

When you use a large training data set, this binning option speeds up training but causes a potential decrease in accuracy. You can try 'NumBins', 50 first, and then change the 'NumBins' value depending on the accuracy and training speed.

A trained model stores the bin edges in the `BinEdges` property.

Example: 'NumBins', 50

Data Types: single | double

PredictorNames — Predictor variable names

string array of unique names | cell array of unique character vectors

Predictor variable names, specified as the comma-separated pair consisting of 'PredictorNames' and a string array of unique names or cell array of unique character vectors. The functionality of 'PredictorNames' depends on the way you supply the training data.

- If you supply `X` and `Y`, then you can use 'PredictorNames' to give the predictor variables in `X` names.
 - The order of the names in `PredictorNames` must correspond to the column order of `X`. That is, `PredictorNames{1}` is the name of `X(:,1)`, `PredictorNames{2}` is the name of `X(:,2)`, and so on. Also, `size(X,2)` and `numel(PredictorNames)` must be equal.
 - By default, `PredictorNames` is `{'x1', 'x2', ...}`.
- If you supply `Tbl`, then you can use 'PredictorNames' to choose which predictor variables to use in training. That is, `fitrtree` uses only the predictor variables in `PredictorNames` and the response variable in training.

- `PredictorNames` must be a subset of `Tbl.Properties.VariableNames` and cannot include the name of the response variable.
- By default, `PredictorNames` contains the names of all predictor variables.
- It is a good practice to specify the predictors for training using either `'PredictorNames'` or formula only.

Example: `'PredictorNames'`,
`{'SepalLength', 'SepalWidth', 'PetalLength', 'PetalWidth'}`

Data Types: `string` | `cell`

PredictorSelection — Algorithm used to select the best split predictor

`'allsplits'` (default) | `'curvature'` | `'interaction-curvature'`

Algorithm used to select the best split predictor at each node, specified as the comma-separated pair consisting of `'PredictorSelection'` and a value in this table.

Value	Description
<code>'allsplits'</code>	Standard CART — Selects the split predictor that maximizes the split-criterion gain over all possible splits of all predictors [1].
<code>'curvature'</code>	Curvature test on page 32-2678 — Selects the split predictor that minimizes the p -value of chi-square tests of independence between each predictor and the response [2]. Training speed is similar to standard CART.
<code>'interaction-curvature'</code>	Interaction test on page 32-2679 — Chooses the split predictor that minimizes the p -value of chi-square tests of independence between each predictor and the response (that is, conducts curvature tests), and that minimizes the p -value of a chi-square test of independence between each pair of predictors and response [2]. Training speed can be slower than standard CART.

For `'curvature'` and `'interaction-curvature'`, if all tests yield p -values greater than 0.05, then `fitrtree` stops splitting nodes.

Tip

- Standard CART tends to select split predictors containing many distinct values, e.g., continuous variables, over those containing few distinct values, e.g., categorical variables [3]. Consider specifying the curvature or interaction test if any of the following are true:
 - If there are predictors that have relatively fewer distinct values than other predictors, for example, if the predictor data set is heterogeneous.
 - If an analysis of predictor importance is your goal. For more on predictor importance estimation, see `predictorImportance`.
- Trees grown using standard CART are not sensitive to predictor variable interactions. Also, such trees are less likely to identify important variables in the presence of many irrelevant predictors than the application of the interaction test. Therefore, to account for predictor interactions and identify importance variables in the presence of many irrelevant variables, specify the interaction test .
- Prediction speed is unaffected by the value of `'PredictorSelection'`.

For details on how `fitree` selects split predictors, see “Node Splitting Rules” on page 32-2681 and “Choose Split Predictor Selection Technique” on page 19-19.

Example: `'PredictorSelection', 'curvature'`

Prune — Flag to estimate optimal sequence of pruned subtrees

`'on'` (default) | `'off'`

Flag to estimate the optimal sequence of pruned subtrees, specified as the comma-separated pair consisting of `'Prune'` and `'on'` or `'off'`.

If `Prune` is `'on'`, then `fitree` grows the regression tree and estimates the optimal sequence of pruned subtrees, but does not prune the regression tree. Otherwise, `fitree` grows the regression tree without estimating the optimal sequence of pruned subtrees.

To prune a trained regression tree, pass the regression tree to `prune`.

Example: `'Prune', 'off'`

PruneCriterion — Pruning criterion

`'mse'` (default)

Pruning criterion, specified as the comma-separated pair consisting of 'PruneCriterion' and 'mse'.

QuadraticErrorTolerance — Quadratic error tolerance

1e-6 (default) | positive scalar value

Quadratic error tolerance per node, specified as the comma-separated pair consisting of 'QuadraticErrorTolerance' and a positive scalar value. The function stops splitting nodes when the weighted mean squared error per node drops below $\text{QuadraticErrorTolerance} \times \varepsilon$, where ε is the weighted mean squared error of all n responses computed before growing the decision tree.

$$\varepsilon = \sum_{i=1}^n w_i (y_i - \bar{y})^2.$$

w_i is the weight of observation i , given that the weights of all the observations sum to one

($\sum_{i=1}^n w_i = 1$), and

$$\bar{y} = \sum_{i=1}^n w_i y_i$$

is the weighted average of all the responses.

For more details on node splitting, see Node Splitting Rules on page 32-2681.

Example: 'QuadraticErrorTolerance', 1e-4

Reproducible — Flag to enforce reproducibility

false (logical 0) (default) | true (logical 1)

Flag to enforce reproducibility over repeated runs of training a model, specified as the comma-separated pair consisting of 'Reproducible' and either false or true.

If 'NumVariablesToSample' is not 'all', then the software selects predictors at random for each split. To reproduce the random selections, you must specify 'Reproducible', true and set the seed of the random number generator by using rng. Note that setting 'Reproducible' to true can slow down training.

Example: 'Reproducible', true

Data Types: logical

ResponseName — Response variable name

'Y' (default) | character vector | string scalar

Response variable name, specified as the comma-separated pair consisting of 'ResponseName' and a character vector or string scalar.

- If you supply Y, then you can use 'ResponseName' to specify a name for the response variable.
- If you supply ResponseVarName or formula, then you cannot use 'ResponseName'.

Example: 'ResponseName', 'response'

Data Types: char | string

ResponseTransform — Response transformation

'none' (default) | function handle

Response transformation, specified as the comma-separated pair consisting of 'ResponseTransform' and either 'none' or a function handle. The default is 'none', which means $@(y)y$, or no transformation. For a MATLAB function or a function you define, use its function handle. The function handle must accept a vector (the original response values) and return a vector of the same size (the transformed response values).

Example: Suppose you create a function handle that applies an exponential transformation to an input vector by using `myfunction = @(y)exp(y)`. Then, you can specify the response transformation as 'ResponseTransform', myfunction.

Data Types: char | string | function_handle

SplitCriterion — Split criterion

'MSE' (default)

Split criterion, specified as the comma-separated pair consisting of 'SplitCriterion' and 'MSE', meaning mean squared error.

Example: 'SplitCriterion', 'MSE'

Surrogate — Surrogate decision splits flag

'off' (default) | 'on' | 'all' | positive integer

Surrogate decision splits flag, specified as the comma-separated pair consisting of 'Surrogate' and 'on', 'off', 'all', or a positive integer.

- When 'on', `fitrtree` finds at most 10 surrogate splits at each branch node.
- When set to a positive integer, `fitrtree` finds at most the specified number of surrogate splits at each branch node.
- When set to 'all', `fitrtree` finds all surrogate splits at each branch node. The 'all' setting can use much time and memory.

Use surrogate splits to improve the accuracy of predictions for data with missing values. The setting also enables you to compute measures of predictive association between predictors.

Example: 'Surrogate', 'on'

Data Types: `single` | `double` | `char` | `string`

Weights — Observation weights

`ones(size(X,1),1)` (default) | vector of scalar values | name of variable in `Tbl`

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a vector of scalar values or the name of a variable in `Tbl`. The software weights the observations in each row of `X` or `Tbl` with the corresponding value in `Weights`. The size of `Weights` must equal the number of rows in `X` or `Tbl`.

If you specify the input data as a table `Tbl`, then `Weights` can be the name of a variable in `Tbl` that contains a numeric vector. In this case, you must specify `Weights` as a character vector or string scalar. For example, if weights vector `W` is stored as `Tbl.W`, then specify it as 'W'. Otherwise, the software treats all columns of `Tbl`, including `W`, as predictors when training the model.

`fitrtree` normalizes the weights in each class to add up to 1.

Data Types: `single` | `double` | `char` | `string`

Cross-Validation

CrossVal — Cross-validation flag

'off' (default) | 'on'

Cross-validation flag, specified as the comma-separated pair consisting of 'CrossVal' and either 'on' or 'off'.

If 'on', `fitrtree` grows a cross-validated decision tree with 10 folds. You can override this cross-validation setting using one of the 'KFold', 'Holdout', 'Leaveout', or 'CVPartition' name-value pair arguments. You can only use one of these four options

('KFold', 'Holdout', 'Leaveout', or 'CVPartition') at a time when creating a cross-validated tree.

Alternatively, cross-validate `tree` later using the `crossval` method.

Example: `'CrossVal', 'on'`

CVPartition — Partition for cross-validation tree

`cvpartition` object

Partition for cross-validated tree, specified as the comma-separated pair consisting of 'CVPartition' and an object created using `cvpartition`.

If you use 'CVPartition', you cannot use any of the 'KFold', 'Holdout', or 'Leaveout' name-value pair arguments.

Holdout — Fraction of data for holdout validation

0 (default) | scalar value in the range [0, 1]

Fraction of data used for holdout validation, specified as the comma-separated pair consisting of 'Holdout' and a scalar value in the range [0, 1]. Holdout validation tests the specified fraction of the data, and uses the rest of the data for training.

If you use 'Holdout', you cannot use any of the 'CVPartition', 'KFold', or 'Leaveout' name-value pair arguments.

Example: `'Holdout', 0.1`

Data Types: `single` | `double`

KFold — Number of folds

10 (default) | positive integer greater than 1

Number of folds to use in a cross-validated tree, specified as the comma-separated pair consisting of 'KFold' and a positive integer value greater than 1.

If you use 'KFold', you cannot use any of the 'CVPartition', 'Holdout', or 'Leaveout' name-value pair arguments.

Example: `'KFold', 8`

Data Types: `single` | `double`

Leaveout — Leave-one-out cross-validation flag

'off' (default) | 'on'

Leave-one-out cross-validation flag, specified as the comma-separated pair consisting of 'Leaveout' and either 'on' or 'off'. Use leave-one-out cross-validation by setting to 'on'.

If you use 'Leaveout', you cannot use any of the 'CVPartition', 'Holdout', or 'Kfold' name-value pair arguments.

Example: 'Leaveout', 'on'

Hyperparameters

MaxNumSplits — Maximal number of decision splits

size(X,1) - 1 (default) | positive integer

Maximal number of decision splits (or branch nodes), specified as the comma-separated pair consisting of 'MaxNumSplits' and a positive integer. `fitrtree` splits `MaxNumSplits` or fewer branch nodes. For more details on splitting behavior, see “Tree Depth Control” on page 32-2684.

Example: 'MaxNumSplits', 5

Data Types: single | double

MinLeafSize — Minimum number of leaf node observations

1 (default) | positive integer value

Minimum number of leaf node observations, specified as the comma-separated pair consisting of 'MinLeafSize' and a positive integer value. Each leaf has at least `MinLeafSize` observations per tree leaf. If you supply both `MinParentSize` and `MinLeafSize`, `fitrtree` uses the setting that gives larger leaves: `MinParentSize = max(MinParentSize, 2*MinLeafSize)`.

Example: 'MinLeafSize', 3

Data Types: single | double

NumVariablesToSample — Number of predictors to select at random for each split

'all' (default) | positive integer value

Number of predictors to select at random for each split, specified as the comma-separated pair consisting of 'NumVariablesToSample' and a positive integer value. Alternatively, you can specify 'all' to use all available predictors.

If the training data includes many predictors and you want to analyze predictor importance, then specify `'NumVariablesToSample'` as `'all'`. Otherwise, the software might not select some predictors, underestimating their importance.

To reproduce the random selections, you must set the seed of the random number generator by using `rng` and specify `'Reproducible',true`.

Example: `'NumVariablesToSample',3`

Data Types: `char` | `string` | `single` | `double`

Hyperparameter Optimization

OptimizeHyperparameters — Parameters to optimize

`'none'` (default) | `'auto'` | `'all'` | string array or cell array of eligible parameter names | vector of `optimizableVariable` objects

Parameters to optimize, specified as the comma-separated pair consisting of `'OptimizeHyperparameters'` and one of the following:

- `'none'` — Do not optimize.
- `'auto'` — Use `{'MinLeafSize'}`.
- `'all'` — Optimize all eligible parameters.
- String array or cell array of eligible parameter names.
- Vector of `optimizableVariable` objects, typically the output of hyperparameters.

The optimization attempts to minimize the cross-validation loss (error) for `fitrtree` by varying the parameters. To control the cross-validation type and other aspects of the optimization, use the `HyperparameterOptimizationOptions` name-value pair.

Note `'OptimizeHyperparameters'` values override any values you set using other name-value pair arguments. For example, setting `'OptimizeHyperparameters'` to `'auto'` causes the `'auto'` values to apply.

The eligible parameters for `fitrtree` are:

- `MaxNumSplits` — `fitrtree` searches among integers, by default log-scaled in the range `[1,max(2,NumObservations-1)]`.
- `MinLeafSize` — `fitrtree` searches among integers, by default log-scaled in the range `[1,max(2,floor(NumObservations/2))]`.

- `NumVariablesToSample` — `fitrtree` does not optimize over this hyperparameter. If you pass `NumVariablesToSample` as a parameter name, `fitrtree` simply uses the full number of predictors. However, `fitrensemble` does optimize over this hyperparameter.

Set nondefault parameters by passing a vector of `optimizableVariable` objects that have nondefault values. For example,

```
load carsmall
params = hyperparameters('fitrtree',[Horsepower,Weight],MPG);
params(1).Range = [1,30];
```

Pass `params` as the value of `OptimizeHyperparameters`.

By default, iterative display appears at the command line, and plots appear according to the number of hyperparameters in the optimization. For the optimization and plots, the objective function is $\log(1 + \text{cross-validation loss})$ for regression and the misclassification rate for classification. To control the iterative display, set the `Verbose` field of the `'HyperparameterOptimizationOptions'` name-value pair argument. To control the plots, set the `ShowPlots` field of the `'HyperparameterOptimizationOptions'` name-value pair argument.

For an example, see “Optimize Regression Tree” on page 32-2637.

Example: `'auto'`

HyperparameterOptimizationOptions — Options for optimization structure

Options for optimization, specified as the comma-separated pair consisting of `'HyperparameterOptimizationOptions'` and a structure. This argument modifies the effect of the `OptimizeHyperparameters` name-value pair argument. All fields in the structure are optional.

Field Name	Values	Default
Optimizer	<ul style="list-style-type: none"> • 'bayesopt' — Use Bayesian optimization. Internally, this setting calls bayesopt. • 'gridsearch' — Use grid search with NumGridDivisions values per dimension. • 'randomsearch' — Search at random among MaxObjectiveEvaluations points. <p>'gridsearch' searches in a random order, using uniform sampling without replacement from the grid. After optimization, you can get a table in grid order by using the command <code>sortrows(Mdl.HyperparameterOptimizationResults)</code>.</p>	'bayesopt'
AcquisitionFunctionName	<ul style="list-style-type: none"> • 'expected-improvement-per-second-plus' • 'expected-improvement' • 'expected-improvement-plus' • 'expected-improvement-per-second' • 'lower-confidence-bound' • 'probability-of-improvement' <p>Acquisition functions whose names include <code>per-second</code> do not yield reproducible results because the optimization depends on the runtime of the objective function. Acquisition functions whose names include <code>plus</code> modify their behavior when they are overexploiting an area. For more details, see “Acquisition Function Types” on page 10-4.</p>	'expected-improvement-per-second-plus'

Field Name	Values	Default
MaxObjectiveEvaluations	Maximum number of objective function evaluations.	30 for 'bayesopt' or 'randomsearch', and the entire grid for 'gridsearch'
MaxTime	Time limit, specified as a positive real. The time limit is in seconds, as measured by tic and toc. Run time can exceed MaxTime because MaxTime does not interrupt function evaluations.	Inf
NumGridDivisions	For 'gridsearch', the number of values in each dimension. The value can be a vector of positive integers giving the number of values for each dimension, or a scalar that applies to all dimensions. This field is ignored for categorical variables.	10
ShowPlots	Logical value indicating whether to show plots. If true, this field plots the best objective function value against the iteration number. If there are one or two optimization parameters, and if Optimizer is 'bayesopt', then ShowPlots also plots a model of the objective function against the parameters.	true
SaveIntermediateResults	Logical value indicating whether to save results when Optimizer is 'bayesopt'. If true, this field overwrites a workspace variable named 'BayesoptResults' at each iteration. The variable is a BayesianOptimization object.	false

Field Name	Values	Default
Verbose	Display to the command line. <ul style="list-style-type: none"> • 0 — No iterative display • 1 — Iterative display • 2 — Iterative display with extra information For details, see the <code>bayesopt</code> <code>Verbose</code> name-value pair argument.	1
UseParallel	Logical value indicating whether to run Bayesian optimization in parallel, which requires Parallel Computing Toolbox. For details, see “Parallel Bayesian Optimization” on page 10-8.	false
Repartition	Logical value indicating whether to repartition the cross-validation at every iteration. If <code>false</code> , the optimizer uses a single partition for the optimization. <code>true</code> usually gives the most robust results because this setting takes partitioning noise into account. However, for good results, <code>true</code> requires at least twice as many function evaluations.	false
Use no more than one of the following three field names.		
CVPartition	A <code>cvpartition</code> object, as created by <code>cvpartition</code> .	'Kfold', 5 if you do not specify any cross-validation field
Holdout	A scalar in the range (0, 1) representing the holdout fraction.	
Kfold	An integer greater than 1.	

Example:

```
'HyperparameterOptimizationOptions', struct('MaxObjectiveEvaluations', 60)
```

Data Types: struct

Output Arguments

tree — Regression tree

regression tree object

Regression tree, returned as a regression tree object. Using the 'Crossval', 'Kfold', 'Holdout', 'Leaveout', or 'CVPartition' options results in a tree of class `RegressionPartitionedModel`. You cannot use a partitioned tree for prediction, so this kind of tree does not have a `predict` method.

Otherwise, `tree` is of class `RegressionTree`, and you can use the `predict` method to make predictions.

Definitions

Curvature Test

The curvature test is a statistical test assessing the null hypothesis that two variables are unassociated.

The curvature test between predictor variable x and y is conducted using this process.

- 1 If x is continuous, then partition it into its quartiles. Create a nominal variable that bins observations according to which section of the partition they occupy. If there are missing values, then create an extra bin for them.
- 2 For each level in the partitioned predictor $j = 1..J$ and class in the response $k = 1, \dots, K$, compute the weighted proportion of observations in class k

$$\hat{\pi}_{jk} = \sum_{i=1}^n I\{y_i = k\} w_i.$$

w_i is the weight of observation i , $\sum w_i = 1$, I is the indicator function, and n is the sample size. If all observations have the same weight, then $\hat{\pi}_{jk} = \frac{n_{jk}}{n}$, where n_{jk} is the number of observations in level j of the predictor that are in class k .

- 3 Compute the test statistic

$$t = n \sum_{k=1}^K \sum_{j=1}^J \frac{(\hat{\pi}_{jk} - \hat{\pi}_{j+} \hat{\pi}_{+k})^2}{\hat{\pi}_{j+} \hat{\pi}_{+k}}$$

$\hat{\pi}_{j+} = \sum_k \hat{\pi}_{jk}$, that is, the marginal probability of observing the predictor at level j .

$\hat{\pi}_{+k} = \sum_j \hat{\pi}_{jk}$, that is the marginal probability of observing class k . If n is large enough, then t is distributed as a χ^2 with $(K - 1)(J - 1)$ degrees of freedom.

- 4 If the p -value for the test is less than 0.05, then reject the null hypothesis that there is no association between x and y .

When determining the best split predictor at each node, the standard CART algorithm prefers to select continuous predictors that have many levels. Sometimes, such a selection can be spurious and can also mask more important predictors that have fewer levels, such as categorical predictors.

The curvature test can be applied instead of standard CART to determine the best split predictor at each node. In that case, the best split predictor variable is the one that minimizes the significant p -values (those less than 0.05) of curvature tests between each predictor and the response variable. Such a selection is robust to the number of levels in individual predictors.

For more details on how the curvature test applies to growing regression trees, see “Node Splitting Rules” on page 32-2681 and [3].

Interaction Test

The interaction test is a statistical test that assesses the null hypothesis that there is no interaction between a pair of predictor variables and the response variable.

The interaction test assessing the association between predictor variables x_1 and x_2 with respect to y is conducted using this process.

- 1 If x_1 or x_2 is continuous, then partition that variable into its quartiles. Create a nominal variable that bins observations according to which section of the partition they occupy. If there are missing values, then create an extra bin for them.
- 2 Create the nominal variable z with $J = J_1 J_2$ levels that assigns an index to observation i according to which levels of x_1 and x_2 it belongs. Remove any levels of z that do not correspond to any observations.

- 3 Conduct a curvature test on page 32-2678 between z and y .

When growing decision trees, if there are important interactions between pairs of predictors, but there are also many other less important predictors in the data, then standard CART tends to miss the important interactions. However, conducting curvature and interaction tests for predictor selection instead can improve detection of important interactions, which can yield more accurate decision trees.

For more details on how the interaction test applies to growing decision trees, see “Curvature Test” on page 32-2678, “Node Splitting Rules” on page 32-2681 and [2].

Predictive Measure of Association

The predictive measure of association is a value that indicates the similarity between decision rules that split observations. Among all possible decision splits that are compared to the optimal split (found by growing the tree), the best surrogate decision split on page 32-2176 yields the maximum predictive measure of association. The second-best surrogate split has the second-largest predictive measure of association.

Suppose x_j and x_k are predictor variables j and k , respectively, and $j \neq k$. At node t , the predictive measure of association between the optimal split $x_j < u$ and a surrogate split $x_k < v$ is

$$\lambda_{jk} = \frac{\min(P_L, P_R) - (1 - P_{L_jL_k} - P_{R_jR_k})}{\min(P_L, P_R)}.$$

- P_L is the proportion of observations in node t , such that $x_j < u$. The subscript L stands for the left child of node t .
- P_R is the proportion of observations in node t , such that $x_j \geq u$. The subscript R stands for the right child of node t .
- $P_{L_jL_k}$ is the proportion of observations at node t , such that $x_j < u$ and $x_k < v$.
- $P_{R_jR_k}$ is the proportion of observations at node t , such that $x_j \geq u$ and $x_k \geq v$.
- Observations with missing values for x_j or x_k do not contribute to the proportion calculations.

λ_{jk} is a value in $(-\infty, 1]$. If $\lambda_{jk} > 0$, then $x_k < v$ is a worthwhile surrogate split for $x_j < u$.

Surrogate Decision Splits

A surrogate decision split is an alternative to the optimal decision split at a given node in a decision tree. The optimal split is found by growing the tree; the surrogate split uses a similar or correlated predictor variable and split criterion.

When the value of the optimal split predictor for an observation is missing, the observation is sent to the left or right child node using the best surrogate predictor. When the value of the best surrogate split predictor for the observation is also missing, the observation is sent to the left or right child node using the second-best surrogate predictor, and so on. Candidate splits are sorted in descending order by their predictive measure of association on page 32-2680.

Tip

- By default, Prune is 'on'. However, this specification does not prune the regression tree. To prune a trained regression tree, pass the regression tree to `prune`.
- After training a model, you can generate C/C++ code that predicts responses for new data. Generating C/C++ code requires MATLAB Coder. For details, see “Introduction to Code Generation” on page 31-2.

Algorithms

Node Splitting Rules

`fitree` uses these processes to determine how to split node t .

- For standard CART (that is, if `PredictorSelection` is 'allpairs') and for all predictors x_i , $i = 1, \dots, p$:
 - 1 `fitree` computes the weighted mean squared error (MSE) of the responses in node t using

$$\varepsilon_t = \sum_{j \in T} w_j (y_j - \bar{y}_t)^2.$$

w_j is the weight of observation j , and T is the set of all observation indices in node t . If you do not specify `Weights`, then $w_j = 1/n$, where n is the sample size.

- 2 `fitrtree` estimates the probability that an observation is in node t using

$$P(T) = \sum_{j \in T} w_j.$$

- 3 `fitrtree` sorts x_i in ascending order. Each element of the sorted predictor is a splitting candidate or cut point. `fitrtree` records any indices corresponding to missing values in the set T_U , which is the unsplit set.
- 4 `fitrtree` determines the best way to split node t using x_i by maximizing the reduction in MSE (ΔI) over all splitting candidates. That is, for all splitting candidates in x_i :
- a `fitrtree` splits the observations in node t into left and right child nodes (t_L and t_R , respectively).
 - b `fitrtree` computes ΔI . Suppose that for a particular splitting candidate, t_L and t_R contain observation indices in the sets T_L and T_R , respectively.
 - If x_i does not contain any missing values, then the reduction in MSE for the current splitting candidate is

$$\Delta I = P(T)\varepsilon_t - P(T_L)\varepsilon_{t_L} - P(T_R)\varepsilon_{t_R}.$$

- If x_i contains missing values, then, assuming that the observations are missing at random, the reduction in MSE is

$$\Delta I_U = P(T - T_U)\varepsilon_t - P(T_L)\varepsilon_{t_L} - P(T_R)\varepsilon_{t_R}.$$

$T - T_U$ is the set of all observation indices in node t that are not missing.

- If you use surrogate decision splits on page 32-2681, then:
 - i `fitrtree` computes the predictive measures of association on page 32-2680 between the decision split $x_j < u$ and all possible decision splits $x_k < v$, $j \neq k$.
 - ii `fitrtree` sorts the possible alternative decision splits in descending order by their predictive measure of association with the optimal split. The surrogate split is the decision split yielding the largest measure.
 - iii `fitrtree` decides the child node assignments for observations with a missing value for x_i using the surrogate split. If the surrogate predictor also contains a missing value, then `fitrtree` uses the decision split with the second largest measure, and so on, until there are no other surrogates. It is possible for `fitrtree` to split two

different observations at node t using two different surrogate splits. For example, suppose the predictors x_1 and x_2 are the best and second best surrogates, respectively, for the predictor x_i , $i \notin \{1, 2\}$, at node t . If observation m of predictor x_i is missing (i.e., x_{mi} is missing), but x_{m1} is not missing, then x_1 is the surrogate predictor for observation x_{mi} . If observations $x_{(m+1),i}$ and $x_{(m+1),1}$ are missing, but $x_{(m+1),2}$ is not missing, then x_2 is the surrogate predictor for observation $m+1$.

- iv `fitrtree` uses the appropriate MSE reduction formula. That is, if `fitrtree` fails to assign all missing observations in node t to children nodes using surrogate splits, then the MSE reduction is ΔI_U . Otherwise, `fitrtree` uses ΔI for the MSE reduction.
- c `fitrtree` chooses the candidate that yields the largest MSE reduction.

`fitrtree` splits the predictor variable at the cut point that maximizes the MSE reduction.

- For the curvature test (that is, if `PredictorSelection` is 'curvature'):
 - 1 `fitrtree` computes the residuals $r_{ti} = y_{ti} - \bar{y}_t$ for all observations in node t .

$$\bar{y}_t = \frac{1}{\sum_i w_i} \sum_i w_i y_{ti}$$
, which is the weighted average of the responses in node t . The weights are the observation weights in `Weights`.
 - 2 `fitrtree` assigns observations to one of two bins according to the sign of the corresponding residuals. Let z_t be a nominal variable that contains the bin assignments for the observations in node t .
 - 3 `fitrtree` conducts curvature tests on page 32-2678 between each predictor and z_t . For regression trees, $K = 2$.
 - If all p -values are at least 0.05, then `fitrtree` does not split node t .
 - If there is a minimal p -value, then `fitrtree` chooses the corresponding predictor to split node t .
 - If more than one p -value is zero due to underflow, then `fitrtree` applies standard CART to the corresponding predictors to choose the split predictor.
 - 4 If `fitrtree` chooses a split predictor, then it uses standard CART to choose the cut point (see step 4 in the standard CART process).
- For the interaction test (that is, if `PredictorSelection` is 'interaction-curvature'):

- 1 For observations in node t , `fitrtree` conducts curvature tests on page 32-2678 between each predictor and the response and interaction tests on page 32-2679 between each pair of predictors and the response.
 - If all p -values are at least 0.05, then `fitrtree` does not split node t .
 - If there is a minimal p -value and it is the result of a curvature test, then `fitrtree` chooses the corresponding predictor to split node t .
 - If there is a minimal p -value and it is the result of an interaction test, then `fitrtree` chooses the split predictor using standard CART on the corresponding pair of predictors.
 - If more than one p -value is zero due to underflow, then `fitrtree` applies standard CART to the corresponding predictors to choose the split predictor.
- 2 If `fitrtree` chooses a split predictor, then it uses standard CART to choose the cut point (see step 4 in the standard CART process).

Tree Depth Control

- If `MergeLeaves` is 'on' and `PruneCriterion` is 'mse' (which are the default values for these name-value pair arguments), then the software applies pruning only to the leaves and by using MSE. This specification amounts to merging leaves coming from the same parent node whose MSE is at most the sum of the MSE of its two leaves.
- To accommodate `MaxNumSplits`, `fitrtree` splits all nodes in the current layer, and then counts the number of branch nodes. A layer is the set of nodes that are equidistant from the root node. If the number of branch nodes exceeds `MaxNumSplits`, `fitrtree` follows this procedure:
 - 1 Determine how many branch nodes in the current layer must be unsplit so that there are at most `MaxNumSplits` branch nodes.
 - 2 Sort the branch nodes by their impurity gains.
 - 3 Unsplit the number of least successful branches.
 - 4 Return the decision tree grown so far.

This procedure produces maximally balanced trees.

- The software splits branch nodes layer by layer until at least one of these events occurs:

- There are `MaxNumSplits` branch nodes.
- A proposed split causes the number of observations in at least one branch node to be fewer than `MinParentSize`.
- A proposed split causes the number of observations in at least one leaf node to be fewer than `MinLeafSize`.
- The algorithm cannot find a good split within a layer (i.e., the pruning criterion (see `PruneCriterion`), does not improve for all proposed splits in a layer). A special case is when all nodes are pure (i.e., all observations in the node have the same class).
- For values `'curvature'` or `'interaction-curvature'` of `PredictorSelection`, all tests yield p -values greater than 0.05.

`MaxNumSplits` and `MinLeafSize` do not affect splitting at their default values. Therefore, if you set `'MaxNumSplits'`, splitting might stop due to the value of `MinParentSize`, before `MaxNumSplits` splits occur.

Parallelization

For dual-core systems and above, `fitrtree` parallelizes training decision trees using Intel Threading Building Blocks (TBB). For details on Intel TBB, see <https://software.intel.com/en-us/intel-tbb>.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

Usage notes and limitations:

- Supported syntaxes are:
 - `tree = fitrtree(Tbl,Y)`
 - `tree = fitrtree(X,Y)`
 - `tree = fitrtree(__,Name,Value)`
 - `[tree,FitInfo,HyperparameterOptimizationResults] = fitrtree(__,Name,Value)` — `fitrtree` returns the additional output arguments `FitInfo` and `HyperparameterOptimizationResults` when you specify the `'OptimizeHyperparameters'` name-value pair argument.

`tree` is a `CompactRegressionTree` object; therefore, it does not include the data used in training the regression tree.

- The `FitInfo` output argument is an empty structure array currently reserved for possible future use.
- The `HyperparameterOptimizationResults` output argument is a `BayesianOptimization` object or a table of hyperparameters with associated values that describe the cross-validation optimization of hyperparameters.

`'HyperparameterOptimizationResults'` is nonempty when the `'OptimizeHyperparameters'` name-value pair argument is nonempty at the time you create the model. The values in `'HyperparameterOptimizationResults'` depend on the value you specify for the `'HyperparameterOptimizationOptions'` name-value pair argument when you create the model.

- If you specify `'bayesopt'` (default), then `HyperparameterOptimizationResults` is an object of class `BayesianOptimization`.
- If you specify `'gridsearch'` or `'randomsearch'`, then `HyperparameterOptimizationResults` is a table of the hyperparameters used, observed objective function values (cross-validation loss), and rank of observations from lowest (best) to highest (worst).

- Supported name-value pair arguments are:
 - 'CategoricalPredictors'
 - 'HyperparameterOptimizationOptions' — For cross-validation, tall optimization supports only 'Holdout' validation. For example, you can specify `fitrtree(X,Y,'OptimizeHyperparameters','auto','HyperparameterOptimizationOptions',struct('Holdout',0.2))`.
 - 'MaxNumSplits' — For tall optimization, `fitrtree` searches among integers, log-scaled (by default) in the range $[1, \max(2, \min(10000, \text{NumObservations}-1))]$.
 - 'MergeLeaves'
 - 'MinLeafSize' — For tall optimization, `fitrtree` searches among integers, log-scaled (by default) in the range $[1, \max(2, \text{floor}(\text{NumObservations}/2))]$.
 - 'MinParentSize'
 - 'NumVariablesToSample' — For tall optimization, `fitrtree` searches among integers in the range $[1, \max(2, \text{NumPredictors})]$.
 - 'OptimizeHyperparameters'
 - 'PredictorNames'
 - 'QuadraticErrorTolerance'
 - 'ResponseName'
 - 'ResponseTransform'
 - 'SplitCriterion'
 - 'Weights'
- This additional name-value pair argument is specific to tall arrays:
 - 'MaxDepth' — A positive integer specifying the maximum depth of the output tree. Specify a value for this argument to return a tree that has fewer levels and requires fewer passes through the tall array to compute. Generally, the algorithm of `fitrtree` takes one pass through the data and an additional pass for each tree level. The function does not set a maximum tree depth, by default.

For more information, see “Tall Arrays” (MATLAB).

Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the 'UseParallel' option to true.

To perform parallel hyperparameter optimization, use the 'HyperparameterOptions', struct('UseParallel', true) name-value pair argument in the call to this function.

For more information on parallel hyperparameter optimization, see “Parallel Bayesian Optimization” on page 10-8.

For more general information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

Introduced in R2014a

fitSVMPosterior

Fit posterior probabilities

Syntax

```
ScoreSVMMoDel = fitSVMPoSterior(SVMMoDel)

ScoreSVMMoDel = fitSVMPoSterior(SVMMoDel, TBL, ResponseVarName)
ScoreSVMMoDel = fitSVMPoSterior(SVMMoDel, TBL, Y)

ScoreSVMMoDel = fitSVMPoSterior(SVMMoDel, X, Y)

ScoreSVMMoDel = fitSVMPoSterior( ____, Name, Value)

[ScoreSVMMoDel, ScoreTransform] = fitSVMPoSterior( ____, )
```

Description

`ScoreSVMMoDel = fitSVMPoSterior(SVMMoDel)` returns `ScoreSVMMoDel`, which is a trained, support vector machine (SVM) classifier containing the optimal score-to-posterior-probability transformation function for two-class learning.

The software fits the appropriate score-to-posterior-probability transformation function using the SVM classifier `SVMMoDel`, and by cross validation using the stored predictor data (`SVMMoDel.X`) and the class labels (`SVMMoDel.Y`). The transformation function computes the posterior probability that an observation is classified into the positive class (`SVMMoDel.Classnames(2)`).

- If the classes are inseparable, then the transformation function is the sigmoid function on page 32-2700.
- If the classes are perfectly separable, the transformation function is the step function on page 32-2700.
- In two-class learning, if one of the two classes has a relative frequency of 0, then the transformation function is the constant function on page 32-2700. `fitSVMPoSterior` is not appropriate for one-class learning.

- If `SVMMModel` is a `ClassificationSVM` classifier, then the software estimates the optimal transformation function by 10-fold cross validation as outlined in [1]. Otherwise, `SVMMModel` must be a `ClassificationPartitionedModel` classifier. `SVMMModel` specifies the cross-validation method.
- The software stores the optimal transformation function in `ScoreSVMMModel.ScoreTransform`.

`ScoreSVMMModel = fitSVMPosterior(SVMMModel, TBL, ResponseVarName)` returns a trained support vector classifier containing the transformation function from the trained, compact SVM classifier `SVMMModel`. The software estimates the score transformation function using predictor data in the table `TBL` and class labels `TBL.ResponseVarName`.

`ScoreSVMMModel = fitSVMPosterior(SVMMModel, TBL, Y)` returns a trained support vector classifier containing the transformation function from the trained, compact SVM classifier `SVMMModel`. The software estimates the score transformation function using predictor data in the table `TBL` and class labels `Y`.

`ScoreSVMMModel = fitSVMPosterior(SVMMModel, X, Y)` returns a trained support vector classifier containing the transformation function from the trained, compact SVM classifier `SVMMModel`. The software estimates the score transformation function using predictor data `X` and class labels `Y`.

`ScoreSVMMModel = fitSVMPosterior(____, Name, Value)` uses additional options specified by one or more `Name, Value` pair arguments provided `SVMMModel` is a `ClassificationSVM` classifier. For example, you can specify the number of folds to use in *k*-fold cross validation.

`[ScoreSVMMModel, ScoreTransform] = fitSVMPosterior(____)` additionally returns the transformation function parameters (`ScoreTransform`) using any of the input arguments in the previous syntaxes.

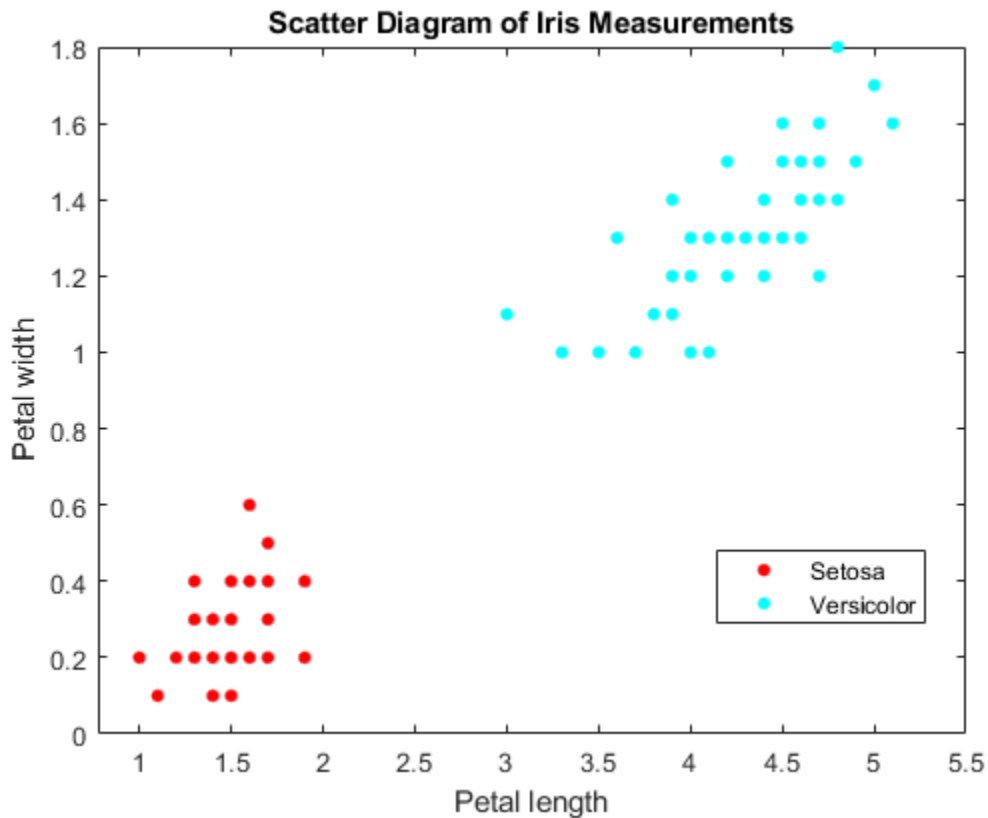

Examples

Fit the Score-to-Posterior Probability Function for Separable Classes

Load Fisher's iris data set. Train the classifier using the petal lengths and widths, and remove the virginica species from the data.

```
load fisheriris
classKeep = ~strcmp(species, 'virginica');
```

```
X = meas(classKeep,3:4);  
y = species(classKeep);  
  
gscatter(X(:,1),X(:,2),y);  
title('Scatter Diagram of Iris Measurements')  
xlabel('Petal length')  
ylabel('Petal width')  
legend('Setosa', 'Versicolor')
```

The classes are perfectly separable. Therefore, the score transformation function is a step function.

Train an SVM classifier using the data. Cross validate the classifier using 10-fold cross validation (the default).

```
rng(1);  
CVSVMModel = fitcsvm(X,y,'CrossVal','on');
```

CVSVMModel is a trained `ClassificationPartitionedModel` SVM classifier.

Estimate the step function that transforms scores to posterior probabilities.

```
[ScoreCVSVMModel,ScoreParameters] = fitSVMPosterior(CVSVMModel);
```

Warning: Classes are perfectly separated. The optimal score-to-posterior transformation

`fitSVMPosterior` does the following:

- Uses the data that the software stored in `CVSVMModel` to fit the transformation function
- Warns whenever the classes are separable
- Stores the step function in `ScoreCVSVMModel.ScoreTransform`

Display the score function type and its parameter values.

`ScoreParameters`

```
ScoreParameters = struct with fields:  
    Type: 'step'  
    LowerBound: -0.8431  
    UpperBound: 0.6897  
    PositiveClassProbability: 0.5000
```

`ScoreParameters` is a structure array with four fields:

- The score transformation function type (`Type`)
- The score corresponding to the negative class boundary (`LowerBound`)
- The score corresponding to the positive class boundary (`UpperBound`)
- The positive class probability (`PositiveClassProbability`)

Since the classes are separable, the step function transforms the score to either 0 or 1, which is the posterior probability that an observation is a versicolor iris.

Fit the Score-to-Posterior Probability Function for Inseparable Classes

Load the ionosphere data set.

```
load ionosphere
```

The classes of this data set are not separable.

Train an SVM classifier. Cross validate using 10-fold cross validation (the default). It is good practice to standardize the predictors and specify the class order.

```
rng(1) % For reproducibility
CVSVMModel = fitcsvm(X,Y,'ClassNames',{ 'b', 'g'}, 'Standardize', true, ...
    'CrossVal', 'on');
ScoreTransform = CVSVMModel.ScoreTransform
```

```
ScoreTransform =
'none'
```

CVSVMModel is a trained ClassificationPartitionedModel SVM classifier. The positive class is 'g'. The ScoreTransform property is none.

Estimate the optimal score function for mapping observation scores to posterior probabilities of an observation being classified as 'g'.

```
[ScoreCVSVMModel,ScoreParameters] = fitSVMPosterior(CVSVMModel);
ScoreTransform = ScoreCVSVMModel.ScoreTransform
```

```
ScoreTransform =
'@(S)sigmoid(S,-9.481576e-01,-1.218300e-01)'
```

```
ScoreParameters
```

```
ScoreParameters = struct with fields:
    Type: 'sigmoid'
    Slope: -0.9482
    Intercept: -0.1218
```

ScoreTransform is the optimal score transform function. ScoreParameters contains the score transformation function, slope estimate, and the intercept estimate.

You can estimate test-sample, posterior probabilities by passing ScoreCVSVMModel to kfoldPredict.

Estimate Posterior Probabilities for Test Samples

Estimate positive class posterior probabilities for the test set of an SVM algorithm.

Load the ionosphere data set.

```
load ionosphere
```

Train an SVM classifier. Specify a 20% holdout sample. It is good practice to standardize the predictors and specify the class order.

```
rng(1) % For reproducibility
CVSVMModel = fitcsvm(X,Y,'Holdout',0.2,'Standardize',true,...
    'ClassNames',{'b','g'});
```

CVSVMModel is a trained `ClassificationPartitionedModel` cross-validated classifier.

