<code>upperparams</code>	Upper Pareto tail parameters

Examples

Create `paretotails` with Empirical Distribution

Generate a sample data set and fit a piecewise distribution with Pareto tails to the data. Specify an empirical distribution for the center by using `paretotails` with its default settings.

Generate a sample data set containing 100 random numbers from a t distribution with 3 degrees of freedom.

```
rng('default'); % For reproducibility
t = trnd(3,100,1);
```

Create a `paretotails` object by fitting a piecewise distribution to `t`. Specify the boundaries of the tails using the lower and upper tail cumulative probabilities so that a fitted object consists of the empirical distribution for the middle 80% of the data set and GPDs for the lower and upper 10% of the data set.

```
pd = paretotails(t,0.1,0.9)

pd =
Piecewise distribution with 3 segments
  -Inf < x < -1.84875    (0 < p < 0.1): lower tail, GPD(0.183032,1.00347)
 -1.84875 < x < 2.07662 (0.1 < p < 0.9): interpolated empirical cdf
  2.07662 < x < Inf     (0.9 < p < 1): upper tail, GPD(0.333239,1.19705)
```

Each line of the object display shows the summary of each segment, including the GPD parameters (shape and scale parameters) and the boundary values in the quantiles and cumulative probabilities. Use the object functions `boundary`, `lowerparams`, and `upperparams` to return these values.

You can use the `nsegments` function to return the number of segments and the `segment` function to return the segment that contains input values.

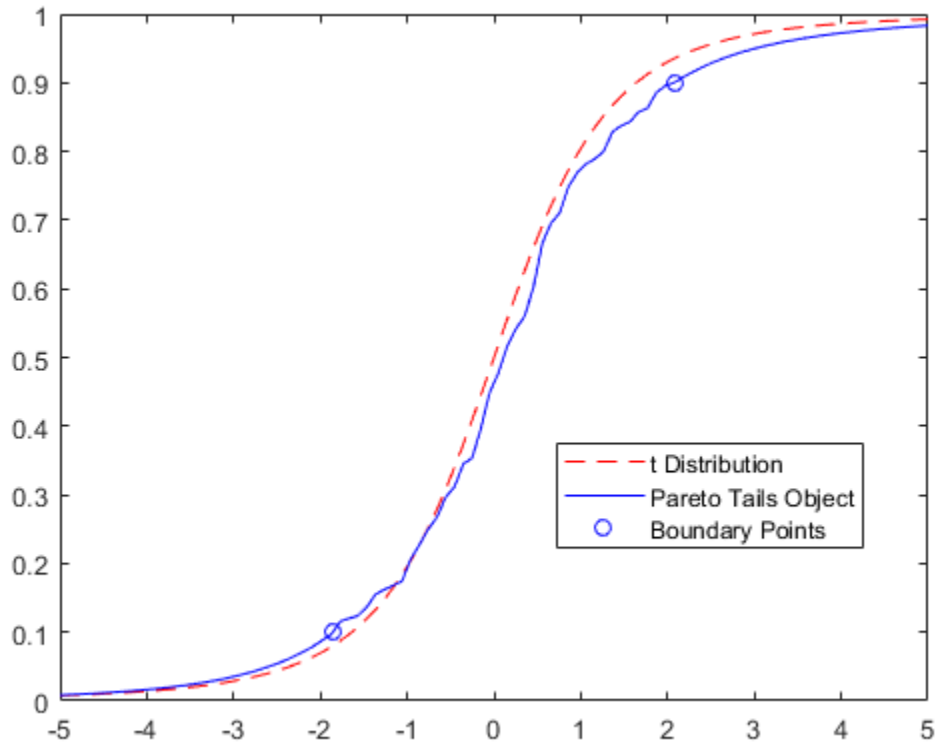

You can also use the distribution functions `cdf`, `icdf`, `pdf`, and `random` to evaluate the distribution and generate random samples.

Plot the cdf of the t distribution and the cdf of the `paretotails` object on the same figure.

```
x = linspace(-5,5);
plot(x,tcdf(x,3),'r--')
hold on
plot(x,cdf(pd,x),'b-')
```

Find the boundary points between the segments of the `paretotails` object by using `boundary`, and mark the points on the figure.

```
[p,q] = boundary(pd);
plot(q,p,'bo')
legend('t Distribution','Pareto Tails Object','Boundary Points','Location','best')
hold off
```

Create paretotails with Function Handle

Generate a sample data set and fit a piecewise distribution with Pareto tails to the data. Fit a center segment by using `paretotails` with a function handle.

Generate a sample data set containing 20% outliers.

```
rng('default'); % For reproducibility
left_tail = -exprnd(1,100,1);
right_tail = exprnd(5,100,1);
center = randn(800,1);
x = [left_tail;center;right_tail];
```

Define a function handle using `ksdensity` to specify a nondefault value of the bandwidth.

```
myfun1 = @(x)ksdensity(x,'Bandwidth',.1,'Function','cdf');
```

Create a `paretotails` object by fitting a piecewise distribution with the specified kernel smoothing estimator to `x`. Specify the boundaries of the tails using the lower and upper tail cumulative probabilities so that a fitted object consists of the kernel estimator for the middle 80% of the data set and GPDs for the lower and upper 10% of the data set.

```
pd1 = paretotails(x,0.1,0.9,myfun1)
```

```
pd1 =  
Piecewise distribution with 3 segments  
  -Inf < x < -1.35204    (0 < p < 0.1): lower tail, GPD(0.0104112,0.54947)  
 -1.35204 < x < 1.80824 (0.1 < p < 0.9): function: @(x)ksdensity(x,'Bandwidth',.1,'  
  1.80824 < x < Inf    (0.9 < p < 1): upper tail, GPD(0.227542,3.10586)
```

You can also use a parametric distribution for the center segment. Define a function that fits a normal distribution to data and returns the cdf values, and pass the function handle when you create a `paretotails` object.

```
pd2 = paretotails(x,0.1,0.9,@myfun2)
```

```
pd2 =  
Piecewise distribution with 3 segments  
  -Inf < x < -2.70875    (0 < p < 0.1): lower tail, GPD(-0.358104,0.831855)  
 -2.70875 < x < 3.52195 (0.1 < p < 0.9): function: myfun2  
  3.52195 < x < Inf    (0.9 < p < 1): upper tail, GPD(-0.0661815,5.04694)
```

```
function [p,xi] = myfun2(x)  
    pd = fitdist(x,'Normal');  
    xi = linspace(min(x),max(x),length(x)*2);  
    p = cdf(pd,xi);  
end
```

Introduced in R2007a

partialcorr

Linear or rank partial correlation coefficients

Syntax

```
rho = partialcorr(x)
rho = partialcorr(x,z)
rho = partialcorr(x,y,z)
rho = partialcorr( ____,Name,Value)
[rho,pval] = partialcorr( ____)
```

Description

`rho = partialcorr(x)` returns the sample linear partial correlation coefficients between pairs of variables in `x`, controlling for the remaining variables in `x`.

`rho = partialcorr(x,z)` returns the sample linear partial correlation coefficients between pairs of variables in `x`, controlling for the variables in `z`.

`rho = partialcorr(x,y,z)` returns the sample linear partial correlation coefficients between pairs of variables in `x` and `y`, controlling for the variables in `z`.

`rho = partialcorr(____,Name,Value)` returns the sample linear partial correlation coefficients with additional options specified by one or more name-value pair arguments, using input arguments from any of the previous syntaxes. For example, you can specify whether to use Pearson or Spearman partial correlations, or specify how to treat missing values.

`[rho,pval] = partialcorr(____)` also returns a matrix `pval` of p -values for testing the hypothesis of no partial correlation against the one- or two-sided alternative that there is a nonzero partial correlation.

Examples

Compute Partial Correlation Coefficients

Compute partial correlation coefficients between pairs of variables in the input matrix.

Load the sample data. Convert the genders in `hospital.Sex` to numeric group identifiers.

```
load hospital;
hospital.SexID = grp2idx(hospital.Sex);
```

Create an input matrix containing the sample data.

```
x = [hospital.SexID hospital.Age hospital.Smoker hospital.Weight];
```

Each row in `x` contains a patient's gender, age, smoking status, and weight.

Compute partial correlation coefficients between pairs of variables in `x`, while controlling for the effects of the remaining variables in `x`.

```
rho = partialcorr(x)
```

```
rho = 4×4
```

```
    1.0000    -0.0105     0.0273     0.9421
   -0.0105     1.0000     0.0419     0.0369
    0.0273     0.0419     1.0000     0.0451
    0.9421     0.0369     0.0451     1.0000
```

The matrix `rho` indicates, for example, a correlation of 0.9421 between gender and weight after controlling for all other variables in `x`. You can return the p -values as a second output, and examine them to confirm whether these correlations are statistically significant.

For a clearer display, create a table with appropriate variable and row labels.

```
rho = array2table(rho, ...
    'VariableNames', {'SexID', 'Age', 'Smoker', 'Weight'}, ...
    'RowNames', {'SexID', 'Age', 'Smoker', 'Weight'});
```

```
disp('Partial Correlation Coefficients')
```

```
Partial Correlation Coefficients
```

```
disp(rho)
```

	SexID	Age	Smoker	Weight
SexID	1	-0.01052	0.027324	0.9421
Age	-0.01052	1	0.041945	0.036873
Smoker	0.027324	0.041945	1	0.045106
Weight	0.9421	0.036873	0.045106	1

Test for Partial Correlations with Controlled Variables

Test for partial correlation between pairs of variables in the input matrix, while controlling for the effects of a second set of variables.

Load the sample data. Convert the genders in `hospital.Sex` to numeric group identifiers.

```
load hospital;  
hospital.SexID = grp2idx(hospital.Sex);
```

Create two matrices containing the sample data.

```
x = [hospital.Age hospital.BloodPressure];  
z = [hospital.SexID hospital.Smoker hospital.Weight];
```

The `x` matrix contains the variables to test for partial correlation. The `z` matrix contains the variables to control for. The measurements for `BloodPressure` are contained in two columns: The first column contains the upper (systolic) number, and the second column contains the lower (diastolic) number. `partialcorr` treats each column as a separate variable.

Test for partial correlation between pairs of variables in `x`, while controlling for the effects of the variables in `z`. Compute the correlation coefficients.

```
[rho,pval] = partialcorr(x,z)
```

```
rho = 3×3
```

```
1.0000    0.1300    0.0462  
0.1300    1.0000    0.0012  
0.0462    0.0012    1.0000
```

```
pval = 3x3
      0      0.2044      0.6532
0.2044      0      0.9903
0.6532      0.9903      0
```

The large values in `pval` indicate that there is no significant correlation between age and either blood pressure measurement after controlling for gender, smoking status, and weight.

For a clearer display, create tables with appropriate variable and row labels.

```
rho = array2table(rho, ...
  'VariableNames',{'Age','BPTop','BPBottom'},...
  'RowNames',{'Age','BPTop','BPBottom'});

pval = array2table(pval, ...
  'VariableNames',{'Age','BPTop','BPBottom'},...
  'RowNames',{'Age','BPTop','BPBottom'});
```

```
disp('Partial Correlation Coefficients')
```

```
Partial Correlation Coefficients
```

```
disp(rho)
```

	Age	BPTop	BPBottom
Age	1	0.13	0.046202
BPTop	0.13	1	0.0012475
BPBottom	0.046202	0.0012475	1

```
disp('p-values')
```

```
p-values
```

```
disp(pval)
```

	Age	BPTop	BPBottom
Age	0	0.20438	0.65316
BPTop	0.20438	0	0.99032
BPBottom	0.65316	0.99032	0

Test for Paired Partial Correlation Coefficients

Test for partial correlation between pairs of variables in the x and y input matrices, while controlling for the effects of a third set of variables.

Load the sample data. Convert the genders in `hospital.Sex` to numeric group identifiers.

```
load hospital;
hospital.SexID = grp2idx(hospital.Sex);
```

Create three matrices containing the sample data.

```
x = [hospital.BloodPressure];
y = [hospital.Weight hospital.Age];
z = [hospital.SexID hospital.Smoker];
```

`partialcorr` can test for partial correlation between the pairs of variables in x (the systolic and diastolic blood pressure measurements) and y (weight and age), while controlling for the variables in z (gender and smoking status). The measurements for `BloodPressure` are contained in two columns: The first column contains the upper (systolic) number, and the second column contains the lower (diastolic) number. `partialcorr` treats each column as a separate variable.

Test for partial correlation between pairs of variables in x and y , while controlling for the effects of the variables in z . Compute the correlation coefficients.

```
[rho,pval] = partialcorr(x,y,z)
```

```
rho = 2×2
```

```
   -0.0257    0.1289
    0.0292    0.0472
```

```
pval = 2×2
```

```
   0.8018    0.2058
   0.7756    0.6442
```

The results in `pval` indicate that, after controlling for gender and smoking status, there is no significant correlation between either of a patient's blood pressure measurements and that patient's weight or age.

For a clearer display, create tables with appropriate variable and row labels.

```
rho = array2table(rho, ...
    'RowNames', {'BPTop', 'BPBottom'}, ...
    'VariableNames', {'Weight', 'Age'});

pval = array2table(pval, ...
    'RowNames', {'BPTop', 'BPBottom'}, ...
    'VariableNames', {'Weight', 'Age'});
```

```
disp('Partial Correlation Coefficients')
```

```
Partial Correlation Coefficients
```

```
disp(rho)
```

	Weight	Age
BPTop	-0.02568	0.12893
BPBottom	0.029168	0.047226

```
disp('p-values')
```

```
p-values
```

```
disp(pval)
```

	Weight	Age
BPTop	0.80182	0.2058
BPBottom	0.77556	0.64424

One-Tailed Partial Correlation Test

Test the hypothesis that pairs of variables have no correlation, against the alternative hypothesis that the correlation is greater than 0.

Load the sample data. Convert the genders in `hospital.Sex` to numeric group identifiers.

```
load hospital;
hospital.SexID = grp2idx(hospital.Sex);
```

Create three matrices containing the sample data.

```
x = [hospital.BloodPressure];
y = [hospital.Weight hospital.Age];
z = [hospital.SexID hospital.Smoker];
```

`partialcorr` can test for partial correlation between the pairs of variables in `x` (the systolic and diastolic blood pressure measurements) and `y` (weight and age), while controlling for the variables in `z` (gender and smoking status). The measurements for `BloodPressure` are contained in two columns: The first column contains the upper (systolic) number, and the second column contains the lower (diastolic) number. `partialcorr` treats each column as a separate variable.

Compute the correlation coefficients using a right-tailed test.

```
[rho,pval] = partialcorr(x,y,z,'Tail','right')
```

```
rho = 2×2
```

```
-0.0257    0.1289
 0.0292    0.0472
```

```
pval = 2×2
```

```
0.5991    0.1029
0.3878    0.3221
```

The results in `pval` indicate that `partialcorr` does not reject the null hypothesis of nonzero correlations between the variables in `x` and `y`, after controlling for the variables in `z`, when the alternative hypothesis is that the correlations are greater than 0.

For a clearer display, create tables with appropriate variable and row labels.

```
rho = array2table(rho, ...
    'RowNames', {'BPTop', 'BPBottom'}, ...
    'VariableNames', {'Weight', 'Age'});
```

```
pval = array2table(pval, ...
    'RowNames',{'BPTop','BPBottom'},...
    'VariableNames',{'Weight','Age'});
```

```
disp('Partial Correlation Coefficients')
```

```
Partial Correlation Coefficients
```

```
disp(rho)
```

	Weight	Age
BPTop	-0.02568	0.12893
BPBottom	0.029168	0.047226

```
disp('p-values')
```

```
p-values
```

```
disp(pval)
```

	Weight	Age
BPTop	0.59909	0.1029
BPBottom	0.38778	0.32212

Input Arguments

x — Data matrix

matrix

Data matrix, specified as an n -by- p_x matrix. The rows of x correspond to observations, and the columns correspond to variables.

Data Types: single | double

y — Data matrix

matrix

Data matrix, specified as an n -by- p_y matrix. The rows of y correspond to observations, and the columns correspond to variables.

Data Types: `single` | `double`

z — Data matrix

matrix

Data matrix, specified as an n -by- p_z matrix. The rows of `z` correspond to observations, and columns correspond to variables.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'Type', 'Spearman', 'Rows', 'complete'` computes Spearman partial correlations using only the data in rows that contain no missing values.

Type — Type of partial correlations

`'Pearson'` (default) | `'Spearman'`

Type of partial correlations to compute, specified as the comma-separated pair consisting of `'Type'` and one of the following.

<code>'Pearson'</code>	Compute Pearson (linear) partial correlations.
<code>'Spearman'</code>	Compute Spearman (rank) partial correlations.

Example: `'Type', 'Spearman'`

Rows — Rows to use in computation

`'all'` (default) | `'complete'` | `'pairwise'`

Rows to use in computation, specified as the comma-separated pair consisting of `'Rows'` and one of the following.

<code>'all'</code>	Use all rows of the input regardless of missing values (NaNs).
<code>'complete'</code>	Use only rows of the input with no missing values.

'pairwise' Compute $\rho(i, j)$ using rows with no missing values in column i or j .

Example: 'Rows', 'complete'

Tail – Alternative hypothesis

'both' (default) | 'right' | 'left'

Alternative hypothesis to test against, specified as the comma-separated pair consisting of 'Tail' and one of the following.

'both' Test the alternative hypothesis that the correlation is not 0.
 'right' Test the alternative hypothesis that the correlation is greater than 0.
 'left' Test the alternative hypothesis that the correlation is less than 0.

Example: 'Tail', 'right'

Output Arguments

rho – Sample linear partial correlation coefficients

matrix

Sample linear partial correlation coefficients, returned as a matrix.

- If you input only an x matrix, ρ is a symmetric p_x -by- p_x matrix. The (i,j) th entry is the sample linear partial correlation between the i -th and j -th columns in x .
- If you input x and z matrices, ρ is a symmetric p_x -by- p_x matrix. The (i,j) th entry is the sample linear partial correlation between the i th and j th columns in x , controlled for the variables in z .
- If you input x , y , and z matrices, ρ is a p_x -by- p_y matrix, where the (i,j) th entry is the sample linear partial correlation between the i th column in x and the j th column in y , controlled for the variables in z .

If the covariance matrix of $[x, z]$ is

$$S = \begin{pmatrix} S_{xx} & S_{xz} \\ S_{xz}^T & S_{zz} \end{pmatrix},$$

then the partial correlation matrix of x , controlling for z , can be defined formally as a normalized version of the covariance matrix: $S_{xx} - (S_{xz}S_{zz}^{-1}S_{xz}^T)$.

pval — *p*-values

matrix

p-values, returned as a matrix. Each element of `pval` is the *p*-value for the corresponding element of `rho`.

If `pval(i, j)` is small, then the corresponding partial correlation `rho(i, j)` is statistically significantly different from 0.

`partialcorr` computes *p*-values for linear and rank partial correlations using a Student's *t* distribution for a transformation of the correlation. This is exact for linear partial correlation when x and z are normal, but is a large-sample approximation otherwise.

See Also

`corr` | `corrcoef` | `partialcorri` | `tiedrank`

Introduced before R2006a

partialcorri

Partial correlation coefficients adjusted for internal variables

Syntax

```
rho = partialcorri(y,x)
rho = partialcorri(y,x,z)
rho = partialcorri( ____,Name,Value)
[rho,pval] = partialcorri( ____)
```

Description

`rho = partialcorri(y,x)` returns the sample linear partial correlation coefficients between pairs of variables in `y` and `x`, adjusting for the remaining variables in `x`.

`rho = partialcorri(y,x,z)` returns the sample linear partial correlation coefficients between pairs of variables in `y` and `x`, adjusting for the remaining variables in `x`, after first controlling both `x` and `y` for the variables in `z`.

`rho = partialcorri(____,Name,Value)` returns the sample linear partial correlation coefficients with additional options specified by one or more name-value pair arguments, using input arguments from any of the previous syntaxes. For example, you can specify whether to use Pearson or Spearman partial correlations, or specify how to treat missing values.

`[rho,pval] = partialcorri(____)` also returns a matrix `pval` of p -values for testing the hypothesis of no partial correlation against the one- or two-sided alternative that there is a nonzero partial correlation.

Examples

Compute Partial Correlation Coefficients

Compute partial correlation coefficients for each pair of variables in the `x` and `y` input matrices, while controlling for the effects of the remaining variables in `x`.

Load the sample data.

```
load carsmall;
```

The data contains measurements from cars manufactured in 1970, 1976, and 1982. It includes `MPG` and `Acceleration` as performance measures, and `Displacement`, `Horsepower`, and `Weight` as design variables. `Acceleration` is the time required to accelerate from 0 to 60 miles per hour, so a high value for `Acceleration` corresponds to a vehicle with low acceleration.

Define the input matrices. The `y` matrix includes the performance measures, and the `x` matrix includes the design variables.

```
y = [MPG,Acceleration];  
x = [Displacement,Horsepower,Weight];
```

Compute the correlation coefficients. Include only rows with no missing values in the computation.

```
rho = partialcorri(y,x,'Rows','complete')
```

```
rho = 2×3  
    -0.0537    -0.1520    -0.4856  
    -0.3994    -0.4008     0.4912
```

The results suggest, for example, a 0.4912 correlation between weight and acceleration after controlling for the effects of displacement and horsepower. You can return the p -values as a second output, and examine them to confirm whether these correlations are statistically significant.

For a clearer display, create a table with appropriate variable and row labels.

```
rho = array2table(rho, ...  
    'VariableNames',{ 'Displacement','Horsepower','Weight'}, ...  
    'RowNames',{ 'MPG','Acceleration'});  
  
disp('Partial Correlation Coefficients')
```

Partial Correlation Coefficients

disp(rho)

	Displacement	Horsepower	Weight
MPG	-0.053684	-0.15199	-0.48563
Acceleration	-0.39941	-0.40075	0.49123

Test Partial Correlations While Controlling for Additional Variables

Test for partial correlation between pairs of variables in the x and y input matrices, while controlling for the effects of the remaining variables in x plus additional variables in matrix z .

Load the sample data.

```
load carsmall;
```

The data contains measurements from cars manufactured in 1970, 1976, and 1982. It includes MPG and Acceleration as performance measures, and Displacement, Horsepower, and Weight as design variables. Acceleration is the time required to accelerate from 0 to 60 miles per hour, so a high value for Acceleration corresponds to a vehicle with low acceleration.

Create a new variable Headwind, and randomly generate data to represent the notion of an average headwind along the performance measurement route.

```
rng('default'); % For reproducibility
Headwind = (10:-0.2:-9.8)' + 5*randn(100,1);
```

Since headwind can affect the performance measures, control for its effects when testing for partial correlation between the remaining variables.

Define the input matrices. The y matrix includes the performance measures, and the x matrix includes the design variables. The z matrix contains additional variables to control for when computing the partial correlations, such as headwind.

```
y = [MPG,Acceleration];
x = [Displacement,Horsepower,Weight];
z = Headwind;
```

Compute the partial correlation coefficients. Include only rows with no missing values in the computation.

```
[rho,pval] = partialcorri(y,x,z, 'Rows', 'complete')
```

```
rho = 2×3
```

```
    0.0572    -0.1055    -0.5736
   -0.3845    -0.3966     0.4674
```

```
pval = 2×3
```

```
    0.5923    0.3221    0.0000
    0.0002    0.0001    0.0000
```

The small returned p -value of 0.001 in `pval` indicates, for example, a significant negative correlation between horsepower and acceleration, after controlling for displacement, weight, and headwind.

For a clearer display, create tables with appropriate variable and row labels.

```
rho = array2table(rho, ...
    'VariableNames', {'Displacement', 'Horsepower', 'Weight'}, ...
    'RowNames', {'MPG', 'Acceleration'});

pval = array2table(pval, ...
    'VariableNames', {'Displacement', 'Horsepower', 'Weight'}, ...
    'RowNames', {'MPG', 'Acceleration'});

disp('Partial Correlation Coefficients, Accounting for Headwind')
Partial Correlation Coefficients, Accounting for Headwind

disp(rho)

           Displacement    Horsepower    Weight
           _____    _____    _____

Acceleration  -0.38452         -0.39658         0.4674

disp('p-values, Accounting for Headwind')
p-values, Accounting for Headwind
```

```
disp(pval)
```

	Displacement	Horsepower	Weight
MPG	0.59233	0.32212	3.4401e-09
Acceleration	0.00018272	0.00010902	3.4091e-06

Input Arguments

x — Data matrix

matrix

Data matrix, specified as an n -by- p_x matrix. The rows of **x** correspond to observations, and the columns correspond to variables.

Data Types: `single` | `double`

y — Data matrix

matrix

Data matrix, specified as an n -by- p_y matrix. The rows of **y** correspond to observations, and the columns correspond to variables.

Data Types: `single` | `double`

z — Data matrix

matrix

Data matrix, specified as an n -by- p_z matrix. The rows of **z** correspond to observations, and the columns correspond to variables.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: 'Type', 'Spearman', 'Rows', 'complete' computes Spearman partial correlations using only the data in rows that contain no missing values.

Type — Type of partial correlations

'Pearson' (default) | 'Spearman'

Type of partial correlations to compute, specified as the comma-separated pair consisting of 'Type' and either 'Pearson' or 'Spearman'. Pearson computes the Pearson (linear) partial correlations. Spearman computes the Spearman (rank) partial correlations.

Example: 'Type', 'Spearman'

Rows — Rows to use in computation

'all' (default) | 'complete' | 'pairwise'

Rows to use in computation, specified as the comma-separated pair consisting of 'Rows' and one of the following.

'all'	Use all rows regardless of missing (NaN) values.
'complete'	Use only rows with no missing values.
'pairwise'	Use all available values in each column of y when computing the partial correlation coefficients and p -values corresponding to that column. For each column of y , rows will be dropped corresponding to missing values in x (and/or z , if supplied). However, remaining rows with valid values in that column of y are used, even if there are missing values in other columns of y .

Example: 'Rows', 'complete'

Tail — Alternative hypothesis

'both' (default) | 'right' | 'left'

Alternative hypothesis to test against, specified as the comma-separated pair consisting of 'Tail' and one of the following.

'both'	Test the alternative hypothesis that the correlation is not zero.
--------	---

'right'	Test the alternative hypothesis that the correlation is greater than 0.
'left'	Test the alternative hypothesis that the correlation is less than 0.

Example: 'Tail', 'right'

Output Arguments

rho — Sample linear partial correlation coefficients

matrix

Sample linear partial correlation coefficients, returned as a p_y -by- p_x matrix.

- If you input x and y matrices, the (i,j) th entry is the sample linear partial correlation between the i th column in y and the j th column in x , controlled for all the columns of x except column j .
- If you input x , y , and z matrices, the (i,j) th entry is the sample linear partial correlation between the i th column in y and the j th column in x , adjusted for all the columns of x except column j , after first controlling both x and y for the variables in z .

pval — p -values

matrix

p -values, returned as a matrix. Each element of `pval` is the p -value for the corresponding element of `rho`. If `pval(i, j)` is small, then the corresponding partial correlation `rho(i, j)` is statistically significantly different from zero.

`partialcorri` computes p -values for linear and rank partial correlations using a Student's t distribution for a transformation of the correlation. This is exact for linear partial correlation when x and z are normal, but is a large-sample approximation otherwise.

Introduced in R2013b

pca

Principal component analysis of raw data

Syntax

```
coeff = pca(X)
coeff = pca(X,Name,Value)
[coeff,score,latent] = pca(____)
[coeff,score,latent,tsquared] = pca(____)
[coeff,score,latent,tsquared,explained,mu] = pca(____)
```

Description

`coeff = pca(X)` returns the principal component coefficients, also known as loadings, for the n -by- p data matrix X . Rows of X correspond to observations and columns correspond to variables. The coefficient matrix is p -by- p . Each column of `coeff` contains coefficients for one principal component, and the columns are in descending order of component variance. By default, `pca` centers the data and uses the singular value decomposition (SVD) algorithm.

`coeff = pca(X,Name,Value)` returns any of the output arguments in the previous syntaxes using additional options for computation and handling of special data types, specified by one or more `Name,Value` pair arguments.

For example, you can specify the number of principal components `pca` returns or an algorithm other than SVD to use.

`[coeff,score,latent] = pca(____)` also returns the principal component scores in `score` and the principal component variances in `latent`. You can use any of the input arguments in the previous syntaxes.

Principal component scores are the representations of X in the principal component space. Rows of `score` correspond to observations, and columns correspond to components.

The principal component variances are the eigenvalues of the covariance matrix of X .

`[coeff, score, latent, tsquared] = pca(___)` also returns the Hotelling's T-squared statistic for each observation in X .

`[coeff, score, latent, tsquared, explained, mu] = pca(___)` also returns `explained`, the percentage of the total variance explained by each principal component and `mu`, the estimated mean of each variable in X .

Examples

Principal Components of a Data Set

Load the sample data set.

```
load hald
```

The ingredients data has 13 observations for 4 variables.

Find the principal components for the ingredients data.

```
coeff = pca(ingredients)
coeff = 4×4
    -0.0678    -0.6460     0.5673     0.5062
    -0.6785    -0.0200    -0.5440     0.4933
     0.0290     0.7553     0.4036     0.5156
     0.7309    -0.1085    -0.4684     0.4844
```

The rows of `coeff` contain the coefficients for the four ingredient variables, and its columns correspond to four principal components.

PCA in the Presence of Missing Data

Find the principal component coefficients when there are missing values in a data set.

Load the sample data set.

```
load imports-85
```

Data matrix `X` has 13 continuous variables in columns 3 to 15: wheel-base, length, width, height, curb-weight, engine-size, bore, stroke, compression-ratio, horsepower, peak-rpm, city-mpg, and highway-mpg. The variables `bore` and `stroke` are missing four values in rows 56 to 59, and the variables `horsepower` and `peak-rpm` are missing two values in rows 131 and 132.

Perform principal component analysis.

```
coeff = pca(X(:,3:15));
```

By default, `pca` performs the action specified by the `'Rows'`, `'complete'` name-value pair argument. This option removes the observations with NaN values before calculation. Rows of NaNs are reinserted into `score` and `tsquared` at the corresponding locations, namely rows 56 to 59, 131, and 132.

Use `'pairwise'` to perform the principal component analysis.

```
coeff = pca(X(:,3:15), 'Rows', 'pairwise');
```

In this case, `pca` computes the (i,j) element of the covariance matrix using the rows with no NaN values in the columns i or j of `X`. Note that the resulting covariance matrix might not be positive definite. This option applies when the algorithm `pca` uses is eigenvalue decomposition. When you don't specify the algorithm, as in this example, `pca` sets it to `'eig'`. If you require `'svd'` as the algorithm, with the `'pairwise'` option, then `pca` returns a warning message, sets the algorithm to `'eig'` and continues.

If you use the `'Rows'`, `'all'` name-value pair argument, `pca` terminates because this option assumes there are no missing values in the data set.

```
coeff = pca(X(:,3:15), 'Rows', 'all');
```

```
Error using pca (line 180)
```

```
Raw data contains NaN missing value while 'Rows' option is set to 'all'. Consider using
```

Weighted PCA

Use the inverse variable variances as weights while performing the principal components analysis.

Load the sample data set.

```
load hald
```

Perform the principal component analysis using the inverse of variances of the ingredients as variable weights.

```
[wcoeff,~,latent,~,explained] = pca(ingredients,...
'VariableWeights','variance')
```

```
wcoeff = 4×4
```

```
-2.7998    2.9940   -3.9736    1.4180
-8.7743   -6.4411    4.8927    9.9863
 2.5240   -3.8749   -4.0845    1.7196
 9.1714    7.5529    3.2710   11.3273
```

```
latent = 4×1
```

```
2.2357
1.5761
0.1866
0.0016
```

```
explained = 4×1
```

```
55.8926
39.4017
 4.6652
 0.0406
```

Note that the coefficient matrix, `wcoeff`, is not orthonormal.

Calculate the orthonormal coefficient matrix.

```
coefforth = inv(diag(std(ingredients))) * wcoeff
```

```
coefforth = 4×4
```

```
-0.4760    0.5090   -0.6755    0.2411
-0.5639   -0.4139    0.3144    0.6418
 0.3941   -0.6050   -0.6377    0.2685
 0.5479    0.4512    0.1954    0.6767
```

Check orthonormality of the new coefficient matrix, `coefforth`.

```
coefforth*coefforth'  
ans = 4x4  
  
    1.0000    0.0000    0.0000    0.0000  
    0.0000    1.0000   -0.0000   -0.0000  
    0.0000   -0.0000    1.0000    0.0000  
    0.0000   -0.0000    0.0000    1.0000
```

PCA Using ALS for Missing Data

Find the principal components using the alternating least squares (ALS) algorithm when there are missing values in the data.

Load the sample data.

```
load hald
```

The ingredients data has 13 observations for 4 variables.

Perform principal component analysis using the ALS algorithm and display the component coefficients.

```
[coeff,score,latent,tsquared,explained] = pca(ingredients);  
coeff
```

```
coeff = 4x4  
  
   -0.0678   -0.6460    0.5673    0.5062  
   -0.6785   -0.0200   -0.5440    0.4933  
    0.0290    0.7553    0.4036    0.5156  
    0.7309   -0.1085   -0.4684    0.4844
```

Introduce missing values randomly.

```
y = ingredients;  
rng('default'); % for reproducibility  
ix = random('unif',0,1,size(y))<0.30;  
y(ix) = NaN
```

```

y = 13x4
      7    26     6   NaN
      1    29    15   52
     NaN   NaN     8   20
     11    31   NaN   47
      7    52     6   33
     NaN   55   NaN   NaN
     NaN   71   NaN    6
      1    31   NaN   44
      2   NaN   NaN   22
     21    47    4   26
      :

```

Approximately 30% of the data has missing values now, indicated by NaN.

Perform principal component analysis using the ALS algorithm and display the component coefficients.

```

[coeff1,score1,latent,tsquared,explained,mu1] = pca(y,...
'algorithm','als');
coeff1

```

```

coeff1 = 4x4
      -0.0362    0.8215   -0.5252    0.2190
      -0.6831   -0.0998    0.1828    0.6999
      0.0169    0.5575    0.8215   -0.1185
      0.7292   -0.0657    0.1261    0.6694

```

Display the estimated mean.

```

mu1
mu1 = 1x4
      8.9956   47.9088    9.0451   28.5515

```

Reconstruct the observed data.

```

t = score1*coeff1' + repmat(mu1,13,1)

```

```
t = 13×4
    7.0000    26.0000    6.0000    51.5250
    1.0000    29.0000    15.0000    52.0000
   10.7819    53.0230    8.0000    20.0000
   11.0000    31.0000    13.5500    47.0000
    7.0000    52.0000    6.0000    33.0000
   10.4818    55.0000    7.8328    17.9362
    3.0982    71.0000    11.9491    6.0000
    1.0000    31.0000   -0.5161    44.0000
    2.0000    53.7914    5.7710    22.0000
   21.0000    47.0000    4.0000    26.0000
    :
```

The ALS algorithm estimates the missing values in the data.

Another way to compare the results is to find the angle between the two spaces spanned by the coefficient vectors. Find the angle between the coefficients found for complete data and data with missing values using ALS.

```
subspace(coeff,coeff1)
```

```
ans = 5.1543e-16
```

This is a small value. It indicates that the results if you use `pca` with `'Rows', 'complete'` name-value pair argument when there is no missing data and if you use `pca` with `'algorithm', 'als'` name-value pair argument when there is missing data are close to each other.

Perform the principal component analysis using `'Rows', 'complete'` name-value pair argument and display the component coefficients.

```
[coeff2,score2,latent,tsquared,explained,mu2] = pca(y,...
'Rows','complete');
coeff2
```

```
coeff2 = 4×3
```

```
-0.2054    0.8587    0.0492
-0.6694   -0.3720    0.5510
 0.1474   -0.3513   -0.5187
 0.6986   -0.0298    0.6518
```

In this case, `pca` removes the rows with missing values, and `y` has only four rows with no missing values. `pca` returns only three principal components. You cannot use the 'Rows', 'pairwise' option because the covariance matrix is not positive semidefinite and `pca` returns an error message.

Find the angle between the coefficients found for complete data and data with missing values using listwise deletion (when 'Rows', 'complete').

```
subspace(coeff(:,1:3),coeff2)
```

```
ans = 0.3576
```

The angle between the two spaces is substantially larger. This indicates that these two results are different.

Display the estimated mean.

```
mu2
```

```
mu2 = 1×4
```

```
7.8889 46.9091 9.8750 29.6000
```

In this case, the mean is just the sample mean of `y`.

Reconstruct the observed data.

```
score2*coeff2'
```

```
ans = 13×4
```

```
NaN NaN NaN NaN
-7.5162 -18.3545 4.0968 22.0056
NaN NaN NaN NaN
NaN NaN NaN NaN
-0.5644 5.3213 -3.3432 3.6040
NaN NaN NaN NaN
NaN NaN NaN NaN
NaN NaN NaN NaN
NaN NaN NaN NaN
12.8315 -0.1076 -6.3333 -3.7758
⋮
```

This shows that deleting rows containing NaN values does not work as well as the ALS algorithm. Using ALS is better when the data has too many missing values.

Principal Component Coefficients, Scores, and Variances

Find the coefficients, scores, and variances of the principal components.

Load the sample data set.

```
load hald
```

The ingredients data has 13 observations for 4 variables.

Find the principal component coefficients, scores, and variances of the components for the ingredients data.

```
[coeff,score,latent] = pca(ingredients)
```

```
coeff = 4×4
```

```

13.5385  -1.1538  -7.7692  -4.0000
  :
```

The new data in `Xcentered` is the original ingredients data centered by subtracting the column means from corresponding columns.

Visualize both the orthonormal principal component coefficients for each variable and the principal component scores for each observation in a single plot.

```
biplot(coeff(:,1:2), 'scores', score(:,1:2), 'varlabels', {'v_1', 'v_2', 'v_3', 'v_4'});
```

All four variables are represented in this biplot by a vector, and the direction and length of the vector indicate how each variable contributes to the two principal components in the plot. For example, the first principal component, which is on the horizontal axis, has positive coefficients for the third and fourth variables. Therefore, vectors v_3 and v_4 are directed into the right half of the plot. The largest coefficient in the first principal component is the fourth, corresponding to the variable v_4 .

The second principal component, which is on the vertical axis, has negative coefficients for the variables v_1 , v_2 , and v_4 , and a positive coefficient for the variable v_3 .

This 2-D biplot also includes a point for each of the 13 observations, with coordinates indicating the score of each observation for the two principal components in the plot. For example, points near the left edge of the plot have the lowest scores for the first principal

component. The points are scaled with respect to the maximum score value and maximum coefficient length, so only their relative locations can be determined from the plot.

T-Squared Statistic

Find the Hotelling's T-squared statistic values.

Load the sample data set.

```
load hald
```

The ingredients data has 13 observations for 4 variables.

Perform the principal component analysis and request the T-squared values.

```
[coeff,score,latent,tsquared] = pca(ingredients);

Percent Variability Explained by Principal Components

Find the percent variability explained by the principal components. Show the data representation in the principal components space.

Load the sample data set.

```
load imports-85
```

Data matrix X has 13 continuous variables in columns 3 to 15: wheel-base, length, width, height, curb-weight, engine-size, bore, stroke, compression-ratio, horsepower, peak-rpm, city-mpg, and highway-mpg.

Find the percent variability explained by principal components of these variables.

```
[coeff,score,latent,tsquared,explained] = pca(X(:,3:15));
```

```
explained
```

```
explained = 13x1
```

```

64.3429
35.4484
0.1550
0.0379
0.0078
0.0048
0.0013
0.0011
0.0005
0.0002

```

⋮

The first three components explain 99.95% of all variability.

Visualize the data representation in the space of the first three principal components.

```
scatter3(score(:,1),score(:,2),score(:,3))  
axis equal  
xlabel('1st Principal Component')  
ylabel('2nd Principal Component')  
zlabel('3rd Principal Component')
```

The data shows the largest variability along the first principal component axis. This is the largest possible variance among all possible choices of the first axis. The variability along

the second principal component axis is the largest among all possible remaining choices of the second axis. The third principal component axis has the third largest variability, which is significantly smaller than the variability along the second principal component axis. The fourth through thirteenth principal component axes are not worth inspecting, because they explain only 0.05% of all variability in the data.

To skip any of the outputs, you can use ~ instead in the corresponding element. For example, if you don't want to get the T-squared values, specify

```
[coeff,score,latent,~,explained] = pca(X(:,3:15));
```

Apply PCA to New Data and Generate C/C++ Code

Find the principal components for one data set and apply the PCA to another data set. This procedure is useful when you have a training data set and a test data set for a machine learning model. For example, you can preprocess the training data set by using PCA and then train a model. To test the trained model using the test data set, you need to apply the PCA transformation obtained from the training data to the test data set.

This example also describes how to generate C/C++ code. Because `pca` supports code generation, you can generate code that performs PCA using a training data set and apply the PCA to a test data set. Then deploy the code to a device. In this workflow, you must pass training data, which can be of considerable size. To save memory on the device, you can separate training and prediction. Use `pca` in MATLAB® and apply PCA to new data in the generated code on the device.

Generating C/C++ code requires MATLAB® Coder™.

Apply PCA to New Data

Load the data set into a table by using `readtable`. The data set is in the file `CreditRating_Historical.dat`, which contains the historical credit rating data.

```
creditrating = readtable('CreditRating_Historical.dat');
creditrating(1:5,:)
```

```
ans=5x8 table
```

ID	WC_TA	RE_TA	EBIT_TA	MVE_BVTD	S_TA	Industry	Rating
_____	_____	_____	_____	_____	_____	_____	_____

62394	0.013	0.104	0.036	0.447	0.142	3	'BB'
48608	0.232	0.335	0.062	1.969	0.281	8	'A'
42444	0.311	0.367	0.074	1.935	0.366	1	'A'
48631	0.194	0.263	0.062	1.017	0.228	4	'BBB'
43768	0.121	0.413	0.057	3.647	0.466	12	'AAA'

The first column is an ID of each observation, and the last column is a rating. Specify the second to seventh columns as predictor data and specify the last column (`Rating`) as the response.

```
X = table2array(creditrating(:,2:7));
Y = creditrating.Rating;
```

Use the first 100 observations as test data and the rest as training data.

```
XTest = X(1:100,:);
XTrain = X(101:end,:);
YTest = Y(1:100);
YTrain = Y(101:end);
```

Find the principal components for the training data set `XTrain`.

```
[coeff,scoreTrain,~,~,explained,mu] = pca(XTrain);
```

This code returns four outputs: `coeff`, `scoreTrain`, `explained`, and `mu`. Use `explained` (percentage of total variance explained) to find the number of components required to explain at least 95% variability. Use `coeff` (principal component coefficients) and `mu` (estimated means of `XTrain`) to apply the PCA to a test data set. Use `scoreTrain` (principal component scores) instead of `XTrain` when you train a model.

Display the percent variability explained by the principal components.

```
explained
```

```
explained = 6×1
```

```
58.2614
41.2606
0.3875
0.0632
0.0269
0.0005
```

The first two components explain more than 95% of all variability. Programmatically find the number of components required to explain at least 95% variability by using a `while` loop.

```
sum_explained = 0;
idx = 0;
while sum_explained < 95
    idx = idx + 1;
    sum_explained = sum_explained + explained(idx);
end
idx
idx = 2
```

Train a classification tree using the first two components.

```
scoreTrain95 = scoreTrain(:,1:idx);
mdl = fitctree(scoreTrain95,YTrain);
```

`mdl` is a `ClassificationTree` model.

To use the trained model for the test set, you need to transform the test data set by using the PCA obtained from the training data set. Obtain the principal component scores of the test data set by subtracting `mu` from `XTest` and multiplying by `coeff`. Only the scores for the first two components are necessary, so use the first two coefficients `coeff(:,1:idx)`.

```
scoreTest95 = (XTest-mu)*coeff(:,1:idx);
```

Pass the trained model `mdl` and the transformed test data set `scoreTest` to the `predict` function to predict ratings for the test set.

```
YTest_predicted = predict(mdl,scoreTest95);
```

Generate Code

Generate code that applies PCA to data and predicts ratings using the trained model. Note that generating C/C++ code requires MATLAB® Coder™.

Save the classification model to the file `myMdl.mat` by using `saveCompactModel`.

```
saveCompactModel(mdl, 'myMdl');
```

Define an entry-point function named `myPCAPredict` that accepts a test data set (`XTest`) and PCA information (`coeff` and `mu`) and returns the ratings of the test data.

Add the `%#codegen` compiler directive (or pragma) to the entry-point function after the function signature to indicate that you intend to generate code for the MATLAB algorithm. Adding this directive instructs the MATLAB Code Analyzer to help you diagnose and fix violations that would cause errors during code generation.

```
type myPCAPredict % Display contents of myPCAPredict.m

function label = myPCAPredict(XTest,coeff,mu) %#codegen
% Transform data using PCA
scoreTest = bsxfun(@minus,XTest,mu)*coeff;

% Load trained classification model
mdl = loadCompactModel('myMdl');
% Predict ratings using the loaded model
label = predict(mdl,scoreTest);
```

`myPCAPredict` applies PCA to new data using `coeff` and `mu`, and then predicts ratings using the transformed data. In this way, you do not pass training data, which can be of considerable size.

Note: If you click the button located in the upper-right section of this page and open this example in MATLAB®, then MATLAB® opens the example folder. This folder includes the entry-point function file.

Generate code by using `codegen`. Because C and C++ are statically typed languages, you must determine the properties of all variables in the entry-point function at compile time. To specify the data type and exact input array size, pass a MATLAB® expression that represents the set of values with a certain data type and array size by using the `-args` option. If the number of observations is unknown at compile time, you can also specify the input as variable-size by using `coder.typeof`. For details, see “Specify Variable-Size Arguments for Code Generation” on page 31-58.

```
codegen myPCAPredict -args {coder.typeof(XTest,[Inf,6],[1,0]),coeff(:,1:idx),mu}
```

`codegen` generates the MEX function `myPCAPredict_mex` with a platform-dependent extension.

Verify the generated code.

```
YTest_predicted_mex = myPCAPredict_mex(XTest,coeff(:,1:idx),mu);
isequal(YTest_predicted,YTest_predicted_mex)
```

```
ans = logical
     1
```

`isequal` returns logical 1 (true), which means all the inputs are equal. The comparison confirms that the `predict` function of `mdl` and the `myPCAPredict_mex` function return the same ratings.

For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “Code Generation and Classification Learner App” on page 31-32. The latter describes how to perform PCA and train a model by using the Classification Learner app, and how to generate C/C++ code that predicts labels for new data based on the trained model.

Input Arguments

X — Input data

matrix

Input data for which to compute the principal components, specified as an n -by- p matrix. Rows of X correspond to observations and columns to variables.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example:

`'Algorithm', 'eig', 'Centered', false, 'Rows', 'all', 'NumComponents', 3` specifies that `pca` uses eigenvalue decomposition algorithm, not center the data, use all of the observations, and return only the first three principal components.

Algorithm — Principal component algorithm

`'svd'` (default) | `'eig'` | `'als'`

Principal component algorithm that `pca` uses to perform the principal component analysis, specified as the comma-separated pair consisting of `'Algorithm'` and one of the following.

Value	Description
<code>'svd'</code>	Default. Singular value decomposition (SVD) of X .
<code>'eig'</code>	Eigenvalue decomposition (EIG) of the covariance matrix. The EIG algorithm is faster than SVD when the number of observations, n , exceeds the number of variables, p , but is less accurate because the condition number of the covariance is the square of the condition number of X .
<code>'als'</code>	<p>Alternating least squares (ALS) algorithm. This algorithm finds the best rank-k approximation by factoring X into a n-by-k left factor matrix, L, and a p-by-k right factor matrix, R, where k is the number of principal components. The factorization uses an iterative method starting with random initial values.</p> <p>ALS is designed to better handle missing values. It is preferable to pairwise deletion (<code>'Rows', 'pairwise'</code>) and deals with missing values without listwise deletion (<code>'Rows', 'complete'</code>). It can work well for data sets with a small percentage of missing data at random, but might not perform well on sparse data sets.</p>

Example: `'Algorithm', 'eig'`

Centered — Indicator for centering columns

`true` (default) | `false`

Indicator for centering the columns, specified as the comma-separated pair consisting of `'Centered'` and one of these logical expressions.

Value	Description
<code>true</code>	Default. <code>pca</code> centers X by subtracting column means before computing singular value decomposition or eigenvalue decomposition. If X contains NaN missing values, <code>nanmean</code> is used to find the mean with any available data. You can reconstruct the centered data using <code>score*coeff'</code> .
<code>false</code>	In this case <code>pca</code> does not center the data. You can reconstruct the original data using <code>score*coeff'</code> .

Example: `'Centered', false`

Data Types: logical

Economy — Indicator for economy size output

true (default) | false

Indicator for the economy size output when the degrees of freedom on page 32-4858, d , is smaller than the number of variables, p , specified as the comma-separated pair consisting of 'Economy' and one of these logical expressions.

Value	Description
true	Default. <code>pca</code> returns only the first d elements of <code>latent</code> and the corresponding columns of <code>coeff</code> and <code>score</code> . This option can be significantly faster when the number of variables p is much larger than d .
false	<code>pca</code> returns all elements of <code>latent</code> . The columns of <code>coeff</code> and <code>score</code> corresponding to zero elements in <code>latent</code> are zeros.

Note that when $d < p$, `score(:, d+1:p)` and `latent(d+1:p)` are necessarily zero, and the columns of `coeff(:, d+1:p)` define directions that are orthogonal to X .

Example: 'Economy', false

Data Types: logical

NumComponents — Number of components requested

number of variables (default) | scalar integer

Number of components requested, specified as the comma-separated pair consisting of 'NumComponents' and a scalar integer k satisfying $0 < k \leq p$, where p is the number of original variables in X . When specified, `pca` returns the first k columns of `coeff` and `score`.

Example: 'NumComponents', 3

Data Types: single | double

Rows — Action to take for NaN values

'complete' (default) | 'pairwise' | 'all'

Action to take for NaN values in the data matrix X , specified as the comma-separated pair consisting of 'Rows' and one of the following.

Value	Description
'complete'	Default. Observations with NaN values are removed before calculation. Rows of NaNs are reinserted into <code>score</code> and <code>tsquared</code> at the corresponding locations.
'pairwise'	This option only applies when the algorithm is 'eig'. If you don't specify the algorithm along with 'pairwise', then <code>pca</code> sets it to 'eig'. If you specify 'svd' as the algorithm, along with the option 'Rows', 'pairwise', then <code>pca</code> returns a warning message, sets the algorithm to 'eig' and continues. When you specify the 'Rows', 'pairwise' option, <code>pca</code> computes the (i,j) element of the covariance matrix using the rows with no NaN values in the columns i or j of X . Note that the resulting covariance matrix might not be positive definite. In that case, <code>pca</code> terminates with an error message.
'all'	X is expected to have no missing values. <code>pca</code> uses all of the data and terminates if any NaN value is found.

Example: 'Rows', 'pairwise'

Weights — Observation weights

ones (default) | row vector

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a vector of length n containing all positive elements.

Data Types: single | double

VariableWeights — Variable weights

row vector | 'variance'

Variable weights on page 32-4858, specified as the comma-separated pair consisting of 'VariableWeights' and one of the following.

Value	Description
row vector	Vector of length p containing all positive elements.

Value	Description
'variance'	<p>The variable weights are the inverse of sample variance. If you also assign weights to observations using 'Weights', then the variable weights become the inverse of weighted sample variance.</p> <p>If 'Centered' is set to true at the same time, the data matrix X is centered and standardized. In this case, pca returns the principal components based on the correlation matrix.</p>

Example: 'VariableWeights', 'variance'

Data Types: single | double | char | string

Coeff0 — Initial value for coefficients

matrix of random values (default) | p -by- k matrix

Initial value for the coefficient matrix `coeff`, specified as the comma-separated pair consisting of 'Coeff0' and a p -by- k matrix, where p is the number of variables, and k is the number of principal components requested.

Note You can use this name-value pair only when 'algorithm' is 'als'.

Data Types: single | double

Score0 — Initial value for scores

matrix of random values (default) | k -by- m matrix

Initial value for scores matrix `score`, specified as a comma-separated pair consisting of 'Score0' and an n -by- k matrix, where n is the number of observations and k is the number of principal components requested.

Note You can use this name-value pair only when 'algorithm' is 'als'.

Data Types: single | double

Options — Options for iterations

structure

Options for the iterations, specified as a comma-separated pair consisting of 'Options' and a structure created by the `statset` function. `pca` uses the following fields in the options structure.

Field Name	Description
'Display'	Level of display output. Choices are 'off', 'final', and 'iter'.
'MaxIter'	Maximum number steps allowed. The default is 1000. Unlike in optimization settings, reaching the <code>MaxIter</code> value is regarded as convergence.
'TolFun'	Positive number giving the termination tolerance for the cost function. The default is 1e-6.
'TolX'	Positive number giving the convergence threshold for the relative change in the elements of the left and right factor matrices, L and R, in the ALS algorithm. The default is 1e-6.

Note You can use this name-value pair only when 'algorithm' is 'als'.

You can change the values of these fields and specify the new structure in `pca` using the 'Options' name-value pair argument.

```
Example: opt = statset('pca'); opt.MaxIter = 2000; coeff =
pca(X, 'Options', opt);
```

Data Types: struct

Output Arguments

coeff — Principal component coefficients

matrix

Principal component coefficients, returned as a p -by- p matrix. Each column of `coeff` contains coefficients for one principal component. The columns are in the order of descending component variance, `latent`.

score — Principal component scores

matrix

Principal component scores, returned as a matrix. Rows of `score` correspond to observations, and columns to components.

latent — Principal component variances

column vector

Principal component variances, that is the eigenvalues of the covariance matrix of X , returned as a column vector.

tsquared — Hotelling's T-squared statistic

column vector

"Hotelling's T-Squared Statistic" on page 32-4857, which is the sum of squares of the standardized scores for each observation, returned as a column vector.

explained — Percentage of total variance explained

column vector

Percentage of the total variance explained by each principal component, returned as a column vector.

mu — Estimated means

row vector

Estimated means of the variables in X , returned as a row vector when `Centered` is set to `true`. When `Centered` is `false`, the software does not compute the means and returns a vector of zeros.

Definitions

Hotelling's T-Squared Statistic

Hotelling's T-squared statistic is a statistical measure of the multivariate distance of each observation from the center of the data set.

Even when you request fewer components than the number of variables, `pca` uses all principal components to compute the T-squared statistic (computes it in the full space). If you want the T-squared statistic in the reduced or the discarded space, do one of the following:

- For the T-squared statistic in the reduced space, use `mahal(score, score)`.
- For the T-squared statistic in the discarded space, first compute the T-squared statistic using `[coeff, score, latent, tsquared] = pca(X, 'NumComponents', k, ...)`, compute the T-squared statistic in the reduced space using `tsqreduced = mahal(score, score)`, and then take the difference: `tsquared - tsqreduced`.

Degrees of Freedom

The degrees of freedom, d , is equal to $n - 1$, if data is centered and n otherwise, where:

- n is the number of rows without any NaNs if you use `'Rows', 'complete'`.
- n is the number of rows without any NaNs in the column pair that has the maximum number of rows without NaNs if you use `'Rows', 'pairwise'`.

Variable Weights

Note that when variable weights are used, the coefficient matrix is not orthonormal. Suppose the variable weights vector you used is called `varwei`, and the principal component coefficients vector `pca` returned is `wcoeff`. You can then calculate the orthonormal coefficients using the transformation `diag(sqrt(varwei))*wcoeff`.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function supports tall arrays for out-of-memory data with some limitations.

- `pca` works directly with tall arrays by computing the covariance matrix and using the in-memory `pcacov` function to compute the principle components.
- Supported syntaxes are:
 - `coeff = pca(X)`
 - `[coeff,score,latent] = pca(X)`
 - `[coeff,score,latent,explained] = pca(X)`
 - `[coeff,score,latent,tsquared] = pca(X)`
 - `[coeff,score,latent,tsquared,explained] = pca(X)`
- Name-value pair arguments are not supported.

For more information, see “Tall Arrays” (MATLAB).

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- When 'Algorithm' is 'als', the 'Display' value for 'Options' is ignored.
- If supplied, 'Weights' and 'VariableWeights' must be real.
- The generated code always returns the fifth output `explained` as a column vector.
- The generated code always returns the sixth output `mu` as a row vector.
- If `mu` is empty, `pca` returns `mu` as a 1-by-0 array. `pca` does not convert `mu` to a 0-by-0 empty array.
- The generated code does not treat an input matrix `X` that has all NaN values as a special case. The output dimensions are commensurate with corresponding finite inputs.

- To save memory on the device to which you deploy generated code, you can separate training (constructing PCA components from input data) and prediction (performing PCA transformation). Construct PCA components in MATLAB. Then, define an entry-point function that performs PCA transformation using the principal component coefficients (`coeff`) and estimated means (`mu`), which are the outputs of `pca`. Finally, generate code for the entry-point function. For an example, see “Apply PCA to New Data and Generate C/C++ Code” on page 32-4847.

For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “General Code Generation Workflow” on page 31-5.

Topics

“Analyze Quality of Life in U.S. Cities Using PCA” on page 15-80

“Principal Component Analysis (PCA)” on page 15-78

Introduced in R2012b

pcacov

Principal component analysis on covariance matrix

Syntax

```
COEFF = pcacov(V)
[COEFF,latent] = pcacov(V)
[COEFF,latent,explained] = pcacov(V)
```

Description

`COEFF = pcacov(V)` performs principal components analysis on the p-by-p covariance matrix `V` and returns the principal component coefficients, also known as loadings. `COEFF` is a p-by-p matrix, with each column containing coefficients for one principal component. The columns are in order of decreasing component variance.

`pcacov` does not standardize `V` to have unit variances. To perform principal components analysis on standardized variables, use the correlation matrix $R = V ./ (SD * SD')$, where $SD = \text{sqrt}(\text{diag}(V))$, in place of `V`. To perform principal components analysis directly on the data matrix, use `pca`.

`[COEFF,latent] = pcacov(V)` returns `latent`, a vector containing the principal component variances, that is, the eigenvalues of `V`.

`[COEFF,latent,explained] = pcacov(V)` returns `explained`, a vector containing the percentage of the total variance explained by each principal component.

Examples

```
load hald
covx = cov(ingredients);
[COEFF,latent,explained] = pcacov(covx)
COEFF =
    0.0678 -0.6460  0.5673 -0.5062
    0.6785 -0.0200 -0.5440 -0.4933
```

```
-0.0290  0.7553  0.4036 -0.5156  
-0.7309 -0.1085 -0.4684 -0.4844
```

```
latent =  
 517.7969  
 67.4964  
 12.4054  
 0.2372
```

```
explained =  
 86.5974  
 11.2882  
 2.0747  
 0.0397
```

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

`pcacov` and `factoran` do *not* work directly on tall arrays. Instead, use `C = gather(cov(X))` to compute the covariance matrix of a tall array. Then, you can use `pcacov` or `factoran` on the in-memory covariance matrix. Alternatively, you can use `pca` directly on a tall array.

For more information, see “Tall Arrays” (MATLAB).

Introduced before R2006a

pcares

Residuals from principal component analysis

Syntax

```
residuals = pcares(X,ndim)
[residuals,reconstructed] = pcares(X,ndim)
```

Description

`residuals = pcares(X,ndim)` returns the `residuals` obtained by retaining `ndim` principal components of the `n`-by-`p` matrix `X`. Rows of `X` correspond to observations, columns to variables. `ndim` is a scalar and must be less than or equal to `p`. `residuals` is a matrix of the same size as `X`. Use the data matrix, *not* the covariance matrix, with this function.

`pcares` does not normalize the columns of `X`. To perform the principal components analysis based on standardized variables, that is, based on correlations, use `pcares(zscore(X), ndim)`. You can perform principal components analysis directly on a covariance or correlation matrix, but without constructing residuals, by using `pcacov`.

`[residuals,reconstructed] = pcares(X,ndim)` returns the reconstructed observations; that is, the approximation to `X` obtained by retaining its first `ndim` principal components.

Examples

This example shows the drop in the residuals from the first row of the Hald data as the number of component dimensions increases from one to three.

```
load hald
r1 = pcares(ingredients,1);
r2 = pcares(ingredients,2);
r3 = pcares(ingredients,3);
```

```
r11 = r1(1, :)
r11 =
    2.0350    2.8304   -6.8378    3.0879

r21 = r2(1, :)
r21 =
   -2.4037    2.6930   -1.6482    2.3425

r31 = r3(1, :)
r31 =
    0.2008    0.1957    0.2045    0.1921
```

factoran | pca | pcacov

Introduced before R2006a

ppca

Probabilistic principal component analysis

Syntax

```
[coeff, score, pcvar] = ppca(Y, K)
[coeff, score, pcvar] = ppca(Y, K, Name, Value)
[coeff, score, pcvar, mu] = ppca( ___ )
[coeff, score, pcvar, mu, v, S] = ppca( ___ )
```

Description

`[coeff, score, pcvar] = ppca(Y, K)` returns the principal component coefficients for the n -by- p data matrix Y based on a probabilistic principal component analysis on page 32-4875 (PPCA). It also returns the principal component scores, which are the representations of Y in the principal component space, and the principal component variances, which are the eigenvalues of the covariance matrix of Y , in `pcvar`.

Each column of `coeff` contains coefficients for one principal component, and the columns are in descending order of component variance. Rows of `score` correspond to observations, and columns correspond to components. Rows of Y correspond to observations and columns correspond to variables.

Probabilistic principal component analysis might be preferable to other algorithms that handle missing data, such as the alternating least squares algorithm when any data vector has one or more missing values. It assumes that the values are missing at random through the data set. An expectation-maximization algorithm is used for both complete and missing data.

`[coeff, score, pcvar] = ppca(Y, K, Name, Value)` returns the principal component coefficients, scores, and variances using additional options for computation and handling of special data types, specified by one or more `Name, Value` pair arguments.

For example, you can introduce initial values for the residual variance, `v`, or change the termination criteria.

`[coeff,score,pcvar,mu] = ppca(___)` also returns the estimated mean of each variable in Y . You can use any of the input arguments in the previous syntaxes.

`[coeff,score,pcvar,mu,v,S] = ppca(___)` also returns the isotropic residual variance in v and the final results at convergence in structure S .

Examples

Perform Probabilistic Principal Component Analysis

Load the sample data.

```
load fisheriris
```

The double matrix `meas` consists of four types of measurements on the flowers, which, respectively, are the length and width of sepals and petals.

Introduce missing values randomly.

```
y = meas;
rng('default'); % for reproducibility
ix = random('unif',0,1,size(y))<0.20;
y(ix) = NaN;
```

Now, approximately 20% of the data is missing, indicated by NaN.

Perform probabilistic principal component analysis and request the component coefficients and variances.

```
[coeff,score,pcvar,mu] = ppca(y,3);
coeff
```

```
coeff = 4x3
```

```
    0.3562    0.6709   -0.5518
   -0.0765    0.7120    0.6332
    0.8592   -0.1597    0.0596
    0.3592   -0.1318    0.5395
```

```
pcvar
```

```
pcvar = 3×1  
  
    4.0914  
    0.2125  
    0.0617
```

Perform principal component analysis using the alternating least squares algorithm and request the component coefficients and variances.

```
[coeff2,score2,pcvar2,mu2] = pca(y,'algorithm','als',...  
'NumComponents',3);  
coeff2
```

```
coeff2 = 4×3  
  
    0.3376    0.4952    0.7406  
   -0.0731    0.8609   -0.4476  
    0.8657   -0.1168   -0.1233  
    0.3623   -0.0086   -0.4857
```

```
pcvar2  
  
pcvar2 = 3×1  
  
    4.0733  
    0.2652  
    0.1222
```

The coefficients and the variances of the first two principal components are similar.

Another way to compare the results is to find the angle between the two spaces spanned by the coefficient vectors.

```
subspace(coeff,coeff2)  
  
ans = 0.0884
```

The angle between the two spaces is pretty small. This indicates that these two results are close to each other.

Change the Termination Criteria for Probabilistic Principal Component Analysis

Load the sample data set.

```
load imports-85
```

Data matrix X has 13 continuous variables in columns 3 to 15: wheel-base, length, width, height, curb-weight, engine-size, bore, stroke, compression-ratio, horsepower, peak-rpm, city-mpg, and highway-mpg. The variables bore and stroke are missing four values in rows 56 to 59, and the variables horsepower and peak-rpm are missing two values in rows 131 and 132.

Perform probabilistic principal component analysis and display the first three principal components.

```
[coeff,score,pcvar] = ppca(X(:,3:15),3);
```

```
Warning: Maximum number of iterations 1000 reached.
```

Change the termination tolerance for the cost function to 0.01.

```
opt = statset('ppca');  
opt.TolFun = 0.01;
```

Perform probabilistic principal component analysis.

```
[coeff,score,pcvar] = ppca(X(:,3:15),3,'Options',opt);
```

```
Warning: Maximum number of iterations 1000 reached.
```

ppca now terminates before the maximum number of iterations is reached because it meets the tolerance for the cost function.

Reconstruct Observations

Load the sample data.

```
load hald  
y = ingredients;
```

The ingredients data has 13 observations for 4 variables.

Introduce missing values to the data.

```
y(2:16:end) = NaN;
```

Every 16th value is NaN. This corresponds to 7.69% of the data.

Find the first three principal components of data using PPCA and display the reconstructed observations.

```
[coeff,score,pcvar,mu,v,S] = ppca(y,3);
```

```
Warning: Maximum number of iterations 1000 reached.
```

S.Recon

```
ans = 13×4
```

```
    6.8536    25.8700    5.8389    59.8730
    1.0433    28.9710   14.9654    51.9738
   11.5770    56.5067    8.6352    20.5076
   11.0835    31.0722    8.0920    47.0748
    7.0679    52.2556    6.0748    33.0598
   11.0486    55.0430    9.0534    22.0423
    2.8493    70.8691   16.8339     5.8656
    1.0333    31.0281   19.6907    44.0306
    2.0400    54.0354   18.0440    22.0349
   20.7822    46.8091    3.7603    25.8081
      :
```

You can also reconstruct the observations using the principal components and the estimated mean.

```
t = score*coeff' + repmat(mu,13,1);
```

Results at Convergence

Load the data.

```
load hald
```

Here, `ingredients` is a real-valued matrix of predictor variables.

Perform the probabilistic principal components analysis and display coefficients.

```
[coeff,score,pcvariance,mu,v,S] = ppca(ingredients,3);
```

Warning: Maximum number of iterations 1000 reached.

coeff

coeff = 4×3

```
-0.0693   -0.6459    0.5673
-0.6786   -0.0184   -0.5440
 0.0308    0.7552    0.4036
 0.7306   -0.1102   -0.4684
```

Display the algorithm results at convergence of the PPCA.

S

```
S = struct with fields:
      W: [4x3 double]
      Xexp: [13x3 double]
      Recon: [13x4 double]
      v: 0.2372
      NumIter: 1000
      RMSResid: 0.2340
      nloglk: 149.3388
```

Display the matrix W.

S.W

ans = 4×3

```
 0.5624    2.0279    5.4075
 4.8320   -10.3894    5.9202
 -3.7521   -3.0555   -4.1552
 -1.5144   11.7122   -7.2564
```

Orthogonalizing W recovers the coefficients.

orth(S.W)

```
ans = 4×3
    -0.0693    0.6459    0.5673
    -0.6786    0.0184   -0.5440
     0.0308   -0.7552    0.4036
     0.7306    0.1102   -0.4684
```

Input Arguments

Y — Input data

n-by-*p* matrix

Input data for which to compute the principal components, specified as an *n*-by-*p* matrix. Rows of Y correspond to observations and columns correspond to variables.

Data Types: `single` | `double`

K — Number of principal components

positive integer value less than rank

Number of principal components to return, specified as an integer value less than the rank of data. The maximum possible rank is $\min(n,p)$, where *n* is the number of observations and *p* is the number of variables. However, if the data is correlated, the rank might be smaller than $\min(n,p)$.

`ppca` orders the components based on their variance.

If K is $\min(n,p)$, `ppca` sets K equal to $\min(n,p) - 1$, and 'W0' is truncated to $\min(p,n) - 1$ columns if you specify a *p*-by-*p* W0 matrix.

For example, you can request only the first three components, based on the component variance as follows.

Example: `coeff = ppca(Y,3)`

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes.

You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'W0', init, 'Options', opt` specifies that the initial values for `'W0'` are in matrix `init` and `ppca` uses the options defined by `opt`.

W0 — Initial value of W

matrix of random values (default) | p -by- k matrix

Initial value of W in the probabilistic principal component analysis on page 32-4875 algorithm, specified as a comma-separated pair consisting of `'W0'` and a p -by- k matrix.

Data Types: `single` | `double`

v0 — Initial value of residual variance

random number (default) | positive scalar value

Initial value of residual variance, specified as the comma-separated pair consisting of `'v0'` and a positive scalar value.

Data Types: `single` | `double`

Options — Options for iterations

structure

Options for the iterations, specified as a comma-separated pair `'Options'` and a structure created by the `statset` function. `ppca` uses the following fields in the options structure.

<code>'Display'</code>	Level of display output. Choices are <code>'off'</code> , <code>'final'</code> , and <code>'iter'</code> .
<code>'MaxIter'</code>	Maximum number of steps allowed. The default is 1000. Unlike in optimization settings, reaching the <code>MaxIter</code> value is regarded as convergence.
<code>'TolFun'</code>	Positive integer stating the termination tolerance for the cost function. The default is $1e-6$.
<code>'TolX'</code>	Positive integer stating the convergence threshold for the relative change in the elements of W . The default is $1e-6$.

You can change the values of these fields and specify the new structure in `ppca` using the `'Options'` name-value pair argument.

```
Example: opt = statset('ppca'); opt.MaxIter = 2000; coeff =  
ppca(Y,3,'Options',opt);
```

Data Types: struct

Output Arguments

coeff — Principal component coefficients

p-by-*k* matrix

Principal component coefficients, returned as a *p*-by-*k* matrix. Each column of **coeff** contains coefficients for one principal component. The columns are in the order of descending component variance, **pcvar**.

score — Principal component scores

n-by-*k* matrix

Principal component scores, returned as an *n*-by-*k* matrix. Rows of **score** correspond to observations, and columns correspond to components.

pcvar — Principal component variances

column vector

Principal component variances, which are the eigenvalues of the covariance matrix of *Y*, returned as a column vector.

mu — Estimated mean

row vector

Estimated mean of each variable in *Y*, returned as a row vector.

v — Isotropic residual variance

scalar value

Isotropic residual variance, returned as a scalar value.

S — Final results at convergence

structure

Final results at convergence, returned as a structure containing the following fields.

W	W at convergence.
Xexp	Conditional expectation of the estimated latent variable x .
Recon	Reconstructed observations using k principal components. This is a low dimension approximation of the input data Y , and is equal to $\mu + \text{score} * \text{coeff}'$.
v	Residual variance.
RMSResid	Root mean square of residuals.
NumIter	Number of iteration counts.
$n \log l k$	Negative loglikelihood function value.

Definitions

Probabilistic Principal Component Analysis

Probabilistic principal component analysis (PPCA) is a method to estimate the principal axes when any data vector has one or more missing values.

PPCA is based on an isotropic error model. It seeks to relate a p -dimensional observation vector y to a corresponding k -dimensional vector of latent (or unobserved) variable x , which is normal with mean zero and covariance $I(k)$. The relationship is

$$y^T = W * x^T + \mu + \varepsilon,$$

where y is the row vector of observed variable, x is the row vector of latent variables, and ε is the isotropic error term. ε is Gaussian with mean zero and covariance of $v * I(k)$, where v is the residual variance. Here, k needs to be smaller than the rank for the residual variance to be greater than 0 ($v > 0$). Standard principal component analysis, where the residual variance is zero, is the limiting case of PPCA. The observed variables, y , are conditionally independent given the values of the latent variables, x . So, the latent variables explain the correlations between the observation variables and the error explains the variability unique to a particular y_i . The p -by- k matrix W relates the latent and observation variables, and the vector μ permits the model to have a nonzero mean. PPCA assumes that the values are missing at random through the data set. This means that whether a data value is missing or not does not depend on the latent variable given the observed data values.

Under this model,

$$y \sim N(\mu, W * W^T + v * I(k)).$$

There is no closed-form analytical solution for W and v , so their estimates are determined by iterative maximization of the corresponding loglikelihood using an expectation-maximization (EM) algorithm. This EM algorithm handles missing values by treating them as additional latent variables. At convergence, the columns of W spans the subspace, but they are not orthonormal. `ppca` obtains the orthonormal coefficients, `coeff`, for the components by orthogonalization of W .

Introduced in R2013a

pdf

Package: prob

Probability density function

Syntax

```
y = pdf('name', x, A)
y = pdf('name', x, A, B)
y = pdf('name', x, A, B, C)
y = pdf('name', x, A, B, C, D)

y = pdf(pd, x)
```

Description

`y = pdf('name', x, A)` returns the probability density function (pdf) for the one-parameter distribution family specified by 'name' and the distribution parameter A, evaluated at the values in `x`.

`y = pdf('name', x, A, B)` returns the pdf for the two-parameter distribution family specified by 'name' and the distribution parameters A and B, evaluated at the values in `x`.

`y = pdf('name', x, A, B, C)` returns the pdf for the three-parameter distribution family specified by 'name' and the distribution parameters A, B, and C, evaluated at the values in `x`.

`y = pdf('name', x, A, B, C, D)` returns the pdf for the four-parameter distribution family specified by 'name' and the distribution parameters A, B, C, and D, evaluated at the values in `x`.

`y = pdf(pd, x)` returns the pdf of the probability distribution object `pd`, evaluated at the values in `x`.

Examples

Compute the Normal Distribution pdf

Create a standard normal distribution object with the mean μ equal to 0 and the standard deviation σ equal to 1.

```
mu = 0;  
sigma = 1;  
pd = makedist('Normal','mu',mu,'sigma',sigma);
```

Define the input vector x to contain the values at which to calculate the pdf.

```
x = [-2 -1 0 1 2];
```

Compute the pdf values for the standard normal distribution at the values in x .

```
y = pdf(pd,x)  
  
y = 1×5  
    0.0540    0.2420    0.3989    0.2420    0.0540
```

Each value in y corresponds to a value in the input vector x . For example, at the value x equal to 1, the corresponding pdf value y is equal to 0.2420.

Alternatively, you can compute the same pdf values without creating a probability distribution object. Use the `pdf` function, and specify a standard normal distribution using the same parameter values for μ and σ .

```
y2 = pdf('Normal',x,mu,sigma)  
  
y2 = 1×5  
    0.0540    0.2420    0.3989    0.2420    0.0540
```

The pdf values are the same as those computed using the probability distribution object.

Compute the Poisson Distribution pdf

Create a Poisson distribution object with the rate parameter, λ , equal to 2.

```
lambda = 2;  
pd = makedist('Poisson', 'lambda', lambda);
```

Define the input vector x to contain the values at which to calculate the pdf.

```
x = [0 1 2 3 4];
```

Compute the pdf values for the Poisson distribution at the values in x .

```
y = pdf(pd, x)
```

```
y = 1×5
```

```
    0.1353    0.2707    0.2707    0.1804    0.0902
```

Each value in y corresponds to a value in the input vector x . For example, at the value x equal to 3, the corresponding pdf value in y is equal to 0.1804.

Alternatively, you can compute the same pdf values without creating a probability distribution object. Use the `pdf` function, and specify a Poisson distribution using the same value for the rate parameter, λ .

```
y2 = pdf('Poisson', x, lambda)
```

```
y2 = 1×5
```

```
    0.1353    0.2707    0.2707    0.1804    0.0902
```

The pdf values are the same as those computed using the probability distribution object.

Plot the pdf of a Standard Normal Distribution

Create a standard normal distribution object.

```
pd = makedist('Normal')
```

```
pd =  
    NormalDistribution  
  
    Normal distribution  
        mu = 0  
        sigma = 1
```

Specify the x values and compute the pdf.

```
x = -3:.1:3;  
pdf_normal = pdf(pd,x);
```

Plot the pdf.

```
plot(x,pdf_normal,'LineWidth',2)
```

Plot the pdf of a Weibull Distribution

Create a Weibull probability distribution object.

```
pd = makedist('Weibull','a',5,'b',2)
```

```
pd =  
WeibullDistribution
```

```
Weibull distribution
```

```
A = 5
```

```
B = 2
```

Specify the x values and compute the pdf.

```
x = 0:.1:15;  
y = pdf(pd,x);
```

Plot the pdf.

```
plot(x,y,'LineWidth',2)
```

Input Arguments

'name' — Probability distribution name

character vector or string scalar of probability distribution name

Probability distribution name, specified as one of the probability distribution names in this table.

'name'	Distribution	Input Parameter A	Input Parameter B	Input Parameter C	Input Parameter D
'Beta'	"Beta Distribution" on page B-4	a first shape parameter	b second shape parameter	—	—
'Binomial'	"Binomial Distribution" on page B-9	n number of trials	p probability of success for each trial	—	—
'BirnbauSaunders'	"Birnbau-Saunders Distribution" on page B-13	β scale parameter	γ shape parameter	—	—

Example: 'Normal'

x — Values at which to evaluate pdf

scalar value | array of scalar values

Values at which to evaluate the pdf, specified as a scalar value or an array of scalar values.

If one or more of the input arguments x , A , B , C , and D are arrays, then the array sizes must be the same. In this case, pdf expands each scalar input into a constant array of the same size as the array inputs. See 'name' for the definitions of A , B , C , and D for each distribution.

Example: [-1,0,3,4]

Data Types: single | double

A — First probability distribution parameter

scalar value | array of scalar values

First probability distribution parameter, specified as a scalar value or an array of scalar values.

If one or more of the input arguments x , A , B , C , and D are arrays, then the array sizes must be the same. In this case, pdf expands each scalar input into a constant array of the same size as the array inputs. See 'name' for the definitions of A , B , C , and D for each distribution.

Data Types: `single` | `double`

B — Second probability distribution parameter

scalar value | array of scalar values

Second probability distribution parameter, specified as a scalar value or an array of scalar values.

If one or more of the input arguments x , A , B , C , and D are arrays, then the array sizes must be the same. In this case, `pdf` expands each scalar input into a constant array of the same size as the array inputs. See 'name' for the definitions of A , B , C , and D for each distribution.

Data Types: `single` | `double`

C — Third probability distribution parameter

scalar value | array of scalar values

Third probability distribution parameter, specified as a scalar value or an array of scalar values.

If one or more of the input arguments x , A , B , C , and D are arrays, then the array sizes must be the same. In this case, `pdf` expands each scalar input into a constant array of the same size as the array inputs. See 'name' for the definitions of A , B , C , and D for each distribution.

Data Types: `single` | `double`

D — Fourth probability distribution parameter

scalar value | array of scalar values

Fourth probability distribution parameter, specified as a scalar value or an array of scalar values.

If one or more of the input arguments x , A , B , C , and D are arrays, then the array sizes must be the same. In this case, `pdf` expands each scalar input into a constant array of the same size as the array inputs. See 'name' for the definitions of A , B , C , and D for each distribution.

Data Types: `single` | `double`

pd — Probability distribution

probability distribution object

Probability distribution, specified as a probability distribution object created with a function or app in this table.

Function or App	Description
<code>makedist</code>	Create a probability distribution object using specified parameter values.
<code>fitdist</code>	Fit a probability distribution object to sample data.
Distribution Fitter	Fit a probability distribution to sample data using the interactive Distribution Fitter app and export the fitted object to the workspace.
<code>paretotails</code>	Create a piecewise distribution object that has generalized Pareto distributions in the tails.

Output Arguments

y — pdf values

scalar value | array of scalar values

pdf values, returned as a scalar value or an array of scalar values. **y** is the same size as **x** after any necessary scalar expansion. Each element in **y** is the pdf value of the distribution, specified by the corresponding elements in the distribution parameters (A, B, C, and D) or specified by the probability distribution object (**pd**), evaluated at the corresponding element in **x**.

Alternative Functionality

- `pdf` is a generic function that accepts either a distribution by its name 'name' or a probability distribution object `pd`. It is faster to use a distribution-specific function, such as `normpdf` for the normal distribution and `binopdf` for the binomial distribution. For a list of distribution-specific functions, see “Supported Distributions” on page 5-20.
- Use the **Probability Distribution Function** app to create an interactive plot of the cumulative distribution function (cdf) or probability density function (pdf) for a probability distribution.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The input argument 'name' must be a compile-time constant. For example, to use the normal distribution, include `coder.Constant('Normal')` in the `-args` value of `codegen`.
- Code generation does not support the probability distribution object (pd) input argument.

For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “General Code Generation Workflow” on page 31-5.

Introduced before R2006a

pdf

Probability density function for Gaussian mixture distribution

Syntax

```
y = pdf(gm,X)
```

Description

`y = pdf(gm,X)` returns the probability density function (pdf) of the Gaussian mixture distribution `gm`, evaluated at the values in `X`.

Examples

Compute pdf Values

Create a `gmdistribution` object and compute its pdf values.

Define the distribution parameters (means and covariances) of a two-component bivariate Gaussian mixture distribution.

```
mu = [1 2;-3 -5];  
sigma = [1 1]; % shared diagonal covariance matrix
```

Create a `gmdistribution` object by using the `gmdistribution` function. By default, the function creates an equal proportion mixture.

```
gm = gmdistribution(mu,sigma)
```

```
gm =
```

```
Gaussian mixture distribution with 2 components in 2 dimensions  
Component 1:  
Mixing proportion: 0.500000  
Mean:      1      2
```

```
Component 2:
Mixing proportion: 0.500000
Mean:      -3      -5
```

Compute the pdf values of gm.

```
X = [0 0;1 2;3 3;5 3];
pdf(gm,X)
```

```
ans = 4×1
```

```
    0.0065
    0.0796
    0.0065
    0.0000
```

Plot pdf

Create a gmdistribution object and plot its pdf.

Define the distribution parameters (means, covariances, and mixing proportions) of two bivariate Gaussian mixture components.

```
p = [0.4 0.6];           % Mixing proportions
mu = [1 2;-3 -5];       % Means
sigma = cat(3,[2 .5],[1 1]) % Covariances 1-by-2-by-2 array
```

```
sigma =
sigma(:,:,1) =
    2.0000    0.5000
```

```
sigma(:,:,2) =
    1    1
```

The `cat` function concatenates the covariances along the third array dimension. The defined covariance matrices are diagonal matrices. `sigma(1,:,i)` contains the diagonal elements of the covariance matrix of component `i`.

Create a `gmdistribution` object by using the `gmdistribution` function.

```
gm = gmdistribution(mu,sigma)
```

```
gm =
```

```
Gaussian mixture distribution with 2 components in 2 dimensions
```

```
Component 1:
```

```
Mixing proportion: 0.500000
```

```
Mean:      1      2
```

```
Component 2:
```

```
Mixing proportion: 0.500000
```

```
Mean:     -3     -5
```

Plot the pdf of the Gaussian mixture distribution by using `fsurf`.

```
fsurf(@(x,y) reshape(pdf(gm,[x(:),y(:)]),size(x)),-10 10)
```

Input Arguments

gm — Gaussian mixture distribution

`gmdistribution` object

Gaussian mixture distribution, also called Gaussian mixture model (GMM), specified as a `gmdistribution` object.

You can create a `gmdistribution` object using `gmdistribution` or `fitgmdist`. Use the `gmdistribution` function to create a `gmdistribution` object by specifying the

distribution parameters. Use the `fitgmdist` function to fit a `gmdistribution` model to data given a fixed number of components.

X — Values at which to evaluate pdf

n-by-*m* numeric matrix

Values at which to evaluate the pdf, specified as an *n*-by-*m* numeric matrix, where *n* is the number of observations and *m* is the number of variables in each observation.

Data Types: `single` | `double`

Output Arguments

y — pdf values

n-by-1 numeric vector

pdf values of the Gaussian mixture distribution `gm`, evaluated at `X`, returned as an *n*-by-1 numeric vector, where *n* is the number of observations in `X`.

The `pdf` function computes the pdf values by using the likelihood of each component given each observation and the component probabilities.

$$y(i) = \sum_{j=1}^k L(C_j|O_i)P(C_j),$$

where $L(C_j|O_i)$ is the likelihood of component *j* given observation *i*, and $P(C_j)$ is the probability of component *j*. The `pdf` function computes the likelihood term by using the multivariate normal pdf of the *j*th Gaussian mixture component evaluated at observation *i*. The component probabilities are the mixing proportions of mixture components, the `ComponentProportion` property of `gm`.

Introduced in R2007b

pdist

Pairwise distance between pairs of observations

Syntax

```
D = pdist(X)
D = pdist(X,Distance)
D = pdist(X,Distance,DistParameter)
```

Description

`D = pdist(X)` returns the Euclidean distance between pairs of observations in `X`.

`D = pdist(X,Distance)` returns the distance by using the method specified by `Distance`.

`D = pdist(X,Distance,DistParameter)` returns the distance by using the method specified by `Distance` and `DistParameter`. You can specify `DistParameter` only when `Distance` is 'seuclidean', 'minkowski', or 'mahalanobis'.

Examples

Compute Euclidean Distance and Convert Distance Vector to Matrix

Compute the Euclidean distance between pairs of observations, and convert the distance vector to a matrix using `squareform`.

Create a matrix with three observations and two variables.

```
rng('default') % For reproducibility
X = rand(3,2);
```

Compute the Euclidean distance.

```
D = pdist(X)
```

```
D = 1×3
    0.2954    1.0670    0.9448
```

The pairwise distances are arranged in the order (2,1), (3,1), (3,2). You can easily locate the distance between observations *i* and *j* by using `squareform`.

```
Z = squareform(D)
Z = 3×3
     0    0.2954    1.0670
0.2954     0    0.9448
1.0670    0.9448     0
```

`squareform` returns a symmetric matrix where `Z(i, j)` corresponds to the pairwise distance between observations *i* and *j*. For example, you can find the distance between observations 2 and 3.

```
Z(2,3)
ans = 0.9448
```

Pass `Z` to the `squareform` function to reproduce the output of the `pdist` function.

```
y = squareform(Z)
y = 1×3
    0.2954    1.0670    0.9448
```

The outputs `y` from `squareform` and `D` from `pdist` are the same.

Compute Minkowski Distance

Create a matrix with three observations and two variables.

```
rng('default') % For reproducibility
X = rand(3,2);
```

Compute the Minkowski distance with the default exponent 2.

```
D1 = pdist(X, 'minkowski')  
D1 = 1×3  
    0.2954    1.0670    0.9448
```

Compute the Minkowski distance with an exponent of 1, which is equal to the city block distance.

```
D2 = pdist(X, 'minkowski', 1)  
D2 = 1×3  
    0.3721    1.5036    1.3136
```

```
D3 = pdist(X, 'cityblock')  
D3 = 1×3  
    0.3721    1.5036    1.3136
```

Compute Pairwise Distance with Missing Elements Using a Custom Distance Function

Define a custom distance function that ignores coordinates with NaN values, and compute pairwise distance by using the custom distance function.

Create a matrix with three observations and two variables.

```
rng('default') % For reproducibility  
X = rand(3,2);
```

Assume that the first element of the first observation is missing.

```
X(1,1) = NaN;
```

Compute the Euclidean distance.

```
D1 = pdist(X)
```

```
D1 =
```

```
NaN NaN 0.9448
```

If observation *i* or *j* contains **NaN** values, the function `pdist` returns **NaN** for the pairwise distance between *i* and *j*. Therefore, `D1(1)` and `D1(2)`, the pairwise distances (2,1) and (3,1), are **NaN** values.

Define a custom distance function `naneucdist` that ignores coordinates with **NaN** values and returns the Euclidean distance.

```
function D2 = naneucdist(XI,XJ)
%NANEUCDIST Euclidean distance ignoring coordinates with NaNs
n = size(XI,2);
sqdx = (XI-XJ).^2;
nstar = sum(~isnan(sqdx),2); % Number of pairs that do not contain NaNs
nstar(nstar == 0) = NaN; % To return NaN if all pairs include NaNs
D2squared = nansum(sqdx,2).*n./nstar; % Correction for missing coordinates
D2 = sqrt(D2squared);
```

Compute the distance with `naneucdist` by passing the function handle as an input argument of `pdist`.

```
D2 = pdist(X,@naneucdist)
```

```
D2 =
```

```
0.3974 1.1538 0.9448
```

Input Arguments

X — Input data

numeric matrix

Input data, specified as a numeric matrix of size m -by- n . Rows correspond to individual observations, and columns correspond to individual variables.

Data Types: `single` | `double`

Distance — Distance metric

character vector | string scalar | function handle

Distance metric, specified as a character vector, string scalar, or function handle, as described in the following table.

Value	Description
'euclidean'	Euclidean distance (default).
'squaredeuclidean'	Squared Euclidean distance. (This option is provided for efficiency only. It does not satisfy the triangle inequality.)
'seuclidean'	Standardized Euclidean distance. Each coordinate difference between observations is scaled by dividing by the corresponding element of the standard deviation, $S = \text{nanstd}(X)$. Use <code>DistParameter</code> to specify another value for S .
'mahalanobis'	Mahalanobis distance using the sample covariance of X , $C = \text{nancov}(X)$. Use <code>DistParameter</code> to specify another value for C , where the matrix C is symmetric and positive definite.
'cityblock'	City block distance.
'minkowski'	Minkowski distance. The default exponent is 2. Use <code>DistParameter</code> to specify a different exponent P , where P is a positive scalar value of the exponent.
'chebychev'	Chebychev distance (maximum coordinate difference).
'cosine'	One minus the cosine of the included angle between points (treated as vectors).
'correlation'	One minus the sample correlation between points (treated as sequences of values).
'hamming'	Hamming distance, which is the percentage of coordinates that differ.
'jaccard'	One minus the Jaccard coefficient, which is the percentage of nonzero coordinates that differ.

Value	Description
'spearman'	One minus the sample Spearman's rank correlation between observations (treated as sequences of values).
@ <i>distfun</i>	<p>Custom distance function handle. A distance function has the form</p> <pre>function D2 = distfun(ZI,ZJ) % calculation of distance ...</pre> <p>where</p> <ul style="list-style-type: none"> • ZI is a 1-by-n vector containing a single observation. • ZJ is an m2-by-n matrix containing multiple observations. <code>distfun</code> must accept a matrix ZJ with an arbitrary number of observations. • D2 is an m2-by-1 vector of distances, and D2(k) is the distance between observations ZI and ZJ(k, :). <p>If your data is not sparse, you can generally compute distance more quickly by using a built-in distance instead of a function handle.</p>

For definitions, see “Distance Metrics” on page 32-4902.

When you use 'seuclidean', 'minkowski', or 'mahalanobis', you can specify an additional input argument `DistParameter` to control these metrics. You can also use these metrics in the same way as the other metrics with a default value of `DistParameter`.

Example: 'minkowski'

DistParameter — Distance metric parameter values

positive scalar | numeric vector | numeric matrix

Distance metric parameter values, specified as a positive scalar, numeric vector, or numeric matrix. This argument is valid only when you specify `Distance` as 'seuclidean', 'minkowski', or 'mahalanobis'.

- If `Distance` is 'seuclidean', `DistParameter` is a vector of scaling factors for each dimension, specified as a positive vector. The default value is `nanstd(X)`.

- If `Distance` is 'minkowski', `DistParameter` is the exponent of Minkowski distance, specified as a positive scalar. The default value is 2.
- If `Distance` is 'mahalanobis', `DistParameter` is a covariance matrix, specified as a numeric matrix. The default value is `nancov(X)`. `DistParameter` must be symmetric and positive definite.

Example: 'minkowski',3

Data Types: single | double

Output Arguments

D — Pairwise distances

numeric row vector

Pairwise distances, returned as a numeric row vector of length $m(m-1)/2$, corresponding to pairs of observations, where m is the number of observations in X .

The distances are arranged in the order (2,1), (3,1), ..., (m,1), (3,2), ..., (m,2), ..., (m,m-1), i.e., the lower-left triangle of the m -by- m distance matrix in column order. The pairwise distance between observations i and j is in $D((i-1)*(m-i/2)+j-i)$ for $i \leq j$.

You can convert D into a symmetric matrix by using the `squareform` function. $Z = \text{squareform}(D)$ returns an m -by- m matrix where $Z(i, j)$ corresponds to the pairwise distance between observations i and j .

If observation i or j contains NaNs, then the corresponding value in D is NaN for the built-in distance functions.

D is commonly used as a dissimilarity matrix in clustering or multidimensional scaling. For details, see “Hierarchical Clustering” on page 16-4 and the function reference pages for `cmdscale`, `cophenet`, `linkage`, `mdscale`, and `optimalleaforder`. These functions take D as an input argument.

Definitions

Distance Metrics

A distance metric is a function that defines a distance between two observations. `pdist` supports various distance metrics: Euclidean distance, standardized Euclidean distance,

Mahalanobis distance, city block distance, Minkowski distance, Chebychev distance, cosine distance, correlation distance, Hamming distance, Jaccard distance, and Spearman distance.

Given an m -by- n data matrix X , which is treated as m (1-by- n) row vectors x_1, x_2, \dots, x_m , the various distances between the vector x_s and x_t are defined as follows:

- Euclidean distance

$$d_{st}^2 = (x_s - x_t)(x_s - x_t)'$$

The Euclidean distance is a special case of the Minkowski distance, where $p = 2$.

- Standardized Euclidean distance

$$d_{st}^2 = (x_s - x_t)V^{-1}(x_s - x_t)'$$

where V is the n -by- n diagonal matrix whose j th diagonal element is $(S(j))^2$, where S is a vector of scaling factors for each dimension.

- Mahalanobis distance

$$d_{st}^2 = (x_s - x_t)C^{-1}(x_s - x_t)'$$

where C is the covariance matrix.

- City block distance

$$d_{st} = \sum_{j=1}^n |x_{sj} - x_{tj}|$$

The city block distance is a special case of the Minkowski distance, where $p = 1$.

- Minkowski distance

$$d_{st} = \sqrt[p]{\sum_{j=1}^n |x_{sj} - x_{tj}|^p}$$

For the special case of $p = 1$, the Minkowski distance gives the city block distance. For the special case of $p = 2$, the Minkowski distance gives the Euclidean distance. For the special case of $p = \infty$, the Minkowski distance gives the Chebychev distance.

- Chebychev distance

$$d_{st} = \max_j \{|x_{sj} - x_{tj}|\}.$$

The Chebychev distance is a special case of the Minkowski distance, where $p = \infty$.

- Cosine distance

$$d_{st} = 1 - \frac{x_s x_t'}{\sqrt{(x_s x_s')(x_t x_t')}}.$$

- Correlation distance

$$d_{st} = 1 - \frac{(x_s - \bar{x}_s)(x_t - \bar{x}_t)'}{\sqrt{(x_s - \bar{x}_s)(x_s - \bar{x}_s)'}\sqrt{(x_t - \bar{x}_t)(x_t - \bar{x}_t)'}}.$$

where

$$\bar{x}_s = \frac{1}{n} \sum_j x_{sj} \text{ and } \bar{x}_t = \frac{1}{n} \sum_j x_{tj}.$$

- Hamming distance

$$d_{st} = (\#(x_{sj} \neq x_{tj})/n).$$

- Jaccard distance

$$d_{st} = \frac{\#[(x_{sj} \neq x_{tj}) \cap ((x_{sj} \neq 0) \cup (x_{tj} \neq 0))]}{\#[(x_{sj} \neq 0) \cup (x_{tj} \neq 0)]}.$$

- Spearman distance

$$d_{st} = 1 - \frac{(r_s - \bar{r}_s)(r_t - \bar{r}_t)'}{\sqrt{(r_s - \bar{r}_s)(r_s - \bar{r}_s)'}\sqrt{(r_t - \bar{r}_t)(r_t - \bar{r}_t)'}}.$$

where

- r_{sj} is the rank of x_{sj} taken over $x_{1j}, x_{2j}, \dots, x_{mj}$, as computed by `tiedrank`.
- r_s and r_t are the coordinate-wise rank vectors of x_s and x_t , i.e., $r_s = (r_{s1}, r_{s2}, \dots, r_{sn})$.
- $\bar{r}_s = \frac{1}{n} \sum_j r_{sj} = \frac{(n+1)}{2}$.
- $\bar{r}_t = \frac{1}{n} \sum_j r_{tj} = \frac{(n+1)}{2}$.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The distance input argument value (`Distance`) must be a compile-time constant. For example, to use the Minkowski distance, include `coder.Constant('Minkowski')` in the `-args` value of `codegen`.
- The distance input argument value (`Distance`) cannot be a custom distance function.
- The generated code of `pdist` uses `parfor` to create loops that run in parallel on supported shared-memory multicore platforms in the generated code. If your compiler does not support the Open Multiprocessing (OpenMP) application interface or you disable OpenMP library, MATLAB Coder treats the `parfor`-loops as `for`-loops. To find supported compilers, see https://www.mathworks.com/support/compilers/current_release/. To disable OpenMP library, set the `EnableOpenMP` property of the configuration object to `false`. For details, see `coder.CodeConfig`.
- You can generate optimized CUDA® code using GPU Coder™. The supported distance input argument values (`Distance`) for optimized CUDA code are `'euclidean'`, `'squaredeuclidean'`, `'seuclidean'`, `'cityblock'`, `'minkowski'`, `'chebychev'`, `'cosine'`, `'correlation'`, `'hamming'`, and `'jaccard'`. For more information on GPU coder, see “Getting Started with GPU Coder” (GPU Coder) and “Supported Functions” (GPU Coder).

For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “General Code Generation Workflow” on page 31-5.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Usage notes and limitations:

- The `Distance` argument must be specified as a character vector.

For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

Introduced before R2006a

pdist2

Pairwise distance between two sets of observations

Syntax

```
D = pdist2(X,Y,Distance)
```

```
D = pdist2(X,Y,Distance,DistParameter)
```

```
D = pdist2(___,Name,Value)
```

```
[D,I] = pdist2(___,Name,Value)
```

Description

`D = pdist2(X,Y,Distance)` returns the distance between each pair of observations in `X` and `Y` using the metric specified by `Distance`.

`D = pdist2(X,Y,Distance,DistParameter)` returns the distance using the metric specified by `Distance` and `DistParameter`. You can specify `DistParameter` only when `Distance` is 'seuclidean', 'minkowski', or 'mahalanobis'.

`D = pdist2(___,Name,Value)` specifies an additional option using one of the name-value pair arguments 'Smallest' or 'Largest' in addition to any of the arguments in the previous syntaxes.

For example,

- `D = pdist2(X,Y,Distance,'Smallest',K)` computes the distance using the metric specified by `Distance` and returns the `K` smallest pairwise distances to observations in `X` for each observation in `Y` in ascending order.
- `D = pdist2(X,Y,Distance,DistParameter,'Largest',K)` computes the distance using the metric specified by `Distance` and `DistParameter` and returns the `K` largest pairwise distances in descending order.

`[D,I] = pdist2(____, Name, Value)` also returns the matrix `I` using any of the arguments in the previous syntaxes. The matrix `I` contains the indices of the observations in `X` corresponding to the distances in `D`.

Examples

Compute Euclidean Distance

Create two matrices with three observations and two variables.

```
rng('default') % For reproducibility
X = rand(3,2);
Y = rand(3,2);
```

Compute the Euclidean distance. The default value of the input argument `Distance` is `'euclidean'`. When computing the Euclidean distance without using a name-value pair argument, you do not need to specify `Distance`.

```
D = pdist2(X,Y)

D = 3×3

    0.5387    0.8018    0.1538
    0.7100    0.5951    0.3422
    0.8805    0.4242    1.2050
```

`D(i, j)` corresponds to the pairwise distance between observation `i` in `X` and observation `j` in `Y`.

Compute Minkowski Distance

Create two matrices with three observations and two variables.

```
rng('default') % For reproducibility
X = rand(3,2);
Y = rand(3,2);
```

Compute the Minkowski distance with the default exponent 2.

```
D1 = pdist2(X,Y,'minkowski')
```

```
D1 = 3×3
```

```
    0.5387    0.8018    0.1538
    0.7100    0.5951    0.3422
    0.8805    0.4242    1.2050
```

Compute the Minkowski distance with an exponent of 1, which is equal to the city block distance.

```
D2 = pdist2(X,Y,'minkowski',1)
```

```
D2 = 3×3
```

```
    0.5877    1.0236    0.2000
    0.9598    0.8337    0.3899
    1.0189    0.4800    1.7036
```

```
D3 = pdist2(X,Y,'cityblock')
```

```
D3 = 3×3
```

```
    0.5877    1.0236    0.2000
    0.9598    0.8337    0.3899
    1.0189    0.4800    1.7036
```

Find the Two Smallest Pairwise Distances

Create two matrices with three observations and two variables.

```
rng('default') % For reproducibility
X = rand(3,2);
Y = rand(3,2);
```

Find the two smallest pairwise Euclidean distances to observations in X for each observation in Y.

```
[D,I] = pdist2(X,Y,'euclidean','Smallest',2)
```

```
D = 2×3
    0.5387    0.4242    0.1538
    0.7100    0.5951    0.3422
```

```
I = 2×3
     1     3     1
     2     2     2
```

For each observation in *Y*, `pdist2` finds the two smallest distances by computing and comparing the distance values to all the observations in *X*. The function then sorts the distances in each column of *D* in ascending order. *I* contains the indices of the observations in *X* corresponding to the distances in *D*.

Compute Pairwise Distance with Missing Elements Using a Custom Distance Function

Define a custom distance function that ignores coordinates with NaN values, and compute pairwise distance by using the custom distance function.

Create two matrices with three observations and three variables.

```
rng('default') % For reproducibility
X = rand(3,3)
Y = [X(:,1:2) rand(3,1)]
```

```
X =
    0.8147    0.9134    0.2785
    0.9058    0.6324    0.5469
    0.1270    0.0975    0.9575
```

```
Y =
    0.8147    0.9134    0.9649
    0.9058    0.6324    0.1576
```

```
0.1270    0.0975    0.9706
```

The first two columns of X and Y are identical. Assume that X(1,1) is missing.

```
X(1,1) = NaN
```

```
X =
```

```
      NaN    0.9134    0.2785
0.9058    0.6324    0.5469
0.1270    0.0975    0.9575
```

Compute the Hamming distance.

```
D1 = pdist2(X,Y,'hamming')
```

```
D1 =
```

```
      NaN      NaN      NaN
1.0000    0.3333    1.0000
1.0000    1.0000    0.3333
```

If observation *i* in X or observation *j* in Y contains NaN values, the function `pdist2` returns NaN for the pairwise distance between *i* and *j*. Therefore, D1(1,1), D1(1,2), and D1(1,3) are NaN values.

Define a custom distance function `nanhamdist` that ignores coordinates with NaN values and computes the Hamming distance. When working with a large number of observations, you can compute the distance more quickly by looping over coordinates of the data.

```
function D2 = nanhamdist(XI,XJ)
%NANHAMDIST Hamming distance ignoring coordinates with NaNs
[m,p] = size(XJ);
nesum = zeros(m,1);
pstar = zeros(m,1);
for q = 1:p
    notnan = ~(isnan(XI(q)) | isnan(XJ(:,q)));
    nesum = nesum + ((XI(q) ~= XJ(:,q)) & notnan);
    pstar = pstar + notnan;
```

```
end  
D2 = nesum./pstar;
```

Compute the distance with `nanhamdist` by passing the function handle as an input argument of `pdist2`.

```
D2 = pdist2(X,Y,@nanhamdist)
```

```
D2 =  
  
    0.5000    1.0000    1.0000  
    1.0000    0.3333    1.0000  
    1.0000    1.0000    0.3333
```

Assign New Data to Existing Clusters and Generate C/C++ Code

`kmeans` performs k -means clustering to partition data into k clusters. When you have a new data set to cluster, you can create new clusters that include the existing data and the new data by using `kmeans`. The `kmeans` function supports C/C++ code generation, so you can generate code that accepts training data and returns clustering results, and then deploy the code to a device. In this workflow, you must pass training data, which can be of considerable size. To save memory on the device, you can separate training and prediction by using `kmeans` and `pdist2`, respectively.

Use `kmeans` to create clusters in MATLAB® and use `pdist2` in the generated code to assign new data to existing clusters. For code generation, define an entry-point function that accepts the cluster centroid positions and the new data set, and returns the index of the nearest cluster. Then, generate code for the entry-point function.

Generating C/C++ code requires MATLAB® Coder™.

Perform k -Means Clustering

Generate a training data set using three distributions.

```
rng('default') % For reproducibility  
X = [randn(100,2)*0.75+ones(100,2);  
     randn(100,2)*0.5-ones(100,2);  
     randn(100,2)*0.75];
```

Partition the training data into three clusters by using kmeans.

```
[idx,C] = kmeans(X,3);
```

Plot the clusters and the cluster centroids.

```
figure  
gscatter(X(:,1),X(:,2),idx,'bgm')  
hold on  
plot(C(:,1),C(:,2),'kx')  
legend('Cluster 1','Cluster 2','Cluster 3','Cluster Centroid')
```

Assign New Data to Existing Clusters

Generate a test data set.

```
Xtest = [randn(10,2)*0.75+ones(10,2);
         randn(10,2)*0.5-ones(10,2);
         randn(10,2)*0.75];
```

Classify the test data set using the existing clusters. Find the nearest centroid from each test data point by using `pdist2`.

```
[~,idx_test] = pdist2(C,Xtest,'euclidean','Smallest',1);
```

Plot the test data and label the test data using `idx_test` by using `gscatter`.

```
gscatter(Xtest(:,1),Xtest(:,2),idx_test,'bgm','ooo')
legend('Cluster 1','Cluster 2','Cluster 3','Cluster Centroid', ...
      'Data classified to Cluster 1','Data classified to Cluster 2', ...
      'Data classified to Cluster 3')
```

Generate Code

Generate C code that assigns new data to the existing clusters. Note that generating C/C++ code requires MATLAB® Coder™.

Define an entry-point function named `findNearestCentroid` that accepts centroid positions and new data, and then find the nearest cluster by using `pdist2`.

Add the `%#codegen` compiler directive (or pragma) to the entry-point function after the function signature to indicate that you intend to generate code for the MATLAB algorithm. Adding this directive instructs the MATLAB Code Analyzer to help you diagnose and fix violations that would cause errors during code generation.

```
type findNearestCentroid % Display contents of findNearestCentroid.m

function idx = findNearestCentroid(C,X) %#codegen
[~,idx] = pdist2(C,X,'euclidean','Smallest',1); % Find the nearest centroid
```

Note: If you click the button located in the upper-right section of this page and open this example in MATLAB®, then MATLAB® opens the example folder. This folder includes the entry-point function file.

Generate code by using `codegen`. Because C and C++ are statically typed languages, you must determine the properties of all variables in the entry-point function at compile time. To specify the data type and array size of the inputs of `findNearestCentroid`, pass a MATLAB expression that represents the set of values with a certain data type and array size by using the `-args` option. For details, see “Specify Variable-Size Arguments for Code Generation” on page 31-58.

```
codegen findNearestCentroid -args {C,Xtest}
```

Warning: C Compiler produced warnings. See the build log for further details.

Code generation successful (with warnings): To view the report, open('codegen\mex\findNearestCentroid_mex')

`codegen` generates the MEX function `findNearestCentroid_mex` with a platform-dependent extension.

Verify the generated code.

```
myIdx = findNearestCentroid(C,Xtest);
myIndex_mex = findNearestCentroid_mex(C,Xtest);
verifyMEX = isequal(idx_test,myIdx,myIndex_mex)
```

```
verifyMEX = logical
    1
```

`isequal` returns logical 1 (true), which means all the inputs are equal. The comparison confirms that the `pdist2` function, the `findNearestCentroid` function, and the MEX function return the same index.

You can also generate optimized CUDA® code using GPU Coder™.

```
cfg = coder.gpuConfig('mex');
codegen -config cfg findNearestCentroid -args {C,Xtest}
```

For more information on code generation, see “General Code Generation Workflow” on page 31-5. For more information on GPU coder, see “Getting Started with GPU Coder” (GPU Coder) and “Supported Functions” (GPU Coder).

Input Arguments

X, Y — Input data

numeric matrix

Input data, specified as a numeric matrix. *X* is an *m*x-by-*n* matrix and *Y* is an *m*y-by-*n* matrix. Rows correspond to individual observations, and columns correspond to individual variables.

Data Types: `single` | `double`

Distance — Distance metric

character vector | string scalar | function handle

Distance metric, specified as a character vector, string scalar, or function handle, as described in the following table.

Value	Description
'euclidean'	Euclidean distance (default).
'squaredeuclidean'	Squared Euclidean distance. (This option is provided for efficiency only. It does not satisfy the triangle inequality.)

Value	Description
'seuclidean'	Standardized Euclidean distance. Each coordinate difference between observations is scaled by dividing by the corresponding element of the standard deviation, $S = \text{nanstd}(X)$. Use <code>DistParameter</code> to specify another value for S .
'mahalanobis'	Mahalanobis distance using the sample covariance of X , $C = \text{nancov}(X)$. Use <code>DistParameter</code> to specify another value for C , where the matrix C is symmetric and positive definite.
'cityblock'	City block distance.
'minkowski'	Minkowski distance. The default exponent is 2. Use <code>DistParameter</code> to specify a different exponent P , where P is a positive scalar value of the exponent.
'chebychev'	Chebychev distance (maximum coordinate difference).
'cosine'	One minus the cosine of the included angle between points (treated as vectors).
'correlation'	One minus the sample correlation between points (treated as sequences of values).
'hamming'	Hamming distance, which is the percentage of coordinates that differ.
'jaccard'	One minus the Jaccard coefficient, which is the percentage of nonzero coordinates that differ.
'spearman'	One minus the sample Spearman's rank correlation between observations (treated as sequences of values).

Value	Description
@ <i>distfun</i>	<p>Custom distance function handle. A distance function has the form</p> <pre>function D2 = distfun(ZI,ZJ) % calculation of distance ...</pre> <p>where</p> <ul style="list-style-type: none"> • ZI is a 1-by-n vector containing a single observation. • ZJ is an m2-by-n matrix containing multiple observations. <code>distfun</code> must accept a matrix ZJ with an arbitrary number of observations. • D2 is an m2-by-1 vector of distances, and D2(k) is the distance between observations ZI and ZJ(k, :). <p>If your data is not sparse, you can generally compute distance more quickly by using a built-in distance instead of a function handle.</p>

For definitions, see “Distance Metrics” on page 32-4920.

When you use 'seuclidean', 'minkowski', or 'mahalanobis', you can specify an additional input argument `DistParameter` to control these metrics. You can also use these metrics in the same way as the other metrics with a default value of `DistParameter`.

Example: 'minkowski'

DistParameter — Distance metric parameter values

positive scalar | numeric vector | numeric matrix

Distance metric parameter values, specified as a positive scalar, numeric vector, or numeric matrix. This argument is valid only when you specify `Distance` as 'seuclidean', 'minkowski', or 'mahalanobis'.

- If `Distance` is 'seuclidean', `DistParameter` is a vector of scaling factors for each dimension, specified as a positive vector. The default value is `nanstd(X)`.
- If `Distance` is 'minkowski', `DistParameter` is the exponent of Minkowski distance, specified as a positive scalar. The default value is 2.

- If `Distance` is `'mahalanobis'`, `DistParameter` is a covariance matrix, specified as a numeric matrix. The default value is `nancov(X)`. `DistParameter` must be symmetric and positive definite.

Example: `'minkowski',3`

Data Types: `single | double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: Either `'Smallest',K` or `'Largest',K`. You cannot use both `'Smallest'` and `'Largest'`.

Smallest — Number of smallest distances to find

positive integer

Number of smallest distances to find, specified as the comma-separated pair consisting of `'Smallest'` and a positive integer. If you specify `'Smallest'`, then `pdist2` sorts the distances in each column of `D` in ascending order.

Example: `'Smallest',3`

Data Types: `single | double`

Largest — Number of largest distances to find

positive integer

Number of largest distances to find, specified as the comma-separated pair consisting of `'Largest'` and a positive integer. If you specify `'Largest'`, then `pdist2` sorts the distances in each column of `D` in descending order.

Example: `'Largest',3`

Data Types: `single | double`

Output Arguments

D — Pairwise distances

numeric matrix

Pairwise distances, returned as a numeric matrix.

If you do not specify either 'Smallest' or 'Largest', then D is an m_x -by- m_y matrix, where m_x and m_y are the number of observations in X and Y, respectively. $D(i, j)$ is the distance between observation i in X and observation j in Y. If observation i in X or observation j in Y contains NaN, then $D(i, j)$ is NaN for the built-in distance functions.

If you specify either 'Smallest' or 'Largest' as K, then D is a K-by- m_y matrix. D contains either the K smallest or K largest pairwise distances to observations in X for each observation in Y. For each observation in Y, `pdist2` finds the K smallest or largest distances by computing and comparing the distance values to all the observations in X. If K is greater than m_x , `pdist2` returns an m_x -by- m_y matrix.

I — Sort index

positive integer matrix

Sort index, returned as a positive integer matrix. I is the same size as D. I contains the indices of the observations in X corresponding to the distances in D.

Definitions

Distance Metrics

A distance metric is a function that defines a distance between two observations. `pdist2` supports various distance metrics: Euclidean distance, standardized Euclidean distance, Mahalanobis distance, city block distance, Minkowski distance, Chebychev distance, cosine distance, correlation distance, Hamming distance, Jaccard distance, and Spearman distance.

Given an m_x -by- n data matrix X, which is treated as m_x (1-by- n) row vectors x_1, x_2, \dots, x_{m_x} , and an m_y -by- n data matrix Y, which is treated as m_y (1-by- n) row vectors y_1, y_2, \dots, y_{m_y} , the various distances between the vector x_s and y_t are defined as follows:

- Euclidean distance

$$d_{st}^2 = (x_s - y_t)(x_s - y_t)'.$$

The Euclidean distance is a special case of the Minkowski distance, where $p = 2$.

- Standardized Euclidean distance

$$d_{st}^2 = (x_s - y_t)V^{-1}(x_s - y_t)',$$

where V is the n -by- n diagonal matrix whose j th diagonal element is $(S(j))^2$, where S is a vector of scaling factors for each dimension.

- Mahalanobis distance

$$d_{st}^2 = (x_s - y_t)C^{-1}(x_s - y_t)',$$

where C is the covariance matrix.

- City block distance

$$d_{st} = \sum_{j=1}^n |x_{sj} - y_{tj}|.$$

The city block distance is a special case of the Minkowski distance, where $p = 1$.

- Minkowski distance

$$d_{st} = \sqrt[p]{\sum_{j=1}^n |x_{sj} - y_{tj}|^p}.$$

For the special case of $p = 1$, the Minkowski distance gives the city block distance. For the special case of $p = 2$, the Minkowski distance gives the Euclidean distance. For the special case of $p = \infty$, the Minkowski distance gives the Chebychev distance.

- Chebychev distance

$$d_{st} = \max_j \{|x_{sj} - y_{tj}|\}.$$

The Chebychev distance is a special case of the Minkowski distance, where $p = \infty$.

- Cosine distance

$$d_{st} = \left(1 - \frac{x_s y_t'}{\sqrt{(x_s x_s')(y_t y_t')}}\right).$$

- Correlation distance

$$d_{st} = 1 - \frac{(x_s - \bar{x}_s)(y_t - \bar{y}_t)'}{\sqrt{(x_s - \bar{x}_s)(x_s - \bar{x}_s)}\sqrt{(y_t - \bar{y}_t)(y_t - \bar{y}_t)'}}$$

where

$$\bar{x}_s = \frac{1}{n} \sum_j x_{sj}$$

and

$$\bar{y}_t = \frac{1}{n} \sum_j y_{tj}.$$

- Hamming distance

$$d_{st} = (\# (x_{sj} \neq y_{tj})/n).$$

- Jaccard distance

$$d_{st} = \frac{\# [(x_{sj} \neq y_{tj}) \cap ((x_{sj} \neq 0) \cup (y_{tj} \neq 0))]}{\# [(x_{sj} \neq 0) \cup (y_{tj} \neq 0)]}.$$

- Spearman distance

$$d_{st} = 1 - \frac{(r_s - \bar{r}_s)(r_t - \bar{r}_t)'}{\sqrt{(r_s - \bar{r}_s)(r_s - \bar{r}_s)}\sqrt{(r_t - \bar{r}_t)(r_t - \bar{r}_t)'}}$$

where

- r_{sj} is the rank of x_{sj} taken over $x_{1j}, x_{2j}, \dots, x_{mj}$, as computed by `tiedrank`.
- r_{tj} is the rank of y_{tj} taken over $y_{1j}, y_{2j}, \dots, y_{mj}$, as computed by `tiedrank`.
- r_s and r_t are the coordinate-wise rank vectors of x_s and y_t i.e., $r_s = (r_{s1}, r_{s2}, \dots, r_{sn})$ and $r_t = (r_{t1}, r_{t2}, \dots, r_{tn})$.
- $\bar{r}_s = \frac{1}{n} \sum_j r_{sj} = \frac{(n+1)}{2}$.
- $\bar{r}_t = \frac{1}{n} \sum_j r_{tj} = \frac{(n+1)}{2}$.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The distance input argument value (`Distance`) must be a compile-time constant. For example, to use the Minkowski distance, include `coder.Constant('Minkowski')` in the `-args` value of `codegen`.
- The distance input argument value (`Distance`) cannot be a custom distance function.
- Names in name-value pair arguments must be compile-time constants. For example, to use the 'Smallest' name-value pair argument in the generated code, include `{coder.Constant('Smallest'),0}` in the `-args` value of `codegen`.
- The sorted order of tied distances in the generated code can be different from the order in MATLAB due to numerical precision.
- The generated code of `pdist2` uses `parfor` to create loops that run in parallel on supported shared-memory multicore platforms in the generated code. If your compiler does not support the Open Multiprocessing (OpenMP) application interface or you disable OpenMP library, MATLAB Coder treats the `parfor`-loops as `for`-loops. To find supported compilers, see https://www.mathworks.com/support/compilers/current_release/. To disable OpenMP library, set the `EnableOpenMP` property of the configuration object to `false`. For details, see `coder.CodeConfig`.
- You can generate optimized CUDA code using GPU Coder. The supported distance input argument values (`Distance`) for optimized CUDA code are 'euclidean', 'squaredeuclidean', 'seuclidean', 'cityblock', 'minkowski', 'chebychev', 'cosine', 'correlation', 'hamming', and 'jaccard'. For more information on GPU coder, see “Getting Started with GPU Coder” (GPU Coder) and “Supported Functions” (GPU Coder).

For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “General Code Generation Workflow” on page 31-5.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Usage notes and limitations:

- The `Distance` argument must be specified as a character vector.

For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

Introduced in R2010a

pearsrnd

Pearson system random numbers

Syntax

```
r = pearsrnd(mu,sigma,skew,kurt,m,n)
r = pearsrnd(mu,sigma,skew,kurt)
r = pearsrnd(mu,sigma,skew,kurt,m,n,...)
r = pearsrnd(mu,sigma,skew,kurt,[m,n,...])
[r,type] = pearsrnd(...)
[r,type,coefs] = pearsrnd(...)
```

Description

`r = pearsrnd(mu,sigma,skew,kurt,m,n)` returns an m -by- n matrix of random numbers drawn from the distribution in the Pearson system with mean `mu`, standard deviation `sigma`, skewness `skew`, and kurtosis `kurt`. The parameters `mu`, `sigma`, `skew`, and `kurt` must be scalars.

Note Because `r` is a random sample, its sample moments, especially the skewness and kurtosis, typically differ somewhat from the specified distribution moments.

`pearsrnd` uses the definition of kurtosis for which a normal distribution has a kurtosis of 3. Some definitions of kurtosis subtract 3, so that a normal distribution has a kurtosis of 0. The `pearsrnd` function does not use this convention.

Some combinations of moments are not valid; in particular, the kurtosis must be greater than the square of the skewness plus 1. The kurtosis of the normal distribution is defined to be 3.

`r = pearsrnd(mu,sigma,skew,kurt)` returns a scalar value.

`r = pearsrnd(mu,sigma,skew,kurt,m,n,...)` or `r = pearsrnd(mu,sigma,skew,kurt,[m,n,...])` returns an m -by- n -by-... array.

`[r,type] = pearsrnd(...)` returns the type of the specified distribution within the Pearson system. `type` is a scalar integer from 0 to 7. Set `m` and `n` to 0 to identify the distribution type without generating any random values.

The seven distribution types in the Pearson system correspond to the following distributions:

- 0 — Normal on page B-136 distribution
- 1 — Four-parameter beta on page B-4 distribution
- 2 — Symmetric four-parameter beta on page B-4 distribution
- 3 — Three-parameter gamma on page B-45 distribution
- 4 — Not related to any standard distribution. The density is proportional to:

$$(1 + ((x - a)/b)^2)^{-c} \exp(-d \arctan((x - a)/b)).$$

- 5 — Inverse gamma on page B-45 location-scale distribution
- 6 — F on page B-42 location-scale distribution
- 7 — Student's t location-scale on page B-181 distribution

`[r,type,coefs] = pearsrnd(...)` returns the coefficients `coefs` of the quadratic polynomial that defines the distribution via the differential equation

$$\frac{d}{dx} \log(p(x)) = \frac{-(a+x)}{c(0) + c(1)x + c(2)x^2}.$$

Examples

Generate random values from the standard normal distribution:

```
r = pearsrnd(0,1,0,3,100,1); % Equivalent to randn(100,1)
```

Determine the distribution type:

```
[r,type] = pearsrnd(0,1,1,4,0,0);
r =
     []
type =
     1
```

Introduced in R2006a

perfcurve

Receiver operating characteristic (ROC) curve or other performance curve for classifier output

Syntax

```
[X,Y] = perfcurve(labels,scores,posclass)
[X,Y,T] = perfcurve(labels,scores,posclass)
[X,Y,T,AUC] = perfcurve(labels,scores,posclass)
[X,Y,T,AUC,OPTROCPT] = perfcurve(labels,scores,posclass)
[X,Y,T,AUC,OPTROCPT,SUBY] = perfcurve(labels,scores,posclass)
[X,Y,T,AUC,OPTROCPT,SUBY,SUBYNAMES] = perfcurve(labels,scores,
posclass)
[___] = perfcurve(labels,scores,posclass,Name,Value)
```

Description

`[X,Y] = perfcurve(labels,scores,posclass)` returns the X and Y coordinates of an ROC curve for a vector of classifier predictions, `scores`, given true class labels, `labels`, and the positive class label, `posclass`. You can visualize the performance curve using `plot(X,Y)`.

`[X,Y,T] = perfcurve(labels,scores,posclass)` returns an array of thresholds on classifier scores for the computed values of X and Y.

`[X,Y,T,AUC] = perfcurve(labels,scores,posclass)` returns the area under the curve for the computed values of X and Y.

`[X,Y,T,AUC,OPTROCPT] = perfcurve(labels,scores,posclass)` returns the optimal operating point of the ROC curve.

`[X,Y,T,AUC,OPTROCPT,SUBY] = perfcurve(labels,scores,posclass)` returns the Y values for negative subclasses.

`[X,Y,T,AUC,OPTROCPT,SUBY,SUBYNAMES] = perfcurve(labels,scores, posclass)` returns the negative class names.

[___] = perfcurve(labels, scores, posclass, Name, Value) returns the coordinates of a ROC curve and any other output argument from the previous syntaxes, with additional options specified by one or more Name, Value pair arguments.

For example, you can provide a list of negative classes, change the X or Y criterion, compute pointwise confidence bounds on page 32-4958 using cross validation or bootstrap, specify the misclassification cost, or compute the confidence bounds in parallel.

Examples

Plot ROC Curve for Classification by Logistic Regression

Load the sample data.

```
load fisheriris
```

Use only the first two features as predictor variables. Define a binary classification problem by using only the measurements that correspond to the species versicolor and virginica.

```
pred = meas(51:end,1:2);
```

Define the binary response variable.

```
resp = (1:100) '>50; % Versicolor = 0, virginica = 1
```

Fit a logistic regression model.

```
mdl = fitglm(pred, resp, 'Distribution', 'binomial', 'Link', 'logit');
```

Compute the ROC curve. Use the probability estimates from the logistic regression model as scores.

```
scores = mdl.Fitted.Probability;
[X, Y, T, AUC] = perfcurve(species(51:end, :), scores, 'virginica');
```

perfcurve stores the threshold values in the array T.

Display the area under the curve.

```
AUC
```

AUC = 0.7918

The area under the curve is 0.7918. The maximum AUC is 1, which corresponds to a perfect classifier. Larger AUC values indicate better classifier performance.

Plot the ROC curve.

```
plot(X,Y)
xlabel('False positive rate')
ylabel('True positive rate')
title('ROC for Classification by Logistic Regression')
```

Compare Classification Methods Using ROC Curve

Load the sample data.

```
load ionosphere
```

X is a 351x34 real-valued matrix of predictors. Y is a character array of class labels: 'b' for bad radar returns and 'g' for good radar returns.

Reformat the response to fit a logistic regression. Use the predictor variables 3 through 34.

```
resp = strcmp(Y,'b'); % resp = 1, if Y = 'b', or 0 if Y = 'g'
pred = X(:,3:34);
```

Fit a logistic regression model to estimate the posterior probabilities for a radar return to be a bad one.

```
mdl = fitglm(pred,resp,'Distribution','binomial','Link','logit');
score_log = mdl.Fitted.Probability; % Probability estimates
```

Compute the standard ROC curve using the probabilities for scores.

```
[Xlog,Ylog,Tlog,AUClog] = perfcurve(resp,score_log,'true');
```

Train an SVM classifier on the same sample data. Standardize the data.

```
mdlSVM = fitcsvm(pred,resp,'Standardize',true);
```

Compute the posterior probabilities (scores).

```
mdlSVM = fitPosterior(mdlSVM);
[~,score_svm] = resubPredict(mdlSVM);
```

The second column of score_svm contains the posterior probabilities of bad radar returns.

Compute the standard ROC curve using the scores from the SVM model.

```
[Xsvm,Ysvm,Tsvm,AUCsvm] = perfcurve(resp,score_svm(:,mdlSVM.ClassNames),'true');
```

Fit a naive Bayes classifier on the same sample data.

```
mdlNB = fitcnb(pred,resp);
```

Compute the posterior probabilities (scores).

```
[~,score_nb] = resubPredict(md1NB);
```

Compute the standard ROC curve using the scores from the naive Bayes classification.

```
[Xnb,Ynb,Tnb,AUCnb] = perfcurve(resp,score_nb(:,md1NB.ClassNames),'true');
```

Plot the ROC curves on the same graph.

```
plot(Xlog,Ylog)
hold on
plot(Xsvm,Ysvm)
plot(Xnb,Ynb)
legend('Logistic Regression','Support Vector Machines','Naive Bayes','Location','Best')
xlabel('False positive rate'); ylabel('True positive rate');
title('ROC Curves for Logistic Regression, SVM, and Naive Bayes Classification')
hold off
```

ROC Curves for Logistic Regression, SVM, and Naive Bayes Classification

Although SVM produces better ROC values for higher thresholds, logistic regression is usually better at distinguishing the bad radar returns from the good ones. The ROC curve for naive Bayes is generally lower than the other two ROC curves, which indicates worse in-sample performance than the other two classifier methods.

Compare the area under the curve for all three classifiers.

AUC_{log}

AUC_{log} = 0.9659

AUC_{svm}

AUC_{svm} = 0.9488

AUCnb

```
AUCnb = 0.9393
```

Logistic regression has the highest AUC measure for classification and naive Bayes has the lowest. This result suggests that logistic regression has better in-sample average performance for this sample data.

Determine the Parameter Value for Custom Kernel Function

This example shows how to determine the better parameter value for a custom kernel function in a classifier using the ROC curves.

Generate a random set of points within the unit circle.

```
rng(1); % For reproducibility
n = 100; % Number of points per quadrant

r1 = sqrt(rand(2*n,1)); % Random radii
t1 = [pi/2*rand(n,1); (pi/2*rand(n,1)+pi)]; % Random angles for Q1 and Q3
X1 = [r1.*cos(t1) r1.*sin(t1)]; % Polar-to-Cartesian conversion

r2 = sqrt(rand(2*n,1));
t2 = [pi/2*rand(n,1)+pi/2; (pi/2*rand(n,1)-pi/2)]; % Random angles for Q2 and Q4
X2 = [r2.*cos(t2) r2.*sin(t2)];
```

Define the predictor variables. Label points in the first and third quadrants as belonging to the positive class, and those in the second and fourth quadrants in the negative class.

```
pred = [X1; X2];
resp = ones(4*n,1);
resp(2*n + 1:end) = -1; % Labels
```

Create the function `mysigmoid.m`, which accepts two matrices in the feature space as inputs, and transforms them into a Gram matrix using the sigmoid kernel.

```
function G = mysigmoid(U,V)
% Sigmoid kernel function with slope gamma and intercept c
gamma = 1;
c = -1;
G = tanh(gamma*U*V' + c);
```

end

Train an SVM classifier using the sigmoid kernel function. It is good practice to standardize the data.

```
SVMMoDel1 = fitcsvm(pred,resp,'KernelFunction','mysigmoid',...
    'Standardize',true);
SVMMoDel1 = fitPosterior(SVMMoDel1);
[~,scores1] = resubPredict(SVMMoDel1);
```

Set $\gamma = 0.5$; within `mysigmoid.m` and save as `mysigmoid2.m`. And, train an SVM classifier using the adjusted sigmoid kernel.

```
function G = mysigmoid2(U,V)
% Sigmoid kernel function with slope gamma and intercept c
gamma = 0.5;
c = -1;
G = tanh(gamma*U*V' + c);
end
```

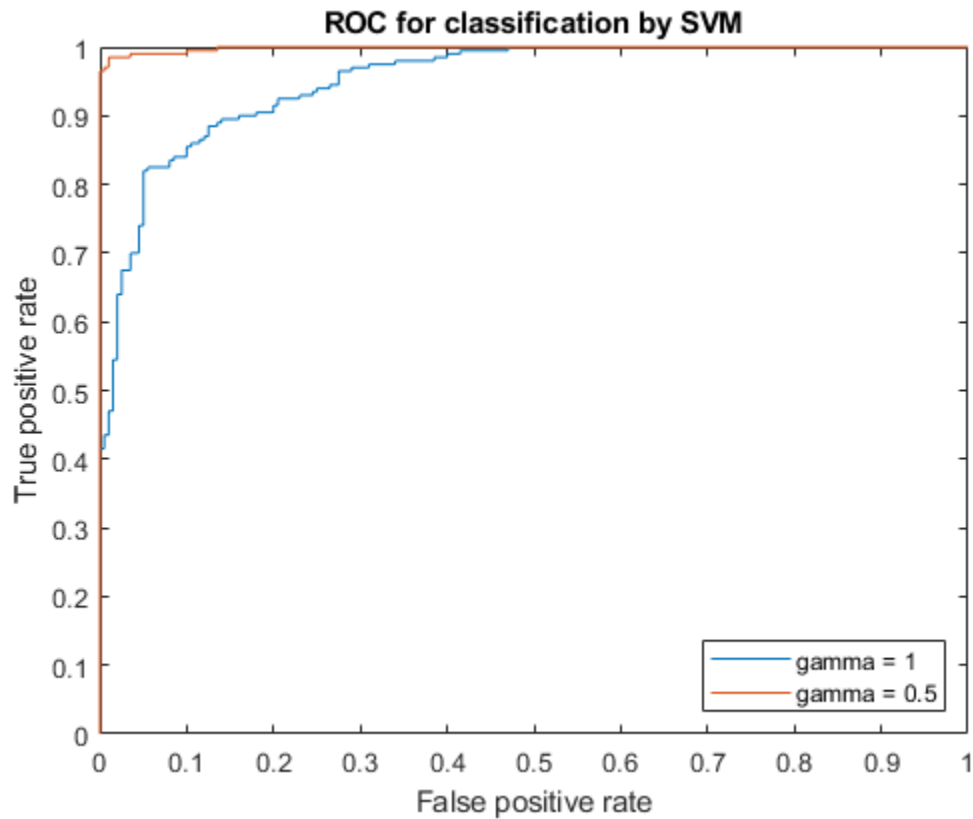

```
SVMMoDel2 = fitcsvm(pred,resp,'KernelFunction','mysigmoid2',...
    'Standardize',true);
SVMMoDel2 = fitPosterior(SVMMoDel2);
[~,scores2] = resubPredict(SVMMoDel2);
```

Compute the ROC curves and the area under the curve (AUC) for both models.

```
[x1,y1,~,auc1] = perfcurve(resp,scores1(:,2),1);
[x2,y2,~,auc2] = perfcurve(resp,scores2(:,2),1);
```

Plot the ROC curves.

```
plot(x1,y1)
hold on
plot(x2,y2)
hold off
legend('gamma = 1','gamma = 0.5','Location','SE');
xlabel('False positive rate'); ylabel('True positive rate');
title('ROC for classification by SVM');
```

The kernel function with the gamma parameter set to 0.5 gives better in-sample results.

Compare the AUC measures.

```
auc1  
auc2
```

```
auc1 =  
    0.9518
```

```
auc2 =
```

0.9985

The area under the curve for gamma set to 0.5 is higher than that for gamma set to 1. This also confirms that gamma parameter value of 0.5 produces better results. For visual comparison of the classification performance with these two gamma parameter values, see “Train SVM Classifier Using Custom Kernel” on page 18-202.

Plot ROC Curve for Classification Tree

Load the sample data.

```
load fisheriris
```

The column vector, `species`, consists of iris flowers of three different species: `setosa`, `versicolor`, `virginica`. The double matrix `meas` consists of four types of measurements on the flowers: sepal length, sepal width, petal length, and petal width. All measures are in centimeters.

Train a classification tree using the sepal length and width as the predictor variables. It is a good practice to specify the class names.

```
Model = fitctree(meas(:,1:2),species, ...
    'ClassNames',{'setosa','versicolor','virginica'});
```

Predict the class labels and scores for the species based on the tree `Model`.

```
[~,score] = resubPredict(Model);
```

The scores are the posterior probabilities that an observation (a row in the data matrix) belongs to a class. The columns of `score` correspond to the classes specified by `'ClassNames'`. So, the first column corresponds to `setosa`, the second corresponds to `versicolor`, and the third column corresponds to `virginica`.

Compute the ROC curve for the predictions that an observation belongs to `versicolor`, given the true class labels `species`. Also compute the optimal operating point and `y` values for negative subclasses. Return the names of the negative classes.

Because this is a multiclass problem, you cannot merely supply `score(:,2)` as input to `perfcurve`. Doing so would not give `perfcurve` enough information about the scores

for the two negative classes (setosa and virginica). This problem is unlike a binary classification problem, where knowing the scores of one class is enough to determine the scores of the other class. Therefore, you must supply `perfcurve` with a function that factors in the scores of the two negative classes. One such function is `score(:,2) - max(score(:,1), score(:,3))`.

```
diffscore = score(:,2) - max(score(:,1), score(:,3));  
[X,Y,T,~,OPTROCPT,suby,subnames] = perfcurve(species,diffscore,'versicolor');
```

X, by default, is the false positive rate (fallout or 1-specificity) and Y, by default, is the true positive rate (recall or sensitivity). The positive class label is `versicolor`. Because a negative class is not defined, `perfcurve` assumes that the observations that do not belong to the positive class are in one class. The function accepts it as the negative class.

OPTROCPT

```
OPTROCPT = 1x2  
    0.1000    0.8000
```

suby

```
suby = 12x2  
      0      0  
    0.1800    0.1800  
    0.4800    0.4800  
    0.5800    0.5800  
    0.6200    0.6200  
    0.8000    0.8000  
    0.8800    0.8800  
    0.9200    0.9200  
    0.9600    0.9600  
    0.9800    0.9800  
      :
```

subnames

```
subnames = 1x2 cell array  
    {'setosa'}    {'virginica'}
```

Plot the ROC curve and the optimal operating point on the ROC curve.

```

plot(X,Y)
hold on
plot(OPTRCPT(1),OPTRCPT(2), 'ro')
xlabel('False positive rate')
ylabel('True positive rate')
title('ROC Curve for Classification by Classification Trees')
hold off

```

Find the threshold that corresponds to the optimal operating point.

```
T((X==OPTRCPT(1))&(Y==OPTRCPT(2)))
```

```
ans = 0.2857
```

Specify *virginica* as the negative class and compute and plot the ROC curve for *versicolor*.

Again, you must supply `perfcurve` with a function that factors in the scores of the negative class. An example of a function to use is `score(:,2) - score(:,3)`.

```
diffscore = score(:,2) - score(:,3);  
[X,Y,~,~,OPTROCPT] = perfcurve(species,diffscore,'versicolor', ...  
    'negClass','virginica');  
OPTROCPT
```

```
OPTROCPT = 1×2  
  
    0.1800    0.8200
```

```
figure, plot(X,Y)  
hold on  
plot(OPTROCPT(1),OPTROCPT(2),'ro')  
xlabel('False positive rate')  
ylabel('True positive rate')  
title('ROC Curve for Classification by Classification Trees')  
hold off
```

Compute Pointwise Confidence Intervals for ROC Curve

Load the sample data.

```
load fisheriris
```

The column vector `species` consists of iris flowers of three different species: `setosa`, `versicolor`, `virginica`. The double matrix `meas` consists of four types of measurements on the flowers: sepal length, sepal width, petal length, and petal width. All measures are in centimeters.

Use only the first two features as predictor variables. Define a binary problem by using only the measurements that correspond to the versicolor and virginica species.

```
pred = meas(51:end,1:2);
```

Define the binary response variable.

```
resp = (1:100) '>50'; % Versicolor = 0, virginica = 1
```

Fit a logistic regression model.

```
mdl = fitglm(pred,resp,'Distribution','binomial','Link','logit');
```

Compute the pointwise confidence intervals on the true positive rate (TPR) by vertical averaging (VA) and sampling using bootstrap.

```
[X,Y,T] = perfcurve(species(51:end,:),mdl.Fitted.Probability,...  
    'virginica','NBoot',1000,'XVals',[0:0.05:1]);
```

'NBoot', 1000 sets the number of bootstrap replicas to 1000. 'XVals', 'All' prompts `perfcurve` to return X, Y, and T values for all scores, and average the Y values (true positive rate) at all X values (false positive rate) using vertical averaging. If you do not specify XVals, then `perfcurve` computes the confidence bounds using threshold averaging by default.

Plot the pointwise confidence intervals.

```
errorbar(X,Y(:,1),Y(:,1)-Y(:,2),Y(:,3)-Y(:,1));  
xlim([-0.02,1.02]); ylim([-0.02,1.02]);  
xlabel('False positive rate')  
ylabel('True positive rate')  
title('ROC Curve with Pointwise Confidence Bounds')  
legend('PCBwVA','Location','Best')
```

It might not always be possible to control the false positive rate (FPR, the X value in this example). So you might want to compute the pointwise confidence intervals on true positive rates (TPR) by threshold averaging.

```
[X1,Y1,T1] = perfcurve(species(51:end,:),mdl.Fitted.Probability,...
    'virginica','NBoot',1000);
```

If you set 'TVals' to 'All', or if you do not specify 'TVals' or 'Xvals', then perfcurve returns X, Y, and T values for all scores and computes pointwise confidence bounds for X and Y using threshold averaging.

Plot the confidence bounds.

```

figure()
errorbar(X1(:,1),Y1(:,1),Y1(:,1)-Y1(:,2),Y1(:,3)-Y1(:,1));
xlim([-0.02,1.02]); ylim([-0.02,1.02]);
xlabel('False positive rate')
ylabel('True positive rate')
title('ROC Curve with Pointwise Confidence Bounds')
legend('PCBwTA', 'Location', 'Best')

```

Specify the threshold values to fix and compute the ROC curve. Then plot the curve.