Estimate the optimal score function for mapping observation scores to posterior probabilities of an observation being classified as 'g'.

```
ScoreCVSVMModel = fitSVMPosterior(CVSVMModel);
```

ScoreSVMModel is a trained `ClassificationPartitionedModel` cross-validated classifier containing the optimal score transformation function estimated from the training data.

Estimate the out-of-sample positive class posterior probabilities. Display the results for the first 10 out-of-sample observations.

```
[~,OOSPostProbs] = kfoldPredict(ScoreCVSVMModel);
indx = ~isnan(OOSPostProbs(:,2));
hoObs = find(indx); % Holdout observation numbers
OOSPostProbs = [hoObs, OOSPostProbs(indx,2)];
table(OOSPostProbs(1:10,1),OOSPostProbs(1:10,2),...
    'VariableNames',{'ObservationIndex','PosteriorProbability'})
```

```
ans=10x2 table
  ObservationIndex  PosteriorProbability
  _____  _____
              6              0.17378
```

Input Arguments

SVMMoDel — Trained SVM classifier

ClassificationSVM classifier | CompactClassificationSVM classifier | ClassificationPartitionedModel classifier

Trained SVM classifier, specified as a ClassificationSVM, CompactClassificationSVM, or ClassificationPartitionedModel classifier.

If SVMMoDel is a ClassificationSVM classifier, then you can set optional name-value pair arguments.

If SVMMoDel is a CompactClassificationSVM classifier, then you must input predictor data X and class labels Y.

TBL — Sample data

table

Sample data, specified as a table. Each row of TBL corresponds to one observation, and each column corresponds to one predictor variable. Optionally, TBL can contain additional columns for the response variable and observation weights. TBL must contain all of the predictors used to train SVMMoDel. Multicolumn variables and cell arrays other than cell arrays of character vectors are not allowed.

If TBL contains the response variable used to train SVMMoDel, then you do not need to specify ResponseVarName or Y.

If you trained SVMMoDel using sample data contained in a table, then the input data for fitSVMPosterior must also be in a table.

If you set `'Standardize', true` in `fitcsvm` when training `SVMModel`, then the software standardizes the columns of the predictor data using the corresponding means in `SVMModel.Mu` and the standard deviations in `SVMModel.Sigma`.

Data Types: `table`

X — Predictor data

`matrix`

Predictor data used to estimate the score-to-posterior-probability transformation function, specified as a matrix.

Each row of X corresponds to one observation (also known as an instance or example), and each column corresponds to one variable (also known as a feature).

The length of Y and the number of rows in X must be equal.

If you set `'Standardize', true` in `fitcsvm` when training `SVMModel`, then the software fits the transformation function parameter estimates using standardized data.

Data Types: `double` | `single`

ResponseVarName — Response variable name

`name of variable in TBL`

Response variable name, specified as the name of a variable in TBL. If TBL contains the response variable used to train `SVMModel`, then you do not need to specify `ResponseVarName`.

If you specify `ResponseVarName`, then you must do so as a character vector or string scalar. For example, if the response variable is stored as `TBL.Response`, then specify `ResponseVarName` as `'Response'`. Otherwise, the software treats all columns of TBL, including `TBL.Response`, as predictors.

The response variable must be a categorical, character, or string array, logical or numeric vector, or cell array of character vectors. If the response variable is a character array, then each element must correspond to one row of the array.

Data Types: `char` | `string`

Y — Class labels

`categorical array` | `character array` | `string array` | `logical vector` | `numeric vector` | `cell array of character vectors`

Class labels used to estimate the score-to-posterior-probability transformation function, specified as a categorical, character, or string array, a logical or numeric vector, or a cell array of character vectors.

If `Y` is a character array, then each element must correspond to one class label.

The length of `Y` and the number of rows in `X` must be equal.

Data Types: `categorical` | `char` | `string` | `logical` | `single` | `double` | `cell`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'Kfold', 8` performs 8-fold cross validation when `SVMModel` is a `ClassificationSVM` classifier.

CVPartition — Cross-validation partition

`[]` (default) | `cvpartition` partition

Cross-validation partition used to compute the transformation function, specified as the comma-separated pair consisting of `'CVPartition'` and a `cvpartition` partition object as created by `cvpartition`. You can use only one of these four options at a time for creating a cross-validated model: `'Kfold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'`.

The `crossval` name-value pair argument of `fitsvm` splits the data into subsets using `cvpartition`.

Example: Suppose you create a random partition for 5-fold cross-validation on 500 observations by using `cvp = cvpartition(500, 'Kfold', 5)`. Then, you can specify the cross-validated model by using `'CVPartition', cvp`.

Holdout — Fraction of data for holdout validation

scalar value in the range (0,1)

Fraction of the data for holdout validation used to compute the transformation function, specified as the comma-separated pair consisting of `'Holdout'` and a scalar value in the range (0,1). Holdout validation tests the specified fraction of the data and uses the remaining data for training.

You can use only one of these four options at a time for creating a cross-validated model: 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'.

Example: 'Holdout', 0.1

Data Types: double | single

KFold — Number of folds

10 (default) | positive integer value greater than 1

Number of folds to use when computing the transformation function, specified as the comma-separated pair consisting of 'KFold' and a positive integer value greater than 1.

You can use only one of these four options at a time for creating a cross-validated model: 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'.

Example: 'KFold', 8

Data Types: single | double

Leaveout — Leave-one-out cross-validation flag

'off' (default) | 'on'

Leave-one-out cross-validation flag indicating whether to use leave-one-out cross-validation to compute the transformation function, specified as the comma-separated pair consisting of 'Leaveout' and 'on' or 'off'. Use leave-one-out cross-validation by specifying 'Leaveout', 'on'.

You can use only one of these four options at a time for creating a cross-validated model: 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'.

Example: 'Leaveout', 'on'

Output Arguments

ScoreSVMModel — Trained SVM classifier

ClassificationSVM classifier | CompactClassificationSVM classifier | ClassificationPartitionedModel classifier

Trained SVM classifier containing the estimated score transformation function, returned as a ClassificationSVM, CompactClassificationSVM, or ClassificationPartitionedModel classifier.

The `ScoreSVMModel` classifier type is the same as the `SVMModel` classifier type.

To estimate posterior probabilities, pass `ScoreSVMModel` and predictor data to `predict`. If you set `'Standardize', true` in `fitcsvm` to train `SVMModel`, then `predict` standardizes the columns of `X` using the corresponding means in `SVMModel.Mu` and standard deviations in `SVMModel.Sigma`.

ScoreTransform — Optimal score-to-posterior-probability transformation function parameters

structure array

Optimal score-to-posterior-probability transformation function parameters, specified as a structure array. If field `Type` is:

- `sigmoid`, then `ScoreTransform` has these fields:
 - `Slope` — The value of A in the sigmoid function on page 32-2700
 - `Intercept` — The value of B in the sigmoid function
- `step`, then `ScoreTransform` has these fields:
 - `PositiveClassProbability`: the value of π in the step function on page 32-2700. π represents:
 - The probability that an observation is in the positive class.
 - The posterior probability that a score is in the interval `(LowerBound,UpperBound)`.
 - `LowerBound`: the value $\max_{y_n = -1} s_n$ in the step function. It represents the lower bound of the interval that assigns the posterior probability of being in the positive class `PositiveClassProbability` to scores. Any observation with a score less than `LowerBound` has posterior probability of being the positive class `0`.
 - `UpperBound`: the value $\min_{y_n = +1} s_n$ in the step function. It represents the upper bound of the interval that assigns the posterior probability of being in the positive class `PositiveClassProbability`. Any observation with a score greater than `UpperBound` has posterior probability of being the positive class `1`.
- `constant`, then `ScoreTransform.PredictedClass` contains the name of the class prediction.

This result is the same as `SVMModel.ClassNames`. The posterior probability of an observation being in `ScoreTransform.PredictedClass` is always `1`.

Definitions

Sigmoid Function

The sigmoid function that maps score s_j corresponding to observation j to the positive class posterior probability is

$$P(s_j) = \frac{1}{1 + \exp(As_j + B)}.$$

If the value of the Type field of ScoreTransform is `sigmoid`, then parameters A and B correspond to the fields `Scale` and `Intercept` of ScoreTransform, respectively.

Step Function

The step function that maps score s_j corresponding to observation j to the positive class posterior probability is

$$P(s_j) = \begin{cases} 0; & s < \max_{y_k = -1} s_k \\ \pi; & \max_{y_k = -1} s_k \leq s_j \leq \min_{y_k = +1} s_k, \\ 1; & s_j > \min_{y_k = +1} s_k \end{cases}$$

where:

- s_j is the score of observation j .
- $+1$ and -1 denote the positive and negative classes, respectively.
- π is the prior probability that an observation is in the positive class.

If the value of the Type field of ScoreTransform is `step`, then the quantities $\max_{y_k = -1} s_k$

and $\min_{y_k = +1} s_k$ correspond to the fields `LowerBound` and `UpperBound` of

ScoreTransform, respectively.

Constant Function

The constant function maps all scores in a sample to posterior probabilities 1 or 0.

If all observations have posterior probability 1, then they are expected to come from the positive class.

If all observations have posterior probability 0, then they are not expected to come from the positive class.

Tips

- This process describes one way to predict positive class posterior probabilities.
 - 1 Train an SVM classifier by passing the data to `fitcsvm`. The result is a trained SVM classifier, such as `SVMModel`, that stores the data. The software sets the score transformation function property (`SVMModel.ScoreTransformation`) to `none`.
 - 2 Pass the trained SVM classifier `SVMModel` to `fitSVMPosterior` or `fitPosterior`. The result, such as `ScoreSVMModel`, is the same trained SVM classifier as `SVMModel`, except the software sets `ScoreSVMModel.ScoreTransformation` to the optimal score transformation function.
 - 3 Pass the predictor data matrix and the trained SVM classifier containing the optimal score transformation function (`ScoreSVMModel`) to `predict`. The second column in the second output argument of `predict` stores the positive class posterior probabilities corresponding to each row of the predictor data matrix.

If you skip step 2, then `predict` returns the positive class score rather than the positive class posterior probability.
- After fitting posterior probabilities, you can generate C/C++ code that predicts labels for new data. Generating C/C++ code requires MATLAB Coder. For details, see “Introduction to Code Generation” on page 31-2.

Algorithms

If you re-estimate the score-to-posterior-probability transformation function, that is, if you pass an SVM classifier to `fitPosterior` or `fitSVMPosterior` and its `ScoreTransform` property is not `none`, then the software:

- Displays a warning

- Resets the original transformation function to 'none' before estimating the new one

Introduced in R2014a

fitted

Class: GeneralizedLinearMixedModel

Fitted responses from generalized linear mixed-effects model

Syntax

```
mufit = fitted(glme)
mufit = fitted(glme, Name, Value)
```

Description

`mufit = fitted(glme)` returns the fitted conditional response of the generalized linear mixed-effects model `glme`.

`mufit = fitted(glme, Name, Value)` returns the fitted response with additional options specified by one or more name-value pair arguments. For example, you can specify to compute the marginal fitted response.

Input Arguments

glme — Generalized linear mixed-effects model

GeneralizedLinearMixedModel object

Generalized linear mixed-effects model, specified as a GeneralizedLinearMixedModel object. For properties and methods of this object, see GeneralizedLinearMixedModel.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Conditional — Indicator for conditional response`true (default) | false`

Indicator for conditional response, specified as the comma-separated pair consisting of 'Conditional' and one of the following.

Value	Description
<code>true</code>	Contributions from both fixed effects and random effects (conditional)
<code>false</code>	Contribution from only fixed effects (marginal)

To obtain fitted marginal response values, `fitted` computes the conditional mean of the response with the empirical Bayes predictor vector of random effects b set equal to 0. For more information, see “Conditional and Marginal Response” on page 32-2707

Example: `'Conditional', false`

Output Arguments

mufit — Fitted response values`n`-by-1 vector

Fitted response values, returned as an n -by-1 vector, where n is the number of observations.

Examples

Plot Observed Versus Fitted Values

Load the sample data.

```
load mfr
```

This simulated data is from a manufacturing company that operates 50 factories across the world, with each factory running a batch process to create a finished product. The company wants to decrease the number of defects in each batch, so it developed a new

manufacturing process. To test the effectiveness of the new process, the company selected 20 of its factories at random to participate in an experiment: Ten factories implemented the new process, while the other ten continued to run the old process. In each of the 20 factories, the company ran five batches (for a total of 100 batches) and recorded the following data:

- Flag to indicate whether the batch used the new process (`newprocess`)
- Processing time for each batch, in hours (`time`)
- Temperature of the batch, in degrees Celsius (`temp`)
- Categorical variable indicating the supplier (A, B, or C) of the chemical used in the batch (`supplier`)
- Number of defects in the batch (`defects`)

The data also includes `time_dev` and `temp_dev`, which represent the absolute deviation of time and temperature, respectively, from the process standard of 3 hours at 20 degrees Celsius.

Fit a generalized linear mixed-effects model using `newprocess`, `time_dev`, `temp_dev`, and `supplier` as fixed-effects predictors. Include a random-effects term for intercept grouped by `factory`, to account for quality differences that might exist due to factory-specific variations. The response variable `defects` has a Poisson distribution, and the appropriate link function for this model is log. Use the Laplace fit method to estimate the coefficients. Specify the dummy variable encoding as `'effects'`, so the dummy variable coefficients sum to 0.

The number of defects can be modeled using a Poisson distribution

$$\text{defects}_{ij} \sim \text{Poisson}(\mu_{ij})$$

This corresponds to the generalized linear mixed-effects model

$$\log(\mu_{ij}) = \beta_0 + \beta_1 \text{newprocess}_{ij} + \beta_2 \text{time_dev}_{ij} + \beta_3 \text{temp_dev}_{ij} + \beta_4 \text{supplier_C}_{ij} + \beta_5 \text{supplier_B}_{ij} + b_i,$$

where

- defects_{ij} is the number of defects observed in the batch produced by factory i during batch j .
- μ_{ij} is the mean number of defects corresponding to factory i (where $i = 1, 2, \dots, 20$) during batch j (where $j = 1, 2, \dots, 5$).

- newprocess_{ij} , time_dev_{ij} , and temp_dev_{ij} are the measurements for each variable that correspond to factory i during batch j . For example, newprocess_{ij} indicates whether the batch produced by factory i during batch j used the new process.
- supplier_C_{ij} and supplier_B_{ij} are dummy variables that use effects (sum-to-zero) coding to indicate whether company C or B, respectively, supplied the process chemicals for the batch produced by factory i during batch j .
- $b_i \sim N(0, \sigma_b^2)$ is a random-effects intercept for each factory i that accounts for factory-specific variation in quality.

```
glme = fitglme(mfr, 'defects ~ 1 + newprocess + time_dev + temp_dev + supplier + (1|factory) + (1|batch) + (1|factory:batch)' +  
  'Distribution', 'Poisson', 'Link', 'log', 'FitMethod', 'Laplace', 'DummyVarCoding', 'effects')
```

Generate the fitted conditional mean values for the model.

```
mufit = fitted(glme);
```

Create a scatterplot of the observed values versus fitted values.

```
figure  
scatter(mfr.defects, mufit)  
title('Residuals versus Fitted Values')  
xlabel('Fitted Values')  
ylabel('Residuals')
```

Definitions

Conditional and Marginal Response

A *conditional response* includes contributions from both fixed- and random-effects predictors. A *marginal response* includes contribution from only fixed effects.

Suppose the generalized linear mixed-effects model $g\text{lme}$ has an n -by- p fixed-effects design matrix X and an n -by- q random-effects design matrix Z . Also, suppose the

estimated p -by-1 fixed-effects vector is $\widehat{\beta}$, and the q -by-1 empirical Bayes predictor vector of random effects is \widehat{b} .

The fitted conditional response corresponds to the 'Conditional', true name-value pair argument, and is defined as

$$\widehat{\mu}_{cond} = g^{-1}(\widehat{\eta}_{ME}),$$

where $\widehat{\eta}_{ME}$ is the linear predictor including the fixed- and random-effects of the generalized linear mixed-effects model

$$\widehat{\eta}_{ME} = X\widehat{\beta} + Z\widehat{b} + \delta .$$

The fitted marginal response corresponds to the 'Conditional', false name-value pair argument, and is defined as

$$\widehat{\mu}_{mar} = g^{-1}(\widehat{\eta}_{FE}),$$

where $\widehat{\eta}_{FE}$ is the linear predictor including only the fixed-effects portion of the generalized linear mixed-effects model

$$\widehat{\eta}_{FE} = X\widehat{\beta} + \delta .$$

fitted

Class: LinearMixedModel

Fitted responses from a linear mixed-effects model

Syntax

```
yfit = fitted(lme)
yfit = fitted(lme, Name, Value)
```

Description

`yfit = fitted(lme)` returns the fitted conditional response on page 32-2716 from the linear mixed-effects model `lme`.

`yfit = fitted(lme, Name, Value)` returns the fitted response from the linear mixed-effects model `lme` with additional options specified by one or more `Name, Value` pair arguments.

For example, you can specify if you want to compute the fitted marginal response on page 32-2716.

Input Arguments

lme — Linear mixed-effects model

LinearMixedModel object

Linear mixed-effects model, specified as a LinearMixedModel object constructed using `fitlme` or `fitlmematrix`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes.

You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Conditional — Indicator for conditional response

`true` (default) | `false`

Indicator for conditional response, specified as the comma-separated pair consisting of 'Conditional' and either of the following.

<code>true</code>	Contribution from both fixed effects and random effects (conditional)
<code>false</code>	Contribution from only fixed effects (marginal)

Example: `'Conditional', false`

Data Types: `logical`

Output Arguments

yfit — Fitted response values

n-by-1 vector

Fitted response values, returned as an *n*-by-1 vector, where *n* is the number of observations.

Examples

Compute Fitted Conditional and Marginal Responses

Load the sample data.

```
load flu
```

The `flu` dataset array has a `Date` variable, and 10 variables containing estimated influenza rates (in 9 different regions, estimated from Google® searches, plus a nationwide estimate from the Center for Disease Control and Prevention, CDC).

To fit a linear-mixed effects model, your data must be in a properly formatted dataset array. To fit a linear mixed-effects model with the influenza rates as the responses and region as the predictor variable, combine the nine columns corresponding to the regions into an array. The new dataset array, `flu2`, must have the response variable, `FluRate`, the nominal variable, `Region`, that shows which region each estimate is from, and the grouping variable `Date`.

```
flu2 = stack(flu,2:10, 'NewDataVarName', 'FluRate', 'IndVarName', 'Region');
flu2.Date = nominal(flu2.Date);
```

Fit a linear mixed-effects model with fixed effects for region and a random intercept that varies by `Date`.

`Region` is a categorical variable. You can specify the contrasts for categorical variables using the `DummyVarCoding` name-value pair argument when fitting the model. When you do not specify the contrasts, `fitlme` uses the 'reference' contrast by default. Because the model has an intercept, `fitlme` takes the first region, NE, as the reference and creates eight dummy variables representing the other eight regions. For example, `I[MidAtl]` is the dummy variable representing the region `MidAtl`. For details, see "Dummy Indicator Variables" on page 2-60.

The corresponding model is

$$y_{im} = \beta_0 + \beta_1 I[\text{MidAtl}]_i + \beta_2 I[\text{ENCentral}]_i + \beta_3 I[\text{WNCentral}]_i + \beta_4 I[\text{SATl}]_i \\ + \beta_5 I[\text{ESCentral}]_i + \beta_6 I[\text{WSCentral}]_i + \beta_7 I[\text{Mtn}]_i + \beta_8 I[\text{Pac}]_i + b_{0m} + \varepsilon_{im}, \quad m = 1, 2, \dots, 52,$$

where y_{im} is the observation i for level m of grouping variable `Date`, β_j , $j = 0, 1, \dots, 8$, are the fixed-effects coefficients, with β_0 being the coefficient for region NE. b_{0m} is the random effect for level m of the grouping variable `Date`, and ε_{im} is the observation error for observation i . The random effect has the prior distribution, $b_{0m} \sim N(0, \sigma_b^2)$ and the error term has the distribution, $\varepsilon_{im} \sim N(0, \sigma^2)$.

```
lme = fitlme(flu2, 'FluRate ~ 1 + Region + (1|Date)')
```

```
lme =
Linear mixed-effects model fit by ML
```

```
Model information:
  Number of observations      468

7.3324e-06	0.13424	0.33949
0.14902	-0.02714	0.1781
2.1623e-10	0.23655	0.44179
0.18705	-0.033621	0.17162
0.37191	-0.055948	0.14929
0.0022936	-0.26276	-0.057514

Random effects covariance parameters (95% CIs):

Group: Date (52 Levels)

Name1	Name2	Type	Estimate	Lower
'(Intercept)'	'(Intercept)'	'std'	0.6443	0.5297
Upper				
0.78368				

Group: Error

Name	Estimate	Lower	Upper
------	----------	-------	-------

'Res Std' 0.26627 0.24878 0.285

The p -values 7.3324e-06 and 2.1623e-10 respectively show that the fixed effects of the flu rates in regions `WNCentral` and `ESCentral` are significantly different relative to the flu rates in region `NE`.

The confidence limits for the standard deviation of the random-effects term, σ_b , do not include 0 (0.5297, 0.78368), which indicates that the random-effects term is significant. You can also test the significance of the random-effects terms using the `compare` method.

The conditional fitted response from the model at a given observation includes contributions from fixed and random effects. For example, the estimated best linear unbiased predictor (BLUP) of the flu rate for region `WNCentral` in week 10/9/2005 is

$$\begin{aligned}\hat{y}_{\text{WNCentral}, 10/9/2005} &= \hat{\beta}_0 + \hat{\beta}_3 I[\text{WNCentral}] + \hat{b}_{10/9/2005} \\ &= 1.2233 + 0.23687 - 0.1718 \\ &= 1.28837.\end{aligned}$$

This is the fitted conditional response, since it includes contributions to the estimate from both the fixed and random effects. You can compute this value as follows.

```
beta = fixedEffects(lme);
[~,~,STATS] = randomEffects(lme); % Compute the random-effects statistics (STATS)
STATS.Level = nominal(STATS.Level);
y_hat = beta(1) + beta(4) + STATS.Estimate(STATS.Level=='10/9/2005')
y_hat = 1.2884
```

In the previous calculation, `beta(1)` corresponds to the estimate for β_0 and `beta(4)` corresponds to the estimate for β_3 . You can simply display the fitted value using the `fitted` method.

```
F = fitted(lme);
F(flu2.Date == '10/9/2005' & flu2.Region == 'WNCentral')
ans = 1.2884
```

The estimated marginal response for region `WNCentral` in week 10/9/2005 is

$$\begin{aligned}\hat{y}_{\text{WNCentral}, 10/9/2005}^{(\text{marginal})} &= \hat{\beta}_0 + \hat{\beta}_3 I[\text{WNCentral}] \\ &= 1.2233 + 0.23687 \\ &= 1.46017.\end{aligned}$$

Compute the fitted marginal response.

```
F = fitted(lme, 'Conditional', false);  
F(flu2.Date == '10/9/2005' & flu2.Region == 'WNCentral')  
  
ans = 1.4602
```

Plot Residuals vs. Fitted Values

Load the sample data.

```
load(fullfile(matlabroot, 'examples', 'stats', 'weight.mat'));
```

`weight` contains data from a longitudinal study, where 20 subjects are randomly assigned to 4 exercise programs, and their weight loss is recorded over six 2-week time periods. This is simulated data.

Store the data in a table. Define `Subject` and `Program` as categorical variables.

```
tbl = table(InitialWeight, Program, Subject, Week, y);  
tbl.Subject = nominal(tbl.Subject);  
tbl.Program = nominal(tbl.Program);
```

Fit a linear mixed-effects model where the initial weight, type of program, week, and the interaction between the week and type of program are the fixed effects. The intercept and week vary by subject.

```
lme = fitlme(tbl, 'y ~ InitialWeight + Program*Week + (Week|Subject)');
```

Compute the fitted values and raw residuals.

```
F = fitted(lme);  
R = residuals(lme);
```

Plot the residuals versus the fitted values.

```
plot(F, R, 'bx')  
xlabel('Fitted Values')  
ylabel('Residuals')
```

Now, plot the residuals versus the fitted values, grouped by program.

```
figure()  
gscatter(F,R,Program)
```

Definitions

Fitted Conditional and Marginal Response

A conditional response includes contributions from both fixed and random effects, whereas a marginal response includes contribution from only fixed effects.

Suppose the linear mixed-effects model, lme , has an n -by- p fixed-effects design matrix X and an n -by- q random-effects design matrix Z . Also, suppose the p -by-1 estimated fixed-

effects vector is $\widehat{\beta}$, and the q -by-1 estimated best linear unbiased predictor (BLUP) vector of random effects is \widehat{b} . The fitted conditional response is

$$\widehat{y}_{Cond} = X\widehat{\beta} + Z\widehat{b},$$

and the fitted marginal response is

$$\widehat{y}_{Mar} = X\widehat{\beta},$$

LinearMixedModel | residuals | response

fixedEffects

Class: GeneralizedLinearMixedModel

Estimates of fixed effects and related statistics

Syntax

```
beta = fixedEffects(glme)
[beta,betanames] = fixedEffects(glme)
[beta,betanames,stats] = fixedEffects(glme)
[ ___ ] = fixedEffects(glme,Name,Value)
```

Description

`beta = fixedEffects(glme)` returns the estimated fixed-effects coefficients, `beta`, of the generalized linear mixed-effects model `glme`.

`[beta,betanames] = fixedEffects(glme)` also returns the names of estimated fixed-effects coefficients in `betanames`. Each name corresponds to a fixed-effects coefficient in `beta`.

`[beta,betanames,stats] = fixedEffects(glme)` also returns a table of statistics, `stats`, related to the estimated fixed-effects coefficients of `glme`.

`[___] = fixedEffects(glme,Name,Value)` returns any of the output arguments in previous syntaxes using additional options specified by one or more `Name,Value` pair arguments. For example, you can specify the confidence level, or the method for computing the approximate degrees of freedom for the *t*-statistic.

Input Arguments

glme — Generalized linear mixed-effects model

GeneralizedLinearMixedModel object

Generalized linear mixed-effects model, specified as a `GeneralizedLinearMixedModel` object. For properties and methods of this object, see `GeneralizedLinearMixedModel`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Alpha — Significance level

0.05 (default) | scalar value in the range [0,1]

Significance level, specified as the comma-separated pair consisting of `'Alpha'` and a scalar value in the range [0,1]. For a value α , the confidence level is $100 \times (1 - \alpha)\%$.

For example, for 99% confidence intervals, you can specify the confidence level as follows.

Example: `'Alpha', 0.01`

Data Types: `single` | `double`

DFMethod — Method for computing approximate degrees of freedom

`'residual'` (default) | `'none'`

Method for computing approximate degrees of freedom, specified as the comma-separated pair consisting of `'DFMethod'` and one of the following.

Value	Description
<code>'residual'</code>	The degrees of freedom value is assumed to be constant and equal to $n - p$, where n is the number of observations and p is the number of fixed effects.
<code>'none'</code>	The degrees of freedom is set to infinity.

Example: `'DFMethod', 'none'`

Output Arguments

beta — Estimated fixed-effects coefficients

vector

Estimated fixed-effects coefficients of the fitted generalized linear mixed-effects model `glme`, returned as a vector.

betanames — Names of fixed-effects coefficients

table

Names of fixed-effects coefficients in `beta`, returned as a table.

stats — Fixed-effects estimates and related statistics

dataset array

Fixed-effects estimates and related statistics, returned as a dataset array that has one row for each of the fixed effects and one column for each of the following statistics.

Column Name	Description
Name	Name of the fixed-effects coefficient
Estimate	Estimated coefficient value
SE	Standard error of the estimate
tStat	<i>t</i> -statistic for a test that the coefficient is 0
DF	Estimated degrees of freedom for the <i>t</i> -statistic
pValue	<i>p</i> -value for the <i>t</i> -statistic
Lower	Lower limit of a 95% confidence interval for the fixed-effects coefficient
Upper	Upper limit of a 95% confidence interval for the fixed-effects coefficient

When fitting a model using `fitglme` and one of the maximum likelihood fit methods ('Laplace' or 'ApproximateLaplace'), if you specify the 'CovarianceMethod' name-value pair argument as 'conditional', then SE does not account for the uncertainty in estimating the covariance parameters. To account for this uncertainty, specify 'CovarianceMethod' as 'JointHessian'.

When fitting a GLME model using `fitglme` and one of the pseudo likelihood fit methods ('MPL' or 'REML'), `fixedEffects` bases the fixed effects estimates and related statistics on the fitted linear mixed-effects model from the final pseudo likelihood iteration.

Examples

Estimate Fixed-Effects Coefficients

Load the sample data.

```
load mfr
```

This simulated data is from a manufacturing company that operates 50 factories across the world, with each factory running a batch process to create a finished product. The company wants to decrease the number of defects in each batch, so it developed a new manufacturing process. To test the effectiveness of the new process, the company selected 20 of its factories at random to participate in an experiment: Ten factories implemented the new process, while the other ten continued to run the old process. In each of the 20 factories, the company ran five batches (for a total of 100 batches) and recorded the following data:

- Flag to indicate whether the batch used the new process (`newprocess`)
- Processing time for each batch, in hours (`time`)
- Temperature of the batch, in degrees Celsius (`temp`)
- Categorical variable indicating the supplier (A, B, or C) of the chemical used in the batch (`supplier`)
- Number of defects in the batch (`defects`)

The data also includes `time_dev` and `temp_dev`, which represent the absolute deviation of time and temperature, respectively, from the process standard of 3 hours at 20 degrees Celsius.

Fit a generalized linear mixed-effects model using `newprocess`, `time_dev`, `temp_dev`, and `supplier` as fixed-effects predictors. Include a random-effects term for intercept grouped by `factory`, to account for quality differences that might exist due to factory-specific variations. The response variable `defects` has a Poisson distribution, and the appropriate link function for this model is log. Use the Laplace fit method to estimate the

coefficients. Specify the dummy variable encoding as 'effects', so the dummy variable coefficients sum to 0.

The number of defects can be modeled using a Poisson distribution

$$\text{defects}_{ij} \sim \text{Poisson}(\mu_{ij})$$

This corresponds to the generalized linear mixed-effects model

$$\log(\mu_{ij}) = \beta_0 + \beta_1 \text{newprocess}_{ij} + \beta_2 \text{time_dev}_{ij} + \beta_3 \text{temp_dev}_{ij} + \beta_4 \text{supplier_C}_{ij} + \beta_5 \text{supplier_B}_{ij} + b_i,$$

where

- defects_{ij} is the number of defects observed in the batch produced by factory i during batch j .
- μ_{ij} is the mean number of defects corresponding to factory i (where $i = 1, 2, \dots, 20$) during batch j (where $j = 1, 2, \dots, 5$).
- newprocess_{ij} , time_dev_{ij} , and temp_dev_{ij} are the measurements for each variable that correspond to factory i during batch j . For example, newprocess_{ij} indicates whether the batch produced by factory i during batch j used the new process.
- supplier_C_{ij} and supplier_B_{ij} are dummy variables that use effects (sum-to-zero) coding to indicate whether company C or B, respectively, supplied the process chemicals for the batch produced by factory i during batch j .
- $b_i \sim N(0, \sigma_b^2)$ is a random-effects intercept for each factory i that accounts for factory-specific variation in quality.

```
glme = fitglme(mfr, 'defects ~ 1 + newprocess + time_dev + temp_dev + supplier + (1|factory)')
      fitglme(mfr, 'defects ~ 1 + newprocess + time_dev + temp_dev + supplier + (1|factory) |
      Distribution', 'Poisson', 'Link', 'log', 'FitMethod', 'Laplace', 'DummyVarCoding', 'effects')
```

Compute and display the estimated fixed-effects coefficient values and related statistics.

```
[beta, betanames, stats] = fixedEffects(glme);
stats
```

```
stats =
    Fixed effect coefficients: DFMethod = 'residual', Alpha = 0.05

    Name              Estimate      SE          tStat      DF      pValue
    '(Intercept)'      1.4689      0.15988      9.1875     94      9.8194e-15
```

'newprocess'	-0.36766	0.17755	-2.0708	94	0.041122
'time_dev'	-0.094521	0.82849	-0.11409	94	0.90941
'temp_dev'	-0.28317	0.9617	-0.29444	94	0.76907
'supplier_C'	-0.071868	0.078024	-0.9211	94	0.35936
'supplier_B'	0.071072	0.07739	0.91836	94	0.36078

Lower	Upper
1.1515	1.7864
-0.72019	-0.015134
-1.7395	1.5505
-2.1926	1.6263
-0.22679	0.083051
-0.082588	0.22473

The returned results indicate, for example, that the estimated coefficient for `temp_dev` is -0.28317 . Its large p -value, 0.76907 , indicates that it is not a statistically significant predictor at the 5% significance level. Additionally, the confidence interval boundaries `Lower` and `Upper` indicate that the 95% confidence interval for the coefficient for `temp_dev` is $[-2.1926, 1.6263]$. This interval contains 0, which supports the conclusion that `temp_dev` is not statistically significant at the 5% significance level.

fixedEffects

Class: LinearMixedModel

Estimates of fixed effects and related statistics

Syntax

```
beta = fixedEffects(lme)
[beta,betaname] = fixedEffects(lme)
[beta,betaname,stats] = fixedEffects(lme)
[beta,betaname,stats] = fixedEffects(lme,Name,Value)
```

Description

`beta = fixedEffects(lme)` returns the estimated fixed-effects coefficients, `beta`, of the linear mixed-effects model `lme`.

`[beta,betaname] = fixedEffects(lme)` also returns the names of estimated fixed-effects coefficients in `betaname`. Each name corresponds to a fixed-effects coefficient in `beta`.

`[beta,betaname,stats] = fixedEffects(lme)` also returns the estimated fixed-effects coefficients of the linear mixed-effects model `lme` and related statistics in `stats`.

`[beta,betaname,stats] = fixedEffects(lme,Name,Value)` also returns the estimated fixed-effects coefficients of the linear mixed-effects model `lme` and related statistics with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

lme — Linear mixed-effects model

LinearMixedModel object

Linear mixed-effects model, specified as a LinearMixedModel object constructed using `fitlme` or `fitlmematrix`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Alpha — Significance level

0.05 (default) | scalar value in the range 0 to 1

Significance level, specified as the comma-separated pair consisting of `'Alpha'` and a scalar value in the range 0 to 1. For a value α , the confidence level is $100*(1-\alpha)\%$.

For example, for 99% confidence intervals, you can specify the confidence level as follows.

Example: `'Alpha', 0.01`

Data Types: `single` | `double`

DFMethod — Method for computing approximate degrees of freedom

`'residual'` (default) | `'satterthwaite'` | `'none'`

Method for computing approximate degrees of freedom for the t -statistic that tests the fixed-effects coefficients against 0, specified as the comma-separated pair consisting of `'DFMethod'` and one of the following.

<code>'residual'</code>	Default. The degrees of freedom are assumed to be constant and equal to $n - p$, where n is the number of observations and p is the number of fixed effects.
<code>'satterthwaite'</code>	Satterthwaite approximation.
<code>'none'</code>	All degrees of freedom are set to infinity.

For example, you can specify the Satterthwaite approximation as follows.

Example: `'DFMethod', 'satterthwaite'`

Output Arguments

beta — Fixed-effects coefficients estimates

vector

Fixed-effects coefficients estimates of the fitted linear mixed-effects model `lme`, returned as a vector.

betanames — Names of fixed-effects coefficients

table

Names of fixed-effects coefficients in `beta`, returned as a table.

stats — Fixed-effects estimates and related statistics

dataset array

Fixed-effects estimates and related statistics, returned as a dataset array that has one row for each of the fixed effects and one column for each of the following statistics.

Name	Name of the fixed effect coefficient
Estimate	Estimated coefficient value
SE	Standard error of the estimate
tStat	<i>t</i> -statistic for a test that the coefficient is zero
DF	Estimated degrees of freedom for the <i>t</i> -statistic
pValue	<i>p</i> -value for the <i>t</i> -statistic
Lower	Lower limit of a 95% confidence interval for the fixed-effect coefficient
Upper	Upper limit of a 95% confidence interval for the fixed-effect coefficient

Examples

Display Fixed-Effects Coefficient Estimates and Names

Load the sample data.

```
load(fullfile(matlabroot, 'examples', 'stats', 'weight.mat'));
```

The data set `weight` contains data from a longitudinal study, where 20 subjects are randomly assigned to 4 exercise programs, and their weight loss is recorded over six 2-week time periods. This is simulated data.

Store the data in a table. Define `Subject` and `Program` as categorical variables.

```
tbl = table(InitialWeight, Program, Subject, Week, y);
tbl.Subject = nominal(tbl.Subject);
tbl.Program = nominal(tbl.Program);
```

Fit a linear mixed-effects model where the initial weight, type of program, week, and the interaction between week and program are the fixed effects. The intercept and week vary by subject.

```
lme = fitlme(tbl, 'y ~ InitialWeight + Program*Week + (Week|Subject)');
```

Display the fixed-effects coefficient estimates and corresponding fixed-effects names.

```
[beta, betanames] = fixedEffects(lme)
```

```
beta = 9×1
```

```
    0.6610
    0.0032
    0.3608
   -0.0333
    0.1132
    0.1732
    0.0388
    0.0305
    0.0331
```

```
betanames=9×1 table
```

```
    Name
```

```
-----
'(Intercept)'  
'InitialWeight'  
'Program_B'  
'Program_C'  
'Program_D'  
'Week'
```

```
'Program_B:Week'  
'Program_C:Week'  
'Program_D:Week'
```

Compute Coefficient Estimates and Related Statistics

Load the sample data.

```
load carbig
```

Fit a linear mixed-effects model for miles per gallon (MPG), with fixed effects for acceleration and horsepower, and potentially correlated random effects for intercept and acceleration grouped by model year. First, store the data in a table.

```
tbl = table(Acceleration,Horsepower,Model_Year,MPG);
```

Fit the model.

```
lme = fitlme(tbl, 'MPG ~ Acceleration + Horsepower + (Acceleration|Model_Year)');
```

Compute the fixed-effects coefficients estimates and related statistics.

```
[~,~,stats] = fixedEffects(lme)
```

```
stats =
```

```
Fixed effect coefficients: DFMethod = 'Residual', Alpha = 0.05
```

Name	Estimate	SE	tStat	DF	pValue
'(Intercept)'	50.133	2.2652	22.132	389	7.7727e-71
'Acceleration'	-0.58327	0.13394	-4.3545	389	1.7075e-05
'Horsepower'	-0.16954	0.0072609	-23.35	389	5.188e-76

Lower	Upper
45.679	54.586
-0.84661	-0.31992
-0.18382	-0.15527

The small *p*-values (under `pValue`) indicate that all fixed-effects coefficients are significant.

Compute Confidence Intervals with Specified Options

Load the sample data.

```
load(fullfile(matlabroot, 'examples', 'stats', 'shift.mat'));
```

The data shows the deviations from the target quality characteristic measured from the products that five operators manufacture during three shifts: morning, evening, and night. This is a randomized block design, where the operators are the blocks. The experiment is designed to study the impact of the time of shift on the performance. The performance measure is the deviation of the quality characteristics from the target value. This is simulated data.

Shift and Operator are nominal variables.

```
shift.Shift = nominal(shift.Shift);
shift.Operator = nominal(shift.Operator);
```

Fit a linear mixed-effects model with a random intercept grouped by operator to assess if performance significantly differs according to the time of the shift.

```
lme = fitlme(shift, 'QCDev ~ Shift + (1|Operator)');
```

Compute the 99% confidence intervals for fixed-effects coefficients, using the residual method to compute the degrees of freedom. This is the default method.

```
[~,~,stats] = fixedEffects(lme, 'alpha', 0.01)
```

```
stats =
```

```
Fixed effect coefficients: DFMethod = 'Residual', Alpha = 0.01
```

Name	Estimate	SE	tStat	DF	pValue
'(Intercept)'	3.1196	0.88681	3.5178	12	0.0042407
'Shift_Morning'	-0.3868	0.48344	-0.80009	12	0.43921
'Shift_Night'	1.9856	0.48344	4.1072	12	0.0014535

Lower	Upper
0.41081	5.8284
-1.8635	1.0899
0.5089	3.4623

Compute the 99% confidence intervals for fixed-effects coefficients, using the Satterthwaite approximation to compute the degrees of freedom.