```

[X1,Y1,T1] = perfcurve(species(51:end,:),mdl.Fitted.Probability,...
    'virginica','NBoot',1000,'TVals',0:0.05:1);
figure()
errorbar(X1(:,1),Y1(:,1),Y1(:,1)-Y1(:,2),Y1(:,3)-Y1(:,1));

```

```
xlim([-0.02,1.02]); ylim([-0.02,1.02]);
xlabel('False positive rate')
ylabel('True positive rate')
title('ROC Curve with Pointwise Confidence Bounds')
legend('PCBwTA','Location','Best')
```

Input Arguments

labels — True class labels

numeric vector | logical vector | character matrix | string array | cell array of character vectors | categorical array

True class labels, specified as a numeric vector, logical vector, character matrix, string array, cell array of character vectors, or categorical array. For more information, see “Grouping Variables” on page 2-57.

Example: {'hi', 'mid', 'hi', 'low', ..., 'mid'}

Example: ['H', 'M', 'H', 'L', ..., 'M']

Data Types: single | double | logical | char | string | cell | categorical

scores — Scores returned by a classifier

vector of floating points

Scores returned by a classifier for some sample data, specified as a vector of floating points. `scores` must have the same number of elements as `labels`.

Data Types: single | double

posclass — Positive class label

numeric scalar | logical scalar | character vector | string scalar | cell containing a character vector | categorical scalar

Positive class label, specified as a numeric scalar, logical scalar, character vector, string scalar, cell containing a character vector, or categorical scalar. The positive class must be a member of the input labels. The value of `posclass` that you can specify depends on the value of `labels`.

labels value	posclass value
Numeric vector	Numeric scalar
Logical vector	Logical scalar
Character matrix	Character vector
String array	String scalar
Cell array of character vectors	Character vector or cell containing character vector
Categorical vector	Categorical scalar

For example, in a cancer diagnosis problem, if a malignant tumor is the positive class, then specify `posclass` as 'malignant'.

Data Types: single | double | logical | char | string | cell | categorical

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example:

`'NegClass', 'versicolor', 'XCrit', 'fn', 'NBoot', 1000, 'BootType', 'per'` specifies the species `versicolor` as the negative class, the criterion for the X-coordinate as false negative, the number of bootstrap samples as 1000. It also specifies that the pointwise confidence bounds are computed using the percentile method.

NegClass — List of negative classes

`'all'` (default) | numeric array | categorical array | string array | cell array of character vectors

List of negative classes, specified as the comma-separated pair consisting of `'NegClass'`, and a numeric array, a categorical array, a string array, or a cell array of character vectors. By default, `perfcurve` sets `NegClass` to `'all'` and considers all nonpositive classes found in the input array of labels to be negative.

If `NegClass` is a subset of the classes found in the input array of labels, then `perfcurve` discards the instances with labels that do not belong to either positive or negative classes.

Example: `'NegClass', {'versicolor', 'setosa'}`

Data Types: `single` | `double` | `categorical` | `char` | `string` | `cell`

XCrit — Criterion to compute for X

`'fpr'` (default) | `'fnr'` | `'tnr'` | `'ppv'` | `'ecost'` | ...

Criterion to compute for X, specified as the comma-separated pair consisting of `'XCrit'` and one of the following.

Criterion	Description
<code>tp</code>	Number of true positive instances
<code>fn</code>	Number of false negative instances.
<code>fp</code>	Number of false positive instances.

Criterion	Description
tn	Number of true negative instances.
tp+fp	Sum of true positive and false positive instances.
rpp	Rate of positive predictions. $rpp = (tp+fp)/(tp+fn+fp+tn)$
rnp	Rate of negative predictions. $rnp = (tn+fn)/(tp+fn+fp+tn)$
accu	Accuracy. $accu = (tp+tn)/(tp+fn+fp+tn)$
tpr, or sens, or reca	True positive rate, or sensitivity, or recall. $tpr = sens = reca = tp/(tp+fn)$
fnr, or miss	False negative rate, or miss. $fnr = miss = fn/(tp+fn)$
fpr, or fall	False positive rate, or fallout, or 1 - specificity. $fpr = fall = fp/(tn+fp)$
tnr, or spec	True negative rate, or specificity. $tnr = spec = tn/(tn+fp)$
ppv, or prec	Positive predictive value, or precision. $ppv = prec = tp/(tp+fp)$
npv	Negative predictive value. $npv = tn/(tn+fn)$
ecost	Expected cost. $ecost = (tp*Cost(P P)+fn*Cost(N P)+fp*Cost(P N)+tn*Cost(N N))/(tp+fn+fp+tn)$
Custom criterion	A custom-defined function with the input arguments (C, scale, cost), where C is a 2-by-2 confusion matrix, scale is a 2-by-1 array of class scales, and cost is a 2-by-2 misclassification cost matrix.

Caution Some of these criteria return NaN values at one of the two special thresholds, 'reject all' and 'accept all'.

Example: 'XCrit', 'ecost'

YCrit — Criterion to compute for Y`'tpr'` (default) | same criteria options for X

Criterion to compute for Y, specified as the comma-separated pair consisting of 'YCrit' and one of the same criteria options as for X. This criterion does not have to be a monotone function of the positive class score.

Example: 'YCrit', 'ecost'

XVals — Values for the X criterion`'all'` (default) | numeric array

Values for the X criterion, specified as the comma-separated pair consisting of 'XVals' and a numeric array.

- If you specify XVals, then perfcurve computes X and Y and the pointwise confidence bounds on page 32-4958 for Y (when applicable) only for the specified XVals.
- If you do not specify XVals, then perfcurve, computes X and Y and the values for all scores by default.

Note You cannot set XVals and TVals at the same time.

Example: 'XVals', [0:0.05:1]

Data Types: single | double | char | string

TVals — Thresholds for the positive class score`'all'` (default) | numeric array

Thresholds for the positive class score, specified as the comma-separated pair consisting of 'TVals' and either 'all' or a numeric array.

- If TVals is set to 'all' or not specified, and XVals is not specified, then perfcurve returns X, Y, and T values for all scores and computes pointwise confidence bounds on page 32-4958 for X and Y using threshold averaging.
- If TVals is set to a numeric array, then perfcurve returns X, Y, and T values for the specified thresholds and computes pointwise confidence bounds for X and Y at these thresholds using threshold averaging.

Note You cannot set XVals and TVals at the same time.

Example: 'TVals', [0:0.05:1]

Data Types: single | double | char | string

UseNearest — Indicator to use the nearest values in the data

'on' (default) | 'off'

Indicator to use the nearest values in the data instead of the specified numeric XVals or TVals, specified as the comma-separated pair consisting of 'UseNearest' and either 'on' or 'off'.

- If you specify numeric XVals and set UseNearest to 'on', then `perfcurve` returns the nearest unique X values found in the data, and it returns the corresponding values of Y and T.
- If you specify numeric XVals and set UseNearest to 'off', then `perfcurve` returns the sorted XVals.
- If you compute confidence bounds by cross validation or bootstrap, then this parameter is always 'off'.

Example: 'UseNearest', 'off'

ProcessNaN — perfcurve method for processing NaN scores

'ignore' (default) | 'addtofalse'

`perfcurve` method for processing NaN scores, specified as the comma-separated pair consisting of 'ProcessNaN' and 'ignore' or 'addtofalse'.

- If ProcessNaN is 'ignore', then `perfcurve` removes observations with NaN scores from the data.
- If ProcessNaN is 'addtofalse', then `perfcurve` adds instances with NaN scores to false classification counts in the respective class. That is, `perfcurve` always counts instances from the positive class as false negative (FN), and it always counts instances from the negative class as false positive (FP).

Example: 'ProcessNaN', 'addtofalse'

Prior — Prior probabilities for positive and negative classes

'empirical' (default) | 'uniform' | array with two elements

Prior probabilities for positive and negative classes, specified as the comma-separated pair consisting of 'Prior' and 'empirical', 'uniform', or an array with two elements.

If `Prior` is 'empirical', then perfcurve derives prior probabilities from class frequencies.

If `Prior` is 'uniform', then perfcurve sets all prior probabilities to be equal.

Example: 'Prior', [0.3,0.7]

Data Types: single | double | char | string

Cost — Misclassification costs

[0 0.5;0.5 0] (default) | 2-by-2 matrix

Misclassification costs, specified as the comma-separated pair consisting of 'Cost' and a 2-by-2 matrix, containing [Cost(P|P), Cost(N|P); Cost(P|N), Cost(N|N)].

Cost(N|P) is the cost of misclassifying a positive class as a negative class. Cost(P|N) is the cost of misclassifying a negative class as a positive class. Usually, Cost(P|P) = 0 and Cost(N|N) = 0, but perfcurve allows you to specify nonzero costs for correct classification as well.

Example: 'Cost', [0 0.7;0.3 0]

Data Types: single | double

Alpha — Significance level

0.05 (default) | scalar value in the range 0 through 1

Significance level for the confidence bounds, specified as the comma-separated pair consisting of 'Alpha' and a scalar value in the range 0 through 1. perfcurve computes $100 \cdot (1 - \alpha)$ percent pointwise confidence bounds on page 32-4958 for X, Y, T, and AUC for a confidence level of $1 - \alpha$.

Example: 'Alpha', 0.01 specifies 99% confidence bounds

Data Types: single | double

Weights — Observation weights

vector of nonnegative scalar values | cell array of vectors of nonnegative scalar values

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a vector of nonnegative scalar values. This vector must have as many elements as `scores` or `labels` do.

If `scores` and `labels` are in cell arrays and you need to supply `Weights`, the weights must be in a cell array as well. In this case, every element in `Weights` must be a numeric

vector with as many elements as the corresponding element in `scores`. For example, `numel(weights{1}) == numel(scores{1})`.

When `perfcurve` computes the X, Y and T or confidence bounds using cross-validation, it uses these observation weights instead of observation counts.

When `perfcurve` computes confidence bounds using bootstrap, it samples N out of N observations with replacement, using these weights as multinomial sampling probabilities.

The default is a vector of 1s or a cell array in which each element is a vector of 1s.

Data Types: `single` | `double` | `cell`

NBoot — Number of bootstrap replicas

0 (default) | positive integer

Number of bootstrap replicas for computation of confidence bounds, specified as the comma-separated pair consisting of `'NBoot'` and a positive integer. The default value 0 means the confidence bounds are not computed.

If `labels` and `scores` are cell arrays, this parameter must be 0 because `perfcurve` can use either cross-validation or bootstrap to compute confidence bounds.

Example: `'NBoot', 500`

Data Types: `single` | `double`

BootType — Confidence interval type for bootci

`'bca'` (default) | `'norm'` | `'per'` | `'cper'` | `'stud'`

Confidence interval type for `bootci` to use to compute confidence bounds, specified as the comma-separated pair consisting of `'BootType'` and one of the following:

- `'bca'` — Bias corrected and accelerated percentile method
- `'norm'` or `'normal'` — Normal approximated interval with bootstrapped bias and standard error
- `'per'` or `'percentile'` — Percentile method
- `'cper'` or `'corrected percentile'` — Bias corrected percentile method
- `'stud'` or `'student'` — Studentized confidence interval

Example: `'BootType', 'cper'`

BootArg — Optional input arguments for bootci

[] (default) | {'Nbootstd', nbootstd} | {'Stderr', stderr}

Optional input arguments for `bootci` to compute confidence bounds, specified as the comma-separated pair consisting of `'BootArg'` and `{'Nbootstd', nbootstd}` or `{'Stderr', stderr}`, name-value pair arguments of `bootci`.

When you compute the studentized bootstrap confidence intervals (`'BootType'` is `'student'`), you can additionally specify `'Nbootstd'` or `'Stderr'`, name-value pair arguments of `bootci`, by using `'BootArg'`.

- `'BootArg', {'Nbootstd', nbootstd}` estimates the standard error of the bootstrap statistics using bootstrap with `nbootstd` data samples. `nbootstd` is a positive integer and its default is 100.
- `'BootArg', {'Stderr', stderr}` evaluates the standard error of the bootstrap statistics by a user-defined function `stderr` that takes `[1:numel(scores)]'` as an input argument. `stderr` is a function handle.

Example: `'BootArg', {'Nbootstd', nbootstd}`

Data Types: `cell`

Options — Options for controlling the computation of confidence intervals

[] (default) | structure array returned by `statset`

Options for controlling the computation of confidence intervals, specified as the comma-separated pair consisting of `'Options'` and a structure array returned by `statset`. These options require Parallel Computing Toolbox. `perfcurve` uses this argument for computing pointwise confidence bounds only. To compute these bounds, you must pass cell arrays for labels and scores or set `NBoot` to a positive integer.

This table summarizes the available options.

Option	Description
<code>'UseParallel'</code>	<ul style="list-style-type: none"> • <code>false</code> — Serial computation (default). • <code>true</code> — Parallel computation. You need Parallel Computing Toolbox for this option to work.

Option	Description
'UseSubstreams'	<ul style="list-style-type: none"> • <code>false</code> — Do not use a separate substream for each iteration (default). • <code>true</code> — Use a separate substream for each iteration to compute in parallel in a reproducible fashion. To compute reproducibly, set <code>Streams</code> to a type allowing substreams: <code>'mlfg6331_64'</code> or <code>'mrg32k3a'</code>.
'Streams'	<p>A <code>RandStream</code> object, or a cell array of such objects. If you specify <code>Streams</code>, use a single object, except when:</p> <ul style="list-style-type: none"> • <code>UseParallel</code> is <code>true</code>. • <code>UseSubstreams</code> is <code>false</code>. <p>In that case, use a cell array of the same size as the parallel pool. If a parallel pool is not open, then <code>Streams</code> must supply a single random number stream.</p>

If `'UseParallel'` is `true` and `'UseSubstreams'` is `false`, then the length of `'Streams'` must equal the number of workers used by `perfcurve`. If a parallel pool is already open, then the length of `'Streams'` is the size of the parallel pool. If a parallel pool is not already open, then MATLAB might open a pool for you, depending on your installation and preferences. To ensure more predictable results, use `parpool` and explicitly create a parallel pool before invoking `perfcurve` and setting `'Options',statset('UseParallel',true)`.

Example: `'Options',statset('UseParallel',true)`

Data Types: `struct`

Output Arguments

X — x-coordinates for the performance curve

vector, `fpr` (default) | *m*-by-3 matrix

x-coordinates for the performance curve, returned as a vector or an m -by-3 matrix. By default, X values are the false positive rate, FPR (fallout or $1 - \text{specificity}$). To change X, use the XCrit name-value pair argument.

- If perfcurve does not compute the pointwise confidence bounds on page 32-4958, or if it computes them using vertical averaging, then X is a vector.
- If perfcurve computes the confidence bounds using threshold averaging, then X is an m -by-3 matrix, where m is the number of fixed threshold values. The first column of X contains the mean value. The second and third columns contain the lower bound and the upper bound, respectively, of the pointwise confidence bounds.

Y — y-coordinates for the performance curve

vector, tpr (default) | m -by-3 matrix

y-coordinates for the performance curve, returned as a vector or an m -by-3 matrix. By default, Y values are the true positive rate, TPR (recall or sensitivity). To change Y, use YCrit name-value pair argument.

- If perfcurve does not compute the pointwise confidence bounds on page 32-4958, then Y is a vector.
- If perfcurve computes the confidence bounds, then Y is an m -by-3 matrix, where m is the number of fixed X values or thresholds (T values). The first column of Y contains the mean value. The second and third columns contain the lower bound and the upper bound, respectively, of the pointwise confidence bounds.

T — Thresholds on classifier scores

vector | m -by-3 matrix

Thresholds on classifier scores for the computed values of X and Y, returned as a vector or m -by-3 matrix.

- If perfcurve does not compute the pointwise confidence bounds on page 32-4958, or computes them using threshold averaging, then T is a vector.
- If perfcurve computes the confidence bounds using vertical averaging, T is an m -by-3 matrix, where m is the number of fixed X values. The first column of T contains the mean value. The second and third columns contain the lower bound, and the upper bound, respectively, of the pointwise confidence bounds.

For each threshold, TP is the count of true positive observations with scores greater than or equal to this threshold, and FP is the count of false positive observations with scores greater than or equal to this threshold. perfcurve defines negative counts, TN and FN, in

a similar way. The function then sorts the thresholds in the descending order that corresponds to the ascending order of positive counts.

For the m distinct thresholds found in the array of scores, `perfcurve` returns the X, Y and T arrays with $m + 1$ rows. `perfcurve` sets elements $T(2:m+1)$ to the distinct thresholds, and $T(1)$ replicates $T(2)$. By convention, $T(1)$ represents the highest 'reject all' threshold, and `perfcurve` computes the corresponding values of X and Y for $TP = 0$ and $FP = 0$. The $T(\text{end})$ value is the lowest 'accept all' threshold for which $TN = 0$ and $FN = 0$.

AUC — Area under the curve

scalar value | 3-by-1 vector

Area under the curve (AUC) for the computed values of X and Y, returned as a scalar value or a 3-by-1 vector.

- If `perfcurve` does not compute the pointwise confidence bounds on page 32-4958, AUC is a scalar value.
- If `perfcurve` computes the confidence bounds using vertical averaging, AUC is a 3-by-1 vector. The first column of AUC contains the mean value. The second and third columns contain the lower bound and the upper bound, respectively, of the confidence bound.

For a perfect classifier, $AUC = 1$. For a classifier that randomly assigns observations to classes, $AUC = 0.5$.

If you set `XVals` to 'all' (default), then `perfcurve` computes AUC using the returned X and Y values.

If `XVals` is a numeric array, then `perfcurve` computes AUC using X and Y values from all distinct scores in the interval, which are specified by the smallest and largest elements of `XVals`. More precisely, `perfcurve` finds X values for all distinct thresholds as if `XVals` were set to 'all', and then uses a subset of these (with corresponding Y values) between $\min(XVals)$ and $\max(XVals)$ to compute AUC.

`perfcurve` uses trapezoidal approximation to estimate the area. If the first or last value of X or Y are NaNs, then `perfcurve` removes them to allow calculation of AUC. This takes care of criteria that produce NaNs for the special 'reject all' or 'accept all' thresholds, for example, positive predictive value (PPV) or negative predictive value (NPV).

OPTROCPT — Optimal operating point of the ROC curve

1-by-2 array

Optimal operating point of the ROC curve, returned as a 1-by-2 array with false positive rate (FPR) and true positive rate (TPR) values for the optimal ROC operating point.

perfcurve computes OPTROCPT for the standard ROC curve only, and sets to NaNs otherwise. To obtain the optimal operating point for the ROC curve, perfcurve first finds the slope, S , using

$$S = \frac{\text{Cost}(P|N) - \text{Cost}(N|N) * N}{\text{Cost}(N|P) - \text{Cost}(P|P) * P}$$

- $\text{Cost}(N|P)$ is the cost of misclassifying a positive class as a negative class. $\text{Cost}(P|N)$ is the cost of misclassifying a negative class as a positive class.
- $P = TP + FN$ and $N = TN + FP$. They are the total instance counts in the positive and negative class, respectively.

perfcurve then finds the optimal operating point by moving the straight line with slope S from the upper left corner of the ROC plot ($FPR = 0$, $TPR = 1$) down and to the right, until it intersects the ROC curve.

SUBY — Values for negative subclasses

array

Values for negative subclasses, returned as an array.

- If you specify only one negative class, then SUBY is identical to Y.
- If you specify k negative classes, then SUBY is a matrix of size m -by- k , where m is the number of returned values for X and Y, and k is the number of negative classes. perfcurve computes Y values by summing counts over all negative classes.

SUBY gives values of the Y criterion for each negative class separately. For each negative class, perfcurve places a new column in SUBY and fills it with Y values for true negative (TN) and false positive (FP) counted just for this class.

SUBYNAMES — Negative class names

cell array

Negative class names, returned as a cell array.

- If you provide an input array of negative class names, `NegClass`, then `perfcurve` copies names into `SUBYNAMES`.
- If you do not provide `NegClass`, then `perfcurve` extracts `SUBYNAMES` from the input labels. The order of `SUBYNAMES` is the same as the order of columns in `SUBY`. That is, `SUBY(:, 1)` is for negative class `SUBYNAMES{1}`, `SUBY(:, 2)` is for negative class `SUBYNAMES{2}`, and so on.

Algorithms

Pointwise Confidence Bounds

If you supply cell arrays for `labels` and `scores`, or if you set `NBoot` to a positive integer, then `perfcurve` returns pointwise confidence bounds for `X`, `Y`, `T`, and `AUC`. You cannot supply cell arrays for `labels` and `scores` and set `NBoot` to a positive integer at the same time.

`perfcurve` resamples data to compute confidence bounds using either cross validation or bootstrap.

- Cross-validation — If you supply cell arrays for `labels` and `scores`, then `perfcurve` uses cross-validation and treats elements in the cell arrays as cross-validation folds. `labels` can be a cell array of numeric vectors, logical vectors, character matrices, cell arrays of character vectors, or categorical vectors. All elements in `labels` must have the same type. `scores` can be a cell array of numeric vectors. The cell arrays for `labels` and `scores` must have the same number of elements. The number of labels in cell `j` of `labels` must be equal to the number of scores in cell `j` of `scores` for any `j` in the range from 1 to the number of elements in `scores`.
- Bootstrap — If you set `NBoot` to a positive integer `n`, `perfcurve` generates `n` bootstrap replicas to compute pointwise confidence bounds. If you use `XCrit` or `YCrit` to set the criterion for `X` or `Y` to an anonymous function, `perfcurve` can compute confidence bounds only using bootstrap.

`perfcurve` estimates the confidence bounds using one of two methods:

- Vertical averaging (VA) — `perfcurve` estimates confidence bounds on `Y` and `T` at fixed values of `X`. That is, `perfcurve` takes samples of the ROC curves for fixed `X` values, averages the corresponding `Y` and `T` values, and computes the standard errors. You can use the `XVals` name-value pair argument to fix the `X` values for computing

confidence bounds. If you do not specify `XVals`, then `perfcurve` computes the confidence bounds at all `X` values.

- Threshold averaging (TA) — `perfcurve` takes samples of the ROC curves at fixed thresholds `T` for the positive class score, averages the corresponding `X` and `Y` values, and estimates the confidence bounds. You can use the `TVals` name-value pair argument to use this method for computing confidence bounds. If you set `TVals` to `'all'` or do not specify `TVals` or `XVals`, then `perfcurve` returns `X`, `Y`, and `T` values for all scores and computes pointwise confidence bounds for `Y` and `X` using threshold averaging.

When you compute the confidence bounds, `Y` is an m -by-3 array, where m is the number of fixed `X` values or thresholds (`T` values). The first column of `Y` contains the mean value. The second and third columns contain the lower bound and the upper bound, respectively, of the pointwise confidence bounds. `AUC` is a row vector with three elements, following the same convention. If `perfcurve` computes the confidence bounds using `VA`, then `T` is an m -by-3 matrix, and `X` is a column vector. If `perfcurve` uses `TA`, then `X` is an m -by-3 matrix and `T` is a column-vector.

`perfcurve` returns pointwise confidence bounds. It does not return a simultaneous confidence band for the entire curve.

Extended Capabilities

Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the 'UseParallel' option to true.

Set the 'UseParallel' field of the options structure to true using `statset` and specify the 'Options' name-value pair argument in the call to this function.

For example: `'Options',statset('UseParallel',true)`

For more information, see the 'Options' name-value pair argument.

For more general information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

Introduced in R2009a

plot

Class: clustering.evaluation.ClusterCriterion

Package: clustering.evaluation

Plot clustering evaluation object criterion values

Syntax

```
plot(eva)  
h = plot(eva)
```

Description

`plot(eva)` displays a plot of the criterion values versus the number of clusters, based on the values stored in the clustering evaluation object `eva`.

`h = plot(eva)` returns a handle to the plot line.

Input Arguments

eva — Clustering evaluation data

clustering evaluation object

Clustering evaluation data, specified as a clustering evaluation object. Create a clustering evaluation object using `evalclusters`.

Output Arguments

h — Handle to plot line

scalar value

Handle to the plot line, returned as a scalar value.

Examples

Plot the Clustering Evaluation Criterion Values

Plot the criterion values versus the number of clusters for each clustering solution stored in a clustering evaluation object.

Load the sample data.

```
load fisheriris
```

The data contains length and width measurements from the sepals and petals of three species of iris flowers.

Create a clustering evaluation object. Cluster the data using `kmeans`, and evaluate the optimal number of clusters using the Calinski-Harabasz criterion.

```
rng('default'); % For reproducibility
eva = evalclusters(meas,'kmeans','CalinskiHarabasz','KList',[1:6]);
```

Plot the Calinski-Harabasz criterion values for each number of clusters tested.

```
figure;
plot(eva);
```

The plot shows that the highest Calinski-Harabasz value occurs at three clusters, suggesting that the optimal number of clusters is three.

`evalclusters`

plot

Scatter plot or added variable plot of linear regression model

Syntax

```
plot mdl  
h = plot mdl
```

Description

`plot mdl` creates a plot of the linear regression model `mdl`. The plot type depends on the number of predictor variables.

- If `mdl` includes multiple predictor variables, `plot` creates an “Added Variable Plot” on page 32-4970 for the whole model except the constant (intercept) term, equivalent to `plotAdded mdl`.
- If `mdl` includes a single predictor variable, `plot` creates a scatter plot of the data along with a fitted curve and confidence bounds.
- If `mdl` does not include a predictor, `plot` creates a histogram of the residuals, equivalent to `plotResiduals mdl`.

`h = plot mdl` returns graphics objects for the lines or patch in the plot. Use `h` to modify the properties of a specific line or patch after you create the plot. For a list of properties, see [Chart Line and Patch Properties](#).

Examples

Create Added Variable Plot

Create a linear regression model of car mileage as a function of weight and model year. Then create an added variable plot to see the significance of the model.

Create a linear regression model of mileage from the `carsmall` data set.

```
load carsmall
Year = categorical(Model_Year);
tbl = table(MPG,Weight,Year);
mdl = fitlm(tbl,'MPG ~ Year + Weight^2');
```

Create an added variable plot of the model.

```
plot(mdl)
```

The plot illustrates that the model is significant because a horizontal line does not fit between the confidence bounds.

Create the same plot by using the `plotAdded` function.

```
plotAdded(mdl)
```

Create Scatter Plot for Simple Linear Regression

Create a scatter plot of data along with a fitted curve and confidence bounds for a simple linear regression model. A simple linear regression model includes only one predictor variable.

Create a simple linear regression model of mileage from the `carsmall` data set.

```
load carsmall
tbl = table(MPG,Weight);
mdl = fitlm(tbl,'MPG ~ Weight')
```

```
mdl =  
Linear regression model:  
MPG ~ 1 + Weight
```

```
Estimated Coefficients:
```

	Estimate	SE	tStat	pValue
(Intercept)	49.238	1.6411	30.002	2.7015e-49
Weight	-0.0086119	0.0005348	-16.103	1.6434e-28

```
Number of observations: 94, Error degrees of freedom: 92
```

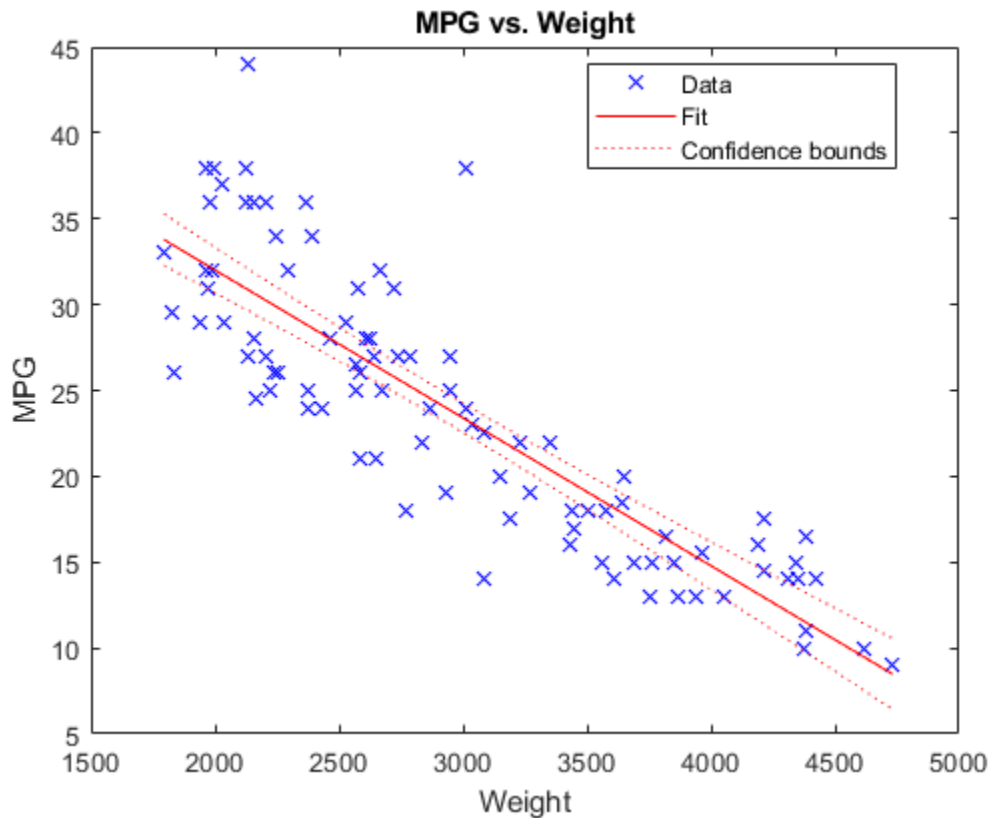

```
Root Mean Squared Error: 4.13
```

```
R-squared: 0.738, Adjusted R-Squared: 0.735
```

```
F-statistic vs. constant model: 259, p-value = 1.64e-28
```

pValue of the **Weight** variable is very small, which means that the variable is statistically significant in the model. Visualize this result by creating a scatter plot of the data, along with a fitted curve and its 95% confidence bounds, using the `plot` function.

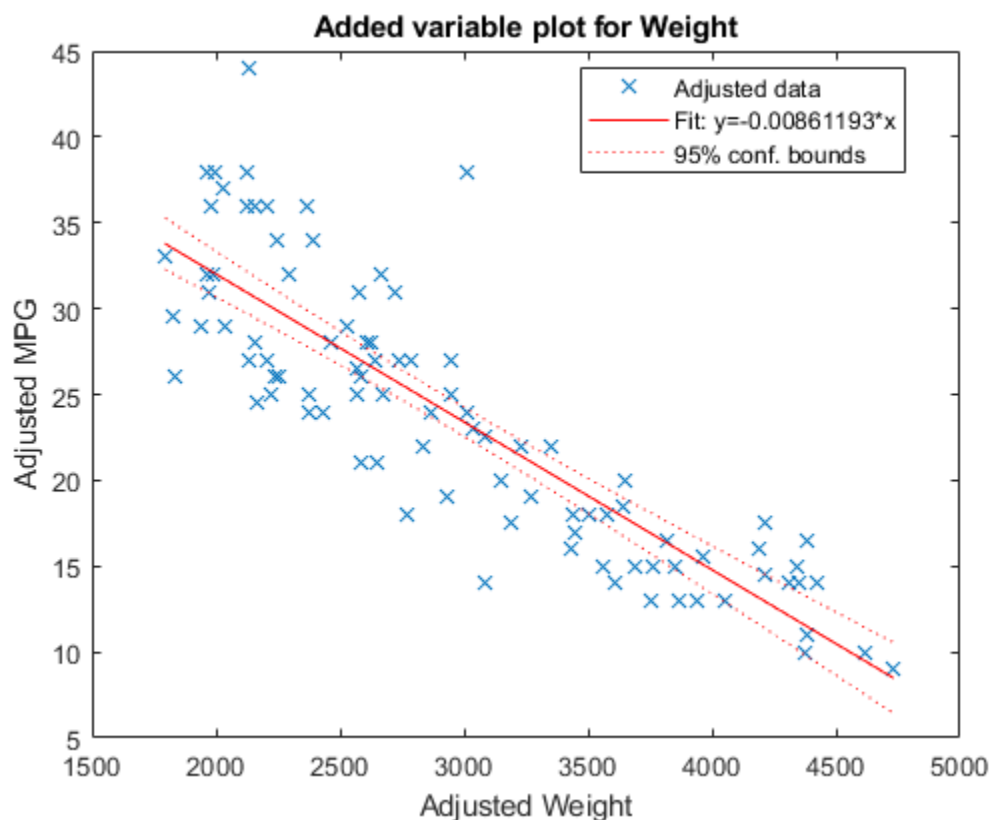

```
plot(mdl)
```

The plot illustrates that the model is significant because a horizontal line does not fit between the confidence bounds, which is consistent with the `pValue` result.

Create the same plot by using the `plotAdded` function.

```
plotAdded(mdl)
```

When a model includes only one term in addition to the constant term, an adjusted value is equivalent to its original value. Therefore, this added variable plot is the same as the scatter plot created by the `plot` function.

Input Arguments

mdl — Linear regression model

LinearModel object

Linear regression model, specified as a LinearModel object created using `fitlm` or `stepwiselm`.

Output Arguments

h — Graphics objects

graphics array

Graphics objects corresponding to the lines or patch in the plot, returned as a graphics array. Use dot notation to query and set properties of graphics objects. For details, see Line Properties and Patch Properties.

If `mdl` includes a one or more predictors, then `h(1)`, `h(2)`, `h(3)`, and `h(4)` correspond to adjusted data points, the fitted line, and the lower and upper bounds of the fitted line, respectively.

If `mdl` does not include a predictor, then `h` corresponds to the histogram of residuals.

Definitions

Added Variable Plot

An added variable plot, also known as a partial regression leverage plot, illustrates the incremental effect on the response of specified terms caused by removing the effects of all other terms.

An added variable plot created by `plotAdded` with a single selected term corresponding to a single predictor variable includes these plots:

- Scatter plot of adjusted response values against adjusted predictor variable values
- Fitted line for adjusted response values as a function of adjusted predictor variable values
- 95% confidence bounds of the fitted line

The adjusted values are equal to the average of the variable plus the residuals of the variable fit to all predictors except the selected predictor. For example, consider an added variable plot for the first predictor variable x_1 . Fit the response variable y and the selected predictor variable x_1 to all predictors except x_1 as follows:

$$y_i = g_y(x_{2i}, x_{3i}, \dots, x_{pi}) + r_{yi},$$

$$x_{1i} = g_x(x_{2i}, x_{3i}, \dots, x_{pi}) + r_{xi},$$

where g_y and g_x are the fit of y and x_1 , respectively, against all predictors except the selected predictor (x_1). r_y and r_x are the corresponding residual vectors. The subscript i

represents the observation number. The adjusted value is the sum of the average value and the residual for each observation.

$$\begin{aligned}\tilde{y}_i &= \bar{y} + r_{yi}, \\ \tilde{x}_{1i} &= \bar{x}_1 + r_{xi},\end{aligned}$$

where \bar{x}_1 and \bar{y} represent the average of x_1 and y , respectively.

`plotAdded` plots a scatter plot of $(\tilde{x}_{1i}, \tilde{y}_i)$, a fitted line for \tilde{y} as a function of \tilde{x}_1 (that is, $\beta_1 \tilde{x}_1$), and the 95% confidence bounds of the fitted line. The coefficient β_1 is the same as the coefficient estimate of x_1 in the full model, which includes all predictors.

r_{yi} represents the part of the response values unexplained by the predictors (except x_1), and r_{xi} represents the part of the x_1 values unexplained by the other predictors. Therefore, the fitted line represents how the new information introduced by adding x_1 can explain the unexplained part of the response values. If the slope of the fitted line is close to zero and the confidence bounds can include a horizontal line, then the plot indicates that the new information from x_1 does not explain the unexplained part of the response values well. That is, x_1 is not significant in the model fit.

`plotAdded` also supports an extension of the added variable plot so that you can select multiple terms instead of a single term. Therefore, you can also specify a categorical predictor, all terms that involve a specific predictor, or the model as a whole (except a constant (intercept) term). Consider a set of predictors X with a coefficient vector β , where β_i is the coefficient estimate of x_i in the full model if you specify the i th coefficient for an added variable plot; otherwise, β_i is zero. Define a unit direction vector u as $u = \beta/s$ where $s = \text{norm}(\beta)$. Then, $X\beta = (Xu)s$. Treat Xu as a single predictor with a coefficient s , and create an added variable plot for Xu in the same way as creating the plot for a single term. The coefficient of the fitted line in the added variable plot corresponds to s .

`plot` creates an added variable plot for the model as a whole (except a constant term) if the model includes multiple terms.

Tips

- The data cursor displays the values of the selected plot point in a data tip (small text box located next to the data point). The data tip includes the x -axis and y -axis values for the selected point, along with the observation name or number.

Alternative Functionality

- A `LinearModel` object provides multiple plotting functions.
 - When creating a model, use `plotAdded` to understand the effect of adding or removing a predictor variable.
 - When verifying a model, use `plotDiagnostics` to find questionable data and to understand the effect of each observation. Also, use `plotResiduals` to analyze the residuals of the model.
 - After fitting a model, use `plotAdjustedResponse`, `plotPartialDependence`, and `plotEffects` to understand the effect of a particular predictor. Use `plotInteraction` to understand the interaction effect between two predictors. Also, use `plotSlice` to plot slices through the prediction surface.
- The `plot` function creates an added variable plot for the model as a whole (except a constant term) if the model includes multiple terms. Use `plotAdded` to select particular predictors for an added variable plot.

Introduced in R2012a

plot

Class: RepeatedMeasuresModel

Plot data with optional grouping

Syntax

```
plot(rm)
plot(rm, Name, Value)
H = plot( ___ )
```

Description

`plot(rm)` plots the measurements in the repeated measures model `rm` for each subject as a function of time. If there is a single numeric within-subjects factor, `plot` uses the values of that factor as the time values. Otherwise, `plot` uses the discrete values 1 through `r` as the time values, where `r` is the number of repeated measurements.

`plot(rm, Name, Value)` also plots the measurements in the repeated measures model `rm`, with additional options specified by one or more `Name, Value` pair arguments.

For example, you can specify the factors to group by or change the line colors.

`H = plot(___)` returns handles, `H`, to the plotted lines.

Input Arguments

rm — Repeated measures model

RepeatedMeasuresModel object

Repeated measures model, returned as a RepeatedMeasuresModel object.

For properties and methods of this object, see RepeatedMeasuresModel.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Group — Name of between-subject factor or factors

character vector | string array | cell array of character vectors

Name of between-subject factor or factors, specified as the comma-separated pair consisting of `'Group'` and a character vector, string array, or cell array of character vectors. This name-value pair argument groups the lines according to the factor values.

For example, if you have two between-subject factors, drug and sex, and you want to group the lines in the plot according to them, you can specify these factors as follows.

Example: `'Group', {'Drug', 'Sex'}`

Data Types: `char` | `string` | `cell`

Marker — Marker to use for each group

string array | cell array of character vectors

Marker to use for each group, specified as the comma-separated pair consisting of `'Marker'` and a string array or cell array of character vectors.

For example, if you have two between-subject factors, drug and sex, with each having two groups, you can specify `o` as the marker for the groups of drug and `x` as the marker for the groups of sex as follows.

Example: `'Marker', {'o', 'o', 'x', 'x'}`

Data Types: `string` | `cell`

Color — Color for each group

character vector | string array | cell array of character vectors | rows of a three-column RGB matrix

Color for each group, specified as the comma-separated pair consisting of `'Color'` and a character vector, string array, cell array of character vectors, or rows of a three-column RGB matrix.

For example, if you have two between-subject factors, drug and sex, with each having two groups, you can specify red as the color for the groups of drug and blue as the color for the groups of sex as follows.

Example: `'Color', 'rrbb'`

Data Types: `single | double | char | string | cell`

LineStyle — Line style for each group

string array | cell array of character vectors

Line style for each group, specified as the comma-separated pair consisting of 'LineStyle' and a string array or cell array of character vectors.

For example, if you have two between-subject factors, drug and sex, with each having two groups, you can specify - as the line style of one group and : as the line style for the other group as follows.

Example: `'LineStyle', {'-' ':' '-' ':'}`

Data Types: `string | cell`

Output Arguments

H — Handle to plotted lines

handle

Handle to plotted lines, returned as a handle.

Examples

Plot Data by Group

Load the sample data.

```
load fisheriris
```

The column vector `species` consists of iris flowers of three different species: `setosa`, `versicolor`, and `virginica`. The double matrix `meas` consists of four types of measurements on the flowers: the length and width of sepals and petals in centimeters, respectively.

Store the data in a table array.

```
t = table(species,meas(:,1),meas(:,2),meas(:,3),meas(:,4),...  
'VariableNames',{'species','meas1','meas2','meas3','meas4'});  
Meas = dataset([1 2 3 4'],'VarNames',{'Measurements'});
```

Fit a repeated measures model, where the measurements are the responses and the species is the predictor variable.

```
rm = fitrm(t,'meas1-meas4~species','WithinDesign',Meas);
```

Plot data grouped by the factor species.

```
plot(rm,'group','species')
```

Change the line style for each group.

```
plot(rm, 'group', 'species', 'LineStyle', {'-', '--', ':-'})
```

Plot Data Grouped by Two Factors

Load the sample data.

```
load repeatedmeas
```

The table `between` includes the between-subject variables `age`, `IQ`, `group`, `gender`, and eight repeated measures `y1` through `y8` as responses. The table `within` includes the within-subject variables `w1` and `w2`. This is simulated data.

Fit a repeated measures model, where the repeated measures `y1` through `y8` are the responses, and `age`, `IQ`, `group`, `gender`, and the group-gender interaction are the predictor variables. Also specify the within-subject design matrix.

```
rm = fitrm(between, 'y1-y8 ~ Group*Gender + Age + IQ', 'WithinDesign', within);
```

Plot data with `Group` coded by color and `Gender` coded by line type.

```
plot(rm, 'group', {'Group' 'Gender'}, 'Color', 'rbbgg', ...
      'LineStyle', {'-' ':'} {'-' ':'} {'-' ':'} {'-' ':'}, 'Marker', '.')
```

`fitrm` | `multcompare` | `plotprofile`

plotAdded

Added variable plot of linear regression model

Syntax

```
plotAdded mdl  
plotAdded mdl, coef  
plotAdded mdl, coef, Name, Value  
h = plotAdded( ___ )
```

Description

`plotAdded(mdl)` produces an added variable plot on page 32-4991 for the whole model `mdl` except the constant (intercept) term.

`plotAdded(mdl, coef)` produces an added variable plot for the specified terms `coef`.

`plotAdded(mdl, coef, Name, Value)` specifies graphical properties of adjusted data points using one or more name-value pair arguments. For example, you can specify the marker symbol and size for the data points.

`h = plotAdded(___)` returns line objects using any of the input argument combinations in the previous syntaxes. Use `h` to modify the properties of a specific line after you create the plot. For a list of properties, see [Line Properties](#).

Examples

Create Added Variable Plot

Create a linear regression model of car mileage as a function of weight and model year. Then create an added variable plot to see the significance of the model.

Create a linear regression model of mileage from the `carsmall` data set.

```
load carsmall
Year = categorical(Model_Year);
tbl = table(MPG,Weight,Year);
mdl = fitlm(tbl,'MPG ~ Year + Weight^2');
```

Create an added variable plot of the model.

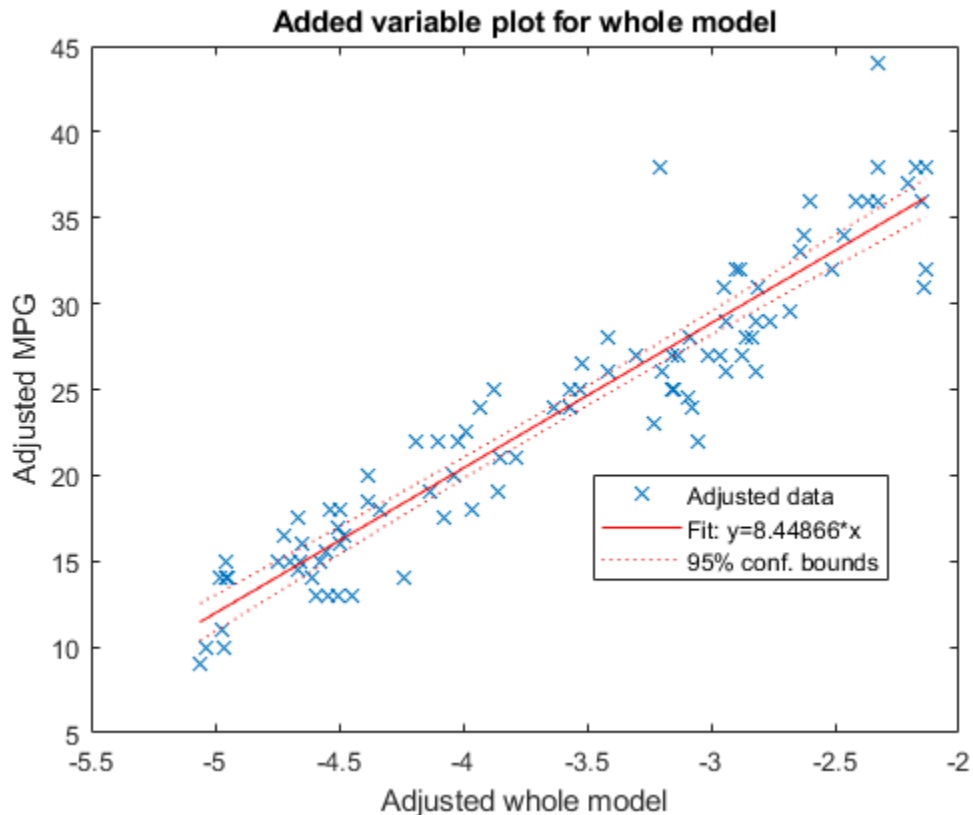

```
plot(mdl)
```

The plot illustrates that the model is significant because a horizontal line does not fit between the confidence bounds.

Create the same plot by using the plotAdded function.

```
plotAdded(mdl)
```

Create Added Variable Plot for Specified Variables

Create a linear regression model of car mileage as a function of weight and model year. Then create an added variable plot to see the effect of the weight terms (`Weight` and `Weight^2`).

Create the linear regression model using the `carsmall` data set.

```
load carsmall
Year = categorical(Model_Year);
tbl = table(MPG,Weight,Year);
mdl = fitlm(tbl,'MPG ~ Year + Weight^2');
```

Find the terms in the model corresponding to Weight and Weight².

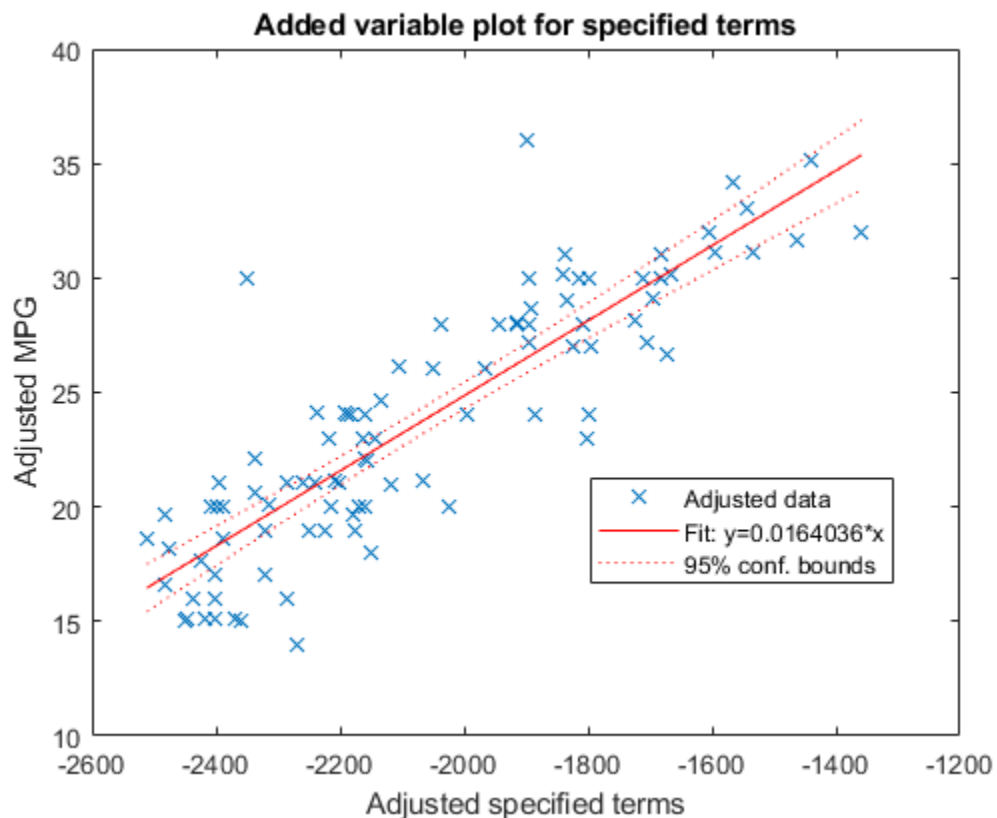

```
mdl.CoefficientNames
```

```
ans = 1x5 cell array  
    {'(Intercept)'}    {'Weight'}    {'Year_76'}    {'Year_82'}    {'Weight^2'}
```

The weight terms are 2 and 5.

Create an added variable plot with the weight terms.

```
coef = [2 5];  
plotAdded(mdl,coef)
```

The plot illustrates that the weight terms are significant because a horizontal line does not fit between the confidence bounds.

Create Scatter Plot for Simple Linear Regression

Create a scatter plot of data along with a fitted curve and confidence bounds for a simple linear regression model. A simple linear regression model includes only one predictor variable.

Create a simple linear regression model of mileage from the `carsmall` data set.

```
load carsmall
tbl = table(MPG,Weight);
mdl = fitlm(tbl,'MPG ~ Weight')
```

```
mdl =
Linear regression model:
    MPG ~ 1 + Weight
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	49.238	1.6411	30.002	2.7015e-49
Weight	-0.0086119	0.0005348	-16.103	1.6434e-28

Number of observations: 94, Error degrees of freedom: 92

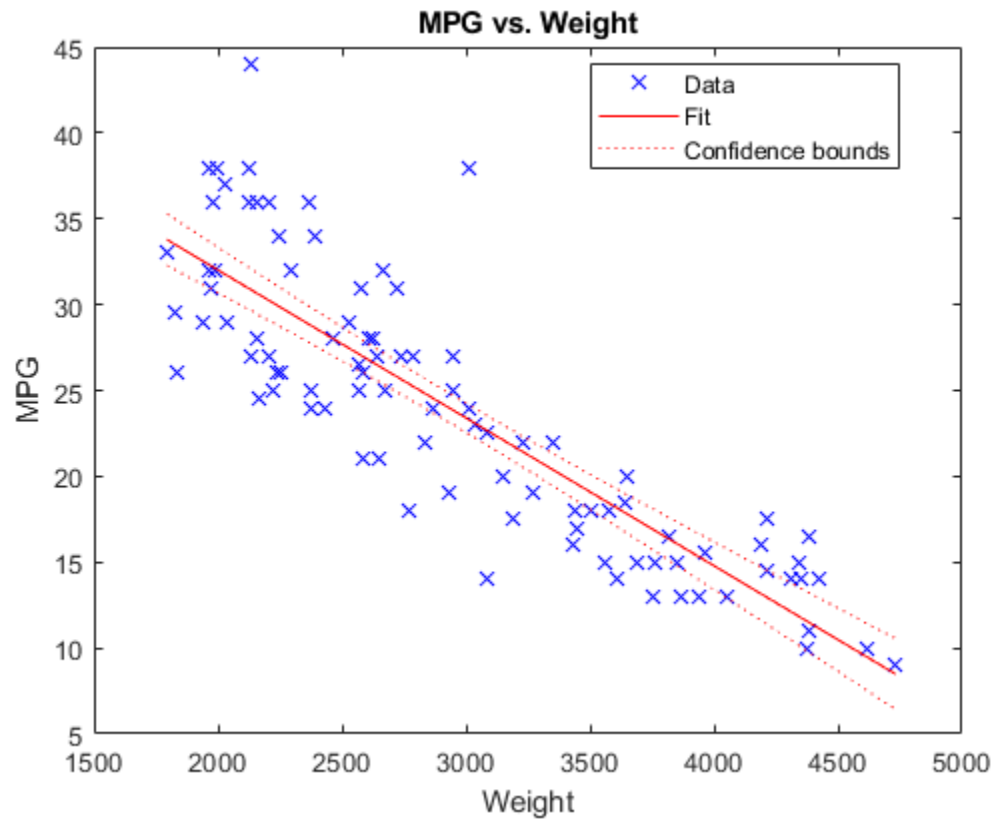

Root Mean Squared Error: 4.13

R-squared: 0.738, Adjusted R-Squared: 0.735

F-statistic vs. constant model: 259, p-value = 1.64e-28

pValue of the `Weight` variable is very small, which means that the variable is statistically significant in the model. Visualize this result by creating a scatter plot of the data, along with a fitted curve and its 95% confidence bounds, using the `plot` function.

```
plot(mdl)
```

The plot illustrates that the model is significant because a horizontal line does not fit between the confidence bounds, which is consistent with the `pValue` result.

Create the same plot by using the `plotAdded` function.

```
plotAdded mdl
```

When a model includes only one term in addition to the constant term, an adjusted value is equivalent to its original value. Therefore, this added variable plot is the same as the scatter plot created by the `plot` function.

Input Arguments

mdl — Linear regression model

LinearModel object

Linear regression model, specified as a LinearModel object created using `fitlm` or `stepwiselm`.

coef — Coefficients in regression model

character vector | string scalar | vector of positive integers

Coefficients in the regression model `mdl`, specified as one of the following:

- Character vector or string scalar of a single coefficient name in `mdl.CoefficientNames` (`CoefficientNames` property of `mdl`).
- Vector of positive integers representing the indexes of coefficients in `mdl.CoefficientNames`. Use a vector to specify multiple coefficients.

Data Types: `char` | `string` | `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'Color', 'blue', 'Marker', '*'`

Note The graphical properties listed here are only a subset. For a complete list, see [Line Properties](#). The specified properties determine the appearance of adjusted data points.

Color — Line color

RGB triplet | hexadecimal color code | color name | short name

Line color, specified as the comma-separated pair consisting of `'Color'` and an RGB triplet, hexadecimal color code, color name, or short name for one of the color options listed in the following table.

The `'Color'` name-value pair argument also determines marker outline color and marker fill color if `'MarkerEdgeColor'` is `'auto'` (default) and `'MarkerFaceColor'` is `'auto'`.

For a custom color, specify an RGB triplet or a hexadecimal color code.

- An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0, 1]`; for example, `[0.4 0.6 0.7]`.

- A hexadecimal color code is a character vector or a string scalar that starts with a hash symbol (#) followed by three or six hexadecimal digits, which can range from 0 to F. The values are not case sensitive. Thus, the color codes '#FF8800', '#ff8800', '#F80', and '#f80' are equivalent.

Alternatively, you can specify some common colors by name. This table lists the named color options, the equivalent RGB triplets, and hexadecimal color codes.

Color Name	Short Name	RGB Triplet	Hexadecimal Color Code	Appearance
'red'	'r'	[1 0 0]	'#FF0000'	
'green'	'g'	[0 1 0]	'#00FF00'	
'blue'	'b'	[0 0 1]	'#0000FF'	
'cyan'	'c'	[0 1 1]	'#00FFFF'	
'magenta'	'm'	[1 0 1]	'#FF00FF'	
'yellow'	'y'	[1 1 0]	'#FFFF00'	
'black'	'k'	[0 0 0]	'#000000'	
'white'	'w'	[1 1 1]	'#FFFFFF'	
'none'	Not applicable	Not applicable	Not applicable	No color

Here are the RGB triplets and hexadecimal color codes for the default colors MATLAB uses in many types of plots.

RGB Triplet	Hexadecimal Color Code	Appearance
[0 0.4470 0.7410]	'#0072BD'	
[0.8500 0.3250 0.0980]	'#D95319'	
[0.9290 0.6940 0.1250]	'#EDB120'	
[0.4940 0.1840 0.5560]	'#7E2F8E'	
[0.4660 0.6740 0.1880]	'#77AC30'	
[0.3010 0.7450 0.9330]	'#4DBEEE'	
[0.6350 0.0780 0.1840]	'#A2142F'	

Example: 'Color', 'blue'

LineWidth — Line width

positive value

Line width, specified as the comma-separated pair consisting of 'LineWidth' and a positive value in points. If the line has markers, then the line width also affects the marker edges.

Example: 'LineWidth',0.75

Marker — Marker symbol

'o' | '+' | '*' | '.' | 'x' | ...

Marker symbol, specified as the comma-separated pair consisting of 'Marker' and one of the values in this table.

Value	Description
'o'	Circle
'+'	Plus sign
'*'	Asterisk
'.'	Point
'x'	Cross
'square' or 's'	Square
'diamond' or 'd'	Diamond
'^'	Upward-pointing triangle
'v'	Downward-pointing triangle
'>'	Right-pointing triangle
'<'	Left-pointing triangle
'pentagram' or 'p'	Five-pointed star (pentagram)
'hexagram' or 'h'	Six-pointed star (hexagram)
'none'	No markers

Example: 'Marker', '+'

MarkerEdgeColor — Marker outline color

'auto' (default) | 'none' | RGB triplet | hexadecimal color code | color name | short name

Marker outline color, specified as the comma-separated pair consisting of 'MarkerEdgeColor' and an RGB triplet, hexadecimal color code, color name, or short name for one of the color options listed in the Color name-value pair argument.

The default value of 'auto' uses the same color specified by using 'Color'.

Example: 'MarkerEdgeColor', 'blue'

MarkerFaceColor — Marker fill color

'none' (default) | 'auto' | RGB triplet | hexadecimal color code | color name | short name

Marker fill color, specified as the comma-separated pair consisting of 'MarkerFaceColor' and an RGB triplet, hexadecimal color code, color name, or short name for one of the color options listed in the Color name-value pair argument.

The 'auto' value uses the same color specified by using 'Color'.

Example: 'MarkerFaceColor', 'blue'

MarkerSize — Marker size

6 (default) | positive value

Marker size, specified as the comma-separated pair consisting of 'MarkerSize' and a positive value in points.

Example: 'MarkerSize', 2

Output Arguments

h — Line objects

vector

Line objects, returned as a 3-by-1 vector. $h(1)$, $h(2)$, and $h(3)$ correspond to the adjusted data points, fitted line, and 95% confidence bounds of the fitted line, respectively. Use dot notation to query and set properties of the line objects. For details, see Line Properties.

You can use name-value pair arguments to specify the appearance of adjusted data points corresponding to the first graphics object $h(1)$.

Definitions

Added Variable Plot

An added variable plot, also known as a partial regression leverage plot, illustrates the incremental effect on the response of specified terms caused by removing the effects of all other terms.

An added variable plot created by `plotAdded` with a single selected term corresponding to a single predictor variable includes these plots:

- Scatter plot of adjusted response values against adjusted predictor variable values
- Fitted line for adjusted response values as a function of adjusted predictor variable values
- 95% confidence bounds of the fitted line

The adjusted values are equal to the average of the variable plus the residuals of the variable fit to all predictors except the selected predictor. For example, consider an added variable plot for the first predictor variable x_1 . Fit the response variable y and the selected predictor variable x_1 to all predictors except x_1 as follows:

$$y_i = g_y(x_{2i}, x_{3i}, \dots, x_{pi}) + r_{yi},$$

$$x_{1i} = g_x(x_{2i}, x_{3i}, \dots, x_{pi}) + r_{xi},$$

where g_y and g_x are the fit of y and x_1 , respectively, against all predictors except the selected predictor (x_1). r_y and r_x are the corresponding residual vectors. The subscript i represents the observation number. The adjusted value is the sum of the average value and the residual for each observation.

$$\tilde{y}_i = \bar{y} + r_{yi},$$

$$\tilde{x}_{1i} = \bar{x}_1 + r_{xi},$$

where \bar{x}_1 and \bar{y} represent the average of x_1 and y , respectively.

`plotAdded` plots a scatter plot of $(\tilde{x}_{1i}, \tilde{y}_i)$, a fitted line for \tilde{y} as a function of \tilde{x}_1 (that is, $\beta_1 \tilde{x}_1$), and the 95% confidence bounds of the fitted line. The coefficient β_1 is the same as the coefficient estimate of x_1 in the full model, which includes all predictors.

r_{yi} represents the part of the response values unexplained by the predictors (except x_1), and r_{xi} represents the part of the x_1 values unexplained by the other predictors. Therefore, the fitted line represents how the new information introduced by adding x_1 can

explain the unexplained part of the response values. If the slope of the fitted line is close to zero and the confidence bounds can include a horizontal line, then the plot indicates that the new information from x_1 does not explain the unexplained part of the response values well. That is, x_1 is not significant in the model fit.

`plotAdded` also supports an extension of the added variable plot so that you can select multiple terms instead of a single term. Therefore, you can also specify a categorical predictor, all terms that involve a specific predictor, or the model as a whole (except a constant (intercept) term). Consider a set of predictors X with a coefficient vector β , where β_i is the coefficient estimate of x_i in the full model if you specify the i th coefficient for an added variable plot; otherwise, β_i is zero. Define a unit direction vector u as $u = \beta/s$ where $s = \text{norm}(\beta)$. Then, $X\beta = (Xu)s$. Treat Xu as a single predictor with a coefficient s , and create an added variable plot for Xu in the same way as creating the plot for a single term. The coefficient of the fitted line in the added variable plot corresponds to s .

Tips

- The data cursor displays the values of the selected plot point in a data tip (small text box located next to the data point). The data tip includes the x -axis and y -axis values for the selected point, along with the observation name or number.

Alternative Functionality

- A `LinearModel` object provides multiple plotting functions.
 - When creating a model, use `plotAdded` to understand the effect of adding or removing a predictor variable.
 - When verifying a model, use `plotDiagnostics` to find questionable data and to understand the effect of each observation. Also, use `plotResiduals` to analyze the residuals of the model.
 - After fitting a model, use `plotAdjustedResponse`, `plotPartialDependence`, and `plotEffects` to understand the effect of a particular predictor. Use `plotInteraction` to understand the interaction effect between two predictors. Also, use `plotSlice` to plot slices through the prediction surface.
- `plotAdded` shows the incremental effect on the response of specified terms by removing the effects of the other terms, whereas `plotAdjustedResponse` shows the effect of a selected predictor in the model fit with the other predictors averaged out by

averaging the fitted values. Note that the definitions of adjusted values in `plotAdded` and `plotAdjustedResponse` are not the same.

plotAdjustedResponse

Adjusted response plot of linear regression model

Syntax

```
plotAdjustedResponse mdl, var  
plotAdjustedResponse mdl, var, Name, Value  
h = plotAdjustedResponse( ___ )
```

Description

`plotAdjustedResponse(mdl, var)` creates an adjusted response on page 32-5001 plot for the variable `var` in the linear regression model `mdl`.

`plotAdjustedResponse(mdl, var, Name, Value)` specifies graphical properties of adjusted response data points using one or more name-value pair arguments. For example, you can specify the marker symbol and size for the data points.

`h = plotAdjustedResponse(___)` returns line objects using any of the input argument combinations in the previous syntaxes. Use `h` to modify the properties of a specific line after you create the plot. For a list of properties, see [Line Properties](#).

Examples

Plot Adjusted Responses

Load the `carsmall` data set and fit a linear model of the mileage as a function of model year, weight, and weight squared.

```
load carsmall  
tbl = table(MPG,Weight);  
tbl.Year = categorical(Model_Year);  
mdl = fitlm(tbl,'MPG ~ Year + Weight^2');
```

Plot the effect of Weight averaged over Year.

```
plotAdjustedResponse mdl, 'Weight')
```

Plot the effect of Year averaged over Weight.

```
plotAdjustedResponse mdl, 'Year');
```

Input Arguments

mdl — Linear regression model

LinearModel object

Linear regression model, specified as a LinearModel object created using `fitlm` or `stepwiselm`.

var — Variable for adjusted response plot

character vector | string array | positive integer

Variable for the adjusted response plot, specified as a character vector or string array of the variable name in `mdl.VariableNames`, or a positive integer representing the index of a variable in `mdl.VariableNames`.

Data Types: `char` | `string` | `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'Color', 'blue', 'Marker', '*'`

Note The graphical properties listed here are only a subset. For a complete list, see [Line Properties](#). The specified properties determine the appearance of adjusted response data points.

Color — Line color

RGB triplet | hexadecimal color code | color name | short name

Line color, specified as the comma-separated pair consisting of `'Color'` and an RGB triplet, hexadecimal color code, color name, or short name for one of the color options listed in the following table.

The `'Color'` name-value pair argument also determines marker outline color and marker fill color if `'MarkerEdgeColor'` is `'auto'` (default) and `'MarkerFaceColor'` is `'auto'`.

For a custom color, specify an RGB triplet or a hexadecimal color code.

- An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0, 1]`; for example, `[0.4 0.6 0.7]`.
- A hexadecimal color code is a character vector or a string scalar that starts with a hash symbol (`#`) followed by three or six hexadecimal digits, which can range from `0` to `F`. The values are not case sensitive. Thus, the color codes `'#FF8800'`, `'#ff8800'`, `'#F80'`, and `'#f80'` are equivalent.

Alternatively, you can specify some common colors by name. This table lists the named color options, the equivalent RGB triplets, and hexadecimal color codes.

Color Name	Short Name	RGB Triplet	Hexadecimal Color Code	Appearance
'red'	'r'	[1 0 0]	'#FF0000'	
'green'	'g'	[0 1 0]	'#00FF00'	
'blue'	'b'	[0 0 1]	'#0000FF'	
'cyan'	'c'	[0 1 1]	'#00FFFF'	
'magenta'	'm'	[1 0 1]	'#FF00FF'	
'yellow'	'y'	[1 1 0]	'#FFFF00'	
'black'	'k'	[0 0 0]	'#000000'	
'white'	'w'	[1 1 1]	'#FFFFFF'	
'none'	Not applicable	Not applicable	Not applicable	No color

Here are the RGB triplets and hexadecimal color codes for the default colors MATLAB uses in many types of plots.

RGB Triplet	Hexadecimal Color Code	Appearance
[0 0.4470 0.7410]	'#0072BD'	
[0.8500 0.3250 0.0980]	'#D95319'	
[0.9290 0.6940 0.1250]	'#EDB120'	
[0.4940 0.1840 0.5560]	'#7E2F8E'	
[0.4660 0.6740 0.1880]	'#77AC30'	
[0.3010 0.7450 0.9330]	'#4DBEEE'	
[0.6350 0.0780 0.1840]	'#A2142F'	

Example: 'Color', 'blue'

LineWidth — Line width

positive value

Line width, specified as the comma-separated pair consisting of 'LineWidth' and a positive value in points. If the line has markers, then the line width also affects the marker edges.

Example: 'LineWidth', 0.75

Marker — Marker symbol

'o' | '+' | '*' | '.' | 'x' | ...

Marker symbol, specified as the comma-separated pair consisting of 'Marker' and one of the values in this table.

Value	Description
'o'	Circle
'+'	Plus sign
'*'	Asterisk
'.'	Point
'x'	Cross
'square' or 's'	Square
'diamond' or 'd'	Diamond
'^'	Upward-pointing triangle
'v'	Downward-pointing triangle
'>'	Right-pointing triangle
'<'	Left-pointing triangle
'pentagram' or 'p'	Five-pointed star (pentagram)
'hexagram' or 'h'	Six-pointed star (hexagram)
'none'	No markers

Example: 'Marker', '+'

MarkerEdgeColor — Marker outline color

'auto' (default) | 'none' | RGB triplet | hexadecimal color code | color name | short name

Marker outline color, specified as the comma-separated pair consisting of 'MarkerEdgeColor' and an RGB triplet, hexadecimal color code, color name, or short name for one of the color options listed in the Color name-value pair argument.

The default value of `'auto'` uses the same color specified by using `'Color'`.

Example: `'MarkerEdgeColor','blue'`

MarkerFaceColor — Marker fill color

`'none'` (default) | `'auto'` | RGB triplet | hexadecimal color code | color name | short name

Marker fill color, specified as the comma-separated pair consisting of `'MarkerFaceColor'` and an RGB triplet, hexadecimal color code, color name, or short name for one of the color options listed in the `Color` name-value pair argument.

The `'auto'` value uses the same color specified by using `'Color'`.

Example: `'MarkerFaceColor','blue'`

MarkerSize — Marker size

6 (default) | positive value

Marker size, specified as the comma-separated pair consisting of `'MarkerSize'` and a positive value in points.

Example: `'MarkerSize',2`

Output Arguments

h — Line objects

vector

Line objects, returned as a 2-by-1 vector. `h(1)` corresponds to the adjusted response data points, and `h(2)` corresponds to the adjusted response function. Use dot notation to query and set properties of the line objects. For details, see [Line Properties](#).

You can use name-value pair arguments to specify the appearance of adjusted response data points corresponding to the first graphics object `h(1)`.

Definitions

Adjusted Response

An adjusted response function describes the relationship between the fitted response and a single predictor, with the other predictors averaged out by averaging the fitted values over the data used in the fit.

A regression model for the predictor variables (x_1, x_2, \dots, x_p) and the response variable y has the form

$$y_i = f(x_{1i}, x_{2i}, \dots, x_{pi}) + r_i,$$

where f is a fitted regression function and r is a residual. The subscript i represents the observation number.

The adjusted response function for the first predictor variable x_1 , for example, is defined as

$$g(x_1) = \frac{1}{n} \sum_{i=1}^n f(x_1, x_{2i}, x_{3i}, \dots, x_{pi}),$$

where n is the number of observations. The adjusted response data value is the sum of the adjusted fitted value and the residual for each observation.

$$\tilde{y}_i = g(x_{1i}) + r_i.$$

`plotAdjustedResponse` plots the adjusted response function and the adjusted response data values for a selected predictor variable.

Tips

- The data cursor displays the values of the selected plot point in a data tip (small text box located next to the data point). The data tip includes the x-axis and y-axis values for the selected point, along with the observation name or number.

Alternative Functionality

- A `LinearModel` object provides multiple plotting functions.

- When creating a model, use `plotAdded` to understand the effect of adding or removing a predictor variable.
- When verifying a model, use `plotDiagnostics` to find questionable data and to understand the effect of each observation. Also, use `plotResiduals` to analyze the residuals of the model.
- After fitting a model, use `plotAdjustedResponse`, `plotPartialDependence`, and `plotEffects` to understand the effect of a particular predictor. Use `plotInteraction` to understand the interaction effect between two predictors. Also, use `plotSlice` to plot slices through the prediction surface.
- `plotPartialDependence` creates either a line plot or a surface plot of predicted responses against a single feature or a pair of features, respectively, by marginalizing over the other variables. A line plot for a single feature from `plotPartialDependence` and an adjusted response function plot from `plotAdjustedResponse` are the same within numerical precision.
- `plotEffects` creates a summary plot that shows separate effects for all predictors.
- `plotAdded` shows the incremental effect on the response of specified terms by removing the effects of the other terms, whereas `plotAdjustedResponse` shows the effect of a selected predictor in the model fit with the other predictors averaged out by averaging the fitted values. Note that the definitions of adjusted values in `plotAdded` and `plotAdjustedResponse` are not the same.

plot

Plot Bayesian optimization results

Syntax

```
plot(results, 'all')  
plot(results, plotFcn1, plotFcn2, ...)
```

Description

`plot(results, 'all')` calls all predefined plot functions on `results`.

`plot(results, plotFcn1, plotFcn2, ...)` calls the listed plot functions on `results`.

Examples

Plot After Optimization

This example shows how to plot the error model and the best objective trace after the optimization has finished. The objective function for this example throws an error for points with norm larger than 2.

```
function f = makeanerror(x)  
f = x.x1 - x.x2 - sqrt(4-x.x1^2-x.x2^2);
```

```
fun = @makeanerror;
```

Create the variables for optimization.

```
var1 = optimizableVariable('x1', [-5,5]);  
var2 = optimizableVariable('x2', [-5,5]);  
vars = [var1, var2];
```

Run the optimization without any plots. For reproducibility, set the random seed and use the 'expected-improvement-plus' acquisition function. Optimize for 60 iterations so the error model becomes well-trained.

```
rng default
results = bayesopt(fun,vars,'MaxObjectiveEvaluations',60,...
    'AcquisitionFunctionName','expected-improvement-plus',...
    'PlotFcn',[], 'Verbose',0);
```

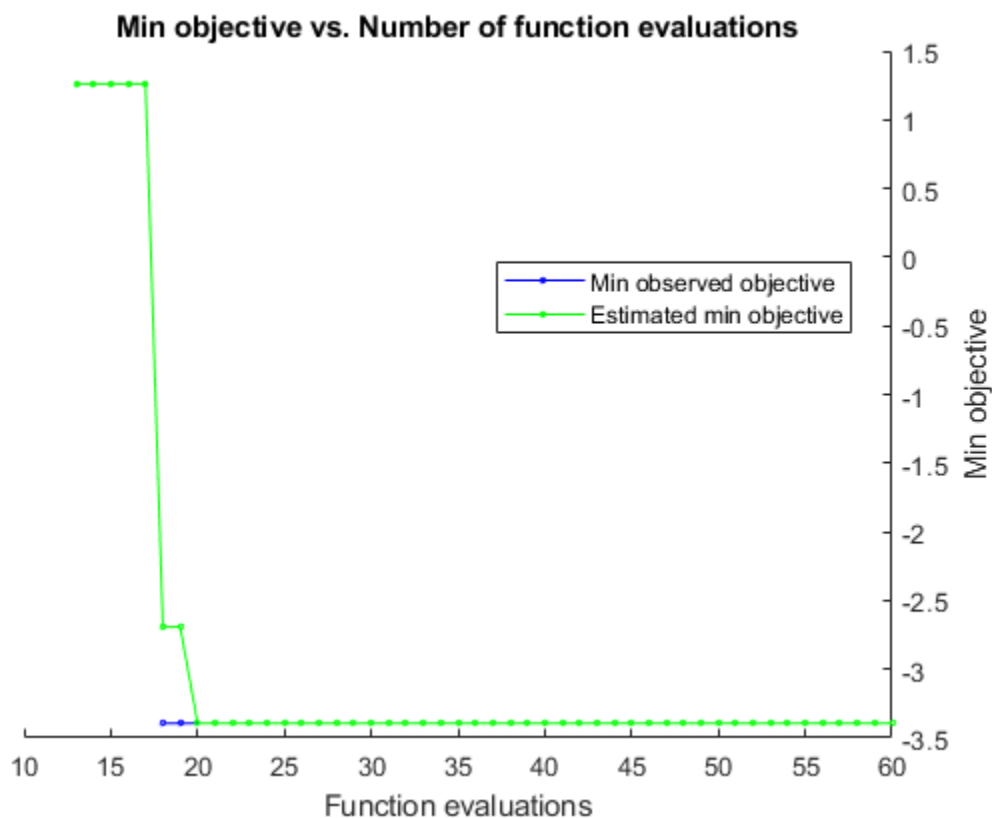

Plot the error model and the best objective trace.

```
plot(results,@plotConstraintModels,@plotMinObjective)
```

Probability of feasibility

Input Arguments

results — Bayesian optimization results

BayesianOptimization object

Bayesian optimization results, specified as a BayesianOptimization object.

plotFcn — Plot function

function handle

Plot function, specified as a function handle.

There are several built-in plot functions:

Model Plots — Apply When $D \leq 2$	Description
@plotAcquisitionFunction	Plot the acquisition function surface.
@plotConstraintModels	Plot each constraint model surface. Negative values indicate feasible points. Also plot a $P(\text{feasible})$ surface. Also plot the error model, if it exists, which ranges from -1 to 1 . Negative values mean that the model probably does not error, positive values mean that it probably does error. The model is: Plotted error = $2 * \text{Probability}(\text{error}) - 1$.
@plotObjectiveEvaluationTimeModel	Plot the objective function evaluation time model surface.
@plotObjectiveModel	Plot the fun model surface, the estimated location of the minimum, and the location of the next proposed point to evaluate. For one-dimensional problems, plot envelopes one credible interval above and below the mean function, and envelopes one noise standard deviation above and below the mean.
Trace Plots — Apply to All D	Description
@plotObjective	Plot each observed function value versus the number of function evaluations.
@plotObjectiveEvaluationTime	Plot each observed function evaluation run time versus the number of function evaluations.
@plotMinObjective	Plot the minimum observed and estimated function values versus the number of function evaluations.
@plotElapsedTime	Plot three curves: the total elapsed time of the optimization, the total function evaluation time, and the total modeling and point selection time, all versus the number of function evaluations.

You can include a handle to your own plot functions. For details, see “Bayesian Optimization Plot Functions” on page 10-13.

Example: `@plotObjective`

Data Types: `function_handle`

Alternative Functionality

You can specify plot functions in the `bayesopt PlotFcn` name-value pair. This allows you to monitor the progress of the optimization.

`BayesianOptimization` | `bayesopt`

Introduced in R2016b

plotDiagnostics

Class: GeneralizedLinearModel

Plot diagnostics of generalized linear regression model

Syntax

```
plotDiagnostics mdl
plotDiagnostics mdl, plottype
h = plotDiagnostics(...)
h = plotDiagnostics(mdl, plottype, Name, Value)
```

Description

`plotDiagnostics(mdl)` plots diagnostics from the `mdl` linear model using leverage as the plot type.

`plotDiagnostics(mdl, plottype)` plots diagnostics from the `mdl` generalized linear model in a plot of type `plottype`.

`h = plotDiagnostics(...)` returns handles to the lines in the plot.

`h = plotDiagnostics(mdl, plottype, Name, Value)` plots with additional options specified by one or more `Name, Value` pair arguments.

Input Arguments

mdl

Generalized linear model, as constructed by `fitglm` or `stepwiseglm`.

plottype

Character vector or string scalar specifying the type of plot:

'contour'	Residual vs. leverage with overlaid Cook's contours
'cookd'	Cook's distance
'leverage'	Leverage (diagonal of Hat matrix)

Default: 'leverage'

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Note The plot property name-value pairs apply to the first returned handle `h(1)`.

Color

Color of the line or marker, specified as an RGB triplet, hexadecimal color code, color name, or short name for one of the color options listed in the following table.

For a custom color, specify an RGB triplet or a hexadecimal color code.

- An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range $[0, 1]$; for example, `[0.4 0.6 0.7]`.
- A hexadecimal color code is a character vector or a string scalar that starts with a hash symbol (`#`) followed by three or six hexadecimal digits, which can range from `0` to `F`. The values are not case sensitive. Thus, the color codes `'#FF8800'`, `'#ff8800'`, `'#F80'`, and `'#f80'` are equivalent.

Alternatively, you can specify some common colors by name. This table lists the named color options, the equivalent RGB triplets, and hexadecimal color codes.

Color Name	Short Name	RGB Triplet	Hexadecimal Color Code	Appearance
'red'	'r'	<code>[1 0 0]</code>	<code>'#FF0000'</code>	

Color Name	Short Name	RGB Triplet	Hexadecimal Color Code	Appearance
'green'	'g'	[0 1 0]	'#00FF00'	
'blue'	'b'	[0 0 1]	'#0000FF'	
'cyan'	'c'	[0 1 1]	'#00FFFF'	
'magenta'	'm'	[1 0 1]	'#FF00FF'	
'yellow'	'y'	[1 1 0]	'#FFFF00'	
'black'	'k'	[0 0 0]	'#000000'	
'white'	'w'	[1 1 1]	'#FFFFFF'	

Here are the RGB triplets and hexadecimal color codes for the default colors MATLAB uses in many types of plots.

RGB Triplet	Hexadecimal Color Code	Appearance
[0 0.4470 0.7410]	'#0072BD'	
[0.8500 0.3250 0.0980]	'#D95319'	
[0.9290 0.6940 0.1250]	'#EDB120'	
[0.4940 0.1840 0.5560]	'#7E2F8E'	
[0.4660 0.6740 0.1880]	'#77AC30'	
[0.3010 0.7450 0.9330]	'#4DBEEE'	
[0.6350 0.0780 0.1840]	'#A2142F'	

LineStyle

Type of line, a Chart Line specification. For details, see `linespec`.

LineWidth

Width of the line or edges of filled area, in points, a positive scalar. One point is 1/72 inch.

Default: 0.5

MarkerEdgeColor

Marker outline color, specified as an RGB triplet, hexadecimal color code, color name, or short name for one of the color options listed in the `Color` name-value pair argument.

MarkerFaceColor

Fill color for filled markers, specified as an RGB triplet, hexadecimal color code, color name, or short name for one of the color options listed in the `Color` name-value pair argument.

MarkerSize

Size of the marker in points, a strictly positive scalar. One point is 1/72 inch.

Output Arguments

h

Vector of handles to lines or patches in the plot.

Examples

Diagnostic Plots for Generalized Linear Models

Create leverage and Cook's distance plots of a fitted generalized linear model.

Generate artificial data for the model, Poisson random numbers with two underlying predictors $X(1)$ and $X(2)$.

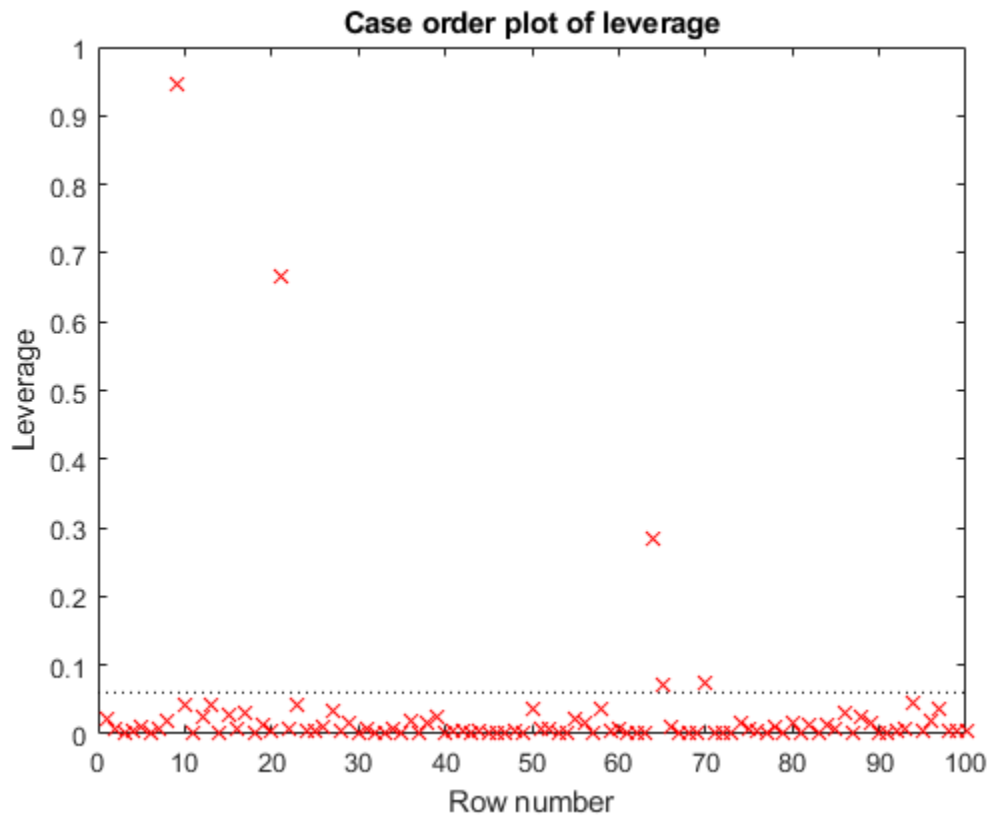

```
rng default % for reproducibility
rndvars = randn(100,2);
X = [2+rndvars(:,1),rndvars(:,2)];
mu = exp(1 + X*[1;2]);
y = poissrnd(mu);
```

Create a generalized linear regression model of Poisson data.

```
mdl = fitglm(X,y,'y ~ x1 + x2','distr','poisson');
```

Create a leverage plot.

```
plotDiagnostics(mdl)
```

Create a contour plot with Cook's distance.

```
plotDiagnostics mdl, 'contour'
```

Definitions

Hat Matrix

The hat matrix H is defined in terms of the data matrix X and a diagonal weight matrix W :

$$H = X(X^T W X)^{-1} X^T W^T.$$

W has diagonal elements w_i :

$$w_i = \frac{g'(\mu_i)}{\sqrt{V(\mu_i)'}}$$

where

- g is the link function mapping y_i to $x_i b$.
- g' is the derivative of the link function g .
- V is the variance function.
- μ_i is the i th mean.

The diagonal elements H_{ii} satisfy

$$0 \leq h_{ii} \leq 1$$

$$\sum_{i=1}^n h_{ii} = p,$$

where n is the number of observations (rows of X), and p is the number of coefficients in the regression model.

Leverage

Leverage is a measure of the effect of a particular observation on the regression predictions due to the position of that observation in the space of the inputs.

The leverage of observation i is the value of the i th diagonal term h_{ii} of the hat matrix H . The hat matrix H is defined in terms of the data matrix X :

$$H = X(X^T X)^{-1} X^T.$$

The hat matrix is also known as the *projection matrix* because it projects the vector of observations y onto the vector of predictions \hat{y} , thus putting the "hat" on y .

Because the sum of the leverage values is p (the number of coefficients in the regression model), an observation i can be considered an outlier if its leverage substantially exceeds p/n , where n is the number of observations.

For more details, see "Hat Matrix and Leverage" on page 11-99.

Cook's Distance

The Cook's distance D_i of observation i is

$$D_i = w_i \frac{e_i^2}{p\widehat{\varphi}} \frac{h_{ii}}{(1 - h_{ii})^2},$$

where

- $\widehat{\varphi}$ is the dispersion parameter (estimated or theoretical).
- e_i is the linear predictor residual, $g(y_i) - x_i\widehat{\beta}$, where
 - g is the link function.
 - y_i is the observed response.
 - x_i is the observation.
 - $\widehat{\beta}$ is the estimated coefficient vector.
- p is the number of coefficients in the regression model.
- h_{ii} is the i th diagonal element of the Hat Matrix on page 32-2865 *H*.

Tips

- The data cursor displays the values of the selected plot point in a data tip (small text box located next to the data point). The data tip includes the x -axis and y -axis values for the selected point, along with the observation name or number.

“Generalized Linear Models” on page 12-12

plotDiagnostics

Plot observation diagnostics of linear regression model

`plotDiagnostics` creates a plot of observation diagnostics such as leverage, Cook's distance, and delete-1 statistics to identify outliers and influential observations.

Syntax

```
plotDiagnostics mdl
plotDiagnostics mdl, plottype
plotDiagnostics mdl, plottype, Name, Value
h = plotDiagnostics( ___ )
```

Description

`plotDiagnostics(mdl)` creates a leverage plot of the linear regression model (`mdl`) observations. A dotted line in the plot represents the recommended threshold values.

`plotDiagnostics(mdl, plottype)` specifies the type of observation diagnostics `plottype`.

`plotDiagnostics(mdl, plottype, Name, Value)` specifies the graphical properties of diagnostic data points using one or more name-value pair arguments. For example, you can specify the marker symbol and size for the data points.

`h = plotDiagnostics(___)` returns graphics objects for the lines or contour in the plot using any of the input argument combination in the previous syntaxes. Use `h` to modify the properties of a specific line or contour after you create the plot. For a list of properties, see [Line Properties](#) and [Contour Properties](#).

Examples

Find Outliers Using Leverage and Cook's Distance

Plot the leverage values and Cook's distances of observations and find the outliers.

Load the `carsmall` data set and fit a linear regression model of the mileage as a function of model year, weight, and weight squared.

```
load carsmall
tbl = table(MPG,Weight);
tbl.Year = categorical(Model_Year);
mdl = fitlm(tbl,'MPG ~ Year + Weight^2');
```

Plot the leverage values.

```
plotDiagnostics(mdl)
legend('show') % Show the legend
```

The dotted line represents the recommended threshold value $2p/n$, where p is the number of coefficients, and n is the number of observations. Find the threshold value using the `NumCoefficients` and `NumObservations` properties.

```
t_leverage = 2*mdl.NumCoefficients/mdl.NumObservations
t_leverage = 0.1064
```

Find the observations with leverage values that exceed the threshold value.

```
find(mdl.Diagnostics.Leverage > t_leverage)
ans = 3×1
```

26
32
35

You can also find an observation number by using a data tip. Select the data points above the threshold line to display their data tips. The data tip includes the x -axis and y -axis values for the selected point, along with the observation number.

Plot the Cook's distance values.

```
plotDiagnostics mdl, 'cookd'
```

The dotted line represents the recommended threshold value t_{cookd} .

```
t_cookd = 3*mean mdl.Diagnostics.CooksDistance, 'omitnan')
```

```
t_cookd = 0.0320
```

Find the observations with the Cook's distance values that exceed the threshold value.

```
find(mdl.Diagnostics.CooksDistance > t_cookd)
```

```
ans = 6×1
```

```
26
```

```
35
```

```
80
```

```
90
```

```
92
```

```
97
```

Two observations (26 and 35) are outliers by both measures, but some points (32, 80, 90, 92, and 97) are outliers by only one measure.

Input Arguments

mdl — Linear regression model

LinearModel object

Linear regression model, specified as a LinearModel object created using fitlm or stepwiselm.

plottype — Type of plot

'leverage' (default) | 'contour' | 'cookd' | 'covratio' | 'dfbetas' | 'dffits' | 's2_i'

Type of plot, specified as one of the values in this table.

Value	Plot Type	Dotted Reference Line in Plot	Purpose
'contour'	Residual vs. leverage with overlaid contours of Cook's distance	Contours of Cook's distance	Identify observations with large residual values, high leverage, and large Cook's distance values.
'cookd'	Cook's distance	Recommended threshold, computed by $3 * \text{mean}(\text{mdl.Diagnostics.CooksDistance})$	Identify observations with large Cook's distance value.
'covratio'	Delete-1 ratio of determinant of covariance	Recommended thresholds, computed by $1 \pm 3 * p / n$, where p is the number of coefficients (<code>mdl.NumCoefficients</code>) and n is the number of observations (<code>mdl.NumObservations</code>)	Identify observations where the delete-1 statistic value is not in the range of the recommended thresholds.
'dfbetas'	Delete-1 scaled differences in coefficient estimates	Recommended threshold, computed by $3 / \sqrt{n}$	Identify observations with large delete-1 statistic values.
'dffits'	Delete-1 scaled differences in fitted values	Recommended threshold, computed by $2 * \sqrt{p/n}$ in an absolute value	Identify observations with large delete-1 statistic values in an absolute value.
'leverage'	Leverage	Recommended threshold, computed by $2 * p / n$	Identify high leverage observations.
's2_i'	Delete-1 variance	Mean squared error (<code>mdl.MSE</code>)	Compare the delete-1 variance with the mean squared error.

For all plot types except 'contour', the x-axis is the row number (case order) of observations.

The `Diagnostics` property of `mdl` contains the diagnostic values used by `plotDiagnostics` to create plots.

For more information about observation diagnostics, see “Cook’s Distance” on page 32-5028, “Delete-1 Statistics” on page 32-5028, and “Leverage” on page 32-5029.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'Color', 'blue', 'Marker', 'o'`

Note The graphical properties listed here are only a subset. For a complete list, see `Line Properties`. The specified properties determine the appearance of diagnostic data points.

Color — Line color

RGB triplet | hexadecimal color code | color name | short name

Line color, specified as the comma-separated pair consisting of `'Color'` and an RGB triplet, hexadecimal color code, color name, or short name for one of the color options listed in the following table.

The `'Color'` name-value pair argument also determines marker outline color and marker fill color if `'MarkerEdgeColor'` is `'auto'` (default) and `'MarkerFaceColor'` is `'auto'`.

For a custom color, specify an RGB triplet or a hexadecimal color code.

- An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0, 1]`; for example, `[0.4 0.6 0.7]`.
- A hexadecimal color code is a character vector or a string scalar that starts with a hash symbol (`#`) followed by three or six hexadecimal digits, which can range from `0` to `F`. The values are not case sensitive. Thus, the color codes `'#FF8800'`, `'#ff8800'`, `'#F80'`, and `'#f80'` are equivalent.

Alternatively, you can specify some common colors by name. This table lists the named color options, the equivalent RGB triplets, and hexadecimal color codes.

Color Name	Short Name	RGB Triplet	Hexadecimal Color Code	Appearance
'red'	'r'	[1 0 0]	'#FF0000'	
'green'	'g'	[0 1 0]	'#00FF00'	
'blue'	'b'	[0 0 1]	'#0000FF'	
'cyan'	'c'	[0 1 1]	'#00FFFF'	
'magenta'	'm'	[1 0 1]	'#FF00FF'	
'yellow'	'y'	[1 1 0]	'#FFFF00'	
'black'	'k'	[0 0 0]	'#000000'	
'white'	'w'	[1 1 1]	'#FFFFFF'	
'none'	Not applicable	Not applicable	Not applicable	No color

Here are the RGB triplets and hexadecimal color codes for the default colors MATLAB uses in many types of plots.

RGB Triplet	Hexadecimal Color Code	Appearance
[0 0.4470 0.7410]	'#0072BD'	
[0.8500 0.3250 0.0980]	'#D95319'	
[0.9290 0.6940 0.1250]	'#EDB120'	
[0.4940 0.1840 0.5560]	'#7E2F8E'	
[0.4660 0.6740 0.1880]	'#77AC30'	
[0.3010 0.7450 0.9330]	'#4DBEEE'	
[0.6350 0.0780 0.1840]	'#A2142F'	

Example: 'Color', 'blue'

LineWidth — Line width

positive value

Line width, specified as the comma-separated pair consisting of 'LineWidth' and a positive value in points. If the line has markers, then the line width also affects the marker edges.

Example: 'LineWidth', 0.75

Marker — Marker symbol

'o' | '+' | '*' | '.' | 'x' | ...

Marker symbol, specified as the comma-separated pair consisting of 'Marker' and one of the values in this table.

Value	Description
'o'	Circle
'+'	Plus sign
'*'	Asterisk
'.'	Point
'x'	Cross
'square' or 's'	Square
'diamond' or 'd'	Diamond
'^'	Upward-pointing triangle
'v'	Downward-pointing triangle
'>'	Right-pointing triangle
'<'	Left-pointing triangle
'pentagram' or 'p'	Five-pointed star (pentagram)
'hexagram' or 'h'	Six-pointed star (hexagram)
'none'	No markers

Example: 'Marker', '+'

MarkerEdgeColor — Marker outline color

'auto' (default) | 'none' | RGB triplet | hexadecimal color code | color name | short name

Marker outline color, specified as the comma-separated pair consisting of 'MarkerEdgeColor' and an RGB triplet, hexadecimal color code, color name, or short name for one of the color options listed in the Color name-value pair argument.

The default value of 'auto' uses the same color specified by using 'Color'.

Example: 'MarkerEdgeColor', 'blue'

MarkerFaceColor — Marker fill color

'none' (default) | 'auto' | RGB triplet | hexadecimal color code | color name | short name

Marker fill color, specified as the comma-separated pair consisting of 'MarkerFaceColor' and an RGB triplet, hexadecimal color code, color name, or short name for one of the color options listed in the Color name-value pair argument.

The 'auto' value uses the same color specified by using 'Color'.

Example: 'MarkerFaceColor', 'blue'

MarkerSize — Marker size

6 (default) | positive value

Marker size, specified as the comma-separated pair consisting of 'MarkerSize' and a positive value in points.

Example: 'MarkerSize', 2

Output Arguments

h — Graphics objects

graphics array

Graphics objects corresponding to the lines or contour in the plot, returned as a graphics array. Use dot notation to query and set properties of the graphics objects. For details, see Line Properties and Contour Properties.

You can use name-value pair arguments to specify the appearance of diagnostic data points corresponding to the first graphics object `h(1)`. If `plottype` is 'dfbetas', the plot includes a line object for each coefficient. Name-value pair arguments specify the line object properties of all coefficients. You can modify the properties of each coefficient separately by using the corresponding graphics object.

Definitions

Cook's Distance

Cook's distance is the scaled change in fitted values, which is useful for identifying outliers in the X values (observations for predictor variables). Cook's distance shows the influence of each observation on the fitted response values. An observation with Cook's distance larger than three times the mean Cook's distance might be an outlier.

Each element in the Cook's distance D is the normalized change in the fitted response values due to the deletion of an observation. The Cook's distance of observation i is

$$D_i = \frac{\sum_{j=1}^n (\hat{y}_j - \hat{y}_{j(i)})^2}{p \text{MSE}},$$

where

- \hat{y}_j is the j th fitted response value.
- $\hat{y}_{j(i)}$ is the j th fitted response value, where the fit does not include observation i .
- MSE is the mean squared error.
- p is the number of coefficients in the regression model.

Cook's distance is algebraically equivalent to the following expression:

$$D_i = \frac{r_i^2}{p \text{MSE}} \left(\frac{h_{ii}}{(1 - h_{ii})^2} \right),$$

where r_i is the i th residual, and h_{ii} is the i th leverage value.

For more details, see "Cook's Distance" on page 11-69.

Delete-1 Statistics

Delete-1 statistics are useful for finding the influence of each observation. These statistics capture the changes that would result from excluding each observation in turn from the fit. If the delete-1 statistics differ significantly from the model using all observations, then the observation is influential.

See “Delete-1 Statistics” on page 11-80 for the definitions and usages of the delete-1 statistics.

Leverage

Leverage is a measure of the effect of a particular observation on the regression predictions due to the position of that observation in the space of the inputs.

The leverage of observation i is the value of the i th diagonal term h_{ii} of the hat matrix H . The hat matrix H is defined in terms of the data matrix X :

$$H = X(X^T X)^{-1} X^T.$$

The hat matrix is also known as the *projection matrix* because it projects the vector of observations y onto the vector of predictions \hat{y} , thus putting the "hat" on y .

Because the sum of the leverage values is p (the number of coefficients in the regression model), an observation i can be considered an outlier if its leverage substantially exceeds p/n , where n is the number of observations.

For more details, see “Hat Matrix and Leverage” on page 11-99.

Tips

- The data cursor displays the values of the selected plot point in a data tip (small text box located next to the data point). The data tip includes the x-axis and y-axis values for the selected point, along with the observation name or number.
- Use `legend('show')` to show the pre-populated legend.

Alternative Functionality

- A `LinearModel` object provides multiple plotting functions.
 - When creating a model, use `plotAdded` to understand the effect of adding or removing a predictor variable.
 - When verifying a model, use `plotDiagnostics` to find questionable data and to understand the effect of each observation. Also, use `plotResiduals` to analyze the residuals of the model.
 - After fitting a model, use `plotAdjustedResponse`, `plotPartialDependence`, and `plotEffects` to understand the effect of a particular predictor. Use

`plotInteraction` to understand the interaction effect between two predictors. Also, use `plotSlice` to plot slices through the prediction surface.

Introduced in R2012a

plotDiagnostics

Class: NonLinearModel

Plot diagnostics of nonlinear regression model

Syntax

```
plotDiagnostics mdl
plotDiagnostics mdl,plottype
h = plotDiagnostics(...)
h = plotDiagnostics(mdl,plottype,Name,Value)
```

Description

`plotDiagnostics(mdl)` plots diagnostics from the `mdl` linear model using leverage as the plot type.

`plotDiagnostics(mdl,plottype)` plots diagnostics in a plot of type `plottype`.

`h = plotDiagnostics(...)` returns handles to the lines in the plot.

`h = plotDiagnostics(mdl,plottype,Name,Value)` plots with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

mdl

Nonlinear regression model, constructed by `fitnlm`.

plottype

Character vector or string scalar specifying the type of plot:

'contour'	Residual vs. leverage with overlaid Cook's contours
'cookd'	Cook's distance
'leverage'	Leverage (diagonal of Hat matrix)

Default: 'leverage'

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Note The plot property name-value pairs apply to the first returned handle `h(1)`.

Color

Color of the line or marker, specified as an RGB triplet, hexadecimal color code, color name, or short name for one of the color options listed in the following table.

For a custom color, specify an RGB triplet or a hexadecimal color code.

- An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range $[0, 1]$; for example, `[0.4 0.6 0.7]`.
- A hexadecimal color code is a character vector or a string scalar that starts with a hash symbol (`#`) followed by three or six hexadecimal digits, which can range from `0` to `F`. The values are not case sensitive. Thus, the color codes `'#FF8800'`, `'#ff8800'`, `'#F80'`, and `'#f80'` are equivalent.

Alternatively, you can specify some common colors by name. This table lists the named color options, the equivalent RGB triplets, and hexadecimal color codes.

Color Name	Short Name	RGB Triplet	Hexadecimal Color Code	Appearance
'red'	'r'	<code>[1 0 0]</code>	<code>'#FF0000'</code>	

Color Name	Short Name	RGB Triplet	Hexadecimal Color Code	Appearance
'green'	'g'	[0 1 0]	'#00FF00'	
'blue'	'b'	[0 0 1]	'#0000FF'	
'cyan'	'c'	[0 1 1]	'#00FFFF'	
'magenta'	'm'	[1 0 1]	'#FF00FF'	
'yellow'	'y'	[1 1 0]	'#FFFF00'	
'black'	'k'	[0 0 0]	'#000000'	
'white'	'w'	[1 1 1]	'#FFFFFF'	

Here are the RGB triplets and hexadecimal color codes for the default colors MATLAB uses in many types of plots.

RGB Triplet	Hexadecimal Color Code	Appearance
[0 0.4470 0.7410]	'#0072BD'	
[0.8500 0.3250 0.0980]	'#D95319'	
[0.9290 0.6940 0.1250]	'#EDB120'	
[0.4940 0.1840 0.5560]	'#7E2F8E'	
[0.4660 0.6740 0.1880]	'#77AC30'	
[0.3010 0.7450 0.9330]	'#4DBEEE'	
[0.6350 0.0780 0.1840]	'#A2142F'	

LineStyle

Type of line, a Chart Line specification. For details, see `linespec`.

LineWidth

Width of the line or edges of filled area, in points, a positive scalar. One point is 1/72 inch.

Default: 0.5

MarkerEdgeColor

Marker outline color, specified as an RGB triplet, hexadecimal color code, color name, or short name for one of the color options listed in the `Color` name-value pair argument.

MarkerFaceColor

Fill color for filled markers, specified as an RGB triplet, hexadecimal color code, color name, or short name for one of the color options listed in the `Color` name-value pair argument.

MarkerSize

Size of the marker in points, a strictly positive scalar. One point is 1/72 inch.

Output Arguments

h

Vector of handles to lines or patches in the plot.

Examples

Nonlinear Model Leverage Plot

Create a leverage plot of a fitted nonlinear model, and find the points with high leverage.

Load the reaction data and fit a model of the reaction rate as a function of reactants.

```
load reaction
mdl = fitnlm(reactants,rate,@hougen,[1 .05 .02 .1 2]);
```

Create a leverage plot of the fitted model.

```
plotDiagnostics(mdl)
```

Use data tips to examine the observation with high leverage. A data tip appears when you hover over a data point.

Alternatively, find the high-leverage observation at the command line.

```
find mdl.Diagnostics.Leverage > 0.8)
```

ans =

6

Definitions

Hat Matrix

The hat matrix H is defined in terms of the data matrix X and the Jacobian matrix J :

$$J_{i,j} = \left. \frac{\partial f}{\partial \beta_j} \right|_{x_i, \beta}$$

Here f is the nonlinear model function, and β is the vector of model coefficients.

The Hat Matrix H is

$$H = J(J^T J)^{-1} J^T.$$

The diagonal elements H_{ii} satisfy

$$0 \leq h_{ii} \leq 1$$

$$\sum_{i=1}^n h_{ii} = p,$$

where n is the number of observations (rows of X), and p is the number of coefficients in the regression model.

Leverage

Leverage is a measure of the effect of a particular observation on the regression predictions due to the position of that observation in the space of the inputs.

The leverage of observation i is the value of the i th diagonal term h_{ii} of the hat matrix H . The hat matrix H is defined in terms of the data matrix X :

$$H = X(X^T X)^{-1} X^T.$$

The hat matrix is also known as the *projection matrix* because it projects the vector of observations y onto the vector of predictions \hat{y} , thus putting the "hat" on y .

Because the sum of the leverage values is p (the number of coefficients in the regression model), an observation i can be considered an outlier if its leverage substantially exceeds p/n , where n is the number of observations.

For more details, see “Hat Matrix and Leverage” on page 11-99.

Cook’s Distance

The Cook’s distance D_i of observation i is

$$D_i = \frac{\sum_{j=1}^n (\hat{y}_j - \hat{y}_{j(i)})^2}{p \text{MSE}},$$

where

- \hat{y}_j is the j th fitted response value.
- $\hat{y}_{j(i)}$ is the j th fitted response value, where the fit does not include observation i .
- MSE is the mean squared error.
- p is the number of coefficients in the regression model.

Cook’s distance is algebraically equivalent to the following expression:

$$D_i = \frac{r_i^2}{p \text{MSE}} \left(\frac{h_{ii}}{(1 - h_{ii})^2} \right),$$

where e_i is the i th residual.

Tips

- The data cursor displays the values of the selected plot point in a data tip (small text box located next to the data point). The data tip includes the x-axis and y-axis values for the selected point, along with the observation name or number.

plotEffects

Package:

Plot main effects of predictors in linear regression model

Syntax

```
plotEffects mdl  
h = plotEffects(mdl)
```

Description

`plotEffects(mdl)` creates an effects plot of the predictors in the linear regression model `mdl`. An effects plot shows the estimated main effect on page 32-5042 on the response from changing each predictor value, averaging out the effects of the other predictors. A horizontal line through an effect value indicates the 95% confidence interval for the effect value.

`h = plotEffects(mdl)` returns line objects. Use `h` to modify the properties of a specific line after you create the plot. For a list of properties, see [Line Properties](#).

Examples

Effects Plot for Linear Regression Model

Load the `carsmall` data set and fit a linear regression model of the mileage as a function of model year, weight, and weight squared.

```
load carsmall  
tbl = table(MPG,Weight);  
tbl.Year = categorical(Model_Year);  
mdl = fitlm(tbl,'MPG ~ Year + Weight^2');
```

Create an effects plot.

```
plotEffects mdl
```

The length of each horizontal line in the figure shows a 95% confidence interval for the effect on the response of the change shown for each predictor. For example, the estimated effect of changing Year from 70 to 82 is an increase of about 8, and is between 6 and 10 with 95% confidence.

Input Arguments

mdl — Linear regression model object

LinearModel object | CompactLinearModel object

Linear regression model object, specified as a `LinearModel` object created by using `fitlm` or `stepwiselm`, or a `CompactLinearModel` object created by using `compact`.

Output Arguments

h — Line objects

vector

Line objects, returned as a vector. `h(1)` corresponds to the circles that represent the effect estimates, and `h(j+1)` corresponds to the 95% confidence interval for the effect of predictor `j`. Use dot notation to query and set properties of line objects. For details, see [Line Properties](#).

Definitions

Main Effect

An effect, or main effect, of a predictor represents an effect of one predictor on the response from changing the predictor value while averaging out the effects of the other predictors.

For a predictor variable x_s , the effect is defined by

$$g(x_{si}) - g(x_{sj}),$$

where g is an “Adjusted Response” on page 32-5042 function. The `plotEffects` function chooses the observations i and j as follows. For a categorical variable that is not ordinal, x_{si} and x_{sj} are the predictor values that produce the maximum and minimum adjusted responses, respectively, so that the effect value is always positive. For a numeric variable or an ordinal categorical variable, the function chooses two predictor values that produce the minimum and maximum adjusted responses where $x_{si} < x_{sj}$.

`plotEffects` plots the effect value and the 95% confidence interval of the effect value for each predictor variable.

Adjusted Response

An adjusted response function describes the relationship between the fitted response and a single predictor, with the other predictors averaged out by averaging the fitted values over the data used in the fit.

A regression model for the predictor variables (x_1, x_2, \dots, x_p) and the response variable y has the form

$$y_i = f(x_{1i}, x_{2i}, \dots, x_{pi}) + r_i,$$

where f is a fitted regression function and r is a residual. The subscript i represents the observation number.

The adjusted response function for the first predictor variable x_1 , for example, is defined as

$$g(x_1) = \frac{1}{n} \sum_{i=1}^n f(x_{1i}, x_{2i}, x_{3i}, \dots, x_{pi}),$$

where n is the number of observations. The adjusted response data value is the sum of the adjusted fitted value and the residual for each observation.

$$\tilde{y}_i = g(x_{1i}) + r_i.$$

`plotAdjustedResponse` plots the adjusted response function and the adjusted response data values for a selected predictor variable.

Tips

- The data cursor displays the values of the selected plot point in a data tip (small text box located next to the data point). The data tip includes the x -axis and y -axis values for the selected point. Use the x -axis values to view an estimated effect value and its confidence bounds.

Alternative Functionality

- A `LinearModel` object provides multiple plotting functions.
 - When creating a model, use `plotAdded` to understand the effect of adding or removing a predictor variable.
 - When verifying a model, use `plotDiagnostics` to find questionable data and to understand the effect of each observation. Also, use `plotResiduals` to analyze the residuals of the model.
 - After fitting a model, use `plotAdjustedResponse`, `plotPartialDependence`, and `plotEffects` to understand the effect of a particular predictor. Use

`plotInteraction` to understand the interaction effect between two predictors. Also, use `plotSlice` to plot slices through the prediction surface.

“Linear Regression with Interaction Effects” on page 11-54

“Interpret Linear Regression Results” on page 11-62

“Linear Regression Workflow” on page 11-41

“Linear Regression” on page 11-11

Introduced in R2012a

plotInteraction

Package:

Plot interaction effects of two predictors in linear regression model

Syntax

```
plotInteraction mdl, var1, var2
plotInteraction mdl, var1, var2, ptype
h = plotInteraction( ___ )
```

Description

`plotInteraction(mdl, var1, var2)` creates a plot of the main effects on page 32-5053 of the two selected predictors `var1` and `var2` and their conditional effects on page 32-5054 in the linear regression model `mdl`. Horizontal lines through the effect values indicate their 95% confidence intervals.

`plotInteraction(mdl, var1, var2, ptype)` specifies the plot type `ptype`. For example, if `ptype` is 'predictions', then `plotInteraction` plots the adjusted response function as a function of the second predictor, with the first predictor fixed at specific values. For details, see “Conditional Effect” on page 32-5054.

`h = plotInteraction(___)` returns line objects using any of the input argument combinations in the previous syntaxes. Use `h` to modify the properties of a specific line after you create the plot. For a list of properties, see Line Properties.

Examples

Interaction Plot of Main Effects and Conditional Effects

Fit a model with an interaction term and create an interaction plot that shows the main effects and conditional effects.

Using the data in the `carsmall` data set, create response values that include an interaction term. First, load the data set and normalize the predictor data.

```
load carsmall
Acceleration = normalize(Acceleration);
Horsepower = normalize(Horsepower);
Displacement = normalize(Displacement);
```

Define a response variable that includes the interaction term `Acceleration*Horsepower`.

```
y = Acceleration + 4*Horsepower + Acceleration.*Horsepower + Displacement;
```

Add some noise to the response values.

```
rng('default') % For reproducibility
y = y + normrnd(10,0.25*nanstd(y),size(y));
```

Create a table that includes the predictor data and response values.

```
tbl = table(Acceleration,Horsepower,Displacement,y);
```

Fit a linear regression model.

```
mdl = fitlm(tbl,'y ~ Acceleration + Horsepower + Acceleration*Horsepower + Displacement');
```

```
mdl =
```

```
Linear regression model:
```

```
    y ~ 1 + Acceleration*Horsepower + Horsepower*Displacement
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	9.8652	0.16177	60.982	8.587e-77
Acceleration	0.63726	0.1626	3.9191	0.00016967
Horsepower	3.6168	0.34	10.638	9.273e-18
Displacement	0.95032	0.31828	2.9858	0.0036144
Acceleration:Horsepower	0.60108	0.1851	3.2473	0.0016209
Horsepower:Displacement	-0.0096069	0.20947	-0.045863	0.96352

Number of observations: 99, Error degrees of freedom: 93

Root Mean Squared Error: 1.07

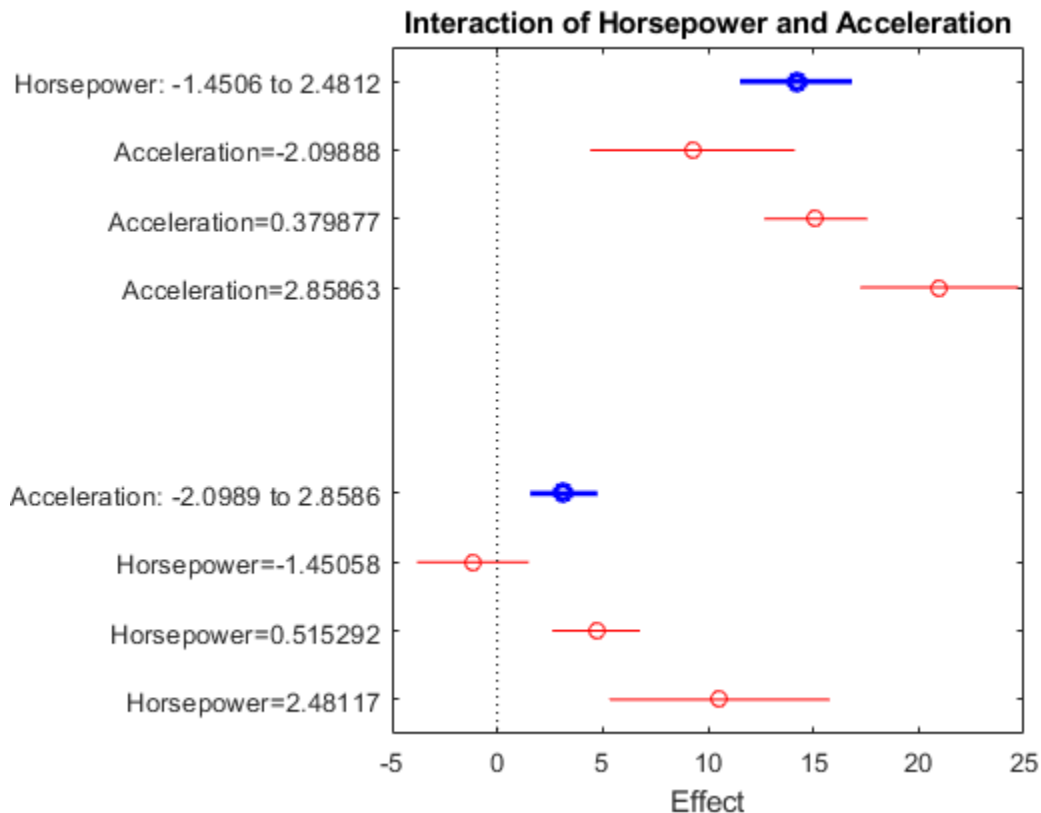

R-squared: 0.93, Adjusted R-Squared: 0.927

F-statistic vs. constant model: 249, p-value = 3.3e-52

pValue of the interaction term Acceleration*Horsepower is very small, meaning that the interaction term is statistically significant.

Create an interaction plot that shows the main effects and conditional effects of Horsepower and Acceleration.

```
plotInteraction mdl, 'Horsepower', 'Acceleration')
```

For each predictor, the main effect point and its conditional effect points are not vertically aligned. Therefore, you cannot find any vertical lines that pass through the confidence intervals of the main and conditional effect points for each predictor. This plot indicates the existence of interaction effects on the response variable.

For comparison, create an interaction plot for Displacement and Horsepower. This p -value of this interaction term (Displacement*Horsepower) is large, meaning that the interaction term is not statistically significant.

```
plotInteraction mdl, 'Displacement', 'Horsepower'
```

For each predictor, the main effect point and its conditional effect points are aligned vertically. This plot indicates no interaction.

Interaction Plot of Adjusted Response Curve

Fit a model with an interaction term and create an interaction plot of adjusted response curves.

Using the data in the `carsmall` data set, create response values that include an interaction term. First, load the data set and normalize the predictor data.

```
load carsmall
Acceleration = normalize(Acceleration);
Horsepower = normalize(Horsepower);
Displacement = normalize(Displacement);
```

Define a response variable that includes the interaction term
`Acceleration*Horsepower`.

```
y = Acceleration + 4*Horsepower + Acceleration.*Horsepower + Displacement;
```

Add some noise to the response values.

```
rng('default') % For reproducibility
y = y + normrnd(10,0.25*nanstd(y),size(y));
```

Create a table that includes the predictor data and response values.

```
tbl = table(Acceleration,Horsepower,Displacement,y);
```

Fit a linear regression model.

```
mdl = fitlm(tbl,'y ~ Acceleration + Horsepower + Acceleration*Horsepower + Displacement');
```

```
mdl =
```

```
Linear regression model:
```

```
    y ~ 1 + Acceleration*Horsepower + Horsepower*Displacement
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	9.8652	0.16177	60.982	8.587e-77
Acceleration	0.63726	0.1626	3.9191	0.00016967
Horsepower	3.6168	0.34	10.638	9.273e-18
Displacement	0.95032	0.31828	2.9858	0.0036144
Acceleration:Horsepower	0.60108	0.1851	3.2473	0.0016209
Horsepower:Displacement	-0.0096069	0.20947	-0.045863	0.96352

Number of observations: 99, Error degrees of freedom: 93
Root Mean Squared Error: 1.07
R-squared: 0.93, Adjusted R-Squared: 0.927
F-statistic vs. constant model: 249, p-value = 3.3e-52

pValue of the interaction term `Acceleration*Horsepower` is very small, meaning that the interaction term is statistically significant.

Create an interaction plot that shows the adjusted response function as a function of `Acceleration`, with `Horsepower` fixed at specific values.

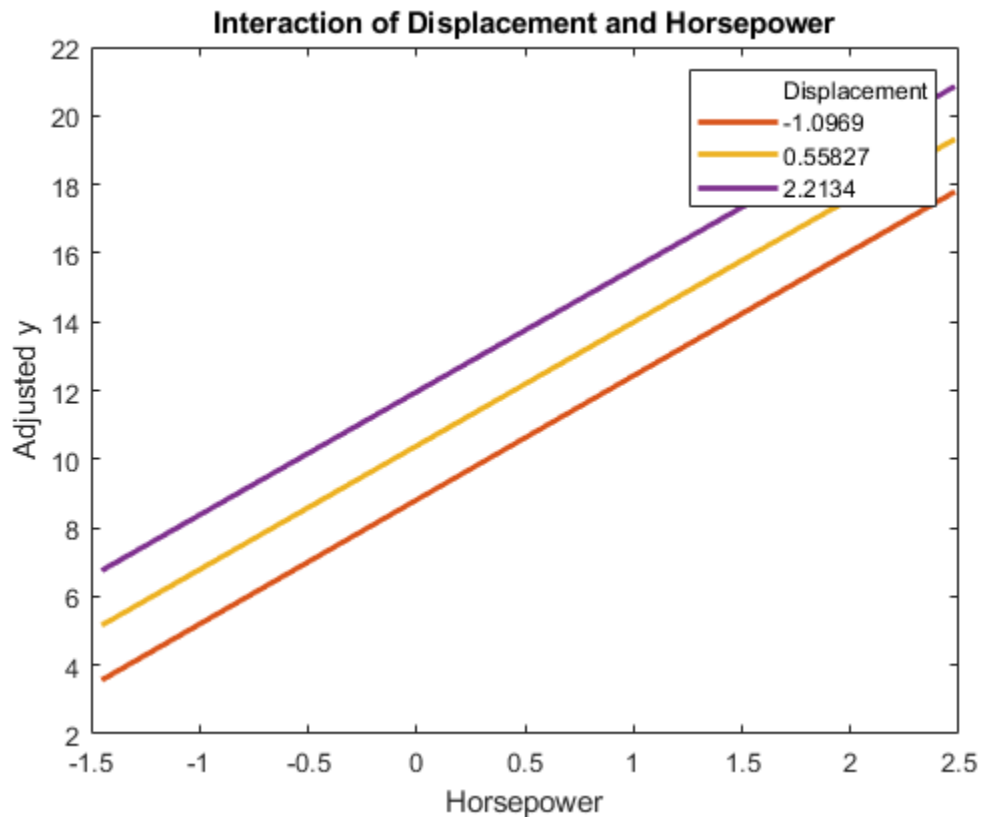

```
plotInteraction mdl, 'Horsepower', 'Acceleration', 'predictions')
```

The curves are not parallel. This plot indicates interactions between the predictors.

For comparison, create an interaction plot for the Displacement and Horsepower. The p -value of this interaction term (Displacement*Horsepower) is large, meaning that the interaction term is not statistically significant.

```
plotInteraction mdl, 'Displacement', 'Horsepower', 'predictions')
```

The curves are parallel, indicating no interaction.

Input Arguments

mdl — Linear regression model object

LinearModel object | CompactLinearModel object

Linear regression model object, specified as a LinearModel object created by using `fitlm` or `stepwiselm`, or a CompactLinearModel object created by using `compact`.

var1 — First variable for plot

character vector | string array | positive integer

First variable for the plot, specified as a character vector or string array of the variable name in `mdl.VariableNames` (`VariableNames` property of `mdl`), or a positive integer representing the index of a variable in `mdl.VariableNames`.

Data Types: `char` | `string` | `single` | `double`

var2 — Second variable for plot

character vector | string array | positive integer

Second variable for the plot, specified as a character vector or string array of the variable name in `mdl.VariableNames` (`VariableNames` property of `mdl`), or a positive integer representing the index of a variable in `mdl.VariableNames`.

Data Types: `char` | `string` | `single` | `double`

ptype — Plot type

'effects' (default) | 'predictions'

Plot type, specified as one of these values:

- 'effects' — `plotInteraction` creates a plot of the main effects of the two selected predictors `var1` and `var2` and their conditional effects. Horizontal lines through the effect values indicate their 95% confidence intervals.
- 'predictions' — `plotInteraction` plots the adjusted response function as a function of `var2`, with `var1` fixed at specific values.

For details, see “Main Effect” on page 32-5053 and “Conditional Effect” on page 32-5054.

Output Arguments

h — Line objects

vector

Line objects, returned as a vector. Use dot notation to query and set properties of the line objects. For details, see Line Properties.

If the plot type is 'effects' (default), `h(1)` corresponds to the circles that represent the main effect estimates, and `h(2)` and `h(3)` correspond to the 95% confidence intervals for the two main effects. The remaining entries in `h` correspond to the conditional effects and their confidence intervals. The line objects associated with the main effects have the tag 'main'. The line objects associated with the conditional effects of `var1` and `var2` have the tags 'conditional1' and 'conditional2', respectively.

If the plot type is 'predictions', each entry in `h` corresponds to each curve on the plot.

Definitions

Main Effect

An effect, or main effect, of a predictor represents an effect of one predictor on the response from changing the predictor value while averaging out the effects of the other predictors.

For a predictor variable x_s , the effect is defined by

$$g(x_{si}) - g(x_{sj}),$$

where g is an "Adjusted Response" on page 32-5054 function. The `plotEffects` function chooses the observations i and j as follows. For a categorical variable that is not ordinal, x_{si} and x_{sj} are the predictor values that produce the maximum and minimum adjusted responses, respectively, so that the effect value is always positive. For a numeric variable or an ordinal categorical variable, the function chooses two predictor values that produce the minimum and maximum adjusted responses where $x_{si} < x_{sj}$.

`plotEffects` plots the effect value and the 95% confidence interval of the effect value for each predictor variable.

Adjusted Response

An adjusted response function describes the relationship between the fitted response and a single predictor, with the other predictors averaged out by averaging the fitted values over the data used in the fit.

A regression model for the predictor variables (x_1, x_2, \dots, x_p) and the response variable y has the form

$$y_i = f(x_{1i}, x_{2i}, \dots, x_{pi}) + r_i,$$

where f is a fitted regression function and r is a residual. The subscript i represents the observation number.

The adjusted response function for the first predictor variable x_1 , for example, is defined as

$$g(x_1) = \frac{1}{n} \sum_{i=1}^n f(x_1, x_{2i}, x_{3i}, \dots, x_{pi}),$$

where n is the number of observations. The adjusted response data value is the sum of the adjusted fitted value and the residual for each observation.

$$\tilde{y}_i = g(x_{1i}) + r_i.$$

`plotAdjustedResponse` plots the adjusted response function and the adjusted response data values for a selected predictor variable.

Conditional Effect

When a model contains an interaction term, the main effect of one predictor depends on the value of another predictor that interacts with it. In this case, a conditional effect of one predictor given a specific value of another is helpful in understanding the actual effect of both predictors. You can examine whether the effect of one predictor depends on the value of another by using conditional effect values.

To define a conditional effect, define the adjusted response function as a function of two predictor variables. For example, the adjusted response function of x_1 and x_2 is

$$h(x_1, x_2) = \frac{1}{n} \sum_{i=1}^n f(x_1, x_2, x_{3i}, \dots, x_{pi}),$$

where f is a fitted regression function, and n is the number of observations.

The conditional effect of one predictor (x_2) given a specific value of another predictor (x_{1k}) is defined by

$$h(x_{1k}, x_{2i}) - h(x_{1k}, x_{2j}).$$

To compute conditional effect values, `plotInteraction` chooses the observations i and j of x_2 in the same way as when the function computes the “Main Effect” on page 32-5053 and chooses the x_{1k} values. If x_1 is a categorical variable, then `plotInteraction` computes the conditional effect for all levels of x_1 . If x_1 is a numeric variable, then `plotInteraction` computes the conditional effect for three values of x_1 : the minimum value of x_1 , the maximum value of x_1 , and the average value of the minimum and maximum.

If the plot type is 'effects' (default), `plotInteraction` plots the main effects of the two selected predictors, their conditional effects, and the 95% confidence bounds for the effect values.

If the plot type is 'predictions', `plotInteraction` plots the adjusted response function as a function of the second predictor, with the first predictor fixed at specific values. For example, `plotInteraction mdl, 'x1', 'x2', 'predictions'` plots the curve of $h(x_{1k}, x_2)$ for each x_{1k} value.

Tips

- The data cursor displays the values of the selected plot point in a data tip (small text box located next to the data point). The data tip includes the x-axis and y-axis values for the selected point, along with the observation name or number.

Alternative Functionality

- A `LinearModel` object provides multiple plotting functions.
 - When creating a model, use `plotAdded` to understand the effect of adding or removing a predictor variable.
 - When verifying a model, use `plotDiagnostics` to find questionable data and to understand the effect of each observation. Also, use `plotResiduals` to analyze the residuals of the model.
 - After fitting a model, use `plotAdjustedResponse`, `plotPartialDependence`, and `plotEffects` to understand the effect of a particular predictor. Use

`plotInteraction` to understand the interaction effect between two predictors. Also, use `plotSlice` to plot slices through the prediction surface.

Introduced in R2012a

plotprofile

Class: RepeatedMeasuresModel

Plot expected marginal means with optional grouping

Syntax

```
plotprofile(rm,X)
plotprofile(rm,Name,Value)
H = plotprofile( ___ )
```

Description

`plotprofile(rm,X)` plots the expected marginal means computed from the repeated measures model `rm` as a function of the variable `X`.

`plotprofile(rm,Name,Value)` plots the expected marginal means computed from the repeated measures model `rm` with additional options specified by one or more `Name,Value` pair arguments.

For example, you can specify the factors to group by or change the line colors.

`H = plotprofile(___)` returns handles, `H`, to the plotted lines.

Input Arguments

rm — Repeated measures model

RepeatedMeasuresModel object

Repeated measures model, returned as a RepeatedMeasuresModel object.

For properties and methods of this object, see RepeatedMeasuresModel.

X — Name of between-subjects or within-subjects factor

character vector | string scalar

Name of a between-subjects or within-subjects factor, specified as a character vector or string scalar.

For example, if you want to plot the marginal means as a function of the groups of a between-subjects variable `drug`, you can specify it as follows.

Example: `'Drug'`

Data Types: `char` | `string`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Group — Name of between-subject factor or factors

character vector | string array | cell array of character vectors

Name of between-subject factor or factors, specified as the comma-separated pair consisting of `'Group'` and a character vector, string array, or cell array of character vectors. This name-value pair argument groups the lines according to the factor values.

For example, if you have two between-subject factors, `drug` and `sex`, and you want to group the lines in the plot according to them, you can specify these factors as follows.

Example: `'Group', {'Drug', 'Sex'}`

Data Types: `char` | `string` | `cell`

Marker — Marker to use for each group

string array | cell array of character vectors

Marker to use for each group, specified as the comma-separated pair consisting of `'Marker'` and a string array or cell array of character vectors.

For example, if you have two between-subject factors, `drug` and `sex`, with each having two groups, you can specify `o` as the marker for the groups of `drug` and `x` as the marker for the groups of `sex` as follows.

Example: `'Marker', {'o', 'o', 'x', 'x'}`

Data Types: `string` | `cell`

Color — Color for each group

character vector | string array | cell array of character vectors | rows of a three-column RGB matrix

Color for each group, specified as the comma-separated pair consisting of 'Color' and a character vector, string array, cell array of character vectors, or rows of a three-column RGB matrix.

For example, if you have two between-subject factors, drug and sex, with each having two groups, you can specify red as the color for the groups of drug and blue as the color for the groups of sex as follows.

Example: 'Color', 'r rbb'

Data Types: single | double | char | string | cell

LineStyle — Line style for each group

string array | cell array of character vectors

Line style for each group, specified as the comma-separated pair consisting of 'LineStyle' and a string array or cell array of character vectors.

For example, if you have two between-subject factors, drug and sex, with each having two groups, you can specify - as the line style of one group and : as the line style for the other group as follows.

Example: 'LineStyle', {'-' ':' '-' ':'}

Data Types: string | cell

Output Arguments

H — Handle to plotted lines

handle

Handle to plotted lines, returned as a handle.

Examples

Plot Expected Marginal Means

Load the sample data.

```
load fisheriris
```

The column vector `species` consists of iris flowers of three different species: *setosa*, *versicolor*, and *virginica*. The double matrix `meas` consists of four types of measurements on the flowers: the length and width of sepals and petals in centimeters, respectively.

Store the data in a table array.

```
t = table(species,meas(:,1),meas(:,2),meas(:,3),meas(:,4),...  
'VariableNames',{'species','meas1','meas2','meas3','meas4'});  
Meas = dataset([1 2 3 4]','VarNames',{'Measurements'});
```

Fit a repeated measures model, where the measurements are the responses and the species is the predictor variable.

```
rm = fitrm(t,'meas1-meas4~species','WithinDesign',Meas);
```

Perform data grouped by the factor species.

```
plotprofile(rm,'species')
```

The estimated marginal means seem to differ with group. You can compute the standard error and the 95% confidence intervals for the marginal means using the `margmean` method.

Plot Marginal Means for Two Groups

Load the sample data.

```
load repeatedmeas
```

The table `between` includes the between-subject variables `age`, `IQ`, `group`, `gender`, and eight repeated measures `y1` through `y8` as responses. The table `within` includes the within-subject variables `w1` and `w2`. This is simulated data.

Fit a repeated measures model, where the repeated measures `y1` through `y8` are the responses, and `age`, `IQ`, `group`, `gender`, and the group-gender interaction are the predictor variables. Also specify the within-subject design matrix.

```
rm = fitrm(between, 'y1-y8 ~ Group*Gender + Age + IQ', 'WithinDesign', within);
```

Plot the estimated marginal means based on the factors `Group` and `Gender`.

```
ax1 = subplot(1,2,1);  
plotprofile(rm, 'Group')  
ax2 = subplot(1,2,2);  
plotprofile(rm, 'Gender')  
linkaxes([ax1 ax2], 'y')
```

Plot the estimated marginal means based on the factor Group and grouped by Gender.

```
figure()  
plotprofile(rm, 'Group', 'Group', 'Gender')
```

See Also

`fitrm` | `margmean` | `plot`

plotResiduals

Class: GeneralizedLinearModel

Plot residuals of generalized linear regression model

Syntax

```
plotResiduals mdl
plotResiduals mdl,plottype
h = plotResiduals(...)
h = plotResiduals(mdl,plottype,Name,Value)
```

Description

`plotResiduals(mdl)` gives a histogram plot of the residuals of the `mdl` nonlinear model.

`plotResiduals(mdl,plottype)` plots residuals in a plot of type `plottype`.

`h = plotResiduals(...)` returns handles to the lines in the plot.

`h = plotResiduals(mdl,plottype,Name,Value)` plots with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

mdl

Generalized linear model, as constructed by `fitglm` or `stepwiseglm`.

plottype

Character vector or string scalar specifying the type of plot:

'caseorder'	Residuals vs. case (row) order
'fitted'	Residuals vs. fitted values
'histogram'	Histogram
'lagged'	Residuals vs. lagged residual ($r(t)$ vs. $r(t-1)$)
'probability'	Normal probability plot
'symmetry'	Symmetry plot

Default: 'histogram'

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Note The plot property name-value pairs apply to the first returned handle `h(1)`.

Color

Color of the line or marker, specified as an RGB triplet, hexadecimal color code, color name, or short name for one of the color options listed in the following table.

For a custom color, specify an RGB triplet or a hexadecimal color code.

- An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0, 1]`; for example, `[0.4 0.6 0.7]`.
- A hexadecimal color code is a character vector or a string scalar that starts with a hash symbol (`#`) followed by three or six hexadecimal digits, which can range from `0` to `F`. The values are not case sensitive. Thus, the color codes `'#FF8800'`, `'#ff8800'`, `'#F80'`, and `'#f80'` are equivalent.

Alternatively, you can specify some common colors by name. This table lists the named color options, the equivalent RGB triplets, and hexadecimal color codes.

Color Name	Short Name	RGB Triplet	Hexadecimal Color Code	Appearance
'red'	'r'	[1 0 0]	'#FF0000'	
'green'	'g'	[0 1 0]	'#00FF00'	
'blue'	'b'	[0 0 1]	'#0000FF'	
'cyan'	'c'	[0 1 1]	'#00FFFF'	
'magenta'	'm'	[1 0 1]	'#FF00FF'	
'yellow'	'y'	[1 1 0]	'#FFFF00'	
'black'	'k'	[0 0 0]	'#000000'	
'white'	'w'	[1 1 1]	'#FFFFFF'	

Here are the RGB triplets and hexadecimal color codes for the default colors MATLAB uses in many types of plots.

RGB Triplet	Hexadecimal Color Code	Appearance
[0 0.4470 0.7410]	'#0072BD'	
[0.8500 0.3250 0.0980]	'#D95319'	
[0.9290 0.6940 0.1250]	'#EDB120'	
[0.4940 0.1840 0.5560]	'#7E2F8E'	
[0.4660 0.6740 0.1880]	'#77AC30'	
[0.3010 0.7450 0.9330]	'#4DBEEE'	
[0.6350 0.0780 0.1840]	'#A2142F'	

LineStyle

Type of line, a Chart Line specification. For details, see `linespec`.

LineWidth

Width of the line or edges of filled area, in points, a positive scalar. One point is 1/72 inch.

Default: 0.5

MarkerEdgeColor

Marker outline color, specified as an RGB triplet, hexadecimal color code, color name, or short name for one of the color options listed in the `Color` name-value pair argument.

MarkerFaceColor

Fill color for filled markers, specified as an RGB triplet, hexadecimal color code, color name, or short name for one of the color options listed in the `Color` name-value pair argument.

MarkerSize

Size of the marker in points, a strictly positive scalar. One point is 1/72 inch.

ResidualType

Type of residual used in the plot.

'Raw'	Observed minus fitted values
'LinearPredictor'	Residuals on the linear predictor scale, equal to the adjusted response value minus the fitted linear combination of the predictors
'Pearson'	Raw residuals divided by RMSE
'Anscombe'	Residuals defined on transformed data with the transformation chosen to remove skewness
'Deviance'	Residuals based on the contribution of each observation to the deviance

Default: 'Raw'

Output Arguments

h

Vector of handles to lines or patches in the plot.

Examples

Residual Plots for Generalized Linear Models

Create residual plots of a fitted generalized linear model.

Generate artificial data for the model, Poisson random numbers with two underlying predictors $X(1)$ and $X(2)$.

```
rng('default') % for reproducibility
rndvars = randn(100,2);
X = [2+rndvars(:,1),rndvars(:,2)];
mu = exp(1 + X*[1;2]);
y = poissrnd(mu);
```

Create a generalized linear regression model of Poisson data.

```
mdl = fitglm(X,y,'y ~ x1 + x2','distr','poisson');
```

Create a default residuals plot.

```
plotResiduals(mdl)
```

Create a probability plot. The residuals do not match a normal distribution in the tails because they are more spread out.

```
plotResiduals mdl, 'probability'
```

Create a plot of the fitted residuals of Anscombe type.

```
plotResiduals mdl, 'fitted', 'ResidualType', 'Anscombe')
```

Definitions

Deviance

Deviance is twice the log likelihood of the model. Because this overall log likelihood is a sum of log likelihoods for each observation, the residual plot of deviance type shows the log likelihood per observation.

Tips

- The data cursor displays the values of the selected plot point in a data tip (small text box located next to the data point). The data tip includes the x-axis and y-axis values for the selected point, along with the observation name or number.

“Generalized Linear Models” on page 12-12

plotResiduals

Class: GeneralizedLinearMixedModel

Plot residuals of generalized linear mixed-effects model

Syntax

```
plotResiduals(glme,plottype)
plotResiduals(glme,plottype,Name,Value)
```

```
h = plotResiduals( ___ )
```

Description

`plotResiduals(glme,plottype)` plots the raw conditional residuals of the generalized linear mixed-effects model `glme` in a plot of the type specified by `plottype`.

`plotResiduals(glme,plottype,Name,Value)` plots the conditional residuals of `glme` using additional options specified by one or more `Name,Value` pair arguments. For example, you can specify to plot the Pearson residuals.

`h = plotResiduals(___)` returns a handle, `h`, to the lines or patches in the plot of residuals.

Input Arguments

glme — Generalized linear mixed-effects model

GeneralizedLinearMixedModel object

Generalized linear mixed-effects model, specified as a GeneralizedLinearMixedModel object. For properties and methods of this object, see GeneralizedLinearMixedModel.

plottype — Type of residual plot

'histogram' (default) | 'caseorder' | 'fitted' | 'lagged' | 'probability' | 'symmetry'

Type of residual plot, specified as one of the following.

Value	Description
'histogram'	Histogram of residuals
'caseorder'	Residuals versus case order. Case order is the same as the row order used in the input data tbl when fitting the model using fitglm.
'fitted'	Residuals versus fitted values
'lagged'	Residuals versus lagged residual ($r(t)$ versus $r(t - 1)$)
'probability'	Normal probability plot
'symmetry'	Symmetry plot

Example: `plotResiduals(glm, 'lagged')`

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

ResidualType — Residual type

'raw' (default) | 'Pearson'

Residual type, specified by the comma-separated pair consisting of ResidualType and one of the following.

Residual Type	Formula
'raw'	$r_{ci} = y_i - g^{-1}(x_i^T \hat{\beta} + z_i^T \hat{b} + \delta_i)$
'Pearson'	$r_{ci}^{pearson} = \frac{r_{ci}}{\sqrt{\frac{\sigma^2}{w_i} v_i(\mu_i(\hat{\beta}, \hat{b}))}}$

In each of these equations:

- y_i is the i th element of the n -by-1 response vector, y , where $i = 1, \dots, n$.
- g^{-1} is the inverse link function for the model.
- x_i^T is the i th row of the fixed-effects design matrix X .
- z_i^T is the i th row of the random-effects design matrix Z .
- δ_i is the i th offset value.
- σ^2 is the dispersion parameter.
- w_i is the i th observation weight.
- v_i is the variance term for the i th observation.
- μ_i is the mean of the response for the i th observation.
- $\hat{\beta}$ and \hat{b} are estimated values of β and b .

Raw residuals from a generalized linear mixed-effects model have nonconstant variance. Pearson residuals are expected to have an approximately constant variance, and are generally used for analysis.

Example: 'ResidualType', 'Pearson'

Output Arguments

h — Handle to residual plot

graphics object

Handle to the residual plot, returned as a graphics object. You can use dot notation to change certain property values of the object, including face color for a histogram, and marker style and color for a scatterplot. For more information, see “Access Property Values” (MATLAB).

Examples

Create Plots of Residuals

Load the sample data.

```
load mfr
```

This simulated data is from a manufacturing company that operates 50 factories across the world, with each factory running a batch process to create a finished product. The company wants to decrease the number of defects in each batch, so it developed a new manufacturing process. To test the effectiveness of the new process, the company selected 20 of its factories at random to participate in an experiment: Ten factories implemented the new process, while the other ten continued to run the old process. In each of the 20 factories, the company ran five batches (for a total of 100 batches) and recorded the following data:

- Flag to indicate whether the batch used the new process (`newprocess`)
- Processing time for each batch, in hours (`time`)
- Temperature of the batch, in degrees Celsius (`temp`)
- Categorical variable indicating the supplier (A, B, or C) of the chemical used in the batch (`supplier`)
- Number of defects in the batch (`defects`)

The data also includes `time_dev` and `temp_dev`, which represent the absolute deviation of time and temperature, respectively, from the process standard of 3 hours at 20 degrees Celsius.

Fit a generalized linear mixed-effects model using `newprocess`, `time_dev`, `temp_dev`, and `supplier` as fixed-effects predictors. Include a random-effects term for intercept grouped by `factory`, to account for quality differences that might exist due to factory-specific variations. The response variable `defects` has a Poisson distribution, and the appropriate link function for this model is `log`. Use the Laplace fit method to estimate the coefficients. Specify the dummy variable encoding as `'effects'`, so the dummy variable coefficients sum to 0.

The number of defects can be modeled using a Poisson distribution:

$$\text{defects}_{ij} \sim \text{Poisson}(\mu_{ij})$$

This corresponds to the generalized linear mixed-effects model

$$\log(\mu_{ij}) = \beta_0 + \beta_1 \text{newprocess}_{ij} + \beta_2 \text{time_dev}_{ij} + \beta_3 \text{temp_dev}_{ij} + \beta_4 \text{supplier_C}_{ij} + \beta_5 \text{supplier_B}_{ij} + b_i,$$

where

- defects_{ij} is the number of defects observed in the batch produced by factory i during batch j .

- μ_{ij} is the mean number of defects corresponding to factory i (where $i = 1, 2, \dots, 20$) during batch j (where $j = 1, 2, \dots, 5$).
- `newprocessij`, `time_devij`, and `temp_devij` are the measurements for each variable that correspond to factory i during batch j . For example, `newprocessij` indicates whether the batch produced by factory i during batch j used the new process.
- `supplier_Cij` and `supplier_Bij` are dummy variables that use effects (sum-to-zero) coding to indicate whether company C or B, respectively, supplied the process chemicals for the batch produced by factory i during batch j .
- $b_i \sim N(0, \sigma_b^2)$ is a random-effects intercept for each factory i that accounts for factory-specific variation in quality.

```
glme = fitglme(mfr, 'defects ~ 1 + newprocess + time_dev + temp_dev + supplier + (1|factory)')
```

Create diagnostic plots using Pearson residuals to test the model assumptions.

Plot a histogram to visually confirm that the mean of the Pearson residuals is equal to 0. If the model is correct, we expect the Pearson residuals to be centered at 0.

```
plotResiduals(glme, 'histogram', 'ResidualType', 'Pearson')
```

The histogram shows that the Pearson residuals are centered at 0.

Plot the Pearson residuals versus the fitted values, to check for signs of nonconstant variance among the residuals (heteroscedasticity). We expect the conditional Pearson residuals to have a constant variance. Therefore, a plot of conditional Pearson residuals versus conditional fitted values should not reveal any systematic dependence on the conditional fitted values.

```
plotResiduals(glm, 'fitted', 'ResidualType', 'Pearson')
```

The plot does not show a systematic dependence on the fitted values, so there are no signs of nonconstant variance among the residuals.

Plot the Pearson residuals versus lagged residuals, to check for correlation among the residuals. The conditional independence assumption in GLME implies that the conditional Pearson residuals are approximately uncorrelated.

```
plotResiduals(glme, 'lagged', 'ResidualType', 'Pearson')
```

There is no pattern to the plot, so there are no signs of correlation among the residuals.

`GeneralizedLinearMixedModel` | `fitglme` | `fitted` | `plot` | `residuals`

plotResiduals

Plot residuals of linear regression model

Syntax

```
plotResiduals mdl
plotResiduals mdl, plottype
plotResiduals mdl, plottype, Name, Value
h = plotResiduals( ___ )
```

Description

`plotResiduals(mdl)` creates a histogram plot of the linear regression model (`mdl`) residuals.

`plotResiduals(mdl, plottype)` specifies the residual plot type `plottype`.

`plotResiduals(mdl, plottype, Name, Value)` specifies additional options using one or more name-value pair arguments. For example, you can specify the residual type and the graphical properties of residual data points.

`h = plotResiduals(___)` returns graphics objects for the lines and patch in the plot using any of the input argument combinations in the previous syntaxes. Use `h` to modify the properties of a specific line or patch after you create the plot. For a list of properties, see [Chart Line and Patch Properties](#).

Examples

Histogram of Residuals

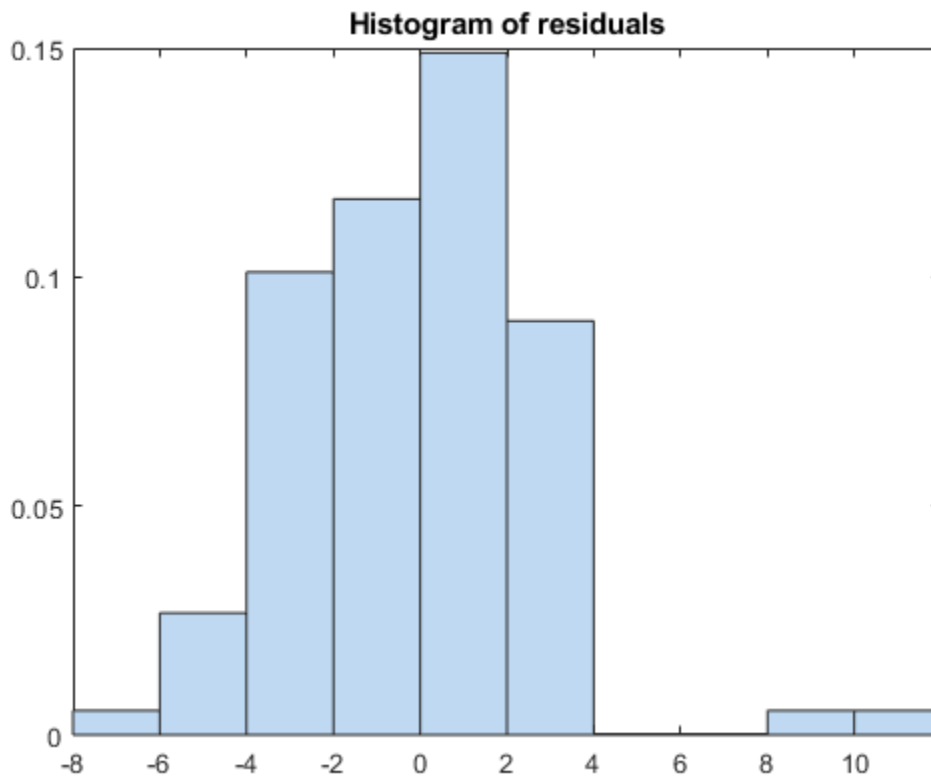

Plot a histogram of the residuals of a fitted linear regression model.

Load the `carsmall` data set and fit a linear regression model of the mileage as a function of model year, weight, and weight squared.

```
load carsmall
tbl = table(MPG,Weight);
tbl.Year = categorical(Model_Year);
mdl = fitlm(tbl,'MPG ~ Year + Weight^2');
```

Create a histogram of the raw residuals using probability density function scaling.

```
plotResiduals(mdl)
```

The area of each bar is the relative number of observations. The sum of the bar areas is equal to 1.

Normal Probability Plot of Residuals

Create a normal probability plot of the residuals of a fitted linear regression model.

Load the `carsmall` data set and fit a linear regression model of the mileage as a function of model year, weight, and weight squared.

```
load carsmall
X = [Weight,Model_Year];
mdl = fitlm(X,MPG,...
    'y ~ x2 + x1^2','Categorical',2);
```

Create a normal probability plot of the residuals of the fitted model.

```
plotResiduals(mdl,'probability')
```

Input Arguments

mdl — Linear regression model

LinearModel object

Linear regression model, specified as a LinearModel object created using fitlm or stepwiselm.

plottype — Plot type

'histogram' (default) | 'caseorder' | 'fitted' | 'lagged' | 'probability' | 'symmetry'

Plot type, specified as one of the values in this table:

Value	Description
'caseorder'	Residuals vs. case order (row number)
'fitted'	Residuals vs. fitted values
'histogram'	Histogram of residuals using probability density function scaling. The area of each bar is the relative number of observations. The sum of the bar areas is equal to 1.
'lagged'	Residuals vs. lagged residuals ($r(t)$ vs. $r(t - 1)$)
'probability'	Normal probability plot of residuals. For details, see probplot.
'symmetry'	Symmetry plot of residuals around their median (residuals in upper tail - median vs. median - residuals in lower tail). This plot includes a dotted reference line of $y = x$ to examine the symmetry of residuals.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Example: 'Color', 'blue', 'Marker', 'o'

Note The graphical properties listed here are only a subset. For a complete list, see Chart Line for lines and Patch Properties for histogram. The specified properties apply to the appearance of residual data points or the appearance of the histogram.

ResidualType — Type of residual

'raw' (default) | 'pearson' | 'standardized' | 'studentized'

Type of residual used in the plot, specified as the comma-separated pair consisting of 'ResidualType' and one of these values:

Value	Description
'raw'	Observed minus fitted values
'pearson'	Raw residuals divided by the root mean squared error (RMSE)
'standardized'	Raw residuals divided by their estimated standard deviation
'studentized'	Raw residuals divided by an independent (delete-1) estimate of their standard deviation

The `Residuals` property of `mdl` contains the residual values used by `plotResiduals` to create plots.

For details, see “Residuals” on page 11-104.

Color — Line color

RGB triplet | hexadecimal color code | color name | short name

Line color, specified as the comma-separated pair consisting of 'Color' and an RGB triplet, hexadecimal color code, color name, or short name for one of the color options listed in the following table.

The 'Color' name-value pair argument also determines marker outline color and marker fill color if 'MarkerEdgeColor' is 'auto' (default) and 'MarkerFaceColor' is 'auto'.

For a custom color, specify an RGB triplet or a hexadecimal color code.

- An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0,1]`; for example, `[0.4 0.6 0.7]`.

- A hexadecimal color code is a character vector or a string scalar that starts with a hash symbol (#) followed by three or six hexadecimal digits, which can range from 0 to F. The values are not case sensitive. Thus, the color codes '#FF8800', '#ff8800', '#F80', and '#f80' are equivalent.

Alternatively, you can specify some common colors by name. This table lists the named color options, the equivalent RGB triplets, and hexadecimal color codes.

Color Name	Short Name	RGB Triplet	Hexadecimal Color Code	Appearance
'red'	'r'	[1 0 0]	'#FF0000'	
'green'	'g'	[0 1 0]	'#00FF00'	
'blue'	'b'	[0 0 1]	'#0000FF'	
'cyan'	'c'	[0 1 1]	'#00FFFF'	
'magenta'	'm'	[1 0 1]	'#FF00FF'	
'yellow'	'y'	[1 1 0]	'#FFFF00'	
'black'	'k'	[0 0 0]	'#000000'	
'white'	'w'	[1 1 1]	'#FFFFFF'	
'none'	Not applicable	Not applicable	Not applicable	No color

Here are the RGB triplets and hexadecimal color codes for the default colors MATLAB uses in many types of plots.

RGB Triplet	Hexadecimal Color Code	Appearance
[0 0.4470 0.7410]	'#0072BD'	
[0.8500 0.3250 0.0980]	'#D95319'	
[0.9290 0.6940 0.1250]	'#EDB120'	
[0.4940 0.1840 0.5560]	'#7E2F8E'	
[0.4660 0.6740 0.1880]	'#77AC30'	
[0.3010 0.7450 0.9330]	'#4DBEEE'	
[0.6350 0.0780 0.1840]	'#A2142F'	

Example: 'Color', 'blue'

LineWidth — Line width

positive value

Line width, specified as the comma-separated pair consisting of 'LineWidth' and a positive value in points. If the line has markers, then the line width also affects the marker edges.

Example: 'LineWidth',0.75

Marker — Marker symbol

'o' | '+' | '*' | '.' | 'x' | ...

Marker symbol, specified as the comma-separated pair consisting of 'Marker' and one of the values in this table.

Value	Description
'o'	Circle
'+'	Plus sign
'*'	Asterisk
'.'	Point
'x'	Cross
'square' or 's'	Square
'diamond' or 'd'	Diamond
'^'	Upward-pointing triangle
'v'	Downward-pointing triangle
'>'	Right-pointing triangle
'<'	Left-pointing triangle
'pentagram' or 'p'	Five-pointed star (pentagram)
'hexagram' or 'h'	Six-pointed star (hexagram)
'none'	No markers

Example: 'Marker', '+'

MarkerEdgeColor — Marker outline color

'auto' (default) | 'none' | RGB triplet | hexadecimal color code | color name | short name

Marker outline color, specified as the comma-separated pair consisting of 'MarkerEdgeColor' and an RGB triplet, hexadecimal color code, color name, or short name for one of the color options listed in the Color name-value pair argument.

The default value of 'auto' uses the same color specified by using 'Color'.

Example: 'MarkerEdgeColor','blue'

MarkerFaceColor — Marker fill color

'none' (default) | 'auto' | RGB triplet | hexadecimal color code | color name | short name

Marker fill color, specified as the comma-separated pair consisting of 'MarkerFaceColor' and an RGB triplet, hexadecimal color code, color name, or short name for one of the color options listed in the Color name-value pair argument.

The 'auto' value uses the same color specified by using 'Color'.

Example: 'MarkerFaceColor','blue'

MarkerSize — Marker size

6 (default) | positive value

Marker size, specified as the comma-separated pair consisting of 'MarkerSize' and a positive value in points.

Example: 'MarkerSize',2

Output Arguments

h — Graphics objects

graphics array

Graphics objects corresponding to the lines or patch in the plot, returned as a graphics array. Use dot notation to query and set properties of the graphics objects. For details, see Line Properties and Patch Properties.

You can use name-value pair arguments to specify the appearance of residual data points or the appearance of the histogram, corresponding to the first graphics object `h(1)`.

Tips

- The data cursor displays the values of the selected plot point in a data tip (small text box located next to the data point). The data tip includes the x-axis and y-axis values for the selected point, along with the observation name or number.