```
[~,~,stats] = fixedEffects(lme, 'DFMethod', 'satterthwaite', 'alpha', 0.01)
```

```
stats =
```

```
Fixed effect coefficients: DFMethod = 'Satterthwaite', Alpha = 0.01
```

Name	Estimate	SE	tStat	DF	pValue
'(Intercept)'	3.1196	0.88681	3.5178	6.123	0.01214
'Shift_Morning'	-0.3868	0.48344	-0.80009	10	0.44225
'Shift_Night'	1.9856	0.48344	4.1072	10	0.00212

Lower	Upper
-0.14122	6.3804
-1.919	1.1454
0.45343	3.5178

The Satterthwaite approximation usually produces smaller DF values than the residual method. That is why it produces larger *p*-values (`pValue`) and larger confidence intervals (see `Lower` and `Upper`).

fpdf

F probability density function

Syntax

`Y = fpdf(X,V1,V2)`

Description

`Y = fpdf(X,V1,V2)` computes the *F* pdf at each of the values in *X* using the corresponding numerator degrees of freedom *V1* and denominator degrees of freedom *V2*. *X*, *V1*, and *V2* can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other inputs. *V1* and *V2* parameters must contain real positive values, and the values in *X* must lie on the interval $[0 \text{ Inf}]$.

The probability density function for the *F* distribution is

$$y = f(x) \left| \nu_1, \nu_2 \right) = \frac{\Gamma\left[\frac{(\nu_1 + \nu_2)}{2}\right] \left(\frac{\nu_1}{\nu_2}\right)^{\frac{\nu_1}{2}} \frac{x^{\frac{\nu_1 - 2}{2}}}{\left[1 + \left(\frac{\nu_1}{\nu_2}\right)x\right]^{\frac{\nu_1 + \nu_2}{2}}}{\Gamma\left(\frac{\nu_1}{2}\right)\Gamma\left(\frac{\nu_2}{2}\right)}$$

Examples

```
y = fpdf(1:6,2,2)
```

```
y =
    0.2500    0.1111    0.0625    0.0400    0.0278    0.0204
```

```
z = fpdf(3,5:10,5:10)
```

```
z =
    0.0689    0.0659    0.0620    0.0577    0.0532    0.0487
```

fracfact

Fractional factorial design

Syntax

```
X = fracfact(gen)
[X,conf] = fracfact(gen)
[X,conf] = fracfact(gen,Name,Value)
```

Description

`X = fracfact(gen)` creates the two-level fractional factorial design defined by the generator `gen`.

`[X,conf] = fracfact(gen)` returns a cell array of character vectors containing the confounding pattern for the design.

`[X,conf] = fracfact(gen,Name,Value)` creates a fractional factorial designs with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

`gen`

Either a string array or cell array of character vectors where each element contains one “word,” or a character array or string scalar consisting of “words” separated by spaces. “Words” consist of case-sensitive letters or groups of letters, where 'a' represents value 1, 'b' represents value 2, ..., 'A' represents value 27, ..., 'Z' represents value 52.

Each word defines how the corresponding factor’s levels are defined as products of generators from a 2^K full-factorial design. K is the number of letters of the alphabet in `gen`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

FactorNames

String array or cell array specifying the name for each factor.

Default: {'X1', 'X2', ...}

MaxInt

Positive integer setting the maximum level of interaction to include in the confounding output.

Default: 2

Output Arguments

X

The two-level fractional factorial design. `X` is a matrix of size `N`-by-`P`, where

- $N = 2^K$, where `K` is the number of letters of the alphabet in `gen`.
- `P` is the number of words in `gen`.

Because `X` is a two-level design, the components of `X` are ± 1 . For the meaning of `X`, see “Fractional Factorial Designs” on page 27-5.

conf

Cell array of character vectors containing the confounding pattern for the design.

Examples

Generate a fractional factorial design for four variables, where the fourth variable is the product of the first three:

```
x = fracfact('a b c abc')
```

```
x =
   -1   -1   -1   -1
   -1   -1    1    1
   -1    1   -1    1
   -1    1    1   -1
    1   -1   -1    1
    1   -1    1   -1
    1    1   -1   -1
    1    1    1    1
```

Find generators for a six-factor design that uses four factors and achieves resolution IV using `fracfactgen`. Use the result to specify the design:

```
generators = fracfactgen('a b c d e f',4, ... % 4 factors
    4) % resolution 4
```

```
generators =
    'a'
    'b'
    'c'
    'd'
    'bcd'
    'acd'
```

```
x = fracfact(generators)
```

```
x =
   -1   -1   -1   -1   -1   -1
   -1   -1   -1    1    1    1
   -1   -1    1   -1    1    1
   -1   -1    1    1   -1   -1
   -1    1   -1   -1    1   -1
   -1    1   -1    1   -1    1
   -1    1    1   -1   -1    1
   -1    1    1    1    1   -1
    1   -1   -1   -1   -1    1
    1   -1   -1    1    1   -1
    1   -1    1   -1    1   -1
    1   -1    1    1   -1    1
    1    1   -1   -1    1    1
    1    1   -1    1   -1   -1
    1    1    1   -1   -1   -1
    1    1    1    1    1    1
```

Topics

“Fractional Factorial Designs” on page 27-5

Introduced before R2006a

fracfactgen

Fractional factorial design generators

Syntax

```
generators = fracfactgen(terms)
generators = fracfactgen(terms,k)
generators = fracfactgen(terms,k,R)
generators = fracfactgen(terms,k,R,basic)
```

Description

`generators = fracfactgen(terms)` uses the Franklin-Bailey algorithm to find generators for the smallest two-level fractional-factorial design for estimating linear model terms specified by `terms`. `terms` is a character vector or string scalar consisting of words formed from the 52 case-sensitive letters a-Z, separated by spaces. Use 'a' - 'z' for the first 26 factors, and, if necessary, 'A' - 'Z' for the remaining factors. For example, `terms = 'a b c ab ac'`. Single-letter words indicate main effects to be estimated; multiple-letter words indicate interactions. Alternatively, `terms` is an m -by- n matrix of 0s and 1s where m is the number of model terms to be estimated and n is the number of factors. For example, if `terms` contains rows `[0 1 0 0]` and `[1 0 0 1]`, then the factor `b` and the interaction between factors `a` and `d` are included in the model. `generators` is a cell array of character vectors with one generator per cell. Pass `generators` to `fracfact` to produce the fractional-factorial design and corresponding confounding pattern.

`generators = fracfactgen(terms,k)` returns generators for a two-level fractional-factorial design with 2^k -runs, if possible. If `k` is `[]`, `fracfactgen` finds the smallest design.

`generators = fracfactgen(terms,k,R)` finds a design with resolution `R`, if possible. The default resolution is 3.

A design of resolution R is one in which no n -factor interaction is confounded with any other effect containing less than $R - n$ factors. Thus a resolution III design does not

confound main effects with one another but may confound them with two-way interactions, while a resolution IV design does not confound either main effects or two-way interactions but may confound two-way interactions with each other.

If `fracfactgen` is unable to find a design at the requested resolution, it tries to find a lower-resolution design sufficient to calibrate the model. If it is successful, it returns the generators for the lower-resolution design along with a warning. If it fails, it returns an error.

`generators = fracfactgen(terms,k,R,basic)` also accepts a vector `basic` specifying the indices of factors that are to be treated as basic. These factors receive full-factorial treatments in the design. The default includes factors that are part of the highest-order interaction in `terms`.

Examples

Suppose you wish to determine the effects of four two-level factors, for which there may be two-way interactions. A full-factorial design would require $2^4 = 16$ runs. The `fracfactgen` function finds generators for a resolution IV (separating main effects) fractional-factorial design that requires only $2^3 = 8$ runs:

```
generators = fracfactgen('a b c d',3,4)
generators =
  'a'
  'b'
  'c'
  'abc'
```

The more economical design and the corresponding confounding pattern are returned by `fracfact`:

```
[dfF,confounding] = fracfact(generators)
dfF =
  -1  -1  -1  -1
  -1  -1   1   1
  -1   1  -1   1
  -1   1   1  -1
   1  -1  -1   1
   1  -1   1  -1
   1   1  -1  -1
   1   1   1   1
confounding =
```

'Term'	'Generator'	'Confounding'
'X1'	'a'	'X1'
'X2'	'b'	'X2'
'X3'	'c'	'X3'
'X4'	'abc'	'X4'
'X1*X2'	'ab'	'X1*X2 + X3*X4'
'X1*X3'	'ac'	'X1*X3 + X2*X4'
'X1*X4'	'bc'	'X1*X4 + X2*X3'
'X2*X3'	'bc'	'X1*X4 + X2*X3'
'X2*X4'	'ac'	'X1*X3 + X2*X4'
'X3*X4'	'ab'	'X1*X2 + X3*X4'

The confounding pattern shows, for example, that the two-way interaction between X1 and X2 is confounded by the two-way interaction between X3 and X4.

friedman

Friedman's test

Syntax

```
p = friedman(x, reps)
p = friedman(x, reps, displayopt)
[p, tbl] = friedman( ___ )
[p, tbl, stats] = friedman( ___ )
```

Description

`p = friedman(x, reps)` returns the p -value for the nonparametric Friedman's test to compare column effects in a two-way layout. `friedman` tests the null hypothesis that the column effects are all the same against the alternative that they are not all the same.

`p = friedman(x, reps, displayopt)` enables the ANOVA table display when `displayopt` is 'on' (default) and suppresses the display when `displayopt` is 'off'.

`[p, tbl] = friedman(___)` returns the ANOVA table (including column and row labels) in cell array `tbl`.

`[p, tbl, stats] = friedman(___)` also returns a structure `stats` that you can use to perform a follow-up multiple comparison test.

Examples

Test For Column Effects Using Friedman's Test

This example shows how to test for column effects in a two-way layout using Friedman's test.

Load the sample data.

```
load popcorn
popcorn
```

```
popcorn = 6x3
```

```
 5.5000  4.5000  3.5000
 5.5000  4.5000  4.0000
 6.0000  4.0000  3.0000
 6.5000  5.0000  4.0000
 7.0000  5.5000  5.0000
 7.0000  5.0000  4.5000
```

This data comes from a study of popcorn brands and popper type (Hogg 1987). The columns of the matrix `popcorn` are brands (Gourmet, National, and Generic). The rows are popper type (Oil and Air). The study popped a batch of each brand three times with each popper. The values are the yield in cups of popped popcorn.

Use Friedman's test to determine whether the popcorn brand affects the yield of popcorn.

```
p = friedman(popcorn,3)
```

Friedman's ANOVA Table

Source	SS	df	MS	Chi-sq	Prob>Chi-sq
Columns	99.75	2	49.875	13.76	0.001
Interaction	0.0833	2	0.0417		
Error	16.1667	12	1.3472		
Total	116	17			

Test for column effects after row effects are removed

$$p = 0.0010$$

The small value of $p = 0.001$ indicates the popcorn brand affects the yield of popcorn.

Input Arguments

x — Sample data

matrix

Sample data for the hypothesis test, specified as a matrix. The columns of x represent changes in a factor A. The rows represent changes in a blocking factor B. If there is more

than one observation for each combination of factors, input reps indicates the number of replicates in each “cell,” which must be constant.

Data Types: `single` | `double`

reps — Number of replicates per cell

1 (default) | positive integer value

Number of replicates per cell, specified as a positive integer value.

Data Types: `single` | `double`

displayopt — ANOVA table display option

'off' (default) | 'on'

ANOVA table display option, specified as 'off' or 'on'.

If `displayopt` is 'on', then `friedman` displays a figure showing an ANOVA table, which divides the variability of the ranks into two or three parts:

- The variability due to the differences among the column effects
- The variability due to the interaction between rows and columns (if `reps` is greater than its default value of 1)
- The remaining variability not explained by any systematic source

The ANOVA table has six columns:

- The first shows the source of the variability.
- The second shows the Sum of Squares (SS) due to each source.
- The third shows the degrees of freedom (df) associated with each source.
- The fourth shows the Mean Squares (MS), which is the ratio SS/df.
- The fifth shows Friedman's chi-square statistic.
- The sixth shows the p value for the chi-square statistic.

You can copy a text version of the ANOVA table to the clipboard by selecting `Copy Text` from the **Edit** menu.

Output Arguments

p — *p*-value

scalar value in the range $[0, 1]$

p-value of the test, returned as a scalar value in the range $[0, 1]$. *p* is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. Small values of *p* cast doubt on the validity of the null hypothesis.

tbl — ANOVA table

cell array

ANOVA table, including column and row labels, returned as a cell array. The ANOVA table has six columns:

- The first shows the source of the variability.
- The second shows the Sum of Squares (SS) due to each source.
- The third shows the degrees of freedom (df) associated with each source.
- The fourth shows the Mean Squares (MS), which is the ratio SS/df.
- The fifth shows Friedman's chi-square statistic.
- The sixth shows the *p* value for the chi-square statistic.

You can copy a text version of the ANOVA table to the clipboard by selecting Copy Text from the **Edit** menu.

stats — Test data

structure

Test data, returned as a structure. `friedman` evaluates the hypothesis that the column effects are all the same against the alternative that they are not all the same. However, sometimes it is preferable to perform a test to determine which pairs of column effects are significantly different, and which are not. You can use the `multcompare` function to perform such tests by supplying `stats` as the input value.

Definitions

Friedman's Test

Friedman's test is similar to classical balanced two-way ANOVA, but it tests only for column effects after adjusting for possible row effects. It does not test for row effects or interaction effects. Friedman's test is appropriate when columns represent treatments that are under study, and rows represent nuisance effects (blocks) that need to be taken into account but are not of any interest.

The different columns of X represent changes in a factor A. The different rows represent changes in a blocking factor B. If there is more than one observation for each combination of factors, input `reps` indicates the number of replicates in each "cell," which must be constant.

The matrix below illustrates the format for a set-up where column factor A has three levels, row factor B has two levels, and there are two replicates (`reps=2`). The subscripts indicate row, column, and replicate, respectively.

$$\begin{bmatrix} x_{111} & x_{121} & x_{131} \\ x_{112} & x_{122} & x_{132} \\ x_{211} & x_{221} & x_{231} \\ x_{212} & x_{222} & x_{232} \end{bmatrix}$$

Friedman's test assumes a model of the form

$$x_{ijk} = \mu + \alpha_i + \beta_j + \varepsilon_{ijk}$$

where μ is an overall location parameter, α_i represents the column effect, β_j represents the row effect, and ε_{ijk} represents the error. This test ranks the data within each level of B, and tests for a difference across levels of A. The `p` that `friedman` returns is the p value for the null hypothesis that $\alpha_i = 0$. If the p value is near zero, this casts doubt on the null hypothesis. A sufficiently small p value suggests that at least one column-sample median is significantly different than the others; i.e., there is a main effect due to factor A. The choice of a critical p value to determine whether a result is "statistically significant" is left to the researcher. It is common to declare a result significant if the p value is less than 0.05 or 0.01.

Friedman's test makes the following assumptions about the data in X :

- All data come from populations having the same continuous distribution, apart from possibly different locations due to column and row effects.
- All observations are mutually independent.

The classical two-way ANOVA replaces the first assumption with the stronger assumption that data come from normal distributions.

Introduced before R2006a

frnd

F random numbers

Syntax

```
R = frnd(V1,V2)
R = frnd(V1,V2,m,n,...)
R = frnd(V1,V2,[m,n,...])
```

Description

`R = frnd(V1,V2)` generates random numbers from the *F* distribution with numerator degrees of freedom *V1* and denominator degrees of freedom *V2*. *V1* and *V2* can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input for *V1* or *V2* is expanded to a constant array with the same dimensions as the other input. *V1* and *V2* parameters must contain real positive values.

`R = frnd(V1,V2,m,n,...)` or `R = frnd(V1,V2,[m,n,...])` generates an *m*-by-*n*-by-... array containing random numbers from the *F* distribution with parameters *V1* and *V2*. *V1* and *V2* can each be scalars or arrays of the same size as *R*.

Examples

```
n1 = frnd(1:6,1:6)
n1 =
    0.0022    0.3121    3.0528    0.3189    0.2715    0.9539
```

```
n2 = frnd(2,2,[2 3])
n2 =
    0.3186    0.9727    3.0268
    0.2052   148.5816    0.2191
```

```
n3 = frnd([1 2 3;4 5 6],1,2,3)
n3 =
    0.6233    0.2322   31.5458
    2.5848    0.2121    4.4955
```

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

The generated code can return a different sequence of numbers than MATLAB if either of the following is true:

- The output is nonscalar.
- An input parameter is invalid for the distribution.

For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “General Code Generation Workflow” on page 31-5.

fscnca

Feature selection using neighborhood component analysis for classification

Syntax

```
mdl = fscnca(X,Y)
mdl = fscnca(X,Y,Name,Value)
```

Description

`mdl = fscnca(X,Y)` performs feature selection for classification using the predictors in `X` and responses in `Y`.

`fscnca` learns the feature weights by using a diagonal adaptation of neighborhood component analysis (NCA) with regularization.

`mdl = fscnca(X,Y,Name,Value)` performs feature selection for classification with additional options specified by one or more name-value pair arguments.

Examples

Detect Relevant Features in Data Using NCA for Classification

Generate toy data where the response variable depends on the 3rd, 9th, and 15th predictors.

```
rng(0,'twister'); % For reproducibility
N = 100;
X = rand(N,20);
y = -ones(N,1);
y(X(:,3).*X(:,9)./X(:,15) < 0.4) = 1;
```

Fit the neighborhood component analysis model for classification.

```
mdl = fscnca(X,y,'Solver','sgd','Verbose',1);
```

o Tuning initial learning rate: NumTuningIterations = 20, TuningSubsetSize = 100

Two norm of the final step = 2.946e-01
 Relative two norm of the final step = 6.588e-02, TolX = 1.000e-06
 EXIT: Iteration or pass limit reached.

Plot the selected features. The weights of the irrelevant features should be close to zero.

```
figure()
plot mdl.FeatureWeights, 'ro'
grid on
xlabel('Feature index')
ylabel('Feature weight')
```

fscnca correctly detects the relevant features.

Identify Relevant Features for Classification

Load sample data

```
load ovariancancer;  
whos
```

Name	Size	Bytes	Class	Attributes
grp	216x1	26784	cell	
obs	216x4000	3456000	single	

This example uses the high-resolution ovarian cancer data set that was generated using the WCX2 protein array. The data is from the FDA-NCI Clinical Proteomics Program Databank. After some preprocessing steps, the data set has two variables: `obs` and `grp`. The `obs` variable consists 216 observations with 4000 features. Each element in `grp` defines the group to which the corresponding row of `obs` belongs.

Divide data into training and test sets

Use `cvpartition` to divide data into a training set of size 160 and a test set of size 56. Both the training set and the test set have roughly the same group proportions as in `grp`.

```
rng(1); % For reproducibility  
cvp = cvpartition(grp, 'holdout', 56)  
  
cvp =  
Hold-out cross validation partition  
  NumObservations: 216  
  NumTestSets: 1  
  TrainSize: 160  
  TestSize: 56  
  
Xtrain = obs(cvp.training,:);  
ytrain = grp(cvp.training,:);  
Xtest = obs(cvp.test,:);  
ytest = grp(cvp.test,:);
```

Determine if feature selection is necessary

Compute generalization error without fitting.

```
nca = fscnca(Xtrain,ytrain, 'FitMethod', 'none');  
L = loss(nca,Xtest,ytest)  
  
L = 0.0893
```

This option computes the generalization error of the neighborhood component analysis (NCA) feature selection model using the initial feature weights (in this case the default feature weights) provided in `fscnca`.

Fit NCA without regularization parameter ($\text{Lambda} = 0$)

```
nca = fscnca(Xtrain,ytrain,'FitMethod','exact','Lambda',0,...
            'Solver','sgd','Standardize',true);
L = loss(nca,Xtest,ytest)

L = 0.0714
```

The improvement on the loss value suggests that feature selection is a good idea. Tuning the λ value usually improves the results.

Tune the regularization parameter for NCA using five-fold cross-validation

Tuning λ means finding the λ value that produces the minimum classification loss. To tune λ using cross-validation:

1. Partition the training data into five folds and extract the number of validation (test) sets. For each fold, `cvpartition` assigns four-fifths of the data as a training set, and one-fifth of the data as a test set.

```
cvp = cvpartition(ytrain,'kfold',5);
numvalidsets = cvp.NumTestSets;
```

Assign λ values and create an array to store the loss function values.

```
n = length(ytrain);
lambdaval = linspace(0,20,20)/n;
lossvals = zeros(length(lambdaval),numvalidsets);
```

2. Train the NCA model for each λ value, using the training set in each fold.

3. Compute the classification loss for the corresponding test set in the fold using the NCA model. Record the loss value.

4. Repeat this process for all folds and all λ values.

```
for i = 1:length(lambdaval)
    for k = 1:numvalidsets
        X = Xtrain(cvp.training(k),:);
        y = ytrain(cvp.training(k),:);
```

```
Xvalid = Xtrain(cvp.test(k),:);
yvalid = ytrain(cvp.test(k),:);

nca = fscnca(X,y,'FitMethod','exact', ...
            'Solver','sgd','Lambda',lambdaval(i), ...
            'IterationLimit',30,'GradientTolerance',1e-4, ...
            'Standardize',true);

    lossvals(i,k) = loss(nca,Xvalid,yvalid,'LossFunction','classiferror');
end
end
```

Compute the average loss obtained from the folds for each λ value.

```
meanloss = mean(lossvals,2);
```

Plot the average loss values versus the λ values.

```
figure()
plot(lambdaval,meanloss,'ro-')
xlabel('Lambda')
ylabel('Loss (MSE)')
grid on
```

Find the best lambda value that corresponds to the minimum average loss.

```
[~,idx] = min(meanloss) % Find the index
```

```
idx = 2
```

```
bestlambda = lambdaval(idx) % Find the best lambda value
```

```
bestlambda = 0.0066
```

```
bestloss = meanloss(idx)
```

```
bestloss = 0.0250
```

Fit the nca model on all data using best λ and plot the feature weights

Use the solver lbfgs and standardize the predictor values.

```
nca = fscnca(Xtrain,ytrain,'FitMethod','exact','Solver','sgd',...
            'Lambda',bestlambda,'Standardize',true,'Verbose',1);
```

Input Arguments

X — Predictor variable values

n-by-*p* matrix

Predictor variable values, specified as an *n*-by-*p* matrix, where *n* is the number of observations and *p* is the number of predictor variables.

Data Types: `single` | `double`

Y — Class labels

categorical vector | logical vector | numeric vector | string array | cell array of character vectors of length *n* | character matrix with *n* rows

Class labels, specified as a categorical vector, logical vector, numeric vector, string array, cell array of character vectors of length n , or character matrix with n rows, where n is the number of observations. Element i or row i of Y is the class label corresponding to row i of X (observation i).

Data Types: `single` | `double` | `logical` | `char` | `string` | `cell` | `categorical`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'Solver', 'sgd', 'Weights', W, 'Lambda', 0.0003` specifies the solver as the stochastic gradient descent, the observation weights as the values in the vector W , and sets the regularization parameter at 0.0003.

Fitting Options

FitMethod — Method for fitting the model

`'exact'` (default) | `'none'` | `'average'`

Method for fitting the model, specified as the comma-separated pair consisting of `'FitMethod'` and one of the following:

- `'exact'` — Performs fitting using all of the data.
- `'none'` — No fitting. Use this option to evaluate the generalization error of the NCA model using the initial feature weights supplied in the call to `fscna`.
- `'average'` — Divides the data into partitions (subsets), fits each partition using the `exact` method, and returns the average of the feature weights. You can specify the number of partitions using the `NumPartitions` name-value pair argument.

Example: `'FitMethod', 'none'`

NumPartitions — Number of partitions

`max(2, min(10, n))` (default) | integer between 2 and n

Number of partitions to split the data for using with `'FitMethod', 'average'` option, specified as the comma-separated pair consisting of `'NumPartitions'` and an integer value between 2 and n , where n is the number of observations.

Example: 'NumPartitions',15

Data Types: double | single

Lambda — Regularization parameter

1/n (default) | nonnegative scalar

Regularization parameter to prevent overfitting, specified as the comma-separated pair consisting of 'Lambda' and a nonnegative scalar.

As the number of observations n increases, the chance of overfitting decreases and the required amount of regularization also decreases. See “Identify Relevant Features for Classification” on page 32-2751 and “Tune Regularization Parameter to Detect Features Using NCA for Classification” to learn how to tune the regularization parameter.

Example: 'Lambda',0.002

Data Types: double | single

LengthScale — Width of the kernel

1 (default) | positive real scalar

Width of the kernel, specified as the comma-separated pair consisting of 'LengthScale' and a positive real scalar.

A length scale value of 1 is sensible when all predictors are on the same scale. If the predictors in X are of very different magnitudes, then consider standardizing the predictor values using 'Standardize',true and setting 'LengthScale',1.

Example: 'LengthScale',1.5

Data Types: double | single

InitialFeatureWeights — Initial feature weights

ones(p ,1) (default) | p -by-1 vector of real positive scalars

Initial feature weights, specified as the comma-separated pair consisting of 'InitialFeatureWeights' and a p -by-1 vector of real positive scalars, where p is the number of predictors in the training data.

The regularized objective function for optimizing feature weights is nonconvex. As a result, using different initial feature weights can give different results. Setting all initial feature weights to 1 generally works well, but in some cases, random initialization using `rand(p,1)` can give better quality solutions.

Data Types: `double` | `single`

Weights — Observation weights

`n`-by-1 vector of 1s (default) | `n`-by-1 vector of real positive scalars

Observation weights, specified as the comma-separated pair consisting of `'ObservationWeights'` and an `n`-by-1 vector of real positive scalars. Use observation weights to specify higher importance of some observations compared to others. The default weights assign equal importance to all observations.

Data Types: `double` | `single`

Prior — Prior probabilities for each class

`'empirical'` (default) | `'uniform'` | structure

Prior probabilities for each class, specified as the comma-separated pair consisting of `'Prior'` and one of the following:

- `'empirical'` — `fscnca` obtains the prior class probabilities from class frequencies.
- `'uniform'` — `fscnca` sets all class probabilities equal.
- Structure with two fields:
 - `ClassProbs` — Vector of class probabilities. If these are numeric values with a total greater than 1, `fscnca` normalizes them to add up to 1.
 - `ClassNames` — Class names corresponding to the class probabilities in `ClassProbs`.

Example: `'Prior','uniform'`

Standardize — Indicator for standardizing predictor data

`false` (default) | `true`

Indicator for standardizing the predictor data, specified as the comma-separated pair consisting of `'Standardize'` and either `false` or `true`. For more information, see “Impact of Standardization” on page 15-124.

Example: `'Standardize',true`

Data Types: `logical`

Verbose — Verbosity level indicator

0 (default) | 1 | >1

Verbosity level indicator for the convergence summary display, specified as the comma-separated pair consisting of 'Verbose' and one of the following:

- 0 — No convergence summary
- 1 — Convergence summary, including norm of gradient and objective function values
- > 1 — More convergence information, depending on the fitting algorithm

When using 'minibatch-lbfgs' solver and verbosity level > 1, the convergence information includes iteration the log from intermediate mini-batch LBFGS fits.

Example: 'Verbose', 1

Data Types: double | single

Solver — Solver type

'lbfgs' | 'sgd' | 'minibatch-lbfgs'

Solver type for estimating feature weights, specified as the comma-separated pair consisting of 'Solver' and one of the following:

- 'lbfgs' — Limited memory Broyden-Fletcher-Goldfarb-Shanno (LBFGS) algorithm
- 'sgd' — Stochastic gradient descent (SGD) algorithm
- 'minibatch-lbfgs' — Stochastic gradient descent with LBFGS algorithm applied to mini-batches

Default is 'lbfgs' for $n \leq 1000$, and 'sgd' for $n > 1000$.

Example: 'solver', 'minibatch-lbfgs'

LossFunction — Loss function

'classiferror' (default) | function handle

Loss function, specified as the comma-separated pair consisting of 'LossFunction' and one of the following.

- 'classiferror' — Misclassification error

$$l(y_i, y_j) = \begin{cases} 1 & \text{if } y_i \neq y_j, \\ 0 & \text{otherwise.} \end{cases}$$

- @*lossfun* — Custom loss function handle. A loss function has this form.

```
function L = lossfun(Yu,Yv)
% calculation of loss
...
```

Y_u is a u -by-1 vector and Y_v is a v -by-1 vector. L is a u -by- v matrix of loss values such that $L(i, j)$ is the loss value for $Y_u(i)$ and $Y_v(j)$.

The objective function for minimization includes the loss function $l(y_i, y_j)$ as follows:

$$f(w) = \frac{1}{n} \sum_{i=1}^n \sum_{j=1, j \neq i}^n p_{ij} l(y_i, y_j) + \lambda \sum_{r=1}^p w_r^2,$$

where w is the feature weight vector, n is the number of observations, and p is the number of predictor variables. p_{ij} is the probability that x_j is the reference point for x_i . For details, see “NCA Feature Selection for Classification” on page 15-120.

Example: 'LossFunction', @lossfun

CacheSize — Memory size

1000MB (default) | integer

Memory size, in MB, to use for objective function and gradient computation, specified as the comma-separated pair consisting of 'CacheSize' and an integer.

Example: 'CacheSize', 1500MB

Data Types: double | single

LBFGS Options

HessianHistorySize — Size of history buffer for Hessian approximation

15 (default) | positive integer

Size of history buffer for Hessian approximation for the 'lbfgs' solver, specified as the comma-separated pair consisting of 'HessianHistorySize' and a positive integer. At each iteration the function uses the most recent HessianHistorySize iterations to build an approximation to the inverse Hessian.

Example: 'HessianHistorySize', 20

Data Types: double | single

InitialStepSize — Initial step size

'auto' (default) | positive real scalar

Initial step size for the 'lbfgs' solver, specified as the comma-separated pair consisting of 'InitialStepSize' and a positive real scalar. By default, the function determines the initial step size automatically.

Data Types: double | single

LineSearchMethod — Line search method

'weakwolfe' (default) | 'strongwolfe' | 'backtracking'

Line search method, specified as the comma-separated pair consisting of 'LineSearchMethod' and one of the following:

- 'weakwolfe' — Weak Wolfe line search
- 'strongwolfe' — Strong Wolfe line search
- 'backtracking' — Backtracking line search

Example: 'LineSearchMethod', 'backtracking'

MaxLineSearchIterations — Maximum number of line search iterations

20 (default) | positive integer

Maximum number of line search iterations, specified as the comma-separated pair consisting of 'MaxLineSearchIterations' and a positive integer.

Example: 'MaxLineSearchIterations', 25

Data Types: double | single

GradientTolerance — Relative convergence tolerance

1e-6 (default) | positive real scalar

Relative convergence tolerance on the gradient norm for solver lbfgs, specified as the comma-separated pair consisting of 'GradientTolerance' and a positive real scalar.

Example: 'GradientTolerance', 0.000002

Data Types: double | single

SGD Options

InitialLearningRate — Initial learning rate for 'sgd' solver

'auto' (default) | positive real scalar

Initial learning rate for the 'sgd' solver, specified as the comma-separated pair consisting of 'InitialLearningRate' and a positive real scalar.

When using solver type 'sgd', the learning rate decays over iterations starting with the value specified for 'InitialLearningRate'.

The default 'auto' means that the initial learning rate is determined using experiments on small subsets of data. Use the `NumTuningIterations` name-value pair argument to specify the number of iterations for automatically tuning the initial learning rate. Use the `TuningSubsetSize` name-value pair argument to specify the number of observations to use for automatically tuning the initial learning rate.

For solver type 'minibatch-lbfgs', you can set 'InitialLearningRate' to a very high value. In this case, the function applies LBFGS to each mini-batch separately with initial feature weights from the previous mini-batch.

To make sure the chosen initial learning rate decreases the objective value with each iteration, plot the `Iteration` versus the `Objective` values saved in the `mdl.FitInfo` property.

You can use the `refit` method with 'InitialFeatureWeights' equal to `mdl.FeatureWeights` to start from the current solution and run additional iterations

Example: 'InitialLearningRate',0.9

Data Types: double | single

MiniBatchSize — Number of observations to use in each batch for the 'sgd' solver

`min(10,n)` (default) | positive integer value from 1 to n

Number of observations to use in each batch for the 'sgd' solver, specified as the comma-separated pair consisting of 'MiniBatchSize' and a positive integer from 1 to n .

Example: 'MiniBatchSize',25

Data Types: double | single

PassLimit — Maximum number of passes for solver 'sgd'

5 (default) | positive integer

Maximum number of passes through all n observations for solver 'sgd', specified as the comma-separated pair consisting of 'PassLimit' and a positive integer. Each pass through all of the data is called an epoch.

Example: 'PassLimit',10

Data Types: double | single

NumPrint — Frequency of batches for displaying convergence summary

10 (default) | positive integer value

Frequency of batches for displaying convergence summary for the 'sgd' solver, specified as the comma-separated pair consisting of 'NumPrint' and a positive integer. This argument applies when the 'Verbose' value is greater than 0. NumPrint mini-batches are processed for each line of the convergence summary that is displayed on the command line.

Example: 'NumPrint',5

Data Types: double | single

NumTuningIterations — Number of tuning iterations

20 (default) | positive integer

Number of tuning iterations for the 'sgd' solver, specified as the comma-separated pair consisting of 'NumTuningIterations' and a positive integer. This option is valid only for 'InitialLearningRate', 'auto'.

Example: 'NumTuningIterations',15

Data Types: double | single

TuningSubsetSize — Number of observations to use for tuning initial learning rate

min(100,n) (default) | positive integer value from 1 to n

Number of observations to use for tuning the initial learning rate, specified as the comma-separated pair consisting of 'TuningSubsetSize' and a positive integer value from 1 to n . This option is valid only for 'InitialLearningRate', 'auto'.

Example: 'TuningSubsetSize',25

Data Types: double | single

SGD or LBFGS Options

IterationLimit — Maximum number of iterations

positive integer

Maximum number of iterations, specified as the comma-separated pair consisting of 'IterationLimit' and a positive integer. The default is 10000 for SGD and 1000 for LBFGS and mini-batch LBFGS.

Each pass through a batch is an iteration. Each pass through all of the data is an epoch. If the data is divided into k mini-batches, then every epoch is equivalent to k iterations.

Example: 'IterationLimit',250

Data Types: double | single

StepTolerance — Convergence tolerance on the step size

1e-6 (default) | positive real scalar

Convergence tolerance on the step size, specified as the comma-separated pair consisting of 'StepTolerance' and a positive real scalar. The 'lbfgs' solver uses an absolute step tolerance, and the 'sgd' solver uses a relative step tolerance.

Example: 'StepTolerance',0.000005

Data Types: double | single

Mini-Batch LBFGS Options

MiniBatchLBFGSIterations — Maximum number of iterations per mini-batch LBFGS step

10 (default) | positive integer

Maximum number of iterations per mini-batch LBFGS step, specified as the comma-separated pair consisting of 'MiniBatchLBFGSIterations' and a positive integer.

Example: 'MiniBatchLBFGSIterations',15

Mini-batch LBFGS algorithm is a combination of SGD and LBFGS methods. Therefore, all of the name-value pair arguments that apply to SGD and LBFGS solvers also apply to the mini-batch LBFGS algorithm.

Data Types: double | single

Output Arguments

mdl — Neighborhood component analysis model for classification

FeatureSelectionNCAClassification object

Neighborhood component analysis model for classification, returned as a `FeatureSelectionNCAClassification` object.

See Also

`FeatureSelectionNCAClassification` | `loss` | `predict` | `refit`

Topics

“Tune Regularization Parameter to Detect Features Using NCA for Classification”

“Neighborhood Component Analysis (NCA) Feature Selection” on page 15-120

Introduced in R2016b

fsrnca

Feature selection using neighborhood component analysis for regression

Syntax

```
mdl = fsrnca(X,Y)
mdl = fsrnca(X,Y,Name,Value)
```

Description

`mdl = fsrnca(X,Y)` performs feature selection for regression using the predictors in X and responses in Y .

`fsrnca` learns the feature weights by a diagonal adaptation of neighborhood component analysis (NCA) with regularization.

`mdl = fsrnca(X,Y,Name,Value)` performs feature selection for regression with additional options specified by one or more name-value pair arguments.

Examples

Detect Relevant Features in Data Using NCA for Regression

Generate toy data where the response variable depends on the 3rd, 9th, and 15th predictors.

```
rng(0, 'twister'); % For reproducibility
N = 100;
X = rand(N,20);
y = 1 + X(:,3)*5 + sin(X(:,9)./X(:,15) + 0.25*randn(N,1));
```

Fit the neighborhood component analysis model for regression.

```
mdl = fsrnca(X,y, 'Verbose', 1, 'Lambda', 0.5/N);
```

o Solver = LBFGS, HessianHistorySize = 15, LineSearchMethod = weakwolfe

25	6.943545e-01	2.596e-07	1.111e-04	OK	3.154e+01	1.000

Infinity norm of the final gradient = 2.596e-07

Two norm of the final step = 1.111e-04, TolX = 1.000e-06

Relative infinity norm of the final gradient = 2.596e-07, TolFun = 1.000e-06

EXIT: Local minimum found.

Plot the selected features. The weights of the irrelevant features should be close to zero.

```
figure()
plot mdl.FeatureWeights, 'ro'
```

```
grid on
xlabel('Feature index')
ylabel('Feature weight')
```

`fsrnca` correctly detects the relevant predictors for this response.

Tune Regularization Parameter in NCA for Regression

Load the sample data.

```
load robotarm.mat
```

The `robotarm` (`pumadyn32nm`) dataset is created using a robot arm simulator with 7168 training observations and 1024 test observations with 32 features [1][2]. This is a preprocessed version of the original data set. The data are preprocessed by subtracting off a linear regression fit, followed by normalization of all features to unit variance.

Perform neighborhood component analysis (NCA) feature selection for regression with the default λ (regularization parameter) value.

```
nca = fsrnca(Xtrain,ytrain,'FitMethod','exact', ...  
            'Solver','lbfgs');
```

Plot the selected values.

```
figure  
plot(nca.FeatureWeights,'ro')  
xlabel('Feature index')  
ylabel('Feature weight')  
grid on
```

More than half of the feature weights are nonzero. Compute the loss using the test set as a measure of the performance by using the selected features.

```
L = loss(nca,Xtest,ytest)
```

```
L =
```

```
0.0837
```

Try improving the performance. Tune the regularization parameter λ for feature selection using five-fold cross-validation. Tuning λ means finding the λ value that produces the minimum regression loss. To tune λ using cross-validation:

1. Partition the data into five folds. For each fold, `cvpartition` assigns 4/5th of the data as a training set, and 1/5th of the data as a test set.

```
rng(1) % For reproducibility
n = length(ytrain);
cvp = cvpartition(length(ytrain), 'kfold', 5);
numvalidsets = cvp.NumTestSets;
```

Assign the λ values for the search. Multiplying response values by a constant increases the loss function term by a factor of the constant. Therefore, including the `std(ytrain)` factor in the λ values balances the default loss function ('mad', mean absolute deviation) term and the regularization term in the objective function. In this example, the `std(ytrain)` factor is one because the loaded sample data is a preprocessed version of the original data set.

```
lambdaval = linspace(0,50,20)*std(ytrain)/n;
```

Create an array to store the loss values.

```
lossvals = zeros(length(lambdaval), numvalidsets);
```

2. Train the NCA model for each λ value, using the training set in each fold.

3. Compute the regression loss for the corresponding test set in the fold using the NCA model. Record the loss value.

4. Repeat this for each λ value and each fold.

```
for i = 1:length(lambdaval)
    for k = 1:numvalidsets
        X = Xtrain(cvp.training(k),:);
        y = ytrain(cvp.training(k),:);
        Xvalid = Xtrain(cvp.test(k),:);
        yvalid = ytrain(cvp.test(k),:);

        nca = fsrnca(X,y, 'FitMethod','exact', ...
                    'Solver','minibatch-lbfgs', 'Lambda', lambdaval(i), ...
                    'GradientTolerance', 1e-4, 'IterationLimit', 30);

        lossvals(i,k) = loss(nca,Xvalid,yvalid, 'LossFunction', 'mse');
    end
end
```

Compute the average loss obtained from the folds for each λ value.

```
meanloss = mean(lossvals,2);
```

Plot the mean loss versus the λ values.

```
figure  
plot(lambdaval,meanloss,'ro-')  
xlabel('Lambda')  
ylabel('Loss (MSE)')  
grid on
```

Find the λ value that gives the minimum loss value.

```
[~,idx] = min(meanloss)
```

```
bestlambda = lambdaval(idx)  
bestloss = meanloss(idx)
```

```
idx =
```

```
17
```

```
bestlambda =
```

```
0.0059
```

```
bestloss =
```

```
0.0590
```

Fit the NCA feature selection model for regression using the best λ value.

```
nca = fsrnca(Xtrain,ytrain,'FitMethod','exact', ...  
            'Solver','lbfgs','Lambda',bestlambda);
```

Plot the selected features.

```
figure  
plot(nca.FeatureWeights,'ro')  
xlabel('Feature Index')  
ylabel('Feature Weight')  
grid on
```

Most of the feature weights are zero. `fsrnca` identifies the four most relevant features.

Compute the loss for the test set.

```
L = loss(nca,Xtest,ytest)
```

```
L =
```

```
0.0571
```

Tuning the regularization parameter, λ , eliminated more of the irrelevant features and improved the performance.

Compare NCA and ARD Feature Selection

This example uses the Abalone data [3] [4] from the UCI Machine Learning Repository [5]. Download the data and save it in your current folder with the name 'abalone.data'.

Store the data into a table. Display the first seven rows.

```
tbl = readtable('abalone.data', 'Filetype', 'text', 'ReadVariableNames', false);
tbl.Properties.VariableNames = {'Sex', 'Length', 'Diameter', 'Height', ...
    'WWeight', 'SWeight', 'VWeight', 'ShWeight'};
tbl(1:7,:)
```

ans =

7×9 table

Sex	Length	Diameter	Height	WWeight	SWeight	VWeight	ShWeight
'M'	0.455	0.365	0.095	0.514	0.2245	0.101	0.15
'M'	0.35	0.265	0.09	0.2255	0.0995	0.0485	0.07
'F'	0.53	0.42	0.135	0.677	0.2565	0.1415	0.21
'M'	0.44	0.365	0.125	0.516	0.2155	0.114	0.155
'I'	0.33	0.255	0.08	0.205	0.0895	0.0395	0.055
'I'	0.425	0.3	0.095	0.3515	0.141	0.0775	0.12
'F'	0.53	0.415	0.15	0.7775	0.237	0.1415	0.33

The dataset has 4177 observations. The goal is to predict the age of abalone from eight physical measurements. The last variable, the number of shell rings, shows the age of the abalone. The first predictor is a categorical variable. The last variable in the table is the response variable.

Prepare the predictor and response variables for `fsrnca`. The last column of `tbl` contains the number of shell rings, which is the response variable. The first predictor variable, `sex`, is categorical. You must create dummy variables.

```

y = table2array(tbl(:,end));
X(:,1:3) = dummyvar(categorical(tbl.Sex));
X = [X,table2array(tbl(:,2:end-1))];

```

Use four-fold cross-validation to tune the regularization parameter in the NCA model. First partition the data into four folds.

```

rng('default') % For reproducibility
n = length(y);
cvp = cvpartition(n,'kfold',4);
numtestsets = cvp.NumTestSets;

```

`cvpartition` divides the data into four partitions (folds). In each fold, about three-fourths of the data is assigned as a training set and one-fourth is assigned as a test set.

Generate a variety of λ (regularization parameter) values for fitting the model to determine the best λ value. Create a vector to collect the loss values from each fit.

```

lambdaval = linspace(0,25,20)*std(y)/n;
lossvals = zeros(length(lambdaval),numtestsets);

```

The rows of `lossvals` corresponds to the λ values and the columns correspond to the folds.

Fit the NCA model for regression using `fsrnca` to the data from each fold using each λ value. Compute the loss for each model using the test data from each fold.

```

for i = 1:length(lambdaval)
    for k = 1:numtestsets
        Xtrain = X(cvp.training(k),:);
        ytrain = y(cvp.training(k),:);
        Xtest = X(cvp.test(k),:);
        ytest = y(cvp.test(k),:);

        nca = fsrnca(Xtrain,ytrain,'FitMethod','exact', ...
                    'Solver','lbfgs','Lambda',lambdaval(i),'Standardize',true);

        lossvals(i,k) = loss(nca,Xtest,ytest,'LossFunction','mse');
    end
end

```

Compute the average loss for the folds, that is, compute the mean in the second dimension of `lossvals`.

```

meanloss = mean(lossvals,2);

```

Plot the λ values versus the mean loss from the four folds.

```
figure
plot(lambdaval,meanloss,'ro-')
xlabel('Lambda')
ylabel('Loss (MSE)')
grid on

Compute the regression loss on the training data (resubstitution loss) for the trained model.

```
L = resubLoss(gprMdl)
```

```
L =
```

```
4.0306
```

The smallest cross-validated loss using `fsrnca` is comparable to the loss obtained using a GPR model with an ARD kernel.

Input Arguments

X — Predictor variable values

n-by-*p* matrix

Predictor variable values, specified as an *n*-by-*p* matrix, where *n* is the number of observations and *p* is the number of predictor variables.

Data Types: `single` | `double`

Y — Response values

numeric real vector of length *n*

Response values, specified as a numeric real vector of length *n*, where *n* is the number of observations.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'Solver', 'sgd', 'Weights', W, 'Lambda', 0.0003` specifies the solver as the stochastic gradient descent, the observation weights as the values in the vector *W*, and sets the regularization parameter at 0.0003.

Fitting Options

FitMethod — Method for fitting the model

`'exact'` (default) | `'none'` | `'average'`

Method for fitting the model, specified as the comma-separated pair consisting of `'FitMethod'` and one of the following:

- `'exact'` — Performs fitting using all of the data.

- 'none' — No fitting. Use this option to evaluate the generalization error of the NCA model using the initial feature weights supplied in the call to `fsrnca`.
- 'average' — Divides the data into partitions (subsets), fits each partition using the exact method, and returns the average of the feature weights. You can specify the number of partitions using the `NumPartitions` name-value pair argument.

Example: `'FitMethod','none'`

NumPartitions — Number of partitions

`max(2,min(10,n))` (default) | integer between 2 and n

Number of partitions to split the data for using with `'FitMethod','average'` option, specified as the comma-separated pair consisting of `'NumPartitions'` and an integer value between 2 and n , where n is the number of observations.

Example: `'NumPartitions',15`

Data Types: `double` | `single`

Lambda — Regularization parameter

$1/n$ (default) | nonnegative scalar

Regularization parameter to prevent overfitting, specified as the comma-separated pair consisting of `'Lambda'` and a nonnegative scalar.

As the number of observations n increases, the chance of overfitting decreases and the required amount of regularization also decreases. See “Tune Regularization Parameter in NCA for Regression” on page 32-2772 to learn how to tune the regularization parameter.

Example: `'Lambda',0.002`

Data Types: `double` | `single`

LengthScale — Width of the kernel

1 (default) | positive real scalar

Width of the kernel, specified as the comma-separated pair consisting of `'LengthScale'` and a positive real scalar.

A length scale value of 1 is sensible when all predictors are on the same scale. If the predictors in X are of very different magnitudes, then consider standardizing the predictor values using `'Standardize',true` and setting `'LengthScale',1`.