Alternative Functionality

- A `LinearModel` object provides multiple plotting functions.
 - When creating a model, use `plotAdded` to understand the effect of adding or removing a predictor variable.
 - When verifying a model, use `plotDiagnostics` to find questionable data and to understand the effect of each observation. Also, use `plotResiduals` to analyze the residuals of the model.
 - After fitting a model, use `plotAdjustedResponse`, `plotPartialDependence`, and `plotEffects` to understand the effect of a particular predictor. Use `plotInteraction` to understand the interaction effect between two predictors. Also, use `plotSlice` to plot slices through the prediction surface.

plotResiduals

Class: LinearMixedModel

Plot residuals of linear mixed-effects model

Syntax

```
plotResiduals(lme,plottype)  
plotResiduals(lme,plottype,Name,Value)
```

```
h = plotResiduals( ___ )
```

Description

`plotResiduals(lme,plottype)` plots the raw conditional residuals of the linear mixed-effects model `lme` in a plot of the type specified by `plottype`.

`plotResiduals(lme,plottype,Name,Value)` also plots the residuals of the linear mixed-effects model `lme` with additional options specified by one or more name-value pair arguments. For example, you can specify the residual type to plot.

`plotResiduals` also accepts some other name-value pair arguments that specify the properties of the primary line in the plot. For those name-value pairs, see `plot`.

`h = plotResiduals(___)` returns a handle, `h`, to the lines or patches in the plot of residuals.

Input Arguments

lme — Linear mixed-effects model

LinearMixedModel object

Linear mixed-effects model, specified as a `LinearMixedModel` object constructed using `fitlme` or `fitlmematrix`.

plottype — Type of residual plot

'histogram' (default) | 'caseorder' | 'fitted' | 'lagged' | 'probability' | 'symmetry'

Type of residual plot, specified as one of the following.

- 'histogram' Default. Histogram of residuals
- 'caseorder' Residuals versus case (row) order
- 'fitted' Residuals versus fitted values
- 'lagged' Residuals versus lagged residual ($r(t)$ versus $r(t - 1)$)
- 'probability' Normal probability plot
- 'symmetry' Symmetry plot

Example: `plotResiduals(lme, 'lagged')`

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

ResidualType — Residual type

'Raw' (default) | 'Pearson' | 'Standardized'

Residual type, specified by the comma-separated pair consisting of ResidualType and one of the following.

Residual Type	Conditional	Marginal
'Raw'	$r_i^C = [y - X\hat{\beta} - Z\hat{b}]_i$	$r_i^M = [y - X\hat{\beta}]_i$
'Pearson'	$pr_i^C = \frac{r_i^C}{\sqrt{[\widehat{Var}_{y,b}(y - X\hat{\beta} - Z\hat{b})]_{ii}}}$	$pr_i^M = \frac{r_i^M}{\sqrt{[\widehat{Var}_y(y - X\hat{\beta})]_{ii}}}$

Residual Type	Conditional	Marginal
'Standardized'	$st_i^C = \frac{r_i^C}{\sqrt{[\widehat{Var}_y(r^C)]_{ii}}}$	$st_i^M = \frac{r_i^M}{\sqrt{[\widehat{Var}_y(r^M)]_{ii}}}$

For more information on the conditional and marginal residuals and residual variances, see [Definitions](#) at the end of this page.

Example: 'ResidualType', 'Standardized'

Output Arguments

h — Handle to residual plot

handle

Handle to the residual plot, returned as a handle.

Examples

Examine Residuals

Load the sample data.

```
load(fullfile(matlabroot, 'examples', 'stats', 'weight.mat'));
```

`weight` contains data from a longitudinal study, where 20 subjects are randomly assigned to 4 exercise programs, and their weight loss is recorded over six 2-week time periods. This is simulated data.

Store the data in a table. Define `Subject` and `Program` as categorical variables.

```
tbl = table(InitialWeight, Program, Subject, Week, y);
tbl.Subject = nominal(tbl.Subject);
tbl.Program = nominal(tbl.Program);
```

Fit a linear mixed-effects model where the initial weight, type of program, week, and the interaction between the week and type of program are the fixed effects. The intercept and week vary by subject.

```
lme = fitlme(tbl, 'y ~ InitialWeight + Program*Week + (Week|Subject)');
```

Plot the histogram of the raw residuals.

```
plotResiduals(lme)
```

Plot the residuals versus the fitted values.

```
figure();  
plotResiduals(lme, 'fitted')
```

There is no obvious pattern, so there are no immediate signs of heteroscedasticity.

Create the normal probability plot of residuals.

```
figure();  
plotResiduals(lme, 'probability')
```

Data appears to be normal.

Find the observation number for the data that appears to be an outlier to the right of the plot.

```
find(residuals(lme)>0.25)
```

```
ans =
```

```
101
```

Create a box plot of the raw, Pearson, and standardized residuals.

```
r = residuals(lme);  
pr = residuals(lme, 'ResidualType', 'Pearson');  
st = residuals(lme, 'ResidualType', 'Standardized');  
X = [r pr st];  
boxplot(X, 'labels', {'Raw', 'Pearson', 'Standardized'});
```

All three box plots point out the outlier on the right tail of the distribution. The box plots of raw and Pearson residuals also point out a second possible outlier on the left tail. Find the corresponding observation number.

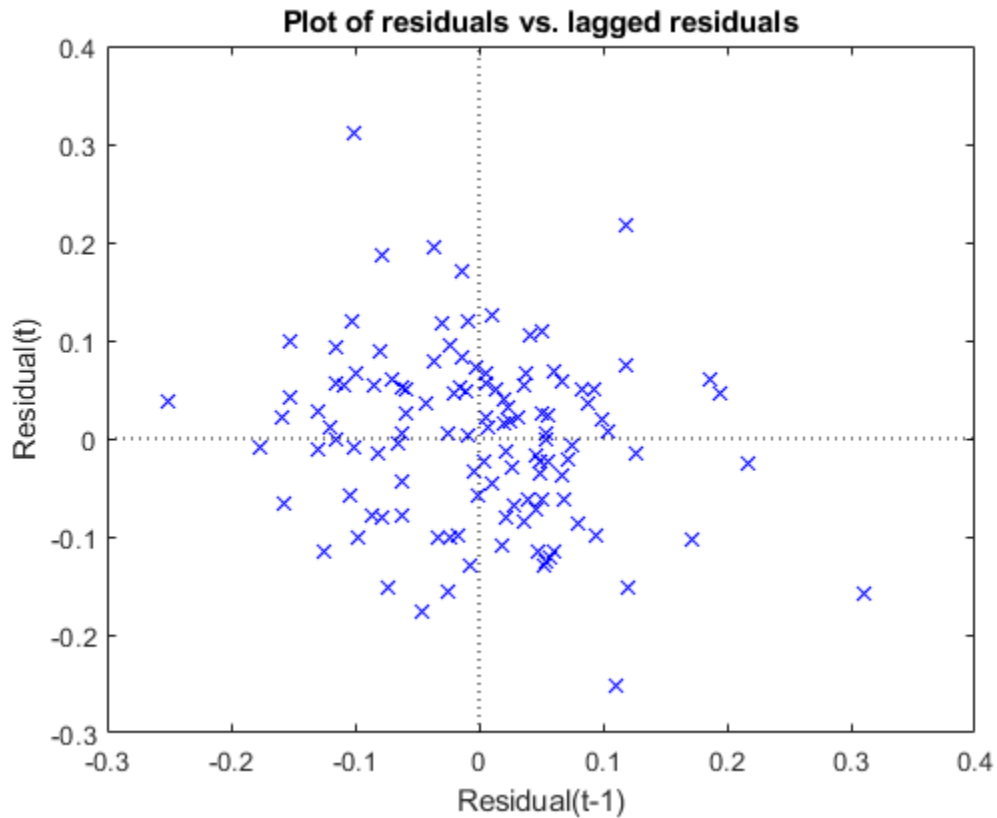

```
find(pr<-2)
```

```
ans =
```

10

Plot the raw residuals versus lagged residuals.

```
plotResiduals(lme, 'lagged')
```

There is no obvious pattern in the graph. The residuals do not appear to be correlated.

See Also

`LinearMixedModel` | `fitted` | `residuals`

plotResiduals

Class: NonLinearModel

Plot residuals of nonlinear regression model

Syntax

```
plotResiduals mdl
plotResiduals mdl,plottype
h = plotResiduals(...)
h = plotResiduals(mdl,plottype,Name,Value)
```

Description

`plotResiduals(mdl)` gives a histogram plot of the residuals of the `mdl` nonlinear model.

`plotResiduals(mdl,plottype)` plots residuals in a plot of type `plottype`.

`h = plotResiduals(...)` returns handles to the lines in the plot.

`h = plotResiduals(mdl,plottype,Name,Value)` plots with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

mdl

Nonlinear regression model, constructed by `fitnlm`.

plottype

Character vector or string scalar specifying the type of plot:

'caseorder'	Residuals vs. case (row) order
'fitted'	Residuals vs. fitted values
'histogram'	Histogram
'lagged'	Residuals vs. lagged residual ($r(t)$ vs. $r(t-1)$)
'probability'	Normal probability plot
'symmetry'	Symmetry plot

Default: 'histogram'

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Note The plot property name-value pairs apply to the first returned handle `h(1)`.

Color

Color of the line or marker, specified as an RGB triplet, hexadecimal color code, color name, or short name for one of the color options listed in the following table.

For a custom color, specify an RGB triplet or a hexadecimal color code.

- An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0, 1]`; for example, `[0.4 0.6 0.7]`.
- A hexadecimal color code is a character vector or a string scalar that starts with a hash symbol (`#`) followed by three or six hexadecimal digits, which can range from `0` to `F`. The values are not case sensitive. Thus, the color codes `'#FF8800'`, `'#ff8800'`, `'#F80'`, and `'#f80'` are equivalent.

Alternatively, you can specify some common colors by name. This table lists the named color options, the equivalent RGB triplets, and hexadecimal color codes.

Color Name	Short Name	RGB Triplet	Hexadecimal Color Code	Appearance
'red'	'r'	[1 0 0]	'#FF0000'	
'green'	'g'	[0 1 0]	'#00FF00'	
'blue'	'b'	[0 0 1]	'#0000FF'	
'cyan'	'c'	[0 1 1]	'#00FFFF'	
'magenta'	'm'	[1 0 1]	'#FF00FF'	
'yellow'	'y'	[1 1 0]	'#FFFF00'	
'black'	'k'	[0 0 0]	'#000000'	
'white'	'w'	[1 1 1]	'#FFFFFF'	

Here are the RGB triplets and hexadecimal color codes for the default colors MATLAB uses in many types of plots.

RGB Triplet	Hexadecimal Color Code	Appearance
[0 0.4470 0.7410]	'#0072BD'	
[0.8500 0.3250 0.0980]	'#D95319'	
[0.9290 0.6940 0.1250]	'#EDB120'	
[0.4940 0.1840 0.5560]	'#7E2F8E'	
[0.4660 0.6740 0.1880]	'#77AC30'	
[0.3010 0.7450 0.9330]	'#4DBEEE'	
[0.6350 0.0780 0.1840]	'#A2142F'	

LineStyle

Type of line, a Chart Line specification. For details, see `linespec`.

LineWidth

Width of the line or edges of filled area, in points, a positive scalar. One point is 1/72 inch.

Default: 0.5

MarkerEdgeColor

Marker outline color, specified as an RGB triplet, hexadecimal color code, color name, or short name for one of the color options listed in the `Color` name-value pair argument.

MarkerFaceColor

Fill color for filled markers, specified as an RGB triplet, hexadecimal color code, color name, or short name for one of the color options listed in the `Color` name-value pair argument.

MarkerSize

Size of the marker in points, a strictly positive scalar. One point is 1/72 inch.

ResidualType

Type of residual used in the plot:

'Raw'	Observed minus fitted values
'Pearson'	Raw residuals divided by RMSE
'Standardized'	Raw residuals divided by their estimated standard deviation
'Studentized'	Raw residuals divided by an independent (delete-1) estimate of their standard deviation

Default: 'Raw'

Output Arguments

h

Vector of handles to lines or patches in the plot.

Examples

Residual Plot

Plot the residuals of a fitted nonlinear model.

Load the reaction data and fit a model of the reaction rate as a function of reactants.

```
load reaction  
mdl = fitnlm(reactants,rate,@hougen,[1 .05 .02 .1 2]);
```

Plot the residuals of the fitted model.

```
plotResiduals(mdl)
```

Residual Probability Plot

Create a normal probability plot of the residuals of a fitted nonlinear model.

Load the reaction data and fit a model of the reaction rate as a function of reactants.

```
load reaction
mdl = fitnlm(reactants,rate,@hougen,[1 .05 .02 .1 2]);
```

Create a normal probability plot of the residuals of the fitted model.

```
plotResiduals(mdl,'probability')
```

Tips

- The data cursor displays the values of the selected plot point in a data tip (small text box located next to the data point). The data tip includes the x-axis and y-axis values for the selected point, along with the observation name or number.

Topics

“Examine Quality and Adjust the Fitted Nonlinear Model” on page 13-7

“Nonlinear Regression Workflow” on page 13-15

“Nonlinear Regression” on page 13-2

plotSlice

Plot of slices through fitted generalized linear regression surface

Syntax

```
plotSlice mdl  
h = plotSlice(mdl)
```

Description

`plotSlice(mdl)` creates a new figure containing a series of plots, each representing a slice through the regression surface predicted by `mdl`. For each plot, the surface slice is shown as a function of a single predictor variable, with the other predictor variables held constant.

`h = plotSlice(mdl)` returns handles to the lines in the plot.

Input Arguments

mdl

Generalized linear model, specified as a full `GeneralizedLinearModel` object constructed using `fitglm` or `stepwiseglm`, or a compacted `CompactGeneralizedLinearModel` object constructed using `compact`.

Output Arguments

h

Vector of handles to lines or patches in the plot.

Examples

Slice Plot of Generalized Linear Regression Model

Create a slice plot of a Poisson generalized linear model.

Generate artificial data for the model using Poisson random numbers with two underlying predictors $X(1)$ and $X(2)$.

```
rng('default') % for reproducibility
rndvars = randn(100,2);
X = [2+rndvars(:,1), rndvars(:,2)];
mu = exp(1 + X*[1;2]);
y = poissrnd(mu);
```

Create a generalized linear regression model of Poisson data.

```
mdl = fitglm(X,y,'y ~ x1 + x2','Distribution','poisson');
```

Create the slice plot.

```
plotSlice(mdl)
```

Drag the x1 prediction line to the right and view the changes in the prediction and the response curve for the x2 predictor.

Tips

- If there are more than eight predictors, `plotSlice` selects the first five for plotting. Use the **Predictors** menu to control which predictors are plotted.
- The **Bounds** menu lets you choose between simultaneous or non-simultaneous bounds, and between bounds on the function or bounds on a new observation.

`CompactGeneralizedLinearModel` | `GeneralizedLinearModel` | `predict`

Topics

“Diagnostic Plots” on page 12-22

"Plots to Understand Predictor Effects and How to Modify a Model" on page 12-28
"Generalized Linear Models" on page 12-12

plotSlice

Package:

Plot of slices through fitted linear regression surface

Syntax

```
plotSlice mdl
```

Description

`plotSlice(mdl)` creates a figure containing one or more plots, each representing a slice through the regression surface predicted by `mdl`. Each plot shows the fitted response values as a function of a single predictor variable, with the other predictor variables held constant.

`plotSlice` also displays the 95% confidence bounds for the response values. Use the **Bounds** menu to choose the type of confidence bounds, and use the **Predictors** menu to select which predictors to use for each slice plot. For details, see “Tips” on page 32-5112.

Examples

Slice Plot for Linear Regression Model

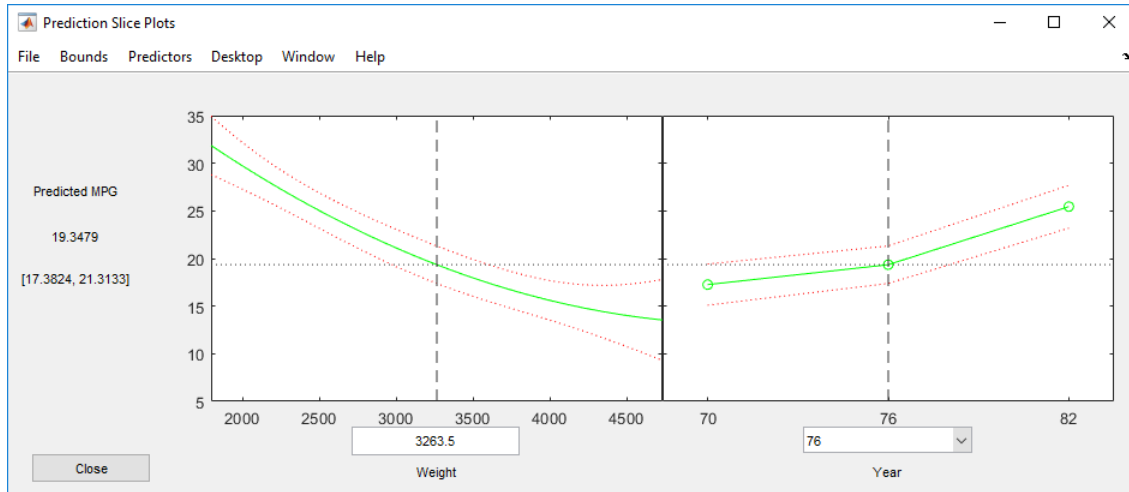

Plot slices through a fitted linear regression model surface.

Load the `carsmall` data set and fit a linear regression model of the mileage as a function of model year, weight, and weight squared.

```
load carsmall
Year = categorical(Model_Year);
tbl = table(MPG,Weight,Year);
mdl = fitlm(tbl,'MPG ~ Year + Weight^2');
```

Create a slice plot.

```
plotSlice mdl
```

The green line in each plot represents the predicted response values as a function of a single predictor variable, with the other predictor variables held constant. The red dotted lines are the 95% confidence bounds. The y-axis label includes the predicted response value and the corresponding confidence bound for the point selected by the vertical and horizontal lines. The x-axis label shows the predictor variable name and the predictor value for the selected point.

Note that `mdl` includes both the `Weight` and `Weight^2` terms, but `plotSlice` creates only one plot for the `Weight` term.

Move the vertical line in the `Weight` plot to the right and observe the change in the y-axis label and the changes in the `Year` plot.

Input Arguments

mdl — Linear regression model object

LinearModel object | CompactLinearModel object

Linear regression model object, specified as a `LinearModel` object created by using `fitlm` or `stepwiselm`, or a `CompactLinearModel` object created by using `compact`.

Tips

- Use the **Bounds** menu in the figure window to choose the type of confidence bounds. You can choose **Simultaneous** or **Non-Simultaneous**, and **Curve** or **Observation**. You can also choose **No Bounds** to have no confidence bounds.
- **Simultaneous** or **Non-Simultaneous**
 - Simultaneous (default) — `plotSlice` computes confidence bounds for the curve of the response values using Scheffe's method. The range between the upper and lower confidence bounds contains the curve consisting of true response values with 95% confidence.

- **Non-Simultaneous** — `plotSlice` computes confidence bounds for the response value at each observation. The confidence interval for a response value at a specific predictor value contains the true response value with 95% confidence.

Simultaneous bounds are wider than separate bounds, because requiring the entire curve of response values to be within the bounds is stricter than requiring the response value at a single predictor value to be within the bounds.

- **Curve or Observation**

A regression model for the predictor variables X and the response variable y has the form

$$y = f(X) + \varepsilon,$$

where f is a function of X and ε is a random noise term.

- **Curve** (default) — `plotSlice` predicts confidence bounds for the fitted responses $f(X)$.
- **Observation** — `plotSlice` predicts confidence bounds for the response observations y .

The bounds for y are wider than the bounds for $f(X)$ because of the additional variability of the noise term.

- Use the **Predictors** menu in the figure window to select which predictors to use for each slice plot. If the regression model `mdl` includes more than eight predictors, `plotSlice` creates plots for the first five predictors by default.

Alternative Functionality

- Use `predict` to return the predicted response values and confidence bounds. You can also specify the confidence level for confidence bounds by using the 'Alpha' name-value pair argument of the `predict` function. Note that `predict` finds nonsimultaneous bounds by default whereas `plotSlice` finds simultaneous bounds by default.
- A `LinearModel` object provides multiple plotting functions.
 - When creating a model, use `plotAdded` to understand the effect of adding or removing a predictor variable.
 - When verifying a model, use `plotDiagnostics` to find questionable data and to understand the effect of each observation. Also, use `plotResiduals` to analyze the residuals of the model.

- After fitting a model, use `plotAdjustedResponse`, `plotPartialDependence`, and `plotEffects` to understand the effect of a particular predictor. Use `plotInteraction` to understand the interaction effect between two predictors. Also, use `plotSlice` to plot slices through the prediction surface.

plotSlice

Class: NonLinearModel

Plot of slices through fitted nonlinear regression surface

Syntax

```
plotSlice mdl  
h = plotSlice(mdl)
```

Description

`plotSlice(mdl)` creates a new figure containing a series of plots, each representing a slice through the regression surface predicted by `mdl`. For each plot, the surface slice is shown as a function of a single predictor variable, with the other predictor variables held constant.

`h = plotSlice(mdl)` returns handles to the lines in the plot.

Input Arguments

mdl

Nonlinear regression model, constructed by `fitnlm`.

Output Arguments

h

Vector of handles to lines or patches in the plot.

Examples

Slice Plot

Plot slices of a fitted nonlinear model.

Load the reaction data and fit a model of the reaction rate as a function of reactants.

```
load reaction
mdl = fitnlm(reactants,rate,@hougen,[1 .05 .02 .1 2]);
```

Create a slice plot.

```
plotSlice(mdl)
```

Drag the X1 prediction line to the right, and observe the change in the predicted response y and in the predicted response curves to X2 and X3.

Tips

- If there are more than eight predictors, plotSlice selects the first five for plotting. Use the **Predictors** menu to control which predictors are plotted.
- The **Bounds** menu lets you choose between simultaneous or non-simultaneous bounds, and between bounds on the function or bounds on a new observation.

plsregress

Partial least-squares regression

Syntax

```
[XL,YL] = plsregress(X,Y,ncomp)
[XL,YL,XS] = plsregress(X,Y,ncomp)
[XL,YL,XS,YS] = plsregress(X,Y,ncomp)
[XL,YL,XS,YS,BETA] = plsregress(X,Y,ncomp,...)
[XL,YL,XS,YS,BETA,PCTVAR] = plsregress(X,Y,ncomp)
[XL,YL,XS,YS,BETA,PCTVAR,MSE] = plsregress(X,Y,ncomp)
[XL,YL,XS,YS,BETA,PCTVAR,MSE] =
plsregress(...,param1,val1,param2,val2,...)
[XL,YL,XS,YS,BETA,PCTVAR,MSE,stats] = plsregress(X,Y,ncomp,...)
```

Description

`[XL,YL] = plsregress(X,Y,ncomp)` computes a partial least-squares (PLS) regression of Y on X , using $ncomp$ PLS components, and returns the predictor and response loadings in XL and YL , respectively. X is an n -by- p matrix of predictor variables, with rows corresponding to observations and columns to variables. Y is an n -by- m response matrix. XL is a p -by- $ncomp$ matrix of predictor loadings, where each row contains coefficients that define a linear combination of PLS components that approximate the original predictor variables. YL is an m -by- $ncomp$ matrix of response loadings, where each row contains coefficients that define a linear combination of PLS components that approximate the original response variables.

`[XL,YL,XS] = plsregress(X,Y,ncomp)` returns the predictor scores XS , that is, the PLS components that are linear combinations of the variables in X . XS is an n -by- $ncomp$ orthonormal matrix with rows corresponding to observations and columns to components.

`[XL,YL,XS,YS] = plsregress(X,Y,ncomp)` returns the response scores YS , that is, the linear combinations of the responses with which the PLS components XS have maximum covariance. YS is an n -by- $ncomp$ matrix with rows corresponding to observations and columns to components. YS is neither orthogonal nor normalized.

`plsregress` uses the SIMPLS algorithm, first centering X and Y by subtracting off column means to get centered variables X_0 and Y_0 . However, it does not rescale the columns. To perform PLS with standardized variables, use `zscore` to normalize X and Y .

If `ncomp` is omitted, its default value is $\min(\text{size}(X,1) - 1, \text{size}(X,2))$.

The relationships between the scores, loadings, and centered variables X_0 and Y_0 are:

$$XL = (XS \setminus X_0)' = X_0' * XS,$$

$$YL = (XS \setminus Y_0)' = Y_0' * XS,$$

XL and YL are the coefficients from regressing X_0 and Y_0 on XS , and $XS * XL'$ and $XS * YL'$ are the PLS approximations to X_0 and Y_0 .

`plsregress` initially computes YS as:

$$YS = Y_0 * YL = Y_0 * Y_0' * XS,$$

By convention, however, `plsregress` then orthogonalizes each column of YS with respect to preceding columns of XS , so that $XS' * YS$ is lower triangular.

`[XL, YL, XS, YS, BETA] = plsregress(X, Y, ncomp, ...)` returns the PLS regression coefficients $BETA$. $BETA$ is a $(p+1)$ -by- m matrix, containing intercept terms in the first row:

$$Y = [\text{ones}(n,1), X] * BETA + Y_{\text{residuals}},$$

$Y_0 = X_0 * BETA(2:\text{end}, :) + Y_{\text{residuals}}$. Here $Y_{\text{residuals}}$ is the vector of response residuals.

`[XL, YL, XS, YS, BETA, PCTVAR] = plsregress(X, Y, ncomp)` returns a 2-by-`ncomp` matrix $PCTVAR$ containing the percentage of variance explained by the model. The first row of $PCTVAR$ contains the percentage of variance explained in X by each PLS component, and the second row contains the percentage of variance explained in Y .

`[XL, YL, XS, YS, BETA, PCTVAR, MSE] = plsregress(X, Y, ncomp)` returns a 2-by- $(ncomp+1)$ matrix MSE containing estimated mean-squared errors for PLS models with $0:ncomp$ components. The first row of MSE contains mean-squared errors for the predictor variables in X , and the second row contains mean-squared errors for the response variable(s) in Y .

[XL, YL, XS, YS, BETA, PCTVAR, MSE] =
`plsregress(..., param1, val1, param2, val2, ...)` specifies optional parameter name/value pairs from the following table to control the calculation of MSE.

Parameter	Value
'cv'	<p>The method used to compute MSE.</p> <ul style="list-style-type: none"> When the value is a positive integer <i>k</i>, <code>plsregress</code> uses <i>k</i>-fold cross-validation. When the value is an object of the <code>cvpartition</code> on page 32-1237 class, other forms of cross-validation can be specified. When the value is 'resubstitution', <code>plsregress</code> uses <i>X</i> and <i>Y</i> both to fit the model and to estimate the mean-squared errors, without cross-validation. <p>The default is 'resubstitution'.</p>
'mcreps'	<p>A positive integer indicating the number of Monte-Carlo repetitions for cross-validation. The default value is 1. The value must be 1 if the value of 'cv' is 'resubstitution'.</p>
options	<p>A structure that specifies whether to run in parallel, and specifies the random stream or streams. Create the <code>options</code> structure with <code>statset</code>. Option fields:</p> <ul style="list-style-type: none"> <code>UseParallel</code> — Set to <code>true</code> to compute in parallel. Default is <code>false</code>. <code>UseSubstreams</code> — Set to <code>true</code> to compute in parallel in a reproducible fashion. Default is <code>false</code>. To compute reproducibly, set <code>Streams</code> to a type allowing substreams: 'mlfg6331_64' or 'mrg32k3a'. <code>Streams</code> — A <code>RandStream</code> object or cell array consisting of one such object. If you do not specify <code>Streams</code>, <code>plsregress</code> uses the default stream. <p>To compute in parallel, you need Parallel Computing Toolbox</p>

[XL, YL, XS, YS, BETA, PCTVAR, MSE, stats] = `plsregress(X, Y, ncomp, ...)`
returns a structure `stats` with the following fields:

- `W` — A *p*-by-*ncomp* matrix of PLS weights so that $XS = X0*W$.
- `T2` — The T^2 statistic for each point in *XS*.
- `Xresiduals` — The predictor residuals, that is, $X0 - XS*XL'$.
- `Yresiduals` — The response residuals, that is, $Y0 - XS*YL'$.

Examples

Perform Partial Least-Squares Regression

Load data on near infrared (NIR) spectral intensities of 60 samples of gasoline at 401 wavelengths, and their octane ratings.

```
load spectra  
X = NIR;  
y = octane;
```

Perform PLS regression with ten components.

```
[XL,yL,XS,YS,beta,PCTVAR] = plsregress(X,y,10);
```

Plot the percent of variance explained in the response variable as a function of the number of components.

```
plot(1:10,cumsum(100*PCTVAR(2,:)),'-bo');  
xlabel('Number of PLS components');  
ylabel('Percent Variance Explained in y');
```

Compute the fitted response and display the residuals.

```
yfit = [ones(size(X,1),1) X]*beta;  
residuals = y - yfit;  
stem(residuals)  
xlabel('Observation');  
ylabel('Residual');
```

Extended Capabilities

Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the `'UseParallel'` option to `true`.

Set the `'UseParallel'` field of the options structure to `true` using `statset` and specify the `'Options'` name-value pair argument in the call to this function.

For example: `'Options',statset('UseParallel',true)`

For more information, see the `'Options'` name-value pair argument.

For more general information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

Introduced in R2008a

PointSet property

Class: grandstream

Point set from which stream is drawn

Description

The PointSet property contains a copy of the point set from which the stream is providing points. The point set is specified during construction of a quasi-random stream and cannot subsequently be altered.

Examples

```
Q = grandstream('sobol', 5, 'Skip', 8);  
% Create a new stream based on the same sequence as that in Q  
Q2 = grandstream(Q.PointSet);  
u1 = grand(Q, 10)  
u2 = grand(Q2, 10) % contains exactly the same values as u1
```

poisscdf

Poisson cumulative distribution function

Syntax

```
y = poisscdf(x,lambda)
y = poisscdf(x,lambda,'upper')
```

Description

`y = poisscdf(x,lambda)` computes the Poisson cumulative distribution function at each of the values in `x` using the rate parameters in `lambda`.

`x` and `lambda` can be scalars, vectors, matrices, or multidimensional arrays that all have the same size. If only one argument is a scalar, `poisscdf` expands it to a constant array with the same dimensions as the other argument.

`y = poisscdf(x,lambda,'upper')` returns the complement of the Poisson cumulative distribution function at each value in `x`, using an algorithm that computes the extreme upper tail probabilities more accurately.

Examples

Compute and Plot Poisson Cumulative Distribution Function

Compute and plot the Poisson cumulative distribution function for the specified range of integer values and average rate.

A computer hard disk manufacturing facility performs random tests of individual hard disks. The policy is to shut down the manufacturing process if an inspector finds more than four bad sectors on a disk. Assuming that on average a disk has two bad sectors, find the probability of a manufacturing process shutdown after the first inspection.

```
1 - poisscdf(4,2)
```

```
ans = 0.0527
```

Compute the probabilities a manufacturing process shutdown after the first inspection if on average a disk has 0, 1, 2, ..., 10 bad sectors.

```
lambda = 0:10;  
y = 1 - poisscdf(4,lambda);
```

Plot the results.

```
scatter(lambda,y,'Marker','o')  
grid on
```

Compute Extreme Upper Tail Probabilities

Compute the complement of the Poisson cumulative distribution function with more accurate upper tail probabilities.

A computer hard disk manufacturing facility performs random tests of individual hard disks. Assuming that on average a disk has 10 bad sectors, find the probability that a disk has more than 100 bad sectors.

```
format long
1 - poisscdf(100,10)

ans =
    0
```

This result shows that `poisscdf(100,10)` is so close to 1 (within `eps`) that subtracting it from 1 gives 0. To approximate the extreme upper tail probabilities better, compute the complement of the Poisson cumulative distribution function directly instead of computing the difference.

```
poisscdf(100,10,'upper')

ans =
    5.339405460719755e-64
```

Input Arguments

x — Values at which to evaluate Poisson cdf

scalar value | array of scalar values

Values at which to evaluate the Poisson cdf, specified as a scalar value or array of scalar values.

Example: `[0,1,3,4]`

Data Types: `single` | `double`

lambda — Rate parameters

positive value | array of positive values

Rate parameters, specified as a positive value or array of positive values. The rate parameter indicates the average number of events in a given time interval.

Example: 2

Data Types: `single` | `double`

Output Arguments

y — Poisson cdf values

scalar value | array of scalar values

Poisson cdf values, returned as a scalar value or array of scalar values. Each element in **y** is the Poisson cdf value of the distribution evaluated at the corresponding element in **x**.

Definitions

Poisson Cumulative Distribution Function

The Poisson cumulative distribution function lets you obtain the probability of an event occurring within a given time or space interval less than or equal to x times if on average the event occurs λ times within that interval.

The Poisson cumulative distribution function for the given values x and λ is

$$p = F(x|\lambda) = e^{-\lambda} \sum_{i=0}^{\text{floor}(x)} \frac{\lambda^i}{i!}$$

Alternative Functionality

- `poisscdf` is a function specific to Poisson distribution. Statistics and Machine Learning Toolbox also offers the generic function `cdf`, which supports various probability distributions. To use `cdf`, specify the probability distribution name and its parameters. Alternatively, create a `PoissonDistribution` probability distribution object and pass the object as an input argument. Note that the distribution-specific function `poisscdf` is faster than the generic function `cdf`.

- Use the **Probability Distribution Function** app to create an interactive plot of the cumulative distribution function (cdf) or probability density function (pdf) for a probability distribution.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU arrays. For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

Introduced before R2006a

poissfit

Poisson parameter estimates

Syntax

```
lambdahat = poissfit(data)
[lambdahat,lambdaci] = poissfit(data)
[lambdahat,lambdaci] = poissfit(data,alpha)
```

Description

`lambdahat = poissfit(data)` returns the maximum likelihood estimate (MLE) of the parameter of the Poisson distribution, λ , given the data `data`.

`[lambdahat,lambdaci] = poissfit(data)` also gives 95% confidence intervals in `lambdaci`.

`[lambdahat,lambdaci] = poissfit(data,alpha)` gives $100(1 - \text{alpha})\%$ confidence intervals. For example `alpha = 0.001` yields 99.9% confidence intervals.

The sample mean is the MLE of λ .

$$\hat{\lambda} = \frac{1}{n} \sum_{i=1}^n x_i$$

Examples

```
r = poissrnd(5,10,2);
[l,lci] = poissfit(r)
l =
    7.4000    6.3000
lci =
    5.8000    4.8000
    9.1000    7.9000
```

See Also

Topics

“Poisson Distribution” on page B-152

Introduced before R2006a

poissinv

Poisson inverse cumulative distribution function

Syntax

```
X = poissinv(P,lambda)
```

Description

`X = poissinv(P,lambda)` returns the smallest value X such that the Poisson cdf evaluated at X equals or exceeds P , using mean parameters in `lambda`. P and `lambda` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other input.

Examples

If the average number of defects (λ) is two, what is the 95th percentile of the number of defects?

```
poissinv(0.95,2)
ans =
     5
```

What is the median number of defects?

```
median_defects = poissinv(0.50,2)
median_defects =
     2
```

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

poisspdf

Poisson probability density function

Syntax

```
y = poisspdf(x,lambda)
```

Description

`y = poisspdf(x,lambda)` computes the Poisson probability density function at each of the values in `x` using the rate parameters in `lambda`.

`x` and `lambda` can be scalars, vectors, matrices, or multidimensional arrays that all have the same size. If only one argument is a scalar, `poisspdf` expands it to a constant array with the same dimensions as the other argument.

Examples

Compute and Plot Poisson Probability Density Function

Compute and plot the Poisson probability density function for the specified range of integer values and average rate.

In the computer hard disk manufacturing process, flaws occur randomly. Assuming that on average a 4 GB hard disk has two flaws, compute the probability that a disk has no flaws.

```
poisspdf(0,2)
```

```
ans = 0.1353
```

Compute the Poisson probability density function values at each value from 0 to 10. These values correspond to the probabilities that a disk has 0, 1, 2, ..., 10 flaws.

```
flaws = 0:10;  
y = poisspdf(flaws,2);
```

Plot the resulting probability values.

```
scatter(flaws,y,'Marker','o')  
grid on
```

Input Arguments

x — Values at which to evaluate Poisson pdf

scalar value | array of scalar values

Values at which to evaluate the Poisson pdf, specified as a scalar value or array of scalar values. For noninteger values x , the Poisson probability density function is zero.

Example: [0,1,3,4]

Data Types: single | double

Lambda — Rate parameters

positive value | array of positive values

Rate parameters, specified as a positive value or array of positive values. The rate parameter indicates the average number of events in a given time interval.

Example: 2

Data Types: single | double

Output Arguments

y — Poisson pdf values

scalar value | array of scalar values

Poisson pdf values, returned as a scalar value or array of scalar values. Each element in y is the Poisson pdf value of the distribution evaluated at the corresponding element in x .

Data Types: single | double

Definitions

Poisson Probability Density Function

The Poisson probability density function lets you obtain the probability of an event occurring within a given time or space interval exactly x times if on average the event occurs λ times within that interval.

The Poisson probability density function for the given values x and λ is

$$f(x|\lambda) = \frac{\lambda^x}{x!} e^{-\lambda}; x = 0, 1, 2, \dots, \infty .$$

Alternative Functionality

- `poisspdf` is a function specific to Poisson distribution. Statistics and Machine Learning Toolbox also offers the generic function `pdf`, which supports various probability distributions. To use `pdf`, specify the probability distribution name and its parameters. Alternatively, create a `PoissonDistribution` probability distribution object and pass the object as an input argument. Note that the distribution-specific function `poisspdf` is faster than the generic function `pdf`.
- Use the **Probability Distribution Function** app to create an interactive plot of the cumulative distribution function (cdf) or probability density function (pdf) for a probability distribution.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

`PoissonDistribution` | `pdf` | `poisscdf` | `poissfit` | `poissinv` | `poissrnd` | `poisstat`

Topics

“Poisson Distribution” on page B-152

Introduced before R2006a

poissrnd

Random numbers from Poisson distribution

Syntax

```
r = poissrnd(lambda)
r = poissrnd(lambda,sz1,...,szN)
r = poissrnd(lambda,[sz1,...,szN])
```

Description

`r = poissrnd(lambda)` generates random numbers from the Poisson distribution specified by the rate parameter `lambda`.

`lambda` can be a scalar, vector, matrix, or multidimensional array.

`r = poissrnd(lambda,sz1,...,szN)` or `r = poissrnd(lambda,[sz1,...,szN])` generates an `sz1`-by-...-by-`szN` array containing random numbers from the Poisson distribution with the scalar rate parameter `lambda`.

Examples

Array of Random Numbers from Several Poisson Distributions

Generate an array of random numbers from the Poisson distributions. Specify the average rate for each distribution.

```
lambda = 10:2:20
```

```
lambda = 1x6
```

```
    10    12    14    16    18    20
```

Generate random numbers from the Poisson distributions.

```
r = poissrnd(lambda)
r = 1×6
    14    13    14     9    14    31
```

Array of Random Numbers from One Poisson Distribution

Generate an array of random numbers from one Poisson distribution. Here, the distribution parameter `lambda` is a scalar.

Use the `poissrnd` function to generate random numbers from the Poisson distribution with the average rate 20. The function returns one number.

```
r_scalar = poissrnd(20)
r_scalar = 9
```

Generate a 2-by-3 array of random numbers from the same distribution by specifying the required array dimensions.

```
r_array = poissrnd(20,2,3)
r_array = 2×3
    13    14    18
    26    16    21
```

Alternatively, specify the required array dimensions as a vector.

```
r_array = poissrnd(20,[2 3])
r_array = 2×3
    22    27    22
    25    19    21
```

Input Arguments

lambda — Rate parameters

positive value | array of positive values

Rate parameters, specified as a positive value or array of positive values. The rate parameter indicates the average number of events in a given time interval.

Example: 2

Data Types: `single` | `double`

sz1, ..., szN — Size of each dimension

integers | row vector of integers

Size of each dimension, specified as integers or a row vector of integers. For example, specifying 5, 3, 2 or [5, 3, 2] generates a 5-by-3-by-2 array of random numbers from the Poisson probability distribution.

If `lambda` is an array, then the specified dimensions `sz1, ..., szN` must match the dimensions of `lambda`.

- If you specify a single value `sz1`, then `r` is a square matrix of size `sz1`.
- If the size of any dimension is 0 or negative, then `r` is an empty array.
- Beyond the second dimension, `poissrnd` ignores trailing dimensions with a size of 1. For example, `poissrnd(3, 1, 1, 1)` produces a 3-by-1 vector of random numbers.

Example: 5, 3, 2 or [5, 3, 2]

Data Types: `single` | `double`

Output Arguments

r — Random numbers from Poisson distribution

scalar value | array of scalar values

Random numbers from the Poisson distribution, returned as a scalar value or an array of scalar values.

Data Types: `single` | `double`

Alternative Functionality

- `poissrnd` is a function specific to Poisson distribution. Statistics and Machine Learning Toolbox also offers the generic function `random`, which supports various probability distributions. To use `random`, specify the probability distribution name and its parameters. Alternatively, create a `PoissonDistribution` probability distribution object and pass the object as an input argument. Note that the distribution-specific function `poissrnd` is faster than the generic function `random`.
- To generate random numbers interactively, use `randtool`, a random number generation user interface.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

The generated code can return a different sequence of numbers than MATLAB if either of the following is true:

- The output is nonscalar.
- An input parameter is invalid for the distribution.

For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “General Code Generation Workflow” on page 31-5.

“Poisson Distribution” on page B-152

Introduced before R2006a

poisstat

Poisson mean and variance

Syntax

```
M = poisstat(lambda)
[M,V] = poisstat(lambda)
```

Description

`M = poisstat(lambda)` returns the mean of the Poisson distribution using mean parameters in `lambda`. The size of `M` is the size of `lambda`.

`[M,V] = poisstat(lambda)` also returns the variance `V` of the Poisson distribution.

For the Poisson distribution with parameter λ , both the mean and variance are equal to λ .

Examples

Find the mean and variance for the Poisson distribution with $\lambda = 2$.

```
[m,v] = poisstat([1 2; 3 4])
m =
     1     2
     3     4
v =
     1     2
     3     4
```

Extended Capabilities

polyconf

Polynomial confidence intervals

Syntax

```
Y = polyconf(p,X)
[Y,DELTA] = polyconf(p,X,S)
[Y,DELTA] = polyconf(p,X,S,param1,val1,param2,val2,...)
```

Description

`Y = polyconf(p,X)` evaluates the polynomial `p` at the values in `X`. `p` is a vector of coefficients in descending powers.

`[Y,DELTA] = polyconf(p,X,S)` takes outputs `p` and `S` from `polyfit` and generates 95% prediction intervals $Y \pm \text{DELTA}$ for new observations at the values in `X`.

`[Y,DELTA] = polyconf(p,X,S,param1,val1,param2,val2,...)` specifies optional parameter name/value pairs chosen from the following list.

Parameter	Value
'alpha'	A value between 0 and 1 specifying a confidence level of $100*(1-\text{alpha})\%$. The default is 0.05.
'mu'	A two-element vector containing centering and scaling parameters. With this option, <code>polyconf</code> uses $(X-\text{mu}(1))/\text{mu}(2)$ in place of <code>X</code> .
'predopt'	Either 'observation' (the default) to compute prediction intervals for new observations at the values in <code>X</code> , or 'curve' to compute confidence intervals for the fit evaluated at the values in <code>X</code> . See below.
'simopt'	Either 'off' (the default) for nonsimultaneous bounds, or 'on' for simultaneous bounds. See below.

The 'predopt' and 'simopt' parameters can be understood in terms of the following functions:

- $p(x)$ — the unknown mean function estimated by the fit
- $l(x)$ — the lower confidence bound
- $u(x)$ — the upper confidence bound

Suppose you make a new observation y_{n+1} at x_{n+1} , so that

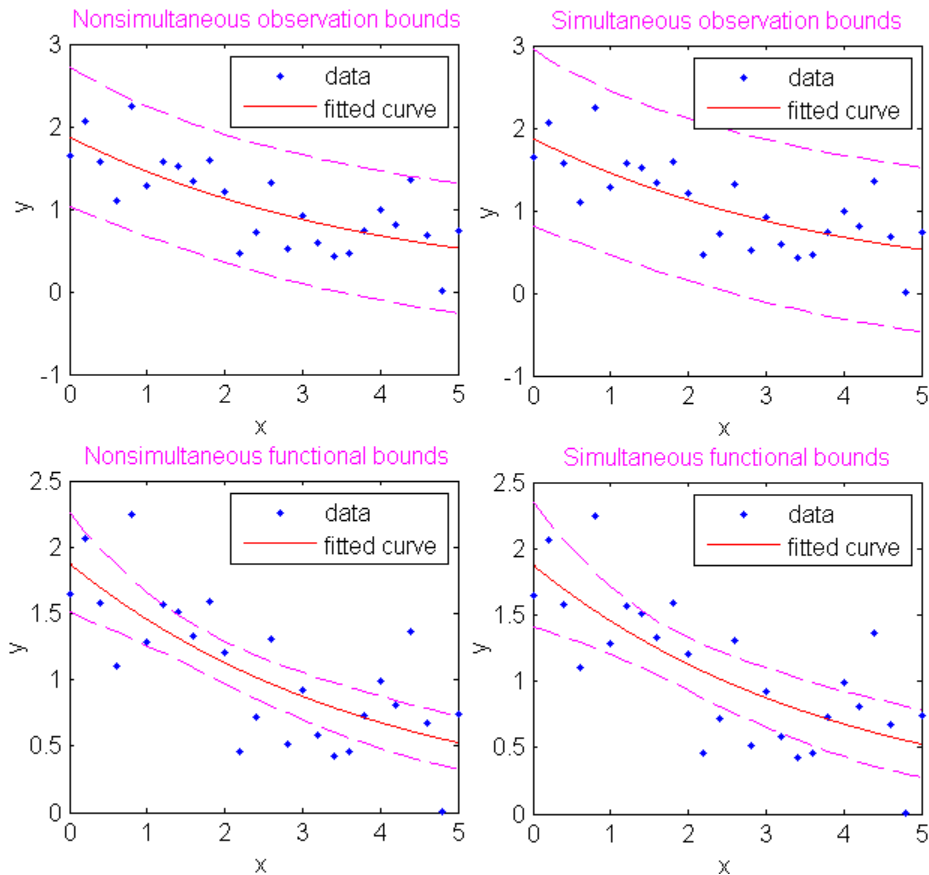

$$y_{n+1}(x_{n+1}) = p(x_{n+1}) + \varepsilon_{n+1}$$

By default, the interval $[l_{n+1}(x_{n+1}), u_{n+1}(x_{n+1})]$ is a 95% confidence bound on $y_{n+1}(x_{n+1})$.

The following combinations of the 'predopt' and 'simopt' parameters allow you to specify other bounds.

'simopt'	'predopt'	Bounded Quantity
'off'	'observation'	$y_{n+1}(x_{n+1})$ (default)
'off'	'curve'	$p(x_{n+1})$
'on'	'observation'	$y_{n+1}(x)$, for all x
'on'	'curve'	$p(x)$, for all x

In general, 'observation' intervals are wider than 'curve' intervals, because of the additional uncertainty of predicting a new response value (the curve plus random errors). Likewise, simultaneous intervals are wider than nonsimultaneous intervals, because of the additional uncertainty of bounding values for all predictors x .

Examples

This example uses code from the documentation example function `polydemo`, and calls the documentation example function `polystr` to convert the coefficient vector `p` into text for the polynomial expression displayed in the figure title. It combines the functions `polyfit`, `polyval`, `roots`, and `polyconf` to produce a formatted display of data with a polynomial fit.

Note Statistics and Machine Learning Toolbox documentation example files are located in the `\help\toolbox\stats\examples` subdirectory of your MATLAB root folder

(matlabroot). This subdirectory is not on the MATLAB path at installation. To use the files in this subdirectory, either add the subdirectory to the MATLAB path (addpath) or make the subdirectory your current working folder (cd).

Display simulated data with a quadratic trend, a fitted quadratic polynomial, and 95% prediction intervals for new observations:

```
xdata = -5:5;
ydata = xdata.^2 - 5*xdata - 3 + 5*randn(size(xdata));

degree = 2;          % Degree of the fit
alpha = 0.05;       % Significance level

% Compute the fit and return the structure used by
% POLYCONF.
[p,S] = polyfit(xdata,ydata,degree);

% Compute the real roots and determine the extent of the
% data.
r = roots(p)';          % Roots as a row vector.
real_r = r(imag(r) == 0); % Real roots.

% Assure that the data are row vectors.
xdata = reshape(xdata,1,length(xdata));
ydata = reshape(ydata,1,length(ydata));

% Extent of the data.
mx = min([real_r,xdata]);
Mx = max([real_r,xdata]);
my = min([ydata,0]);
My = max([ydata,0]);

% Scale factors for plotting.
sx = 0.05*(Mx-mx);
sy = 0.05*(My-my);

% Plot the data, the fit, and the roots.
hdata = plot(xdata,ydata,'md','MarkerSize',5,...
             'LineWidth',2);
hold on
xfit = mx-sx:0.01:Mx+sx;
yfit = polyval(p,xfit);
hfit = plot(xfit,yfit,'b-','LineWidth',2);
```

```
hroots = plot(real_r,zeros(size(real_r)),...
             'bo','MarkerSize',5,...
             'LineWidth',2,...
             'MarkerFaceColor','b');
grid on
plot(xfit,zeros(size(xfit)),'k-','LineWidth',2)
axis([mx-sx Mx+sx my-sy My+sy])

% Add prediction intervals to the plot.
[Y,DELTA] = polyconf(p,xfit,S,'alpha',alpha);
hconf = plot(xfit,Y+DELTA,'b--');
plot(xfit,Y-DELTA,'b--')

% Display the polynomial fit and the real roots.
approx_p = round(100*p)/100; % Round for display.
htitle = title(['{\bf Fit:   }',...
              texlabel(polystr(approx_p))]);
set(htitle,'Color','b')
approx_real_r = round(100*real_r)/100; % Round for display.
hxlabel = xlabel(['{\bf Real Roots:   }',...
                num2str(approx_real_r)]);
set(hxlabel,'Color','b')

% Add a legend.
legend([hdata,hfit,hroots,hconf],...
      'Data','Fit','Real Roots of Fit',...
      '95% Prediction Intervals')
```

polytool

Interactive polynomial fitting

Syntax

```
polytool(x,y)
polytool(x,y,n)
polytool(x,y,n,alpha)
polytool(x,y,n,alpha,xname,yname)
h = polytool(...)
```

Description

`polytool(x,y)` fits a line to the vectors `x` and `y` and displays an interactive plot of the result in a graphical interface. You can use the interface to explore the effects of changing the parameters of the fit and to export fit results to the workspace.

`polytool(x,y,n)` initially fits a polynomial of degree `n`. The default is `1`, which produces a linear fit.

`polytool(x,y,n,alpha)` initially plots `100(1 - alpha)%` confidence intervals on the predicted values. The default is `0.05` which results in 95% confidence intervals.

`polytool(x,y,n,alpha,xname,yname)` labels the `x` and `y` values on the graphical interface using `xname` and `yname`. Specify `n` and `alpha` as `[]` to use their default values.

`h = polytool(...)` outputs a vector of handles, `h`, to the line objects in the plot. The handles are returned in the degree: data, fit, lower bounds, upper bounds.

Examples

Interactive polynomial fitting

This example shows how to start an interactive fitting session with `polytool`.

Generate data from a quadratic curve with added noise.

```
rng('default') % for reproducibility
x = -5:5;
y = x.^2 - 5*x - 3 + 5*randn(size(x));
```

Fit a quadratic (degree-2) model with 0.90 confidence intervals.

```
n = 2;
alpha = 0.1;
polytool(x,y,n,alpha)
```

Introduced before R2006a

posterior

Posterior probability of Gaussian mixture component

Syntax

```
P = posterior(gm,X)
[P,nlogL] = posterior(gm,X)
```

Description

`P = posterior(gm,X)` returns the posterior probability of each Gaussian mixture component in `gm` given each observation in `X`.

`[P,nlogL] = posterior(gm,X)` also returns the negative loglikelihood of the Gaussian mixture model `gm` given the data `X`.

Examples

Compute Posterior Probabilities

Generate random variates that follow a mixture of two bivariate Gaussian distributions by using the `mvnrnd` function. Fit a Gaussian mixture model (GMM) to the generated data by using the `fitgmdist` function, and then compute the posterior probabilities of the mixture components.

Define the distribution parameters (means and covariances) of two bivariate Gaussian mixture components.

```
mu1 = [2 2];           % Mean of the 1st component
sigma1 = [2 0; 0 1];  % Covariance of the 1st component
mu2 = [-2 -1];       % Mean of the 2nd component
sigma2 = [1 0; 0 1]; % Covariance of the 2nd component
```

Generate an equal number of random variates from each component, and combine the two sets of random variates.

```
rng('default') % For reproducibility
r1 = mvnrnd(mu1,sigma1,1000);
r2 = mvnrnd(mu2,sigma2,1000);
X = [r1; r2];
```

The combined data set X contains random variates following a mixture of two bivariate Gaussian distributions.

Fit a two-component GMM to X.

```
gm = fitgmdist(X,2)
```

```
gm =
```

```
Gaussian mixture distribution with 2 components in 2 dimensions
```

```
Component 1:
```

```
Mixing proportion: 0.500765
```

```
Mean:   -1.9675   -0.9654
```

```
Component 2:
```

```
Mixing proportion: 0.499235
```

```
Mean:    1.9657    2.0342
```

Plot X by using `scatter`. Visualize the fitted model `gm` by using `pdf` and `fcontour`.

```
figure
scatter(X(:,1),X(:,2),10,'.') % Scatter plot with points of size 10
hold on
gmPDF = @(x,y)reshape(pdf(gm,[x(:) y(:)]),size(x));
fcontour(gmPDF,[-6 8 -4 6])
c1 = colorbar;
ylabel(c1,'Probability Density Function')
```

Compute the posterior probabilities of the components.

```
P = posterior(gm,X);
```

$P(i, j)$ is the posterior probability of the j th Gaussian mixture component given observation i .

Plot the posterior probabilities of Component 1 by using the `scatter` function. Use the circle colors to visualize the posterior probability values.

```
figure
scatter(X(:,1),X(:,2),10,P(:,1))
c2 = colorbar;
ylabel(c2, 'Posterior Probability of Component 1')
```

Plot the posterior probabilities of Component 2.

```
figure
scatter(X(:,1),X(:,2),10,P(:,2))
c3 = colorbar;
ylabel(c3,'Posterior Probability of Component 2')
```

Input Arguments

gm — Gaussian mixture distribution

`gmdistribution` object

Gaussian mixture distribution, also called Gaussian mixture model (GMM), specified as a `gmdistribution` object.

You can create a `gmdistribution` object using `gmdistribution` or `fitgmdist`. Use the `gmdistribution` function to create a `gmdistribution` object by specifying the

distribution parameters. Use the `fitgmdist` function to fit a `gmdistribution` model to data given a fixed number of components.

X — Data

n-by-*m* numeric matrix

Data, specified as an *n*-by-*m* numeric matrix, where *n* is the number of observations and *m* is the number of variables in each observation.

If a row of *X* contains NaNs, then `posterior` excludes the row from the computation. The corresponding value in *P* is NaN.

Data Types: `single` | `double`

Output Arguments

P — Posterior probability

n-by-*k* numeric vector

Posterior probability of each Gaussian mixture component in `gm` given each observation in *X*, returned as an *n*-by-*k* numeric vector, where *n* is the number of observations in *X* and *k* is the number of mixture components in `gm`.

$P(i, j)$ is the posterior probability of the *j*th Gaussian mixture component given observation *i*, `Probability(component j | observation i)`.

nlogL — Negative loglikelihood

numeric value

Negative loglikelihood value of the Gaussian mixture model `gm` given the data *X*, returned as a numeric value.

Introduced in R2007b

postFitStatistics

Class: RegressionGP

Compute post-fit statistics for the exact Gaussian process regression model

Syntax

```
loores = postFitStatistics(gprMdl)
[loores,neff] = postFitStatistics(gprMdl)
```

Description

`loores = postFitStatistics(gprMdl)` returns the leave-one-out residuals, `loores`, for the trained Gaussian process regression (GPR) model.

`[loores,neff] = postFitStatistics(gprMdl)` also returns the number of effective parameters, `neff`.

Input Arguments

gprMdl — Gaussian process regression model

RegressionGP object

Gaussian process regression model, specified as a RegressionGP object.

Output Arguments

loores — Leave-one-out residuals

n-by-1 matrix

Leave-one-out residuals, returned as an *n*-by-1 matrix, where *n* is the number of observations in the training data.

neff — Number of effective parameters*n*-by-1 matrix

Number of effective parameters, returned as an *n*-by-1 matrix, where *n* is the number of observations in the training data.

Examples

Compute Post-Fit Statistics

Generate sample data.

```
rng(0, 'twister'); % For reproducibility
n = 1500;
x = linspace(-10,10,n)';
y = sin(3*x).*cos(3*x) + sin(2*x).*cos(2*x) + sin(x) + cos(x) + 0.2*randn(n,1);
```

Fit a GPR model using the exact method for fitting and prediction.

```
gprMdl = fitrgp(x,y,'Basis','linear','FitMethod','exact',...
'PredictMethod','exact','KernelFunction','matern52');
```

Compute the leave-one-out residuals and the effective number of parameters in the trained model.

```
[loores,neff] = postFitStatistics(gprMdl);
```

Predict the responses using the trained model.

```
ypred = resubPredict(gprMdl);
```

Plot the true and predicted responses, and display effective number of parameters in the fit.

```
figure()
plot(x,y,'r. ');
hold on;
plot(x,ypred,'b');
xlabel('x');
ylabel('y');
legend('Data','GPR prediction','Location','Best');
```

```
title(['Effective number of parameters = ',num2str(neff)]);  
hold off
```

Plot leave-one-out residuals.

```
figure()  
plot(x,loores,'r.-');  
xlabel('x');  
ylabel('leave-one-out residuals');
```

Tips

- You can only compute the post-fit statistics when `PredictMethod` is 'exact'.
- If `FitMethod` is 'exact', then `postFitStatistics` accounts for the fact that the fixed basis function coefficients are estimated from the data.
- If `FitMethod` is different than 'exact', then `postFitStatistics` treats the fixed basis function coefficients as known.
- For all `PredictMethod` and `FitMethod` options, `postFitStatistics` treats the estimated kernel parameters and noise standard deviation as known.

Introduced in R2015b

prctile

Percentiles of a data set

Syntax

```
Y = prctile(X,p)
Y = prctile(X,p,'all')
Y = prctile(X,p,dim)
Y = prctile(X,p,vecdim)
Y = prctile( ____, 'Method', method)
```

Description

`Y = prctile(X,p)` returns percentiles of the elements in a data vector or array `X` for the percentages `p` in the interval `[0,100]`.

- If `X` is a vector, then `Y` is a scalar or a vector with the same length as the number of percentiles requested (`length(p)`). `Y(i)` contains the `p(i)` percentile.
- If `X` is a matrix, then `Y` is a row vector or a matrix, where the number of rows of `Y` is equal to the number of percentiles requested (`length(p)`). The `i`th row of `Y` contains the `p(i)` percentiles of each column of `X`.
- For multidimensional arrays on page 32-5178, `prctile` operates along the first nonsingleton dimension on page 32-5178 of `X`.

`Y = prctile(X,p,'all')` returns percentiles of all the elements of `X`.

`Y = prctile(X,p,dim)` returns percentiles along the operating dimension `dim`.

`Y = prctile(X,p,vecdim)` returns percentiles over the dimensions specified in the vector `vecdim`. For example, if `X` is a matrix, then `prctile(X,50,[1 2])` returns the 50th percentile of all the elements of `X` because every element of a matrix is contained in the array slice defined by dimensions 1 and 2.

`Y = prctile(____, 'Method', method)` returns either exact or approximate percentiles based on the value of `method`, using any of the input argument combinations in the previous syntaxes.

Examples

Percentiles of a Data Vector

Generate a data set of size 10.

```
rng('default'); % for reproducibility
x = normrnd(5,2,1,10)
```

```
x = 1×10
```

```
    6.0753    8.6678    0.4823    6.7243    5.6375    2.3846    4.1328    5.6852   12.1
```

Calculate the 42nd percentile.

```
Y = prctile(x,42)
```

```
Y = 5.6709
```

Percentiles of All Values

Find the percentiles of all the values in an array.

Create a 3-by-5-by-2 array X.

```
X = reshape(1:30,[3 5 2])
```

```
X =
X(:,:,1) =
```

```
    1    4    7   10   13
    2    5    8   11   14
    3    6    9   12   15
```

```
X(:,:,2) =
```

```
   16   19   22   25   28
   17   20   23   26   29
```

```
18    21    24    27    30
```

Find the 40th and 60th percentiles of the elements of X.

```
Y = prctile(X,[40 60], 'all')
```

```
Y = 2×1
```

```
12.5000  
18.5000
```

Y(1) is the 40th percentile of X, and Y(2) is the 60th percentile of X.

Percentiles of a Data Matrix

Calculate the percentiles along the columns and rows of a data matrix for specified percentages.

Generate a 5-by-5 data matrix.

```
X = (1:5)'*(2:6)
```

```
X = 5×5
```

```
2     3     4     5     6  
4     6     8    10    12  
6     9    12    15    18  
8    12    16    20    24  
10   15    20    25    30
```

Calculate the 25th, 50th, and 75th percentiles along the columns of X.

```
Y = prctile(X,[25 50 75],1)
```

```
Y = 3×5
```

```
3.5000    5.2500    7.0000    8.7500   10.5000  
6.0000    9.0000   12.0000   15.0000   18.0000  
8.5000   12.7500   17.0000   21.2500   25.5000
```

The rows of Y correspond to the percentiles of columns of X. For example, the 25th, 50th, and 75th percentiles of the third column of X with elements (4, 8, 12, 16, 20) are 7, 12, and 17, respectively. `Y = prctile(X,[25 50 75])` returns the same percentile matrix.

Calculate the 25th, 50th, and 75th percentiles along the rows of X.

```
Y = prctile(X,[25 50 75],2)
```

```
Y = 5×3
```

```

    2.7500    4.0000    5.2500
    5.5000    8.0000   10.5000
    8.2500   12.0000   15.7500
   11.0000   16.0000   21.0000
   13.7500   20.0000   26.2500
```

The rows of Y correspond to the percentiles of rows of X. For example, the 25th, 50th, and 75th percentiles of the first row of X with elements (2, 3, 4, 5, 6) are 2.75, 4, and 5.25, respectively.

Percentiles of Multidimensional Array

Find the percentiles of a multidimensional array along multiple dimensions simultaneously.

Create a 3-by-5-by-2 array X.

```
X = reshape(1:30,[3 5 2])
```

```
X =
X(:,:,1) =
```

```

     1     4     7    10    13
     2     5     8    11    14
     3     6     9    12    15
```

```
X(:,:,2) =
```

```

    16    19    22    25    28
    17    20    23    26    29
```

```
18    21    24    27    30
```

Calculate the 40th and 60th percentiles for each page of X by specifying dimensions 1 and 2 as the operating dimensions.

```
Ypage = prctile(X,[40 60],[1 2])
```

```
Ypage =  
Ypage(:,:,1) =
```

```
6.5000  
9.5000
```

```
Ypage(:,:,2) =
```

```
21.5000  
24.5000
```

For example, $Ypage(1,1,1)$ is the 40th percentile of the first page of X , and $Ypage(2,1,1)$ is the 60th percentile of the first page of X .

Calculate the 40th and 60th percentiles of the elements in each $X(:,i,:)$ slice by specifying dimensions 1 and 3 as the operating dimensions.

```
Ycol = prctile(X,[40 60],[1 3])
```

```
Ycol = 2×5
```

```
2.9000    5.9000    8.9000   11.9000   14.9000  
16.1000   19.1000   22.1000   25.1000   28.1000
```

For example, $Ycol(1,4)$ is the 40th percentile of the elements in $X(:,4,:)$, and $Ycol(2,4)$ is the 60th percentile of the elements in $X(:,4,:)$.

Percentiles of Tall Vector for Given Percentage

Calculate exact and approximate percentiles of a tall column vector for a given percentage.

Create a datastore for the `airlinesmall` data set. Treat 'NA' values as missing data so that `datastore` replaces them with NaN values. Specify to work with the `ArrTime` variable.

```
ds = datastore('airlinesmall.csv','TreatAsMissing','NA',...
              'SelectedVariableNames','ArrTime');
```

Create a tall table on top of the datastore, and extract the data from the tall table into a tall vector.

```
t = tall(ds) % Tall table
```

```
Starting parallel pool (parpool) using the 'local' profile ...
connected to 6 workers.
```

```
t =
```

```

Evaluate the tall arrays and bring the results into memory by using `gather`.

```
[yExact,yApprox] = gather(yExact,yApprox)
```

```
Evaluating tall expression using the Parallel Pool 'local':
- Pass 1 of 4: Completed in 9.7 sec
- Pass 2 of 4: Completed in 0.7 sec
- Pass 3 of 4: Completed in 1.8 sec
- Pass 4 of 4: Completed in 1 sec
Evaluation completed in 16 sec
```

```
yExact = 1522
```

```
yApprox = 1.5220e+03
```

The values of the approximate percentile and the exact percentile are the same to the four digits shown.

Percentiles of Tall Matrix Along Different Dimensions

Calculate exact and approximate percentiles of a tall matrix for specified percentages along different dimensions.

Create a tall matrix *X* containing a subset of variables from the `airlinesmall` data set. See “Percentiles of Tall Vector for Given Percentage” on page 32-5170 for details about the steps to extract data from a tall array.

```
varnames = {'ArrDelay', 'ArrTime', 'DepTime', 'ActualElapsedTime'}; % Subset of variables
ds = datastore('airlinesmall.csv', 'TreatAsMissing', 'NA', ...
    'SelectedVariableNames', varnames); % Datastore
t = tall(ds); % Tall table
```

```
Starting parallel pool (parpool) using the 'local' profile ...
Connected to the parallel pool (number of workers: 6).
```

```
X = t{:, varnames} % Tall matrix
```

```
X =
```

```
M×4 tall double matrix
```

When operating along a dimension that is not 1, the `prctile` function calculates the exact percentiles only, so that it can perform the computation efficiently using a sorting-based algorithm (see “Algorithms” on page 32-5181) instead of an approximation algorithm based on “T-Digest” on page 32-5178.

Calculate the exact 25th, 50th, and 75th percentiles of `X` along the second dimension.

```
p = [25 50 75]; % Vector of percentages
Yexact = prctile(X,p,2)
```

```
Yexact =
```

```
M×N×... tall double array
```

```
? ? ? ...
? ? ? ...
? ? ? ...
: : :
: : :
```

Preview deferred. [Learn more.](#)

When the function operates along the first dimension and `p` is a vector of percentages, you must use the approximation algorithm based on `t-digest` to compute the percentiles. Using the sorting-based algorithm to find the percentiles along the first dimension of a tall array is computationally intensive.

Calculate the approximate 25th, 50th, and 75th percentiles of `X` along the first dimension. Because the default dimension is 1, you do not need to specify a value for `dim`.

```
Yapprox = prctile(X,p,'Method','approximate')
```

```
Yapprox =
```

```
M×N×... tall double array
```

```
? ? ? ...
? ? ? ...
```

```

?   ?   ?   ...
:   :   :
:   :   :

```

Preview deferred. Learn more.

Evaluate the tall arrays and bring the results into memory by using `gather`.

```
[Yexact,Yapprox] = gather(Yexact,Yapprox);
```

```
Evaluating tall expression using the Parallel Pool 'local':
- Pass 1 of 1: Completed in 9.9 sec
Evaluation completed in 12 sec
```

Show the first five rows of the exact 25th, 50th, and 75th percentiles along the second dimension of X .

```
Yexact(1:5,:)

```

```
ans = 5x3
103 ×
```

```

0.0305    0.3475    0.6885
0.0355    0.5420    1.0725
0.0520    1.0690    2.1365
0.0360    0.6955    1.3815
0.0405    0.3530    0.6875

```

Each row of the matrix `Yexact` contains the three percentiles of the corresponding row in X . For example, **30.5**, **347.5**, and **688.5** are the 25th, 50th, and 75th percentiles, respectively, of the first row in X .

Show the approximate 25th, 50th, and 75th percentiles of X along the first dimension.

```
Yapprox

```

```
Yapprox = 3x4
103 ×
```

```

-0.0070    1.1149    0.9321    0.0700
         0    1.5220    1.3350    0.1020
0.0110    1.9180    1.7400    0.1510

```

Each column of the matrix `Yapprox` corresponds to the three percentiles for each column of the matrix `X`. For example, the first column of `Yapprox` with elements `(-7, 0, 11)` contains the percentiles for the first column of `X`.

Input Arguments

X — Input data

vector | array

Input data, specified as a vector or array.

Data Types: `double` | `single`

p — Percentages

scalar | vector

Percentages for which to compute percentiles, specified as a scalar or vector of scalars from 0 to 100.

Example: 25

Example: `[25, 50, 75]`

Data Types: `double` | `single`

dim — Dimension

positive integer

Dimension along which the percentiles of `X` are requested, specified as a positive integer. For example, for a matrix `X`, when `dim = 1`, `prctile` returns the percentile(s) of the columns of `X`; when `dim = 2`, `prctile` returns the percentile(s) of the rows of `X`. For a multidimensional array `X`, the length of the `dim`th dimension of `Y` is equal to the length of `p`.

Data Types: `double` | `single`

vecdim — Vector of dimensions

positive integer vector

Vector of dimensions, specified as a positive integer vector. Each element of `vecdim` represents a dimension of the input array `X`. The output `Y` has length `length(p)` in the smallest specified operating dimension (that is, dimension `min(vecdim)`) and has length

1 in each of the remaining operating dimensions. The other dimension lengths are the same for X and Y .

For example, consider a 2-by-3-by-3 array X with $p = [20\ 40\ 60\ 80]$. In this case, `prctile(X,p,[1 2])` returns an array, where each page of the array contains the 20th, 40th, 60th, and 80th percentiles of the elements of the corresponding page of X . Because 1 and 2 are the operating dimensions, with $\min([1\ 2]) = 1$ and $\text{length}(p) = 4$, the output is a 4-by-1-by-3 array.

Data Types: `single` | `double`

method — Method for calculating percentiles

`'exact'` (default) | `'approximate'`

Method for calculating percentiles, specified as `'exact'` or `'approximate'`. By default, `prctile` returns the exact percentiles by implementing an algorithm on page 32-5181 that uses sorting. You can specify `'method'`, `'approximate'` for `prctile` to return approximate percentiles by implementing an algorithm that uses T-Digest on page 32-5178.

Data Types: `char` | `string`

Output Arguments

Y — Percentiles

`scalar` | `array`

Percentiles of a data vector or array, returned as a scalar or array for one or more percentage values.

- If X is a vector, then Y is a scalar or a vector with the same length as the number of percentiles requested ($\text{length}(p)$). $Y(i)$ contains the $p(i)$ th percentile.
- If X is an array of dimension d , then Y is an array with the length of the smallest operating dimension equal to the number of percentiles requested ($\text{length}(p)$).

Definitions

Multidimensional Array

A *multidimensional array* is an array with more than two dimensions. For example, if X is a 1-by-3-by-4 array, then X is a 3-D array.

Nonsingleton Dimension

A *first nonsingleton dimension* is the first dimension of an array whose size is not equal to 1. For example, if X is a 1-by-2-by-3-by-4 array, then the second dimension is the first nonsingleton dimension of X .

Linear Interpolation

Linear interpolation uses linear polynomials to find $y_i = f(x_i)$, the values of the underlying function $Y = f(X)$ at the points in the vector or array x . Given the data points (x_1, y_1) and (x_2, y_2) , where $y_1 = f(x_1)$ and $y_2 = f(x_2)$, linear interpolation finds $y = f(x)$ for a given x between x_1 and x_2 as follows:

$$y = f(x) = y_1 + \frac{(x - x_1)}{(x_2 - x_1)}(y_2 - y_1).$$

Similarly, if the $100(1.5/n)$ th percentile is $y_{1.5/n}$ and the $100(2.5/n)$ th percentile is $y_{2.5/n}$, then linear interpolation finds the $100(2.3/n)$ th percentile, $y_{2.3/n}$ as:

$$y_{\frac{2.3}{n}} = y_{\frac{1.5}{n}} + \frac{\left(\frac{2.3}{n} - \frac{1.5}{n}\right)}{\left(\frac{2.5}{n} - \frac{1.5}{n}\right)} \left(y_{\frac{2.5}{n}} - y_{\frac{1.5}{n}}\right).$$

T-Digest

T-digest[2] on page 32-5181 is a probabilistic data structure that is a sparse representation of the empirical cumulative distribution function (CDF) of a data set. T-digest is useful for computing approximations of rank-based statistics (such as percentiles and quantiles) from online or distributed data in a way that allows for controllable accuracy, particularly near the tails of the data distribution.

For data that is distributed in different partitions, t-digest computes quantile estimates (and percentile estimates) for each data partition separately, and then combines the estimates while maintaining a constant-memory bound and constant relative accuracy of computation ($q(1 - q)$ for the q th quantile). For these reasons, t-digest is practical for working with tall arrays.

To estimate quantiles of an array that is distributed in different partitions, first build a t-digest in each partition of the data. A t-digest clusters the data in the partition and summarizes each cluster by a centroid value and an accumulated weight that represents the number of samples contributing to the cluster. T-digest uses large clusters (widely spaced centroids) to represent areas of the CDF that are near $q = 0.5$ and uses small clusters (tightly spaced centroids) to represent areas of the CDF that are near $q = 0$ or $q = 1$.

T-digest controls the cluster size by using a scaling function that maps a quantile q to an index k with a compression parameter δ . That is,

$$k(q, \delta) = \delta \cdot \left(\frac{\sin^{-1}(2q - 1)}{\pi} + \frac{1}{2} \right),$$

where the mapping k is monotonic with minimum value $k(0, \delta) = 0$ and maximum value $k(1, \delta) = \delta$.

Scaling Function for $\delta = 10$

The scaling function translates the quantile q to the scaling factor k in order to give variable size steps in q . As a result, cluster sizes are unequal (larger around the center quantiles and smaller near $q = 0$ or $q = 1$). The smaller clusters allow for better accuracy near the edges of the data.

To update a t-digest with a new observation that has a weight and location, find the cluster closest to the new observation. Then, add the weight and update the centroid of the cluster based on the weighted average, provided that the updated weight of the cluster does not exceed the size limitation.

You can combine independent t-digests from each partition of the data by taking a union of the t-digests and merging their centroids. To combine t-digests, first sort the clusters from all the independent t-digests in decreasing order of cluster weights. Then, merge neighboring clusters, when they meet the size limitation, to form a new t-digest.

Once you form a t-digest that represents the complete data set, you can estimate the end-points (or boundaries) of each cluster in the t-digest and then use interpolation between the end-points of each cluster to find accurate quantile estimates.

Algorithms

For an n -element vector X , `prctile` returns percentiles by using a sorting-based algorithm as follows:

- 1 The sorted elements in X are taken as the $100(0.5/n)$ th, $100(1.5/n)$ th, ..., $100([n - 0.5]/n)$ th percentiles. For example:
 - For a data vector of five elements such as $\{6, 3, 2, 10, 1\}$, the sorted elements $\{1, 2, 3, 6, 10\}$ respectively correspond to the 10th, 30th, 50th, 70th, and 90th percentiles.
 - For a data vector of six elements such as $\{6, 3, 2, 10, 8, 1\}$, the sorted elements $\{1, 2, 3, 6, 8, 10\}$ respectively correspond to the $(50/6)$ th, $(150/6)$ th, $(250/6)$ th, $(350/6)$ th, $(450/6)$ th, and $(550/6)$ th percentiles.
- 2 `prctile` uses linear interpolation on page 32-5178 to compute percentiles for percentages between $100(0.5/n)$ and $100([n - 0.5]/n)$.
- 3 `prctile` assigns the minimum or maximum values of the elements in X to the percentiles corresponding to the percentages outside that range.

`prctile` treats NaNs as missing values and removes them.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

Usage notes and limitations:

- `Y = prctile(X,p)` and `Y = prctile(X,p,dim)` return the exact percentiles (using a sorting-based algorithm on page 32-5181) under these conditions:
 - `X` is a tall column vector and `p` is a scalar. In this case, `dim` is 1.
 - `X` is a tall array and `dim` is not 1.

If `p` is a vector and `dim` is 1, then you must specify `'Method', 'approximate'` to use an approximation algorithm based on T-Digest on page 32-5178 for computing the percentiles.

- `Y = prctile(X,p,'all')` returns the exact percentiles when `p` is a scalar. If `p` is a vector, then you must specify `'Method', 'approximate'` to use the approximation algorithm.
- `Y = prctile(X,p,vecdim)` returns the exact percentiles if `vecdim` does not include the first dimension. If `vecdim` includes the first dimension, then you must specify `'Method', 'approximate'` to use the approximation algorithm.

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The `'all'` and `vecdim` input arguments are not supported.
- The `'Method'` name-value pair argument is not supported.
- The `dim` input argument must be a compile-time constant.
- If you do not specify the `dim` input argument, the working (or operating) dimension can be different in the generated code. As a result, run-time errors can occur. For more details, see “Automatic dimension restriction” (MATLAB Coder).
- If the output `Y` is a vector, the orientation of `Y` differs from MATLAB when all of the following are true:

- You do not supply `dim`.
- `X` is a variable-size array, and not a variable-size vector, at compile time, but `X` is a vector at run time.
- The orientation of the vector `X` does not match the orientation of the vector `p`.

In this case, the output `Y` matches the orientation of `X`, not the orientation of `p`.

For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “General Code Generation Workflow” on page 31-5.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Usage notes and limitations:

- The `'all'` and `vecdim` input arguments are not supported.
- The `'Method'` name-value pair argument is not supported.

For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

Introduced before R2006a

predict

Predict labels using k -nearest neighbor classification model

Syntax

```
label = predict mdl, X
[label, score, cost] = predict mdl, X
```

Description

`label = predict(mdl, X)` returns a vector of predicted class labels for the predictor data in the table or matrix `X`, based on the trained k -nearest neighbor classification model `mdl`. See “Predicted Class Label” on page 32-5187.

`[label, score, cost] = predict(mdl, X)` also returns:

- A matrix of classification scores (`score`) indicating the likelihood that a label comes from a particular class. For k -nearest neighbor, scores are posterior probabilities. See “Posterior Probability” on page 32-5188.
- A matrix of expected classification cost (`cost`). For each observation in `X`, the predicted class label corresponds to the minimum expected classification costs among all classes. See “Expected Cost” on page 32-5189.

Examples

k -Nearest Neighbor Classification Predictions

Create a k -nearest neighbor classifier for Fisher's iris data, where $k = 5$. Evaluate some model predictions on new data.

Load the Fisher iris data set.