Example: `'LengthScale',1.5`

Data Types: `double` | `single`

InitialFeatureWeights — Initial feature weights

`ones(p, 1)` (default) | p -by-1 vector of real positive scalars

Initial feature weights, specified as the comma-separated pair consisting of 'InitialFeatureWeights' and a p -by-1 vector of real positive scalars, where p is the number of predictors in the training data.

The regularized objective function for optimizing feature weights is nonconvex. As a result, using different initial feature weights can give different results. Setting all initial feature weights to 1 generally works well, but in some cases, random initialization using `rand(p, 1)` can give better quality solutions.

Data Types: `double` | `single`

Weights — Observation weights

n -by-1 vector of 1s (default) | n -by-1 vector of real positive scalars

Observation weights, specified as the comma-separated pair consisting of 'ObservationWeights' and an n -by-1 vector of real positive scalars. Use observation weights to specify higher importance of some observations compared to others. The default weights assign equal importance to all observations.

Data Types: `double` | `single`

Standardize — Indicator for standardizing predictor data

`false` (default) | `true`

Indicator for standardizing the predictor data, specified as the comma-separated pair consisting of 'Standardize' and either `false` or `true`. For more information, see "Impact of Standardization" on page 15-124.

Example: 'Standardize', `true`

Data Types: `logical`

Verbose — Verbosity level indicator

0 (default) | 1 | >1

Verbosity level indicator for the convergence summary display, specified as the comma-separated pair consisting of 'Verbose' and one of the following:

- 0 — No convergence summary
- 1 — Convergence summary, including norm of gradient and objective function values
- > 1 — More convergence information, depending on the fitting algorithm

When using 'minibatch-lbfgs' solver and verbosity level > 1, the convergence information includes iteration the log from intermediate mini-batch LBFGS fits.

Example: 'Verbose', 1

Data Types: double | single

Solver — Solver type

'lbfgs' | 'sgd' | 'minibatch-lbfgs'

Solver type for estimating feature weights, specified as the comma-separated pair consisting of 'Solver' and one of the following:

- 'lbfgs' — Limited memory Broyden-Fletcher-Goldfarb-Shanno (LBFGS) algorithm
- 'sgd' — Stochastic gradient descent (SGD) algorithm
- 'minibatch-lbfgs' — Stochastic gradient descent with LBFGS algorithm applied to mini-batches

Default is 'lbfgs' for $n \leq 1000$, and 'sgd' for $n > 1000$.

Example: 'solver', 'minibatch-lbfgs'

LossFunction — Loss function

'mad' (default) | 'mse' | 'epsiloninsensitive' | function handle

Loss function, specified as the comma-separated pair consisting of 'LossFunction' and one of the following:

- 'mad' — Mean absolute deviation

$$l(y_i, y_j) = |y_i - y_j|.$$

- 'mse' — Mean squared error

$$l(y_i, y_j) = (y_i - y_j)^2.$$

- 'epsiloninsensitive' — ϵ -insensitive loss function

$$l(y_i, y_j) = \max(0, |y_i - y_j| - \epsilon).$$

This loss function is more robust to outliers than mean squared error or mean absolute deviation.

- `@lossfun` — Custom loss function handle. A loss function has this form.

```
function L = lossfun(Yu,Yv)
% calculation of loss
...
```

`Yu` is a u -by-1 vector and `Yv` is a v -by-1 vector. `L` is a u -by- v matrix of loss values such that `L(i,j)` is the loss value for `Yu(i)` and `Yv(j)`.

The objective function for minimization includes the loss function $l(y_i, y_j)$ as follows:

$$f(w) = \frac{1}{n} \sum_{i=1}^n \sum_{j=1, j \neq i}^n p_{ij} l(y_i, y_j) + \lambda \sum_{r=1}^p w_r^2,$$

where w is the feature weight vector, n is the number of observations, and p is the number of predictor variables. p_{ij} is the probability that x_j is the reference point for x_i . For details, see “NCA Feature Selection for Regression” on page 15-123.

Example: 'LossFunction', @lossfun

Epsilon — Epsilon value

`iqr(Y)/13.49` (default) | nonnegative real scalar

Epsilon value for the 'LossFunction', 'epsiloninsensitive' option, specified as the comma-separated pair consisting of 'LossFunction' and a nonnegative real scalar. The default value is an estimate of the sample standard deviation using the interquartile range of the response variable.

Example: 'Epsilon', 0.1

Data Types: double | single

CacheSize — Memory size

1000MB (default) | integer

Memory size, in MB, to use for objective function and gradient computation, specified as the comma-separated pair consisting of 'CacheSize' and an integer.

Example: 'CacheSize', 1500MB

Data Types: double | single

LBFGS Options

HessianHistorySize — Size of history buffer for Hessian approximation

15 (default) | positive integer

Size of history buffer for Hessian approximation for the 'lbfgs' solver, specified as the comma-separated pair consisting of 'HessianHistorySize' and a positive integer. At each iteration the function uses the most recent HessianHistorySize iterations to build an approximation to the inverse Hessian.

Example: 'HessianHistorySize',20

Data Types: double | single

InitialStepSize — Initial step size

'auto' (default) | positive real scalar

Initial step size for the 'lbfgs' solver, specified as the comma-separated pair consisting of 'InitialStepSize' and a positive real scalar. By default, the function determines the initial step size automatically.

Data Types: double | single

LineSearchMethod — Line search method

'weakwolfe' (default) | 'strongwolfe' | 'backtracking'

Line search method, specified as the comma-separated pair consisting of 'LineSearchMethod' and one of the following:

- 'weakwolfe' — Weak Wolfe line search
- 'strongwolfe' — Strong Wolfe line search
- 'backtracking' — Backtracking line search

Example: 'LineSearchMethod','backtracking'

MaxLineSearchIterations — Maximum number of line search iterations

20 (default) | positive integer

Maximum number of line search iterations, specified as the comma-separated pair consisting of 'MaxLineSearchIterations' and a positive integer.

Example: 'MaxLineSearchIterations',25

Data Types: double | single

GradientTolerance — Relative convergence tolerance

1e-6 (default) | positive real scalar

Relative convergence tolerance on the gradient norm for solver `lbfgs`, specified as the comma-separated pair consisting of `'GradientTolerance'` and a positive real scalar.

Example: `'GradientTolerance',0.000002`

Data Types: `double` | `single`

SGD Options**InitialLearningRate — Initial learning rate for 'sgd' solver**

'auto' (default) | positive real scalar

Initial learning rate for the `'sgd'` solver, specified as the comma-separated pair consisting of `'InitialLearningRate'` and a positive real scalar.

When using solver type `'sgd'`, the learning rate decays over iterations starting with the value specified for `'InitialLearningRate'`.

The default `'auto'` means that the initial learning rate is determined using experiments on small subsets of data. Use the `NumTuningIterations` name-value pair argument to specify the number of iterations for automatically tuning the initial learning rate. Use the `TuningSubsetSize` name-value pair argument to specify the number of observations to use for automatically tuning the initial learning rate.

For solver type `'minibatch-lbfgs'`, you can set `'InitialLearningRate'` to a very high value. In this case, the function applies LBFGS to each mini-batch separately with initial feature weights from the previous mini-batch.

To make sure the chosen initial learning rate decreases the objective value with each iteration, plot the `Iteration` versus the `Objective` values saved in the `mdl.FitInfo` property.

You can use the `refit` method with `'InitialFeatureWeights'` equal to `mdl.FeatureWeights` to start from the current solution and run additional iterations

Example: `'InitialLearningRate',0.9`

Data Types: `double` | `single`

MiniBatchSize — Number of observations to use in each batch for the 'sgd' solver

$\min(10,n)$ (default) | positive integer value from 1 to n

Number of observations to use in each batch for the 'sgd' solver, specified as the comma-separated pair consisting of 'MiniBatchSize' and a positive integer from 1 to n .

Example: 'MiniBatchSize',25

Data Types: double | single

PassLimit — Maximum number of passes for solver 'sgd'

5 (default) | positive integer

Maximum number of passes through all n observations for solver 'sgd', specified as the comma-separated pair consisting of 'PassLimit' and a positive integer. Each pass through all of the data is called an epoch.

Example: 'PassLimit',10

Data Types: double | single

NumPrint — Frequency of batches for displaying convergence summary

10 (default) | positive integer value

Frequency of batches for displaying convergence summary for the 'sgd' solver, specified as the comma-separated pair consisting of 'NumPrint' and a positive integer. This argument applies when the 'Verbose' value is greater than 0. NumPrint mini-batches are processed for each line of the convergence summary that is displayed on the command line.

Example: 'NumPrint',5

Data Types: double | single

NumTuningIterations — Number of tuning iterations

20 (default) | positive integer

Number of tuning iterations for the 'sgd' solver, specified as the comma-separated pair consisting of 'NumTuningIterations' and a positive integer. This option is valid only for 'InitialLearningRate','auto'.

Example: 'NumTuningIterations',15

Data Types: double | single

TuningSubsetSize — Number of observations to use for tuning initial learning rate

$\min(100,n)$ (default) | positive integer value from 1 to n

Number of observations to use for tuning the initial learning rate, specified as the comma-separated pair consisting of 'TuningSubsetSize' and a positive integer value from 1 to n . This option is valid only for 'InitialLearningRate', 'auto'.

Example: 'TuningSubsetSize',25

Data Types: double | single

SGD or LBFGS Options

IterationLimit — Maximum number of iterations

positive integer

Maximum number of iterations, specified as the comma-separated pair consisting of 'IterationLimit' and a positive integer. The default is 10000 for SGD and 1000 for LBFGS and mini-batch LBFGS.

Each pass through a batch is an iteration. Each pass through all of the data is an epoch. If the data is divided into k mini-batches, then every epoch is equivalent to k iterations.

Example: 'IterationLimit',250

Data Types: double | single

StepTolerance — Convergence tolerance on the step size

1e-6 (default) | positive real scalar

Convergence tolerance on the step size, specified as the comma-separated pair consisting of 'StepTolerance' and a positive real scalar. The 'lbfgs' solver uses an absolute step tolerance, and the 'sgd' solver uses a relative step tolerance.

Example: 'StepTolerance',0.000005

Data Types: double | single

Mini-batch LBFGS Options

MiniBatchLBFGSIterations — Maximum number of iterations per mini-batch LBFGS step

10 (default) | positive integer

Maximum number of iterations per mini-batch LBFGS step, specified as the comma-separated pair consisting of 'MiniBatchLBFGSIterations' and a positive integer.

Example: 'MiniBatchLBFGSIterations',15

Mini-batch LBFGS algorithm is a combination of SGD and LBFGS methods. Therefore, all of the name-value pair arguments that apply to SGD and LBFGS solvers also apply to the mini-batch LBFGS algorithm.

Data Types: `double` | `single`

Output Arguments

mdl — Neighborhood component analysis model for regression

FeatureSelectionNCARegression object

Neighborhood component analysis model for regression, returned as a FeatureSelectionNCARegression object.

“Robust Feature Selection Using NCA for Regression” on page 15-101

“Neighborhood Component Analysis (NCA) Feature Selection” on page 15-120

Introduced in R2016b

fstat

F mean and variance

Syntax

```
[M,V] = fstat(V1,V2)
```

Description

`[M,V] = fstat(V1,V2)` returns the mean and variance for the *F* distribution with numerator degrees of freedom *V1* and denominator degrees of freedom *V2*. *V1* and *V2* can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of *M* and *V*. A scalar input for *V1* or *V2* is expanded to a constant arrays with the same dimensions as the other input. *V1* and *V2* parameters must contain real positive values.

The mean of the *F* distribution for values of ν_2 greater than 2 is

$$\frac{\nu_2}{\nu_2 - 2}$$

The variance of the *F* distribution for values of ν_2 greater than 4 is

$$\frac{2\nu_2^2(\nu_1 + \nu_2 - 2)}{\nu_1(\nu_2 - 2)^2(\nu_2 - 4)}$$

The mean of the *F* distribution is undefined if ν_2 is less than 3. The variance is undefined for ν_2 less than 5.

Examples

`fstat` returns NaN when the mean and variance are undefined.

```
[m,v] = fstat(1:5,1:5)  
m =
```

```
NaN NaN 3.0000 2.0000 1.6667
v =
NaN NaN NaN NaN 8.8889
```

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU arrays. For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

Topics

“F Distribution” on page B-42

Introduced before R2006a

fsurfht

Interactive contour plot

Syntax

```
fsurfht(fun,xlims,ylim)  
fsurfht(fun,xlims,ylim,p1,p2,p3,p4,p5)
```

Description

`fsurfht(fun,xlims,ylim)` is an interactive contour plot of the function specified by the text variable `fun`. The x-axis limits are specified by `xlims` in the form `[xmin xmax]`, and the y-axis limits are specified by `ylim` in the form `[ymin ymax]`.

`fsurfht(fun,xlims,ylim,p1,p2,p3,p4,p5)` allows for five optional parameters that you can supply to the function `fun`.

The intersection of the vertical and horizontal reference lines on the plot defines the current x value and y value. You can drag these reference lines and watch the calculated z -values (at the top of the plot) update simultaneously. Alternatively, you can type the x value and y value into editable text fields on the x -axis and y -axis.

Examples

Plot the Gaussian likelihood function for the `gas.mat` data.

```
load gas
```

Create a function containing the following commands, and name it `gauslike.m`.

```
function z = gauslike(mu,sigma,p1)  
n = length(p1);  
z = ones(size(mu));  
for i = 1:n  
z = z .* (normpdf(p1(i),mu,sigma));  
end
```

The `gauslike` function calls `normpdf`, treating the data sample as fixed and the parameters μ and σ as variables. Assume that the gas prices are normally distributed, and plot the likelihood surface of the sample.

```
fsurfht('gauslike',[112 118],[3 5],pricel)
```

The sample mean is the x value at the maximum, but the sample standard deviation is *not* the y value at the maximum.

```
mumax = mean(pricel)
mumax =
    115.1500
sigmamax = std(pricel)*sqrt(19/20)
```

```
sigmamax =  
  3.7719
```

Introduced before R2006a

fullfact

Full factorial design

Syntax

```
dFF = fullfact(levels)
```

Description

`dFF = fullfact(levels)` gives factor settings `dFF` for a full factorial design with n factors, where the number of levels for each factor is given by the vector `levels` of length n . `dFF` is m -by- n , where m is the number of treatments in the full-factorial design. Each row of `dFF` corresponds to a single treatment. Each column contains the settings for a single factor, with integer values from one to the number of levels.

Examples

The following generates an eight-run full-factorial design with two levels in the first factor and four levels in the second factor:

```
dFF = fullfact([2 4])
dFF =
     1     1
     2     1
     1     2
     2     2
     1     3
     2     3
     1     4
     2     4
```

`ff2n`

Introduced before R2006a

gagerr

Gage repeatability and reproducibility study

Syntax

```
gagerr(y, {part, operator})  
gagerr(y, GROUP)  
gagerr(y, part)  
gagerr(..., param1, val1, param2, val2, ...)  
[TABLE, stats] = gagerr(...)
```

Description

`gagerr(y, {part, operator})` performs a gage repeatability and reproducibility study on measurements in `y` collected by `operator` on `part`. `y` is a column vector containing the measurements on different parts. `part` and `operator` are categorical variables, numeric vectors, character matrices, string arrays, or cell arrays of character vectors. The number of elements in `part` and `operator` should be the same as in `y`.

`gagerr` prints a table in the command window in which the decomposition of variance, standard deviation, study var (5.15 × standard deviation) are listed with respective percentages for different sources. Summary statistics are printed below the table giving the number of distinct categories (NDC) and the percentage of Gage R&R of total variations (PRR).

`gagerr` also plots a bar graph showing the percentage of different components of variations. Gage R&R, repeatability, reproducibility, and part-to-part variations are plotted as four vertical bars. Variance and study var are plotted as two groups.

To determine the capability of a measurement system using NDC, use the following guidelines:

- If $NDC > 5$, the measurement system is capable.
- If $NDC < 2$, the measurement system is not capable.
- Otherwise, the measurement system may be acceptable.

To determine the capability of a measurement system using PRR, use the following guidelines:

- If $PRR < 10\%$, the measurement system is capable.
- If $PRR > 30\%$, the measurement system is not capable.
- Otherwise, the measurement system may be acceptable.

`gagerr(y, GROUP)` performs a gage R&R study on measurements in `y` with `part` and `operator` represented in `GROUP`. `GROUP` is a numeric matrix whose first and second columns specify different parts and operators, respectively. The number of rows in `GROUP` should be the same as the number of elements in `y`.

`gagerr(y, part)` performs a gage R&R study on measurements in `y` without operator information. The assumption is that all variability is contributed by `part`.

`gagerr(..., param1, val1, param2, val2, ...)` performs a gage R&R study using one or more of the following parameter name/value pairs:

- `'spec'` — A two-element vector that defines the lower and upper limit of the process, respectively. In this case, summary statistics printed in the command window include Precision-to-Tolerance Ratio (PTR). Also, the bar graph includes an additional group, the percentage of tolerance.

To determine the capability of a measurement system using PTR, use the following guidelines:

- If $PTR < 0.1$, the measurement system is capable.
- If $PTR > 0.3$, the measurement system is not capable.
- Otherwise, the measurement system may be acceptable.
- `'printtable'` — A value `'on'` or `'off'` that indicates whether the tabular output should be printed in the command window or not. The default value is `'on'`.
- `'printgraph'` — A value `'on'` or `'off'` that indicates whether the bar graph should be plotted or not. The default value is `'on'`.
- `'randomoperator'` — A logical value, `true` or `false`, that indicates whether the effect of operator is random or not. The default value is `true`.
- `'model'` — The model to use, specified by one of:
 - `'linear'` — Main effects only (default)

- 'interaction' — Main effects plus two-factor interactions
- 'nested' — Nest operator in part

The default value is 'linear'.

[TABLE, stats] = gagerr(...) returns a 6-by-5 matrix TABLE and a structure stats. The columns of TABLE, from left to right, represent variance, percentage of variance, standard deviations, study var, and percentage of study var. The rows of TABLE, from top to bottom, represent different sources of variations: gage R&R, repeatability, reproducibility, operator, operator and part interactions, and part. stats is a structure containing summary statistics for the performance of the measurement system. The fields of stats are:

- ndc — Number of distinct categories
- prr — Percentage of gage R&R of total variations
- ptr — Precision-to-tolerance ratio. The value is NaN if the parameter 'spec' is not given.

Examples

Gage R&R Study

Simulate a measurement system by randomly generating the operators, parts, and the measurements, y , operators do on the parts.

```
rng(1234, 'twister')           % for reproducibility
y = randn(100,1);             % measurements
part = ceil(3*rand(100,1));    % parts
operator = ceil(4*rand(100,1)); % operators
```

Conduct a gage R&R study for this system using a mixed ANOVA model without interactions.

```
gagerr(y, {part, operator}, 'randomoperator', true)
```

Columns 1 through 4

'Source'	'Variance'	'% Variance'	'sigma'
'Gage R&R'	[0.9715]	[99.2653]	[0.9857]
' Repeatability'	[0.9535]	[97.4201]	[0.9765]

' Reproducibility'	[0.0181]	[1.8452]	[0.1344]
' Operator'	[0.0181]	[1.8452]	[0.1344]
'Part'	[0.0072]	[0.7347]	[0.0848]
'Total'	[0.9787]	[100]	[0.9893]

Columns 5 through 6

'5.15*sigma'	'% 5.15*sigma'
[5.0762]	[99.6320]
[5.0288]	[98.7016]
[0.6921]	[13.5838]
[0.6921]	[13.5838]
[0.4367]	[8.5716]
[5.0949]	''

Number of distinct categories (NDC):0

% of Gage R&R of total variations (PRR): 99.63

Note: The last column of the above table does not have to sum to 100%

Introduced in R2006b

gamcdf

Gamma cumulative distribution function

Syntax

```
gamcdf(x, a, b)  
[p, plo, pup] = gamcdf(x, a, b, pcov, alpha)  
[p, plo, pup] = gamcdf( ____, 'upper')
```

Description

`gamcdf(x, a, b)` returns the gamma cdf at each of the values in `x` using the corresponding shape parameters in `a` and scale parameters in `b`. `x`, `a`, and `b` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other inputs. The parameters in `a` and `b` must be positive, and the values in `x` must lie on the interval `[0 Inf]`.

`[p, plo, pup] = gamcdf(x, a, b, pcov, alpha)` produces confidence bounds for `p` when the input parameters `a` and `b` are estimates. `pcov` is a 2-by-2 matrix containing the covariance matrix of the estimated parameters. `alpha` has a default value of 0.05, and specifies `100(1-alpha)%` confidence bounds. `plo` and `pup` are arrays of the same size as `p` containing the lower and upper confidence bounds.

`[p, plo, pup] = gamcdf(____, 'upper')` returns the complement of the gamma cdf at each value in `x`, using an algorithm that more accurately computes the extreme upper tail probabilities. You can use the `'upper'` argument with any of the previous syntaxes.

The gamma cdf is

$$p = F(x|a, b) = \frac{1}{b^a \Gamma(a)} \int_0^x t^{a-1} e^{-\frac{t}{b}} dt$$

The result, `p`, is the probability that a single observation from a gamma distribution with parameters `a` and `b` will fall in the interval `[0 x]`.

gammainc is the gamma distribution with b fixed at 1.

Examples

Compute Gamma Distribution CDF

The mean of the gamma distribution is the product of the parameters, ab . In this example, the mean approaches the median as it increases (i.e., the distribution becomes more symmetric).

```
a = 1:6;  
b = 5:10;  
prob = gamcdf(a.*b,a,b)
```

```
prob = 1×6
```

```
    0.6321    0.5940    0.5768    0.5665    0.5595    0.5543
```

gamfit

Gamma parameter estimates

Syntax

```
phat = gamfit(data)
[phat,pci] = gamfit(data)
[phat,pci] = gamfit(data,alpha)
[...] = gamfit(data,alpha,censoring,freq,options)
```

Description

`phat = gamfit(data)` returns the maximum likelihood estimates (MLEs) for the parameters of the gamma distribution given the data in vector `data`.

`[phat,pci] = gamfit(data)` returns MLEs and 95% percent confidence intervals. The first row of `pci` is the lower bound of the confidence intervals; the last row is the upper bound.

`[phat,pci] = gamfit(data,alpha)` returns $100(1 - \alpha)\%$ confidence intervals. For example, `alpha = 0.01` yields 99% confidence intervals.

`[...] = gamfit(data,alpha,censoring)` accepts a Boolean vector of the same size as `data` that is 1 for observations that are right-censored and 0 for observations that are observed exactly.

`[...] = gamfit(data,alpha,censoring,freq)` accepts a frequency vector of the same size as `data`. `freq` typically contains integer frequencies for the corresponding elements in `data`, but may contain any nonnegative values.

`[...] = gamfit(data,alpha,censoring,freq,options)` accepts a structure, `options`, that specifies control parameters for the iterative algorithm the function uses to compute maximum likelihood estimates. The gamma fit function accepts an `options` structure which can be created using the function `statset`. Enter `statset('gamfit')` to see the names and default values of the parameters that `gamfit` accepts in the `options` structure.

Examples

Fit a gamma distribution to random data generated from a specified gamma distribution:

```
a = 2; b = 4;  
data = gamrnd(a,b,100,1);
```

```
[p,ci] = gamfit(data)  
p =  
 2.1990  3.7426  
ci =  
 1.6840  2.8298  
 2.7141  4.6554
```

gaminv

Gamma inverse cumulative distribution function

Syntax

```
X = gaminv(P,A,B)
[X,XL0,XUP] = gaminv(P,A,B,pcov,alpha)
```

Description

`X = gaminv(P,A,B)` computes the inverse of the gamma cdf with shape parameters in `A` and scale parameters in `B` for the corresponding probabilities in `P`. `P`, `A`, and `B` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other inputs. The parameters in `A` and `B` must all be positive, and the values in `P` must lie on the interval `[0 1]`.

The gamma inverse function in terms of the gamma cdf is

$$x = F^{-1}(p|a,b) = \{x: F(x|a,b) = p\}$$

where

$$p = F(x|a,b) = \frac{1}{b^a \Gamma(a)} \int_0^x t^{a-1} e^{-\frac{t}{b}} dt$$

`[X,XL0,XUP] = gaminv(P,A,B,pcov,alpha)` produces confidence bounds for `X` when the input parameters `A` and `B` are estimates. `pcov` is a 2-by-2 matrix containing the covariance matrix of the estimated parameters. `alpha` has a default value of 0.05, and specifies `100(1-alpha)%` confidence bounds. `XL0` and `XUP` are arrays of the same size as `X` containing the lower and upper confidence bounds.

Examples

This example shows the relationship between the gamma cdf and its inverse function.

```
a = 1:5;
b = 6:10;
x = gaminv(gamcdf(1:5,a,b),a,b)
x =
    1.0000    2.0000    3.0000    4.0000    5.0000
```

Algorithms

There is no known analytical solution to the integral equation above. `gaminv` uses an iterative approach (Newton's method) to converge on the solution.

Extended Capabilities

Topics

“Gamma Distribution” on page B-45

Introduced before R2006a

gamlike

Gamma negative log-likelihood

Syntax

```
nlogL = gamlike(params,data)
[nlogL,AVAR] = gamlike(params,data)
```

Description

`nlogL = gamlike(params,data)` returns the negative of the gamma log-likelihood of the parameters, `params`, given `data`. `params(1)=A`, shape parameters, and `params(2)=B`, scale parameters. The parameters in `params` must all be positive

`[nlogL,AVAR] = gamlike(params,data)` also returns `AVAR`, which is the asymptotic variance-covariance matrix of the parameter estimates when the values in `params` are the maximum likelihood estimates. `AVAR` is the inverse of Fisher's information matrix. The diagonal elements of `AVAR` are the asymptotic variances of their respective parameters.

`[...] = gamlike(params,data,censoring)` accepts a Boolean vector of the same size as `data` that is 1 for observations that are right-censored and 0 for observations that are observed exactly.

`[...] = gamfit(params,data,censoring,freq)` accepts a frequency vector of the same size as `data`. `freq` typically contains integer frequencies for the corresponding elements in `data`, but may contain any non-negative values.

`gamlike` is a utility function for maximum likelihood estimation of the gamma distribution. Since `gamlike` returns the negative gamma log-likelihood function, minimizing `gamlike` using `fminsearch` is the same as maximizing the likelihood.

Examples

Compute the negative log-likelihood of parameter estimates computed by the `gamfit` function:

```
a = 2; b = 3;  
r = gamrnd(a,b,100,1);  
  
[nlogL,AVAR] = gamlike(gamfit(r),r)  
nlogL =  
    267.5648  
AVAR =  
    0.0788  -0.1104  
   -0.1104   0.1955
```

Extended Capabilities

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU arrays. For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

gampdf

Gamma probability density function

Syntax

```
Y = gampdf(X,A,B)
```

Description

`Y = gampdf(X,A,B)` computes the gamma pdf at each of the values in `X` using the corresponding shape parameters in `A` and scale parameters in `B`. `X`, `A`, and `B` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other inputs. The parameters in `A` and `B` must all be positive, and the values in `X` must lie on the interval `[0 Inf]`.

The gamma pdf is

$$y = f(x|a,b) = \frac{1}{b^a \Gamma(a)} x^{a-1} e^{-\frac{x}{b}}$$

The gamma probability density function is useful in reliability models of lifetimes. The gamma distribution is more flexible than the exponential distribution in that the probability of a product surviving an additional period may depend on its current age. The exponential and χ^2 functions are special cases of the gamma function.

Examples

The exponential distribution is a special case of the gamma distribution.

```
mu = 1:5;
```

```
y = gampdf(1,1,mu)  
y =
```

```
0.3679 0.3033 0.2388 0.1947 0.1637  
y1 = exppdf(1,mu)  
y1 =  
0.3679 0.3033 0.2388 0.1947 0.1637
```

Extended Capabilities

gamrnd

Gamma random numbers

Syntax

```
R = gamrnd(A,B)
R = gamrnd(A,B,m,n,...)
R = gamrnd(A,B,[m,n,...])
```

Description

`R = gamrnd(A,B)` generates random numbers from the gamma distribution with shape parameters in `A` and scale parameters in `B`. `A` and `B` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input for `A` or `B` is expanded to a constant array with the same dimensions as the other input. The parameters in `A` and `B` must be positive.

`R = gamrnd(A,B,m,n,...)` or `R = gamrnd(A,B,[m,n,...])` generates an `m`-by-`n`-by-... array containing random numbers from the gamma distribution with parameters `A` and `B`. `A` and `B` can each be scalars or arrays of the same size as `R`.

Examples

```
n1 = gamrnd(1:5,6:10)
n1 =
    9.1132  12.8431  24.8025  38.5960 106.4164
```

```
n2 = gamrnd(5,10,[1 5])
n2 =
    30.9486  33.5667  33.6837  55.2014  46.8265
```

```
n3 = gamrnd(2:6,3,1,5)
n3 =
    12.8715  11.3068  3.0982  15.6012  21.6739
```

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

The generated code can return a different sequence of numbers than MATLAB if either of the following is true:

- The output is nonscalar.
- An input parameter is invalid for the distribution.

For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “General Code Generation Workflow” on page 31-5.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU arrays. For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

gamstat

Gamma mean and variance

Syntax

```
[M,V] = gamstat(A,B)
```

Description

`[M,V] = gamstat(A,B)` returns the mean of and variance for the gamma distribution with shape parameters in *A* and scale parameters in *B*. *A* and *B* can be vectors, matrices, or multidimensional arrays that have the same size, which is also the size of *M* and *V*. A scalar input for *A* or *B* is expanded to a constant array with the same dimensions as the other input. The parameters in *A* and *B* must be positive.

The mean of the gamma distribution with parameters *A* and *B* is AB . The variance is AB^2 .

Examples

```
[m,v] = gamstat(1:5,1:5)
```

```
m =  
    1    4    9   16   25  
v =  
    1    8   27   64  125
```

```
[m,v] = gamstat(1:5,1./(1:5))
```

```
m =  
    1    1    1    1    1  
v =  
    1.0000    0.5000    0.3333    0.2500    0.2000
```

Extended Capabilities

ge

Class: grandstream

Greater than or equal relation for handles

Syntax

```
h1 >= h2
```

Description

`h1 >= h2` performs element-wise comparisons between handle arrays `h1` and `h2`. `h1` and `h2` must be of the same dimensions unless one is a scalar. The result is a logical array of the same dimensions, where each element is an element-wise `>=` result.

If one of `h1` or `h2` is scalar, scalar expansion is performed and the result will match the dimensions of the array that is not scalar.

`tf = ge(h1, h2)` stores the result in a logical array of the same dimensions.

See Also

`eq` | `gt` | `le` | `lt` | `ne` | `grandstream`

GeneralizedLinearMixedModel class

Generalized linear mixed-effects model class

Description

A `GeneralizedLinearMixedModel` object represents a regression model of a response variable that contains both fixed and random effects. The object comprises data, a model description, fitted coefficients, covariance parameters, design matrices, residuals, residual plots, and other diagnostic information for a generalized linear mixed-effects (GLME) model. You can predict model responses with the `predict` function and generate random data at new design points using the `random` function.

Construction

You can fit a generalized linear mixed-effects (GLME) model to sample data using `fitglme(tbl, formula)`. For more information, see `fitglme`.

Input Arguments

tbl — Input data

table | dataset array

Input data, which includes the response variable, predictor variables, and grouping variables, specified as a table or dataset array. The predictor variables can be continuous or grouping variables (see “Grouping Variables” on page 2-57). You must specify the model for the variables using `formula`.

Data Types: table

formula — Formula for model specification

character vector or string scalar of the form 'y ~ fixed + (random1|grouping1) + ... + (randomR|groupingR)'

Formula for model specification, specified as a character vector or string scalar of the form `'y ~ fixed + (random1|grouping1) + ... + (randomR|groupingR)'`. For a full description, see Formula on page 32-2843.

Example: `'y ~ treatment +(1|block)'`

Properties

Coefficients — Estimates of fixed-effects coefficients

dataset array

Estimates of fixed-effects coefficients and related statistics, stored as a dataset array that has one row for each coefficient and the following columns:

- **Name** — Name of the coefficient
- **Estimate** — Estimated coefficient value
- **SE** — Standard error of the estimate
- **tStat** — *t*-statistic for a test that the coefficient is equal to 0
- **DF** — Degrees of freedom associated with the *t* statistic
- **pValue** — *p*-value for the *t*-statistic
- **Lower** — Lower confidence limit
- **Upper** — Upper confidence limit

To obtain any of these columns as a vector, index into the property using dot notation.

Use the `coefTest` method to perform other tests on the coefficients.

CoefficientCovariance — Covariance of estimated fixed-effects vector

matrix

Covariance of estimated fixed-effects vector, stored as a matrix.

Data Types: `single` | `double`

CoefficientNames — Names of fixed-effects coefficients

cell array of character vectors

Names of fixed-effects coefficients, stored as a cell array of character vectors. The label for the coefficient of the constant term is (`Intercept`). The labels for other coefficients

indicate the terms that they multiply. When the term includes a categorical predictor, the label also indicates the level of that predictor.

Data Types: `cell`

DFE — Degrees of freedom for error

positive integer value

Degrees of freedom for error, stored as a positive integer value. DFE is the number of observations minus the number of estimated coefficients.

DFE contains the degrees of freedom corresponding to the 'Residual' method of calculating denominator degrees of freedom for hypothesis tests on fixed-effects coefficients. If n is the number of observations and p is the number of fixed-effects coefficients, then DFE is equal to $n - p$.

Data Types: `double`

Dispersion — Model dispersion parameter

scalar value

Model dispersion parameter, stored as a scalar value. The dispersion parameter defines the conditional variance of the response.

For observation i , the conditional variance of the response y_i , given the conditional mean μ_i and the dispersion parameter σ^2 , in a generalized linear mixed-effects model is

$$\text{var}(y_i | \mu_i, \sigma^2) = \frac{\sigma^2}{w_i} v(\mu_i),$$

where w_i is the i th observation weight and v is the variance function for the specified conditional distribution of the response. The `Dispersion` property contains an estimate of σ^2 for the specified GLME model. The value of `Dispersion` depends on the specified conditional distribution of the response. For binomial and Poisson distributions, the theoretical value of `Dispersion` is equal to $\sigma^2 = 1.0$.

- If `FitMethod` is `MPL` or `REMP` and the 'DispersionFlag' name-value pair argument in `fitglme` is `true`, then a dispersion parameter is estimated from data for all distributions, including binomial and Poisson distributions.
- If `FitMethod` is `ApproximateLaplace` or `Laplace`, then the 'DispersionFlag' name-value pair argument in `fitglme` does not apply, and the dispersion parameter is fixed at 1.0 for binomial and Poisson distributions. For all other distributions, `Dispersion` is estimated from data.

Data Types: double

DispersionEstimated — Flag indicating if dispersion parameter was estimated

true | false

Flag indicating estimated dispersion parameter, stored as a logical value.

- If `FitMethod` is `ApproximateLaplace` or `Laplace`, then the dispersion parameter is fixed at its theoretical value of 1.0 for binomial and Poisson distributions, and `DispersionEstimated` is false. For other distributions, the dispersion parameter is estimated from the data, and `DispersionEstimated` is true.
- If `FitMethod` is `MPL` or `REMP`, and the `'DispersionFlag'` name-value pair argument in `fitglm` is specified as `true`, then the dispersion parameter is estimated for all distributions, including binomial and Poisson distributions, and `DispersionEstimated` is true.
- If `FitMethod` is `MPL` or `REMP`, and the `'DispersionFlag'` name-value pair argument in `fitglm` is specified as `false`, then the dispersion parameter is fixed at its theoretical value for binomial and Poisson distributions, and `DispersionEstimated` is false. For distributions other than binomial and Poisson, the dispersion parameter is estimated from the data, and `DispersionEstimated` is true.

Data Types: logical

Distribution — Response distribution name

'Normal' | 'Binomial' | 'Poisson' | 'Gamma' | 'InverseGaussian'

Response distribution name, stored as one of the following:

- `'Normal'` — Normal distribution
- `'Binomial'` — Binomial distribution
- `'Poisson'` — Poisson distribution
- `'Gamma'` — Gamma distribution
- `'InverseGaussian'` — Inverse Gaussian distribution

FitMethod — Method used to fit the model

'MPL' | 'REMP' | 'ApproximateLaplace' | 'Laplace'

Method used to fit the model, stored as one of the following.

- 'MPL' — Maximum pseudo likelihood
- 'REMP' — Restricted maximum pseudo likelihood
- 'ApproximateLaplace' — Maximum likelihood using the approximate Laplace method, with fixed effects profiled out
- 'Laplace' — Maximum likelihood using the Laplace method

Formula — Model specification formula

object

Model specification formula, stored as an object. The model specification formula uses Wilkinson's notation to describe the relationship between the fixed-effects terms, random-effects terms, and grouping variables in the GLME model. For more information see Formula on page 32-2843.

Link — Link function characteristics

structure

Link function characteristics, stored as a structure containing the following fields. The link is a function G that links the distribution parameter μ to the linear predictor η as follows: $G(\mu) = \eta$.

Field	Description
Name	Name of the link function
Link	Function that defines G
Derivative	Derivative of G
SecondDerivative	Second derivative of G
Inverse	Inverse of G

Data Types: struct

LogLikelihood — Log of likelihood function

scalar value

Log of likelihood function evaluated at the estimated coefficient values, stored as a scalar value. LogLikelihood depends on the method used to fit the model.

- If you use 'Laplace' or 'ApproximateLaplace', then LogLikelihood is the maximized log likelihood.

- If you use 'MPL', then `LogLikelihood` is the maximized log likelihood of the pseudo data from the final pseudo likelihood iteration.
- If you use 'REML', then `LogLikelihood` is the maximized restricted log likelihood of the pseudo data from the final pseudo likelihood iteration.

Data Types: double

ModelCriterion — Model criterion

table

Model criterion to compare fitted generalized linear mixed-effects models, stored as a table with the following fields.

Field	Description
AIC	Akaike information criterion
BIC	Bayesian information criterion
LogLikelihood	<ul style="list-style-type: none"> • For a model fit using 'Laplace' or 'ApproximateLaplace', <code>LogLikelihood</code> is the maximized log likelihood. • For a model fit using 'MPL', <code>LogLikelihood</code> is the maximized log likelihood of the pseudo data from the final pseudo likelihood iteration. • For a model fit using 'REML', <code>LogLikelihood</code> is the maximized restricted log likelihood of the pseudo data from the final pseudo likelihood iteration.
Deviance	-2 times <code>LogLikelihood</code>

NumCoefficients — Number of fixed-effects coefficients

positive integer value

Number of fixed-effects coefficients in the fitted generalized linear mixed-effects model, stored as a positive integer value.

Data Types: double

NumEstimatedCoefficients — Number of estimated fixed-effects coefficients

positive integer value

Number of estimated fixed-effects coefficients in the fitted generalized linear mixed-effects model, stored as a positive integer value.

Data Types: double

NumObservations — Number of observations

positive integer value

Number of observations used in the fit, stored as a positive integer value. `NumObservations` is the number of rows in the table or dataset array `tbl`, minus rows excluded using the 'Exclude' name-value pair of `fitglm` or rows containing NaN values.

Data Types: double

NumPredictors — Number of predictors

positive integer value

Number of variables used as predictors in the generalized linear mixed-effects model, stored as a positive integer value.

Data Types: double

NumVariables — Total number of variables

positive integer value

Total number of variables, including the response and predictors, stored as a positive integer value. If the sample data is in a table or dataset array `tbl`, then `NumVariables` is the total number of variables in `tbl`, including the response variable. `NumVariables` includes variables, if any, that are not used as predictors or as the response.

Data Types: double

ObservationInfo — Information about the observations

table

Information about the observations used in the fit, stored as a table.

`ObservationInfo` has one row for each observation and the following columns.

Name	Description
Weights	The weight value for the observation. The default value is 1.
Excluded	If the observation was excluded from the fit using the 'Exclude' name-value pair argument in <code>fitglm</code> , then <code>Excluded</code> is <code>true</code> , or 1. Otherwise, <code>Excluded</code> is <code>false</code> , or 0.
Missing	<p>If the observation was excluded from the fit because any response or predictor value is missing, then <code>Missing</code> is <code>true</code>. Otherwise, <code>Missing</code> is <code>false</code>.</p> <p>Missing values include <code>NaN</code> for numeric variables, empty cells for cell arrays, blank rows for character arrays, and the <code><undefined></code> value for categorical arrays.</p>
Subset	If the observation was used in the fit, then <code>Subset</code> is <code>true</code> . If the observation was not used in the fit because it is missing or excluded, then <code>Subset</code> is <code>false</code> .
BinomSize	Binomial size for each observation. This column only applies when fitting a binomial distribution.

Data Types: `table`

ObservationNames — Names of observations

cell array of character vectors

Names of observations used in the fit, stored as a cell array of character vectors.

- If the data is in a table or dataset array `tbl` that contains observation names, then `ObservationNames` uses those names.
- If the data is provided in matrices, or in a table or dataset array without observation names, then `ObservationNames` is an empty cell array.

Data Types: `cell`

PredictorNames — Names of predictors

cell array of character vectors

Names of the variables used as predictors in the fit, stored as a cell array of character vectors that has the same length as NumPredictors.

Data Types: cell

ResponseName — Name of response variable

character vector

Name of the variable used as the response variable in the fit, stored as a character vector.

Data Types: char

Rsquared — Proportion of variability in the response explained by the fitted model

structure

Proportion of variability in the response explained by the fitted model, stored as a structure. Rsquared contains the *R*-squared value of the fitted model, also known as the multiple correlation coefficient. Rsquared contains the following fields.

Field	Description
Ordinary	R-squared value, stored as a scalar value in a structure. Rsquared.Ordinary = $1 - \text{SSE./SST}$
Adjusted	R-squared value adjusted for the number of fixed-effects coefficients, stored as a scalar value in a structure. Rsquared.Adjusted = $1 - (\text{SSE./SST}) * (\text{DFT./DFE})$, where $\text{DFE} = n - p$, $\text{DFT} = n - 1$, n is the total number of observations, and p is the number of fixed-effects coefficients.

Data Types: struct

SSE — Error sum of squares

positive scalar value

Error sum of squares, stored as a positive scalar value. SSE is the weighted sum of the squared conditional residuals, and is calculated as

$$SSE = \sum_{i=1}^n w_i^{eff} (y_i - f_i)^2,$$

where n is the number of observations, w_i^{eff} is the i th effective weight, y_i is the i th response, and f_i is the i th fitted value.

The i th effective weight is calculated as

$$w_i^{eff} = \left\{ \frac{w_i}{v_i(\mu_i(\widehat{\beta}, \widehat{b}))} \right\},$$

where v_i is the variance term for the i th observation, $\widehat{\beta}$ and \widehat{b} are estimated values of β and b , respectively.

The i th fitted value is calculated as

$$f_i = g^{-1}(x_i^T \widehat{\beta} + z_i^T \widehat{b} + \delta_i),$$

where x_i^T is the i th row of the fixed-effects design matrix X , and z_i^T is the i th row of the random-effects design matrix Z . δ_i is the i th offset value.

Data Types: `double`

SSR — Regression sum of squares

positive scalar value

Regression sum of squares, stored as a positive scalar value. SSR is the sum of squares explained by the generalized linear mixed-effects regression, or equivalently the weighted sum of the squared deviations of the conditional fitted values from their weighted mean. SSR is calculated as

$$SSR = \sum_{i=1}^N w_i^{eff} (f_i - \bar{f})^2,$$

where n is the number of observations, w_i^{eff} is the i th effective weight, f_i is the i th fitted value, and \bar{f} is a weighted average of the fitted values.

The i th effective weight is calculated as

$$w_i^{eff} = \left\{ \frac{w_i}{v_i(\mu_i(\widehat{\beta}, \widehat{b}))} \right\},$$

where $\widehat{\beta}$ and \widehat{b} are estimated values of β and b , respectively.

The i th fitted value is calculated as

$$f_i = g^{-1}(x_i^T \widehat{\beta} + z_i^T \widehat{b} + \delta_i),$$

where x_i^T is the i th row of the fixed-effects design matrix X , and z_i^T is the i th row of the random-effects design matrix Z . δ_i is the i th offset value.

The weighted average of fitted values is calculated as

$$\bar{f} = \frac{\left[\sum_{i=1}^n w_i^{eff} f_i \right]}{\sum_{i=1}^n w_i^{eff}}.$$

Data Types: double

SST — Total sum of squares

positive scalar value

Total sum of squares, stored as a positive scalar value. For a GLME model, SST is defined as $SST = SSE + SSR$.

Data Types: double

VariableInfo — Information about the variables

table

Information about the variables used in the fit, stored as a table. `VariableInfo` has one row for each variable and contains the following columns.

Column Name	Description
Class	Class of the variable ('double', 'cell', 'nominal', and so on).
Range	Value range of the variable. <ul style="list-style-type: none"> For a numerical variable, Range is a two-element vector of the form [min,max]. For a cell or categorical variable, Range is a cell or categorical array containing all unique values of the variable.
InModel	If the variable is a predictor in the fitted model, InModel is true. If the variable is not in the fitted model, InModel is false.
IsCategorical	If the variable type is treated as a categorical predictor (such as cell, logical, or categorical), then IsCategorical is true. If the variable is a continuous predictor, then IsCategorical is false.

Data Types: table

VariableNames — Names of the variables

cell array of character vectors

Names of all the variables contained in the table or dataset array `tbl`, stored as a cell array of character vectors.

Data Types: cell

Variables — Variables

table

Variables, stored as a table. If the fit is based on a table or dataset array `tbl`, then `Variables` is identical to `tbl`.

Data Types: table

Methods

anova	Analysis of variance for generalized linear mixed-effects model
coefCI	Confidence intervals for coefficients of generalized linear mixed-effects model
coefTest	Hypothesis test on fixed and random effects of generalized linear mixed-effects model
compare	Compare generalized linear mixed-effects models
covarianceParameters	Extract covariance parameters of generalized linear mixed-effects model
designMatrix	Fixed- and random-effects design matrices
fitted	Fitted responses from generalized linear mixed-effects model
fixedEffects	Estimates of fixed effects and related statistics
plotResiduals	Plot residuals of generalized linear mixed-effects model
predict	Predict response of generalized linear mixed-effects model
random	Generate random responses from fitted generalized linear mixed-effects model
randomEffects	Estimates of random effects and related statistics
refit	Refit generalized linear mixed-effects model
residuals	Residuals of fitted generalized linear mixed-effects model
response	Response vector of generalized linear mixed-effects model

Examples

Fit a Generalized Linear Mixed-Effects Model

Load the sample data.

```
load mfr
```

This simulated data is from a manufacturing company that operates 50 factories across the world, with each factory running a batch process to create a finished product. The company wants to decrease the number of defects in each batch, so it developed a new

manufacturing process. To test the effectiveness of the new process, the company selected 20 of its factories at random to participate in an experiment: Ten factories implemented the new process, while the other ten continued to run the old process. In each of the 20 factories, the company ran five batches (for a total of 100 batches) and recorded the following data:

- Flag to indicate whether the batch used the new process (`newprocess`)
- Processing time for each batch, in hours (`time`)
- Temperature of the batch, in degrees Celsius (`temp`)
- Categorical variable indicating the supplier (A, B, or C) of the chemical used in the batch (`supplier`)
- Number of defects in the batch (`defects`)

The data also includes `time_dev` and `temp_dev`, which represent the absolute deviation of time and temperature, respectively, from the process standard of 3 hours at 20 degrees Celsius.

Fit a generalized linear mixed-effects model using `newprocess`, `time_dev`, `temp_dev`, and `supplier` as fixed-effects predictors. Include a random-effects term for intercept grouped by `factory`, to account for quality differences that might exist due to factory-specific variations. The response variable `defects` has a Poisson distribution, and the appropriate link function for this model is log. Use the Laplace fit method to estimate the coefficients. Specify the dummy variable encoding as `'effects'`, so the dummy variable coefficients sum to 0.

The number of defects can be modeled using a Poisson distribution

$$\text{defects}_{ij} \sim \text{Poisson}(\mu_{ij})$$

This corresponds to the generalized linear mixed-effects model

$$\log(\mu_{ij}) = \beta_0 + \beta_1 \text{newprocess}_{ij} + \beta_2 \text{time_dev}_{ij} + \beta_3 \text{temp_dev}_{ij} + \beta_4 \text{supplier_C}_{ij} + \beta_5 \text{supplier_B}_{ij} + b_i,$$

where

- defects_{ij} is the number of defects observed in the batch produced by factory i during batch j .
- μ_{ij} is the mean number of defects corresponding to factory i (where $i = 1, 2, \dots, 20$) during batch j (where $j = 1, 2, \dots, 5$).

- newprocess_{ij} , time_dev_{ij} , and temp_dev_{ij} are the measurements for each variable that correspond to factory i during batch j . For example, newprocess_{ij} indicates whether the batch produced by factory i during batch j used the new process.
- supplier_C_{ij} and supplier_B_{ij} are dummy variables that use effects (sum-to-zero) coding to indicate whether company C or B, respectively, supplied the process chemicals for the batch produced by factory i during batch j .
- $b_i \sim N(0, \sigma_b^2)$ is a random-effects intercept for each factory i that accounts for factory-specific variation in quality.

```
glme = fitglme(mfr, 'defects ~ 1 + newprocess + time_dev + temp_dev + supplier + (1|factory)
    Distribution', 'Poisson', 'Link', 'log', 'FitMethod', 'Laplace', 'DummyVarCoding', 'effects')
```

Display the model.

1.1515	1.7864
-0.72019	-0.015134
-1.7395	1.5505
-2.1926	1.6263
-0.22679	0.083051
-0.082588	0.22473

Random effects covariance parameters:

Group: factory (20 Levels)

Name1	Name2	Type	Estimate
'(Intercept)'	'(Intercept)'	'std'	0.31381

Group: Error

Name	Estimate
'sqrt(Dispersion)'	1

The `Model information` table displays the total number of observations in the sample data (100), the number of fixed- and random-effects coefficients (6 and 20, respectively), and the number of covariance parameters (1). It also indicates that the response variable has a `Poisson` distribution, the link function is `Log`, and the fit method is `Laplace`.

`Formula` indicates the model specification using Wilkinson's notation.

The `Model fit statistics` table displays statistics used to assess the goodness of fit of the model. This includes the Akaike information criterion (AIC), Bayesian information criterion (BIC) values, log likelihood (`LogLikelihood`), and deviance (`Deviance`) values.

The `Fixed effects coefficients` table indicates that `fitglm` returned 95% confidence intervals. It contains one row for each fixed-effects predictor, and each column contains statistics corresponding to that predictor. Column 1 (`Name`) contains the name of each fixed-effects coefficient, column 2 (`Estimate`) contains its estimated value, and column 3 (`SE`) contains the standard error of the coefficient. Column 4 (`tStat`) contains the *t*-statistic for a hypothesis test that the coefficient is equal to 0. Column 5 (`DF`) and column 6 (`pValue`) contain the degrees of freedom and *p*-value that correspond to the *t*-statistic, respectively. The last two columns (`Lower` and `Upper`) display the lower and upper limits, respectively, of the 95% confidence interval for each fixed-effects coefficient.

`Random effects covariance parameters` displays a table for each grouping variable (here, only `factory`), including its total number of levels (20), and the type and estimate of the covariance parameter. Here, `std` indicates that `fitglm` returns the standard deviation of the random effect associated with the `factory` predictor, which has

an estimated value of 0.31381. It also displays a table containing the error parameter type (here, the square root of the dispersion parameter), and its estimated value of 1.

The standard display generated by `fitglme` does not provide confidence intervals for the random-effects parameters. To compute and display these values, use `covarianceParameters`.

Definitions

Formula

In general, a formula for model specification is a character vector or string scalar of the form `'y ~ terms'`. For generalized linear mixed-effects models, this formula is in the form `'y ~ fixed + (random1|grouping1) + ... + (randomR|groupingR)'`, where `fixed` and `random` contain the fixed-effects and the random-effects terms, respectively, and `R` is the number of grouping variables in the model.

Suppose a table `tbl` contains the following:

- A response variable, `y`
- Predictor variables, `Xj`, which can be continuous or grouping variables
- Grouping variables, `g1, g2, ..., gR`,

where the grouping variables in `Xj` and `gr` can be categorical, logical, character arrays, string arrays, or cell arrays of character vectors.

Then, in a formula of the form, `'y ~ fixed + (random1|g1) + ... + (randomR|gR)'`, the term `fixed` corresponds to a specification of the fixed-effects design matrix `X`, `random1` is a specification of the random-effects design matrix `Z1` corresponding to grouping variable `g1`, and similarly `randomR` is a specification of the random-effects design matrix `ZR` corresponding to grouping variable `gR`. You can express the `fixed` and `random` terms using Wilkinson notation.

Wilkinson notation describes the factors present in models. The notation relates to factors present in models, not to the multipliers (coefficients) of those factors.

Wilkinson Notation	Factors in Standard Notation
1	Constant (intercept) term
X ^k , where k is a positive integer	X, X ² , ..., X ^k
X1 + X2	X1, X2
X1*X2	X1, X2, X1.*X2 (elementwise multiplication of X1 and X2)
X1:X2	X1.*X2 only
- X2	Do not include X2
X1*X2 + X3	X1, X2, X3, X1*X2
X1 + X2 + X3 + X1:X2	X1, X2, X3, X1*X2
X1*X2*X3 - X1:X2:X3	X1, X2, X3, X1*X2, X1*X3, X2*X3
X1*(X2 + X3)	X1, X2, X3, X1*X2, X1*X3

Statistics and Machine Learning Toolbox notation always includes a constant term unless you explicitly remove the term using -1. Here are some examples for linear mixed-effects model specification.

Examples:

Formula	Description
'y ~ X1 + X2'	Fixed effects for the intercept, X1 and X2. This is equivalent to 'y ~ 1 + X1 + X2'.
'y ~ -1 + X1 + X2'	No intercept and fixed effects for X1 and X2. The implicit intercept term is suppressed by including -1.
'y ~ 1 + (1 g1)'	Fixed effects for the intercept plus random effect for the intercept for each level of the grouping variable g1.
'y ~ X1 + (1 g1)'	Random intercept model with a fixed slope.
'y ~ X1 + (X1 g1)'	Random intercept and slope, with possible correlation between them. This is equivalent to 'y ~ 1 + X1 + (1 + X1 g1)'.

Formula	Description
'y ~ X1 + (1 g1) + (-1 + X1 g1)'	Independent random effects terms for intercept and slope.
'y ~ 1 + (1 g1) + (1 g2) + (1 g1:g2)'	Random intercept model with independent main effects for g1 and g2, plus an independent interaction effect.

Topics

“Fit a Generalized Linear Mixed-Effects Model” on page 12-75

“Generalized Linear Mixed-Effects Models” on page 12-63

GeneralizedLinearModel class

Superclasses:

Generalized linear regression model class

Description

An object comprising training data, model description, diagnostic information, and fitted coefficients for a generalized linear regression. Predict model responses with the `predict` or `feval` methods.

Construction

`mdl = fitglm(tbl)` or `mdl = fitglm(X,y)` creates a generalized linear model of a table or dataset array `tbl`, or of the responses `y` to a data matrix `X`. For details, see `fitglm`.

`mdl = stepwiseglm(tbl)` or `mdl = stepwiseglm(X,y)` creates a generalized linear model of a table or dataset array `tbl`, or of the responses `y` to a data matrix `X`, with unimportant predictors excluded. For details, see `stepwiseglm`.

Input Arguments

tbl — Input data

table | dataset array

Input data, specified as a table or dataset array. When `modelspec` is a formula, the formula specifies the predictor and response variables. Otherwise, if you do not specify the predictor and response variables, the last variable in `tbl` is the response variable and the others are the predictor variables by default.

The predictor variables and response variable can be numeric, logical, categorical, character, or string. The response variable can have a data type other than numeric only if 'Distribution' is 'binomial'.

To set a different column as the response variable, use the `ResponseVar` name-value pair argument. To use a subset of the columns as predictors, use the `PredictorVars` name-value pair argument.

X — Predictor variables

matrix

Predictor variables, specified as an n -by- p matrix, where n is the number of observations and p is the number of predictor variables. Each column of X represents one variable, and each row represents one observation.

By default, there is a constant term in the model, unless you explicitly remove it, so do not include a column of 1s in X .

Data Types: `single` | `double`

y — Response variable

vector

Response variable, specified as an n -by-1 vector, where n is the number of observations. Each entry in y is the response for the corresponding row of X .

Data Types: `single` | `double` | `logical` | `categorical`

Properties

CoefficientCovariance — Covariance matrix of coefficient estimates

numeric matrix

This property is read-only.

Covariance matrix of coefficient estimates, specified as a p -by- p matrix of numeric values. p is the number of coefficients in the fitted model.

For details, see “Coefficient Standard Errors and Confidence Intervals” on page 11-73.

Data Types: `single` | `double`

CoefficientNames — Coefficient names

cell array of character vectors

This property is read-only.

Coefficient names, specified as a cell array of character vectors, each containing the name of the corresponding term.

Data Types: `cell`

Coefficients — Coefficient values

`table`

This property is read-only.

Coefficient values, specified as a table. `Coefficients` contains one row for each coefficient and these columns:

- `Estimate` — Estimated coefficient value
- `SE` — Standard error of the estimate
- `tStat` — t -statistic for a test that the coefficient is zero
- `pValue` — p -value for the t -statistic

Use `anova` (only for a linear regression model) or `coefTest` to perform other tests on the coefficients. Use `coefCI` to find the confidence intervals of the coefficient estimates.

To obtain any of these columns as a vector, index into the property using dot notation. For example, obtain the estimated coefficient vector in the model `mdl`:

```
beta = mdl.Coefficients.Estimate
```

Data Types: `table`

Deviance — Deviance of the fit

`numeric value`

This property is read-only.

Deviance of the fit, specified as a numeric value. Deviance is useful for comparing two models when one model is a special case of the other model. The difference between the deviance of the two models has a chi-square distribution with degrees of freedom equal to the difference in the number of estimated parameters between the two models. For more information on deviance, see “Deviance” on page 32-2867.

Data Types: `single` | `double`

DFE — Degrees of freedom for error

`positive integer`

This property is read-only.

Degrees of freedom for the error (residuals), equal to the number of observations minus the number of estimated coefficients, specified as a positive integer.

Data Types: `double`

Diagnostics – Diagnostic information

`table`

This property is read-only.

Diagnostic information for the model, specified as a table. Diagnostics can help identify outliers and influential observations. `Diagnostics` contains the following fields.

Field	Meaning	Utility
<code>Leverage</code>	Diagonal elements of <code>HatMatrix</code>	<code>Leverage</code> indicates to what extent the predicted value for an observation is determined by the observed value for that observation. A value close to 1 indicates that the prediction is largely determined by that observation, with little contribution from the other observations. A value close to 0 indicates the fit is largely determined by the other observations. For a model with p coefficients and n observations, the average value of <code>Leverage</code> is p/n . An observation with <code>Leverage</code> larger than $2*p/n$ can be an outlier.
<code>CooksDistance</code>	Cook's measure of scaled change in fitted values	<code>CooksDistance</code> is a measure of scaled change in fitted values. An observation with <code>CooksDistance</code> larger than three times the mean Cook's distance can be an outlier.
<code>HatMatrix</code>	Projection matrix to compute fitted from observed responses	<code>HatMatrix</code> is an n -by- n matrix such that <code>Fitted = HatMatrix*Y</code> , where <code>Y</code> is the response vector and <code>Fitted</code> is the vector of fitted response values.

All of these quantities are computed on the scale of the linear predictor. For example, in the equation that defines the hat matrix:

$$Y_{\text{fit}} = \text{glm.Fitted.LinearPredictor}$$

$$Y = \text{glm.Fitted.LinearPredictor} + \text{glm.Residuals.LinearPredictor}$$

Data Types: table

Dispersion — Scale factor of the variance of the response

numeric value

This property is read-only.

Scale factor of the variance of the response, specified as a numeric value. `Dispersion` multiplies the variance function for the distribution.

For example, the variance function for the binomial distribution is $p(1-p)/n$, where p is the probability parameter and n is the sample size parameter. If `Dispersion` is near 1, the variance of the data appears to agree with the theoretical variance of the binomial distribution. If `Dispersion` is larger than 1, the data set is “overdispersed” relative to the binomial distribution.

Data Types: double

DispersionEstimated — Flag to indicate use of dispersion scale factor

logical value

This property is read-only.

Flag to indicate whether `fitglm` used the `Dispersion` scale factor to compute standard errors for the coefficients in `Coefficients.SE`, specified as a logical value. If `DispersionEstimated` is false, `fitglm` used the theoretical value of the variance.

- `DispersionEstimated` can be false only for 'binomial' or 'poisson' distributions.
- Set `DispersionEstimated` by setting the `DispersionFlag` name-value pair in `fitglm`.

Data Types: logical

Distribution — Generalized distribution information

structure

This property is read-only.

Generalized distribution information, specified as a structure with the following fields relating to the generalized distribution.

Field	Description
Name	Name of the distribution, one of 'normal', 'binomial', 'poisson', 'gamma', or 'inverse gaussian'.
DevianceFunction	Function that computes the components of the deviance as a function of the fitted parameter values and the response values.
VarianceFunction	Function that computes the theoretical variance for the distribution as a function of the fitted parameter values. When <code>DispersionEstimated</code> is <code>true</code> , <code>Dispersion</code> multiplies the variance function in the computation of the coefficient standard errors.

Data Types: `struct`

Fitted – Fitted response values based on input data

`table`

This property is read-only.

Fitted (predicted) values based on the input data, specified as a table with one row for each observation and the following columns.

Field	Description
Response	Predicted values on the scale of the response.
LinearPredictor	Predicted values on the scale of the linear predictor. These are the same as the link function applied to the <code>Response</code> fitted values.
Probability	Fitted probabilities (this column is included only with the binomial distribution).

To obtain any of the columns as a vector, index into the property using dot notation. For example, in the model `mdl`, the vector `f` of fitted values on the response scale is

```
f = mdl.Fitted.Response
```

Use `predict` to compute predictions for other predictor values, or to compute confidence bounds on `Fitted`.

Data Types: `table`

Formula – Model information

`LinearFormula` object

This property is read-only.

Model information, specified as a `LinearFormula` object.

Display the formula of the fitted model `mdl` using dot notation:

```
mdl.Formula
```

Link — Link function

structure

This property is read-only.

Link function, specified as a structure with the following fields.

Field	Description
Name	Name of the link function, or '' if you specified the link as a function handle rather than a character vector.
LinkFunction	The function that defines f , a function handle.
DevianceFunction	Derivative of f , a function handle.
VarianceFunction	Inverse of f , a function handle.

The link is a function f that links the distribution parameter μ to the fitted linear combination Xb of the predictors:

$$f(\mu) = Xb.$$

Data Types: `struct`

LogLikelihood — Log likelihood

numeric value

This property is read-only.

Log likelihood of the model distribution at the response values, specified as a numeric value. The mean is fitted from the model, and other parameters are estimated as part of the model fit.

Data Types: `single` | `double`

ModelCriterion — Criterion for model comparison

structure

This property is read-only.

Criterion for model comparison, specified as a structure with these fields:

- **AIC** — Akaike information criterion. $AIC = -2 \cdot \log L + 2 \cdot m$, where $\log L$ is the loglikelihood and m is the number of estimated parameters.
- **AICc** — Akaike information criterion corrected for the sample size. $AICc = AIC + (2 \cdot m \cdot (m + 1)) / (n - m - 1)$, where n is the number of observations.
- **BIC** — Bayesian information criterion. $BIC = -2 \cdot \log L + m \cdot \log(n)$.
- **CAIC** — Consistent Akaike information criterion. $CAIC = -2 \cdot \log L + m \cdot (\log(n) + 1)$.

Information criteria are model selection tools that you can use to compare multiple models fit to the same data. These criteria are likelihood-based measures of model fit that include a penalty for complexity (specifically, the number of parameters). Different information criteria are distinguished by the form of the penalty.

When you compare multiple models, the model with the lowest information criterion value is the best-fitting model. The best-fitting model can vary depending on the criterion used for model comparison.

To obtain any of the criterion values as a scalar, index into the property using dot notation. For example, obtain the AIC value `aic` in the model `mdl`:

```
aic = mdl.ModelCriterion.AIC
```

Data Types: `struct`

NumCoefficients — Number of model coefficients

positive integer

This property is read-only.

Number of model coefficients, specified as a positive integer. `NumCoefficients` includes coefficients that are set to zero when the model terms are rank deficient.

Data Types: `double`

NumEstimatedCoefficients — Number of estimated coefficients

positive integer

This property is read-only.

Number of estimated coefficients in the model, specified as a positive integer. `NumEstimatedCoefficients` does not include coefficients that are set to zero when the model terms are rank deficient. `NumEstimatedCoefficients` is the degrees of freedom for regression.

Data Types: double

NumObservations — Number of observations

positive integer

This property is read-only.

Number of observations the fitting function used in fitting, specified as a positive integer. `NumObservations` is the number of observations supplied in the original table, dataset, or matrix, minus any excluded rows (set with the 'Exclude' name-value pair argument) or rows with missing values.

Data Types: double

NumPredictors — Number of predictor variables

positive integer

This property is read-only.

Number of predictor variables used to fit the model, specified as a positive integer.

Data Types: double

NumVariables — Number of variables

positive integer

This property is read-only.

Number of variables in the input data, specified as a positive integer. `NumVariables` is the number of variables in the original table or dataset, or the total number of columns in the predictor matrix and response vector.

`NumVariables` also includes any variables that are not used to fit the model as predictors or as the response.

Data Types: double

ObservationInfo — Observation information

table

This property is read-only.

Observation information, specified as an n -by-4 table, where n is equal to the number of rows of input data. The `ObservationInfo` contains the columns described in this table.

Column	Description
Weights	Observation weight, specified as a numeric value. The default value is 1.
Excluded	Indicator of excluded observation, specified as a logical value. The value is <code>true</code> if you exclude the observation from the fit by using the 'Exclude' name-value pair argument.
Missing	Indicator of missing observation, specified as a logical value. The value is <code>true</code> if the observation is missing.
Subset	Indicator of whether or not a fitting function uses the observation, specified as a logical value. The value is <code>true</code> if the observation is not excluded or missing, meaning that fitting function uses the observation.

To obtain any of these columns as a vector, index into the property using dot notation. For example, obtain the weight vector `w` of the model `mdl`:

```
w = mdl.ObservationInfo.Weights
```

Data Types: `table`

ObservationNames — Observation names

cell array of character vectors

This property is read-only.

Observation names, specified as a cell array of character vectors containing the names of the observations used in the fit.

- If the fit is based on a table or dataset containing observation names, `ObservationNames` uses those names.
- Otherwise, `ObservationNames` is an empty cell array.

Data Types: `cell`

Offset — Offset variable

numeric vector

This property is read-only.

Offset variable, specified as a numeric vector with the same length as the number of rows in the data. `Offset` is passed from `fitglm` or `stepwiseglm` in the `Offset` name-value pair. The fitting function used `Offset` as a predictor variable, but with the coefficient set to exactly 1. In other words, the formula for fitting was

$$\mu \sim \text{Offset} + (\text{terms involving real predictors})$$

with the `Offset` predictor having coefficient 1.

For example, consider a Poisson regression model. Suppose the number of counts is known for theoretical reasons to be proportional to a predictor `A`. By using the log link function and by specifying `log(A)` as an offset, you can force the model to satisfy this theoretical constraint.

Data Types: `double`

PredictorNames — Names of predictors used to fit model

cell array of character vectors

This property is read-only.

Names of predictors used to fit the model, specified as a cell array of character vectors.

Data Types: `cell`

Residuals — Residuals for fitted model

table

This property is read-only.

Residuals for the fitted model, specified as a table with one row for each observation and the following columns.

Field	Description
Raw	Observed minus fitted values.
LinearPredictor	Residuals on the linear predictor scale, equal to the adjusted response value minus the fitted linear combination of the predictors.

Field	Description
Pearson	Raw residuals divided by the estimated standard deviation of the response.
Anscombe	Residuals defined on transformed data with the transformation chosen to remove skewness.
Deviance	Residuals based on the contribution of each observation to the deviance.

To obtain any of these columns as a vector, index into the property using dot notation. For example, in a model `mdl`, the ordinary raw residual vector `r` is:

```
r = mdl.Residuals.Raw
```

Rows not used in the fit because of missing values (in `ObservationInfo.Missing`) contain NaN values.

Rows not used in the fit because of excluded values (in `ObservationInfo.Excluded`) contain NaN values, with the following exceptions:

- `raw` contains the difference between the observed and predicted values.
- `standardized` is the residual, standardized in the usual way.
- `studentized` matches the standardized values because this residual is not used in the estimate of the residual standard deviation.

Data Types: `table`

ResponseName — Response variable name

character vector

This property is read-only.

Response variable name, specified as a character vector.

Data Types: `char`

Rsquared — R-squared value for the model

structure

This property is read-only.

R-squared value for the model, specified as a structure with five fields:

- **Ordinary** — Ordinary (unadjusted) R-squared
- **Adjusted** — R-squared adjusted for the number of coefficients
- **LLR** — Log-likelihood ratio
- **Deviance** — Deviance
- **AdjGeneralized** — Adjusted generalized R-squared

The R-squared value is the proportion of total sum of squares explained by the model. The ordinary R-squared value relates to the SSR and SST properties:

$$\text{Rsquared} = \text{SSR/SST} = 1 - \text{SSE/SST}.$$

To obtain any of these values as a scalar, index into the property using dot notation. For example, the adjusted R-squared value in `mdl` is

```
r2 = mdl.Rsquared.Adjusted
```

Data Types: `struct`

SSE — Sum of squared errors

numeric value

This property is read-only.

Sum of squared errors (residuals), specified as a numeric value.

The Pythagorean theorem implies

$$\text{SST} = \text{SSE} + \text{SSR},$$

where SST is the total sum of squares, SSE is the sum of squared errors, and SSR is the regression sum of squares.

Data Types: `single` | `double`

SSR — Regression sum of squares

numeric value

This property is read-only.

Regression sum of squares, specified as a numeric value. The regression sum of squares is equal to the sum of squared deviations of the fitted values from their mean.

The Pythagorean theorem implies

$$\text{SST} = \text{SSE} + \text{SSR},$$

where SST is the total sum of squares, SSE is the sum of squared errors, and SSR is the regression sum of squares.

Data Types: `single` | `double`

SST — Total sum of squares

numeric value

This property is read-only.

Total sum of squares, specified as a numeric value. The total sum of squares is equal to the sum of squared deviations of the response vector y from the mean (\bar{y}).

The Pythagorean theorem implies

$$SST = SSE + SSR,$$

where SST is the total sum of squares, SSE is the sum of squared errors, and SSR is the regression sum of squares.

Data Types: `single` | `double`

Steps — Stepwise fitting information

structure

This property is read-only.

Stepwise fitting information, specified as a structure with the fields described in this table.

Field	Description
Start	Formula representing the starting model
Lower	Formula representing the lower bound model. The terms in Lower must remain in the model.
Upper	Formula representing the upper bound model. The model cannot contain more terms than Upper.
Criterion	Criterion used for the stepwise algorithm, such as 'sse'
PEnter	Threshold for Criterion to add a term
PRemove	Threshold for Criterion to remove a term
History	Table representing the steps taken in the fit

The `History` table contains one row for each step, including the initial fit, and the columns described in this table.

Column	Description
Action	Action taken during the step: <ul style="list-style-type: none"> 'Start' — First step 'Add' — A term is added 'Remove' — A term is removed
TermName	<ul style="list-style-type: none"> If Action is 'Start', TermName specifies the starting model specification. If Action is 'Add' or 'Remove', TermName specifies the term added or removed in the step.
Terms	Model specification in a “Terms Matrix” on page 32-2868
DF	Regression degrees of freedom after the step
delDF	Change in regression degrees of freedom from the previous step (negative for steps that remove a term)
Deviance	Deviance (residual sum of squares) at the step (only for a generalized linear regression model)
FStat	F -statistic that leads to the step
PValue	p -value of the F -statistic

The structure is empty unless you fit the model using stepwise regression.

Data Types: `struct`

VariableInfo — Information about variables

table

This property is read-only.

Information about variables contained in `Variables`, specified as a table with one row for each variable and the columns described in this table.

Column	Description
Class	Variable class, specified as a cell array of character vectors, such as 'double' and 'categorical'
Range	Variable range, specified as a cell array of vectors <ul style="list-style-type: none"> • Continuous variable — Two-element vector [<i>min</i>, <i>max</i>], the minimum and maximum values • Categorical variable — Vector of distinct variable values
InModel	Indicator of which variables are in the fitted model, specified as a logical vector. The value is <code>true</code> if the model includes the variable.
IsCategorical	Indicator of categorical variables, specified as a logical vector. The value is <code>true</code> if the variable is categorical.

`VariableInfo` also includes any variables that are not used to fit the model as predictors or as the response.

Data Types: `table`

VariableNames — Names of variables

cell array of character vectors

This property is read-only.

Names of variables, specified as a cell array of character vectors.

- If the fit is based on a table or dataset, this property provides the names of the variables in the table or dataset.
- If the fit is based on a predictor matrix and response vector, `VariableNames` contains the values specified by the 'VarNames' name-value pair argument of the fitting method. The default value of 'VarNames' is {'x1', 'x2', ..., 'xn', 'y'}.

`VariableNames` also includes any variables that are not used to fit the model as predictors or as the response.

Data Types: `cell`

Variables — Input data

`table`

This property is read-only.

Input data, specified as a table. `Variables` contains both predictor and response values. If the fit is based on a table or dataset array, `Variables` contains all the data from the table or dataset array. Otherwise, `Variables` is a table created from the input data matrix `X` and response the vector `y`.

`Variables` also includes any variables that are not used to fit the model as predictors or as the response.

Data Types: `table`

Methods

<code>addTerms</code>	Add terms to generalized linear model
<code>compact</code>	Compact generalized linear regression model
<code>fit</code>	(Not Recommended) Create generalized linear regression model
<code>plotDiagnostics</code>	Plot diagnostics of generalized linear regression model
<code>plotResiduals</code>	Plot residuals of generalized linear regression model
<code>removeTerms</code>	Remove terms from generalized linear model
<code>step</code>	Improve generalized linear regression model by adding or removing terms
<code>stepwise</code>	(Not Recommended) Create generalized linear regression model by stepwise regression

Inherited Methods

<code>coefCI</code>	Confidence intervals of coefficient estimates of generalized linear model
<code>coefTest</code>	Linear hypothesis test on generalized linear regression model coefficients
<code>devianceTest</code>	Analysis of deviance
<code>disp</code>	Display generalized linear regression model
<code>feval</code>	Evaluate generalized linear regression model prediction
<code>plotSlice</code>	Plot of slices through fitted generalized linear regression surface
<code>predict</code>	Predict response of generalized linear regression model
<code>random</code>	Simulate responses for generalized linear regression model

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects (MATLAB).

Examples

Fit a Generalized Linear Model

Fit a logistic regression model of probability of smoking as a function of age, weight, and sex, using a two-way interactions model.

Load the hospital dataset array.

```
load hospital
ds = hospital; % just to use the ds name
```

Specify the model using a formula that allows up to two-way interactions.

```
modelspec = 'Smoker ~ Age*Weight*Sex - Age:Weight:Sex';
```

Create the generalized linear model.

```
mdl = fitglm(ds,modelspec,'Distribution','binomial')
```

```
mdl =
```

```
Generalized linear regression model:
```

```
logit(Smoker) ~ 1 + Sex*Age + Sex*Weight + Age*Weight
```

```
Distribution = Binomial
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	-6.0492	19.749	-0.3063	0.75938
Sex_Male	-2.2859	12.424	-0.18399	0.85402
Age	0.11691	0.50977	0.22934	0.81861
Weight	0.031109	0.15208	0.20455	0.83792
Sex_Male:Age	0.020734	0.20681	0.10025	0.92014
Sex_Male:Weight	0.01216	0.053168	0.22871	0.8191
Age:Weight	-0.00071959	0.0038964	-0.18468	0.85348

```
100 observations, 93 error degrees of freedom
Dispersion: 1
Chi^2-statistic vs. constant model: 5.07, p-value = 0.535
```

The large p -value indicates the model might not differ statistically from a constant.

Create a Generalized Linear Model Stepwise

Create response data using just three of 20 predictors, and create a generalized linear model stepwise to see if it uses just the correct predictors.

Create data with 20 predictors, and Poisson response using just three of the predictors, plus a constant.

```
rng default % for reproducibility
X = randn(100,20);
mu = exp(X(:, [5 10 15])*[.4;.2;.3] + 1);
y = poissrnd(mu);
```

Fit a generalized linear model using the Poisson distribution.

```
mdl = stepwiseglm(X,y,...
    'constant', 'upper', 'linear', 'Distribution', 'poisson')
```

1. Adding x5, Deviance = 134.439, Chi2Stat = 52.24814, PValue = 4.891229e-13
2. Adding x15, Deviance = 106.285, Chi2Stat = 28.15393, PValue = 1.1204e-07
3. Adding x10, Deviance = 95.0207, Chi2Stat = 11.2644, PValue = 0.000790094

```
mdl =
Generalized linear regression model:
log(y) ~ 1 + x5 + x10 + x15
Distribution = Poisson
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	1.0115	0.064275	15.737	8.4217e-56
x5	0.39508	0.066665	5.9263	3.0977e-09
x10	0.18863	0.05534	3.4085	0.0006532
x15	0.29295	0.053269	5.4995	3.8089e-08

```
100 observations, 96 error degrees of freedom
Dispersion: 1
Chi^2-statistic vs. constant model: 91.7, p-value = 9.61e-20
```

Definitions

Canonical Link Function

The default link function for a generalized linear model is the canonical link function.

Canonical Link Functions for Generalized Linear Models

Distribution	Link Function Name	Link Function	Mean (Inverse) Function
'normal'	'identity'	$f(\mu) = \mu$	$\mu = Xb$
'binomial'	'logit'	$f(\mu) = \log(\mu/(1-\mu))$	$\mu = \exp(Xb) / (1 + \exp(Xb))$
'poisson'	'log'	$f(\mu) = \log(\mu)$	$\mu = \exp(Xb)$
'gamma'	-1	$f(\mu) = 1/\mu$	$\mu = 1/(Xb)$
'inverse gaussian'	-2	$f(\mu) = 1/\mu^2$	$\mu = (Xb)^{-1/2}$

Hat Matrix

The hat matrix H is defined in terms of the data matrix X and a diagonal weight matrix W :

$$H = X(X^T W X)^{-1} X^T W^T.$$

W has diagonal elements w_i :

$$w_i = \frac{g'(\mu_i)}{\sqrt{V(\mu_i)}},$$

where

- g is the link function mapping y_i to $x_i b$.

- g' is the derivative of the link function g .
- V is the variance function.
- μ_i is the i th mean.

The diagonal elements H_{ii} satisfy

$$0 \leq h_{ii} \leq 1$$

$$\sum_{i=1}^n h_{ii} = p,$$

where n is the number of observations (rows of X), and p is the number of coefficients in the regression model.

Leverage

Leverage is a measure of the effect of a particular observation on the regression predictions due to the position of that observation in the space of the inputs.

The leverage of observation i is the value of the i th diagonal term h_{ii} of the hat matrix H . The hat matrix H is defined in terms of the data matrix X :

$$H = X(X^T X)^{-1} X^T.$$

The hat matrix is also known as the *projection matrix* because it projects the vector of observations y onto the vector of predictions \hat{y} , thus putting the "hat" on y .

Because the sum of the leverage values is p (the number of coefficients in the regression model), an observation i can be considered an outlier if its leverage substantially exceeds p/n , where n is the number of observations.

For more details, see "Hat Matrix and Leverage" on page 11-99.

Cook's Distance

The Cook's distance D_i of observation i is

$$D_i = w_i \frac{e_i^2}{p \hat{\sigma}^2} \frac{h_{ii}}{(1 - h_{ii})^2},$$

where

- $\hat{\varphi}$ is the dispersion parameter (estimated or theoretical).
- e_i is the linear predictor residual, $g(y_i) - x_i\hat{\beta}$, where
 - g is the link function.
 - y_i is the observed response.
 - x_i is the observation.
 - $\hat{\beta}$ is the estimated coefficient vector.
- p is the number of coefficients in the regression model.
- h_{ii} is the i th diagonal element of the Hat Matrix on page 32-2865 *H*.

Deviance

Deviance of a model M_1 is twice the difference between the loglikelihood of that model and the saturated model, M_S . The saturated model is the model with the maximum number of parameters that can be estimated. For example, if there are n observations y_i , $i = 1, 2, \dots, n$, with potentially different values for $X_i^T\beta$, then you can define a saturated model with n parameters. Let $L(b, y)$ denote the maximum value of the likelihood function for a model. Then the deviance of model M_1 is

$$-2(\log L(b_1, y) - \log L(b_S, y)),$$

where b_1 are the estimated parameters for model M_1 and b_S are the estimated parameters for the saturated model. The deviance has a chi-square distribution with $n - p$ degrees of freedom, where n is the number of parameters in the saturated model and p is the number of parameters in model M_1 .

If M_1 and M_2 are two different generalized linear models, then the fit of the models can be assessed by comparing the deviances D_1 and D_2 of these models. The difference of the deviances is

$$\begin{aligned} D &= D_2 - D_1 = -2(\log L(b_2, y) - \log L(b_S, y)) + 2(\log L(b_1, y) - \log L(b_S, y)) \\ &= -2(\log L(b_2, y) - \log L(b_1, y)). \end{aligned}$$

Asymptotically, this difference has a chi-square distribution with degrees of freedom v equal to the number of parameters that are estimated in one model but fixed (typically at 0) in the other. It is equal to the difference in the number of parameters estimated in M_1 and M_2 . You can get the p -value for this test using $1 - \text{chi2cdf}(D, V)$, where $D = D_2 - D_1$.

Terms Matrix

A terms matrix T is a t -by- $(p + 1)$ matrix specifying terms in a model, where t is the number of terms, p is the number of predictor variables, and $+1$ accounts for the response variable. The value of $T(i, j)$ is the exponent of variable j in term i .

For example, suppose that an input includes three predictor variables A , B , and C and the response variable Y in the order A , B , C , and Y . Each row of T represents one term:

- $[0 \ 0 \ 0 \ 0]$ — Constant term or intercept
- $[0 \ 1 \ 0 \ 0]$ — B ; equivalently, $A^0 * B^1 * C^0$
- $[1 \ 0 \ 1 \ 0]$ — $A * C$
- $[2 \ 0 \ 0 \ 0]$ — A^2
- $[0 \ 1 \ 2 \ 0]$ — $B * (C^2)$

The 0 at the end of each term represents the response variable. In general, a column vector of zeros in a terms matrix represents the position of the response variable. If you have the predictor and response variables in a matrix and column vector, then you must include 0 for the response variable in the last column of each row.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The `predict` and `random` functions support code generation.
- When you fit a model by using `fitglm` or `stepwiseglm`, the following restrictions apply.
 - Code generation does not support categorical predictors. You cannot supply training data in a table that contains a logical vector, character array, categorical array, string array, or cell array of character vectors. Also, you cannot use the `'CategoricalVars'` name-value pair argument. To include categorical predictors

in a model, preprocess the categorical predictors by using `dummyvar` before fitting the model.

- The `Link`, `Derivative`, and `Inverse` fields of the `'Link'` name-value pair argument cannot be anonymous functions. That is, you cannot generate code using a generalized linear model that was created using anonymous functions for links. Instead, define functions for link components.

For more information, see “Introduction to Code Generation” on page 31-2.

Introduced in R2012a

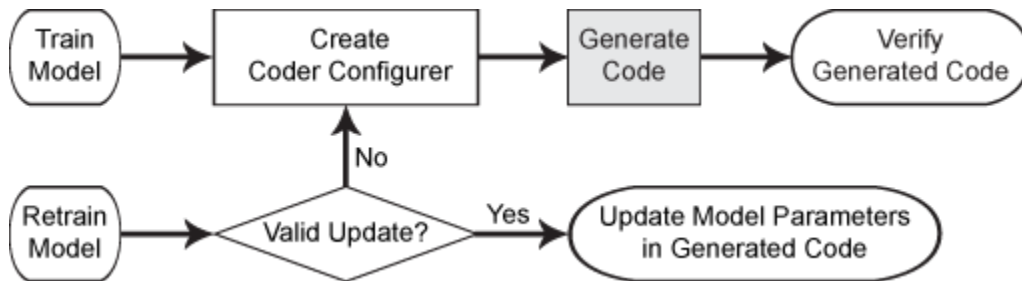

generateCode

Package: classreg.learning.coder.config.svm

Generate C/C++ code using coder configurer

After training a machine learning model, create a coder configurer for the model by using `LearnerCoderConfigurer`. Modify the properties of the configurer to specify code generation options. Then use `generateCode` to generate C/C++ code for the `predict` and `update` functions of the machine learning model. Generating C/C++ code requires MATLAB Coder.

This flow chart shows the code generation workflow using a coder configurer. Use `generateCode` for the highlighted step.

Syntax

```

generateCode(configurer)
generateCode(configurer,cfg)
generateCode( ___, 'OutputPath',outputPath)

```

Description

`generateCode(configurer)` generates a MEX (MATLAB Executable) function for the `predict` and `update` functions of a machine learning model by using `configurer`. The generated MEX function is named *outputFileName*, which is the file name stored in the `OutputFileName` property of `configurer`.

To generate a MEX function, `generateCode` first generates the following MATLAB files required to generate code and stores them in the current folder:

- `predict.m`, `update.m`, and `initialize.m` — `predict.m` and `update.m` are the entry-point functions for the `predict` and `update` functions of the machine learning model, respectively, and these two functions call `initialize.m`.
- A MAT-file that includes machine learning model information — `generateCode` uses the `saveCompactModel` function to save machine learning model information in a MAT-file whose file name is stored in the `OutputFileName` property of a coder configurer. `initialize.m` loads the saved MAT-file by using the `loadCompactModel` function.

After generating the necessary MATLAB files, `generateCode` creates the MEX function and the code for the MEX function in the `codegen\mex\outputFileName` folder and copies the MEX function to the current folder.

`generateCode(configurer, cfg)` generates C/C++ code using the build type specified by `cfg`.

`generateCode(____, 'OutputPath', outputPath)` specifies the folder path for the output files in addition to any of the input arguments in previous syntaxes. `generateCode` generates the MATLAB files in the folder specified by `outputPath` and generates C/C++ code in the folder `outputPath\codegen\type\outputFileName` where `type` is the build type specified by `cfg`.

Examples

Generate Code Using Coder Configurer

Train a machine learning model, and then generate code for the `predict` and `update` functions of the model by using a coder configurer.

Load the `carsmall` data set and train a support vector machine (SVM) regression model.

```
load carsmall
X = [Horsepower,Weight];
Y = MPG;
Mdl = fitrsvm(X,Y);
```

`Mdl` is a `RegressionSVM` object.

Create a coder configurer for the `RegressionSVM` model by using `learnerCoderConfigurer`. Specify the predictor data `X`. The `learnerCoderConfigurer` function uses the input `X` to configure the coder attributes of the `predict` function input.

```
configurer = learnerCoderConfigurer(Mdl,X)

configurer =
  RegressionSVMCoderConfigurer with properties:

    Update Inputs:
      Alpha: [1x1 LearnerCoderInput]
      SupportVectors: [1x1 LearnerCoderInput]
      Scale: [1x1 LearnerCoderInput]
      Bias: [1x1 LearnerCoderInput]

    Predict Inputs:
      X: [1x1 LearnerCoderInput]

    Code Generation Parameters:
      NumOutputs: 1
      OutputFileName: 'RegressionSVMModel'
```

Properties, Methods

`configurer` is a `RegressionSVMCoderConfigurer` object, which is a coder configurer of a `RegressionSVM` object.