```
load fisheriris
X = meas;
Y = species;
```

Create a classifier for five nearest neighbors. Standardize the noncategorical predictor data.

```
mdl = fitcknn(X,Y,'NumNeighbors',5,'Standardize',1);
```

Predict the classifications for flowers with minimum, mean, and maximum characteristics.

```
Xnew = [min(X);mean(X);max(X)];
[label,score,cost] = predict(mdl,Xnew)
```

```
label = 3x1 cell array
    {'versicolor'}
    {'versicolor'}
    {'virginica' }
```

```
score = 3x3
```

```
    0.4000    0.6000         0
         0    1.0000         0
         0         0    1.0000
```

```
cost = 3x3
```

```
    0.6000    0.4000    1.0000
    1.0000         0    1.0000
    1.0000    1.0000         0
```

The second and third rows of the score and cost matrices have binary values, which means all five nearest neighbors of the mean and maximum flower measurements have identical classifications.

Input Arguments

mdl — *k*-nearest neighbor classifier model

ClassificationKNN object

k -nearest neighbor classifier model, specified as a `ClassificationKNN` object.

X — Predictor data to be classified

numeric matrix | table

Predictor data to be classified, specified as a numeric matrix or table.

Each row of X corresponds to one observation, and each column corresponds to one variable.

- For a numeric matrix:
 - The variables that make up the columns of X must have the same order as the predictor variables used to train `mdl`.
 - If you train `mdl` using a table (for example, `Tbl`), then X can be a numeric matrix if `Tbl` contains all numeric predictor variables. k -nearest neighbor classification requires homogeneous predictors. Therefore, to treat all numeric predictors in `Tbl` as categorical during training, set `'CategoricalPredictors'`, `'all'` when you train using `fitcknn`. If `Tbl` contains heterogeneous predictors (for example, numeric and categorical data types) and X is a numeric matrix, then `predict` throws an error.
- For a table:
 - `predict` does not support multicolumn variables and cell arrays other than cell arrays of character vectors.
 - If you train `mdl` using a table (for example, `Tbl`), then all predictor variables in X must have the same variable names and data types as those used to train `mdl` (stored in `mdl.PredictorNames`). However, the column order of X does not need to correspond to the column order of `Tbl`. Both `Tbl` and X can contain additional variables (response variables, observation weights, and so on), but `predict` ignores them.
 - If you train `mdl` using a numeric matrix, then the predictor names in `mdl.PredictorNames` and corresponding predictor variable names in X must be the same. To specify predictor names during training, see the `PredictorNames` name-value pair argument of `fitcknn`. All predictor variables in X must be numeric vectors. X can contain additional variables (response variables, observation weights, and so on), but `predict` ignores them.

If you set `'Standardize'`, `true` in `fitcknn` to train `mdl`, then the software standardizes the columns of X using the corresponding means in `mdl.Mu` and standard deviations in `mdl.Sigma`.

Data Types: `double` | `single` | `table`

Output Arguments

label — Predicted class labels

categorical array | character array | logical vector | vector of numeric values | cell array of character vectors

Predicted class labels for the observations (rows) in X , returned as a categorical array, character array, logical vector, vector of numeric values, or cell array of character vectors. `label` has length equal to the number of rows in X . The label is the class with minimal expected cost. See “Predicted Class Label” on page 32-5187.

score — Predicted class scores or posterior probabilities

numeric matrix

Predicted class scores or posterior probabilities, returned as a numeric matrix of size n -by- K . n is the number of observations (rows) in X , and K is the number of classes (in `mdl.ClassNames`). `score(i,j)` is the posterior probability that observation i in X is of class j in `mdl.ClassNames`. See “Posterior Probability” on page 32-5188.

Data Types: `single` | `double`

cost — Expected classification costs

numeric matrix

Expected classification costs, returned as a numeric matrix of size n -by- K . n is the number of observations (rows) in X , and K is the number of classes (in `mdl.ClassNames`). `cost(i,j)` is the cost of classifying row i of X as class j in `mdl.ClassNames`. See “Expected Cost” on page 32-5189.

Data Types: `single` | `double`

Algorithms

Predicted Class Label

`predict` classifies by minimizing the expected classification cost:

$$\hat{y} = \operatorname{argmin}_{y=1, \dots, K} \sum_{j=1}^K \hat{P}(j|x)C(y|j),$$

where

- \hat{y} is the predicted classification.
- K is the number of classes.
- $\hat{P}(j|x)$ is the posterior probability of class j for observation x .
- $C(y|j)$ is the cost of classifying an observation as y when its true class is j .

Posterior Probability

Consider a vector (single query point) x_{new} and a model mdl .

- k is the number of nearest neighbors used in prediction, mdl.NumNeighbors .
- $\text{nbrd}(\text{mdl}, x_{\text{new}})$ specifies the k nearest neighbors to x_{new} in mdl.X .
- $Y(\text{nbrd})$ specifies the classifications of the points in $\text{nbrd}(\text{mdl}, x_{\text{new}})$, namely $\text{mdl.Y}(\text{nbrd})$.
- $W(\text{nbrd})$ specifies the weights of the points in $\text{nbrd}(\text{mdl}, x_{\text{new}})$.
- prior specifies the priors of the classes in mdl.Y .

If the model contains a vector of prior probabilities, then the observation weights W are normalized by class to sum to the priors. This process might involve a calculation for the point x_{new} , because weights can depend on the distance from x_{new} to the points in mdl.X .

The posterior probability $p(j|x_{\text{new}})$ is

$$p(j|x_{\text{new}}) = \frac{\sum_{i \in \text{nbrd}} W(i)1_{Y(X(i))=j}}{\sum_{i \in \text{nbrd}} W(i)}.$$

Here, $1_{Y(X(i))=j}$ is 1 when $\text{mdl.Y}(i) = j$, and 0 otherwise.

True Misclassification Cost

Two costs are associated with KNN classification: the true misclassification cost per class and the expected misclassification cost per observation.

You can set the true misclassification cost per class by using the 'Cost' name-value pair argument when you run `fitcknn`. The value `Cost(i,j)` is the cost of classifying an observation into class j if its true class is i . By default, `Cost(i,j) = 1` if $i \neq j$, and `Cost(i,j) = 0` if $i = j$. In other words, the cost is 0 for correct classification and 1 for incorrect classification.

Expected Cost

Two costs are associated with KNN classification: the true misclassification cost per class and the expected misclassification cost per observation. The third output of `predict` is the expected misclassification cost per observation.

Suppose you have `Nobs` observations that you want to classify with a trained classifier `mdl`, and you have K classes. You place the observations into a matrix `Xnew` with one observation per row. The command

```
[label,score,cost] = predict(mdl,Xnew)
```

returns a matrix `cost` of size `Nobs`-by- K , among other outputs. Each row of the `cost` matrix contains the expected (average) cost of classifying the observation into each of the K classes. `cost(n,j)` is

$$\sum_{i=1}^K \widehat{P}(i|X_{new}(n))C(j|i),$$

where

- K is the number of classes.
- $\widehat{P}(i|X_{new}(n))$ is the posterior probability on page 32-5188 of class i for observation $X_{new}(n)$.
- $C(j|i)$ is the true misclassification cost of classifying an observation as j when its true class is i .

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. For more information, see “Tall Arrays” (MATLAB).

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Use `saveCompactModel`, `loadCompactModel`, and `codegen` to generate code for the `predict` function. Save a trained model by using `saveCompactModel`. Define an entry-point function that loads the saved model by using `loadCompactModel` and calls the `predict` function. Then use `codegen` to generate code for the entry-point function.
- This table contains notes about the arguments of `predict`. Arguments not included in this table are fully supported.

Argument	Notes and Limitations
mdl	<ul style="list-style-type: none"> • A <code>ClassificationKNN</code> model object is a full object that does not have a corresponding compact object. For this model, <code>saveCompactModel</code> saves a compact version that does not include the hyperparameter optimization properties. • If <code>mdl</code> is a model trained using the <i>kd</i>-tree search algorithm, and the code generation build type is a MEX function, then <code>codegen</code> generates a MEX function using Intel Threading Building Blocks (TBB) for parallel computation. Otherwise, <code>codegen</code> generates code using <code>parfor</code>. <ul style="list-style-type: none"> • MEX function for the <i>kd</i>-tree search algorithm — <code>codegen</code> generates an optimized MEX function using Intel TBB for parallel computation on multicore platforms. You can use the MEX function to accelerate MATLAB algorithms. For details on Intel TBB, see https://software.intel.com/en-us/intel-tbb. <p>If you generate the MEX function to test the generated code of the <code>parfor</code> version, you can disable the usage of Intel TBB. Set the <code>ExtrinsicCalls</code> property of the MEX configuration object to <code>false</code>. For details, see <code>coder.MexCodeConfig</code>.</p> • MEX function for the exhaustive search algorithm and standalone C/C++ code for both algorithms — The generated code of <code>predict</code> uses <code>parfor</code> to create loops that run in parallel on supported shared-memory multicore platforms in the generated code. If your compiler does not support the Open Multiprocessing (OpenMP) application interface or you disable OpenMP library, MATLAB Coder treats the <code>parfor</code>-loops as <code>for</code>-loops. To find supported compilers, see https://www.mathworks.com/support/compilers/current_release/. To disable OpenMP library, set the <code>EnableOpenMP</code> property of the configuration object to <code>false</code>. For details, see <code>coder.CodeConfig</code>.

Argument	Notes and Limitations
	<ul style="list-style-type: none">For the usage notes and limitations of the model object, see “Code Generation” on page 32-487 of the ClassificationKNN object.
X	<ul style="list-style-type: none">Must be a single-precision or double-precision matrix and can be variable-size. However, the number of columns in X must be <code>numel mdl.PredictorNames</code>.Rows and columns must correspond to observations and predictors, respectively.

For more information, see “Introduction to Code Generation” on page 31-2.

Introduced in R2012a

predict

Class: ClassificationLinear

Predict labels for linear classification models

Syntax

```
Label = predict(Mdl,X)
Label = predict(Mdl,X,Name,Value)
[Label,Score] = predict(____)
```

Description

`Label = predict(Mdl,X)` returns predicted class labels for each observation in the predictor data `X` based on the trained, binary, linear classification model `Mdl`. `Label` contains class labels for each regularization strength in `Mdl`.

`Label = predict(Mdl,X,Name,Value)` returns predicted class labels with additional options specified by one or more `Name,Value` pair arguments. For example, you can specify that columns in the predictor data correspond to observations.

`[Label,Score] = predict(____)` also returns classification scores on page 32-5206 for both classes using any of the previous syntaxes. `Score` contains classification scores for each regularization strength in `Mdl`.

Input Arguments

Mdl — Binary, linear classification model

ClassificationLinear model object

Binary, linear classification model, specified as a ClassificationLinear model object. You can create a ClassificationLinear model object using fitlinear.

X — Predictor data

full matrix | sparse matrix

Predictor data, specified as an n -by- p full or sparse matrix. This orientation of X indicates that rows correspond to individual observations, and columns correspond to individual predictor variables.

Note If you orient your predictor matrix so that observations correspond to columns and specify 'ObservationsIn', 'columns', then you might experience a significant reduction in computation time.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

ObservationsIn — Predictor data observation dimension

'rows' (default) | 'columns'

Predictor data observation dimension, specified as the comma-separated pair consisting of 'ObservationsIn' and 'columns' or 'rows'.

Note If you orient your predictor matrix so that observations correspond to columns and specify 'ObservationsIn', 'columns', then you might experience a significant reduction in optimization-execution time.

Output Arguments

Label — Predicted class labels

categorical array | character array | logical matrix | numeric matrix | cell array of character vectors

Predicted class labels, returned as a categorical or character array, logical or numeric matrix, or cell array of character vectors.

In most cases, `Label` is an n -by- L array of the same data type as the observed class labels (Y) used to train `Mdl`. (The software treats string arrays as cell arrays of character

vectors.) n is the number of observations in X and L is the number of regularization strengths in $Mdl.Lambda$. That is, $Label(i, j)$ is the predicted class label for observation i using the linear classification model that has regularization strength $Mdl.Lambda(j)$.

If Y is a character array and $L > 1$, then $Label$ is a cell array of class labels.

Score — Classification scores

numeric array

Classification scores on page 32-5206, returned as a n -by-2-by- L numeric array. n is the number of observations in X and L is the number of regularization strengths in $Mdl.Lambda$. $Score(i, k, j)$ is the score for classifying observation i into class k using the linear classification model that has regularization strength $Mdl.Lambda(j)$. $Mdl.ClassNames$ stores the order of the classes.

If $Mdl.Learner$ is 'logistic', then classification scores are posterior probabilities.

Examples

Predict Training-Sample Labels

Load the NLP data set.

```
load nlpdata
```

X is a sparse matrix of predictor data, and Y is a categorical vector of class labels. There are more than two classes in the data.

The models should identify whether the word counts in a web page are from the Statistics and Machine Learning Toolbox™ documentation. So, identify the labels that correspond to the Statistics and Machine Learning Toolbox™ documentation web pages.

```
Ystats = Y == 'stats';
```

Train a binary, linear classification model using the entire data set, which can identify whether the word counts in a documentation web page are from the Statistics and Machine Learning Toolbox™ documentation.

```
rng(1); % For reproducibility
Mdl = fitclinear(X, Ystats);
```

Mdl is a `ClassificationLinear` model.

Predict the training-sample, or resubstitution, labels.

```
label = predict(Mdl,X);
```

Because there is one regularization strength in Mdl, label is column vectors with lengths equal to the number of observations.

Construct a confusion matrix.

```
ConfusionTrain = confusionchart(Ystats,label);
```

The model misclassifies only one 'stats' documentation page as being outside of the Statistics and Machine Learning Toolbox documentation.

Predict Test-Sample Labels

Load the NLP data set and preprocess it as in “Predict Training-Sample Labels” on page 32-5195. Transpose the predictor data matrix.

```
load nlpdata
Ystats = Y == 'stats';
X = X';
```

Train a binary, linear classification model that can identify whether the word counts in a documentation web page are from the Statistics and Machine Learning Toolbox™ documentation. Specify to hold out 30% of the observations. Optimize the objective function using SpaRSA.

```
rng(1) % For reproducibility
CVMdl = fitlinear(X,Ystats,'Solver','sparsa','Holdout',0.30,...
    'ObservationsIn','columns');
Mdl = CVMdl.Trained{1};
```

CVMdl is a `ClassificationPartitionedLinear` model. It contains the property `Trained`, which is a 1-by-1 cell array holding a `ClassificationLinear` model that the software trained using the training set.

Extract the training and test data from the partition definition.

```
trainIdx = training(CVMdl.Partition);
testIdx = test(CVMdl.Partition);
```

Predict the training- and test-sample labels.

```
labelTrain = predict(Mdl,X(:,trainIdx),'ObservationsIn','columns');
labelTest = predict(Mdl,X(:,testIdx),'ObservationsIn','columns');
```

Because there is one regularization strength in `Mdl`, `labelTrain` and `labelTest` are column vectors with lengths equal to the number of training and test observations, respectively.

Construct a confusion matrix for the training data.

```
ConfusionTrain = confusionchart(Ystats(trainIdx),labelTrain);
```

The model misclassifies only three documentation pages as being outside of Statistics and Machine Learning Toolbox documentation.

Construct a confusion matrix for the test data.

```
ConfusionTest = confusionchart(Ystats(testIdx),labelTest);
```

True Class	false	9003	2
	true	3	463
		false	true
		Predicted Class	

The model misclassifies three documentation pages as being outside the Statistics and Machine Learning Toolbox, and two pages as being inside.

Estimate Posterior Class Probabilities

Estimate test-sample, posterior class probabilities, and determine the quality of the model by plotting a ROC curve. Linear classification models return posterior probabilities for logistic regression learners only.

Load the NLP data set and preprocess it as in “Predict Test-Sample Labels” on page 32-5197.

```
load nlpdata
Ystats = Y == 'stats';
X = X';
```

Randomly partition the data into training and test sets by specifying a 30% holdout sample. Identify the test-set indices.

```
cvp = cvpartition(Ystats, 'Holdout', 0.30);
idxTest = test(cvp);
```

Train a binary linear classification model. Fit logistic regression learners using SpARSA. To hold out the test set, specify the partitioned model.

```
CVMdl = fitlinear(X, Ystats, 'ObservationsIn', 'columns', 'CVPartition', cvp, ...
    'Learner', 'logistic', 'Solver', 'sparsa');
Mdl = CVMdl.Trained{1};
```

`Mdl` is a `ClassificationLinear` model trained using the training set specified in the partition `cvp` only.

Predict the test-sample posterior class probabilities.

```
[~, posterior] = predict(Mdl, X(:, idxTest), 'ObservationsIn', 'columns');
```

Because there is one regularization strength in `Mdl`, `posterior` is a matrix with 2 columns and rows equal to the number of test-set observations. Column i contains posterior probabilities of `Mdl.ClassNames(i)` given a particular observation.

Obtain false and true positive rates, and estimate the AUC. Specify that the second class is the positive class.

```
[fpr, tpr, ~, auc] = perfcurve(Ystats(idxTest), posterior(:, 2), Mdl.ClassNames(2));
auc
```

```
auc = 0.9985
```

The AUC is 1, which indicates a model that predicts well.

Plot an ROC curve.

```
figure;
plot(fpr, tpr)
h = gca;
h.XLim(1) = -0.1;
h.YLim(2) = 1.1;
```

```
xlabel('False positive rate')  
ylabel('True positive rate')  
title('ROC Curve')
```

The ROC curve and AUC indicate that the model classifies the test-sample observations almost perfectly.

Find Good Lasso Penalty Using AUC

To determine a good lasso-penalty strength for a linear classification model that uses a logistic regression learner, compare test-sample values of the AUC.

Load the NLP data set. Preprocess the data as in “Predict Test-Sample Labels” on page 32-5197.

```
load nlpdata
Ystats = Y == 'stats';
X = X';
```

Create a data partition that specifies to holdout 10% of the observations. Extract test-sample indices.

```
rng(10); % For reproducibility
Partition = cvpartition(Ystats, 'Holdout', 0.10);
testIdx = test(Partition);
XTest = X(:, testIdx);
n = sum(testIdx)

n = 3157

YTest = Ystats(testIdx);
```

There are 3157 observations in the test sample.

Create a set of 11 logarithmically-spaced regularization strengths from 10^{-6} through $10^{-0.5}$.

```
Lambda = logspace(-6, -0.5, 11);
```

Train binary, linear classification models that use each of the regularization strengths. Optimize the objective function using SpaRSA. Lower the tolerance on the gradient of the objective function to $1e-8$.

```
CVMdl = fitclinear(X, Ystats, 'ObservationsIn', 'columns', ...
    'CVPartition', Partition, 'Learner', 'logistic', 'Solver', 'sparsa', ...
    'Regularization', 'lasso', 'Lambda', Lambda, 'GradientTolerance', 1e-8)
```

```
CVMdl =
classreg.learning.partition.ClassificationPartitionedLinear
  CrossValidatedModel: 'Linear'
  ResponseName: 'Y'
  NumObservations: 31572
  KFold: 1
  Partition: [1x1 cvpartition]
  ClassNames: [0 1]
  ScoreTransform: 'none'
```

Properties, Methods

Extract the trained linear classification model.

```
Mdl1 = CVMdl.Trained{1}

Mdl1 =
  ClassificationLinear
    ResponseName: 'Y'
    ClassNames: [0 1]
    ScoreTransform: 'logit'
      Beta: [34023x11 double]
      Bias: [1x11 double]
      Lambda: [1x11 double]
    Learner: 'logistic'
```

Properties, Methods

`Mdl` is a `ClassificationLinear` model object. Because `Lambda` is a sequence of regularization strengths, you can think of `Mdl` as 11 models, one for each regularization strength in `Lambda`.

Estimate the test-sample predicted labels and posterior class probabilities.

```
[label,posterior] = predict(Mdl1,XTest,'ObservationsIn','columns');
Mdl1.ClassNames;
posterior(3,1,5)

ans = 1.0000
```

`label` is a 3157-by-11 matrix of predicted labels. Each column corresponds to the predicted labels of the model trained using the corresponding regularization strength. `posterior` is a 3157-by-2-by-11 matrix of posterior class probabilities. Columns correspond to classes and pages correspond to regularization strengths. For example, `posterior(3,1,5)` indicates that the posterior probability that the first class (label 0) is assigned to observation 3 by the model that uses `Lambda(5)` as a regularization strength is 1.0000.

For each model, compute the AUC. Designate the second class as the positive class.

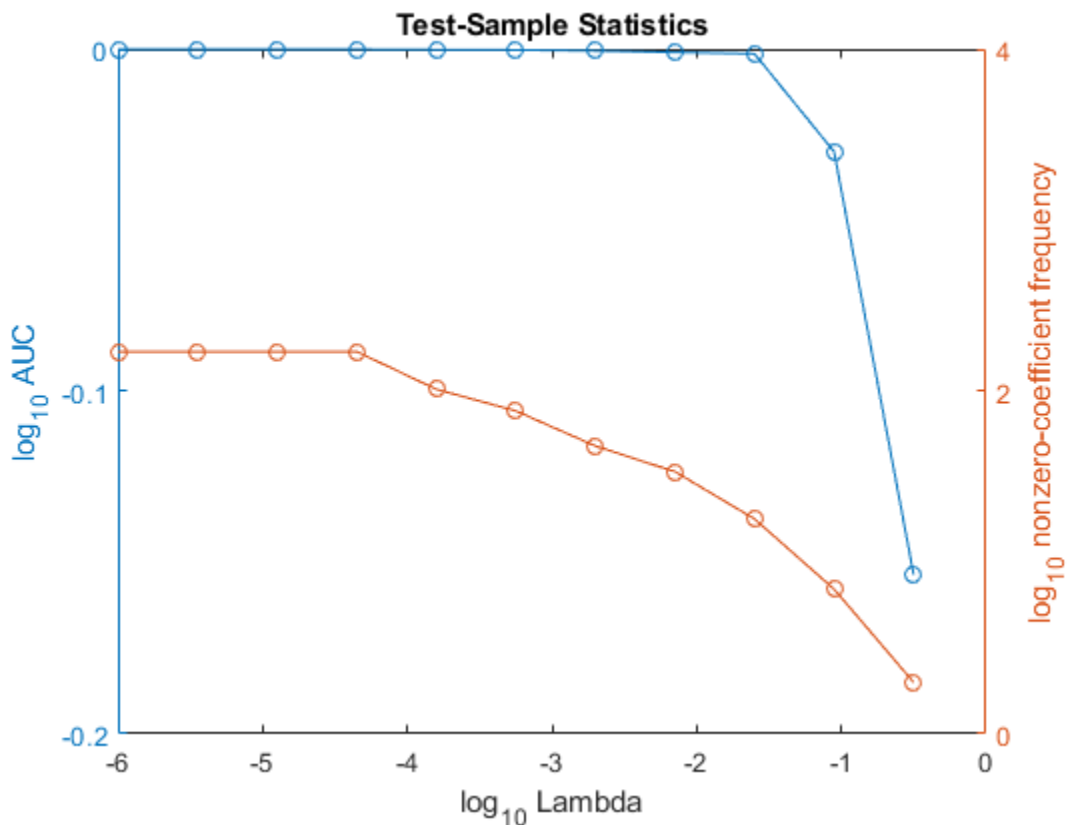

```
auc = 1:numel(Lambda); % Preallocation
for j = 1:numel(Lambda)
    [~,~,~,auc(j)] = perfcurve(YTest,posterior(:,2,j),Mdl1.ClassNames(2));
end
```

Higher values of Lambda lead to predictor variable sparsity, which is a good quality of a classifier. For each regularization strength, train a linear classification model using the entire data set and the same options as when you trained the model. Determine the number of nonzero coefficients per model.

```
Mdl = fitclinear(X,Ystats,'ObservationsIn','columns',...
    'Learner','logistic','Solver','sparsa','Regularization','lasso',...
    'Lambda',Lambda,'GradientTolerance',1e-8);
numNZCoeff = sum(Mdl.Beta~=0);
```

In the same figure, plot the test-sample error rates and frequency of nonzero coefficients for each regularization strength. Plot all variables on the log scale.

```
figure;
[h,hL1,hL2] = plotyy(log10(Lambda),log10(auc),...
    log10(Lambda),log10(numNZCoeff + 1));
hL1.Marker = 'o';
hL2.Marker = 'o';
ylabel(h(1),'log10 AUC')
ylabel(h(2),'log10 nonzero-coefficient frequency')
xlabel('log10 Lambda')
title('Test-Sample Statistics')
hold off
```

Choose the index of the regularization strength that balances predictor variable sparsity and high AUC. In this case, a value between 10^{-2} to 10^{-1} should suffice.

```
idxFinal = 9;
```

Select the model from `Mdl` with the chosen regularization strength.

```
MdlFinal = selectModels(Mdl,idxFinal);
```

`MdlFinal` is a `ClassificationLinear` model containing one regularization strength. To estimate labels for new observations, pass `MdlFinal` and the new data to `predict`.

Definitions

Classification Score

For linear classification models, the raw classification score for classifying the observation x , a row vector, into the positive class is defined by

$$f_j(x) = x\beta_j + b_j.$$

For the model with regularization strength j , β_j is the estimated column vector of coefficients (the model property `Beta (:, j)`) and b_j is the estimated, scalar bias (the model property `Bias (j)`).

The raw classification score for classifying x into the negative class is $-f(x)$. The software classifies observations into the class that yields the positive score.

If the linear classification model consists of logistic regression learners, then the software applies the 'logit' score transformation to the raw classification scores (see `ScoreTransform`).

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. For more information, see “Tall Arrays” (MATLAB).

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Use `saveCompactModel`, `loadCompactModel`, and `codegen` to generate code for the `predict` function. Save a trained model by using `saveCompactModel`. Define an entry-point function that loads the saved model by using `loadCompactModel` and

calls the `predict` function. Then use `codegen` to generate code for the entry-point function.

- This table contains notes about the arguments of `predict`. Arguments not included in this table are fully supported.

Argument	Notes and Limitations
Mdl	For the usage notes and limitations of the model object, see “Code Generation” on page 32-497 of the <code>ClassificationLinear</code> object.
X	<ul style="list-style-type: none"> • Must be a single-precision or double-precision matrix and can be variable-size. • If you specify <code>'ObservationsIn', 'rows'</code> (default), then the number of columns in X must be <code>numel(Mdl.PredictorNames)</code>. Rows and columns must correspond to observations and predictors, respectively. • If you specify <code>'ObservationsIn', 'columns'</code>, then the number of rows in X must be <code>numel(Mdl.PredictorNames)</code>. Rows and columns must correspond to predictors and observations, respectively.
Name-value pair arguments	<ul style="list-style-type: none"> • Names in name-value pair arguments must be compile-time constants. • The value for the <code>'ObservationsIn'</code> name-value pair argument must be a compile-time constant. For example, to use the <code>'ObservationsIn', 'columns'</code> name-value pair argument in the generated code, include <code>{coder.Constant('ObservationsIn'), coder.Constant('columns')}</code> in the <code>-args</code> value of <code>codegen</code>.

For more information, see “Introduction to Code Generation” on page 31-2.

predict

Predict labels using discriminant analysis classification model

Syntax

```
label = predict(Mdl,X)
[label,score,cost] = predict(Mdl,X)
```

Description

`label = predict(Mdl,X)` returns a vector of predicted class labels for the predictor data in the table or matrix `X`, based on the trained discriminant analysis classification model `Mdl`.

`[label,score,cost] = predict(Mdl,X)` also returns:

- A matrix of classification scores (`score`) indicating the likelihood that a label comes from a particular class. For discriminant analysis, scores are posterior probabilities on page 32-5213.
- A matrix of expected classification cost on page 32-5214 (`cost`). For each observation in `X`, the predicted class label corresponds to the minimum expected classification cost among all classes.

Input Arguments

Mdl — Discriminant analysis classification model

`ClassificationDiscriminant` model object |
`CompactClassificationDiscriminant` model object

Discriminant analysis classification model, specified as a `ClassificationDiscriminant` or `CompactClassificationDiscriminant` model object returned by `fitcdiscr`.

X — Predictor data to be classified

numeric matrix | table

Predictor data to be classified, specified as a numeric matrix or table.

Each row of X corresponds to one observation, and each column corresponds to one variable. All predictor variables in X must be numeric vectors.

- For a numeric matrix, the variables that compose the columns of X must have the same order as the predictor variables that trained Mdl .
- For a table:
 - `predict` does not support multi-column variables and cell arrays other than cell arrays of character vectors.
 - If you trained Mdl using a table (for example, `Tbl`), then all predictor variables in X must have the same variable names and data types as those that trained Mdl (stored in `Mdl.PredictorNames`). However, the column order of X does not need to correspond to the column order of `Tbl`. `Tbl` and X can contain additional variables (response variables, observation weights, etc.), but `predict` ignores them.
 - If you trained Mdl using a numeric matrix, then the predictor names in `Mdl.PredictorNames` and corresponding predictor variable names in X must be the same. To specify predictor names during training, see the `PredictorNames` name-value pair argument of `fitcdiscr`. X can contain additional variables (response variables, observation weights, etc.), but `predict` ignores them.

Data Types: `table` | `double` | `single`

Output Arguments

label — Predicted class labels

categorical array | character array | logical vector | vector of numeric values | cell array of character vectors

Predicted class labels on page 32-5214, returned as a categorical or character array, logical or numeric vector, or cell array of character vectors.

`label`:

- Is the same data type as the observed class labels (Y) that trained Mdl . (The software treats string arrays as cell arrays of character vectors.)
- Has length equal to the number of rows of X .

score — Predicted class posterior probabilities

numeric matrix

Predicted class posterior probabilities on page 32-5213, returned as a numeric matrix of size N-by-K. N is the number of observations (rows) in X, and K is the number of classes (in `Mdl.ClassNames`). `score(i,j)` is the posterior probability that observation i in X is of class j in `Mdl.ClassNames`.

cost — Expected classification costs

numeric matrix

Expected classification costs on page 32-5214, returned as a matrix of size N-by-K. N is the number of observations (rows) in X, and K is the number of classes (in `Mdl.ClassNames`). `cost(i,j)` is the cost of classifying row i of X as class j in `Mdl.ClassNames`.

Examples

Predict Class Labels Using Discriminant Analysis Model

Load Fisher's iris data set. Determine the sample size.

```
load fisheriris
N = size(meas,1);
```

Partition the data into training and test sets. Hold out 10% of the data for testing.

```
rng(1); % For reproducibility
cvp = cvpartition(N,'Holdout',0.1);
idxTrn = training(cvp); % Training set indices
idxTest = test(cvp); % Test set indices
```

Store the training data in a table.

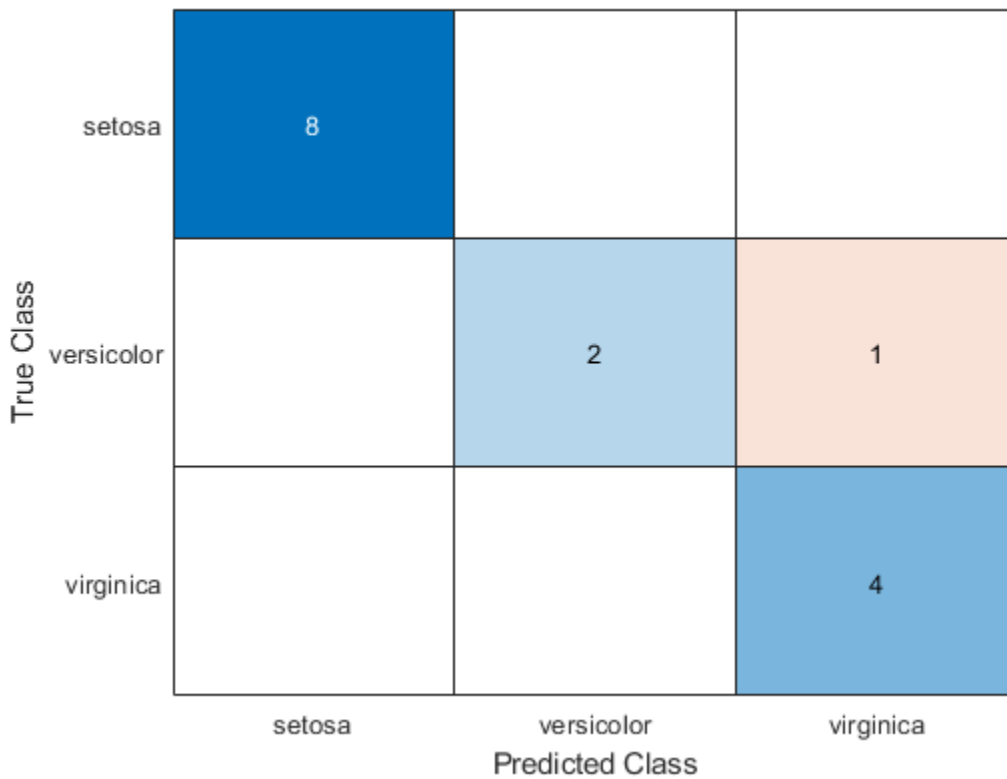

```
tblTrn = array2table(meas(idxTrn,:));
tblTrn.Y = species(idxTrn);
```

Train a discriminant analysis model using the training set and default options.

```
Mdl = fitcdiscr(tblTrn,'Y');
```

Predict labels for the test set. You trained `Mdl` using a table of data, but you can predict labels using a matrix.

```
labels = predict(Mdl,meas(idxTest,:));  
Construct a confusion matrix for the test set.  
confusionchart(species(idxTest),labels);
```

Mdl misclassifies one versicolor iris as virginica in the test set.

Plot Class Posterior Probability Regions

Load Fisher's iris data set. Consider training using the petal lengths and widths only.

```
load fisheriris
X = meas(:,3:4);
```

Train a quadratic discriminant analysis model using the entire data set.

```
Mdl = fitcdiscr(X,species,'DiscrimType','quadratic');
```

Define a grid of values in the observed predictor space. Predict the posterior probabilities for each instance in the grid.

```
xMax = max(X);
xMin = min(X);
d = 0.01;
[x1Grid,x2Grid] = meshgrid(xMin(1):d:xMax(1),xMin(2):d:xMax(2));
```

```
[~,score] = predict(Mdl,[x1Grid(:),x2Grid(:)]);
Mdl.ClassNames
```

```
ans = 3x1 cell array
    {'setosa'   }
    {'versicolor'}
    {'virginica' }
```

`score` is a matrix of class posterior probabilities. The columns correspond to the classes in `Mdl.ClassNames`. For example, `score(j,1)` is the posterior probability that observation `j` is a setosa iris.

Plot the posterior probability of versicolor classification for each observation in the grid and plot the training data.

```
figure;
contourf(x1Grid,x2Grid,reshape(score(:,2),size(x1Grid,1),size(x1Grid,2)));
h = colorbar;
caxis([0 1]);
colormap jet;
hold on
gscatter(X(:,1),X(:,2),species,'mcy','x+');
axis tight
title('Posterior Probability of versicolor');
hold off
```

The posterior probability region exposes a portion of the decision boundary.

Definitions

Posterior Probability

The posterior probability that a point z belongs to class j is the product of the prior probability and the multivariate normal density. The density function of the multivariate normal with mean μ_j and covariance Σ_j at a point z is

$$P(x|k) = \frac{1}{(2\pi|\Sigma_k|)^{1/2}} \exp\left(-\frac{1}{2}(x - \mu_k)^T \Sigma_k^{-1}(x - \mu_k)\right),$$

where $|\Sigma_k|$ is the determinant of Σ_k , and Σ_k^{-1} is the inverse matrix.

Let $P(k)$ represent the prior probability of class k . Then the posterior probability that an observation x is of class k is

$$\hat{P}(k|x) = \frac{P(x|k)P(k)}{P(x)},$$

where $P(x)$ is a normalization constant, the sum over k of $P(x|k)P(k)$.

Prior Probability

The prior probability is one of three choices:

- 'uniform' — The prior probability of class k is one over the total number of classes.
- 'empirical' — The prior probability of class k is the number of training samples of class k divided by the total number of training samples.
- Custom — The prior probability of class k is the k th element of the prior vector. See `fitcdiscr`.

After creating a classification model (Mdl) you can set the prior using dot notation:

```
Mdl.Prior = v;
```

where v is a vector of positive elements representing the frequency with which each element occurs. You do not need to retrain the classifier when you set a new prior.

Cost

The matrix of expected costs per observation is defined in “Cost” on page 20-7.

Predicted Class Label

`predict` classifies so as to minimize the expected classification cost:

$$\hat{y} = \operatorname{argmin}_{y=1, \dots, K} \sum_{k=1}^K \hat{P}(k|x)C(y|k),$$

where

- \hat{y} is the predicted classification.
- K is the number of classes.
- $\hat{P}(k|x)$ is the posterior probability on page 20-6 of class k for observation x .
- $C(y|k)$ is the cost on page 20-7 of classifying an observation as y when its true class is k .

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. For more information, see “Tall Arrays” (MATLAB).

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Use `saveCompactModel`, `loadCompactModel`, and `codegen` to generate code for the `predict` function. Save a trained model by using `saveCompactModel`. Define an entry-point function that loads the saved model by using `loadCompactModel` and calls the `predict` function. Then use `codegen` to generate code for the entry-point function.
- This table contains notes about the arguments of `predict`. Arguments not included in this table are fully supported.

Argument	Notes and Limitations
Mdl	For the usage notes and limitations of the model object, see “Code Generation” on page 32-821 of the <code>CompactClassificationDiscriminant</code> object.

Argument	Notes and Limitations
X	<ul style="list-style-type: none">• Must be a single-precision or double-precision matrix and can be variable-size. However, the number of columns in X must be <code>numel(Mdl.PredictorNames)</code>.• Rows and columns must correspond to observations and predictors, respectively.

Topics

“Discriminant Analysis Classification” on page 20-2

Introduced in R2011b

predict

Package:

Classify observations using multiclass error-correcting output codes (ECOC) model

Syntax

```
label = predict(Mdl,X)
label = predict(Mdl,X,Name,Value)
[label,NegLoss,PBScore] = predict( ___ )
[label,NegLoss,PBScore,Posterior] = predict( ___ )
```

Description

`label = predict(Mdl,X)` returns a vector of predicted class labels (`label`) for the predictor data in the table or matrix `X`, based on the trained multiclass error-correcting output codes (ECOC) model `Mdl`. The trained ECOC model can be either full or compact.

`label = predict(Mdl,X,Name,Value)` uses additional options specified by one or more name-value pair arguments. For example, you can specify the posterior probability estimation method, decoding scheme, and verbosity level.

`[label,NegLoss,PBScore] = predict(___)` uses any of the input argument combinations in the previous syntaxes and additionally returns:

- An array of negated average binary losses on page 32-5234 (**NegLoss**). For each observation in `X`, `predict` assigns the label of the class yielding the largest negated average binary loss (or, equivalently, the smallest average binary loss).
- An array of positive-class scores (**PBScore**) for the observations classified by each binary learner.

`[label,NegLoss,PBScore,Posterior] = predict(___)` additionally returns posterior class probability estimates for the observations (**Posterior**).

To obtain posterior class probabilities, you must set `'FitPosterior', true` when training the ECOC model using `fitcecoc`. Otherwise, `predict` throws an error.

Examples

Predict Test-Sample Labels of Training Data Using ECOC Model

Load Fisher's iris data set. Specify the predictor data X, the response data Y, and the order of the classes in Y.

```
load fisheriris
X = meas;
Y = categorical(species);
classOrder = unique(Y);
rng(1); % For reproducibility
```

Train an ECOC model using SVM binary classifiers. Specify a 30% holdout sample, standardize the predictors using an SVM template, and specify the class order.

```
t = templateSVM('Standardize',true);
PMdl = fitcecoc(X,Y,'Holdout',0.30,'Learners',t,'ClassNames',classOrder);
Mdl = PMdl.Trained{1}; % Extract trained, compact classifier
```

PMdl is a ClassificationPartitionedECOC model. It has the property Trained, a 1-by-1 cell array containing the CompactClassificationECOC model that the software trained using the training set.

Predict the test-sample labels. Print a random subset of true and predicted labels.

```
testInds = test(PMdl.Partition); % Extract the test indices
XTest = X(testInds,:);
YTest = Y(testInds,:);
labels = predict(Mdl,XTest);
```

```
idx = randsample(sum(testInds),10);
table(YTest(idx),labels(idx),...
      'VariableNames',{'TrueLabels','PredictedLabels'})
```

```
ans=10x2 table
  TrueLabels   PredictedLabels
  _____   _____
  setosa       setosa
  versicolor   virginica
  setosa       setosa
  virginica    virginica
```

```

versicolor    versicolor
setosa        setosa
virginica     virginica
virginica     virginica
setosa        setosa
setosa        setosa

```

Mdl correctly labels all except one of the test-sample observations with indices idx.

Predict Test-Sample Labels of ECOC Model Using Custom Binary Loss Function

Load Fisher's iris data set. Specify the predictor data X, the response data Y, and the order of the classes in Y.

```

load fisheriris
X = meas;
Y = categorical(species);
classOrder = unique(Y); % Class order
rng(1); % For reproducibility

```

Train an ECOC model using SVM binary classifiers and specify a 30% holdout sample. Standardize the predictors using an SVM template, and specify the class order.

```

t = templateSVM('Standardize',true);
PMdl = fitcecoc(X,Y,'Holdout',0.30,'Learners',t,'ClassNames',classOrder);
Mdl = PMdl.Trained{1}; % Extract trained, compact classifier

```

PMdl is a ClassificationPartitionedECOC model. It has the property Trained, a 1-by-1 cell array containing the CompactClassificationECOC model that the software trained using the training set.

SVM scores are signed distances from the observation to the decision boundary. Therefore, $(-\infty, \infty)$ is the domain. Create a custom binary loss function that does the following:

- Map the coding design matrix (M) and positive-class classification scores (s) for each learner to the binary loss for each observation.
- Use linear loss.
- Aggregate the binary learner loss using the median.

You can create a separate function for the binary loss function, and then save it on the MATLAB® path. Or, you can specify an anonymous binary loss function. In this case, create a function handle (`customBL`) to an anonymous binary loss function.

```
customBL = @(M,s)nanmedian(1 - bsxfun(@times,M,s),2)/2;
```

Predict test-sample labels and estimate the median binary loss per class. Print the median negative binary losses per class for a random set of 10 test-sample observations.

```
testInds = test(PMdl.Partition); % Extract the test indices
XTest = X(testInds,:);
YTest = Y(testInds,:);
[label,NegLoss] = predict(Mdl,XTest,'BinaryLoss',customBL);
```

```
idx = randsample(sum(testInds),10);
classOrder
```

```
classOrder = 3x1 categorical array
    setosa
    versicolor
    virginica
```

```
table(YTest(idx),label(idx),NegLoss(idx,:), 'VariableNames',...
      {'TrueLabel', 'PredictedLabel', 'NegLoss'})
```

```
ans=10x3 table
    TrueLabel    PredictedLabel    NegLoss
    _____    _____    _____
```

TrueLabel	PredictedLabel	NegLoss		
setosa	versicolor	0.1857	1.9878	-3.6735
versicolor	virginica	-1.3316	-0.12333	-0.045053
setosa	versicolor	0.13898	1.9261	-3.5651
virginica	virginica	-1.5133	-0.38263	0.39592
versicolor	versicolor	-0.87209	0.74777	-1.3757
setosa	versicolor	0.48381	1.9972	-3.981
virginica	virginica	-1.9364	-0.67508	1.1114
virginica	virginica	-1.579	-0.83339	0.91235
setosa	versicolor	0.51001	2.1208	-4.1308
setosa	versicolor	0.36119	2.0594	-3.9206

The order of the columns corresponds to the elements of `classOrder`. The software predicts the label based on the maximum negated loss. The results indicate that the median of the linear losses might not perform as well as other losses.

Estimate Posterior Probabilities Using ECOC Classifier

Train an ECOC classifier using SVM binary learners. First predict the training-sample labels and class posterior probabilities. Then predict the maximum class posterior probability at each point in a grid. Visualize the results.

Load Fisher's iris data set. Specify the petal dimensions as the predictors and the species names as the response.

```
load fisheriris
X = meas(:,3:4);
Y = species;
rng(1); % For reproducibility
```

Create an SVM template. Standardize the predictors, and specify the Gaussian kernel.

```
t = templateSVM('Standardize',true,'KernelFunction','gaussian');
```

t is an SVM template. Most of its properties are empty. When the software trains the ECOC classifier, it sets the applicable properties to their default values.

Train the ECOC classifier using the SVM template. Transform classification scores to class posterior probabilities (which are returned by `predict` or `resubPredict`) using the 'FitPosterior' name-value pair argument. Specify the class order using the 'ClassNames' name-value pair argument. Display diagnostic messages during training by using the 'Verbose' name-value pair argument.

```
Mdl = fitcecoc(X,Y,'Learners',t,'FitPosterior',true,...
    'ClassNames',{'setosa','versicolor','virginica'},...
    'Verbose',2);
```

```
Training binary learner 1 (SVM) out of 3 with 50 negative and 50 positive observations
Negative class indices: 2
Positive class indices: 1
```

```
Fitting posterior probabilities for learner 1 (SVM).
```

```
Training binary learner 2 (SVM) out of 3 with 50 negative and 50 positive observations
Negative class indices: 3
Positive class indices: 1
```

```
Fitting posterior probabilities for learner 2 (SVM).
```

```
Training binary learner 3 (SVM) out of 3 with 50 negative and 50 positive observations
Negative class indices: 3
Positive class indices: 2
```

```
Fitting posterior probabilities for learner 3 (SVM).
```

Mdl is a `ClassificationECOC` model. The same SVM template applies to each binary learner, but you can adjust options for each binary learner by passing in a cell vector of templates.

Predict the training-sample labels and class posterior probabilities. Display diagnostic messages during the computation of labels and class posterior probabilities by using the `'Verbose'` name-value pair argument.

```
[label,~,~,Posterior] = resubPredict(Mdl, 'Verbose',1);
```

```
Predictions from all learners have been computed.
Loss for all observations has been computed.
Computing posterior probabilities...
```

```
Mdl.BinaryLoss
```

```
ans =
'quadratic'
```

The software assigns an observation to the class that yields the smallest average binary loss. Because all binary learners are computing posterior probabilities, the binary loss function is `quadratic`.

Display a random set of results.

```
idx = randsample(size(X,1),10,1);
Mdl.ClassNames
```

```
ans = 3x1 cell array
    {'setosa'    }
    {'versicolor'}
    {'virginica' }
```

```
table(Y(idx),label(idx),Posterior(idx,:),...
    'VariableNames',{'TrueLabel','PredLabel','Posterior'})
```

```
ans=10x3 table
    TrueLabel    PredLabel    Posterior
```

'virginica'	'virginica'	0.0039321	0.0039869	0.99208
'virginica'	'virginica'	0.017067	0.018263	0.96467
'virginica'	'virginica'	0.014948	0.015856	0.9692
'versicolor'	'versicolor'	2.2197e-14	0.87317	0.12683
'setosa'	'setosa'	0.999	0.00025091	0.00074639
'versicolor'	'virginica'	2.2195e-14	0.059429	0.94057
'versicolor'	'versicolor'	2.2194e-14	0.97001	0.029986
'setosa'	'setosa'	0.999	0.0002499	0.00074741
'versicolor'	'versicolor'	0.0085646	0.98259	0.008849
'setosa'	'setosa'	0.999	0.00025013	0.00074718

The columns of `Posterior` correspond to the class order of `Mdl.ClassNames`.

Define a grid of values in the observed predictor space. Predict the posterior probabilities for each instance in the grid.

```
xMax = max(X);
xMin = min(X);

x1Pts = linspace(xMin(1),xMax(1));
x2Pts = linspace(xMin(2),xMax(2));
[x1Grid,x2Grid] = meshgrid(x1Pts,x2Pts);

[~,~,~,PosteriorRegion] = predict(Mdl,[x1Grid(:),x2Grid(:)]);
```

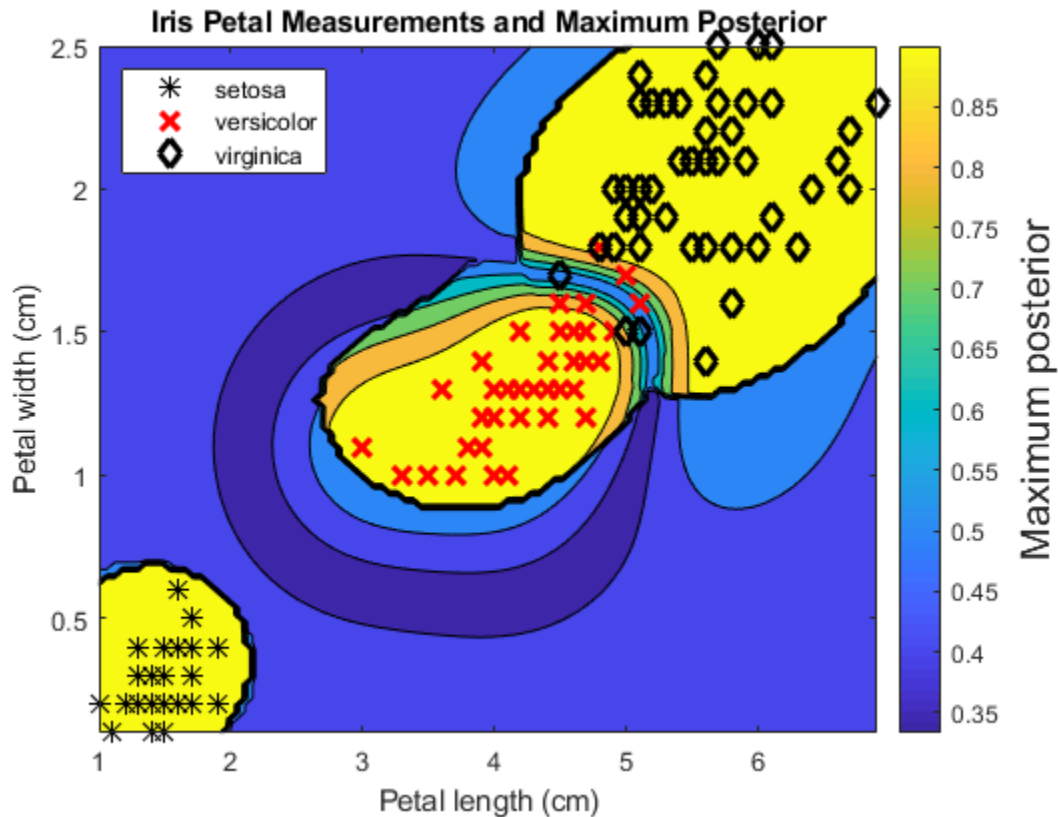

For each coordinate on the grid, plot the maximum class posterior probability among all classes.

```
contourf(x1Grid,x2Grid,...
         reshape(max(PosteriorRegion,[],2),size(x1Grid,1),size(x1Grid,2)));
h = colorbar;
h.YLabel.String = 'Maximum posterior';
h.YLabel.FontSize = 15;

hold on
gh = gscatter(X(:,1),X(:,2),Y,'krk','*xd',8);
gh(2).LineWidth = 2;
gh(3).LineWidth = 2;

title('Iris Petal Measurements and Maximum Posterior')
xlabel('Petal length (cm)')
ylabel('Petal width (cm)')
```

```
axis tight
legend(gh, 'Location', 'NorthWest')
hold off
```

Estimate Test-Sample Posterior Probabilities Using Parallel Computing

Train a multiclass ECOC model and estimate posterior probabilities using parallel computing.

Load the arrhythmia data set. Examine the response data Y , and determine the number of classes.

```
load arrhythmia
Y = categorical(Y);
tabulate(Y)
```

Value	Count	Percent
1	245	54.20%
2	44	9.73%
3	15	3.32%
4	15	3.32%
5	13	2.88%
6	25	5.53%
7	3	0.66%
8	2	0.44%
9	9	1.99%
10	50	11.06%
14	4	0.88%
15	5	1.11%
16	22	4.87%

```
K = numel(unique(Y));
```

Several classes are not represented in the data, and many of the other classes have low relative frequencies.

Specify an ensemble learning template that uses the GentleBoost method and 50 weak classification tree learners.

```
t = templateEnsemble('GentleBoost',50,'Tree');
```

`t` is a template object. Most of its properties are empty (`[]`). The software uses default values for all empty properties during training.

Because the response variable contains many classes, specify a sparse random coding design.

```
rng(1); % For reproducibility
Coding = designecoc(K,'sparserandom');
```

Train an ECOC model using parallel computing. Specify a 15% holdout sample, and fit posterior probabilities.

```
pool = parpool; % Invokes workers
```

```
Starting parallel pool (parpool) using the 'local' profile ...
Connected to the parallel pool (number of workers: 6).
```

```
options = statset('UseParallel',true);
PMdl = fitcecoc(X,Y,'Learner',t,'Options',options,'Coding',Coding,...
'FitPosterior',true,'Holdout',0.15);
Mdl = PMdl.Trained{1}; % Extract trained, compact classifier
```

PMdl is a ClassificationPartitionedECOC model. It has the property Trained, a 1-by-1 cell array containing the CompactClassificationECOC model that the software trained using the training set.

The pool invokes six workers, although the number of workers might vary among systems.

Estimate posterior probabilities, and display the posterior probability of being classified as not having arrhythmia (class 1) given the data for a random set of test-sample observations.

```
testInds = test(PMdl.Partition); % Extract the test indices
XTest = X(testInds,:);
YTest = Y(testInds,:);
[~,~,posterior] = predict(Mdl,XTest,'Options',options);

idx = randsample(sum(testInds),10);
table(idx,YTest(idx),posterior(idx,1),...
'VariableNames',{'TestSampleIndex','TrueLabel','PosteriorNoArrhythmia'})
```

```
ans=10x3 table
   TestSampleIndex   TrueLabel   PosteriorNoArrhythmia
   _____   _____   _____
         11             6             0.60631
         41             4             0.23674
         51             2             0.13802
         33            10             0.43831
         12             1             0.94332
          8             1             0.97278
         37             1             0.62807
         24            10             0.96876
         56            16             0.29375
         30             1             0.64512
```

Input Arguments

Mdl — Full or compact multiclass ECOC model

ClassificationECOC model object | CompactClassificationECOC model object

Full or compact multiclass ECOC model, specified as a `ClassificationECOC` or `CompactClassificationECOC` model object.

To create a full or compact ECOC model, see `ClassificationECOC` or `CompactClassificationECOC`.

X — Predictor data to be classified

numeric matrix | table

Predictor data to be classified, specified as a numeric matrix or table.

Each row of `X` corresponds to one observation, and each column corresponds to one variable.

- For a numeric matrix:
 - The variables that constitute the columns of `X` must have the same order as the predictor variables that train `Mdl`.
 - If you train `Mdl` using a table (for example, `Tbl`), then `X` can be a numeric matrix if `Tbl` contains all numeric predictor variables. To treat numeric predictors in `Tbl` as categorical during training, identify categorical predictors using the `CategoricalPredictors` name-value pair argument of `fitcecoc`. If `Tbl` contains heterogeneous predictor variables (for example, numeric and categorical data types) and `X` is a numeric matrix, then `predict` throws an error.
- For a table:
 - `predict` does not support multicolumn variables and cell arrays other than cell arrays of character vectors.
 - If you train `Mdl` using a table (for example, `Tbl`), then all predictor variables in `X` must have the same variable names and data types as the predictor variables that train `Mdl` (stored in `Mdl.PredictorNames`). However, the column order of `X` does not need to correspond to the column order of `Tbl`. Both `Tbl` and `X` can contain additional variables (response variables, observation weights, and so on), but `predict` ignores them.
 - If you train `Mdl` using a numeric matrix, then the predictor names in `Mdl.PredictorNames` and the corresponding predictor variable names in `X` must

be the same. To specify predictor names during training, see the `PredictorNames` name-value pair argument of `fitcecoc`. All predictor variables in `X` must be numeric vectors. `X` can contain additional variables (response variables, observation weights, and so on), but `predict` ignores them.

Note If `Mdl.BinaryLearners` contains linear or kernel classification models (`ClassificationLinear` or `ClassificationKernel` model objects), then you cannot specify sample data in a table. Instead, pass a matrix of predictor data.

When training `Mdl`, assume that you set `'Standardize', true` for a template object specified in the `'Learners'` name-value pair argument of `fitcecoc`. In this case, for the corresponding binary learner `j`, the software standardizes the columns of the new predictor data using the corresponding means in `Mdl.BinaryLearner{j}.Mu` and standard deviations in `Mdl.BinaryLearner{j}.Sigma`.

Data Types: `table` | `double` | `single`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example:

```
predict(Mdl,X,'BinaryLoss','quadratic','Decoding','lossbased')
```

specifies a quadratic binary learner loss function and a loss-based decoding scheme for aggregating the binary losses.

BinaryLoss — Binary learner loss function

'hamming' | 'linear' | 'logit' | 'exponential' | 'binodeviance' | 'hinge' | 'quadratic' | function handle

Binary learner loss function, specified as the comma-separated pair consisting of `'BinaryLoss'` and a built-in loss function name or function handle.

- This table describes the built-in functions, where y_j is a class label for a particular binary learner (in the set $\{-1, 1, 0\}$), s_j is the score for observation j , and $g(y_j, s_j)$ is the binary loss formula.

Value	Description	Score Domain	$g(y_j, s_j)$
'binodeviance'	Binomial deviance	$(-\infty, \infty)$	$\log[1 + \exp(-2y_j s_j)] / [2\log(2)]$
'exponential'	Exponential	$(-\infty, \infty)$	$\exp(-y_j s_j) / 2$
'hamming'	Hamming	$[0, 1]$ or $(-\infty, \infty)$	$[1 - \text{sign}(y_j s_j)] / 2$
'hinge'	Hinge	$(-\infty, \infty)$	$\max(0, 1 - y_j s_j) / 2$
'linear'	Linear	$(-\infty, \infty)$	$(1 - y_j s_j) / 2$
'logit'	Logistic	$(-\infty, \infty)$	$\log[1 + \exp(-y_j s_j)] / [2\log(2)]$
'quadratic'	Quadratic	$[0, 1]$	$[1 - y_j(2s_j - 1)]^2 / 2$

The software normalizes binary losses so that the loss is 0.5 when $y_j = 0$. Also, the software calculates the mean binary loss for each class.

- For a custom binary loss function, for example `customFunction`, specify its function handle `'BinaryLoss', @customFunction`.

`customFunction` has this form:

```
bLoss = customFunction(M,s)
```

where:

- M is the K -by- L coding matrix stored in `Mdl.CodingMatrix`.
- s is the 1-by- L row vector of classification scores.
- `bLoss` is the classification loss. This scalar aggregates the binary losses for every learner in a particular class. For example, you can use the mean binary loss to aggregate the loss over the learners for each class.
- K is the number of classes.
- L is the number of binary learners.

For an example of passing a custom binary loss function, see “Predict Test-Sample Labels of ECOC Model Using Custom Binary Loss Function” on page 32-5219.

The default `BinaryLoss` value depends on the score ranges returned by the binary learners. This table describes some default `BinaryLoss` values based on the given assumptions.

Assumption	Default Value
All binary learners are SVMs or either linear or kernel classification models of SVM learners.	'hinge'
All binary learners are ensembles trained by <code>AdaboostM1</code> or <code>GentleBoost</code> .	'exponential'
All binary learners are ensembles trained by <code>LogitBoost</code> .	'binodeviance'
All binary learners are linear or kernel classification models of logistic regression learners. Or, you specify to predict class posterior probabilities by setting <code>'FitPosterior', true</code> in <code>fitcecoc</code> .	'quadratic'

To check the default value, use dot notation to display the `BinaryLoss` property of the trained model at the command line.

Example: `'BinaryLoss', 'binodeviance'`

Data Types: `char` | `string` | `function_handle`

Decoding — Decoding scheme

'lossweighted' (default) | 'lossbased'

Decoding scheme that aggregates the binary losses, specified as the comma-separated pair consisting of 'Decoding' and 'lossweighted' or 'lossbased'. For more information, see “Binary Loss” on page 32-5234.

Example: `'Decoding', 'lossbased'`

NumKLInitializations — Number of random initial values

0 (default) | nonnegative integer scalar

Number of random initial values for fitting posterior probabilities by Kullback-Leibler divergence minimization, specified as the comma-separated pair consisting of 'NumKLInitializations' and a nonnegative integer scalar.

If you do not request the fourth output argument (Posterior) and set `'PosteriorMethod', 'kl'` (the default), then the software ignores the value of `NumKLInitializations`.

For more details, see “Posterior Estimation Using Kullback-Leibler Divergence” on page 32-5236.

Example: `'NumKLInitializations', 5`

Data Types: `single` | `double`

ObservationsIn — Predictor data observation dimension

`'rows'` (default) | `'columns'`

Predictor data observation dimension, specified as the comma-separated pair consisting of `'ObservationsIn'` and `'columns'` or `'rows'`. `Mdl.BinaryLearners` must contain `ClassificationLinear` models.

Note If you orient your predictor matrix so that observations correspond to columns and specify `'ObservationsIn'`, `'columns'`, you can experience a significant reduction in execution time.

Options — Estimation options

`[]` (default) | structure array returned by `statset`

Estimation options, specified as the comma-separated pair consisting of `'Options'` and a structure array returned by `statset`.

To invoke parallel computing:

- You need a Parallel Computing Toolbox license.
- Specify `'Options'`, `statset('UseParallel',true)`.

PosteriorMethod — Posterior probability estimation method

`'kl'` (default) | `'qp'`

Posterior probability estimation method, specified as the comma-separated pair consisting of `'PosteriorMethod'` and `'kl'` or `'qp'`.

- If `PosteriorMethod` is `'kl'`, then the software estimates multiclass posterior probabilities by minimizing the Kullback-Leibler divergence between the predicted and expected posterior probabilities returned by binary learners. For details, see “Posterior Estimation Using Kullback-Leibler Divergence” on page 32-5236.
- If `PosteriorMethod` is `'qp'`, then the software estimates multiclass posterior probabilities by solving a least-squares problem using quadratic programming. You need an Optimization Toolbox license to use this option. For details, see “Posterior Estimation Using Quadratic Programming” on page 32-5237.
- If you do not request the fourth output argument (`Posterior`), then the software ignores the value of `PosteriorMethod`.

Example: 'PosteriorMethod', 'qp'

Verbose — Verbosity level

0 (default) | 1

Verbosity level, specified as the comma-separated pair consisting of 'Verbose' and 0 or 1. Verbose controls the number of diagnostic messages that the software displays in the Command Window.

If `Verbose` is 0, then the software does not display diagnostic messages. Otherwise, the software displays diagnostic messages.

Example: 'Verbose', 1

Data Types: single | double

Output Arguments

label — Predicted class labels

categorical array | character array | logical array | numeric array | cell array of character vectors

Predicted class labels, returned as a categorical, character, logical, or numeric array, or a cell array of character vectors. The software predicts the classification of an observation by assigning the observation to the class yielding the largest negated average binary loss (or, equivalently, the smallest average binary loss).

`label` has the same data type as the class labels used to train `Mdl` and has the same number of rows as `X`. (The software treats string arrays as cell arrays of character vectors.)

If `Mdl.BinaryLearners` contains `ClassificationLinear` models, then `label` is an m -by- L matrix, where m is the number of observations in `X`, and L is the number of regularization strengths in the linear classification models (`numel(Mdl.BinaryLearners{1}.Lambda)`). The value `label(i, j)` is the predicted label of observation `i` for the model trained using regularization strength `Mdl.BinaryLearners{1}.Lambda(j)`.

Otherwise, `label` is a column vector of length m .

NegLoss — Negated average binary losses

numeric matrix | numeric array

Negated average binary losses on page 32-5234, returned as a numeric matrix or array.

- If `Mdl.BinaryLearners` contains `ClassificationLinear` models, then `NegLoss` is an m -by- K -by- L array.
 - m is the number of observations in X .
 - K is the number of distinct classes in the training data (`numel(Mdl.ClassNames)`).
 - L is the number of regularization strengths in the linear classification models (`numel(Mdl.BinaryLearners{1}.Lambda)`).

`NegLoss(i, k, j)` is the negated average binary loss for observation i , corresponding to class `Mdl.ClassNames(k)`, for the model trained using regularization strength `Mdl.BinaryLearners{1}.Lambda(j)`.

- Otherwise, `NegLoss` is an m -by- K matrix.

PBScore — Positive-class scores

numeric matrix | numeric array

Positive-class scores for each binary learner, returned as a numeric matrix or array.

- If `Mdl.BinaryLearners` contains `ClassificationLinear` models, then `PBScore` is an m -by- B -by- L array.
 - m is the number of observations in X .
 - B is the number of binary learners (`numel(Mdl.BinaryLearners)`).
 - L is the number of regularization strengths in the linear classification models (`numel(Mdl.BinaryLearners{1}.Lambda)`).

`PBScore(i, b, j)` is the positive-class score for observation i , using binary learner b , for the model trained using regularization strength `Mdl.BinaryLearners{1}.Lambda(j)`.

- Otherwise, `PBScore` is an m -by- B matrix.

Posterior — Posterior class probabilities

numeric matrix | numeric array

Posterior class probabilities, returned as a numeric matrix or array.

- If `Mdl.BinaryLearners` contains `ClassificationLinear` models, then `Posterior` is an m -by- K -by- L array. For dimension definitions, see `NegLoss`.

`Posterior(i, k, j)` is the posterior probability that observation `i` comes from class `Mdl.ClassNames(k)`, for the model trained using regularization strength `Mdl.BinaryLearners{1}.Lambda(j)`.

- Otherwise, `Posterior` is an m -by- K matrix.

Definitions

Binary Loss

A binary loss is a function of the class and classification score that determines how well a binary learner classifies an observation into the class.

Suppose the following:

- m_{kj} is element (k, j) of the coding design matrix M (that is, the code corresponding to class k of binary learner j).
- s_j is the score of binary learner j for an observation.
- g is the binary loss function.
- \hat{k} is the predicted class for the observation.

In loss-based decoding [Escalera et al.] on page 18-228, the class producing the minimum sum of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \operatorname{argmin}_k \sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j).$$

In loss-weighted decoding [Escalera et al.] on page 18-228, the class producing the minimum average of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \operatorname{argmin}_k \frac{\sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j)}{\sum_{j=1}^L |m_{kj}|}.$$

Allwein et al. on page 18-227 suggest that loss-weighted decoding improves classification accuracy by keeping loss values for all classes in the same dynamic range.

This table summarizes the supported loss functions, where y_j is a class label for a particular binary learner (in the set $\{-1,1,0\}$), s_j is the score for observation j , and $g(y_j, s_j)$.

Value	Description	Score Domain	$g(y_j, s_j)$
'binodeviance'	Binomial deviance	$(-\infty, \infty)$	$\log[1 + \exp(-2y_j s_j)] / [2\log(2)]$
'exponential'	Exponential	$(-\infty, \infty)$	$\exp(-y_j s_j) / 2$
'hamming'	Hamming	$[0,1]$ or $(-\infty, \infty)$	$[1 - \text{sign}(y_j s_j)] / 2$
'hinge'	Hinge	$(-\infty, \infty)$	$\max(0, 1 - y_j s_j) / 2$
'linear'	Linear	$(-\infty, \infty)$	$(1 - y_j s_j) / 2$
'logit'	Logistic	$(-\infty, \infty)$	$\log[1 + \exp(-y_j s_j)] / [2\log(2)]$
'quadratic'	Quadratic	$[0,1]$	$[1 - y_j(2s_j - 1)]^2 / 2$

The software normalizes binary losses such that the loss is 0.5 when $y_j = 0$, and aggregates using the average of the binary learners [Allwein et al.] on page 18-227.

Do not confuse the binary loss with the overall classification loss (specified by the 'LossFun' name-value pair argument of the `loss` and `predict` object functions), which measures how well an ECOC classifier performs as a whole.

Algorithms

The software can estimate class posterior probabilities by minimizing the Kullback-Leibler divergence or by using quadratic programming. For the following descriptions of the posterior estimation algorithms, assume that:

- m_{kj} is the element (k,j) of the coding design matrix M .
- I is the indicator function.
- \hat{p}_k is the class posterior probability estimate for class k of an observation, $k = 1, \dots, K$.
- r_j is the positive-class posterior probability for binary learner j . That is, r_j is the probability that binary learner j classifies an observation into the positive class, given the training data.

Posterior Estimation Using Kullback-Leibler Divergence

By default, the software minimizes the Kullback-Leibler divergence to estimate class posterior probabilities. The Kullback-Leibler divergence between the expected and observed positive-class posterior probabilities is

$$\Delta(r, \hat{r}) = \sum_{j=1}^L w_j \left[r_j \log \frac{r_j}{\hat{r}_j} + (1 - r_j) \log \frac{1 - r_j}{1 - \hat{r}_j} \right],$$

where $w_j = \sum_{S_j} w_i^*$ is the weight for binary learner j .

- S_j is the set of observation indices on which binary learner j is trained.
- w_i^* is the weight of observation i .

The software minimizes the divergence iteratively. The first step is to choose initial values $\hat{p}_k^{(0)}$; $k = 1, \dots, K$ for the class posterior probabilities.

- If you do not specify 'NumKLIterations', then the software tries both sets of deterministic initial values described next, and selects the set that minimizes Δ .
 - $\hat{p}_k^{(0)} = 1/K$; $k = 1, \dots, K$.
 - $\hat{p}_k^{(0)}$; $k = 1, \dots, K$ is the solution of the system

$$M_{01} \hat{p}^{(0)} = r,$$

where M_{01} is M with all $m_{kj} = -1$ replaced with 0, and r is a vector of positive-class posterior probabilities returned by the L binary learners [Dietterich et al.] on page 18-228. The software uses `lsqnonneg` to solve the system.

- If you specify 'NumKLIterations', c , where c is a natural number, then the software does the following to choose the set $\hat{p}_k^{(0)}$; $k = 1, \dots, K$, and selects the set that minimizes Δ .
 - The software tries both sets of deterministic initial values as described previously.
 - The software randomly generates c vectors of length K using `rand`, and then normalizes each vector to sum to 1.

At iteration t , the software completes these steps:

- 1 Compute

$$\hat{r}_j^{(t)} = \frac{\sum_{k=1}^K \hat{p}_k^{(t)} I(m_{kj} = +1)}{\sum_{k=1}^K \hat{p}_k^{(t)} I(m_{kj} = +1 \cup m_{kj} = -1)}.$$

- 2 Estimate the next class posterior probability using

$$\hat{p}_k^{(t+1)} = \hat{p}_k^{(t)} \frac{\sum_{j=1}^L w_j [r_j I(m_{kj} = +1) + (1 - r_j) I(m_{kj} = -1)]}{\sum_{j=1}^L w_j [\hat{r}_j^{(t)} I(m_{kj} = +1) + (1 - \hat{r}_j^{(t)}) I(m_{kj} = -1)]}.$$

- 3 Normalize $\hat{p}_k^{(t+1)}$; $k = 1, \dots, K$ so that they sum to 1.
- 4 Check for convergence.

For more details, see [Hastie et al.] on page 18-228 and [Zadrozny] on page 18-230.

Posterior Estimation Using Quadratic Programming

Posterior probability estimation using quadratic programming requires an Optimization Toolbox license. To estimate posterior probabilities for an observation using this method, the software completes these steps:

- 1 Estimate the positive-class posterior probabilities, r_j , for binary learners $j = 1, \dots, L$.
- 2 Using the relationship between r_j and \hat{p}_k [Wu et al.] on page 18-230, minimize

$$\sum_{j=1}^L \left[-r_j \sum_{k=1}^K \hat{p}_k I(m_{kj} = -1) + (1 - r_j) \sum_{k=1}^K \hat{p}_k I(m_{kj} = +1) \right]^2$$

with respect to \hat{p}_k and the restrictions

$$0 \leq \hat{p}_k \leq 1$$

$$\sum_k \hat{p}_k = 1.$$

The software performs minimization using quadprog.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. For more information, see "Tall Arrays" (MATLAB).

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- You can generate C/C++ code for both `predict` and `update` by using a coder configurer or generate code only for `predict` by using `saveCompactModel`, `loadCompactModel`, and `codegen`.
 - Code generation for `predict` and `update` — Create a coder configurer by using `learnerCoderConfigurer` and then generate code by using `generateCode`. Then you can update model parameters in the generated code without having to regenerate the code.
 - Code generation for `predict` — Save a trained model by using `saveCompactModel` and define an entry-point function that loads the saved model by using `loadCompactModel` and calls the `predict` function. Then use `codegen` to generate code for the entry-point function.
- This table contains notes about the arguments of `predict`. Arguments not included in this table are fully supported.

Argument	Notes and Limitations
<code>Mdl</code>	For the usage notes and limitations of the model object, see “Code Generation” on page 32-833 of the <code>CompactClassificationECOC</code> object.
<code>X</code>	<ul style="list-style-type: none"> • Must be a single-precision or double-precision matrix and can be variable-size. • If you specify <code>'ObservationsIn', 'rows'</code> (default), then the number of columns in <code>X</code> must be <code>numel(Mdl.PredictorNames)</code>. Rows and columns must correspond to observations and predictors, respectively. • If you specify <code>'ObservationsIn', 'columns'</code>, then the number of rows in <code>X</code> must be <code>numel(Mdl.PredictorNames)</code>. Rows and columns must correspond to predictors and observations, respectively.
<code>Posterior</code>	This output argument is not supported.

Argument	Notes and Limitations
Name-value pair arguments	Names in name-value pair arguments must be compile-time constants.
BinaryLoss	To set the 'BinaryLoss' name-value pair argument to a custom binary loss function in the generated code, define a custom function on the MATLAB search path, and specify the name of the custom function instead of its function handle. The custom function name must be a compile-time constant. For example, if you define a custom function named <code>customFunction</code> , then include <code>{coder.Constant('BinaryLoss'), coder.Constant('customFunction')}</code> in the <code>-args</code> value of <code>codegen</code> .
NumKLInitializations	This name-value pair argument is not supported.
ObservationsIn	The value for the 'ObservationsIn' name-value pair argument must be a compile-time constant. For example, to use the 'ObservationsIn', 'columns' name-value pair argument in the generated code, include <code>{coder.Constant('ObservationsIn'), coder.Constant('columns')}</code> in the <code>-args</code> value of <code>codegen</code> .
Options	This name-value pair argument is not supported.
PosteriorMethod	This name-value pair argument is not supported.
Verbose	If you plan to generate a MEX file without using a coder configurer, then you can specify <code>Verbose</code> . Otherwise, <code>codegen</code> does not support <code>Verbose</code> .

For more information, see “Introduction to Code Generation” on page 31-2.

Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the 'UseParallel' option to `true`.

Set the 'UseParallel' field of the options structure to `true` using `statset` and specify the 'Options' name-value pair argument in the call to this function.

For example: `'Options',statset('UseParallel',true)`

For more information, see the 'Options' name-value pair argument.

For more general information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

Introduced in R2014b

predict

Classify observations using ensemble of classification models

Syntax

```
labels = predict(Mdl,X)
labels = predict(Mdl,X,Name,Value)
[labels,score] = predict( ___ )
```

Description

`labels = predict(Mdl,X)` returns a vector of predicted class labels for the predictor data in the table or matrix `X`, based on the full or compact, trained classification ensemble `Mdl`.

`labels = predict(Mdl,X,Name,Value)` uses additional options specified by one or more `Name,Value` pair arguments.

`[labels,score] = predict(___)` also returns a matrix of classification scores on page 32-5246 (`score`), indicating the likelihood that a label comes from a particular class, using any of the input arguments in the previous syntaxes. For each observation in `X`, the predicted class label corresponds to the maximum score among all classes.

Input Arguments

Mdl

A classification ensemble created by `fitcensemble` or a compact classification ensemble created by `compact`.

X

Predictor data to be classified, specified as a numeric matrix or table.

Each row of X corresponds to one observation, and each column corresponds to one variable.

- For a numeric matrix:
 - The variables making up the columns of X must have the same order as the predictor variables that trained Mdl .
 - If you trained Mdl using a table (for example, Tbl), then X can be a numeric matrix if Tbl contains all numeric predictor variables. To treat numeric predictors in Tbl as categorical during training, identify categorical predictors using the `CategoricalPredictors` name-value pair argument of `fitcensemble`. If Tbl contains heterogeneous predictor variables (for example, numeric and categorical data types) and X is a numeric matrix, then `predict` throws an error.
- For a table:
 - `predict` does not support multi-column variables and cell arrays other than cell arrays of character vectors.
 - If you trained Mdl using a table (for example, Tbl), then all predictor variables in X must have the same variable names and be of the same data types as those that trained Mdl (stored in `Mdl.PredictorNames`). However, the column order of X does not need to correspond to the column order of Tbl . Tbl and X can contain additional variables (response variables, observation weights, etc.), but `predict` ignores them.
 - If you trained Mdl using a numeric matrix, then the predictor names in `Mdl.PredictorNames` and corresponding predictor variable names in X must be the same. To specify predictor names during training, see the `PredictorNames` name-value pair argument of `fitcensemble`. All predictor variables in X must be numeric vectors. X can contain additional variables (response variables, observation weights, etc.), but `predict` ignores them.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Learners

Indices of weak learners `predict` uses for computation of responses, a numeric vector.

Default: `1:T`, where `T` is the number of weak learners in `Mdl`

UseObsForLearner

A logical matrix of size `N-by-T`, where:

- `N` is the number of rows of `X`.
- `T` is the number of weak learners in `Mdl`.

When `UseObsForLearner(i, j)` is `true`, learner `j` is used in predicting the class of row `i` of `X`.

Default: `true(N,T)`

Output Arguments

labels

Vector of classification labels. `labels` has the same data type as the labels used in training `Mdl`. (The software treats string arrays as cell arrays of character vectors.)

score

A matrix with one row per observation and one column per class. For each observation and each class, the score generated by each tree is the probability of this observation originating from this class computed as the fraction of observations of this class in a tree leaf. `predict` averages these scores over all trees in the ensemble.

Examples

Predict Class Labels Using Classification Ensemble

Load Fisher's iris data set. Determine the sample size.