To generate C/C++ code, you must have access to a C/C++ compiler that is configured properly. MATLAB Coder locates and uses a supported, installed compiler. You can use `mex -setup` to view and change the default compiler. For more details, see “Change Default Compiler” (MATLAB).

Generate code for the `predict` and `update` functions of the SVM regression model (`Mdl`) with default settings.

```
generateCode(configurer)
```

`generateCode` creates these files in output folder:
'initialize.m', 'predict.m', 'update.m', 'RegressionSVMModel.mat'

The `generateCode` function completes these actions:

- Generate the MATLAB files required to generate code, including the two entry-point functions `predict.m` and `update.m` for the `predict` and `update` functions of `Mdl`, respectively.
- Create a MEX function named `RegressionSVMModel` for the two entry-point functions.
- Create the code for the MEX function in the `codegen\mex\RegressionSVMModel` folder.
- Copy the MEX function to the current folder.

Display the contents of the `predict.m`, `update.m`, and `initialize.m` files by using the `type` function.

type `predict.m`

```
function varargout = predict(X,varargin) %#codegen
% Autogenerated by MATLAB, 03-Mar-2019 15:58:37
[varargout{1:nargout}] = initialize('predict',X,varargin{:});
end
```

type `update.m`

```
function update(varargin) %#codegen
% Autogenerated by MATLAB, 03-Mar-2019 15:58:37
initialize('update',varargin{:});
end
```

type `initialize.m`

```
function [varargout] = initialize(command,varargin) %#codegen
% Autogenerated by MATLAB, 03-Mar-2019 15:58:37
coder.inline('always');
persistent model;
if isempty(model)
    model = loadCompactModel('RegressionSVMModel.mat');
end
switch(command)
    case 'update'
        % Update struct fields: Alpha
        %                               SupportVectors
        %                               Scale
        %                               Bias

        model = update(model,varargin{:});
    case 'predict'
```

```
% Predict Inputs: X

X = varargin{1};
if nargin == 2
    [varargout{1:nargout}] = predict(model,X);
else
    PVPairs = cell(1,nargin-2);
    for i = 1:nargin-2
        PVPairs{1,i} = varargin{i+1};
    end
    [varargout{1:nargout}] = predict(model,X,PVPairs{:});
end
end
end
```

Specify Build Type

Train a machine learning model and generate code by using the coder configurer of the trained model. When generating code, specify the build type and other configuration options using a code generation configuration object.

Load the `ionosphere` data set and train a binary support vector machine (SVM) classification model.

```
load ionosphere
Mdl = fitcsvm(X,Y);
```

`Mdl` is a `ClassificationSVM` object.

Create a coder configurer for the `ClassificationSVM` model by using `learnerCoderConfigurer`. Specify the predictor data `X`. The `learnerCoderConfigurer` function uses the input `X` to configure the coder attributes of the `predict` function input.

```
configurer = learnerCoderConfigurer(Mdl,X);
```

`configurer` is a `ClassificationSVMCoderConfigurer` object, which is a coder configurer of a `ClassificationSVM` object.

Create a code generation configuration object by using `coder.config`. Specify `'dll'` to generate a dynamic library and specify the `GenerateReport` property as `true` to enable the code generation report.

```
cfg = coder.config('dll');
cfg.GenerateReport = true;
```

To generate C/C++ code, you must have access to a C/C++ compiler that is configured properly. MATLAB Coder locates and uses a supported, installed compiler. You can use `mex -setup` to view and change the default compiler. For more details, see “Change Default Compiler” (MATLAB).

Use `generateCode` and the configuration object `cfg` to generate code. Also, specify the output folder path.

```
generateCode(configurer, cfg, 'OutputPath', 'testPath')
```

Specified folder does not exist. Folder has been created.

`generateCode` creates these files in output folder:

```
'initialize.m', 'predict.m', 'update.m', 'ClassificationSVMModel.mat'
```

Code generation successful: To view the report, open('codegen\dll\ClassificationSVMModel')

`generateCode` creates the specified folder. The function also generates the MATLAB files required to generate code and stores them in the folder. Then `generateCode` generates C code in the `testPath\codegen\dll\ClassificationSVMModel` folder.

Update Parameters of ECOC Classification Model in Generated Code

Train an error-correcting output codes (ECOC) model using SVM binary learners and create a coder configurer for the model. Use the properties of the coder configurer to specify coder attributes of the ECOC model parameters. Use the object function of the coder configurer to generate C code that predicts labels for new predictor data. Then retrain the model using different settings, and update parameters in the generated code without regenerating the code.

Train Model

Load Fisher's iris data set.

```
load fisheriris
X = meas;
Y = species;
```

Create an SVM binary learner template to use a Gaussian kernel function and to standardize predictor data.

```
t = templateSVM('KernelFunction','gaussian','Standardize',true);
```

Train a multiclass ECOC model using the template `t`.

```
Mdl = fitcecoc(X,Y,'Learners',t);
```

`Mdl` is a `ClassificationECOC` object.

Create Coder Configurer

Create a coder configurer for the `ClassificationECOC` model by using `learnerCoderConfigurer`. Specify the predictor data `X`. The `learnerCoderConfigurer` function uses the input `X` to configure the coder attributes of the `predict` function input. Also, set the number of outputs to 2 so that the generated code returns the first two outputs of the `predict` function, which are the predicted labels and negated average binary losses.

```
configurer = learnerCoderConfigurer(Mdl,X,'NumOutputs',2)
```

```
configurer =
```

```
ClassificationECOCoderConfigurer with properties:
```

```
Update Inputs:
```

```
  BinaryLearners: [1×1 ClassificationSVMCoderConfigurer]
```

```
    Prior: [1×1 LearnerCoderInput]
```

```
    Cost: [1×1 LearnerCoderInput]
```

```
Predict Inputs:
```

```
  X: [1×1 LearnerCoderInput]
```

```
Code Generation Parameters:
```

```
  NumOutputs: 2
```

```
  OutputFileName: 'ClassificationECOCModel'
```

```
Properties, Methods
```

`configurer` is a `ClassificationECOCoderConfigurer` object, which is a coder configurer of a `ClassificationECOC` object. The display shows the tunable input arguments of `predict` and `update`: `X`, `BinaryLearners`, `Prior`, and `Cost`.

Specify Coder Attributes of Parameters

Specify the coder attributes of `predict` arguments (predictor data and the name-value pair arguments 'Decoding' and 'BinaryLoss') and `update` arguments (support vectors of the SVM learners) so that you can use these arguments as the input arguments of `predict` and `update` in the generated code.

First, specify the coder attributes of `X` so that the generated code accepts any number of observations. Modify the `SizeVector` and `VariableDimensions` attributes. The `SizeVector` attribute specifies the upper bound of the predictor data size, and the `VariableDimensions` attribute specifies whether each dimension of the predictor data has a variable size or fixed size.

```
configurer.X.SizeVector = [Inf 4];
configurer.X.VariableDimensions = [true false];
```

The size of the first dimension is the number of observations. In this case, the code specifies that the upper bound of the size is `Inf` and the size is variable, meaning that `X` can have any number of observations. This specification is convenient if you do not know the number of observations when generating code.

The size of the second dimension is the number of predictor variables. This value must be fixed for a machine learning model. `X` contains 4 predictors, so the second value of the `SizeVector` attribute must be 4 and the second value of the `VariableDimensions` attribute must be `false`.

Next, modify the coder attributes of `BinaryLoss` and `Decoding` to use the 'BinaryLoss' and 'Decoding' name-value pair arguments in the generated code. Display the coder attributes of `BinaryLoss`.

```
configurer.BinaryLoss
ans =
    EnumeratedInput with properties:
        Value: 'hinge'
        SelectedOption: 'Built-in'
        BuiltInOptions: {'hamming' 'linear' 'quadratic' 'exponential' 'binodeviance'}
        IsConstant: 1
        Tunability: 0
```

To use a nondefault value in the generated code, you must specify the value before generating the code. Specify the `Value` attribute of `BinaryLoss` as 'exponential'.

```
configurer.BinaryLoss.Value = 'exponential';
configurer.BinaryLoss

ans =
    EnumeratedInput with properties:

        Value: 'exponential'
    SelectedOption: 'Built-in'
    BuiltInOptions: {'hamming' 'linear' 'quadratic' 'exponential' 'binodeviance'
    IsConstant: 1
    Tunability: 1
```

If you modify attribute values when `Tunability` is false (logical 0), the software sets the `Tunability` to true (logical 1).

Display the coder attributes of `Decoding`.

```
configurer.Decoding

ans =
    EnumeratedInput with properties:

        Value: 'lossweighted'
    SelectedOption: 'Built-in'
    BuiltInOptions: {'lossweighted' 'lossbased'}
    IsConstant: 1
    Tunability: 0
```

Specify the `IsConstant` attribute of `Decoding` as false so that you can use all available values in `BuiltInOptions` in the generated code.

```
configurer.Decoding.IsConstant = false;
configurer.Decoding

ans =
    EnumeratedInput with properties:

        Value: [1x1 LearnerCoderInput]
    SelectedOption: 'NonConstant'
    BuiltInOptions: {'lossweighted' 'lossbased'}
    IsConstant: 0
    Tunability: 1
```

The software changes the Value attribute of Decoding to a LearnerCoderInput object so that you can use both 'lossweighted' and 'lossbased' as the value of 'Decoding'. Also, the software sets the SelectedOption to 'NonConstant' and the Tunability to true.

Finally, modify the coder attributes of SupportVectors in BinaryLearners. Display the coder attributes of SupportVectors.

```
configurer.BinaryLearners.SupportVectors
```

```
ans =
  LearnerCoderInput with properties:

      SizeVector: [54 4]
  VariableDimensions: [1 0]
           DataType: 'double'
           Tunability: 1
```

The default value of VariableDimensions is [true false] because each learner has a different number of support vectors. If you retrain the ECOC model using new data or different settings, the number of support vectors in the SVM learners can vary. Therefore, increase the upper bound of the number of support vectors.

```
configurer.BinaryLearners.SupportVectors.SizeVector = [150 4];
```

```
SizeVector attribute for Alpha has been modified to satisfy configuration constraints.
SizeVector attribute for SupportVectorLabels has been modified to satisfy configuration
```

If you modify the coder attributes of SupportVectors, then the software modifies the coder attributes of Alpha and SupportVectorLabels to satisfy configuration constraints. If the modification of the coder attributes of one parameter requires subsequent changes to other dependent parameters to satisfy configuration constraints, then the software changes the coder attributes of the dependent parameters.

Display the coder configurer.

```
configurer
```

```
configurer =
  ClassificationECOCoderConfigurer with properties:

  Update Inputs:
    BinaryLearners: [1x1 ClassificationSVMCoderConfigurer]
```

```
Prior: [1x1 LearnerCoderInput]
Cost: [1x1 LearnerCoderInput]

Predict Inputs:
    X: [1x1 LearnerCoderInput]
BinaryLoss: [1x1 EnumeratedInput]
Decoding: [1x1 EnumeratedInput]

Code Generation Parameters:
    NumOutputs: 2
    OutputFileName: 'ClassificationECOCModel'
```

Properties, Methods

The display now includes `BinaryLoss` and `Decoding` as well.

Generate Code

To generate C/C++ code, you must have access to a C/C++ compiler that is configured properly. MATLAB Coder locates and uses a supported, installed compiler. You can use `mex -setup` to view and change the default compiler. For more details, see “Change Default Compiler” (MATLAB).

Generate code for the `predict` and `update` functions of the ECOC classification model (`Mdl`) with default settings.

```
generateCode(configurer)
```

```
generateCode creates these files in output folder:
'initialize.m', 'predict.m', 'update.m', 'ClassificationECOCModel.mat'
```

The `generateCode` function completes these actions:

- Generate the MATLAB files required to generate code, including the two entry-point functions `predict.m` and `update.m` for the `predict` and `update` functions of `Mdl`, respectively.
- Create a MEX function named `ClassificationECOCModel` for the two entry-point functions.
- Create the code for the MEX function in the `codegen\mex\ClassificationECOCModel` folder.

- Copy the MEX function to the current folder.

Verify Generated Code

Pass some predictor data to verify whether the `predict` function of `Mdl` and the `predict` function in the MEX function return the same labels. To call an entry-point function in a MEX function that has more than one entry point, specify the function name as the first input argument. Because you specified `'Decoding'` as a tunable input argument by changing the `IsConstant` attribute before generating the code, you also need to specify it in the call to the MEX function, even though `'lossweighted'` is the default value of `'Decoding'`.

```
[label,NegLoss] = predict(Mdl,X,'BinaryLoss','exponential');
[label_mex,NegLoss_mex] = ClassificationECOCModel('predict',X,'BinaryLoss','exponential');
```

Compare `label` to `label_mex` by using `isequal`.

```
isequal(label,label_mex)
```

```
ans = logical
      1
```

`isequal` returns logical 1 (true) if all the inputs are equal. The comparison confirms that the `predict` function of `Mdl` and the `predict` function in the MEX function return the same labels.

`NegLoss_mex` might include round-off differences compared to `NegLoss`. In this case, compare `NegLoss_mex` to `NegLoss`, allowing a small tolerance.

```
find(abs(NegLoss-NegLoss_mex) > 1e-8)
```

```
ans =
```

```
    0×1 empty double column vector
```

The comparison confirms that `NegLoss` and `NegLoss_mex` are equal within the tolerance $1e-8$.

Retrain Model and Update Parameters in Generated Code

Retrain the model using a different setting. Specify `'KernelScale'` as `'auto'` so that the software selects an appropriate scale factor using a heuristic procedure.

```
t_new = templateSVM('KernelFunction','gaussian','Standardize',true,'KernelScale','auto');
retrainedMdl = fitcecoc(X,Y,'Learners',t_new);
```

Extract parameters to update by using `validatedUpdateInputs`. This function detects the modified model parameters in `retrainedMdl` and validates whether the modified parameter values satisfy the coder attributes of the parameters.

```
params = validatedUpdateInputs(configurer,retrainedMdl);
```

Update parameters in the generated code.

```
ClassificationECOCModel('update',params)
```

Verify Generated Code

Compare the outputs from the `predict` function of `retrainedMdl` to the outputs from the `predict` function in the updated MEX function.

```
[label,NegLoss] = predict(retrainedMdl,X,'BinaryLoss','exponential','Decoding','lossbase');
[label_mex,NegLoss_mex] = ClassificationECOCModel('predict',X,'BinaryLoss','exponential');
isequal(label,label_mex)
```

```
ans = logical
     1
```

```
find(abs(NegLoss-NegLoss_mex) > 1e-8)
```

```
ans =
```

```
0×1 empty double column vector
```

The comparison confirms that `labels` and `labels_mex` are equal, and `NegLoss` and `NegLoss_mex` are equal within the tolerance.

Input Arguments

configurer — Coder configurer

coder configurer object

Coder configurer of a machine learning model, specified as a coder configurer object created by using `learnerCoderConfigurer`.

Model	Coder Configurer Object
Support vector machine (SVM) regression	RegressionSVMCoderConfigurer
SVM for one-class and binary classification	ClassificationSVMCoderConfigurer
Multiclass model for SVMs	ClassificationECOCCoderConfigurer

cfg — Build type

'mex' (default) | 'dll' | 'lib' | code generation configuration object

Build type, specified as 'mex', 'dll', 'lib', or a code generation configuration object created by `coder.config`.

`generateCode` generates C/C++ code using one of the following build types.

- 'mex' — Generates a MEX function that has a platform-dependent extension. A MEX function is a C/C++ program that is executable from the Command Window. Before generating a C/C++ library for deployment, generate a MEX function to verify that the generated code provides the correct functionality.
- 'dll' — Generate a dynamic C/C++ library.
- 'lib' — Generate a static C/C++ library.
- Code generation configuration object created by `coder.config` — Generate C/C++ code using the code generation configuration object to customize code generation options. You can specify the build type and other configuration options using the object. For example, modify the `GenerateReport` parameter to enable the code generation report, and modify the `TargetLang` parameter to generate C++ code. The default value of the `TargetLang` parameter is 'C', generating C code.

```
cfg = coder.config('mex');
cfg.GenerateReport = true;
cfg.TargetLang = 'C++';
```

For details, see the `-config` option of `codegen`, `coder.config`, and “Configure Build Settings” (MATLAB Coder).

`generateCode` generates C/C++ code in the folder `outputPath\codegen\type\outputFileName`, where `type` is the build type specified by the `cfg` argument and `outputFileName` is the file name stored in the `OutputFileName` property of `configurer`.

outputPath — Folder path for output files

current folder (default) | character vector | string scalar

Folder path for the output files of `generateCode`, specified as a character vector or string array.

The specified folder path can be an absolute path or a relative path to the current folder path.

- The path must not contain spaces because they can lead to code generation failures in certain operating system configurations.
- The path also cannot contain non-7-bit ASCII characters, such as Japanese characters.

If the specified folder does not exist, then `generateCode` creates the folder.

`generateCode` searches the specified folder for the four MATLAB files: `predict.m`, `update.m`, `initialize.m`, and a MAT-file that includes machine learning model information. If the four files do not exist in the folder, then `generateCode` generates the files. Otherwise, `generateCode` does not generate any MATLAB files.

`generateCode` generates C/C++ code in the folder `outputPath\codegen\type\outputFileName`, where `type` is the build type specified by the `cfg` argument and `outputFileName` is the file name stored in the `OutputFileName` property of `configurer`.

Example: 'C:\myfiles'

Data Types: char | string

Limitations

- The `generateCode` function uses the `saveCompactModel`, `loadCompactModel`, and `codegen` functions, so the code generation limitations of these functions also apply to the `generateCode` function. For details, see the function reference pages `saveCompactModel`, `loadCompactModel`, and `codegen`.
- For the code generation usage notes and limitations of a machine learning model and its object functions, see the Code Generation sections of the corresponding reference pages.

Model	Model Object	predict Function
SVM regression	CompactRegressionSVM	predict

Model	Model Object	predict Function
SVM for one-class and binary classification	CompactClassificationSVM	predict
Multiclass model for SVMs	CompactClassificationECOC	predict

Alternative Functionality

- If you want to modify the MATLAB files (`predict.m`, `update.m`, and `initialize.m`) according to your code generation workflow, then use `generateFiles` to generate these files and use `codegen` to generate code.

Introduced in R2018b

generateFiles

Package: `classreg.learning.coder.config.svm`

Generate MATLAB files for code generation using coder configurer

Syntax

```
generateFiles(configurer)
generateFiles(configurer, 'OutputPath', outputPath)
```

Description

`generateFiles(configurer)` generates the MATLAB files required to generate C/C++ code by using the coder configurer `configurer`, and saves the generated files in the current folder.

To customize the code generation workflow, use `generateFiles` and `codegen`. If you do not need to customize your workflow, use `generateCode`.

`generateFiles` generates the following MATLAB files:

- `predict.m`, `update.m`, and `initialize.m` — `predict.m` and `update.m` are the entry-point functions for the `predict` and `update` functions of the machine learning model, respectively, and these two functions call `initialize.m`. You can modify these files according to your code generation workflow. For example, you can modify the `predict.m` file to include data preprocessing, or you can add these entry-point functions to another code generation project.
- A MAT-file that includes machine learning model information — `generateFiles` uses the `saveCompactModel` function to save machine learning model information in a MAT-file whose file name is stored in the `OutputFileName` property of a coder configurer. `initialize.m` loads the saved MAT-file by using the `loadCompactModel` function.

After you generate these files, generate C/C++ code by using `codegen` and the prepared `codegen` argument stored in the `CodeGenerationArguments` property of a coder configurer.

If the folder already includes all four MATLAB files, then `generateFiles` does not generate any files.

`generateFiles(configurer, 'OutputPath', outputPath)` generates the MATLAB files in the folder specified by `outputPath`.

Examples

Generate MATLAB® Files for Code Generation

Train a machine learning model and then generate the MATLAB files required to generate C/C++ code for the `predict` and `update` functions of the model by using a coder configurer.

Load the `ionosphere` data set and train a binary support vector machine (SVM) classification model.

```
load ionosphere
Mdl = fitcsvm(X,Y);
```

`Mdl` is a `ClassificationSVM` object.

Create a coder configurer for the `ClassificationSVM` object.

```
configurer = learnerCoderConfigurer(Mdl,X);
```

`configurer` is a `ClassificationSVMCoderConfigurer` object, which is a coder configurer of a `ClassificationSVM` object.

Use `generateFiles` to generate the MATLAB files required to generate C/C++ code for the `predict` and `update` functions of the model.

```
generateFiles(configurer)
```

`generateFiles` generates `predict.m`, `update.m`, `initialize.m`, and `ClassificationSVMModel.mat` (a MAT-file that includes machine learning model information).

Display the contents of the `predict.m`, `update.m`, and `initialize.m` files.

```
type predict.m % Display contents of predict.m
```

```
function varargout = predict(X,varargin) %#codegen
% Autogenerated by MATLAB, 03-Mar-2019 15:55:58
[varargout{1:nargout}] = initialize('predict',X,varargin{:});
end
```

type `update.m` % Display contents of `update.m`

```
function update(varargin) %#codegen
% Autogenerated by MATLAB, 03-Mar-2019 15:55:58
initialize('update',varargin{:});
end
```

type `initialize.m` % Display contents of `initialize.m`

```
function [varargout] = initialize(command,varargin) %#codegen
% Autogenerated by MATLAB, 03-Mar-2019 15:55:58
coder.inline('always');
persistent model;
if isempty(model)
    model = loadCompactModel('ClassificationSVMModel.mat');
end
switch(command)
    case 'update'
        % Update struct fields: Alpha
        %                               SupportVectors
        %                               SupportVectorLabels
        %                               Scale
        %                               Bias
        %                               Prior
        %                               Cost

        model = update(model,varargin{:});
    case 'predict'
        % Predict Inputs: X

        X = varargin{1};
        if nargin == 2
            [varargout{1:nargout}] = predict(model,X);
        else
            PVPairs = cell(1,nargin-2);
            for i = 1:nargin-2
                PVPairs{1,i} = varargin{i+1};
            end
            [varargout{1:nargout}] = predict(model,X,PVPairs{:});
        end
end
```

```
end
end
```

Generate C/C++ code by using `codegen` and the prepared `codegen` argument stored in the `CodeGenerationArguments` property of `configurer`.

```
cfArgs = configurer.CodeGenerationArguments;
codegen(cfArgs{:})
```

Input Arguments

configurer — Coder configurer

coder configurer object

Coder configurer of a machine learning model, specified as a coder configurer object created by using `learnerCoderConfigurer`.

Model	Coder Configurer Object
Support vector machine (SVM) regression	<code>RegressionSVMCoderConfigurer</code>
SVM for one-class and binary classification	<code>ClassificationSVMCoderConfigurer</code>
Multiclass model for SVMs	<code>ClassificationECOCCoderConfigurer</code>

outputPath — Folder path for output files

current folder (default) | character vector | string scalar

Folder path for the output files of `generateFiles`, specified as a character vector or string array.

The specified folder path can be an absolute path or a relative path to the current folder path.

- The path must not contain spaces because they can lead to code generation failures in certain operating system configurations.
- The path also cannot contain non-7-bit ASCII characters, such as Japanese characters.

If the specified folder does not exist, then `generateFiles` creates the folder.

`generateFiles` searches the specified folder for the four MATLAB files: `predict.m`, `update.m`, `initialize.m`, and a MAT-file that includes machine learning model

information. If the four files do not exist in the folder, then `generateFiles` generates the files. Otherwise, `generateFiles` does not generate any MATLAB files.

Example: 'C:\myfiles'

Data Types: `char` | `string`

Alternative Functionality

- To customize the code generation workflow, use `generateFiles` and `codegen`. If you do not need to customize your workflow, use `generateCode`. In addition to generating the four MATLAB files generated by `generateFiles`, the `generateCode` function also generates the C/C++ code.

Introduced in R2018b

geocdf

Geometric cumulative distribution function

Syntax

```
y = geocdf(x,p)
y = geocdf(x,p,'upper')
```

Description

`y = geocdf(x,p)` returns the cumulative distribution function (cdf) of the geometric distribution at each value in `x` using the corresponding probabilities in `p`. `x` and `p` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other input. The parameters in `p` must lie on the interval $[0, 1]$.

`y = geocdf(x,p,'upper')` returns the complement of the geometric distribution cdf at each value in `x`, using an algorithm that more accurately computes the extreme upper tail probabilities.

Examples

Compute Geometric Distribution cdf

Suppose you toss a fair coin repeatedly, and a "success" occurs when the coin lands with heads facing up. What is the probability of observing three or fewer tails ("failures") before tossing a heads?

To solve, determine the value of the cumulative distribution function (cdf) for the geometric distribution at `x` equal to 3. The probability of success (tossing a heads) `p` in any given trial is 0.5.

```
x = 3;  
p = 0.5;  
y = geocdf(x,p)  
  
y = 0.9375
```

The returned value of y indicates that the probability of observing three or fewer tails before tossing a heads is 0.9375.

Definitions

Geometric Distribution cdf

The cumulative distribution function (cdf) of the geometric distribution is

$$y = F(x|p) = 1 - (1 - p)^{x+1}; x = 0, 1, 2, \dots,$$

where p is the probability of success, and x is the number of failures before the first success. The result y is the probability of observing up to x trials before a success, when the probability of success in any given trial is p .

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU arrays. For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

`cdf` | `geoinv` | `geopdf` | `geornd` | `geostat` | `mle`

Topics

“Geometric Distribution” on page B-60

Introduced before R2006a

geoinv

Geometric inverse cumulative distribution function

Syntax

```
x = geoinv(y,p)
```

Description

`x = geoinv(y,p)` returns the inverse cumulative distribution function (icdf) of the geometric distribution at each value in `y` using the corresponding probabilities in `p`.

`geoinv` returns the smallest positive integer `x` such that the geometric cdf evaluated at `x` is equal to or exceeds `y`. You can think of `y` as the probability of observing `x` successes in a row in independent trials, where `p` is the probability of success in each trial.

`y` and `p` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input for `p` or `y` is expanded to a constant array with the same dimensions as the other input. The values in `p` and `y` must lie on the interval $[0, 1]$.

Examples

Compute Geometric Distribution icdf

Suppose the probability of a five-year-old car battery not starting in cold weather is 0.03. If we want no more than a ten percent chance that the car does not start, what is the maximum number of days in a row that we should try to start the car?

To solve, compute the inverse cdf of the geometric distribution. In this example, a "success" means the car does not start, while a "failure" means the car does start. The probability of success for each trial p equals 0.03, while the probability of observing x failures in a row before observing a success y equals 0.1.

```
y = 0.1;  
p = 0.03;  
x = geoinv(y,p)  
  
x = 3
```

The returned result indicates that if we start the car three times, there is at least a ten percent chance that it will not start on one of those tries. Therefore, if we want no greater than a ten percent chance that the car will not start, we should only attempt to start it for a maximum of two days in a row.

We can confirm this result by evaluating the cdf at values of x equal to 2 and 3, given the probability of success for each trial p equal to 0.03.

```
y2 = geocdf(2,p) % cdf for x = 2  
  
y2 = 0.0873  
  
y3 = geocdf(3,p) % cdf for x = 3  
  
y3 = 0.1147
```

The returned results indicate an 8.7% chance of the car not starting if we try two days in a row, and an 11.5% chance of not starting if we try three days in a row.

Extended Capabilities

Topics

“Geometric Distribution” on page B-60

Introduced before R2006a

geomean

Geometric mean

Syntax

```
m = geomean(X)
m = geomean(X, 'all')
m = geomean(X, dim)
m = geomean(X, vecdim)
m = geomean( ____, nanflag)
```

Description

`m = geomean(X)` returns the geometric mean on page 32-2904 of *X*.

- If *X* is a vector, then `geomean(X)` is the geometric mean of the elements in *X*.
- If *X* is a matrix, then `geomean(X)` is a row vector containing the geometric mean of each column of *X*.
- If *X* is a multidimensional array, then `geomean` operates along the first nonsingleton dimension of *X*.

`m = geomean(X, 'all')` returns the geometric mean of all the elements in *X*.

`m = geomean(X, dim)` returns the geometric mean along the operating dimension `dim` of *X*.

`m = geomean(X, vecdim)` returns the geometric mean over the dimensions specified in the vector `vecdim`. For example, if *X* is a 2-by-3-by-4 array, then `geomean(X, [1 2])` returns a 1-by-1-by-4 array. Each element of the output array is the geometric mean of the elements on the corresponding page of *X*.

`m = geomean(____, nanflag)` specifies whether to exclude NaN values from the calculation, using any of the input argument combinations in previous syntaxes. By default, `geomean` includes NaN values in the calculation (`nanflag` has the value `'includenan'`). To exclude NaN values, set the value of `nanflag` to `'omitnan'`.

Examples

Compare Geometric and Arithmetic Mean

Set the random seed for reproducibility of the results.

```
rng('default')
```

Create a matrix of exponential random numbers with 5 rows and 4 columns.

```
X = exprnd(1,5,4)
```

```
X = 5×4
```

```
    0.2049    2.3275    1.8476    1.9527
    0.0989    1.2783    0.0298    0.8633
    2.0637    0.6035    0.0438    0.0880
    0.0906    0.0434    0.7228    0.2329
    0.4583    0.0357    0.2228    0.0414
```

Compute the geometric and arithmetic means of the columns of X.

```
geometric = geomean(X)
```

```
geometric = 1×4
```

```
    0.2805    0.3083    0.2079    0.2698
```

```
arithmetic = mean(X)
```

```
arithmetic = 1×4
```

```
    0.5833    0.8577    0.5734    0.6357
```

The arithmetic mean is greater than the geometric mean for all the columns of X.

Geometric Mean of All Elements

Find the geometric mean over multiple dimensions by using the 'all' input argument.

Create a 2-by-5-by-4 array X.

```
X = reshape(1:40,[2 5 4])
```

```
X =  
X(:,:,1) =
```

```
     1     3     5     7     9  
     2     4     6     8    10
```

```
X(:,:,2) =
```

```
    11    13    15    17    19  
    12    14    16    18    20
```

```
X(:,:,3) =
```

```
    21    23    25    27    29  
    22    24    26    28    30
```

```
X(:,:,4) =
```

```
    31    33    35    37    39  
    32    34    36    38    40
```

Find the geometric mean of all the elements of X.

```
m = geomean(X, 'all')
```

```
m = 15.7685
```

m is the geometric mean of the entire array X.

Geometric Mean Along Specified Dimensions

Find the geometric mean along different operating dimensions and vectors of dimensions for a multidimensional array.

Create a 3-by-5-by-2 array X.

```
X = reshape(1:30,[3 5 2])
```

```
X =
```

```
X(:,:,1) =
```

```
     1     4     7    10    13
     2     5     8    11    14
     3     6     9    12    15
```

```
X(:,:,2) =
```

```
    16    19    22    25    28
    17    20    23    26    29
    18    21    24    27    30
```

Find the geometric mean of X along the default dimension.

```
gmean1 = geomean(X)
```

```
gmean1 =
```

```
gmean1(:,:,1) =
```

```
    1.8171    4.9324    7.9581   10.9696   13.9761
```

```
gmean1(:,:,2) =
```

```
   16.9804   19.9833   22.9855   25.9872   28.9885
```

By default, `geomean` operates along the first dimension of X whose size does not equal 1. In this case, this dimension is the first dimension of X. Therefore, `gmean1` is a 1-by-5-by-2 array.

Find the geometric mean of X along the second dimension.

```
gmean2 = geomean(X,2)
```

```
gmean2 =
```

```
gmean2(:,:,1) =
```

```
    5.1549
    6.5784
```

```
7.8155
```

```
gmean2(:,:,2) =
```

```
21.5814  
22.6004  
23.6177
```

`gmean2` is a 3-by-1-by-2 array.

Find the geometric mean of `X` along the third dimension.

```
gmean3 = geomean(X,3)
```

```
gmean3 = 3×5
```

```
4.0000    8.7178   12.4097   15.8114   19.0788  
5.8310   10.0000   13.5647   16.9115   20.1494  
7.3485   11.2250   14.6969   18.0000   21.2132
```

`gmean3` is a 3-by-5 array.

Find the geometric mean of each page of `X` by specifying the first and second dimensions using the `vecdim` input argument.

```
mpage = geomean(X,[1 2])
```

```
mpage =  
mpage(:,:,1) =
```

```
6.4234
```

```
mpage(:,:,2) =
```

```
22.5845
```

For example, `mpage(1,1,2)` is the geometric mean of the elements in `X(:,:,2)`.

Find the geometric mean of the elements in each `X(i,:,:) slice` by specifying the second and third dimensions.

```
mrow = geomean(X,[2 3])
```

```
mrow = 3×1
```

```
10.5475  
12.1932  
13.5862
```

For example, `mrow(3)` is the geometric mean of the elements in `X(3, :, :)`, and is equivalent to specifying `geomean(X(3, :, :), 'all')`.

Geometric Mean Excluding NaN

Create a vector and compute its `geomean`, excluding NaN values.

```
x = 1:10;  
x(3) = nan; % Replace the third element of x with a NaN value  
n = geomean(x, 'omitnan')  
  
n = 4.7408
```

If you do not specify `'omitnan'`, then `geomean(x)` returns NaN.

Input Arguments

X — Input data

nonnegative vector | nonnegative matrix | nonnegative multidimensional array

Input data that represents a sample from a population, specified as a nonnegative vector, matrix, or multidimensional array.

- If `X` is a vector, then `geomean(X)` is the geometric mean of the elements in `X`.
- If `X` is a matrix, then `geomean(X)` is a row vector containing the geometric mean of each column of `X`.
- If `X` is a multidimensional array, then `geomean` operates along the first nonsingleton dimension of `X`.

To specify the operating dimension when X is a matrix or an array, use the `dim` input argument.

Data Types: `single` | `double`

dim — Dimension

positive integer scalar

Dimension along which to operate, specified as a positive integer scalar. If you do not specify a value, then the default value is the first array dimension of X whose size does not equal 1.

Consider a two-dimensional array X :

- If `dim` is equal to 1, then `geomean(X,1)` returns a row vector containing the geometric mean for each column in X .
- If `dim` is equal to 2, then `geomean(X,2)` returns a column vector containing the geometric mean for each row in X .

If `dim` is greater than `ndims(X)` or if `size(X,dim)` is 1, then `geomean` returns X .

Data Types: `single` | `double`

vecdim — Vector of dimensions

positive integer vector

Vector of dimensions, specified as a positive integer vector. Each element of `vecdim` represents a dimension of the input array X . The output m has length 1 in the specified operating dimensions. The other dimension lengths are the same for X and m .

For example, if X is a 2-by-3-by-3 array, then `geomean(X,[1 2])` returns a 1-by-1-by-3 array. Each element of the output is the geometric mean of the elements on the corresponding page of X .

Data Types: `single` | `double`

nanflag — NaN condition

`'includenan'` (default) | `'omitnan'`

NaN condition, specified as one of these values:

- `'includenan'` — Include NaN values when computing the `geomean`. This returns NaN.
- `'omitnan'` — Ignore NaN values in the input.

Data Types: `char` | `string`

Output Arguments

m — Geometric mean

`scalar` | `vector` | `matrix` | `multidimensional array`

Geometric mean, returned as a scalar, vector, matrix, or multidimensional array.

Definitions

Geometric Mean

The geometric mean of a sample X is

$$m = \left[\prod_{i=1}^n x_i \right]^{\frac{1}{n}}$$

where n is the number of values in X .

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. For more information, see “Tall Arrays” (MATLAB).

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- These input arguments are not supported: 'all', `vecdim`, and `nanflag`.
- The `dim` input argument must be a compile-time constant.
- If you do not specify the `dim` input argument, the working (or operating) dimension can be different in the generated code. As a result, run-time errors can occur. For more details, see “Automatic dimension restriction” (MATLAB Coder).

For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “General Code Generation Workflow” on page 31-5.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Usage notes and limitations:

- The 'all' and `vecdim` input arguments are not supported.

For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

Topics

“Geometric Distribution” on page B-60

Introduced before R2006a

geopdf

Geometric probability density function

Syntax

```
y = geopdf(x, p)
```

Description

`y = geopdf(x, p)` returns the probability density function (pdf) of the geometric distribution at each value in `x` using the corresponding probabilities in `p`. `x` and `p` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other input. The parameters in `p` must lie on the interval $[0, 1]$.

Examples

Compute Geometric Distribution pdf

Suppose you toss a fair coin repeatedly, and a "success" occurs when the coin lands with heads facing up. What is the probability of observing exactly three tails ("failures") before tossing a heads?

To solve, determine the value of the probability density function (pdf) for the geometric distribution at `x` equal to 3. The probability of success (tossing a heads) `p` in any given trial is 0.5.

```
x = 3;  
p = 0.5;  
y = geopdf(x, p)  
  
y = 0.0625
```

The returned value of `y` indicates that the probability of observing exactly three tails before tossing a heads is 0.0625.

Definitions

Geometric Distribution pdf

The probability distribution function (pdf) of the geometric distribution is

$$y = f(x|p) = p(1 - p)^x ; \quad x = 0, 1, 2, \dots ,$$

where p is the probability of success, and x is the number of failures before the first success. The result y is the probability of observing exactly x trials before a success, when the probability of success in any given trial is p . For discrete distributions, the probability distribution function is also known as the probability mass function (pmf).

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU arrays. For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

Topics

“Geometric Distribution” on page B-60

Introduced before R2006a

geornd

Geometric random numbers

Syntax

```
r = geornd(p)
r = geornd(p,m,n,...)
r = geornd(p,[m,n,...])
```

Description

`r = geornd(p)` generates random numbers from a geometric distribution with probability parameter `p`. `p` can be a vector, a matrix, or a multidimensional array. The size of `r` is equal to the size of `p`. The parameters in `p` must lie in the interval $[0, 1]$.

`r = geornd(p,m,n,...)` or `r = geornd(p,[m,n,...])` generates a multidimensional `m`-by-`n`-by-... array containing random numbers from the geometric distribution with probability parameter `p`. `p` can be a scalar or an array of the same size as `r`.

The geometric distribution is useful to model the number of failures before one success in a series of independent trials, where each trial results in either success or failure, and the probability of success in any individual trial is the constant `p`.

Examples

Generate Random Numbers from Geometric Distribution

Generate a single random number from a geometric distribution with probability parameter `p` equal to 0.01.

```
rng default % For reproducibility
p = 0.01;
r1 = geornd(0.01)
```

```
r1 = 20
```

The returned random number represents a single experiment in which 20 failures were observed before a success, where each independent trial has a probability of success p equal to 0.01.

Generate a 1-by-5 array of random numbers from a geometric distribution with probability parameter p equal to 0.01.

```
r2 = geornd(p,1,5)
```

```
r2 = 1×5
```

```
    9    205    9    45    231
```

Each random number in the returned array represents the result of an experiment to determine the number of failures observed before a success, where each independent trial has a probability of success p equal to 0.01.

Generate a 1-by-3 array containing one random number from each of the three geometric distributions corresponding to the parameters in the 1-by-3 array of probabilities p .

```
p = [0.01 0.1 0.5];  
r3 = geornd(p,[1 3])
```

```
r3 = 1×3
```

```
   127    5    0
```

Each element of the returned 1-by-3 array `r3` contains one random number generated from the geometric distribution described by the corresponding parameter in `P`. For example, the first element in `r3` represents an experiment in which 127 failures were observed before a success, where each independent trial has a probability of success p equal to 0.01. The second element in `r3` represents an experiment in which 5 failures were observed before a success, where each independent trial has a probability of success p equal to 0.1. The third element in `r3` represents an experiment in which zero failures were observed before a success - in other words, the first attempt was a success - where each independent trial has a probability of success p equal to 0.5.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

The generated code can return a different sequence of numbers than MATLAB if either of the following is true:

- The output is nonscalar.
- An input parameter is invalid for the distribution.

For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “General Code Generation Workflow” on page 31-5.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU arrays. For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

Topics

“Geometric Distribution” on page B-60

Introduced before R2006a

geostat

Geometric mean and variance

Syntax

```
[m,v] = geostat(p)
```

Description

`[m,v] = geostat(p)` returns the mean m and variance v of a geometric distribution with corresponding probability parameters in p . p can be a vector, a matrix, or a multidimensional array. The parameters in p must lie in the interval $[0, 1]$.

Examples

Compute Mean and Variance of Geometric Distribution

Define a probability vector that contains six different parameter values.

```
p = 1./(1:6)
```

```
p = 1×6
```

```
1.0000    0.5000    0.3333    0.2500    0.2000    0.1667
```

Compute the mean and variance of the geometric distribution that corresponds to each value contained in probability vector.

```
[m,v] = geostat(1./(1:6))
```

```
m = 1×6
```

```
0    1.0000    2.0000    3.0000    4.0000    5.0000
```

$$v = 1 \times 6$$

0 2.0000 6.0000 12.0000 20.0000 30.0000

The returned values indicate that, for example, the mean of a geometric distribution with probability parameter p equal to 1/3 is 2, and its variance is 6.

Definitions

Geometric Distribution Mean and Variance

The mean of the geometric distribution is

$$\text{mean} = \frac{1 - p}{p},$$

and the variance of the geometric distribution is

$$\text{var} = \frac{1 - p}{p^2},$$

where p is the probability of success.

Extended Capabilities

GapEvaluation

Package: clustering.evaluation

Superclasses:

Gap criterion clustering evaluation object

Description

GapEvaluation is an object consisting of sample data, clustering data, and gap criterion values used to evaluate the optimal number of clusters. Create a gap criterion clustering evaluation object using `evalclusters`.

Construction

`eva = evalclusters(x, clust, 'Gap')` creates a gap criterion clustering evaluation object.

`eva = evalclusters(x, clust, 'Gap', Name, Value)` creates a gap criterion clustering evaluation object using additional options specified by one or more name-value pair arguments.

Input Arguments

x — Input data

matrix

Input data, specified as an N -by- P matrix. N is the number of observations, and P is the number of variables.

Data Types: `single` | `double`

clust — Clustering algorithm

'kmeans' | 'linkage' | 'gmdistribution' | matrix of clustering solutions | function handle

Clustering algorithm, specified as one of the following.

'kmeans'	Cluster the data in <code>x</code> using the kmeans clustering algorithm, with 'EmptyAction' set to 'singleton' and 'Replicates' set to 5.
'linkage'	Cluster the data in <code>x</code> using the clusterdata agglomerative clustering algorithm, with 'Linkage' set to 'ward'.
'gmdistribution'	Cluster the data in <code>x</code> using the gmdistribution Gaussian mixture distribution algorithm, with 'SharedCov' set to true and 'Replicates' set to 5.

If `criterion` is 'CalinskiHarabasz', 'DaviesBouldin', or 'silhouette', you can specify a clustering algorithm using a function handle (MATLAB). The function must be of the form `C = clustfun(DATA,K)`, where `DATA` is the data to be clustered, and `K` is the number of clusters. The output of `clustfun` must be one of the following:

- A vector of integers representing the cluster index for each observation in `DATA`. There must be `K` unique values in this vector.
- A numeric n -by- K matrix of score for n observations and K classes. In this case, the cluster index for each observation is determined by taking the largest score value in each row.

If `criterion` is 'CalinskiHarabasz', 'DaviesBouldin', or 'silhouette', you can also specify `clust` as a n -by- K matrix containing the proposed clustering solutions. n is the number of observations in the sample data, and K is the number of proposed clustering solutions. Column j contains the cluster indices for each of the N points in the j th clustering solution.

Data Types: `single` | `double` | `char` | `string` | `function_handle`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'KList',[1:5],'Distance','cityblock'` specifies to test 1, 2, 3, 4, and 5 clusters using the city block distance metric.

B — Number of reference data sets

100 (default) | positive integer value

Number of reference data sets generated from the reference distribution `ReferenceDistribution`, specified as the comma-separated pair consisting of 'B' and a positive integer value.

Example: 'B',150

Data Types: `single` | `double`

Distance — Distance metric

'sqEuclidean' (default) | 'Euclidean' | 'cityblock' | function | ...

Distance metric used for computing the criterion values, specified as the comma-separated pair consisting of 'Distance' and one of the following.

'sqEuclidean'	Squared Euclidean distance
'Euclidean'	Euclidean distance
'cityblock'	Sum of absolute differences
'cosine'	One minus the cosine of the included angle between points (treated as vectors)
'correlation'	One minus the sample correlation between points (treated as sequences of values)

For detailed information about each distance metric, see `pdist`.

You can also specify a function for the distance metric by using a function handle (MATLAB). The distance function must be of the form

```
d2 = distfun(XI,XJ),
```

where `XI` is a 1-by- n vector corresponding to a single row of the input matrix `X`, and `XJ` is an m_2 -by- n matrix corresponding to multiple rows of `X`. `distfun` must return an m_2 -by-1 vector of distances `d2`, whose k th element is the distance between `XI` and `XJ(k,:)`.

`Distance` only accepts a function handle if the clustering algorithm `clust` accepts a function handle as the distance metric. For example, the `kmeans` clustering algorithm does not accept a function handle as the distance metric. Therefore, if you use the `kmeans` algorithm and then specify a function handle for `Distance`, the software errors.

- When `clust` is 'kmeans' or 'gmdistribution', `evalclusters` uses the distance metric specified for `Distance` to cluster the data.
- If `clust` is 'linkage', and `Distance` is either 'sqEuclidean' or 'Euclidean', then the clustering algorithm uses Euclidean distance and Ward linkage.

- If `clust` is 'linkage' and `Distance` is any other metric, then the clustering algorithm uses the specified distance metric and average linkage.
- In all other cases, the distance metric specified for `Distance` must match the distance metric used in the clustering algorithm to obtain meaningful results.

Example: 'Distance', 'Euclidean'

Data Types: single | double | char | string | function_handle

KList — List of number of clusters to evaluate

vector

List of number of clusters to evaluate, specified as the comma-separated pair consisting of 'KList' and a vector of positive integer values. You must specify `KList` when `clust` is a clustering algorithm name or a function handle. When `criterion` is 'gap', `clust` must be a character vector, a string scalar, or a function handle, and you must specify `KList`.

Example: 'KList', [1:6]

Data Types: single | double

ReferenceDistribution — Reference data generation method

'PCA' (default) | 'uniform'

Reference data generation method, specified as the comma-separated pair consisting of 'ReferenceDistributions' and one of the following.

'PCA'	Generate reference data from a uniform distribution over a box aligned with the principal components of the data matrix x .
'uniform'	Generate reference data uniformly over the range of each feature in the data matrix x .

Example: 'ReferenceDistribution', 'uniform'

SearchMethod — Method for selecting optimal number of clusters

'globalMaxSE' (default) | 'firstMaxSE'

Method for selecting the optimal number of clusters, specified as the comma-separated pair consisting of 'SearchMethod' and one of the following.

'globalMaxSE'

Evaluate each proposed number of clusters in `KList` and select the smallest number of clusters satisfying

$$\text{Gap}(K) \geq \text{GAPMAX} - \text{SE}(\text{GAPMAX}),$$

where K is the number of clusters, $\text{Gap}(K)$ is the gap value for the clustering solution with K clusters, GAPMAX is the largest gap value, and $\text{SE}(\text{GAPMAX})$ is the standard error corresponding to the largest gap value.

'firstMaxSE'

Evaluate each proposed number of clusters in `KList` and select the smallest number of clusters satisfying

$$\text{Gap}(K) \geq \text{Gap}(K + 1) - \text{SE}(K + 1),$$

where K is the number of clusters, $\text{Gap}(K)$ is the gap value for the clustering solution with K clusters, and $\text{SE}(K + 1)$ is the standard error of the clustering solution with $K + 1$ clusters.

Example: 'SearchMethod', 'globalMaxSE'

Properties

B

Number of data sets generated from the reference distribution, stored as a positive integer value.

ClusteringFunction

Clustering algorithm used to cluster the input data, stored as a valid clustering algorithm name or function handle. If the clustering solutions are provided in the input, `ClusteringFunction` is empty.

CriterionName

Name of the criterion used for clustering evaluation, stored as a valid criterion name.

CriterionValues

Criterion values corresponding to each proposed number of clusters in `InspectedK`, stored as a vector of numerical values.

Distance

Distance metric used for clustering data, stored as a valid distance metric name.

ExpectedLogW

Expectation of the natural logarithm of W based on the generated reference data, stored as a vector of scalar values. W is the within-cluster dispersion computed using the distance metric `Distance`.

InspectedK

List of the number of proposed clusters for which to compute criterion values, stored as a vector of positive integer values.

LogW

Natural logarithm of W based on the input data, stored as a vector of scalar values. W is the within-cluster dispersion computed using the distance metric `Distance`.

Missing

Logical flag for excluded data, stored as a column vector of logical values. If `Missing` equals `true`, then the corresponding value in the data matrix x is not used in the clustering solution.

NumObservations

Number of observations in the data matrix X , minus the number of missing (NaN) values in X , stored as a positive integer value.

OptimalK

Optimal number of clusters, stored as a positive integer value.

OptimalY

Optimal clustering solution corresponding to `OptimalK`, stored as a column vector of positive integer values. If the clustering solutions are provided in the input, `OptimalY` is empty.

ReferenceDistribution

Reference data generation method, stored as a valid reference distribution name.

SE

Standard error of the natural logarithm of W with respect to the reference data for each number of clusters in `InspectedK`, stored as a vector of scalar values. W is the within-cluster dispersion computed using the distance metric `Distance`.

SearchMethod

Method for determining the optimal number of clusters, stored as a valid search method name.

StdLogW

Standard deviation of the natural logarithm of W with respect to the reference data for each number of clusters in `InspectedK`. W is the within-cluster dispersion computed using the distance metric `Distance`.

X

Data used for clustering, stored as a matrix of numerical values.

Methods

`increaseB` Increase reference data sets

Inherited Methods

addK Evaluate additional numbers of clusters
plot Plot clustering evaluation object criterion values
compact Compact clustering evaluation object

Examples

Evaluate Clustering Solution Using Gap Criterion

Evaluate the optimal number of clusters using the gap clustering evaluation criterion.

Load the sample data.

```
load fisheriris
```

The data contains sepal and petal measurements from three species of iris flowers.

Evaluate the number of clusters based on the gap criterion values. Cluster the data using kmeans.

```
rng('default'); % For reproducibility
eva = evalclusters(meas,'kmeans','gap','KList',[1:6])
eva =
  GapEvaluation with properties:
    NumObservations: 150
    InspectedK: [1 2 3 4 5 6]
    CriterionValues: [0.0720 0.5928 0.8762 1.0114 1.0534 1.0720]
    OptimalK: 5
```

The `OptimalK` value indicates that, based on the gap criterion, the optimal number of clusters is five.

Plot the gap criterion values for each number of clusters tested.

```
plot(eva)
```

Based on the plot, the maximum value of the gap criterion occurs at six clusters. However, the value at five clusters is within one standard error of the maximum, so the suggested optimal number of clusters is five.

Create a grouped scatter plot to examine the relationship between petal length and width. Group the data by suggested clusters.

```
figure
PetalLength = meas(:,3);
PetalWidth = meas(:,4);
ClusterGroup = eva.OptimalY;
gscatter(PetalLength,PetalWidth,ClusterGroup,'rbgkc','xod^*');
```

The plot shows cluster 4 in the lower-left corner, completely separated from the other four clusters. Cluster 4 contains flowers with the smallest petal widths and lengths. Cluster 2 is in the upper-right corner and contains flowers with the largest petal widths and lengths. Cluster 5 is next to cluster 2 and contains flowers with similar petal widths as the flowers in cluster 2, but smaller petal lengths than the flowers in cluster 2. Clusters 1 and 3 are near the center of the plot and contain flowers with measurements between the extremes.

Definitions

Gap Value

A common graphical approach to cluster evaluation involves plotting an error measurement versus several proposed numbers of clusters, and locating the “elbow” of this plot. The “elbow” occurs at the most dramatic decrease in error measurement. The gap criterion formalizes this approach by estimating the “elbow” location as the number of clusters with the largest gap value. Therefore, under the gap criterion, the optimal number of clusters occurs at the solution with the largest local or global gap value within a tolerance range.

The gap value is defined as

$$\text{Gap}_n(k) = E_n^*\{\log(W_k)\} - \log(W_k),$$

where n is the sample size, k is the number of clusters being evaluated, and W_k is the pooled within-cluster dispersion measurement

$$W_k = \sum_{r=1}^k \frac{1}{2n_r} D_r,$$

where n_r is the number of data points in cluster r , and D_r is the sum of the pairwise distances for all points in cluster r .

The expected value $E_n^*\{\log(W_k)\}$ is determined by Monte Carlo sampling from a reference distribution, and $\log(W_k)$ is computed from the sample data.

The gap value is defined even for clustering solutions that contain only one cluster, and can be used with any distance metric. However, the gap criterion is more computationally expensive than other cluster evaluation criteria, because the clustering algorithm must be applied to the reference data for each proposed clustering solution.

get

Class: dataset

Access dataset array properties

Note The dataset data type might be removed in a future release. To work with heterogeneous data, use the MATLAB® table data type instead. See MATLAB table documentation for more information.

Syntax

```
get(A)
s = get(A)
p = get(A,PropertyName)
p = get(A,{PropertyName1,PropertyName2,...})
```

Description

`get(A)` displays a list of property/value pairs for the dataset array `A`.

`s = get(A)` returns the values in a scalar structure `s` with field names given by the properties.

`p = get(A,PropertyName)` returns the value of the property specified by `PropertyName`.

`p = get(A,{PropertyName1,PropertyName2,...})` allows multiple property names to be specified and returns their values in a cell array.

Examples

Create a dataset array from Fisher's iris data and access the information.

```
load fisheriris
NumObs = size(meas,1);
```

```
NameObs = strcat({'Obs'},num2str((1:NumObs)','%-d'));
iris = dataset({nominal(species),'species'},...
              {meas,'SL','SW','PL','PW'},...
              'ObsNames',NameObs);

get(iris)
  Description: ''
  Units: {}
  DimNames: {'Observations' 'Variables'}
  UserData: []
  ObsNames: {150x1 cell}
  VarNames: {'species' 'SL' 'SW' 'PL' 'PW'}

ON = get(iris,'ObsNames');
ON(1:3)
ans =
  'Obs1'
  'Obs2'
  'Obs3'
```

getlabels

Access nominal or ordinal array labels

Note The `nominal` and `ordinal` array data types might be removed in a future release. To represent ordered and unordered discrete, nonnumeric data, use the “Categorical Arrays” (MATLAB) data type instead.

Syntax

```
labels = getlabels(A)
```

Description

`labels = getlabels(A)` returns the labels of the levels in the nominal or ordinal array `A` as a cell array of character vectors, `labels`. If `A` is an ordinal array, `getlabels` returns the labels in the order of the levels.

Input Arguments

A — Nominal or ordinal array

`nominal` array | `ordinal` array

Nominal or ordinal array, specified as a `nominal` or `ordinal` array object created with `nominal` or `ordinal`.

See Also

`getlevels` | `nominal` | `ordinal`

Topics

“Change Category Labels” on page 2-9

Introduced in R2007a

getlevels

Access nominal or ordinal array levels

Note The `nominal` and `ordinal` array data types might be removed in a future release. To represent ordered and unordered discrete, nonnumeric data, use the “Categorical Arrays” (MATLAB) data type instead.

Syntax

`L = getlevels(A)`

Description

`L = getlevels(A)` returns the levels in the nominal or ordinal array `A`. `L` is a vector of the same type as `A`.

Input Arguments

A — Nominal or ordinal array
`nominal` array | `ordinal` array

Nominal or ordinal array, specified as a `nominal` or `ordinal` array object created with `nominal` or `ordinal`.

gevcdf

Generalized extreme value cumulative distribution function

Syntax

```
p = gevcdf(x,k,sigma,mu)
p = gevcdf(x,k,sigma,mu,'upper')
```

Description

`p = gevcdf(x,k,sigma,mu)` returns the cdf of the generalized extreme value (GEV) distribution with shape parameter `k`, scale parameter `sigma`, and location parameter `mu`, evaluated at the values in `x`. The size of `p` is the common size of the input arguments. A scalar input functions as a constant matrix of the same size as the other inputs.

`p = gevcdf(x,k,sigma,mu,'upper')` returns the complement of the cdf of the GEV distribution, using an algorithm that more accurately computes the extreme upper tail probabilities.

Default values for `k`, `sigma`, and `mu` are 0, 1, and 0, respectively.

When $k < 0$, the GEV is the type III extreme value distribution. When $k > 0$, the GEV distribution is the type II, or Frechet, extreme value distribution. If w has a Weibull distribution as computed by the `wblcdf` function, then $-w$ has a type III extreme value distribution and $1/w$ has a type II extreme value distribution. In the limit as k approaches 0, the GEV is the mirror image of the type I extreme value distribution as computed by the `evcdf` function.

The mean of the GEV distribution is not finite when $k \geq 1$, and the variance is not finite when $k \geq 1/2$. The GEV distribution has positive density only for values of X such that $k*(X-\mu)/\sigma > -1$.

gevfit

Generalized extreme value parameter estimates

Syntax

```
parmhat = gevfit(X)
[parmhat,parmci] = gevfit(X)
[parmhat,parmci] = gevfit(X,alpha)
[...] = gevfit(X,alpha,options)
```

Description

`parmhat = gevfit(X)` returns maximum likelihood estimates of the parameters for the generalized extreme value (GEV) distribution given the data in `X`. `parmhat(1)` is the shape parameter, `k`, `parmhat(2)` is the scale parameter, `sigma`, and `parmhat(3)` is the location parameter, `mu`.

`[parmhat,parmci] = gevfit(X)` returns 95% confidence intervals for the parameter estimates.

`[parmhat,parmci] = gevfit(X,alpha)` returns $100(1-\alpha)\%$ confidence intervals for the parameter estimates.

`[...] = gevfit(X,alpha,options)` specifies control parameters for the iterative algorithm used to compute ML estimates. This argument can be created by a call to `statset`. See `statset('gevfit')` for parameter names and default values. Pass in `[]` for `alpha` to use the default values.

When $k < 0$, the GEV is the type III extreme value distribution. When $k > 0$, the GEV distribution is the type II, or Frechet, extreme value distribution. If `w` has a Weibull distribution as computed by the `wblfit` function, then `-w` has a type III extreme value distribution and `1/w` has a type II extreme value distribution. In the limit as `k` approaches 0, the GEV is the mirror image of the type I extreme value distribution as computed by the `evfit` function.

The mean of the GEV distribution is not finite when $k \geq 1$, and the variance is not finite when $k \geq 1/2$. The GEV distribution is defined for $k*(X-\mu)/\sigma > -1$.

gevinv

Generalized extreme value inverse cumulative distribution function

Syntax

```
X = gevinv(P,k,sigma,mu)
```

Description

`X = gevinv(P,k,sigma,mu)` returns the inverse cdf of the generalized extreme value (GEV) distribution with shape parameter `k`, scale parameter `sigma`, and location parameter `mu`, evaluated at the values in `P`. The size of `X` is the common size of the input arguments. A scalar input functions as a constant matrix of the same size as the other inputs.

Default values for `k`, `sigma`, and `mu` are 0, 1, and 0, respectively.

When $k < 0$, the GEV is the type III extreme value distribution. When $k > 0$, the GEV distribution is the type II, or Frechet, extreme value distribution. If w has a Weibull distribution as computed by the `wblinv` function, then $-w$ has a type III extreme value distribution and $1/w$ has a type II extreme value distribution. In the limit as k approaches 0, the GEV is the mirror image of the type I extreme value distribution as computed by the `evinv` function.

The mean of the GEV distribution is not finite when $k \geq 1$, and the variance is not finite when $k \geq 1/2$. The GEV distribution has positive density only for values of X such that $k*(X-\mu)/\sigma > -1$.

gevlike

Generalized extreme value negative log-likelihood

Syntax

```
nlogL = gevlike(params,data)
[nlogL,ACOV] = gevlike(params,data)
```

Description

`nlogL = gevlike(params,data)` returns the negative of the log-likelihood `nlogL` for the generalized extreme value (GEV) distribution, evaluated at parameters `params`.

`params(1)` is the shape parameter, `k`, `params(2)` is the scale parameter, `sigma`, and `params(3)` is the location parameter, `mu`.

`[nlogL,ACOV] = gevlike(params,data)` returns the inverse of Fisher's information matrix, `ACOV`. If the input parameter values in `params` are the maximum likelihood estimates, the diagonal elements of `ACOV` are their asymptotic variances. `ACOV` is based on the observed Fisher's information, not the expected information.

When $k < 0$, the GEV is the type III extreme value distribution. When $k > 0$, the GEV distribution is the type II, or Frechet, extreme value distribution. If w has a Weibull distribution as computed by the `wbllike` function, then $-w$ has a type III extreme value distribution and $1/w$ has a type II extreme value distribution. In the limit as k approaches 0, the GEV is the mirror image of the type I extreme value distribution as computed by the `evlike` function.

The mean of the GEV distribution is not finite when $k \geq 1$, and the variance is not finite when $k \geq 1/2$. The GEV distribution has positive density only for values of X such that $k*(X-\mu)/\sigma > -1$.

gevpdf

Generalized extreme value probability density function

Syntax

$Y = \text{gevpdf}(X, k, \text{sigma}, \mu)$

Description

$Y = \text{gevpdf}(X, k, \text{sigma}, \mu)$ returns the pdf of the generalized extreme value (GEV) distribution with shape parameter k , scale parameter sigma , and location parameter μ , evaluated at the values in X . The size of Y is the common size of the input arguments. A scalar input functions as a constant matrix of the same size as the other inputs.

Default values for k , sigma , and μ are 0, 1, and 0, respectively.

When $k < 0$, the GEV is the type III extreme value distribution. When $k > 0$, the GEV distribution is the type II, or Frechet, extreme value distribution. If w has a Weibull distribution as computed by the `wblpdf` function, then $-w$ has a type III extreme value distribution and $1/w$ has a type II extreme value distribution. In the limit as k approaches 0, the GEV is the mirror image of the type I extreme value distribution as computed by the `evcdf` function.

The mean of the GEV distribution is not finite when $k \geq 1$, and the variance is not finite when $k \geq 1/2$. The GEV distribution has positive density only for values of X such that $k*(X-\mu)/\text{sigma} > -1$.

gevrnd

Generalized extreme value random numbers

Syntax

```
R = gevrnd(k, sigma, mu)
R = gevrnd(k, sigma, mu, m, n, ...)
R = gevrnd(k, sigma, mu, [m, n, ...])
```

Description

`R = gevrnd(k, sigma, mu)` returns an array of random numbers chosen from the generalized extreme value (GEV) distribution with shape parameter `k`, scale parameter `sigma`, and location parameter, `mu`. The size of `R` is the common size of the input arguments if all are arrays. If any parameter is a scalar, the size of `R` is the size of the other parameters.

`R = gevrnd(k, sigma, mu, m, n, ...)` or `R = gevrnd(k, sigma, mu, [m, n, ...])` generates an `m`-by-`n`-by-... array containing random numbers from the GEV distribution with parameters `k`, `sigma`, and `mu`. The `k`, `sigma`, `mu` parameters can each be scalars or arrays of the same size as `R`.

When $k < 0$, the GEV is the type III extreme value distribution. When $k > 0$, the GEV distribution is the type II, or Frechet, extreme value distribution. If w has a Weibull distribution as computed by the `wblrnd` function, then $-w$ has a type III extreme value distribution and $1/w$ has a type II extreme value distribution. In the limit as k approaches 0, the GEV is the mirror image of the type I extreme value distribution as computed by the `evrnd` function.

The mean of the GEV distribution is not finite when $k \geq 1$, and the variance is not finite when $k \geq 1/2$. The GEV distribution has positive density only for values of X such that $k*(X-mu)/sigma > -1$.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

The generated code can return a different sequence of numbers than MATLAB if either of the following is true:

- The output is nonscalar.
- An input parameter is invalid for the distribution.

For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “General Code Generation Workflow” on page 31-5.

gevstat

Generalized extreme value mean and variance

Syntax

```
[M,V] = gevstat(k,sigma,mu)
```

Description

`[M,V] = gevstat(k,sigma,mu)` returns the mean of and variance for the generalized extreme value (GEV) distribution with shape parameter k , scale parameter σ , and location parameter, μ . The sizes of M and V are the common size of the input arguments. A scalar input functions as a constant matrix of the same size as the other inputs.

Default values for k , σ , and μ are 0, 1, and 0, respectively.

When $k < 0$, the GEV is the type III extreme value distribution. When $k > 0$, the GEV distribution is the type II, or Frechet, extreme value distribution. If w has a Weibull distribution as computed by the `wblstat` function, then $-w$ has a type III extreme value distribution and $1/w$ has a type II extreme value distribution. In the limit as k approaches 0, the GEV is the mirror image of the type I extreme value distribution as computed by the `evstat` function.

The mean of the GEV distribution is not finite when $k \geq 1$, and the variance is not finite when $k \geq 1/2$. The GEV distribution has positive density only for values of X such that $k*(X-\mu)/\sigma > -1$.

Topics

“Generalized Extreme Value Distribution” on page B-49

Introduced before R2006a

gline

Interactively add line to plot

Syntax

```
gline(h)
gline
hline = gline(...)
```

Description

`gline(h)` allows you to draw a line segment in the figure with handle `h` by clicking the pointer at the two endpoints. A rubber-band line tracks the pointer movement.

`gline` with no input arguments defaults to `h = gcf` and draws in the current figure.

`hline = gline(...)` returns the handle `hline` to the line.

Examples

Use `gline` to connect two points in a plot:

```
x = 1:10;

y = x + randn(1,10);
scatter(x,y,25,'b','*')

lsline

mu = mean(y);
hold on
plot([1 10],[mu mu],'ro')

hline = gline; % Connect circles
set(hline,'Color','r')
```

See Also

lsline | refcurve | refline

Introduced before R2006a

glmfit

Generalized linear model regression

Syntax

```
b = glmfit(X,y,distr)
b = glmfit(X,y,distr,param1,val1,param2,val2,...)
[b,dev] = glmfit(...)
[b,dev,stats] = glmfit(...)
```

Description

`b = glmfit(X,y,distr)` returns a $(p + 1)$ -by-1 vector `b` of coefficient estimates for a generalized linear regression of the responses in `y` on the predictors in `X`, using the distribution `distr`. `X` is an n -by- p matrix of p predictors at each of n observations. `distr` can be any of the following: 'binomial', 'gamma', 'inverse gaussian', 'normal' (the default), and 'poisson'.

In most cases, `y` is an n -by-1 vector of observed responses. For the binomial distribution, `y` can be a binary vector indicating success or failure at each observation, or a two column matrix with the first column indicating the number of successes for each observation and the second column indicating the number of trials for each observation.

This syntax uses the canonical link (see below) to relate the distribution to the predictors.

Note By default, `glmfit` adds a first column of 1s to `X`, corresponding to a constant term in the model. Do not enter a column of 1s directly into `X`. You can change the default behavior of `glmfit` using the 'constant' parameter, below.

`glmfit` treats NaNs in either `X` or `y` as missing values, and ignores them.

`b = glmfit(X,y,distr,param1,val1,param2,val2,...)` additionally allows you to specify optional parameter name/value pairs to control the model fit. Acceptable parameters are as follows.

Parameter	Value	Description
'link'	'identity', default for the distribution 'normal'	$\mu = Xb$
	'log', default for the distribution 'poisson'	$\log(\mu) = Xb$
	'logit', default for the distribution 'binomial'	$\log(\mu/(1 - \mu)) = Xb$
	'probit'	$\text{norminv}(\mu) = Xb$
	'complloglog'	$\log(-\log(1 - \mu)) = Xb$
	'reciprocal', default for the distribution 'gamma'	$1/\mu = Xb$
	'loglog'	$\log(-\log(\mu)) = Xb$
	p (a number), default for the distribution 'inverse gaussian' (with $p = -2$)	$\mu^p = Xb$
	cell array of the form {FL FD FI}, containing three function handles, created using @, that define the link (FL), the derivative of the link (FD), and the inverse link (FI).	Custom-defined link function. You must provide <ul style="list-style-type: none"> • FL(mu) • FD = dFL(mu)/dmu • FI = FL^(-1)

Parameter	Value	Description
	structure array having these fields: <ul style="list-style-type: none"> • 'Link' — Link function • 'Derivative' — Derivative of the link function • 'Inverse' — Inverse of the link function The value of each field is a character vector corresponding to a function that is on the path or a function handle (created using @).	Custom-defined link function, its derivative, and its inverse.
'estdisp'	'on'	Estimates a dispersion parameter for the binomial or Poisson distribution.
	'off' (Default for binomial or Poisson distribution)	Uses the theoretical value of 1.0 for those distributions.
'offset'	Vector	Used as an additional predictor variable, but with a coefficient value fixed at 1.0.
'weights'	Vector of prior weights, such as the inverses of the relative variance of each observation	
'constant'	'on' (default)	Includes a constant term in the model. The coefficient of the constant term is the first element of b .
	'off'	Omit the constant term.

[**b**,**dev**] = `glmfit(...)` returns **dev**, the deviance of the fit at the solution vector. The deviance is a generalization of the residual sum of squares. It is possible to perform an analysis of deviance to compare several models, each a subset of the other, and to test

whether the model with more terms is significantly better than the model with fewer terms.

`[b,dev,stats] = glmfit(...)` returns `dev` and `stats`.

`stats` is a structure with the following fields:

- `beta` — Coefficient estimates `b`
- `dfe` — Degrees of freedom for error
- `sfit` — Estimated dispersion parameter
- `s` — Theoretical or estimated dispersion parameter
- `estdisp` — 0 when the `'estdisp'` name-value pair argument value is `'off'` and 1 when the `'estdisp'` name-value pair argument value is `'on'`.
- `covb` — Estimated covariance matrix for `B`
- `se` — Vector of standard errors of the coefficient estimates `b`
- `coeffcorr` — Correlation matrix for `b`
- `t` — t statistics for `b`
- `p` — p -values for `b`
- `resid` — Vector of residuals
- `residp` — Vector of Pearson residuals
- `residd` — Vector of deviance residuals
- `resida` — Vector of Anscombe residuals

If you estimate a dispersion parameter for the binomial or Poisson distribution, then `stats.s` is set equal to `stats.sfit`. Also, the elements of `stats.se` differ by the factor `stats.s` from their theoretical values.

Examples

Fit Generalized Linear Model with Probit Link

Enter the sample data.

```
x = [2100 2300 2500 2700 2900 3100 ...
     3300 3500 3700 3900 4100 4300]';
```

```
n = [48 42 31 34 31 21 23 23 21 16 17 21]';  
y = [1 2 0 3 8 8 14 17 19 15 17 21]';
```

Each y value is the number of successes in the corresponding number of trials in n, and x contains the predictor variable values.

Fit a probit regression model for y on x.

```
b = glmfit(x,[y n], 'binomial', 'link', 'probit');
```

Compute the estimated number of successes. Plot the percent observed and estimated percent success versus the x values.

```
yfit = glmval(b,x,'probit','size',n);  
plot(x, y./n, 'o', x, yfit./n, '-','LineWidth',2)
```

Use Custom-Defined Link Function

Load the sample data.

```
load fisheriris
```

The column vector, `species`, consists of iris flowers of three different species, `setosa`, `versicolor`, `virginica`. The double matrix `meas` consists of four types of measurements on the flowers, the length and width of sepals and petals in centimeters, respectively.

Define the response and predictor variables.

```
X = meas(51:end,:);
y = strcmp('versicolor',species(51:end));
```

Define three function handles, created using `@`, that define the link, the derivative of the link, and the inverse link for a logit link function. Store them in a cell array.

```
link = @(mu) log(mu ./ (1-mu));
derlink = @(mu) 1 ./ (mu .* (1-mu));
invlink = @(resp) 1 ./ (1 + exp(-resp));
F = {link, derlink, invlink};
```

Fit a logistic regression using `glmfit` with the link function that you defined.

```
b = glmfit(X,y,'binomial','link',F)
```

```
b = 5×1

    42.6378
     2.4652
     6.6809
    -9.4294
   -18.2861
```

Fit a generalized linear model by using the `logit` link function and compare the results.

```
b = glmfit(X,y,'binomial','link','logit')
```

```
b = 5×1
```

42.6378
2.4652
6.6809
-9.4294
-18.2861

Introduced before R2006a

glmval

Generalized linear model values

Syntax

```
yhat = glmval(b,X,link)
[yhat,dylo,dyhi] = glmval(b,X,link,stats)
[...] = glmval(...,param1,val1,param2,val2,...)
```

Description

`yhat = glmval(b,X,link)` computes predicted values for the generalized linear model with link function `link` and predictors `X`. Distinct predictor variables should appear in different columns of `X`. `b` is a vector of coefficient estimates as returned by the `glmfit` function. `link` can be any of the character vectors, string scalars, or custom-defined link functions used as values for the 'link' name-value pair argument in the `glmfit` function.

Note By default, `glmval` adds a first column of 1s to `X`, corresponding to a constant term in the model. Do not enter a column of 1s directly into `X`. You can change the default behavior of `glmval` using the 'constant' parameter.

`[yhat,dylo,dyhi] = glmval(b,X,link,stats)` also computes 95% confidence bounds for the predicted values. When the `stats` structure output of the `glmfit` function is specified, `dylo` and `dyhi` are also returned. `dylo` and `dyhi` define a lower confidence bound of `yhat-dylo`, and an upper confidence bound of `yhat+dyhi`. Confidence bounds are nonsimultaneous, and apply to the fitted curve, not to a new observation.

`[...] = glmval(...,param1,val1,param2,val2,...)` specifies optional parameter name/value pairs to control the predicted values. Acceptable parameters are listed in this table:

Parameter	Value
'confidence' — the confidence level for the confidence bounds	A scalar between 0 and 1
'size' — the size parameter (N) for a binomial model	A scalar, or a vector with one value for each row of X
'offset' — used as an additional predictor variable, but with a coefficient value fixed at 1.0	A vector
'constant'	<ul style="list-style-type: none"> 'on' — Includes a constant term in the model. The coefficient of the constant term is the first element of b. 'off' — Omit the constant term
'simultaneous' — Compute simultaneous confidence intervals (true), or compute non-simultaneous confidence intervals (default false)	true or false

Examples

Fit Generalized Linear Model with Probit Link

Enter the sample data.

```
x = [2100 2300 2500 2700 2900 3100 ...
     3300 3500 3700 3900 4100 4300]';
n = [48 42 31 34 31 21 23 23 21 16 17 21]';
y = [1 2 0 3 8 8 14 17 19 15 17 21]';
```

Each **y** value is the number of successes in the corresponding number of trials in **n**, and **x** contains the predictor variable values.

Fit a probit regression model for **y** on **x**.

```
b = glmfit(x,[y n], 'binomial', 'link', 'probit');
```

Compute the estimated number of successes. Plot the percent observed and estimated percent success versus the **x** values.

```
yfit = glmval(b,x,'probit','size',n);
plot(x, y./n,'o',x,yfit./n,'-', 'LineWidth',2)
```

Use Custom-Defined Link Function

Enter sample data.

```
x = [2100 2300 2500 2700 2900 3100 ...
      3300 3500 3700 3900 4100 4300]';
n = [48 42 31 34 31 21 23 23 21 16 17 21]';
y = [1 2 0 3 8 8 14 17 19 15 17 21]';
```

Each y value is the number of successes in corresponding number of trials in n , and x contains the predictor variable values.

Define three function handles, created by using `@`, that define the link, the derivative of the link, and the inverse link for a probit link function,. Store the handles in a cell array.

```
link = @(mu) norminv(mu);  
derlink = @(mu) 1 ./ normpdf(norminv(mu));  
invlink = @(resp) normcdf(resp);  
F = {link, derlink, invlink};
```

Fit a generalized linear model for y on x by using the link function that you defined.

```
b = glmfit(x,[y n], 'binomial', 'link', F);
```

Compute the estimated number of successes. Plot the observed and estimated percent success versus the x values.

```
yfit = glmval(b,x,F, 'size', n);  
plot(x, y./n, 'o', x,yfit./n, '-','LineWidth',2)
```

Generate Code from Function That Predicts Responses Given New Data

Train a generalized linear model, and then generate code from a function that classifies new observations based on the model. This example is based on the “Use Custom-Defined Link Function” on page 32-2959 example.

Enter the sample data.

```
x = [2100 2300 2500 2700 2900 3100 ...
     3300 3500 3700 3900 4100 4300]';
n = [48 42 31 34 31 21 23 23 21 16 17 21]';
y = [1 2 0 3 8 8 14 17 19 15 17 21]';
```

Suppose that the inverse normal pdf is an appropriate link function for the problem.

Define a function named `myInvNorm.m` that accepts values of $X\beta$ and returns corresponding values of the inverse of the standard normal cdf.

```
function in = myInvNorm(mu) %#codegen
%myInvNorm Inverse of standard normal cdf for code generation
% myInvNorm is a GLM link function that accepts a numeric vector mu, and
% returns in, which is a numeric vector of corresponding values of the
% inverse of the standard normal cdf.
%
in = norminv(mu);
end
```

Define another function named `myDInvNorm.m` that accepts values of $X\beta$ and returns corresponding values of the derivative of the link function.

```
function din = myDInvNorm(mu) %#codegen
%myDInvNorm Derivative of inverse of standard normal cdf for code
%generation
% myDInvNorm corresponds to the derivative of the GLM link function
% myInvNorm. myDInvNorm accepts a numeric vector mu, and returns din,
% which is a numeric vector of corresponding derivatives of the inverse
% of the standard normal cdf.
%
din = 1./normpdf(norminv(mu));
end
```

Define another function named `myInvInvNorm.m` that accepts values of $X\beta$ and returns corresponding values of the inverse of the link function.

```
function iin = myInvInvNorm(mu) %#codegen
%myInvInvNorm Standard normal cdf for code generation
% myInvInvNorm is the inverse of the GLM link function myInvNorm.
% myInvInvNorm accepts a numeric vector mu, and returns iin, which is a
% numeric vector of corresponding values of the standard normal cdf.
%
```

```
iin = normcdf(mu);
end
```

Create a structure array that specifies each of the link functions. Specifically, the structure array contains fields named 'Link', 'Derivative', and 'Inverse'. The corresponding values are the names of the functions.

```
link = struct('Link','myInvNorm','Derivative','myDInvNorm',...
            'Inverse','myInvInvNorm')
```

```
link =
    struct with fields:
        Link: 'myInvNorm'
        Derivative: 'myDInvNorm'
        Inverse: 'myInvInvNorm'
```

Fit a GLM for y on x using the link function `link`. Return the structure array of statistics.

```
[b,~,stats] = glmfit(x,[y n],'binomial','link',link);
```

`b` is a 2-by-1 vector of regression coefficients.

In your current working folder, define a function called `classifyGLM.m` that:

- Accepts measurements with columns corresponding to those in `x`, regression coefficients whose dimensions correspond to `b`, a link function, the structure of GLM statistics, and any valid `glmval` name-value pair argument
- Returns predictions and confidence interval margins of error

```
function [yhat,lo,hi] = classifyGLM(b,x,link,varargin) %#codegen
%CLASSIFYGLM Classify measurements using GLM model
% CLASSIFYGLM classifies the n observations in the n-by-1 vector x using
% the GLM model with regression coefficients b and link function link,
% and then returns the n-by-1 vector of predicted values in yhat.
% CLASSIFYGLM also returns margins of error for the predictions using
% additional information in the GLM statistics structure stats.
narginchk(3,Inf);
```

```
if(isstruct(varargin{1}))
    stats = varargin{1};
    [yhat,lo,hi] = glmval(b,x,link,stats,varargin{2:end});
else
    yhat = glmval(b,x,link,varargin{:});
end
end
```

Generate a MEX function from `classifyGLM.m`. Because C uses static typing, `codegen` must determine the properties of all variables in MATLAB® files at compile time. To ensure that the MEX function can use the same inputs, use the `-args` argument to specify the following in the order given:

- Regression coefficients `b` as a compile-time constant
- In-sample observations `x`
- Link function as a compile-time constant
- Resulting GLM statistics as a compile-time constant
- Name 'Confidence' as a compile-time constant
- Confidence level 0.9

To designate arguments as compile-time constants, use `coder.Constant`.

```
codegen -config:mex classifyGLM -args {coder.Constant(b),x,coder.Constant(link),coder.Constant(0.9)}
```

`codegen` generates the MEX file `classifyGLM_mex.mexw64` in your current folder. The file extension depends on your system platform.

Compare predictions by using `glmval` and `classifyGLM_mex`. Specify name-value pair arguments in the same order as in the `-args` argument in the call to `codegen`.

```
[yhat1,melo1,mehi1] = glmval(b,x,link,stats,'Confidence',0.9);
[yhat2,melo2,mehi2] = classifyGLM_mex(b,x,link,stats,'Confidence',0.9);
```

```
comp1 = (yhat1 - yhat2)*(yhat1 - yhat2);
agree1 = comp1 < eps
comp2 = (melo1 - melo2)*(melo1 - melo2);
agree2 = comp2 < eps
comp3 = (mehi1 - mehi2)*(mehi1 - mehi2);
agree3 = comp3 < eps
```

```
agree1 =
```

```
logical
1

agree2 =
logical
1

agree3 =
logical
1
```

The generated MEX function produces the same predictions as `predict`.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

Argument	Notes and Limitations
<code>b</code>	<code>b</code> must be a compile-time constant (the value of <code>b</code> cannot change while codegen generates the C/C++ code). You can designate variables as compile-time constants using <code>coder.Constant</code> .
<code>X</code>	Must be a double- or single-precision numeric matrix
<code>link</code>	<ul style="list-style-type: none"> Does not support function handles, that is, functions created using <code>@</code>. Must be a compile-time constant.
<code>stats</code>	Must be a compile-time constant
'Constant' name-value pair argument	Must be a compile-time constant
Name-value pair arguments	Names in name-value pair arguments must be compile-time constants. For example, to specify a confidence level of 0.9, include <code>{coder.Constant('Confidence'), coder.Constant(0.9)}</code> in the <code>-args</code> value of <code>codegen</code> .

For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “General Code Generation Workflow” on page 31-5.

Introduced before R2006a

glyphplot

Glyph plot

Syntax

```
glyphplot(X)
glyphplot(X, 'glyph', 'face')
glyphplot(X, 'glyph', 'face', 'features', f)
glyphplot(X, ..., 'grid', [rows, cols])
glyphplot(X, ..., 'grid', [rows, cols], 'page', p)
glyphplot(X, ..., 'centers', C)
glyphplot(X, ..., 'centers', C, 'radius', r)
glyphplot(X, ..., 'obslabels', labels)
glyphplot(X, ..., 'standardize', method)
glyphplot(X, ..., prop1, val1, ...)
h = glyphplot(X, ...)
```

Description

`glyphplot(X)` creates a star plot from the multivariate data in the n -by- p matrix X . Rows of X correspond to observations, columns to variables. A star plot represents each observation as a “star” whose i th spoke is proportional in length to the i th coordinate of that observation. `glyphplot` standardizes X by shifting and scaling each column separately onto the interval $[0, 1]$ before making the plot, and centers the glyphs on a rectangular grid that is as close to square as possible. `glyphplot` treats NaNs in X as missing values, and does not plot the corresponding rows of X .

`glyphplot(X, 'glyph', 'star')` is a synonym for `glyphplot(X)`.

`glyphplot(X, 'glyph', 'face')` creates a face plot from X . A face plot represents each observation as a “face,” whose i th facial feature is drawn with a characteristic proportional to the i th coordinate of that observation. The features are described in “Face Features” on page 32-2969.

`glyphplot(X, 'glyph', 'face', 'features', f)` creates a face plot where the i th element of the index vector f defines which facial feature will represent the i th column of

X . f must contain integers from 0 to 17, where 0 indicate that the corresponding column of X should not be plotted. See “Face Features” on page 32-2969 for more information.

`glyphplot(X, ..., 'grid', [rows, cols])` organizes the glyphs into a rows-by-cols grid.

`glyphplot(X, ..., 'grid', [rows, cols], 'page', p)` organizes the glyph into one or more pages of a rows-by-cols grid, and displays the page p . If p is a vector, `glyphplot` displays multiple pages in succession. If p is 'all', `glyphplot` displays all pages. If p is 'scroll', `glyphplot` displays a single plot with a scrollbar.

`glyphplot(X, ..., 'centers', C)` creates a plot with each glyph centered at the locations in the n -by-2 matrix C .

`glyphplot(X, ..., 'centers', C, 'radius', r)` creates a plot with glyphs positioned using C , and scale the glyphs so the largest has radius r .

`glyphplot(X, ..., 'obslabels', labels)` labels each glyph with the text in `labels`. By default, the glyphs are labelled 1:N. Use '' for blank labels.

`glyphplot(X, ..., 'standardize', method)` standardizes X before making the plot. Choices for *method* are

- 'column' — Maps each column of X separately onto the interval [0,1]. This is the default.
- 'matrix' — Maps the entire matrix X onto the interval [0, 1].
- 'PCA' — Transforms X to its principal component scores, in order of decreasing eigenvalue, and maps each one onto the interval [0, 1].
- 'off' — No standardization. Negative values in X may make a star plot uninterpretable.

`glyphplot(X, ..., prop1, val1, ...)` sets properties to the specified property values for all line graphics objects created by `glyphplot`.

`h = glyphplot(X, ...)` returns a matrix of handles to the graphics objects created by `glyphplot`. For a star plot, `h(:, 1)` and `h(:, 2)` contain handles to the line objects for each star's perimeter and spokes, respectively. For a face plot, `h(:, 1)` and `h(:, 2)` contain object handles to the lines making up each face and to the pupils, respectively. `h(:, 3)` contains handles to the text objects for the labels, if present.

Face Features

The following table describes the correspondence between the columns of the vector f , the value of the 'Features' input parameter, and the facial features of the glyph plot. If X has fewer than 17 columns, unused features are displayed at their default value.