```
load fisheriris
N = size(meas,1);
```

Partition the data into training and test sets. Hold out 10% of the data for testing.

```
rng(1); % For reproducibility
cvp = cvpartition(N,'Holdout',0.1);
idxTrn = training(cvp); % Training set indices
idxTest = test(cvp); % Test set indices
```

Store the training data in a table.

```
tblTrn = array2table(meas(idxTrn,:));
tblTrn.Y = species(idxTrn);
```

Train a classification ensemble using AdaBoostM2 and the training set. Specify tree stumps as the weak learners.

```
t = templateTree('MaxNumSplits',1);
Mdl = fitcensemble(tblTrn,'Y','Method','AdaBoostM2','Learners',t);
```

Predict labels for the test set. You trained model using a table of data, but you can predict labels using a matrix.

```
labels = predict(Mdl,meas(idxTest,:));
```

Construct a confusion matrix for the test set.

```
confusionchart(species(idxTest),labels);
```

	setosa		
True Class	setosa	8	
	versicolor		2
	versicolor		1
virginica			4
	setosa	versicolor	virginica
	Predicted Class		

Mdl misclassifies one versicolor iris as virginica in the test set.

Definitions

Score (ensemble)

For ensembles, a classification score represents the confidence of a classification into a class. The higher the score, the higher the confidence.

Different ensemble algorithms have different definitions for their scores. Furthermore, the range of scores depends on ensemble type. For example:

- AdaBoostM1 scores range from $-\infty$ to ∞ .
- Bag scores range from 0 to 1.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. For more information, see “Tall Arrays” (MATLAB).

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Use `saveCompactModel`, `loadCompactModel`, and `codegen` to generate code for the `predict` function. Save a trained model by using `saveCompactModel`. Define an entry-point function that loads the saved model by using `loadCompactModel` and calls the `predict` function. Then use `codegen` to generate code for the entry-point function.
- This table contains notes about the arguments of `predict`. Arguments not included in this table are fully supported.

Argument	Notes and Limitations
Mdl	For the usage notes and limitations of the model object, see “Code Generation” on page 32-842 of the <code>CompactClassificationEnsemble</code> object.
X	<ul style="list-style-type: none"> • Must be a single-precision or double-precision matrix and can be variable-size. However, the number of columns in X must be <code>numel(Mdl.PredictorNames)</code>. • Rows and columns must correspond to observations and predictors, respectively.

Argument	Notes and Limitations
Name-value pair arguments	Names in name-value pair arguments must be compile-time constants. For example, to allow user-defined indices up to 5 weak learners in the generated code, include <code>{coder.Constant('Learners'), coder.typeof(0, [1,5], [0,1])}</code> in the <code>-args</code> value of <code>codegen</code> .

For more information, see “Introduction to Code Generation” on page 31-2.

predict

Predict labels using naive Bayes classification model

Syntax

```
label = predict(Mdl,X)
[label,Posterior,Cost] = predict(Mdl,X)
```

Description

`label = predict(Mdl,X)` returns a vector of predicted class labels for the predictor data in the table or matrix `X`, based on the trained, full or compact naive Bayes classifier `Mdl`.

`[label,Posterior,Cost] = predict(Mdl,X)` also returns:

- A matrix of posterior probabilities on page 32-5258 (**Posterior**) indicating the likelihood that a label comes from a particular class.
- A matrix of misclassification costs on page 32-5257 (**Cost**). For each observation in `X`, the predicted class label corresponds to the minimum expected classification costs among all classes.

Input Arguments

Mdl — Naive Bayes classifier

`ClassificationNaiveBayes` model | `CompactClassificationNaiveBayes` model

Naive Bayes classifier, specified as a `ClassificationNaiveBayes` model or `CompactClassificationNaiveBayes` model returned by `fitcnb` or `compact`, respectively.

X — Predictor data to be classified

numeric matrix | table

Predictor data to be classified, specified as a numeric matrix or table.

Each row of `X` corresponds to one observation, and each column corresponds to one variable.

- For a numeric matrix:
 - The variables making up the columns of `X` must have the same order as the predictor variables that trained `Mdl`.
 - If you trained `Mdl` using a table (for example, `Tbl`), then `X` can be a numeric matrix if `Tbl` contains all numeric predictor variables. To treat numeric predictors in `Tbl` as categorical during training, identify categorical predictors using the `CategoricalPredictors` name-value pair argument of `fitcnb`. If `Tbl` contains heterogeneous predictor variables (for example, numeric and categorical data types) and `X` is a numeric matrix, then `predict` throws an error.
- For a table:
 - `predict` does not support multi-column variables and cell arrays other than cell arrays of character vectors.
 - If you trained `Mdl` using a table (for example, `Tbl`), then all predictor variables in `X` must have the same variable names and data types as those that trained `Mdl` (stored in `Mdl.PredictorNames`). However, the column order of `X` does not need to correspond to the column order of `Tbl`. `Tbl` and `X` can contain additional variables (response variables, observation weights, etc.), but `predict` ignores them.
 - If you trained `Mdl` using a numeric matrix, then the predictor names in `Mdl.PredictorNames` and corresponding predictor variable names in `X` must be the same. To specify predictor names during training, see the `PredictorNames` name-value pair argument of `fitcnb`. All predictor variables in `X` must be numeric vectors. `X` can contain additional variables (response variables, observation weights, etc.), but `predict` ignores them.

Data Types: `table` | `double` | `single`

Notes:

- If `Mdl.DistributionNames` is `'mn'`, then the software returns `NaNs` corresponding to rows of `X` containing at least one `NaN`.
- If `Mdl.DistributionNames` is not `'mn'`, then the software ignores `NaN` values when estimating misclassification costs and posterior probabilities. Specifically, the software

computes the conditional density of the predictors given the class by leaving out the factors corresponding to missing predictor values.

- For predictor distribution specified as 'mvnm', if X contains levels that are not represented in the training data (i.e., not in `Mdl.CategoricalLevels` for that predictor), then the conditional density of the predictors given the class is 0. For those observations, the software returns the corresponding value of `Posterior` as a NaN. The software determines the class label for such observations using the class prior probability, stored in `Mdl.Prior`.

Output Arguments

Label — Predicted class labels

categorical vector | character array | logical vector | numeric vector | cell array of character vectors

Predicted class labels, returned as a categorical vector, character array, logical or numeric vector, or cell array of character vectors.

Label:

- Is the same data type as the observed class labels (`Mdl.Y`) that trained `Mdl`
- Has length equal to the number of rows of `Mdl.X`
- Is the class yielding the lowest expected misclassification cost (`Cost`)

Posterior — Class posterior probabilities

numeric matrix

Class posterior probabilities on page 32-5258, returned as a numeric matrix. `Posterior` has rows equal to the number of rows of X and columns equal to the number of distinct classes in the training data (`size(Mdl.ClassNames, 1)`).

`Posterior(j, k)` is the predicted posterior probability of class k (i.e., in class `Mdl.ClassNames(k)`) given the observation in row j of X.

Data Types: double

Cost — Expected misclassification costs

numeric matrix

Expected misclassification costs on page 32-5257, returned as a numeric matrix. `Cost` has rows equal to the number of rows of `X` and columns equal to the number of distinct classes in the training data (`size(Mdl.ClassNames,1)`).

`Cost(j,k)` is the expected misclassification cost of the observation in row `j` of `X` being predicted into class `k` (i.e., in class `Mdl.ClassNames(k)`).

Examples

Label Test Sample Observations of Naive Bayes Classifiers

Load Fisher's iris data set.

```
load fisheriris
X = meas;    % Predictors
Y = species; % Response
rng(1);
```

Train a naive Bayes classifier and specify to holdout 30% of the data for a test sample. It is good practice to specify the class order. Assume that each predictor is conditionally, normally distributed given its label.

```
CVMDL = fitcnb(X,Y,'Holdout',0.30,...
    'ClassNames',{'setosa','versicolor','virginica'});
CMDL = CVMDL.Trained{1};    % Extract trained, compact classifier
testIdx = test(CVMDL.Partition); % Extract the test indices
XTest = X(testIdx,:);
YTest = Y(testIdx);
```

`CVMDL` is a `ClassificationPartitionedModel` classifier. It contains the property `Trained`, which is a 1-by-1 cell array holding a `CompactClassificationNaiveBayes` classifier that the software trained using the training set.

Label the test sample observations. Display the results for a random set of 10 observations in the test sample.

```
idx = randsample(sum(testIdx),10);
label = predict(CMDL,XTest);
table(YTest(idx),label(idx),'VariableNames',...
    {'TrueLabel','PredictedLabel'})
```

```
ans=10x2 table
  TrueLabel      PredictedLabel
  _____  _____
  'setosa'       'setosa'
  'versicolor'  'versicolor'
  'setosa'       'setosa'
  'virginica'    'virginica'
  'versicolor'  'versicolor'
  'setosa'       'setosa'
  'virginica'    'virginica'
  'virginica'    'virginica'
  'setosa'       'setosa'
  'setosa'       'setosa'
```

Estimate Posterior Probabilities and Misclassification Costs

A goal of classification is to estimate posterior probabilities of new observations using a trained algorithm. Many applications train algorithms on large data sets, which can use resources that are better used elsewhere. This example shows how to efficiently estimate posterior probabilities of new observations using a Naive Bayes classifier.

Load Fisher's iris data set.

```
load fisheriris
X = meas;    % Predictors
Y = species; % Response
rng(1);
```

Partition the data set into two sets: one in the training set, and the other is new unobserved data. Reserve 10 observations for the new data set.

```
n = size(X,1);
newInds = randsample(n,10);
inds = ~ismember(1:n,newInds);
XNew = X(newInds,:);
YNew = Y(newInds);
```

Train a naive Bayes classifier. It is good practice to specify the class order. Assume that each predictor is conditionally, normally distributed given its label. Conserve memory by reducing the size of the trained SVM classifier.

```
Mdl = fitcnb(X(inds,:),Y(inds),...
    'ClassNames',{'setosa','versicolor','virginica'});
CMdl = compact(Mdl);
whos('Mdl','CMdl')
```

Name	Size	Bytes	Class
CMdl	1x1	5346	classreg.learning.classif.CompactClassificationNaive
Mdl	1x1	12671	ClassificationNaiveBayes

The `CompactClassificationNaiveBayes` classifier (`CMdl`) uses less space than the `ClassificationNaiveBayes` classifier (`Mdl`) because the latter stores the data.

Predict the labels, posterior probabilities, and expected class misclassification costs. Since true labels are available, compare them with the predicted labels.

```
CMdl.ClassNames
```

```
ans = 3x1 cell array
    {'setosa' }
    {'versicolor'}
    {'virginica' }
```

```
[labels,PostProbs,MisClassCost] = predict(CMdl,XNew);
table(YNew,labels,PostProbs,'VariableNames',...
    {'TrueLabels','PredictedLabels',...
    'PosteriorProbabilities'})
```

```
ans=10x3 table
    TrueLabels    PredictedLabels    PosteriorProbabilities
```

TrueLabels	PredictedLabels	PosteriorProbabilities		
'setosa'	'setosa'	1	4.1259e-16	1.1846e-23
'versicolor'	'versicolor'	1.0373e-60	0.99999	5.8053e-06
'virginica'	'virginica'	4.8708e-211	0.00085645	0.99914
'setosa'	'setosa'	1	1.4053e-19	2.2672e-26

'versicolor'	'versicolor'	2.0667e-110	0.94237	0.057625
'setosa'	'setosa'	1	4.3779e-19	3.5139e-26
'setosa'	'setosa'	1	1.1792e-17	2.2912e-24

```
MisClassCost
```

```
MisClassCost = 10x3

    0.0000    1.0000    1.0000
    1.0000    0.0000    1.0000
    1.0000    0.9991    0.0009
    0.0000    1.0000    1.0000
    1.0000    0.0001    0.9999
    0.0000    1.0000    1.0000
    1.0000    0.0000    1.0000
    1.0000    0.0576    0.9424
    0.0000    1.0000    1.0000
    0.0000    1.0000    1.0000
```

PostProbs and MisClassCost are 15-by- 3 numeric matrices, where each row corresponds to a new observation and each column corresponds to a class. The order of the columns corresponds to the order of `CMDL.ClassNames`.

Plot Posterior Probability Regions for Naive Bayes Classifiers

Load Fisher's iris data set. Train the classifier using the petal lengths and widths.

```
load fisheriris
X = meas(:,3:4);
Y = species;
```

Train a naive Bayes classifier. It is good practice to specify the class order. Assume that each predictor is conditionally, normally distributed given its label.

```
Mdl = fitcnb(X,Y,...
    'ClassNames',{'setosa','versicolor','virginica'});
```

`Mdl` is a `ClassificationNaiveBayes` model. You can access its properties using dot notation.

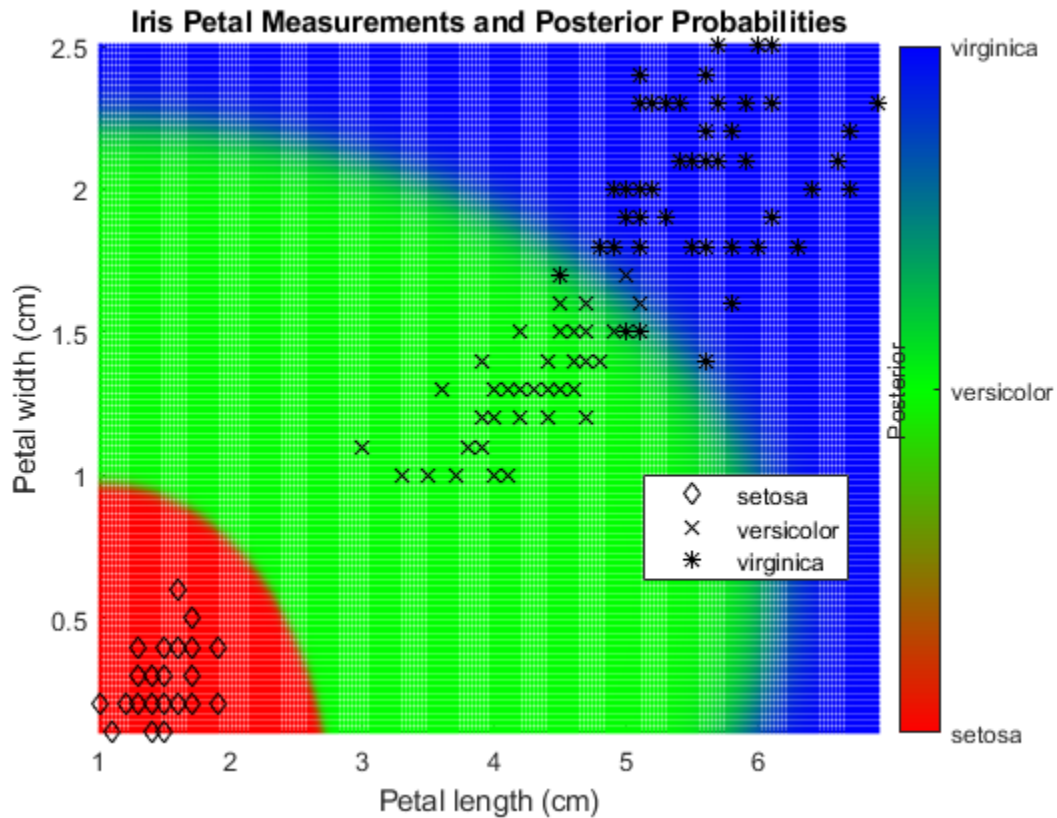

Define a grid of values in the observed predictor space. Predict the posterior probabilities for each instance in the grid.

```
xMax = max(X);
xMin = min(X);
h = 0.01;
[x1Grid,x2Grid] = meshgrid(xMin(1):h:xMax(1),xMin(2):h:xMax(2));
```

```
[~,PosteriorRegion] = predict(Mdl,[x1Grid(:),x2Grid(:)]);
```

Plot the posterior probability regions and the training data.

```
figure;
% Plot posterior regions
scatter(x1Grid(:),x2Grid(:),1,PosteriorRegion);
% Adjust color bar options
h = colorbar;

Definitions

Misclassification Cost

A misclassification cost is the relative severity of a classifier labeling an observation into the wrong class.

There are two types of misclassification costs: true and expected. Let K be the number of classes.

- True misclassification cost — A K -by- K matrix, where element (i, j) indicates the misclassification cost of predicting an observation into class j if its true class is i . The software stores the misclassification cost in the property `Mdl.Cost`, and used in computations. By default, `Mdl.Cost(i, j) = 1` if $i \neq j$, and `Mdl.Cost(i, j) = 0` if $i = j$. In other words, the cost is θ for correct classification, and 1 for any incorrect classification.
- Expected misclassification cost — A K -dimensional vector, where element k is the weighted average misclassification cost of classifying an observation into class k , weighted by the class posterior probabilities. In other words,

$$c_k = \sum_{j=1}^K \widehat{P}(Y = j | x_1, \dots, x_p) \text{Cost}_{jk}.$$

the software classifies observations to the class corresponding with the lowest expected misclassification cost.

Posterior Probability

The posterior probability is the probability that an observation belongs in a particular class, given the data.

For naive Bayes, the posterior probability that a classification is k for a given observation (x_1, \dots, x_p) is

$$\widehat{P}(Y = k | x_1, \dots, x_p) = \frac{P(X_1, \dots, X_p | y = k) \pi(Y = k)}{P(X_1, \dots, X_p)},$$

where:

- $P(X_1, \dots, X_p | y = k)$ is the conditional joint density of the predictors given they are in class k . `Mdl.DistributionNames` stores the distribution names of the predictors.
- $\pi(Y = k)$ is the class prior probability distribution. `Mdl.Prior` stores the prior distribution.
- $P(X_1, \dots, X_p)$ is the joint density of the predictors. The classes are discrete, so

$$P(X_1, \dots, X_p) = \sum_{k=1}^K P(X_1, \dots, X_p | y = k) \pi(Y = k).$$

Prior Probability

The prior probability of a class is the believed relative frequency with which observations from that class occur in a population.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. For more information, see “Tall Arrays” (MATLAB).

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Use `saveCompactModel`, `loadCompactModel`, and `codegen` to generate code for the `predict` function. Save a trained model by using `saveCompactModel`. Define an entry-point function that loads the saved model by using `loadCompactModel` and calls the `predict` function. Then use `codegen` to generate code for the entry-point function.
- This table contains notes about the arguments of `predict`. Arguments not included in this table are fully supported.

Argument	Notes and Limitations
<code>Mdl</code>	For the usage notes and limitations of the model object, see “Code Generation” on page 32-857 of the <code>CompactClassificationNaiveBayes</code> object.

Argument	Notes and Limitations
X	<ul style="list-style-type: none">• Must be a single-precision or double-precision matrix and can be variable-size. However, the number of columns in X must be <code>numel(Mdl.PredictorNames)</code>.• Rows and columns must correspond to observations and predictors, respectively.

predict

Package: classreg.learning.classif

Classify observations using support vector machine (SVM) classifier

Syntax

```
label = predict(SVMModel,X)
[label,score] = predict(SVMModel,X)
```

Description

`label = predict(SVMModel,X)` returns a vector of predicted class labels for the predictor data in the table or matrix `X`, based on the trained support vector machine (SVM) classification model `SVMModel`. The trained SVM model can either be full or compact.

`[label,score] = predict(SVMModel,X)` also returns a matrix of scores (`score`) indicating the likelihood that a label comes from a particular class. For SVM, likelihood measures are either classification scores on page 32-5267 or class posterior probabilities on page 32-5268. For each observation in `X`, the predicted class label corresponds to the maximum score among all classes.

Examples

Label Test Sample Observations of SVM Classifiers

Load the ionosphere data set.

```
load ionosphere
rng(1); % For reproducibility
```

Train an SVM classifier. Specify a 15% holdout sample for testing, standardize the data, and specify that 'g' is the positive class.

```

CVSVMModel = fitcsvm(X,Y,'Holdout',0.15,'ClassNames',{'b','g'},...
    'Standardize',true);
CompactSVMModel = CVSVMModel.Trained{1}; % Extract trained, compact classifier
testInds = test(CVSVMModel.Partition); % Extract the test indices
XTest = X(testInds,:);
YTest = Y(testInds,:);

```

CVSVMModel is a `ClassificationPartitionedModel` classifier. It contains the property `Trained`, which is a 1-by-1 cell array holding a `CompactClassificationSVM` classifier that the software trained using the training set.

Label the test sample observations. Display the results for the first 10 observations in the test sample.

```

[label,score] = predict(CompactSVMModel,XTest);
table(YTest(1:10),label(1:10),score(1:10,2),'VariableNames',...
    {'TrueLabel','PredictedLabel','Score'})

```

```

ans=10x3 table
    TrueLabel    PredictedLabel    Score
    _____    _____    _____
         'b'           'b'          -1.7177
         'g'           'g'           2.0003
         'b'           'b'          -9.6841
         'g'           'g'           2.5618
         'b'           'b'          -1.548
         'g'           'g'           2.0984
         'b'           'b'          -2.7018
         'b'           'b'          -0.66291
         'g'           'g'           1.6046
         'g'           'g'           1.7731

```

Predict Labels and Posterior Probabilities of SVM Classifiers

Label new observations using an SVM classifier.

Load the ionosphere data set. Assume that the last 10 observations become available after you train the SVM classifier.

```

load ionosphere
rng(1); % For reproducibility

```

```

n = size(X,1);      % Training sample size
isInds = 1:(n-10); % In-sample indices
oosInds = (n-9):n; % Out-of-sample indices

```

Train an SVM classifier. Standardize the data and specify that 'g' is the positive class. Conserve memory by reducing the size of the trained SVM classifier.

```

SVMModel = fitcsvm(X(isInds,:),Y(isInds),'Standardize',true,...
    'ClassNames',{'b','g'});
CompactSVMModel = compact(SVMModel);
whos('SVMModel','CompactSVMModel')

```

Name	Size	Bytes	Class
CompactSVMModel	1x1	30288	classreg.learning.classif.CompactClassif
SVMModel	1x1	137628	ClassificationSVM

The `CompactClassificationSVM` classifier (`CompactSVMModel`) uses less space than the `ClassificationSVM` classifier (`SVMModel`) because `SVMModel` stores the data.

Estimate the optimal score-to-posterior-probability transformation function.

```

CompactSVMModel = fitPosterior(CompactSVMModel,...
    X(isInds,:),Y(isInds))

CompactSVMModel =
    classreg.learning.classif.CompactClassificationSVM
        ResponseName: 'Y'
    CategoricalPredictors: []
        ClassNames: {'b' 'g'}
    ScoreTransform: '@(S) sigmoid(S, -1.968452e+00, 3.121267e-01) '
        Alpha: [88x1 double]
        Bias: -0.2143
    KernelParameters: [1x1 struct]
        Mu: [1x34 double]
        Sigma: [1x34 double]
    SupportVectors: [88x34 double]
    SupportVectorLabels: [88x1 double]

```

Properties, Methods

The optimal score transformation function (`CompactSVMModel.ScoreTransform`) is the sigmoid function because the classes are inseparable.

Predict the out-of-sample labels and positive class posterior probabilities. Because true labels are available, compare them with the predicted labels.

```
[labels,PostProbs] = predict(CompactSVMModel,X(oosInds,:));
table(Y(oosInds),labels,PostProbs(:,2),'VariableNames',...
      {'TrueLabels','PredictedLabels','PosClassPosterior'})
```

```
ans=10x3 table
  TrueLabels PredictedLabels PosClassPosterior
  _____ _____
  'g'         'g'         0.98419
  'g'         'g'         0.95545
  'g'         'g'         0.67792
  'g'         'g'         0.94448
  'g'         'g'         0.98744
  'g'         'g'         0.92482
  'g'         'g'         0.97111
  'g'         'g'         0.96986
  'g'         'g'         0.97803
  'g'         'g'         0.94361
```

PostProbs is a 10-by-2 matrix, where the first column is the negative class posterior probabilities, and the second column is the positive class posterior probabilities corresponding to the new observations.

Input Arguments

SVMModel — SVM classification model

ClassificationSVM model object | CompactClassificationSVM model object

SVM classification model, specified as a `ClassificationSVM` model object or `CompactClassificationSVM` model object returned by `fitsvm` or `compact`, respectively.

X — Predictor data to be classified

numeric matrix | table

Predictor data to be classified, specified as a numeric matrix or table.

Each row of `X` corresponds to one observation, and each column corresponds to one variable.

- For a numeric matrix:
 - The variables in the columns of `X` must have the same order as the predictor variables that trained `SVMMODEL`.
 - If you trained `SVMMODEL` using a table (for example, `Tbl`) and `Tbl` contains all numeric predictor variables, then `X` can be a numeric matrix. To treat numeric predictors in `Tbl` as categorical during training, identify categorical predictors by using the `CategoricalPredictors` name-value pair argument of `fitcsvm`. If `Tbl` contains heterogeneous predictor variables (for example, numeric and categorical data types) and `X` is a numeric matrix, then `predict` throws an error.
- For a table:
 - `predict` does not support multicolumn variables and cell arrays other than cell arrays of character vectors.
 - If you trained `SVMMODEL` using a table (for example, `Tbl`), then all predictor variables in `X` must have the same variable names and data types as those that trained `SVMMODEL` (stored in `SVMMODEL.PredictorNames`). However, the column order of `X` does not need to correspond to the column order of `Tbl`. Also, `Tbl` and `X` can contain additional variables (response variables, observation weights, and so on), but `predict` ignores them.
 - If you trained `SVMMODEL` using a numeric matrix, then the predictor names in `SVMMODEL.PredictorNames` and corresponding predictor variable names in `X` must be the same. To specify predictor names during training, see the `PredictorNames` name-value pair argument of `fitcsvm`. All predictor variables in `X` must be numeric vectors. `X` can contain additional variables (response variables, observation weights, and so on), but `predict` ignores them.

If you set `'Standardize', true` in `fitcsvm` to train `SVMMODEL`, then the software standardizes the columns of `X` using the corresponding means in `SVMMODEL.Mu` and the standard deviations in `SVMMODEL.Sigma`.

Data Types: `table` | `double` | `single`

Output Arguments

label — Predicted class labels

categorical array | character array | logical vector | numeric vector | cell array of character vectors

Predicted class labels, returned as a categorical or character array, logical or numeric vector, or cell array of character vectors.

`label` has the same data type as the observed class labels (Y) that trained `SVMModel`, and its length is equal to the number of rows in X . (The software treats string arrays as cell arrays of character vectors.)

For one-class learning, `label` is the one class represented in the observed class labels.

score — Predicted class scores or posterior probabilities

numeric column vector | numeric matrix

Predicted class scores on page 32-5267 or posterior probabilities on page 32-5268, returned as a numeric column vector or numeric matrix.

- For one-class learning, `score` is a column vector with the same number of rows as the observations (X). The elements of `score` are the positive class scores for the corresponding observations. You cannot obtain posterior probabilities for one-class learning.
- For two-class learning, `score` is a two-column matrix with the same number of rows as X .
 - If you fit the optimal score-to-posterior-probability transformation function using `fitPosterior` or `fitSVMPosterior`, then `score` contains class posterior probabilities. That is, if the value of `SVMModel.ScoreTransform` is not `none`, then the first and second columns of `score` contain the negative class (`SVMModel.ClassNames{1}`) and positive class (`SVMModel.ClassNames{2}`) posterior probabilities for the corresponding observations, respectively.
 - Otherwise, the first column contains the negative class scores and the second column contains the positive class scores for the corresponding observations.

If `SVMModel.KernelParameters.Function` is `'linear'`, then the classification score for the observation x is

$$f(x) = (x/s)\beta + b.$$

`SVMModel` stores β , b , and s in the properties `Beta`, `Bias`, and `KernelParameters.Scale`, respectively.

To estimate classification scores manually, you must first apply any transformations to the predictor data that were applied during training. Specifically, if you specify `'Standardize', true` when using `fitcsvm`, then you must standardize the predictor data manually by using the mean `SVMModel.Mu` and standard deviation `SVMModel.Sigma`, and then divide the result by the kernel scale in `SVMModel.KernelParameters.Scale`.

All SVM functions, such as `resubPredict` and `predict`, apply any required transformation before estimation.

If `SVMModel.KernelParameters.Function` is not `'linear'`, then `Beta` is empty (`[]`).

Definitions

Classification Score

The SVM classification score for classifying observation x is the signed distance from x to the decision boundary ranging from $-\infty$ to $+\infty$. A positive score for a class indicates that x is predicted to be in that class. A negative score indicates otherwise.

The positive class classification score $f(x)$ is the trained SVM classification function. $f(x)$ is also the numerical, predicted response for x , or the score for predicting x into the positive class.

$$f(x) = \sum_{j=1}^n \alpha_j y_j G(x_j, x) + b,$$

where $(\alpha_1, \dots, \alpha_n, b)$ are the estimated SVM parameters, $G(x_j, x)$ is the dot product in the predictor space between x and the support vectors, and the sum includes the training set observations. The negative class classification score for x , or the score for predicting x into the negative class, is $-f(x)$.

If $G(x_j, x) = x_j'x$ (the linear kernel), then the score function reduces to

$$f(x) = (x/s)'\beta + b.$$

s is the kernel scale and β is the vector of fitted linear coefficients.

For more details, see “Understanding Support Vector Machines” on page 18-189.

Posterior Probability

The posterior probability is the probability that an observation belongs in a particular class, given the data.

For SVM, the posterior probability is a function of the score $P(s)$ that observation j is in class $k = \{-1, 1\}$.

- For separable classes, the posterior probability is the step function

$$P(s_j) = \begin{cases} 0; & s < \max_{y_k = -1} s_k \\ \pi; & \max_{y_k = -1} s_k \leq s_j \leq \min_{y_k = +1} s_k, \\ 1; & s_j > \min_{y_k = +1} s_k \end{cases}$$

where:

- s_j is the score of observation j .
- $+1$ and -1 denote the positive and negative classes, respectively.
- π is the prior probability that an observation is in the positive class.
- For inseparable classes, the posterior probability is the sigmoid function

$$P(s_j) = \frac{1}{1 + \exp(As_j + B)},$$

where the parameters A and B are the slope and intercept parameters, respectively.

Prior Probability

The prior probability of a class is the believed relative frequency with which observations from that class occur in a population.

Tips

- If you are using a linear SVM model for classification and the model has many support vectors, then using `predict` for the prediction method can be slow. To efficiently classify observations based on a linear SVM model, remove the support vectors from the model object by using `discardSupportVectors`.

Algorithms

- By default and irrespective of the model kernel function, MATLAB uses the dual representation of the score function to classify observations based on trained SVM models, specifically

$$\hat{f}(x) = \sum_{j=1}^n \hat{\alpha}_j y_j G(x, x_j) + \hat{b}.$$

This prediction method requires the trained support vectors and α coefficients (see the `SupportVectors` and `Alpha` properties of the SVM model).

- By default, the software computes optimal posterior probabilities using Platt's method [1]:
 - 1 Perform 10-fold cross-validation.
 - 2 Fit the sigmoid function parameters to the scores returned from the cross-validation.
 - 3 Estimate the posterior probabilities by entering the cross-validation scores into the fitted sigmoid function.
- The software incorporates prior probabilities in the SVM objective function during training.
- For SVM, `predict` and `resubPredict` classify observations into the class yielding the largest score (the largest posterior probability). The software accounts for misclassification costs by applying the average-cost correction before training the classifier. That is, given the class prior vector P , misclassification cost matrix C , and observation weight vector w , the software defines a new vector of observation weights (W) such that

$$W_j = w_j P_j \sum_{k=1}^K C_{jk}.$$

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. For more information, see “Tall Arrays” (MATLAB).

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- You can generate C/C++ code for both `predict` and `update` by using a coder configurer or generate code only for `predict` by using `saveCompactModel`, `loadCompactModel`, and `codegen`.
- Code generation for `predict` and `update` — Create a coder configurer by using `learnerCoderConfigurer` and then generate code by using `generateCode`. Then you can update model parameters in the generated code without having to regenerate the code.
- Code generation for `predict` — Save a trained model by using `saveCompactModel` and define an entry-point function that loads the saved model by using `loadCompactModel` and calls the `predict` function. Then use `codegen` to generate code for the entry-point function.
- This table contains notes about the arguments of `predict`. Arguments not included in this table are fully supported.

Argument	Notes and Limitations
SVMModel	<ul style="list-style-type: none"> If you use <code>saveCompactModel</code> to save an SVM model that is equipped to predict posterior probabilities, and use <code>loadCompactModel</code> to load the model, then <code>loadCompactModel</code> cannot restore the <code>ScoreTransform</code> property into the MATLAB Workspace. However, <code>loadCompactModel</code> can load the model, including the <code>ScoreTransform</code> property, at compile time for code generation, within an entry-point function. For the usage notes and limitations of the model object, see “Code Generation” on page 32-870 of the <code>CompactClassificationSVM</code> object.
X	<ul style="list-style-type: none"> Must be a single-precision or double-precision matrix and can be variable-size. However, the number of columns in X must be <code>numel(SVMdl.PredictorNames)</code>. Rows and columns must correspond to observations and predictors, respectively.

For more information, see “Introduction to Code Generation” on page 31-2.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU arrays. For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

predict

Predict labels using classification tree

Syntax

```
label = predict(Mdl,X)
label = predict(Mdl,X,Name,Value)
[label,score,node,cnum] = predict( ___ )
```

Description

`label = predict(Mdl,X)` returns a vector of predicted class labels for the predictor data in the table or matrix `X`, based on the trained, full or compact classification tree `Mdl`.

`label = predict(Mdl,X,Name,Value)` uses additional options specified by one or more `Name,Value` pair arguments. For example, you can specify to prune `Mdl` to a particular level before predicting labels.

`[label,score,node,cnum] = predict(___)` uses any of the input argument in the previous syntaxes and additionally returns:

- A matrix of classification scores (`score`) indicating the likelihood that a label comes from a particular class. For classification trees, scores are posterior probabilities. For each observation in `X`, the predicted class label on page 32-5280 corresponds to the minimum expected misclassification cost on page 32-5284 among all classes.
- A vector of predicted node numbers for the classification (`node`).
- A vector of predicted class number for the classification (`cnum`).

Input Arguments

Mdl — Trained classification tree

ClassificationTree model object | CompactClassificationTree model object

Trained classification tree, specified as a `ClassificationTree` or `CompactClassificationTree` model object. That is, `Mdl` is a trained classification model returned by `fitctree` or `compact`.

X — Predictor data to be classified

numeric matrix | table

Predictor data to be classified, specified as a numeric matrix or table.

Each row of `X` corresponds to one observation, and each column corresponds to one variable.

- For a numeric matrix:
 - The variables making up the columns of `X` must have the same order as the predictor variables that trained `Mdl`.
 - If you trained `Mdl` using a table (for example, `Tbl`), then `X` can be a numeric matrix if `Tbl` contains all numeric predictor variables. To treat numeric predictors in `Tbl` as categorical during training, identify categorical predictors using the `CategoricalPredictors` name-value pair argument of `fitctree`. If `Tbl` contains heterogeneous predictor variables (for example, numeric and categorical data types) and `X` is a numeric matrix, then `predict` throws an error.
- For a table:
 - `predict` does not support multi-column variables and cell arrays other than cell arrays of character vectors.
 - If you trained `Mdl` using a table (for example, `Tbl`), then all predictor variables in `X` must have the same variable names and data types as those that trained `Mdl` (stored in `Mdl.PredictorNames`). However, the column order of `X` does not need to correspond to the column order of `Tbl`. `Tbl` and `X` can contain additional variables (response variables, observation weights, etc.), but `predict` ignores them.
 - If you trained `Mdl` using a numeric matrix, then the predictor names in `Mdl.PredictorNames` and corresponding predictor variable names in `X` must be the same. To specify predictor names during training, see the `PredictorNames` name-value pair argument of `fitctree`. All predictor variables in `X` must be numeric vectors. `X` can contain additional variables (response variables, observation weights, etc.), but `predict` ignores them.

Data Types: table | double | single

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Subtrees — Pruning level

0 (default) | vector of nonnegative integers | 'all'

Pruning level, specified as the comma-separated pair consisting of 'Subtrees' and a vector of nonnegative integers in ascending order or 'all'.

If you specify a vector, then all elements must be at least 0 and at most `max(Mdl.PruneList)`. 0 indicates the full, unpruned tree and `max(Mdl.PruneList)` indicates the completely pruned tree (i.e., just the root node).

If you specify 'all', then `predict` operates on all subtrees (i.e., the entire pruning sequence). This specification is equivalent to using `0:max(Mdl.PruneList)`.

`predict` prunes `Mdl` to each level indicated in `Subtrees`, and then estimates the corresponding output arguments. The size of `Subtrees` determines the size of some output arguments.

To invoke `Subtrees`, the properties `PruneList` and `PruneAlpha` of `Mdl` must be nonempty. In other words, grow `Mdl` by setting 'Prune', 'on', or by pruning `Mdl` using `prune`.

Example: 'Subtrees', 'all'

Data Types: single | double | char | string

Output Arguments

label — Predicted class labels

vector | array

Predicted class labels on page 32-5280, returned as a vector or array. Each entry of `label` corresponds to the class with minimal expected cost for the corresponding row of `X`.

Suppose `Subtrees` is a numeric vector containing `T` elements (for `'all'`, see `Subtrees`), and `X` has `N` rows.

- If the response data type is `char` and:
 - `T = 1`, then `label` is a character matrix containing `N` rows. Each row contains the predicted label produced by subtree `Subtrees`.
 - `T > 1`, then `label` is an `N`-by-`T` cell array.
- Otherwise, `label` is an `N`-by-`T` array having the same data type as the response. (The software treats string arrays as cell arrays of character vectors.)

In the latter two cases, column `j` of `label` contains the vector of predicted labels produced by subtree `Subtrees(j)`.

score — Posterior probabilities

numeric matrix

Posterior probabilities, returned as a numeric matrix of size `N`-by-`K`, where `N` is the number of observations (rows) in `X`, and `K` is the number of classes (in `Mdl.ClassNames`). `score(i, j)` is the posterior probability that row `i` of `X` is of class `j`.

If `Subtrees` has `T` elements, and `X` has `N` rows, then `score` is an `N`-by-`K`-by-`T` array, and `node` and `cnum` are `N`-by-`T` matrices.

node — Node numbers

numeric vector

Node numbers for the predicted classes, returned as a numeric vector. Each entry corresponds to the predicted node in `Mdl` for the corresponding row of `X`.

cnum — Class numbers

numeric vector

Class numbers corresponding to the predicted `labels`, returned as a numeric vector. Each entry of `cnum` corresponds to a predicted class number for the corresponding row of `X`.

Examples

Predict Labels Using a Classification Tree

Examine predictions for a few rows in a data set left out of training.

Load Fisher's iris data set.

```
load fisheriris
```

Partition the data into training (50%) and validation (50%) sets.

```
n = size(meas,1);
rng(1) % For reproducibility
idxTrn = false(n,1);
idxTrn(randsample(n,round(0.5*n))) = true; % Training set logical indices
idxVal = idxTrn == false; % Validation set logical indices
```

Grow a classification tree using the training set.

```
Mdl = fitctree(meas(idxTrn,:),species(idxTrn));
```

Predict labels for the validation data. Count the number of misclassified observations.

```
label = predict(Mdl,meas(idxVal,:));
label(randsample(numel(label),5)) % Display several predicted labels
```

```
ans = 5x1 cell array
    {'setosa' }
    {'setosa' }
    {'setosa' }
    {'virginica' }
    {'versicolor' }
```

```
numMisclass = sum(~strcmp(label,species(idxVal)))
```

```
numMisclass = 3
```

The software misclassifies three out-of-sample observations.

Estimate Class Posterior Probabilities Using a Classification Tree

Load Fisher's iris data set.

```
load fisheriris
```

Partition the data into training (50%) and validation (50%) sets.

```
n = size(meas,1);  
rng(1) % For reproducibility  
idxTrn = false(n,1);  
idxTrn(randsample(n,round(0.5*n))) = true; % Training set logical indices  
idxVal = idxTrn == false; % Validation set logical indices
```

Grow a classification tree using the training set, and then view it.

```
Mdl = fitctree(meas(idxTrn,:),species(idxTrn));  
view(Mdl,'Mode','graph')
```

The resulting tree has four levels.

Estimate posterior probabilities for the test set using subtrees pruned to levels 1 and 3.

```
[~,Posterior] = predict(Mdl,meas(idxVal,:), 'SubTrees', [1 3]);
Mdl.ClassNames
```

```
ans = 3x1 cell array
    {'setosa' }
    {'versicolor'}
    {'virginica' }
```

```
Posterior(randsample(size(Posterior,1),5),:,:),...
  % Display several posterior probabilities

ans =
ans(:,:,1) =

    1.0000         0         0
    1.0000         0         0
    1.0000         0         0
         0         0    1.0000
         0    0.8571    0.1429

ans(:,:,2) =

    0.3733    0.3200    0.3067
    0.3733    0.3200    0.3067
    0.3733    0.3200    0.3067
    0.3733    0.3200    0.3067
    0.3733    0.3200    0.3067
```

The elements of `Posterior` are class posterior probabilities:

- Rows correspond to observations in the validation set.
- Columns correspond to the classes as listed in `Mdl.ClassNames`.
- Pages correspond to the subtrees.

The subtree pruned to level 1 is more sure of its predictions than the subtree pruned to level 3 (i.e., the root node).

Definitions

Predicted Class Label

`predict` classifies by minimizing the expected classification cost:

$$\hat{y} = \operatorname{argmin}_{y=1,\dots,K} \sum_{j=1}^K \hat{P}(j|x)C(y|j),$$

where

- \hat{y} is the predicted classification.
- K is the number of classes.
- $\hat{P}(j|x)$ is the posterior probability of class j for observation x .
- $C(y|j)$ is the cost of classifying an observation as y when its true class is j .

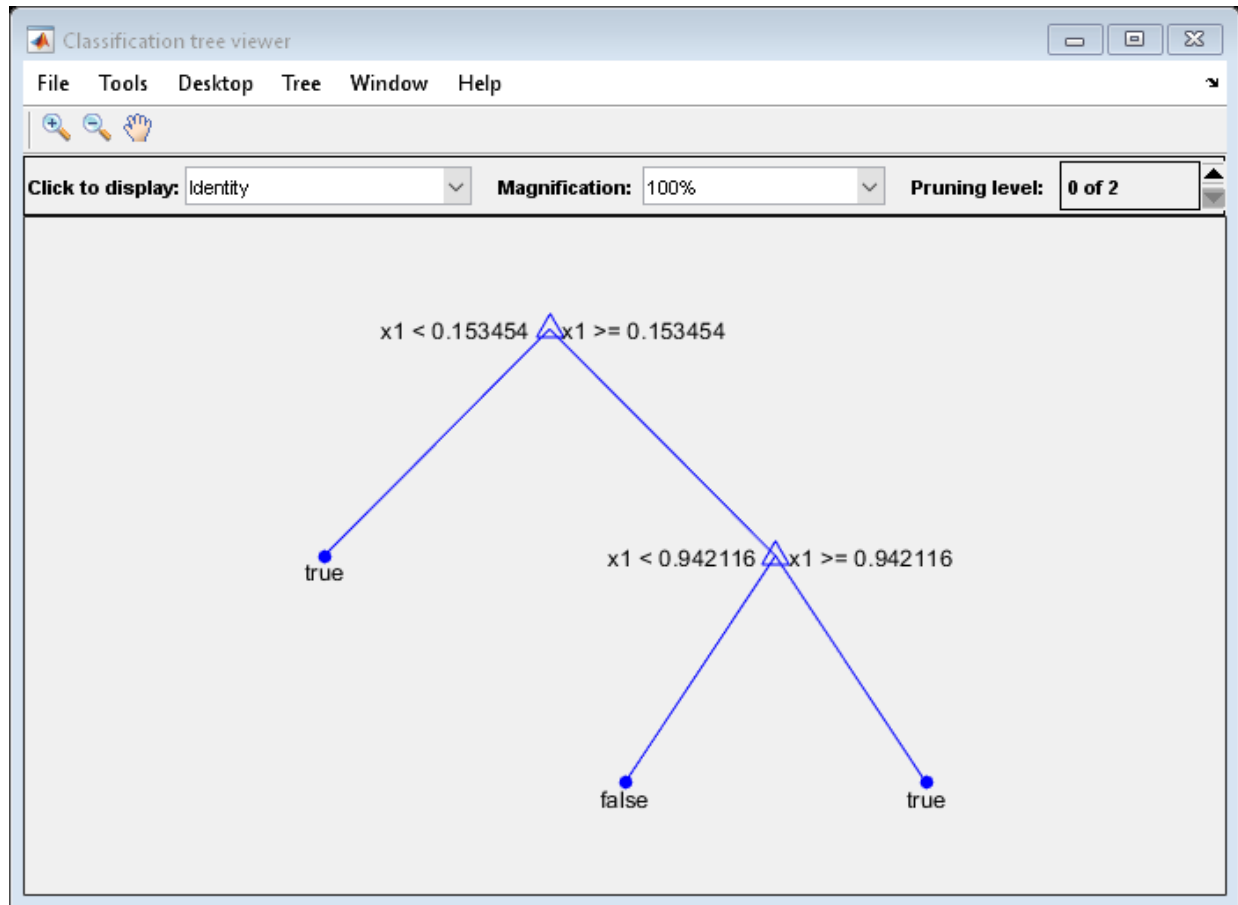

Score (tree)

For trees, the score of a classification of a leaf node is the posterior probability of the classification at that node. The posterior probability of the classification at a node is the number of training sequences that lead to that node with the classification, divided by the number of training sequences that lead to that node.

For example, consider classifying a predictor X as `true` when $X < 0.15$ or $X > 0.95$, and X is false otherwise.

Generate 100 random points and classify them:

```
rng(0, 'twister') % for reproducibility
X = rand(100,1);
Y = (abs(X - .55) > .4);
tree = fitctree(X,Y);
view(tree, 'Mode', 'Graph')
```

Prune the tree:

```
tree1 = prune(tree, 'Level', 1);  
view(tree1, 'Mode', 'Graph')
```

The pruned tree correctly classifies observations that are less than 0.15 as `true`. It also correctly classifies observations from .15 to .94 as `false`. However, it incorrectly classifies observations that are greater than .94 as `false`. Therefore, the score for observations that are greater than .15 should be about $.05/.85 = .06$ for `true`, and about $.8/.85 = .94$ for `false`.

Compute the prediction scores for the first 10 rows of `X`:

```
[~,score] = predict(tree1,X(1:10));  
[score X(1:10,:)]
```

```
ans = 10x3
    0.9059    0.0941    0.8147
    0.9059    0.0941    0.9058
         0     1.0000    0.1270
    0.9059    0.0941    0.9134
    0.9059    0.0941    0.6324
         0     1.0000    0.0975
    0.9059    0.0941    0.2785
    0.9059    0.0941    0.5469
    0.9059    0.0941    0.9575
    0.9059    0.0941    0.9649
```

Indeed, every value of X (the right-most column) that is less than 0.15 has associated scores (the left and center columns) of 0 and 1, while the other values of X have associated scores of 0.91 and 0.09. The difference (score 0.09 instead of the expected .06) is due to a statistical fluctuation: there are 8 observations in X in the range (.95, 1) instead of the expected 5 observations.

True Misclassification Cost

There are two costs associated with classification: the true misclassification cost per class, and the expected misclassification cost per observation.

You can set the true misclassification cost per class in the `Cost` name-value pair when you create the classifier using the `fitctree` method. `Cost(i, j)` is the cost of classifying an observation into class j if its true class is i . By default, `Cost(i, j)=1` if $i \neq j$, and `Cost(i, j)=0` if $i=j$. In other words, the cost is 0 for correct classification, and 1 for incorrect classification.

Expected Cost

There are two costs associated with classification: the true misclassification cost per class, and the expected misclassification cost per observation.

Suppose you have `Nobs` observations that you want to classify with a trained classifier. Suppose you have `K` classes. You place the observations into a matrix `Xnew` with one observation per row.

The expected cost matrix `CE` has size `Nobs`-by-`K`. Each row of `CE` contains the expected (average) cost of classifying the observation into each of the `K` classes. `CE(n, k)` is

$$\sum_{i=1}^K \widehat{P}(i|X_{new}(n))C(k|i),$$

where

- K is the number of classes.
- $\widehat{P}(i|X_{new}(n))$ is the posterior probability of class i for observation $X_{new}(n)$.
- $C(k|i)$ is the true misclassification cost of classifying an observation as k when its true class is i .

Predictive Measure of Association

The predictive measure of association is a value that indicates the similarity between decision rules that split observations. Among all possible decision splits that are compared to the optimal split (found by growing the tree), the best surrogate decision split on page 32-2176 yields the maximum predictive measure of association. The second-best surrogate split has the second-largest predictive measure of association.

Suppose x_j and x_k are predictor variables j and k , respectively, and $j \neq k$. At node t , the predictive measure of association between the optimal split $x_j < u$ and a surrogate split $x_k < v$ is

$$\lambda_{jk} = \frac{\min(P_L, P_R) - (1 - P_{L_j L_k} - P_{R_j R_k})}{\min(P_L, P_R)}.$$

- P_L is the proportion of observations in node t , such that $x_j < u$. The subscript L stands for the left child of node t .
- P_R is the proportion of observations in node t , such that $x_j \geq u$. The subscript R stands for the right child of node t .
- $P_{L_j L_k}$ is the proportion of observations at node t , such that $x_j < u$ and $x_k < v$.
- $P_{R_j R_k}$ is the proportion of observations at node t , such that $x_j \geq u$ and $x_k \geq v$.
- Observations with missing values for x_j or x_k do not contribute to the proportion calculations.

λ_{jk} is a value in $(-\infty, 1]$. If $\lambda_{jk} > 0$, then $x_k < v$ is a worthwhile surrogate split for $x_j < u$.

Algorithms

`predict` generates predictions by following the branches of `Mdl` until it reaches a leaf node or a missing value. If `predict` reaches a leaf node, it returns the classification of that node.

If `predict` reaches a node with a missing value for a predictor, its behavior depends on the setting of the `Surrogate` name-value pair when `fitctree` constructs `Mdl`.

- **Surrogate = 'off'** (default) — `predict` returns the label with the largest number of training samples that reach the node.
- **Surrogate = 'on'** — `predict` uses the best surrogate split at the node. If all surrogate split variables with positive predictive measure of association are missing, `predict` returns the label with the largest number of training samples that reach the node. For a definition, see “Predictive Measure of Association” on page 32-5285.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. For more information, see “Tall Arrays” (MATLAB).

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Use `saveCompactModel`, `loadCompactModel`, and `codegen` to generate code for the `predict` function. Save a trained model by using `saveCompactModel`. Define an entry-point function that loads the saved model by using `loadCompactModel` and calls the `predict` function. Then use `codegen` to generate code for the entry-point function.
- This table contains notes about the arguments of `predict`. Arguments not included in this table are fully supported.

Argument	Notes and Limitations
<code>Mdl</code>	For the usage notes and limitations of the model object, see “Code Generation” on page 32-881 of the <code>CompactClassificationTree</code> object.
<code>X</code>	<ul style="list-style-type: none"> • Must be a single-precision or double-precision matrix and can be variable-size. However, the number of columns in <code>X</code> must be <code>numel(Mdl.PredictorNames)</code>. • Rows and columns must correspond to observations and predictors, respectively.
<code>label</code>	If the response data type is <code>char</code> and <code>codegen</code> cannot determine that the value of <code>Subtrees</code> is a scalar, then <code>label</code> is a cell array of character vectors.
Name-value pair arguments	Names in name-value pair arguments must be compile-time constants. For example, to allow user-defined pruning levels in the generated code, include <code>{coder.Constant('Subtrees'), coder.typeof(0, [1, n], [0, 1])}</code> in the <code>-args</code> value of <code>codegen</code> , where <code>n</code> is <code>max(Mdl.PruneList)</code> .

For more information, see “Introduction to Code Generation” on page 31-2.

Topics

“Specify Variable-Size Arguments for Code Generation” on page 31-58

Introduced in R2011a

predict

Predict responses using ensemble of regression models

Syntax

```
Yfit = predict(Mdl,X)
Yfit = predict(Mdl,X,Name,Value)
```

Description

`Yfit = predict(Mdl,X)` returns predicted responses to the predictor data in the table or matrix `X`, based on the regression ensemble model `Mdl`.

`Yfit = predict(Mdl,X,Name,Value)` uses additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

Mdl

Regression ensemble created by `fitrensemble`, or by the compact method.

X

Predictor data used to generate responses, specified as a numeric matrix or table.

Each row of `X` corresponds to one observation, and each column corresponds to one variable.

- For a numeric matrix:
 - The variables making up the columns of `X` must have the same order as the predictor variables that trained `Mdl`.
 - If you trained `Mdl` using a table (for example, `Tbl`), then `X` can be a numeric matrix if `Tbl` contains all numeric predictor variables. To treat numeric predictors in `Tbl`

as categorical during training, identify categorical predictors using the `CategoricalPredictors` name-value pair argument of `fitrensemble`. If `Tbl` contains heterogeneous predictor variables (for example, numeric and categorical data types) and `X` is a numeric matrix, then `predict` throws an error.

- For a table:
 - `predict` does not support multi-column variables and cell arrays other than cell arrays of character vectors.
 - If you trained `Mdl` using a table (for example, `Tbl`), then all predictor variables in `X` must have the same variable names and data types as those that trained `Mdl` (stored in `Mdl.PredictorNames`). However, the column order of `X` does not need to correspond to the column order of `Tbl`. `Tbl` and `X` can contain additional variables (response variables, observation weights, etc.), but `predict` ignores them.
 - If you trained `Mdl` using a numeric matrix, then the predictor names in `Mdl.PredictorNames` and corresponding predictor variable names in `X` must be the same. To specify predictor names during training, see the `PredictorNames` name-value pair argument of `fitrensemble`. All predictor variables in `X` must be numeric vectors. `X` can contain additional variables (response variables, observation weights, etc.), but `predict` ignores them.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Learners

Indices of weak learners in the ensemble ranging from 1 to `NumTrained`, where `NumTrained` is the number of weak learners.

Default: `1:NumTrained`

UseObsForLearner

A logical matrix of size `N-by-NumTrained`, where `N` is the number of observations in `X`, and `NumTrained` is the number of weak learners. When `UseObsForLearner(I, J)` is true, `predict` uses learner `J` in predicting observation `I`.

Default: true(N, NumTrained)

Output Arguments

Yfit

A numeric column vector with the same number of rows as TBLdata or Xdata. Each row of Yfit gives the predicted response to the corresponding row of TBLdata or Xdata, based on the ens regression model.

Examples

Predict Responses Based on Regression Ensemble

Find the predicted mileage for a car based on regression ensemble trained on the carsmall data.

Load the carsmall data set and select the number of cylinders, engine displacement, horsepower, and vehicle weight as predictors.

```
load carsmall
X = [Cylinders Displacement Horsepower Weight];
```

Train an ensemble of regression trees and predict MPG for a four-cylinder car, with 200 cubic inch engine displacement, 150 horsepower, weighing 3000 lbs.

```
rens = fitensemble(X,MPG);
Mileage = predict(rens,[4 200 150 3000])
```

```
Mileage = 25.6467
```

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. For more information, see “Tall Arrays” (MATLAB).

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Use `saveCompactModel`, `loadCompactModel`, and `codegen` to generate code for the `predict` function. Save a trained model by using `saveCompactModel`. Define an entry-point function that loads the saved model by using `loadCompactModel` and calls the `predict` function. Then use `codegen` to generate code for the entry-point function.
- This table contains notes about the arguments of `predict`. Arguments not included in this table are fully supported.

Argument	Notes and Limitations
<code>Mdl</code>	For the usage notes and limitations of the model object, see “Code Generation” on page 32-914 of the <code>CompactRegressionEnsemble</code> object.
<code>X</code>	<ul style="list-style-type: none"> • Must be a single-precision or double-precision matrix and can be variable-size. However, the number of columns in <code>X</code> must be <code>numel(Mdl.PredictorNames)</code>. • Rows and columns must correspond to observations and predictors, respectively.
Name-value pair arguments	Names in name-value pair arguments must be compile-time constants. For example, to allow user-defined indices up to 5 weak learners in the generated code, include <code>{coder.Constant('Learners'), coder.typeof(0, [1,5], [0,1])}</code> in the <code>-args</code> value of <code>codegen</code> .

For more information, see “Introduction to Code Generation” on page 31-2.

predict

Predict response of Gaussian process regression model

Syntax

```
ypred = predict(gprMdl, Xnew)  
[ypred, ysd] = predict(gprMdl, Xnew)  
[ypred, ysd, yint] = predict(gprMdl, Xnew)  
[ypred, ysd, yint] = predict(gprMdl, Xnew, Name, Value)
```

Description

`ypred = predict(gprMdl, Xnew)` returns the predicted responses `ypred` for the full or compact Gaussian process regression (GPR) model, `gprMdl`, and the predictor values in `Xnew`.

`[ypred, ysd] = predict(gprMdl, Xnew)` also returns the estimated standard deviations for the new responses at the predictor values in `Xnew` from a trained GPR model.

`[ypred, ysd, yint] = predict(gprMdl, Xnew)` also returns the 95% prediction intervals, `yint`, for the true responses corresponding to each row of `Xnew`.

`[ypred, ysd, yint] = predict(gprMdl, Xnew, Name, Value)` also returns the prediction intervals with additional options specified by one or more `Name, Value` pair arguments. For example, you can specify the confidence level of the prediction interval.

Input Arguments

gprMdl — Gaussian process regression model

RegressionGP object | CompactRegressionGP object

Gaussian process regression model, specified as a `RegressionGP` (full) or `CompactRegressionGP` (compact) object.

Xnew — New values for the predictors

table | m -by- d matrix

New values for the predictors that `fitrgp` uses in training the GPR model, specified as a table or an m -by- d matrix. m is the number of observations and d is the number of predictor variables in the training data.

If you trained `gprMdl` on a table, then `Xnew` must be a table that contains all the predictor variables used to train `gprMdl`.

If you trained `gprMdl` on a matrix, then `Xnew` must be a numeric matrix with d columns.

Data Types: single | double | table

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Alpha — Significance level

0.05 (default) | scalar value in the range from 0 to 1

Significance level for the prediction intervals, specified as the comma-separated pair consisting of 'Alpha' and a scalar value in the range from 0 to 1.

Example: 'Alpha', 0.01 specifies 99% prediction intervals.

Data Types: single | double

Output Arguments

ypred — Predicted response values

n -by-1 vector

Predicted response values, returned as an n -by-1 vector.

ysd — Estimated standard deviation of the new response values

n -by-1 vector

Estimated standard deviation of the new response values, returned as an n -by-1 vector, where `ysd(i)`, $i = 1, 2, \dots, n$, contains the estimated standard deviation of the new response corresponding to the predictor values at the i^{th} row of `Xnew` from the trained GPR model.

yint — Prediction intervals for the true response values

n -by-2 matrix

Prediction intervals for the true response values corresponding to each row of `Xnew`, returned as an n -by-2 matrix. The first column of `yint` contains the lower limits and the second column contains the upper limits of the prediction intervals.

Examples

Compute Predicted Responses

Generate the sample data.

```
n = 10000;
rng(1) % For reproducibility
x = linspace(0.5,2.5,n)';
y = sin(10*pi.*x) ./ (2.*x)+(x-1).^4 + 1.5*rand(n,1);
```

Fit a GPR model using the Matern 3/2 kernel function with separate length scale for each predictor and an active set size of 100. Use the subset of regressors approximation method for parameter estimation and fully independent conditional method for prediction.

```
gprMdl = fitrgp(x,y,'KernelFunction','ardmatern32',...
'ActiveSetSize',100,'FitMethod','sr','PredictMethod','fic');
```

Compute the predictions.

```
[ypred,~,yci] = predict(gprMdl,x);
```

Plot the data along with the predictions and prediction intervals.

```
plot(x,y,'r. ');
hold on
plot(x,ypred);
plot(x,yci(:,1),'k--');
plot(x,yci(:,2),'k--');
```

```
xlabel('x');  
ylabel('y');
```

Compute Predictions When Data in Table

Load the sample data and store in a table.

```
load fisheriris  
tbl = table(meas(:,1),meas(:,2),meas(:,3),meas(:,4),species,...  
'VariableNames',{'meas1','meas2','meas3','meas4','species'});
```

Fit a GPR model using the first measurement as the response and the other variables as the predictors.

```
mdl = fitrgp(tbl, 'meas1');
```

Compute the predictions and the 99% confidence intervals.

```
[ypred,~,yci] = predict(mdl,tbl, 'Alpha',0.01);
```

Plot the true response and the predictions along with the prediction intervals.

```
figure();  
plot(mdl.Y, 'r.');
```

```
hold on;  
plot(ypred);  
plot(yci(:,1), 'k:');  
plot(yci(:,2), 'k:');  
legend('True response', 'GPR predictions', ...  
      'Lower prediction limit', 'Upper prediction limit', ...  
      'Location', 'Best');
```

Plot Predicted Response for Test Data

Load the sample data.

```
load(fullfile(matlabroot, 'examples', 'stats', 'gprdata.mat'));
```

The data contains training and test data. There are 500 observations in training data and 100 observations in test data. The data has 8 predictor variables. This is simulated data.

Fit a GPR model using the squared exponential kernel function with a separate length scale for each predictor. Standardize predictors in the training data. Use the exact fitting and prediction methods.

```
gprMdl = fitrgp(Xtrain,ytrain,'Basis','constant',...  
'FitMethod','exact','PredictMethod','exact',...  
'KernelFunction','ardsquaredexponential','Standardize',1);
```

Predict the responses for test data.

```
[ytestpred,~,ytestci] = predict(gprMdl,Xtest);
```

Plot the test response along with the predictions.

```
figure;  
plot(ytest,'r');  
hold on;  
plot(ytestpred,'b');  
plot(ytestci(:,1),'k:');  
plot(ytestci(:,2),'k:');  
legend('Actual response','GPR predictions',...  
'95% lower','95% upper','Location','Best');  
hold off
```

Tips

- You can choose the prediction method while training the GPR model using the `PredictMethod` name-value pair argument in `fitrgp`. The default prediction method is 'exact' for $n \leq 10000$, where n is the number of observations in the training data, and 'bcd' (block coordinate descent), otherwise.
- Computation of standard deviations, `ysd`, and prediction intervals, `yint`, is not supported when `PredictMethod` is 'bcd'.
- If `gprMdl` is a `CompactRegressionGP` object, you cannot compute standard deviations, `ysd`, or prediction intervals, `yint`, for `PredictMethod` equal to 'sr' or

'fic'. To compute `y`sd and `y`int for `PredictMethod` equal to 'sr' or 'fic', use the full regression (`RegressionGP`) object.

Alternatives

You can use `resubPredict` to compute the predicted responses for the trained GPR model at the observations in the training data.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. For more information, see “Tall Arrays” (MATLAB).

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Use `saveCompactModel`, `loadCompactModel`, and `codegen` to generate code for the `predict` function. Save a trained model by using `saveCompactModel`. Define an entry-point function that loads the saved model by using `loadCompactModel` and calls the `predict` function. Then use `codegen` to generate code for the entry-point function.
- This table contains notes about the arguments of `predict`. Arguments not included in this table are fully supported.

Argument	Notes and Limitations
<code>Mdl</code>	For the usage notes and limitations of the model object, see “Code Generation” on page 32-921 of the <code>CompactRegressionGP</code> object.

Argument	Notes and Limitations
X	<ul style="list-style-type: none">• Must be a single-precision or double-precision matrix and can be variable-size. However, the number of columns in Xnew must be <code>numel(gprMdl.PredictorNames)</code>.• Rows and columns must correspond to observations and predictors, respectively.
Name-value pair arguments	Names in name-value pair arguments must be compile-time constants. For example, to allow a user-defined significance level in the generated code, include <code>{coder.Constant('Alpha'),0}</code> in the <code>-args</code> value of <code>codegen</code> .

Introduced in R2015b

predict

Predict responses using support vector machine regression model

Syntax

```
yfit = predict(Mdl,X)
```

Description

`yfit = predict(Mdl,X)` returns a vector of predicted responses for the predictor data in the table or matrix `X`, based on the full or compact, trained support vector machine (SVM) regression model `Mdl`.

Input Arguments

Mdl — SVM regression model

RegressionSVM object | CompactRegressionSVM object

SVM regression model, specified as a `RegressionSVM` model or a `CompactRegressionSVM` model, returned by `fitrsvm` or `compact`, respectively.

X — Predictor data used to generate responses

numeric matrix | table

Predictor data used to generate responses, specified as a numeric matrix or table.

Each row of `X` corresponds to one observation, and each column corresponds to one variable.