Column	Facial Feature
1	Size of face
2	Forehead/jaw relative arc length
3	Shape of forehead
4	Shape of jaw
5	Width between eyes
6	Vertical position of eyes
7	Height of eyes
8	Width of eyes (this also affects eyebrow width)
9	Angle of eyes (this also affects eyebrow angle)
10	Vertical position of eyebrows
11	Width of eyebrows (relative to eyes)
12	Angle of eyebrows (relative to eyes)
13	Direction of pupils
14	Length of nose
15	Vertical position of mouth
16	Shape of mouth
17	Mouth arc length

Examples

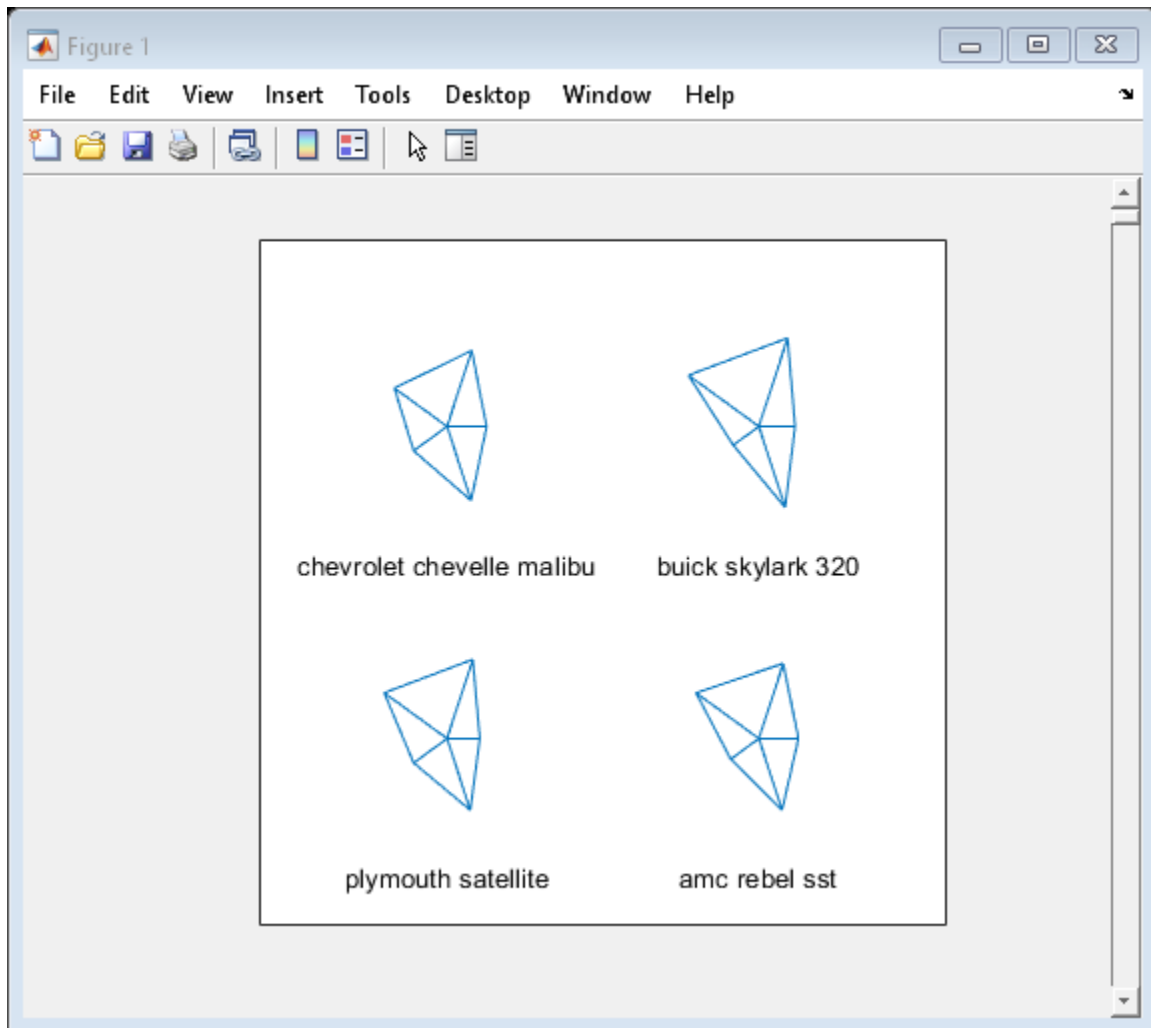

Star and Face Plots of Multivariate Data

Load the sample data.

```
load carsmall
X = [Acceleration Displacement Horsepower MPG Weight];
```

Create a star plot of the data in X . Standardize the data before plotting.

```
glyphplot(X, 'standardize', 'column', 'obslabels', Model, 'grid', [2 2], ...
           'page', 'scroll');
```

Create a faceplot of the data in X .

```
glyphplot(X, 'glyph', 'face', 'obslabels', Model, 'grid', [2 3], 'page', 9);
```

Introduced before R2006a

gmdistribution

Create Gaussian mixture model

Description

A `gmdistribution` object stores a Gaussian mixture distribution, also called a Gaussian mixture model (GMM), which is a multivariate distribution that consists of multivariate Gaussian distribution components. Each component is defined by its mean and covariance, and the mixture is defined by a vector of mixing proportions.

Creation

You can create a `gmdistribution` model object in two ways.

- Use the `gmdistribution` function (described here) to create a `gmdistribution` model object by specifying the distribution parameters.
- Use the `fitgmdist` function to fit a `gmdistribution` model object to data given a fixed number of components.

Syntax

```
gm = gmdistribution(mu,sigma)
gm = gmdistribution(mu,sigma,p)
```

Description

`gm = gmdistribution(mu,sigma)` creates a `gmdistribution` model object using the specified means `mu` and covariances `sigma` with equal mixing proportions.

`gm = gmdistribution(mu,sigma,p)` specifies the mixing proportions of multivariate Gaussian distribution components.

Input Arguments

mu — Means

k-by-*m* numeric matrix

Means of multivariate Gaussian distribution components, specified as a *k*-by-*m* numeric matrix, where *k* is the number of components and *m* is the number of variables in each component. `mu(i, :)` is the mean of component *i*.

Data Types: `single` | `double`

sigma — Covariances

numeric vector | numeric matrix | numeric array

Covariances of multivariate Gaussian distribution components, specified as a numeric vector, matrix, or array.

Given that *k* is the number of components and *m* is the number of variables in each component, `sigma` is one of the values in this table.

Value	Description
<i>m</i> -by- <i>m</i> -by- <i>k</i> array	<code>sigma(:, :, i)</code> is the covariance matrix of component <i>i</i> .
1-by- <i>m</i> -by- <i>k</i> array	Covariance matrices are diagonal. <code>sigma(1, :, i)</code> contains the diagonal elements of the covariance matrix of component <i>i</i> .
<i>m</i> -by- <i>m</i> matrix	Covariance matrices are the same across components.
1-by- <i>m</i> vector	Covariance matrices are diagonal and the same across components.

Data Types: `single` | `double`

p — Mixing proportions of mixture components

numeric vector of length *k*

Mixing proportions of mixture components, specified as a numeric vector of length *k*, where *k* is the number of components. The default is a row vector of $(1/k)$ s, which sets equal proportions. If `p` does not sum to 1, `gmdistribution` normalizes it.

Data Types: `single` | `double`

Properties

Distribution Parameters

mu — Means

k-by-*m* numeric matrix

This property is read-only.

Means of multivariate Gaussian distribution components, specified as a *k*-by-*m* numeric matrix, where *k* is the number of components and *m* is the number of variables in each component. `mu(i, :)` is the mean of component *i*.

- If you create a `gmdistribution` object by using the `gmdistribution` function, then the `mu` input argument of `gmdistribution` sets this property.
- If you fit a `gmdistribution` object to data by using the `fitgmdist` function, then `fitgmdist` estimates this property.

Data Types: `single` | `double`

Sigma — Covariances

numeric vector | numeric matrix | numeric array

This property is read-only.

Covariances of multivariate Gaussian distribution components, specified as a numeric vector, matrix, or array.

Given that *k* is the number of components and *m* is the number of variables in each component, `Sigma` is one of the values in this table.

Value	Description
<i>m</i> -by- <i>m</i> -by- <i>k</i> array	<code>Sigma(:, :, i)</code> is the covariance matrix of component <i>i</i> .
1-by- <i>m</i> -by- <i>k</i> array	Covariance matrices are diagonal. <code>Sigma(1, :, i)</code> contains the diagonal elements of the covariance matrix of component <i>i</i> .
<i>m</i> -by- <i>m</i> matrix	Covariance matrices are the same across components.
1-by- <i>m</i> vector	Covariance matrices are diagonal and the same across components.

- If you create a `gmdistribution` object by using the `gmdistribution` function, then the `sigma` input argument of `gmdistribution` sets this property.
- If you fit a `gmdistribution` object to data by using the `fitgmdist` function, then `fitgmdist` estimates this property.

Data Types: `single` | `double`

ComponentProportion — Mixing proportions of mixture components

1-by-*k* numeric vector

This property is read-only.

Mixing proportions of mixture components, specified as a 1-by-*k* numeric vector.

- If you create a `gmdistribution` object by using the `gmdistribution` function, then the `p` input argument of `gmdistribution` sets this property.
- If you fit a `gmdistribution` object to data by using the `fitgmdist` function, then `fitgmdist` estimates this property.

Data Types: `single` | `double`

Distribution Characteristics

CovarianceType — Type of covariance matrices

'diagonal' | 'full'

This property is read-only.

Type of covariance matrices, specified as either 'diagonal' or 'full'.

- If you create a `gmdistribution` object by using the `gmdistribution` function, then the type of covariance matrices in the `sigma` input argument of `gmdistribution` sets this property.
- If you fit a `gmdistribution` object to data by using the `fitgmdist` function, then the 'CovarianceType' name-value pair argument of `fitgmdist` sets this property.

DistributionName — Distribution name

'gaussian mixture distribution' (default)

This property is read-only.

Distribution name, specified as 'gaussian mixture distribution'.

NumComponents — Number of mixture components

positive integer

This property is read-only.

Number of mixture components, k , specified as a positive integer.

- If you create a `gmdistribution` object by using the `gmdistribution` function, then the input arguments `mu`, `sigma`, and `p` of `gmdistribution` set this property.
- If you fit a `gmdistribution` object to data by using the `fitgmdist` function, then the `k` input argument of `fitgmdist` sets this property.

Data Types: `single` | `double`

NumVariables — Number of variables

positive integer

This property is read-only.

Number of variables in the multivariate Gaussian distribution components, m , specified as a positive integer.

- If you create a `gmdistribution` object by using the `gmdistribution` function, then the input arguments `mu`, `sigma`, and `p` of `gmdistribution` set this property.
- If you fit a `gmdistribution` object to data by using the `fitgmdist` function, then the input data `X` of `fitgmdist` sets this property.

Data Types: `double`

SharedCovariance — Flag indicating shared covariance

`true` | `false`

This property is read-only.

Flag indicating whether a covariance matrix is shared across mixture components, specified as `true` or `false`.

- If you create a `gmdistribution` object by using the `gmdistribution` function, then the type of covariance matrices in the `sigma` input argument of `gmdistribution` sets this property.

- If you fit a `gmdistribution` object to data by using the `fitgmdist` function, then the 'SharedCovariance' name-value pair argument of `fitgmdist` sets this property.

Data Types: `logical`

Properties for Fitted Object

The following properties apply only to a fitted object you create by using `fitgmdist`. The values of these properties are empty if you create a `gmdistribution` object by using the `gmdistribution` function.

AIC — Akaike Information Criterion

scalar

This property is read-only.

Akaike information criterion (AIC), specified as a scalar. $AIC = 2 * N \log L + 2 * p$, where $N \log L$ is the negative loglikelihood (the `NegativeLogLikelihood` property) and p is the number of estimated parameters.

AIC is a model selection tool you can use to compare multiple models fit to the same data. AIC is a likelihood-based measure of model fit that includes a penalty for complexity, specifically, the number of parameters. When you compare multiple models, a model with a smaller value of AIC is better.

This property is empty if you create a `gmdistribution` object by using the `gmdistribution` function.

Data Types: `single` | `double`

BIC — Bayes Information Criterion

scalar

This property is read-only.

Bayes information criterion (BIC), specified as a scalar. $BIC = 2 * N \log L + p * \log(n)$, where $N \log L$ is the negative loglikelihood (the `NegativeLogLikelihood` property), n is the number of observations, and p is the number of estimated parameters.

BIC is a model selection tool you can use to compare multiple models fit to the same data. BIC is a likelihood-based measure of model fit that includes a penalty for complexity,

specifically, the number of parameters. When you compare multiple models, a model with the lowest BIC value is the best fitting model.

This property is empty if you create a `gmdistribution` object by using the `gmdistribution` function.

Data Types: `single` | `double`

Converged — Flag indicating convergence

`true` | `false`

This property is read-only.

Flag indicating whether the Expectation-Maximization (EM) algorithm is converged when fitting a Gaussian mixture model, specified as `true` or `false`.

You can change the optimization options by using the 'Options' name-value pair argument of `fitgmdist`.

This property is empty if you create a `gmdistribution` object by using the `gmdistribution` function.

Data Types: `logical`

NegativeLogLikelihood — Negative loglikelihood

scalar

This property is read-only.

Negative loglikelihood of the fitted Gaussian mixture model given the input data `X` of `fitgmdist`, specified as a scalar.

This property is empty if you create a `gmdistribution` object by using the `gmdistribution` function.

Data Types: `single` | `double`

NumIterations — Number of iterations

positive integer

This property is read-only.

Number of iterations in the Expectation-Maximization (EM) algorithm, specified as a positive integer.

You can change the optimization options, including the maximum number of iterations allowed, by using the 'Options' name-value pair argument of `fitgmdist`.

This property is empty if you create a `gmdistribution` object by using the `gmdistribution` function.

Data Types: `double`

ProbabilityTolerance — Tolerance for posterior probabilities

nonnegative scalar value in range $[0, 1e-6]$

This property is read-only.

Tolerance for posterior probabilities, specified as a nonnegative scalar value in the range $[0, 1e-6]$.

The 'ProbabilityTolerance' name-value pair argument of `fitgmdist` sets this property.

This property is empty if you create a `gmdistribution` object by using the `gmdistribution` function.

Data Types: `single` | `double`

RegularizationValue — Regularization parameter value

nonnegative scalar

This property is read-only.

Regularization parameter value, specified as a nonnegative scalar.

The 'RegularizationValue' name-value pair argument of `fitgmdist` sets this property.

This property is empty if you create a `gmdistribution` object by using the `gmdistribution` function.

Data Types: `single` | `double`

Object Functions

<code>cdf</code>	Cumulative distribution function for Gaussian mixture distribution
<code>cluster</code>	Construct clusters from Gaussian mixture distribution

mahal	Mahalanobis distance to Gaussian mixture component
pdf	Probability density function for Gaussian mixture distribution
posterior	Posterior probability of Gaussian mixture component
random	Random variate from Gaussian mixture distribution

Examples

Create Gaussian Mixture Distribution Using `gmdistribution`

Create a two-component bivariate Gaussian mixture distribution by using the `gmdistribution` function.

Define the distribution parameters (means and covariances) of two bivariate Gaussian mixture components.

```
mu = [1 2;-3 -5];  
sigma = cat(3,[2 .5],[1 1]) % 1-by-2-by-2 array
```

```
sigma =  
sigma(:,:,1) =  
  
    2.0000    0.5000
```

```
sigma(:,:,2) =  
  
    1    1
```

The `cat` function concatenates the covariances along the third array dimension. The defined covariance matrices are diagonal matrices. `sigma(1,:,i)` contains the diagonal elements of the covariance matrix of component `i`.

Create a `gmdistribution` object. By default, the `gmdistribution` function creates an equal proportion mixture.

```
gm = gmdistribution(mu,sigma)
```

```
gm =
```

```
Gaussian mixture distribution with 2 components in 2 dimensions
```

```
Component 1:  
Mixing proportion: 0.500000  
Mean:      1      2
```

```
Component 2:  
Mixing proportion: 0.500000  
Mean:     -3     -5
```

List the properties of the `gm` object.

```
properties(gm)
```

```
Properties for class gmdistribution:
```

```
  NumVariables  
  DistributionName  
  NumComponents  
  ComponentProportion  
  SharedCovariance  
  NumIterations  
  RegularizationValue  
  NegativeLogLikelihood  
  CovarianceType  
  mu  
  Sigma  
  AIC  
  BIC  
  Converged  
  ProbabilityTolerance
```

You can access these properties by using dot notation. For example, access the `ComponentProportion` property, which represents the mixing proportions of mixture components.

```
gm.ComponentProportion
```

```
ans = 1×2
```

```
    0.5000    0.5000
```

A `gmdistribution` object has properties that apply only to a fitted object. The fitted object properties are `AIC`, `BIC`, `Converged`, `NegativeLogLikelihood`, `NumIterations`, `ProbabilityTolerance`, and `RegularizationValue`. The values of the fitted object properties are empty if you create an object by using the

`gmdistribution` function and specifying distribution parameters. For example, access the `NegativeLogLikelihood` property by using dot notation.

```
gm.NegativeLogLikelihood
```

```
ans =
```

```
    []
```

After you create a `gmdistribution` object, you can use the object functions. Use `cdf` and `pdf` to compute the values of the cumulative distribution function (cdf) and the probability density function (pdf). Use `random` to generate random vectors. Use `cluster`, `mahal`, and `posterior` for cluster analysis.

Visualize the object by using `pdf` and `fsurf`.

```
fsurf(@(x,y) reshape(pdf(gm,[x(:) y(:)]),size(x)),-10 10))
```

Fit Gaussian Mixture Model to Data Using `fitgmdist`

Generate random variates that follow a mixture of two bivariate Gaussian distributions by using the `mvnrnd` function. Fit a Gaussian mixture model (GMM) to the generated data by using the `fitgmdist` function.

Define the distribution parameters (means and covariances) of two bivariate Gaussian mixture components.

```
mu1 = [1 2];           % Mean of the 1st component
```

```
sigma1 = [2 0; 0 .5]; % Covariance of the 1st component
mu2 = [-3 -5]; % Mean of the 2nd component
sigma2 = [1 0; 0 1]; % Covariance of the 2nd component
```

Generate an equal number of random variates from each component, and combine the two sets of random variates.

```
rng('default') % For reproducibility
r1 = mvnrnd(mu1,sigma1,1000);
r2 = mvnrnd(mu2,sigma2,1000);
X = [r1; r2];
```

The combined data set X contains random variates following a mixture of two bivariate Gaussian distributions.

Fit a two-component GMM to X.

```
gm = fitgmdist(X,2)
```

```
gm =
```

```
Gaussian mixture distribution with 2 components in 2 dimensions
Component 1:
Mixing proportion: 0.500000
Mean: -2.9617 -4.9727
```

```
Component 2:
Mixing proportion: 0.500000
Mean: 0.9539 2.0261
```

List the properties of the gm object.

```
properties(gm)
```

```
Properties for class gmdistribution:
```

```
NumVariables
DistributionName
NumComponents
ComponentProportion
SharedCovariance
NumIterations
RegularizationValue
NegativeLogLikelihood
CovarianceType
```

```
mu  
Sigma  
AIC  
BIC  
Converged  
ProbabilityTolerance
```

You can access these properties by using dot notation. For example, access the `NegativeLogLikelihood` property, which represents the negative loglikelihood of the data `X` given the fitted model.

```
gm.NegativeLogLikelihood
```

```
ans = 7.0584e+03
```

After you create a `gmdistribution` object, you can use the object functions. Use `cdf` and `pdf` to compute the values of the cumulative distribution function (cdf) and the probability density function (pdf). Use `random` to generate random variates. Use `cluster`, `mahal`, and `posterior` for cluster analysis.

Plot `X` by using `scatter`. Visualize the fitted model `gm` by using `pdf` and `fcontour`.

```
scatter(X(:,1),X(:,2),10,'.') % Scatter plot with points of size 10  
hold on  
gmPDF = @(x,y)reshape(pdf(gm,[x(:) y(:)]),size(x));  
fcontour(gmPDF,[-8 6])
```

gname

Add case names to plot

Syntax

```
gname(cases)
gname
h = gname(cases, line_handle)
```

Description

`gname(cases)` displays a figure window and waits for you to press a mouse button or a keyboard key. The input argument `cases` is a character array, string array, or cell array of character vectors, in which each row of the character array or each element of the string array or cell array contains the case name of a point. Moving the mouse over the graph displays a pair of cross-hairs. If you position the cross-hairs near a point with the mouse and click once, the graph displays the label corresponding to that point. Alternatively, you can click and drag the mouse to create a rectangle around several points. When you release the mouse button, the graph displays the labels for all points in the rectangle. Right-click a point to remove its label. When you are done labelling points, press the **Enter** or **Escape** key to stop labeling.

`gname` with no arguments labels each case with its case number.

`cases` typically contains unique case names for each point, and is a string array, cell array of character vectors, or character matrix with each row representing a name. `cases` can also be any grouping variable, which `gname` converts to labels.

`h = gname(cases, line_handle)` returns a vector of handles to the text objects on the plot. Use the scalar `line_handle` to identify the correct line if there is more than one line object on the plot.

You can use `gname` to label plots created by the `plot`, `scatter`, `gscatter`, `plotmatrix`, and `gplotmatrix` functions.

Examples

This example uses the city ratings data sets to find out which cities are the best and worst for education and the arts.

```
load cities
education = ratings(:,6);
arts = ratings(:,7);
plot(education,arts,'+')
gname(names)
```

Click the point at the top of the graph to display its label, "New York."

gpcdf

Generalized Pareto cumulative distribution function

Syntax

```
p = gpcdf(x,k,sigma,theta)
p = gpcdf(x,k,sigma,theta,'upper')
```

Description

`p = gpcdf(x,k,sigma,theta)` returns the cdf of the generalized Pareto (GP) distribution with the tail index (shape) parameter `k`, scale parameter `sigma`, and threshold (location) parameter, `theta`, evaluated at the values in `x`. The size of `p` is the common size of the input arguments. A scalar input functions as a constant matrix of the same size as the other inputs.

`p = gpcdf(x,k,sigma,theta,'upper')` returns the complement of the cdf of the generalized Pareto (GP) distribution, using an algorithm that more accurately computes the extreme upper tail probabilities.

Default values for `k`, `sigma`, and `theta` are 0, 1, and 0, respectively.

When `k = 0` and `theta = 0`, the GP is equivalent to the exponential distribution. When `k > 0` and `theta = sigma/k`, the GP is equivalent to a Pareto distribution with a scale parameter equal to `sigma/k` and a shape parameter equal to `1/k`. The mean of the GP is not finite when `k ≥ 1`, and the variance is not finite when `k ≥ 1/2`. When `k ≥ 0`, the GP has positive density for

`x > theta`, or, when

$$k < 0, 0 \leq \frac{x - \theta}{\sigma} \leq -\frac{1}{k}.$$

gpfit

Generalized Pareto parameter estimates

Syntax

```
parmhat = gpfit(x)
[parmhat,parmci] = gpfit(x)
[parmhat,parmci] = gpfit(x,alpha)
[...] = gpfit(x,alpha,options)
```

Description

`parmhat = gpfit(x)` returns maximum likelihood estimates of the parameters for the two-parameter generalized Pareto (GP) distribution given the data in `x`. `parmhat(1)` is the tail index (shape) parameter, `k` and `parmhat(2)` is the scale parameter, `sigma`. `gpfit` does not fit a threshold (location) parameter.

`[parmhat,parmci] = gpfit(x)` returns 95% confidence intervals for the parameter estimates.

`[parmhat,parmci] = gpfit(x,alpha)` returns $100(1-\alpha)\%$ confidence intervals for the parameter estimates.

`[...] = gpfit(x,alpha,options)` specifies control parameters for the iterative algorithm used to compute ML estimates. This argument can be created by a call to `statset`. See `statset('gpfit')` for parameter names and default values.

Other functions for the generalized Pareto, such as `gpcdf` allow a threshold parameter, `theta`. However, `gpfit` does not estimate `theta`. It is assumed to be known, and subtracted from `x` before calling `gpfit`.

When `k = 0` and `theta = 0`, the GP is equivalent to the exponential distribution. When `k > 0` and `theta = sigma/k`, the GP is equivalent to a Pareto distribution with a scale parameter equal to `sigma/k` and a shape parameter equal to `1/k`. The mean of the GP is not finite when `k ≥ 1`, and the variance is not finite when `k ≥ 1/2`. When `k ≥ 0`, the GP has positive density for

$k > \theta$, or, when $k < \theta$, for

$$0 \leq \frac{x - \theta}{\sigma} \leq -\frac{1}{k}$$

gpinv

Generalized Pareto inverse cumulative distribution function

Syntax

`x = gpinv(p,k,sigma,theta)`

Description

`x = gpinv(p,k,sigma,theta)` returns the inverse cdf for a generalized Pareto (GP) distribution with tail index (shape) parameter `k`, scale parameter `sigma`, and threshold (location) parameter `theta`, evaluated at the values in `p`. The size of `x` is the common size of the input arguments. A scalar input functions as a constant matrix of the same size as the other inputs.

Default values for `k`, `sigma`, and `theta` are 0, 1, and 0, respectively.

When `k = 0` and `theta = 0`, the GP is equivalent to the exponential distribution. When `k > 0` and `theta = sigma/k`, the GP is equivalent to a Pareto distribution with a scale parameter equal to `sigma/k` and a shape parameter equal to `1/k`. The mean of the GP is not finite when `k ≥ 1`, and the variance is not finite when `k ≥ 1/2`. When `k ≥ 0`, the GP has positive density for

`x > theta`, or, when

$$k < 0, 0 \leq \frac{x - \theta}{\sigma} \leq -\frac{1}{k}.$$

gplike

Generalized Pareto negative loglikelihood

Syntax

```
nlogL = gplike(params,data)
[nlogL,acov] = gplike(params,data)
```

Description

`nlogL = gplike(params,data)` returns the negative of the loglikelihood `nlogL` for the two-parameter generalized Pareto (GP) distribution, evaluated at parameters `params`. `params(1)` is the tail index (shape) parameter, `k`, and `params(2)` is the scale parameter. `gplike` does not allow a threshold (location) parameter.

`[nlogL,acov] = gplike(params,data)` returns the inverse of Fisher's information matrix, `acov`. If the input parameter values in `params` are the maximum likelihood estimates, the diagonal elements of `acov` are their asymptotic variances. `acov` is based on the observed Fisher's information, not the expected information.

When `k = 0` and `theta = 0`, the GP is equivalent to the exponential distribution. When `k > 0` and `theta = sigma/k`, the GP is equivalent to a Pareto distribution with a scale parameter equal to `sigma/k` and a shape parameter equal to `1/k`. The mean of the GP is not finite when `k ≥ 1`, and the variance is not finite when `k ≥ 1/2`. When `k ≥ 0`, the GP has positive density for

`x > theta`, or, when

$$k < 0, 0 \leq \frac{x - \theta}{\sigma} \leq -\frac{1}{k}.$$

gppdf

Generalized Pareto probability density function

Syntax

`p = gppdf(x,k,sigma,theta)`

Description

`p = gppdf(x,k,sigma,theta)` returns the pdf of the generalized Pareto (GP) distribution with the tail index (shape) parameter `k`, scale parameter `sigma`, and threshold (location) parameter, `theta`, evaluated at the values in `x`. The size of `p` is the common size of the input arguments. A scalar input functions as a constant matrix of the same size as the other inputs.

Default values for `k`, `sigma`, and `theta` are 0, 1, and 0, respectively.

When `k = 0` and `theta = 0`, the GP is equivalent to the exponential distribution. When `k > 0` and `theta = sigma/k`, the GP is equivalent to a Pareto distribution with a scale parameter equal to `sigma/k` and a shape parameter equal to `1/k`. The mean of the GP is not finite when `k ≥ 1`, and the variance is not finite when `k ≥ 1/2`. When `k ≥ 0`, the GP has positive density for

`x > theta`, or, when

$$k < 0, 0 \leq \frac{x - \theta}{\sigma} \leq -\frac{1}{k}.$$

gplotmatrix

Matrix of scatter plots by group

Syntax

```
gplotmatrix(x,[],group)
gplotmatrix(x,y,group)
gplotmatrix(x,y,group,clr,sym,siz)
gplotmatrix(x,y,group,clr,sym,siz,doleg)
gplotmatrix(x,[],group,clr,sym,siz,doleg,dispopt)
gplotmatrix(x,[],group,clr,sym,siz,doleg,'variable',xnam)
gplotmatrix(x,y,group,clr,sym,siz,doleg,[],xnam,ynam)
[h,ax,bigax] = gplotmatrix( ___ )
```

Description

`gplotmatrix(x,[],group)` creates a matrix of scatter plots of the data in `x`, grouped by the grouping variable in `group`. Each individual set of axes in the resulting figure contains a scatter plot of a column of `x` against another column of `x`. It also plots the outlines of the grouped histograms in the diagonals.

`gplotmatrix(x,y,group)` creates a matrix of scatter plots. Each individual set of axes in the resulting figure contains a scatter plot of a column of `x` against a column of `y`. All plots are grouped by the grouping variable `group`.

`x` and `y` are matrices with the same number of rows. If `x` has p columns and `y` has q columns, the figure contains a p -by- q matrix of scatter plots. If you omit `y` or specify it as the empty matrix, `[]`, `gplotmatrix` creates a square matrix of scatter plots of columns of `x` against each other.

`group` is a grouping variable that can be a categorical variable, vector, character array, string array, or cell array of character vectors. `group` must have the same number of rows as `x` and `y`. Points with the same value of `group` are placed in the same group, and appear on the graph with the same marker and color. Alternatively, `group` can be a cell array containing several grouping variables (such as `{g1 g2 g3}`); in that case, observations are in the same group if they have common values of all grouping variables.

`gplotmatrix(x,y,group,clr,sym,siz)` specifies the color, marker type, and size for each group. `clr` is a character array or string array of colors recognized by the `plot` function. `sym` is a character array or string array of symbols recognized by the `plot` command, with the default value `'.'`. `siz` is a vector of sizes, with the default value determined based on the number of observations. If you do not specify enough values for all groups, `gplotmatrix` cycles through the specified values as needed.

`gplotmatrix(x,y,group,clr,sym,siz,doleg)` controls whether a legend is displayed on the graph (`doleg` is `'on'`, the default) or not (`doleg` is `'off'`).

`gplotmatrix(x,[],group,clr,sym,siz,doleg,disopt)` controls what appears along the diagonal of a plot matrix of `x`. Allowable values are `'none'`, to leave the diagonals blank, `'hist'`, to plot histograms, `'stairs'` to display the outlines of grouped histograms (default if there is more than one group), `'grpbars'` to plot grouped histogram bars.

`gplotmatrix(x,[],group,clr,sym,siz,doleg,'variable',xnam)` displays the variable names along the diagonal of the plot matrix of `x`. It also uses these column names to label the `x`- and `y`-axes.

`gplotmatrix(x,y,group,clr,sym,siz,doleg,[],xnam,ynam)` labels the `x`- and `y`-axes using the column names specified in `xnam` and `ynam`.

`xnam` and `ynam` must be character arrays, string arrays, or cell arrays of character vectors, with one name for each column of `x` and `y`, respectively.

`[h,ax,bigax] = gplotmatrix(____)` returns three arrays of handles for any of the previous input arguments. `h` is an array of handles to the lines on the graphs. The array's third dimension corresponds to groups in the input argument `group`. `ax` is a matrix of handles to the axes of the individual plots. If `disopt` is `'hist'`, `'stairs'`, or `'grpbars'`, `ax` contains one extra row of handles to invisible axes in which the histograms are plotted. `bigax` is a handle to big (invisible) axes framing the entire plot matrix. `bigax` is fixed to point to the current axes, so a subsequent `title`, `xlabel`, or `ylabel` command will produce labels that are centered with respect to the entire plot matrix.

Examples

Create Grouped Data Scatter Plot Matrix

Load the sample data.

```
load discrim;
```

The `ratings` array contains rating values for 329 U.S. cities in the nine different categories listed in the `categories` array. The `group` array contains a city size code that is equal to 2 for the 26 largest cities, and 1 otherwise.

Create a matrix of scatter plots to compare the first two categories, `climate` and `housing`, with categories 4 (`crime`) and 7 (`arts`). Specify `group` as the grouping variable to visually distinguish the data for large and small cities.

```
figure;  
gplotmatrix(ratings(:,1:2),ratings(:,[4 7]),group);
```

The figure displays a matrix of scatter plots for the specified comparisons, with each city size group represented by a different color.

For better clarity, you can adjust the appearance of the graphs by specifying colors and plotting symbols, and labeling the axes with the rating categories.

```
figure;
gplotmatrix(ratings(:,1:2),ratings(:,[4 7]),group,...
    'br','o',[],'on','',categories(1:2,:),...
    categories([4 7],:));
```

gprnd

Generalized Pareto random numbers

Syntax

```
r = gprnd(k,sigma,theta)
r = gprnd(k,sigma,theta,m,n,...)
R = gprnd(K,sigma,theta,[m,n,...])
```

Description

`r = gprnd(k,sigma,theta)` returns an array of random numbers chosen from the generalized Pareto (GP) distribution with tail index (shape) parameter `k`, scale parameter `sigma`, and threshold (location) parameter, `theta`. The size of `r` is the common size of the input arguments if all are arrays. If any parameter is a scalar, the size of `r` is the size of the other parameters.

`r = gprnd(k,sigma,theta,m,n,...)` or `R = gprnd(K,sigma,theta,[m,n,...])` generates an `m`-by-`n`-by-... array. The `k`, `sigma`, `theta` parameters can each be scalars or arrays of the same size as `r`.

When `k = 0` and `theta = 0`, the GP is equivalent to the exponential distribution. When `k > 0` and `theta = sigma/k`, the GP is equivalent to a Pareto distribution with a scale parameter equal to `sigma/k` and a shape parameter equal to `1/k`. The mean of the GP is not finite when `k ≥ 1`, and the variance is not finite when `k ≥ 1/2`. When `k ≥ 0`, the GP has positive density for

`x > theta`, or, when

$$0 \leq \frac{x - \theta}{\sigma} \leq -\frac{1}{k}$$

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

The generated code can return a different sequence of numbers than MATLAB if either of the following is true:

- The output is nonscalar.
- An input parameter is invalid for the distribution.

For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “General Code Generation Workflow” on page 31-5.

gpstat

Generalized Pareto mean and variance

Syntax

`[m,v] = gpstat(k,sigma,theta)`

Description

`[m,v] = gpstat(k,sigma,theta)` returns the mean of and variance for the generalized Pareto (GP) distribution with the tail index (shape) parameter `k`, scale parameter `sigma`, and threshold (location) parameter, `theta`.

The default value for `theta` is 0.

When `k = 0` and `theta = 0`, the GP is equivalent to the exponential distribution. When `k > 0` and `theta = sigma/k`, the GP is equivalent to a Pareto distribution with a scale parameter equal to `sigma/k` and a shape parameter equal to `1/k`. The mean of the GP is not finite when `k ≥ 1`, and the variance is not finite when `k ≥ 1/2`. When `k ≥ 0`, the GP has positive density for `x > theta`, or when

$$k < 0, 0 \leq \frac{x - \theta}{\sigma} \leq -\frac{1}{k}.$$

growTrees

Class: TreeBagger

Train additional trees and add to ensemble

Syntax

`B = growTrees(B, nTrees)`

`B = growTrees(B, nTrees, 'param1', val1, 'param2', val2, ...)`

Description

`B = growTrees(B, nTrees)` grows `nTrees` new trees and appends them to those trees already stored in the ensemble `B`.

`B = growTrees(B, nTrees, 'param1', val1, 'param2', val2, ...)` specifies optional parameter name/value pairs:

<code>'NumPrint'</code>	Specifies that a diagnostic message showing training progress should display after every <code>value</code> training cycles (grown trees). Default is no diagnostic messages.
-------------------------	---

'Options'

A `struct` that specifies options that govern computation when growing the ensemble of decision trees. One option requests that the computation of decision trees on multiple bootstrap replicates uses multiple processors, if the Parallel Computing Toolbox is available. Two options specify the random number streams to use in selecting bootstrap replicates. You can create this argument with a call to `statset`. You can retrieve values of the individual fields with a call to `statget`. Applicable `statset` parameters are:

- `'UseParallel'` — If `true` and if a `parpool` of the Parallel Computing Toolbox is open, compute decision trees drawn on separate bootstrap replicates in parallel. If the Parallel Computing Toolbox is not installed, or a `parpool` is not open, computation occurs in serial mode. Default is `false`, or serial computation.
- `UseSubstreams` — Set to `true` to compute in parallel in a reproducible fashion. Default is `false`. To compute reproducibly, set `Streams` to a type allowing substreams: `'mlfg6331_64'` or `'mrg32k3a'`.
- `Streams` — A `RandStream` object or cell array of such objects. If you do not specify `Streams`, `growTrees` uses the default stream or streams. If you choose to specify `Streams`, use a single object except in the case
 - `UseParallel` is `true`
 - `UseSubstreams` is `false`

In that case, use a cell array the same size as the Parallel pool.

Extended Capabilities

Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the 'UseParallel' option to true.

Set the 'UseParallel' field of the options structure to true using `statset` and specify the 'Options' name-value pair argument in the call to this function.

For example: `'Options',statset('UseParallel',true)`

For more information, see the 'Options' name-value pair argument.

For more general information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

grp2idx

Create index vector from grouping variable

Syntax

```
[g,gN] = grp2idx(s)
[g,gN,gL] = grp2idx(s)
```

Description

`[g,gN] = grp2idx(s)` creates an index vector `g` from the grouping variable `s`. The output `g` is a vector of integer values from 1 up to the number K of distinct groups. `gN` is a cell array of character vectors representing the list of group names.

`[g,gN,gL] = grp2idx(s)` also returns a column vector `gL` representing the list of the group levels with the same data type as `s`.

Examples

Create Index Vector from Categorical Vector

Create a categorical vector by using `discretize` and convert it to an index vector by using `grp2idx`.

Load the `hospital` data set and convert the ages in `hospital.Ages` to categorical values representing the ages by decade.

```
load hospital
edges = 0:10:100; % Bin edges
labels = strcat(num2str((0:10:90)', '%d'), {'s'}); % Labels for the bins
s = discretize(hospital.Age, edges, 'Categorical', labels);
```

Display the ages and the groups of ages for the first five samples.

```
ages = hospital.Age(1:5)
```

```
ages = 5×1
```

```
38
43
38
40
49
```

```
groups = s(1:5)
```

```
groups = 5×1 categorical array
30s
40s
30s
40s
40s
```

Create an index vector from the categorical vector `s`.

```
[g,gN,gL] = grp2idx(s);
```

Display the index values corresponding to the first five samples.

```
g(1:5)
```

```
ans = 5×1
```

```
4
5
4
5
5
```

Reproduce the input argument `s` using the output `gL`.

```
gL(g(1:5))
```

```
ans = 5×1 categorical array
30s
40s
30s
40s
```

```
40s
```

Use `gN(g)` to reproduce the input argument `s` as a cell array of character vectors.

```
gN(g(1:5))
```

```
ans = 5x1 cell array
    {'30s'}
    {'40s'}
    {'30s'}
    {'40s'}
    {'40s'}
```

Input Arguments

s — Grouping variable

categorical vector | numeric vector | logical vector | `datetime` vector | duration vector | string array | cell array of character vectors | character array

Grouping variable, specified as a categorical, numeric, logical, `datetime`, or duration vector, a string array, a cell array of character vectors, or a character array with each row representing a group label.

`grp2idx` treats NaNs (numeric, duration, or logical), '' (empty character arrays or cell arrays of character vectors), "" (empty strings), <missing> values (string), <undefined> values (categorical), and NaTs (`datetime`) in `s` as missing values and returns NaNs in the corresponding rows of `g`. The outputs `gN` and `gL` do not include entries for missing values.

Data Types: `single` | `double` | `int8` | `int16` | `int32` | `int64` | `uint8` | `uint16` | `uint32` | `uint64` | `logical` | `char` | `string` | `cell` | `categorical` | `datetime` | `duration`

Output Arguments

g — Group index

positive integer vector

Group index, returned as a positive integer vector with values from 1 up to the number K of distinct groups in s .

gN — List of group names

cell array of character vectors

List of group names, returned as a cell array of character vectors.

The order of gN depends on the data type of the grouping variable s .

- For numeric and logical vectors, the order is the sorted order of s .
- For categorical vectors, the order is the order of `categories(s)`.
- For other data types, the order is the order of first appearance in s .

$gN(g)$ reproduces the contents of s in a cell array.

gL — List of group levels

categorical vector | numeric vector | logical vector | datetime vector | duration vector |
cell array of character vectors | character array

List of group levels, returned as the same data type as s : a categorical, numeric, logical, `datetime`, or duration vector, a cell array of character vectors, or a character array with each row representing a group label. (The software treats string arrays as cell arrays of character vectors.)

The set of groups and their order in gL are the same as those in gN , but gL has the same data type as s .

If s is a character matrix, then $gL(g, :)$ reproduces s ; otherwise, $gL(g)$ reproduces s .

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The input argument `s` can be a numeric, logical, or character vector or a cell array of character vectors. Code generation does not support a categorical, `datetime`, or duration vector or a string array for the input argument.
- In the generated code, the second and third outputs, `gN` and `gL`, are identical. `gN` and `gL` have the same data type as the input argument `s`.

For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “General Code Generation Workflow” on page 31-5.

Introduced before R2006a

grpstats

Summary statistics organized by group

Syntax

```
statarray = grpstats(tbl,groupvar)
statarray = grpstats(tbl,groupvar,whichstats)
statarray = grpstats(tbl,groupvar,whichstats,Name,Value)

means = grpstats(X,group)
[stats1,...,statsN] = grpstats(X,group,whichstats)
[stats1,...,statsN] = grpstats(X,group,whichstats,'Alpha',alpha)

grpstats(X,group,alpha)
```

Description

`statarray = grpstats(tbl,groupvar)` returns a table or dataset array with the means for the data groups specified in `tbl` determined by the values of the grouping variable or variables specified in `groupvar`.

- If there is a single grouping variable, then there is a row in `statarray` for each value of the grouping variable. `grpstats` sorts the groups by order of appearance (if the grouping variable is a character vector or string scalar), in ascending numeric order (if the grouping variable is numeric), or in order of the levels (if the grouping variable is categorical).
- If `groupvar` is a string array or cell array of character vectors containing multiple grouping variable names, or a vector of column numbers, then there is a row in `statarray` for each observed unique combination of values of the grouping variables. `grpstats` sorts the groups by the values of the first grouping variable, then the second grouping variable, and so on.
- If any variables in `tbl` (other than those specified in `groupvar`) are not numeric or logical arrays, then you must specify the names or column numbers of the numeric and logical variables for which you want to calculate means using the name-value pair argument, `DataVars`.

`statarray = grpstats(tbl,groupvar,whichstats)` returns the group values for the summary statistics types specified in `whichstats`.

`statarray = grpstats(tbl,groupvar,whichstats,Name,Value)` uses additional options specified by one or more `Name,Value` pair arguments.

`means = grpstats(X,group)` returns a column vector or matrix with the means of the groups of the data in the matrix or vector `X` determined by the values of the grouping variable or variables, `group`. The rows of `means` correspond to the grouping variable values.

- If there is a single grouping variable, then there is a row in `means` for each value of the grouping variable. `grpstats` sorts the groups by order of appearance (if the grouping variable is a character vector or string scalar), in ascending numeric order (if the grouping variable is numeric), or in order of the levels (if the grouping variable is categorical).
- If `group` is a string array or cell array of grouping variables, then there is a row in `means` for each observed unique combination of values of the grouping variables. `grpstats` sorts the groups by the values of the first grouping variable, then the second grouping variable, and so on.
- If `X` is a matrix, then `means` is a matrix with the same number of columns as `X`. Each column of `means` has the group means for the corresponding column of `X`.

`[stats1,...,statsN] = grpstats(X,group,whichstats)` returns column vectors or arrays with group values for the summary statistic types specified in `whichstats`.

`[stats1,...,statsN] = grpstats(X,group,whichstats,'Alpha',alpha)` specifies the significance level for confidence and prediction intervals.

`grpstats(X,group,alpha)` plots the means of the groups of data in the vector or matrix `X` determined by the values of the grouping variable, `group`. The grouping variable values are on the horizontal plot axis. Each group mean has $100 \times (1 - \alpha)\%$ confidence intervals.

- If `X` is a matrix, then `grpstats` plots the means and confidence intervals for each column of `X`.
- If `group` is a cell array of grouping variables, then `grpstats` plots the means and confidence intervals for the groups of data in `X` determined by the unique combinations of values of the grouping variables. For example, if there are two grouping variables, each with two values, there are four possible combinations of

grouping variable values. The plot includes only the combinations of values that exist in the input grouping variables (not all possible combinations).

Examples

Dataset Array Summary Statistics Organized by Group

Load the sample data.

```
load('hospital')
```

The dataset array `hospital` has 100 observations and 7 variables.

Create a dataset array with only the variables `Sex`, `Age`, `Weight`, and `Smoker`.

```
dsa = hospital(:, {'Sex', 'Age', 'Weight', 'Smoker'});
```

`Sex` is a nominal array, with levels `Male` and `Female`. The variables `Age` and `Weight` have numeric values, and `Smoker` has logical values.

Compute the mean for the numeric and logical arrays, `Age`, `Weight`, and `Smoker`, grouped by the levels in `Sex`.

```
statarray = grpstats(dsa, 'Sex')
```

```
statarray =
```

	Sex	GroupCount	mean_Age	mean_Weight	mean_Smoker
Female	Female	53	37.717	130.47	0.24528
Male	Male	47	38.915	180.53	0.44681

`statarray` is a dataset array with two rows, corresponding to the levels in `Sex`. `GroupCount` is the number of observations in each group. The means of `Age`, `Weight`, and `Smoker`, grouped by `Sex`, are given in `mean_Age`, `mean_Weight`, and `mean_Smoker`.

Compute the mean for `Age` and `Weight`, grouped by the values in `Smoker`.

```