- For a numeric matrix:
 - The variables making up the columns of `X` must have the same order as the predictor variables that trained `Mdl`.
 - If you trained `Mdl` using a table (for example, `Tbl`), then `X` can be a numeric matrix if `Tbl` contains all numeric predictor variables. To treat numeric predictors in `Tbl`

as categorical during training, identify categorical predictors using the `CategoricalPredictors` name-value pair argument of `fitrsvm`. If `Tbl` contains heterogeneous predictor variables (for example, numeric and categorical data types) and `X` is a numeric matrix, then `predict` throws an error.

- For a table:
 - `predict` does not support multi-column variables and cell arrays other than cell arrays of character vectors.
 - If you trained `Mdl` using a table (for example, `Tbl`), then all predictor variables in `X` must have the same variable names and data types as those that trained `Mdl` (stored in `Mdl.PredictorNames`). However, the column order of `X` does not need to correspond to the column order of `Tbl`. `Tbl` and `X` can contain additional variables (response variables, observation weights, etc.), but `predict` ignores them.
 - If you trained `Mdl` using a numeric matrix, then the predictor names in `Mdl.PredictorNames` and corresponding predictor variable names in `X` must be the same. To specify predictor names during training, see the `PredictorNames` name-value pair argument of `fitrsvm`. All predictor variables in `X` must be numeric vectors. `X` can contain additional variables (response variables, observation weights, etc.), but `predict` ignores them.

If you set `'Standardize', true` in `fitrsvm` to train `Mdl`, then the software standardizes the columns of `X` using the corresponding means in `Mdl.Mu` and standard deviations in `Mdl.Sigma`.

Data Types: `table` | `double` | `single`

Output Arguments

yfit — Predicted responses

vector

Predicted responses, returned as a vector of length n , where n is the number of observations in the training data.

For details about how to predict responses, see “Equation 25-1” and “Equation 25-2” in “Understanding Support Vector Machine Regression” on page 25-2.

Examples

Predict Test Sample Response for SVM Regression Model

Load the `carsmall` data set. Consider a model that predicts a car's fuel efficiency given its horsepower and weight. Determine the sample size.

```
load carsmall
tbl = table(Horsepower,Weight,MPG);
N = size(tbl,1);
```

Partition the data into training and test sets. Hold out 10% of the data for testing.

```
rng(10); % For reproducibility
cvp = cvpartition(N,'Holdout',0.1);
idxTrn = training(cvp); % Training set indices
idxTest = test(cvp);   % Test set indices
```

Train a linear SVM regression model. Standardize the data.

```
Mdl = fitsvm(tbl(idxTrn,:), 'MPG', 'Standardize', true);
```

`Mdl` is a `RegressionSVM` model.

Predict responses for the test set.

```
YFit = predict(Mdl,tbl(idxTest,:));
```

Create a table containing the observed response values and the predicted response values side by side.

```
table(tbl.MPG(idxTest),YFit,'VariableNames',...
      {'ObservedValue','PredictedValue'})
```

```
ans=10x2 table
  ObservedValue  PredictedValue
  _____  _____
           14           9.4833
           27          28.938
           10           7.765
           28          27.155
           22          21.054
```

29	31.484
24.5	30.306
18.5	19.12
32	28.225
28	26.632

Tips

- If `mdl` is a cross-validated `RegressionPartitionedSVM` model, use `kfoldPredict` instead of `predict` to predict new response values.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. For more information, see “Tall Arrays” (MATLAB).

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- You can generate C/C++ code for both `predict` and `update` by using a coder configurer or generate code only for `predict` by using `saveCompactModel`, `loadCompactModel`, and `codegen`.
 - Code generation for `predict` and `update` — Create a coder configurer by using `learnerCoderConfigurer` and then generate code by using `generateCode`. Then you can update model parameters in the generated code without having to regenerate the code.
 - Code generation for `predict` — Save a trained model by using `saveCompactModel` and define an entry-point function that loads the saved model

by using `loadCompactModel` and calls the `predict` function. Then use `codegen` to generate code for the entry-point function.

- This table contains notes about the arguments of `predict`. Arguments not included in this table are fully supported.

Argument	Notes and Limitations
<code>Mdl</code>	For the usage notes and limitations of the model object, see “Code Generation” on page 32-930 of the <code>CompactRegressionSVM</code> object.
<code>X</code>	<ul style="list-style-type: none">• Must be a single-precision or double-precision matrix and can be variable-size. However, the number of columns in <code>X</code> must be <code>numel(Mdl.PredictorNames)</code>.• Rows and columns must correspond to observations and predictors, respectively.

For more information, see “Introduction to Code Generation” on page 31-2.

`CompactRegressionSVM` | `RegressionSVM` | `fitrsvm` | `kfoldPredict`

Introduced in R2015b

predict

Predict responses using regression tree

Syntax

```
Yfit = predict(Mdl,X)
Yfit = predict(Mdl,X,Name,Value)
[Yfit,node] = predict( ___ )
```

Description

`Yfit = predict(Mdl,X)` returns a vector of predicted responses for the predictor data in the table or matrix `X`, based on the full or compact regression tree `Mdl`.

`Yfit = predict(Mdl,X,Name,Value)` predicts response values with additional options specified by one or more `Name, Value` pair arguments. For example, you can specify to prune `Mdl` to a particular level before predicting responses.

`[Yfit,node] = predict(___)` also returns a vector of predicted node numbers for the responses, using any of the input arguments in the previous syntaxes.

Input Arguments

Mdl — Trained regression tree

`RegressionTree` model object | `CompactRegressionTree` model object

Trained classification tree, specified as a `RegressionTree` or `CompactRegressionTree` model object. That is, `Mdl` is a trained classification model returned by `fitrtree` or `compact`.

X — Predictor data to be classified

numeric matrix | table

Predictor data to be classified, specified as a numeric matrix or table.

Each row of `X` corresponds to one observation, and each column corresponds to one variable.

- For a numeric matrix:
 - The variables making up the columns of `X` must have the same order as the predictor variables that trained `Mdl`.
 - If you trained `Mdl` using a table (for example, `Tbl`), then `X` can be a numeric matrix if `Tbl` contains all numeric predictor variables. To treat numeric predictors in `Tbl` as categorical during training, identify categorical predictors using the `CategoricalPredictors` name-value pair argument of `fitrtree`. If `Tbl` contains heterogeneous predictor variables (for example, numeric and categorical data types) and `X` is a numeric matrix, then `predict` throws an error.
- For a table:
 - `predict` does not support multi-column variables and cell arrays other than cell arrays of character vectors.
 - If you trained `Mdl` using a table (for example, `Tbl`), then all predictor variables in `X` must have the same variable names and data types as those that trained `Mdl` (stored in `Mdl.PredictorNames`). However, the column order of `X` does not need to correspond to the column order of `Tbl`. `Tbl` and `X` can contain additional variables (response variables, observation weights, etc.), but `predict` ignores them.
 - If you trained `Mdl` using a numeric matrix, then the predictor names in `Mdl.PredictorNames` and corresponding predictor variable names in `X` must be the same. To specify predictor names during training, see the `PredictorNames` name-value pair argument of `fitrtree`. All predictor variables in `X` must be numeric vectors. `X` can contain additional variables (response variables, observation weights, etc.), but `predict` ignores them.

Data Types: `table` | `double` | `single`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Subtrees — Pruning level

0 (default) | vector of nonnegative integers | 'all'

Pruning level, specified as the comma-separated pair consisting of 'Subtrees' and a vector of nonnegative integers in ascending order or 'all'.

If you specify a vector, then all elements must be at least 0 and at most $\max(\text{Mdl.PruneList})$. 0 indicates the full, unpruned tree and $\max(\text{Mdl.PruneList})$ indicates the completely pruned tree (i.e., just the root node).

If you specify 'all', then `predict` operates on all subtrees (i.e., the entire pruning sequence). This specification is equivalent to using $0:\max(\text{Mdl.PruneList})$.

`predict` prunes `Mdl` to each level indicated in `Subtrees`, and then estimates the corresponding output arguments. The size of `Subtrees` determines the size of some output arguments.

To invoke `Subtrees`, the properties `PruneList` and `PruneAlpha` of `Mdl` must be nonempty. In other words, grow `Mdl` by setting 'Prune', 'on', or by pruning `Mdl` using `prune`.

Example: 'Subtrees', 'all'

Data Types: single | double | char | string

Output Arguments

Yfit — Predicted response values

numeric column vector

Predicted response values, returned as a numeric column vector with the same number of rows as `X`. Each row of `Yfit` gives the predicted response to the corresponding row of `X`, based on the `Mdl`.

node — Node numbers

numeric vector

Node numbers for the predictions, specified as a numeric vector. Each entry corresponds to the predicted leaf node in `Mdl` for the corresponding row of `X`.

Examples

Predict a Response Using a Regression Tree

Load the `carsmall` data set. Consider Displacement, Horsepower, and Weight as predictors of the response MPG.

```
load carsmall
X = [Displacement Horsepower Weight];
```

Grow a regression tree using the entire data set.

```
Mdl = fitrtree(X,MPG);
```

Predict the MPG for a car with 200 cubic inch engine displacement, 150 horsepower, and that weighs 3000 lbs.

```
X0 = [200 150 3000];
MPG0 = predict(Mdl,X0)
```

```
MPG0 = 21.9375
```

The regression tree predicts the car's efficiency to be 21.94 mpg.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. For more information, see “Tall Arrays” (MATLAB).

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Use `saveCompactModel`, `loadCompactModel`, and `codegen` to generate code for the `predict` function. Save a trained model by using `saveCompactModel`. Define an entry-point function that loads the saved model by using `loadCompactModel` and calls the `predict` function. Then use `codegen` to generate code for the entry-point function.
- This table contains notes about the arguments of `predict`. Arguments not included in this table are fully supported.

Argument	Notes and Limitations
Mdl	For the usage notes and limitations of the model object, see “Code Generation” on page 32-938 of the <code>CompactRegressionTree</code> object.
X	<ul style="list-style-type: none"> • Must be a single-precision or double-precision matrix and can be variable-size. However, the number of columns in X must be <code>numel(Mdl.PredictorNames)</code>. • Rows and columns must correspond to observations and predictors, respectively.
Name-value pair arguments	Names in name-value pair arguments must be compile-time constants. For example, to allow user-defined pruning levels in the generated code, include <code>{coder.Constant('Subtrees'), coder.typeof(0, [1, n], [0, 1])}</code> in the <code>-args</code> value of <code>codegen</code> , where n is <code>max(Mdl.PruneList)</code> .

For more information, see “Introduction to Code Generation” on page 31-2.

Introduced in R2011a

predict

Class: RegressionLinear

Predict response of linear regression model

Syntax

```
YHat = predict(Mdl,X)
YHat = predict(Mdl,X,Name,Value)
```

Description

`YHat = predict(Mdl,X)` returns predicted responses for each observation in the predictor data `X` based on the trained linear regression model `Mdl`. `YHat` contains responses for each regularization strength in `Mdl`.

`YHat = predict(Mdl,X,Name,Value)` returns predicted responses with additional options specified by one or more `Name, Value` pair arguments. For example, specify that columns in the predictor data correspond to observations.

Input Arguments

Mdl — Linear regression model

RegressionLinear model object

Linear regression model, specified as a RegressionLinear model object. You can create a RegressionLinear model object using `fitrlinear`.

X — Predictor data

full matrix | sparse matrix

Predictor data, specified as an n -by- p full or sparse matrix. This orientation of `X` indicates that rows correspond to individual observations, and columns correspond to individual predictor variables.

Note If you orient your predictor matrix so that observations correspond to columns and specify 'ObservationsIn', 'columns', then you might experience a significant reduction in computation time.

The length of Y and the number of observations in X must be equal.

Data Types: single | double

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

ObservationsIn — Predictor data observation dimension

'rows' (default) | 'columns'

Predictor data observation dimension, specified as the comma-separated pair consisting of 'ObservationsIn' and 'columns' or 'rows'.

Note If you orient your predictor matrix so that observations correspond to columns and specify 'ObservationsIn', 'columns', then you might experience a significant reduction in optimization-execution time.

Output Arguments

YHat — Predicted responses

numeric matrix

Predicted responses, returned as a n -by- L numeric matrix. n is the number of observations in X and L is the number of regularization strengths in `Mdl.Lambda`. $\text{YHat}(i, j)$ is the response for observation i using the linear regression model that has regularization strength `Mdl.Lambda(j)`.

The predicted response using the model with regularization strength j is $\hat{y}_j = x\beta_j + b_j$.

- x is an observation from the predictor data matrix X, and is row vector.

- β_j is the estimated column vector of coefficients. The software stores this vector in `Mdl.Beta(:,j)`.
- b_j is the estimated, scalar bias, which the software stores in `Mdl.Bias(j)`.

Examples

Predict Test-Sample Responses

Simulate 10000 observations from this model

$$y = x_{100} + 2x_{200} + e.$$

- $X = x_1, \dots, x_{1000}$ is a 10000-by-1000 sparse matrix with 10% nonzero standard normal elements.
- e is random normal error with mean 0 and standard deviation 0.3.

```
rng(1) % For reproducibility
n = 1e4;
d = 1e3;
nz = 0.1;
X = sprandn(n,d,nz);
Y = X(:,100) + 2*X(:,200) + 0.3*randn(n,1);
```

Train a linear regression model. Reserve 30% of the observations as a holdout sample.

```
CVMDL = fitrlinear(X,Y,'Holdout',0.3);
Mdl = CVMDL.Trained{1}
```

```
Mdl =
  RegressionLinear
    ResponseName: 'Y'
  ResponseTransform: 'none'
           Beta: [1000x1 double]
           Bias: -0.0066
           Lambda: 1.4286e-04
           Learner: 'svm'
```

Properties, Methods

CVMdl is a `RegressionPartitionedLinear` model. It contains the property `Trained`, which is a 1-by-1 cell array holding a `RegressionLinear` model that the software trained using the training set.

Extract the training and test data from the partition definition.

```
trainIdx = training(CVMdl.Partition);
testIdx = test(CVMdl.Partition);
```

Predict the training- and test-sample responses.

```
yHatTrain = predict(Mdl,X(trainIdx,:));
yHatTest = predict(Mdl,X(testIdx,:));
```

Because there is one regularization strength in `Mdl`, `yHatTrain` and `yHatTest` are numeric vectors.

Predict from Best-Performing Model

Predict responses from the best-performing, linear regression model that uses a lasso-penalty and least squares.

Simulate 10000 observations as in “Predict Test-Sample Responses” on page 32-5314.

```
rng(1) % For reproducibility
n = 1e4;
d = 1e3;
nz = 0.1;
X = sprandn(n,d,nz);
Y = X(:,100) + 2*X(:,200) + 0.3*randn(n,1);
```

Create a set of 15 logarithmically-spaced regularization strengths from 10^{-5} through 10^{-1} .

```
Lambda = logspace(-5,-1,15);
```

Cross-validate the models. To increase execution speed, transpose the predictor data and specify that the observations are in columns. Optimize the objective function using `SpaRSA`.

```
X = X';
CVMdl = fitrlinear(X,Y,'ObservationsIn','columns','KFold',5,'Lambda',Lambda,...
```

```
    'Learner','leastsquares','Solver','sparsa','Regularization','lasso');  
numCLModels = numel(CVMdl.Trained)  
  
numCLModels = 5
```

CVMdl is a `RegressionPartitionedLinear` model. Because `fitrlinear` implements 5-fold cross-validation, CVMdl contains 5 `RegressionLinear` models that the software trains on each fold.

Display the first trained linear regression model.

```
Mdl1 = CVMdl.Trained{1}  
  
Mdl1 =  
    RegressionLinear  
        ResponseName: 'Y'  
        ResponseTransform: 'none'  
            Beta: [1000x15 double]  
            Bias: [1x15 double]  
            Lambda: [1x15 double]  
        Learner: 'leastsquares'
```

Properties, Methods

Mdl1 is a `RegressionLinear` model object. `fitrlinear` constructed Mdl1 by training on the first four folds. Because `Lambda` is a sequence of regularization strengths, you can think of Mdl1 as 11 models, one for each regularization strength in `Lambda`.

Estimate the cross-validated MSE.

```
mse = kfoldLoss(CVMdl);
```

Higher values of `Lambda` lead to predictor variable sparsity, which is a good quality of a regression model. For each regularization strength, train a linear regression model using the entire data set and the same options as when you cross-validated the models. Determine the number of nonzero coefficients per model.

```
Mdl = fitrlinear(X,Y,'ObservationsIn','columns','Lambda',Lambda,...  
    'Learner','leastsquares','Solver','sparsa','Regularization','lasso');  
numNZCoeff = sum(Mdl.Beta~=0);
```

In the same figure, plot the cross-validated MSE and frequency of nonzero coefficients for each regularization strength. Plot all variables on the log scale.

```
figure;
[h,hL1,hL2] = plotyy(log10(Lambda),log10(mse),...
    log10(Lambda),log10(numNZCoeff));
hL1.Marker = 'o';
hL2.Marker = 'o';
ylabel(h(1),'log_{10} MSE')
ylabel(h(2),'log_{10} nonzero-coefficient frequency')
xlabel('log_{10} Lambda')
hold off
```

Choose the index of the regularization strength that balances predictor variable sparsity and low MSE (for example, `Lambda(10)`).

```
idxFinal = 10;
```

Extract the model with corresponding to the minimal MSE.

```
MdlFinal = selectModels(Mdl,idxFinal)
```

```
MdlFinal =  
  RegressionLinear  
    ResponseName: 'Y'  
    ResponseTransform: 'none'  
      Beta: [1000x1 double]  
      Bias: -0.0050  
      Lambda: 0.0037  
      Learner: 'leastquares'
```

Properties, Methods

```
idxNZCoeff = find(MdlFinal.Beta~=0)
```

```
idxNZCoeff = 2×1
```

```
 100  
 200
```

```
EstCoeff = Mdl.Beta(idxNZCoeff)
```

```
EstCoeff = 2×1
```

```
 1.0051  
 1.9965
```

`MdlFinal` is a `RegressionLinear` model with one regularization strength. The nonzero coefficients `EstCoeff` are close to the coefficients that simulated the data.

Simulate 10 new observations, and predict corresponding responses using the best-performing model.

```
XNew = sprandn(d,10,nz);  
YHat = predict(MdlFinal,XNew,'ObservationsIn','columns');
```

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. For more information, see “Tall Arrays” (MATLAB).

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Use `saveCompactModel`, `loadCompactModel`, and `codegen` to generate code for the `predict` function. Save a trained model by using `saveCompactModel`. Define an entry-point function that loads the saved model by using `loadCompactModel` and calls the `predict` function. Then use `codegen` to generate code for the entry-point function.
- This table contains notes about the arguments of `predict`. Arguments not included in this table are fully supported.

Argument	Notes and Limitations
<code>Mdl</code>	For the usage notes and limitations of the model object, see “Code Generation” on page 32-5810 of the <code>RegressionLinear</code> object.

Argument	Notes and Limitations
X	<ul style="list-style-type: none"> • Must be a single-precision or double-precision matrix and can be variable-size. • If you specify 'ObservationsIn', 'rows' (default), then the number of columns in X must be <code>numel(Mdl.PredictorNames)</code>. Rows and columns must correspond to observations and predictors, respectively. • If you specify 'ObservationsIn', 'columns', then the number of rows in X must be <code>numel(Mdl.PredictorNames)</code>. Rows and columns must correspond to predictors and observations, respectively.
Name-value pair arguments	<ul style="list-style-type: none"> • Names in name-value pair arguments must be compile-time constants. • The value for the 'ObservationsIn' name-value pair argument must be a compile-time constant. `RegressionLinear` | `fitrlinear`

Introduced in R2016a

predict

Class: CompactTreeBagger

Predict responses using ensemble of bagged decision trees

Syntax

```
Yfit = predict(B,X)
Yfit = predict(B,X,Name,Value)
[Yfit,stdevs] = predict( ___ )
[Yfit,scores] = predict( ___ )
[Yfit,scores,stdevs] = predict( ___ )
```

Description

`Yfit = predict(B,X)` returns a vector of predicted responses for the predictor data in the table or matrix `X`, based on the compact ensemble of bagged decision trees `B`. `Yfit` is a cell array of character vectors for classification and a numeric array for regression. By default, `predict` takes a democratic (nonweighted) average vote from all trees in the ensemble.

`B` is a trained `CompactTreeBagger` model object, that is, a model returned by `compact`.

`X` is a table or matrix of predictor data used to generate responses. Rows represent observations and columns represent variables.

- If `X` is a numeric matrix:
 - The variables making up the columns of `X` must have the same order as the predictor variables that trained `B`.
 - If you trained `B` using a table (for example, `Tbl`), then `X` can be a numeric matrix if `Tbl` contains all numeric predictor variables. To treat numeric predictors in `Tbl` as categorical during training, identify categorical predictors using the `CategoricalPredictors` name-value pair argument of `TreeBagger`. If `Tbl` contains heterogeneous predictor variables (for example, numeric and categorical data types) and `X` is a numeric matrix, then `predict` throws an error.

- If `X` is a table:
 - `predict` does not support multi-column variables and cell arrays other than cell arrays of character vectors.
 - If you trained `B` using a table (for example, `Tbl`), then all predictor variables in `X` must have the same variable names and be of the same data types as those that trained `B` (stored in `B.PredictorNames`). However, the column order of `X` does not need to correspond to the column order of `Tbl`. `Tbl` and `X` can contain additional variables (response variables, observation weights, etc.), but `predict` ignores them.
 - If you trained `B` using a numeric matrix, then the predictor names in `B.PredictorNames` and corresponding predictor variable names in `X` must be the same. To specify predictor names during training, see the `PredictorNames` name-value pair argument of `TreeBagger`. All predictor variables in `X` must be numeric vectors. `X` can contain additional variables (response variables, observation weights, etc.), but `predict` ignores them.

`Yfit = predict(B,X,Name,Value)` specifies additional options using one or more name-value pair arguments:

- `'Trees'` — Array of tree indices to use for computation of responses. The default is `'all'`.
- `'TreeWeights'` — Array of `NTrees` weights for weighting votes from the specified trees, where `NTrees` is the number of trees in the ensemble.
- `'UseInstanceForTree'` — Logical matrix of size `Nobs-by-NTrees` indicating which trees to use to make predictions for each observation, where `Nobs` is the number of observations. By default all trees are used for all observations.

For regression, `[Yfit,stdevs] = predict(____)` also returns standard deviations of the computed responses over the ensemble of the grown trees using any of the input argument combinations in previous syntaxes.

For classification, `[Yfit,scores] = predict(____)` also returns scores for all classes. `scores` is a matrix with one row per observation and one column per class. For each observation and each class, the score generated by each tree is the probability of the observation originating from the class, computed as the fraction of observations of the class in a tree leaf. `predict` averages these scores over all trees in the ensemble.

`[Yfit,scores,stdevs] = predict(____)` also returns standard deviations of the computed scores for classification. `stdevs` is a matrix with one row per observation and

one column per class, with standard deviations taken over the ensemble of the grown trees.

Algorithms

- For regression problems, the predicted response for an observation is the weighted average of the predictions using selected trees only. That is,

$$\hat{y}_{\text{bag}} = \frac{1}{\sum_{t=1}^T \alpha_t I(t \in S)} \sum_{t=1}^T \alpha_t \hat{y}_t I(t \in S).$$

- \hat{y}_t is the prediction from tree t in the ensemble.
 - S is the set of indices of selected trees that comprise the prediction (see 'Trees' and 'UseInstanceForTree'). $I(t \in S)$ is 1 if t is in the set S , and 0 otherwise.
 - α_t is the weight of tree t (see 'TreeWeights').
- For classification problems, the predicted class for an observation is the class that yields the largest weighted average of the class posterior probabilities (i.e., classification scores) computed using selected trees only. That is,
 - 1 For each class $c \in C$ and each tree $t = 1, \dots, T$, `predict` computes $\hat{P}_t(c|x)$, which is the estimated posterior probability of class c given observation x using tree t . C is the set of all distinct classes in the training data. For more details on classification tree posterior probabilities, see `fitctree` and `predict`.
 - 2 `predict` computes the weighted average of the class posterior probabilities over the selected trees.

$$\hat{P}_{\text{bag}}(c|x) = \frac{1}{\sum_{t=1}^T \alpha_t I(t \in S)} \sum_{t=1}^T \alpha_t \hat{P}_t(c|x) I(t \in S).$$

- 3 The predicted class is the class that yields the largest weighted average.

$$\hat{y}_{\text{bag}} = \operatorname{argmax}_{c \in C} \{ \hat{P}_{\text{bag}}(c|x) \}.$$

“Bootstrap Aggregation (Bagging) of Classification Trees Using TreeBagger” on page 18-158

predict

Predict response of generalized linear regression model

Syntax

```
ypred = predict mdl, Xnew  
[ypred, yci] = predict mdl, Xnew  
[ypred, yci] = predict mdl, Xnew, Name, Value
```

Description

`ypred = predict(mdl, Xnew)` returns the predicted response of the `mdl` generalized linear regression model to the points in `Xnew`.

`[ypred, yci] = predict(mdl, Xnew)` returns confidence intervals for the true mean responses.

`[ypred, yci] = predict(mdl, Xnew, Name, Value)` predicts responses with additional options specified by one or more `Name, Value` pair arguments.

Input Arguments

`mdl`

Generalized linear model, specified as a full `GeneralizedLinearModel` object constructed using `fitglm` or `stepwiseglm`, or a compacted `CompactGeneralizedLinearModel` object constructed using `compact`.

`Xnew`

Points at which `mdl` predicts responses.

- If `Xnew` is a table or dataset array, it must contain the predictor names in `mdl`.

- If `Xnew` is a numeric matrix, it must have the same number of variables (columns) as was used to create `mdl`. Furthermore, all variables used in creating `mdl` must be numeric.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Alpha

Positive scalar from 0 to 1. Confidence level of `yci` is $100(1 - \text{alpha})\%$.

Default: 0.05, meaning a 95% confidence interval.

BinomialSize

Value of the binomial n parameter for each row in the training data. `BinomialSize` can be a vector the same length as `Xnew`, or a scalar that applies to each row. The default value 1 produces `ypred` values that are predicted proportions. Use `BinomialSize` only if `mdl` is fit to a binomial distribution.

Default: 1

Offset

Value of the offset for each row in `Xnew`. `Offset` can be a vector the same length as `Xnew`, or a scalar that applies to each row. The offset is used as an additional predictor with a coefficient value fixed at 1. In other words, if `b` is the fitted coefficient vector, and `link` is the link function,

$$\text{link}(\text{ypred}) = \text{Offset} + \text{Xnew} * \mathbf{b}.$$

Default: `zeros(size(Xnew,1))`

Simultaneous

Logical value specifying whether the confidence bounds are for all predictor values simultaneously (`true`), or hold for each individual predictor value (`false`). Simultaneous bounds are wider than separate bounds, because it is more stringent to require that the

entire curve be within the bounds than to require that the curve at a single predictor value be within the bounds.

For details, see `polyconf`.

Default: `false`

Output Arguments

ypred

Vector of predicted mean values at `Xnew`.

yci

Confidence intervals, a two-column matrix with each row providing one interval. The meaning of the confidence interval depends on the settings of the name-value pairs.

Examples

Generalized Linear Model Predictions

Create a generalized linear model, and predict its response to new data.

Generate artificial data for the model using Poisson random numbers with two underlying predictors `X(1)` and `X(2)`.

```
rng('default') % For reproducibility
rndvars = randn(100,2);
X = [2+rndvars(:,1),rndvars(:,2)];
mu = exp(1 + X*[1;2]);
y = poissrnd(mu);
```

Create a generalized linear regression model of Poisson data.

```
mdl = fitglm(X,y,'y ~ x1 + x2','distr','poisson');
```

Create points for prediction.

```
[Xtest1 Xtest2] = meshgrid(-1:.5:3,-2:.5:2);  
Xnew = [Xtest1(:),Xtest2(:)];
```

Predict responses at the new points.

```
ypred = predict mdl,Xnew;
```

Plot the predictions.

```
surf(Xtest1,Xtest2,reshape(ypred,9,9))
```

Create confidence intervals on the predictions.

```
[ypred yci] = predict mdl,Xnew;
```

Generate Code from Function That Predicts Responses Given New Data

Train a generalized linear model, and then generate code from a function that classifies new observations based on the model. This example is based on the “Generalized Linear Model Predictions” on page 32-5327 example.

Generate artificial data.

```
rng('default') % For reproducibility
rndvars = randn(100,2);
X = [2+rndvars(:,1),rndvars(:,2)];
mu = exp(1 + X*[1;2]);
y = poissrnd(mu);
```

Create a generalized linear regression model. Specify that the distribution of the response is Poisson.

```
mdl = fitglm(X,y,'y ~ x1 + x2','Distribution','poisson');
```

Create points for prediction.

```
[Xtest1 Xtest2] = meshgrid(-1:.5:3,-2:.5:2);
Xnew = [Xtest1(:),Xtest2(:)];
```

Save the fitted generalized linear model to the file `GLMMdl.mat`.

```
saveCompactModel(mdl,'GLMMdl');
```

Define a function in your working folder called `mypredictGLM.m` that:

- Accepts measurements with columns corresponding to those in `Xnew` and valid name-value pair arguments
- Loads the fitted generalized linear model in `GLMMdl.mat`
- Returns predictions and confidence interval bounds

```
function [yhat,ci] = mypredictGLM(x,varargin) %#codegen
%MYPREDICTGLM Predict response using GLM model
% MYPREDICTGLM predicts responses for the n observations in the n-by-1
% vector x using using the GLM model stored in the MAT-file GLMMdl.mat,
% and then returns the predictions in the n-by-1 vector yhat.
% MYPREDICTGLM also returns confidence interval bounds for the
```

```
% predictions in the n-by-2 vector ci.  
CompactMdl = loadCompactModel('GLMMdl');  
narginchk(1,Inf);  
[yhat,ci] = predict(CompactMdl,x,varargin{:});  
end
```

Generate a MEX function from `mypredictGLM.m`. Specify returning 90% simultaneous confidence intervals on the predictions. Because C uses static typing, `codegen` must determine the properties of all variables in MATLAB® files at compile time. To designate arguments as compile-time constants, use `coder.Constant`.

```
codegen -config:mex mypredictGLM -args {Xnew,coder.Constant('Alpha'),0.1,coder.Constant
```

The MEX file `mypredictGLM_mex.mexw64` generates to your working directory. The file extension depends on your system platform.

Compare predictions by using `predict` and `mypredictGLM_mex`. Specify name-value pair arguments in the same order as in the `-args` argument in the call to `codegen`.

```
[yhat1,ci1] = predict mdl,Xnew,'Alpha',0.1,'Simultaneous',true);  
[yhat2,ci2] = mypredictGLM_mex(Xnew,'Alpha',0.1,'Simultaneous',true);  
  
comp1 = (yhat1 - yhat2)'*(yhat1 - yhat2);  
comp2 = diag((ci1 - ci2)'*(ci1 - ci2));  
agree1 = comp1 < eps  
agree2 = comp2 < eps
```

```
agree1 =
```

```
logical
```

```
1
```

```
agree2 =
```

```
2x1 logical array
```

```
1
```

```
1
```

The generated MEX file produces the same predictions as `predict`.

Tips

- For predictions with added noise, use `random`.
- For a syntax that can be easier to use with models created from dataset arrays, try `feval`.

Alternatives

`feval` returns the same predictions, but uses separate input arrays for each predictor, instead of one input array containing all predictors.

`random` returns predictions with added noise.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Use `saveCompactModel`, `loadCompactModel`, and `codegen` to generate code for the `predict` function. Save a trained model by using `saveCompactModel`. Define an entry-point function that loads the saved model by using `loadCompactModel` and calls the `predict` function. Then use `codegen` to generate code for the entry-point function.
- This table contains notes about the arguments of `predict`. Arguments not included in this table are fully supported.

Argument	Notes and Limitations
<code>mdl</code>	For the usage notes and limitations of the model object, see “Code Generation” on page 32-907 of the <code>CompactGeneralizedLinearModel</code> object.
<code>Xnew</code>	<ul style="list-style-type: none"> • Must be a single-precision or double-precision matrix and can be variable-size. However, the number of columns in <code>Xnew</code> must be <code>numel(mdl.PredictorNames)</code>. • Rows and columns must correspond to observations and predictors, respectively.
Name-value pair arguments	Names in name-value pair arguments must be compile-time constants. For example, to allow a user-defined significance level in the generated code, include <code>{coder.Constant('Alpha'),0}</code> in the <code>-args</code> value of <code>codegen</code> .

For more information, see “Introduction to Code Generation” on page 31-2.

Introduced in R2012a

predict

Class: GeneralizedLinearMixedModel

Predict response of generalized linear mixed-effects model

Syntax

```
ypred = predict(glme)
ypred = predict(glme, tblnew)
ypred = predict( ____, Name, Value)
[ypred, ypredCI] = predict( ____)
[ypred, ypredCI, DF] = predict( ____)
```

Description

`ypred = predict(glme)` returns the predicted conditional means of the response, `ypred`, using the original predictor values used to fit the generalized linear mixed-effects model `glme`.

`ypred = predict(glme, tblnew)` returns the predicted conditional means using the new predictor values specified in `tblnew`.

If a grouping variable in `tblnew` has levels that are not in the original data, then the random effects for that grouping variable do not contribute to the 'Conditional' prediction at observations where the grouping variable has new levels.

`ypred = predict(____, Name, Value)` returns the predicted conditional means of the response using additional options specified by one or more `Name, Value` pair arguments. For example, you can specify the confidence level, simultaneous confidence bounds, or contributions from only fixed effects. You can use any of the input arguments in the previous syntaxes.

`[ypred, ypredCI] = predict(____)` also returns 95% point-wise confidence intervals, `ypredCI`, for each predicted value.

[ypred,ypredCI,DF] = predict(___) also returns the degrees of freedom, DF, used to compute the confidence intervals.

Input Arguments

glme — Generalized linear mixed-effects model

GeneralizedLinearMixedModel object

Generalized linear mixed-effects model, specified as a GeneralizedLinearMixedModel object. For properties and methods of this object, see GeneralizedLinearMixedModel.

tblnew — New input data

table | dataset array

New input data, which includes the response variable, predictor variables, and grouping variables on page 2-57, specified as a table or dataset array. The predictor variables can be continuous or grouping variables. `tblnew` must have the same variables as the original table or dataset array used in `fitglme` to fit the generalized linear mixed-effects model `glme`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Alpha — Significance level

0.05 (default) | scalar value in the range [0,1]

Significance level, specified as the comma-separated pair consisting of 'Alpha' and a scalar value in the range [0,1]. For a value α , the confidence level is $100 \times (1 - \alpha)\%$.

For example, for 99% confidence intervals, you can specify the confidence level as follows.

Example: 'Alpha',0.01

Data Types: single | double

Conditional — Indicator for conditional predictions

true (default) | false

Indicator for conditional predictions, specified as the comma-separated pair consisting of 'Conditional' and one of the following.

Value	Description
true	Contributions from both fixed effects and random effects (conditional)
false	Contribution from only fixed effects (marginal)

Example: 'Conditional', false

DFMethod — Method for computing approximate degrees of freedom

'residual' (default) | 'none'

Method for computing approximate degrees of freedom, specified as the comma-separated pair consisting of 'DFMethod' and one of the following.

Value	Description
'residual'	The degrees of freedom value is assumed to be constant and equal to $n - p$, where n is the number of observations and p is the number of fixed effects.
'none'	The degrees of freedom is set to infinity.

Example: 'DFMethod', 'none'

Offset — Model offsetzeros($m, 1$) (default) | m -by-1 vector of scalar values

Model offset, specified as a vector of scalar values of length m , where m is the number of rows in `tblnew`. The offset is used as an additional predictor and has a coefficient value fixed at 1.

Simultaneous — Type of confidence bounds

false (default) | true

Type of confidence bounds, specified as the comma-separated pair consisting of 'Simultaneous' and either false or true.

- If 'Simultaneous' is false, then `predict` computes nonsimultaneous confidence bounds.
- If 'Simultaneous' is true, `predict` returns simultaneous confidence bounds.

Example: `'Simultaneous', true`

Output Arguments

ypred — Predicted responses

vector

Predicted responses, returned as a vector. If the 'Conditional' name-value pair argument is specified as `true`, `ypred` contains predictions for the conditional means of the responses given the random effects. Conditional predictions include contributions from both fixed and random effects. Marginal predictions include only contributions from fixed effects.

To compute marginal predictions, `predict` computes conditional predictions, but substitutes a vector of zeros in place of the empirical Bayes predictors (EBPs) of the random effects.

ypredCI — Point-wise confidence intervals

two-column matrix

Point-wise confidence intervals for the predicted values, returned as a two-column matrix. The first column of `ypredCI` contains the lower bound, and the second column contains the upper bound. By default, `ypredCI` contains the 95% nonsimultaneous confidence intervals for the predictions. You can change the confidence level using the `Alpha` name-value pair argument, and make them simultaneous using the `Simultaneous` name-value pair argument.

When fitting a GLME model using `fitglme` and one of the maximum likelihood fit methods ('Laplace' or 'ApproximateLaplace'), `predict` computes the confidence intervals using the conditional mean squared error of prediction (CMSEP) approach conditional on the estimated covariance parameters and the observed response. Alternatively, you can interpret the confidence intervals as approximate Bayesian credible intervals conditional on the estimated covariance parameters and the observed response.

When fitting a GLME model using `fitglme` and one of the pseudo likelihood fit methods ('MPL' or 'REML'), `predict` bases the computations on the fitted linear mixed-effects model from the final pseudo likelihood iteration.

DF — Degrees of freedom

vector | scalar value

Degrees of freedom used in computing the confidence intervals, returned as a vector or a scalar value.

- If 'Simultaneous' is false, then DF is a vector.
- If 'Simultaneous' is true, then DF is a scalar value.

Examples

Predict Responses at Original Design Values

Load the sample data.

```
load mfr
```

This simulated data is from a manufacturing company that operates 50 factories across the world, with each factory running a batch process to create a finished product. The company wants to decrease the number of defects in each batch, so it developed a new manufacturing process. To test the effectiveness of the new process, the company selected 20 of its factories at random to participate in an experiment: Ten factories implemented the new process, while the other ten continued to run the old process. In each of the 20 factories, the company ran five batches (for a total of 100 batches) and recorded the following data:

- Flag to indicate whether the batch used the new process (`newprocess`)
- Processing time for each batch, in hours (`time`)
- Temperature of the batch, in degrees Celsius (`temp`)
- Categorical variable indicating the supplier (A, B, or C) of the chemical used in the batch (`supplier`)
- Number of defects in the batch (`defects`)

The data also includes `time_dev` and `temp_dev`, which represent the absolute deviation of time and temperature, respectively, from the process standard of 3 hours at 20 degrees Celsius.

Fit a generalized linear mixed-effects model using `newprocess`, `time_dev`, `temp_dev`, and `supplier` as fixed-effects predictors. Include a random-effects term for intercept grouped by `factory`, to account for quality differences that might exist due to factory-specific variations. The response variable `defects` has a Poisson distribution, and the appropriate link function for this model is log. Use the Laplace fit method to estimate the coefficients. Specify the dummy variable encoding as `'effects'`, so the dummy variable coefficients sum to 0.

The number of defects can be modeled using a Poisson distribution:

$$\text{defects}_{ij} \sim \text{Poisson}(\mu_{ij})$$

This corresponds to the generalized linear mixed-effects model

$$\log(\mu_{ij}) = \beta_0 + \beta_1 \text{newprocess}_{ij} + \beta_2 \text{time_dev}_{ij} + \beta_3 \text{temp_dev}_{ij} + \beta_4 \text{supplier_C}_{ij} + \beta_5 \text{supplier_B}_{ij} + b_i,$$

where

- defects_{ij} is the number of defects observed in the batch produced by factory i during batch j .
- μ_{ij} is the mean number of defects corresponding to factory i (where $i = 1, 2, \dots, 20$) during batch j (where $j = 1, 2, \dots, 5$).
- newprocess_{ij} , time_dev_{ij} , and temp_dev_{ij} are the measurements for each variable that correspond to factory i during batch j . For example, newprocess_{ij} indicates whether the batch produced by factory i during batch j used the new process.
- supplier_C_{ij} and supplier_B_{ij} are dummy variables that use effects (sum-to-zero) coding to indicate whether company C or B, respectively, supplied the process chemicals for the batch produced by factory i during batch j .
- $b_i \sim N(0, \sigma_b^2)$ is a random-effects intercept for each factory i that accounts for factory-specific variation in quality.

```
glme = fitglme(mfr, 'defects ~ 1 + newprocess + time_dev + temp_dev + supplier + (1|factory)')
```

Predict the response values at the original design values. Display the first ten predictions along with the observed response values.

```
ypred = predict(glme);  
[ypred(1:10),mfr.defects(1:10)]
```

```
ans = 10×2
```

```
4.9883    6.0000  
5.9423    7.0000  
5.1318    6.0000  
5.6295    5.0000  
5.3499    6.0000  
5.2134    5.0000  
4.6430    4.0000  
4.5342    4.0000  
5.3903    9.0000  
4.6529    4.0000
```

Column 1 contains the predicted response values at the original design values. Column 2 contains the observed response values.

Predict Responses at Values in New Table

Load the sample data.

```
load mfr
```

This simulated data is from a manufacturing company that operates 50 factories across the world, with each factory running a batch process to create a finished product. The company wants to decrease the number of defects in each batch, so it developed a new manufacturing process. To test the effectiveness of the new process, the company selected 20 of its factories at random to participate in an experiment: Ten factories implemented the new process, while the other ten continued to run the old process. In each of the 20 factories, the company ran five batches (for a total of 100 batches) and recorded the following data:

- Flag to indicate whether the batch used the new process (`newprocess`)
- Processing time for each batch, in hours (`time`)
- Temperature of the batch, in degrees Celsius (`temp`)
- Categorical variable indicating the supplier (A, B, or C) of the chemical used in the batch (`supplier`)

- Number of defects in the batch (`defects`)

The data also includes `time_dev` and `temp_dev`, which represent the absolute deviation of time and temperature, respectively, from the process standard of 3 hours at 20 degrees Celsius.

Fit a generalized linear mixed-effects model using `newprocess`, `time_dev`, `temp_dev`, and `supplier` as fixed-effects predictors. Include a random-effects term for intercept grouped by `factory`, to account for quality differences that might exist due to factory-specific variations. The response variable `defects` has a Poisson distribution, and the appropriate link function for this model is log. Use the Laplace fit method to estimate the coefficients. Specify the dummy variable encoding as `'effects'`, so the dummy variable coefficients sum to 0.

The number of defects can be modeled using a Poisson distribution:

$$\text{defects}_{ij} \sim \text{Poisson}(\mu_{ij})$$

This corresponds to the generalized linear mixed-effects model

$$\log(\mu_{ij}) = \beta_0 + \beta_1 \text{newprocess}_{ij} + \beta_2 \text{time_dev}_{ij} + \beta_3 \text{temp_dev}_{ij} + \beta_4 \text{supplier_C}_{ij} + \beta_5 \text{supplier_B}_{ij} + b_i,$$

where

- `defectsij` is the number of defects observed in the batch produced by factory *i* during batch *j*.
- μ_{ij} is the mean number of defects corresponding to factory *i* (where $i = 1, 2, \dots, 20$) during batch *j* (where $j = 1, 2, \dots, 5$).
- `newprocessij`, `time_devij`, and `temp_devij` are the measurements for each variable that correspond to factory *i* during batch *j*. For example, `newprocessij` indicates whether the batch produced by factory *i* during batch *j* used the new process.
- `supplier_Cij` and `supplier_Bij` are dummy variables that use effects (sum-to-zero) coding to indicate whether company C or B, respectively, supplied the process chemicals for the batch produced by factory *i* during batch *j*.
- $b_i \sim N(0, \sigma_b^2)$ is a random-effects intercept for each factory *i* that accounts for factory-specific variation in quality.

```
glme = fitglme(mfr, 'defects ~ 1 + newprocess + time_dev + temp_dev + supplier + (1|factory)
```

Predict the response values at the original design values.

```
ypred = predict(glme);
```

Create a new table by copying the first 10 rows of `mfr` into `tblnew`.

```
tblnew = mfr(1:10, :);
```

The first 10 rows of `mfr` include data collected from trials 1 through 5 for factories 1 and 2. Both factories used the old process for all of their trials during the experiment, so `newprocess = 0` for all 10 observations.

Change the value of `newprocess` to 1 for the observations in `tblnew`.

```
tblnew.newprocess = ones(height(tblnew), 1);
```

Compute predicted response values and nonsimultaneous 99% confidence intervals using `tblnew`. Display the first 10 rows of the predicted values based on `tblnew`, the predicted values based on `mfr`, and the observed response values.

```
[ypred_new, ypredCI] = predict(glme, tblnew, 'Alpha', 0.01);  
[ypred_new, ypred(1:10), mfr.defects(1:10)]
```

```
ans = 10x3
```

3.4536	4.9883	6.0000
4.1142	5.9423	7.0000
3.5530	5.1318	6.0000
3.8976	5.6295	5.0000
3.7040	5.3499	6.0000
3.6095	5.2134	5.0000
3.2146	4.6430	4.0000
3.1393	4.5342	4.0000
3.7320	5.3903	9.0000
3.2214	4.6529	4.0000

Column 1 contains predicted response values based on the data in `tblnew`, where `newprocess = 1`. Column 2 contains predicted response values based on the original data in `mfr`, where `newprocess = 0`. Column 3 contains the observed response values in `mfr`. Based on these results, if all other predictors retain their original values, the predicted number of defects appears to be smaller when using the new process.

Display the 99% confidence intervals for rows 1 through 10 corresponding to the new predicted response values.

```
ypredCI(1:10,1:2)
```

```
ans = 10×2
```

```
    1.6983    7.0235  
    1.9191    8.8201

predict

Package:

Predict responses of linear regression model

Syntax

```
ypred = predict mdl, Xnew)
[ypred, yci] = predict(mdl, Xnew)
[ypred, yci] = predict(mdl, Xnew, Name, Value)
```

Description

`ypred = predict(mdl, Xnew)` returns the predicted response values of the linear regression model `mdl` to the points in `Xnew`.

`[ypred, yci] = predict(mdl, Xnew)` also returns confidence intervals for the responses at `Xnew`.

`[ypred, yci] = predict(mdl, Xnew, Name, Value)` specifies additional options using one or more name-value pair arguments. For example, you can specify the confidence level of the confidence interval and the prediction type.

Examples

Predict Response Values

Create a quadratic model of car mileage as a function of weight from the `carsmall` data set.

```
load carsmall
X = Weight;
y = MPG;
mdl = fitlm(X, y, 'quadratic');
```

Create predicted responses to the data.

```
y_pred = predict mdl, X;
```

Plot the original responses and the predicted responses to see how they differ.

```
plot(X, y, 'o', X, y_pred, 'x')  
legend('Data', 'Predictions')
```

Generate C/C++ Code for Prediction

Fit a linear regression model, and then save the model by using `saveCompactModel`. Define an entry-point function that loads the model by using `loadCompactModel` and calls the `predict` function of the fitted model. Then use `codegen` to generate C/C++ code. Note that generating C/C++ code requires MATLAB® Coder™.

This example briefly explains the code generation workflow for the prediction of linear regression models at the command line. For more details, see “Code Generation for Prediction of Machine Learning Model at Command Line” on page 31-10. You can also generate code using the MATLAB Coder app. For details, see “Code Generation for Prediction of Machine Learning Model Using MATLAB Coder App” on page 31-20.

Train Model

Load the `carsmall` data set, and then fit the quadratic regression model.

```
load carsmall
X = Weight;
y = MPG;
mdl = fitlm(X,y,'quadratic');
```

Save Model

Save the fitted quadratic model to the file `QLMMdl.mat` by using `saveCompactModel`.

```
saveCompactModel(mdl,'QLMMdl');
```

Define Entry-Point Function

Define an entry-point function named `mypredictQLM` that does the following:

- Accept measurements corresponding to `X` and optional, valid name-value pair arguments.
- Load the fitted quadratic model in `QLMMdl.mat`.
- Return predictions and confidence interval bounds.

```
type mypredictQLM.m % Display contents of mypredictQLM.m
```

```
function [yhat,ci] = mypredictQLM(x,varargin) %#codegen
%MYPREDICTQLM Predict response using linear model
% MYPREDICTQLM predicts responses for the n observations in the n-by-1
% vector x using the linear model stored in the MAT-file QLMMdl.mat, and
```

```
% then returns the predictions in the n-by-1 vector yhat. MYPREDICTQLM
% also returns confidence interval bounds for the predictions in the
% n-by-2 vector ci.
CompactMdl = loadCompactModel('QLMMdl');
[yhat,ci] = predict(CompactMdl,x,varargin{:});
end
```

Add the `%#codegen` compiler directive (or pragma) to the entry-point function after the function signature to indicate that you intend to generate code for the MATLAB algorithm. Adding this directive instructs the MATLAB Code Analyzer to help you diagnose and fix violations that would result in errors during code generation.

Note: If you click the button located in the upper-right section of this example and open the example in MATLAB®, then MATLAB® opens the example folder. This folder includes the entry-point function file.

Generate Code

Generate code for the entry-point function using `codegen`. Because C and C++ are statically typed languages, you must determine the properties of all variables in the entry-point function at compile time. To specify the data type and exact input array size, pass a MATLAB® expression that represents the set of values with a certain data type and array size. Use `coder.Constant` for the names of name-value pair arguments.

If the number of observations is unknown at compile time, you can also specify the input as variable-size by using `coder.typeof`. For details, see “Specify Variable-Size Arguments for Code Generation” on page 31-58 and “Specify Properties of Entry-Point Function Inputs” (MATLAB Coder).

```
codegen mypredictQLM -args {X,coder.Constant('Alpha'),0.1,coder.Constant('Simultaneous
```

`codegen` generates the MEX function `mypredictQLM_mex` with a platform-dependent extension.

Verify Generated Code

Compare predictions and confidence intervals using `predict` and `mypredictQLM_mex`. Specify name-value pair arguments in the same order as in the `-args` argument in the call to `codegen`.

```
Xnew = sort(X);
[yhat1,ci1] = predict(mdl,Xnew,'Alpha',0.1,'Simultaneous',true);
[yhat2,ci2] = mypredictQLM_mex(Xnew,'Alpha',0.1,'Simultaneous',true);
```

The returned values from `mypredictQLM_mex` might include round-off differences compared to the values from `predict`. In this case, compare the values allowing a small tolerance.

```
find(abs(yhat1-yhat2) > 1e-6)
```

```
ans =
```

```
0x1 empty double column vector
```

```
find(abs(ci1-ci2) > 1e-6)
```

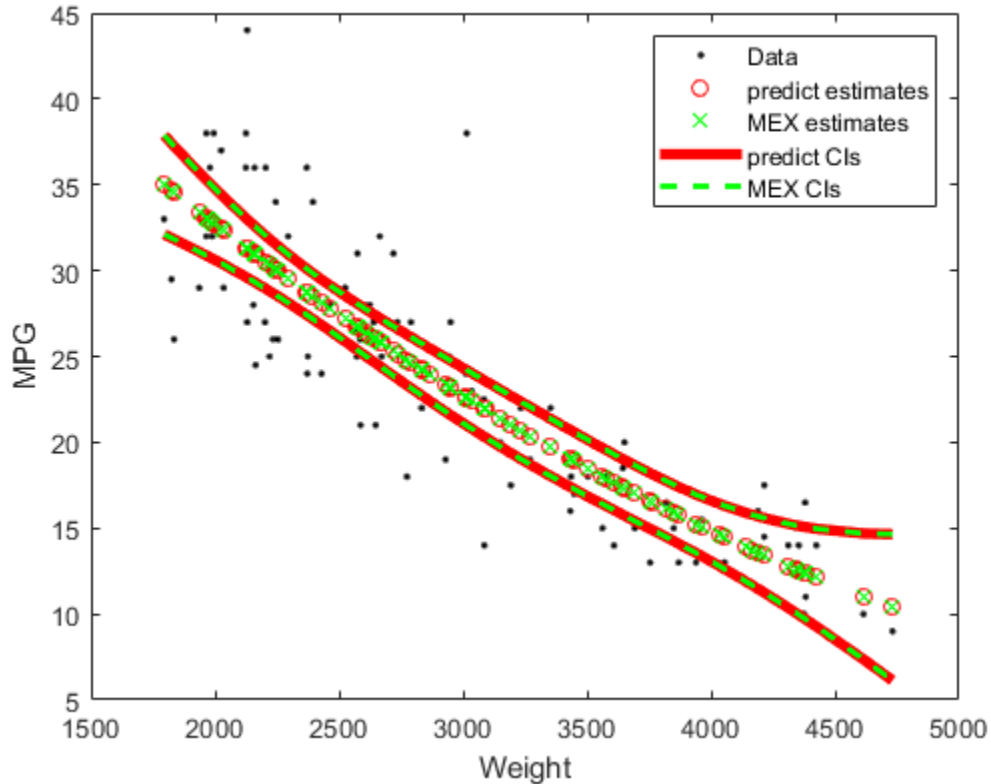

```
ans =
```

```
0x1 empty double column vector
```

The comparison confirms that the returned values are equal within the tolerance $1e-6$.

Plot the returned values for comparison.

```
h1 = plot(X,y,'k. ');
hold on
h2 = plot(Xnew,yhat1,'ro',Xnew,yhat2,'gx');
h3 = plot(Xnew,ci1,'r-','LineWidth',4);
h4 = plot(Xnew,ci2,'g--','LineWidth',2);
legend([h1; h2; h3(1); h4(1)], ...
       {'Data','predict estimates','MEX estimates','predict CIs','MEX CIs'});
xlabel('Weight');
ylabel('MPG');
```

Input Arguments

mdl — Linear regression model object

LinearModel object | CompactLinearModel object

Linear regression model object, specified as a LinearModel object created by using `fitlm` or `stepwiselm`, or a CompactLinearModel object created by using `compact`.

Xnew — New predictor input values

table | dataset array | matrix

New predictor input values, specified as a table, dataset array, or matrix. Each row of `Xnew` corresponds to one observation, and each column corresponds to one variable.

- If `Xnew` is a table or dataset array, it must contain predictors that have the same predictor names as in the `PredictorNames` property of `mdl`.
- If `Xnew` is a matrix, it must have the same number of variables (columns) in the same order as the predictor input used to create `mdl`. Note that `Xnew` must also contain any predictor variables that are not used as predictors in the fitted model. Also, all variables used in creating `mdl` must be numeric or logical. To treat numerical predictors as categorical, identify the predictors using the `'CategoricalVars'` name-value pair argument when you create `mdl`.

Data Types: `single` | `double` | `table`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `[ypred, yci] = predict(Mdl, Xnew, 'Alpha', 0.01, 'Simultaneous', true)` returns the confidence interval `yci` with a 99% confidence level, computed simultaneously for all predictor values.

Alpha — Significance level

0.05 (default) | numeric value in the range [0,1]

Significance level for the confidence interval, specified as the comma-separated pair consisting of `'Alpha'` and a numeric value in the range [0,1]. The confidence level of `yci` is equal to $100(1 - \text{Alpha})\%$. `Alpha` is the probability that the confidence interval does not contain the true value.

Example: `'Alpha', 0.01`

Data Types: `single` | `double`

Prediction — Prediction type

`'curve'` (default) | `'observation'`

Prediction type, specified as the comma-separated pair consisting of `'Prediction'` and either `'curve'` or `'observation'`.

A regression model for the predictor variables X and the response variable y has the form

$$y = f(X) + \varepsilon,$$

where f is a fitted regression function and ε is a random noise term.

- If 'Prediction' is 'curve', then `predict` predicts confidence bounds for $f(X_{new})$, the fitted responses at X_{new} .
- If 'Prediction' is 'observation', then `predict` predicts confidence bounds for y , the response observations at X_{new} .

The bounds for y are wider than the bounds for $f(X)$ because of the additional variability of the noise term.

Example: 'Prediction', 'observation'

Simultaneous — Flag to compute simultaneous confidence bounds

false (default) | true

Flag to compute simultaneous confidence bounds, specified as the comma-separated pair consisting of 'Simultaneous' and either true or false.

- `true` — `predict` computes confidence bounds for the curve of response values corresponding to all predictor values in X_{new} , using Scheffe's method. The range between the upper and lower bounds contains the curve consisting of true response values with $100(1 - \alpha)\%$ confidence.
- `false` — `predict` computes confidence bounds for the response value at each observation in X_{new} . The confidence interval for a response value at a specific predictor value contains the true response value with $100(1 - \alpha)\%$ confidence.

Simultaneous bounds are wider than separate bounds, because requiring the entire curve of response values to be within the bounds is stricter than requiring the response value at a single predictor value to be within the bounds.

Example: 'Simultaneous', true

Output Arguments

ypred — Predicted response values

numeric vector

Predicted response values evaluated at X_{new} , returned as a numeric vector.

yCi — Confidence intervals for responses

two-column numeric matrix

Confidence intervals for the responses, returned as a two-column matrix with each row providing one interval. The meaning of the confidence interval depends on the settings of the name-value pair arguments 'Alpha', 'Prediction', and 'Simultaneous'.

Alternative Functionality

- `feval` returns the same predictions as `predict`. The `feval` function can take multiple input arguments, with one input for each predictor variable, and does not give confidence intervals on its predictions.
- `random` returns predictions with added noise.
- Use `plotSlice` to create a figure containing a series of plots, each representing a slice through the predicted regression surface. Each plot shows the fitted response values as a function of a single predictor variable, with the other predictor variables held constant.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Use `saveCompactModel`, `loadCompactModel`, and `codegen` to generate code for the `predict` function. Save a trained model by using `saveCompactModel`. Define an entry-point function that loads the saved model by using `loadCompactModel` and calls the `predict` function. Then use `codegen` to generate code for the entry-point function.
- This table contains notes about the arguments of `predict`. Arguments not included in this table are fully supported.

Argument	Notes and Limitations
<code>mdl</code>	<ul style="list-style-type: none"> Suppose you train a linear model by using <code>fitlm</code> and specifying 'RobustOpts' as a structure with an anonymous function handle for the <code>RobustWgtFun</code> field, use <code>saveCompactModel</code> to save the model, and then use <code>loadCompactModel</code> to load the model. In this case, <code>loadCompactModel</code> cannot restore the Robust property into the MATLAB Workspace. However, <code>loadCompactModel</code> can load the model at compile time within an entry-point function for code generation. For the usage notes and limitations of the model object, see “Code Generation” on page 32-893 of the <code>CompactLinearModel</code> object.
<code>Xnew</code>	<ul style="list-style-type: none"> Must be a single-precision or double-precision matrix and can be variable-size. However, the number of columns in <code>Xnew</code> must be <code>numel(mdl.PredictorNames)</code>. Rows and columns must correspond to observations and predictors, respectively.
Name-value pair arguments	Names in name-value pair arguments must be compile-time constants. For example, to allow a user-defined significance level in the generated code, include <code>{coder.Constant('Alpha'),0}</code> in the <code>-args</code> value of <code>codegen</code> .

For more information, see “Introduction to Code Generation” on page 31-2.

predict

Class: LinearMixedModel

Predict response of linear mixed-effects model

Syntax

```
ypréd = predict(lme)
ypréd = predict(lme,tblnew)
ypréd = predict(lme,Xnew,Znew)
ypréd = predict(lme,Xnew,Znew,Gnew)
ypréd = predict( ____,Name,Value)
[ypréd,yprédCI] = predict( ____)
[ypréd,yprédCI,DF] = predict( ____)
```

Description

`ypréd = predict(lme)` returns a vector of conditional predicted responses on page 32-5367 `ypréd` at the original predictors used to fit the linear mixed-effects model `lme`.

`ypréd = predict(lme,tblnew)` returns a vector of conditional predicted responses `ypréd` from the fitted linear mixed-effects model `lme` at the values in the new table or dataset array `tblnew`. Use a table or dataset array for `predict` if you use a table or dataset array for fitting the model `lme`.

If a particular grouping variable in `tblnew` has levels that are not in the original data, then the random effects for that grouping variable do not contribute to the 'Conditional' prediction at observations where the grouping variable has new levels.

`ypréd = predict(lme,Xnew,Znew)` returns a vector of conditional predicted responses `ypréd` from the fitted linear mixed-effects model `lme` at the values in the new fixed- and random-effects design matrices, `Xnew` and `Znew`, respectively. `Znew` can also be a cell array of matrices. In this case, the grouping variable `G` is ones ($n, 1$), where n is the number of observations used in the fit.

Use the matrix format for `predict` if using design matrices for fitting the model `lme`.

`ypred = predict(lme, Xnew, Znew, Gnew)` returns a vector of conditional predicted responses `ypred` from the fitted linear mixed-effects model `lme` at the values in the new fixed- and random-effects design matrices, `Xnew` and `Znew`, respectively, and the grouping variable `Gnew`.

`Znew` and `Gnew` can also be cell arrays of matrices and grouping variables, respectively.

`ypred = predict(____, Name, Value)` returns a vector of predicted responses `ypred` from the fitted linear mixed-effects model `lme` with additional options specified by one or more `Name, Value` pair arguments.

For example, you can specify the confidence level, simultaneous confidence bounds, or contributions from only fixed effects.

`[ypred, ypredCI] = predict(____)` also returns confidence intervals `ypredCI` for the predictions `ypred` for any of the input arguments in the previous syntaxes.

`[ypred, ypredCI, DF] = predict(____)` also returns the degrees of freedom `DF` used in computing the confidence intervals for any of the input arguments in the previous syntaxes.

Input Arguments

lme — Linear mixed-effects model

`LinearMixedModel` object

Linear mixed-effects model, specified as a `LinearMixedModel` object constructed using `fitlme` or `fitlmematrix`.

tblnew — New input data

table | dataset array

New input data, which includes the response variable, predictor variables, and grouping variables on page 2-57, specified as a table or dataset array. The predictor variables can be continuous or grouping variables. `tblnew` must have the same variables as in the original table or dataset array used to fit the linear mixed-effects model `lme`.

Xnew — New fixed-effects design matrix

n-by-*p* matrix

New fixed-effects design matrix, specified as an n -by- p matrix, where n is the number of observations and p is the number of fixed predictor variables. Each row of X corresponds to one observation and each column of X corresponds to one variable.

Data Types: `single` | `double`

Znew — New random-effects design

n -by- q matrix | cell array of length R

New random-effects design, specified as an n -by- q matrix or a cell array of R design matrices $Z\{r\}$, where $r = 1, 2, \dots, R$. If $Znew$ is a cell array, then each $Z\{r\}$ is an n -by- $q(r)$ matrix, where n is the number of observations, and $q(r)$ is the number of random predictor variables.

Data Types: `single` | `double` | `cell`

Gnew — New grouping variable or variables

vector | cell array of grouping variables of length R

New grouping variable or variables on page 2-57, specified as a vector or a cell array, of length R , of grouping variables with the same levels or groups as the original grouping variables used to fit the linear mixed-effects model `lme`.

Data Types: `single` | `double` | `categorical` | `logical` | `char` | `string` | `cell`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Alpha — Significance level

0.05 (default) | scalar value in the range 0 to 1

Significance level, specified as the comma-separated pair consisting of `'Alpha'` and a scalar value in the range 0 to 1. For a value α , the confidence level is $100*(1-\alpha)\%$.

For example, for 99% confidence intervals, you can specify the confidence level as follows.

Example: `'Alpha', 0.01`

Data Types: `single` | `double`

Conditional — Indicator for conditional predictions`true (default) | false`

Indicator for conditional prediction on page 32-5367s, specified as the comma-separated pair consisting of 'Conditional' and one of the following.

<code>true</code>	Contributions from both fixed effects and random effects (conditional)
<code>false</code>	Contribution from only fixed effects (marginal)

Example: `'Conditional, false`

DFMethod — Method for computing approximate degrees of freedom`'residual' (default) | 'satterthwaite' | 'none'`

Method for computing approximate degrees of freedom to use in the confidence interval computation, specified as the comma-separated pair consisting of 'DFMethod' and one of the following.

<code>'residual'</code>	Default. The degrees of freedom are assumed to be constant and equal to $n - p$, where n is the number of observations and p is the number of fixed effects.
<code>'satterthwaite'</code>	Satterthwaite approximation.
<code>'none'</code>	All degrees of freedom are set to infinity.

For example, you can specify the Satterthwaite approximation as follows.

Example: `'DFMethod', 'satterthwaite'`

Simultaneous — Type of confidence bounds`false (default) | true`

Type of confidence bounds, specified as the comma-separated pair consisting of 'Simultaneous' and one of the following.

<code>false</code>	Default. Nonsimultaneous bounds.
<code>true</code>	Simultaneous bounds.

Example: `'Simultaneous', true`

Prediction — Type of prediction

'curve' (default) | 'observation'

Type of prediction, specified as the comma-separated pair consisting of 'Prediction' and one of the following.

'curve'

Default. Confidence bounds for the predictions based on the fitted function.

'observation'

Variability due to observation error for the new observations is also included in the confidence bound calculations and this results in wider bounds.

Example: 'Prediction', 'observation'

Output Arguments

ypred — Predicted responses

vector

Predicted responses, returned as a vector. `ypred` can contain the conditional or marginal responses, depending on the value choice of the 'Conditional' name-value pair argument. Conditional predictions include contributions from both fixed and random effects.

ypredCI — Point-wise confidence intervals

two-column matrix

Point-wise confidence intervals for the predicted values, returned as a two-column matrix. The first column of `yCI` contains the lower bounds, and the second column contains the upper bound. By default, `yCI` contains the 95% confidence intervals for the predictions. You can change the confidence level using the `Alpha` name-value pair argument, make them simultaneous using the `Simultaneous` name-value pair argument, and also make them for a new observation rather than for the curve using the `Prediction` name-value pair argument.

DF — Degrees of freedom

vector | scalar value

Degrees of freedom used in computing the confidence intervals, returned as a vector or a scalar value.

- If the 'Simultaneous' name-value pair argument is `false`, then `DF` is a vector.
- If the 'Simultaneous' name-value pair argument is `true`, then `DF` is a scalar value.

Examples

Predict Responses at the Original Design Values

Load the sample data.

```
load(fullfile(matlabroot, 'examples', 'stats', 'fertilizer.mat'));
```

The dataset array includes data from a split-plot experiment, where soil is divided into three blocks based on the soil type: sandy, silty, and loamy. Each block is divided into five plots, where five different types of tomato plants (cherry, heirloom, grape, vine, and plum) are randomly assigned to these plots. The tomato plants in the plots are then divided into subplots, where each subplot is treated by one of four fertilizers. This is simulated data.

Store the data in a dataset array called `ds`, for practical purposes, and define `Tomato`, `Soil`, and `Fertilizer` as categorical variables.

```
ds = fertilizer;  
ds.Tomato = nominal(ds.Tomato);  
ds.Soil = nominal(ds.Soil);  
ds.Fertilizer = nominal(ds.Fertilizer);
```

Fit a linear mixed-effects model, where `Fertilizer` and `Tomato` are the fixed-effects variables, and the mean yield varies by the block (soil type), and the plots within blocks (tomato types within soil types) independently.

```
lme = fitlme(ds, 'Yield ~ Fertilizer * Tomato + (1|Soil) + (1|Soil:Tomato)');
```

Predict the response values at the original design values. Display the first five predictions with the observed response values.

```
yhat = predict(lme);  
[yhat(1:5) ds.Yield(1:5)]
```

```
ans = 5×2
```

```
115.4788 104.0000
135.1455 136.0000
152.8121 158.0000
160.4788 174.0000
 58.0839  57.0000
```

Plot Predictions vs. Observed Responses

Load the sample data.

```
load carsmall
```

Fit a linear mixed-effects model, with a fixed effect for `Weight`, and a random intercept grouped by `Model_Year`. First, store the data in a table.

```
tbl = table(MPG,Weight,Model_Year);
lme = fitlme(tbl, 'MPG ~ Weight + (1|Model_Year)');
```

Create predicted responses to the data.

```
yhat = predict(lme,tbl);
```

Plot the original responses and the predicted responses to see how they differ. Group them by model year.

```
figure()
gscatter(Weight,MPG,Model_Year)
hold on
gscatter(Weight,yhat,Model_Year,[], 'o+x')
legend('70-data', '76-data', '82-data', '70-pred', '76-pred', '82-pred')
hold off
```

Predict Responses at Values in a New Dataset Array

Load the sample data.

```
load(fullfile(matlabroot, 'examples', 'stats', 'fertilizer.mat'));
```

The dataset array includes data from a split-plot experiment, where soil is divided into three blocks based on the soil type: sandy, silty, and loamy. Each block is divided into five plots, where five different types of tomato plants (cherry, heirloom, grape, vine, and plum) are randomly assigned to these plots. The tomato plants in the plots are then divided into subplots, where each subplot is treated by one of four fertilizers. This is simulated data.

Store the data in a dataset array called `ds`, for practical purposes, and define `Tomato`, `Soil`, and `Fertilizer` as categorical variables.

```
ds = fertilizer;
ds.Tomato = nominal(ds.Tomato);
ds.Soil = nominal(ds.Soil);
ds.Fertilizer = nominal(ds.Fertilizer);
```

Fit a linear mixed-effects model, where `Fertilizer` and `Tomato` are the fixed-effects variables, and the mean yield varies by the block (soil type), and the plots within blocks (tomato types within soil types) independently.

```
lme = fitlme(ds, 'Yield ~ Fertilizer * Tomato + (1|Soil) + (1|Soil:Tomato)');
```

Create a new dataset array with design values. The new dataset array must have the same variables as the original dataset array you use for fitting the model `lme`.

```
dsnew = dataset();
dsnew.Soil = nominal({'Sandy'; 'Silty'});
dsnew.Tomato = nominal({'Cherry'; 'Vine'});
dsnew.Fertilizer = nominal([2;2]);
```

Predict the conditional and marginal responses at the original design points.

```
yhatC = predict(lme, dsnew);
yhatM = predict(lme, dsnew, 'Conditional', false);
[yhatC yhatM]
```

```
ans = 2×2
```

```
    92.7505    111.6667
    87.5891     82.6667
```

Predict Responses at the Values in New Design Matrices

Load the sample data.

```
load carbig
```

Fit a linear mixed-effects model for miles per gallon (MPG), with fixed effects for acceleration, horsepower, and cylinders, and potentially correlated random effects for intercept and acceleration grouped by model year.

First, prepare the design matrices for fitting the linear mixed-effects model.

```
X = [ones(406,1) Acceleration Horsepower];
Z = [ones(406,1) Acceleration];
Model_Year = nominal(Model_Year);
G = Model_Year;
```

Now, fit the model using `fitlmematrix` with the defined design matrices and grouping variables.

```
lme = fitlmematrix(X,MPG,Z,G,'FixedEffectPredictors',...
{'Intercept','Acceleration','Horsepower'},'RandomEffectPredictors',...
{{'Intercept','Acceleration'}},'RandomEffectGroups',{'Model_Year'});
```

Create the design matrices that contain the data at which to predict the response values. `Xnew` must have three columns as in `X`. The first column must be a column of 1s. And the values in the last two columns must correspond to `Acceleration` and `Horsepower`, respectively. The first column of `Znew` must be a column of 1s, and the second column must contain the same `Acceleration` values as in `Xnew`. The original grouping variable in `G` is the model year. So, `Gnew` must contain values for the model year. Note that `Gnew` must contain nominal values.

```
Xnew = [1,13.5,185; 1,17,205; 1,21.2,193];
Znew = [1,13.5; 1,17; 1,21.2]; % alternatively Znew = Xnew(:,1:2);
Gnew = nominal([73 77 82]);
```

Predict the responses for the data in the new design matrices.

```
yhat = predict(lme,Xnew,Znew,Gnew)
```

```
yhat = 3×1
      8.7063
      5.4423
     12.5384
```

Now, repeat the same for a linear mixed-effects model with uncorrelated random-effects terms for intercept and acceleration. First, change the original random effects design and the random effects grouping variables. Then, refit the model.

```
Z = {ones(406,1),Acceleration};
G = {Model_Year,Model_Year};
```

```
lme = fitlmematrix(X,MPG,Z,G,'FixedEffectPredictors',...
{'Intercept','Acceleration','Horsepower'},'RandomEffectPredictors',...
{'Intercept'},{'Acceleration'}},'RandomEffectGroups',{'Model_Year','Model_Year'});
```

Now, recreate the new random effects design, Znew, and the grouping variable design, Gnew, using which to predict the response values.

```
Znew = {[1;1;1],[13.5;17;21.2]};
MY = nominal([73 77 82]);
Gnew = {MY,MY};
```

Predict the responses using the new design matrices.

```
yhat = predict(lme,Xnew,Znew,Gnew)
```

```
yhat = 3×1
```

```
    8.6365
    5.9199
   12.1247
```

Compute Confidence Intervals for Predictions

Load the sample data.

```
load carbig
```

Fit a linear mixed-effects model for miles per gallon (MPG), with fixed effects for acceleration, horsepower, and cylinders, and potentially correlated random effects for intercept and acceleration grouped by model year. First, store the variables in a table.

```
tbl = table(MPG,Acceleration,Horsepower,Model_Year);
```

Now, fit the model using fitlme with the defined design matrices and grouping variables.

```
lme = fitlme(tbl,'MPG ~ Acceleration + Horsepower + (Acceleration|Model_Year)');
```

Create the new data and store it in a new table.

```
tblnew = table();
tblnew.Acceleration = linspace(8,25)';
```

```
tblnew.Horsepower = linspace(nanmin(Horsepower),nanmax(Horsepower))';  
tblnew.Model_Year = repmat(70,100,1);
```

`linspace` creates 100 equally distanced values between the lower and the upper input limits. `Model_Year` is fixed at 70. You can repeat this for any model year.

Compute and plot the predicted values and 95% confidence limits (nonsimultaneous).

```
[ypred,yCI,DF] = predict(lme,tblnew);  
figure();  
h1 = line(tblnew.Acceleration,ypred);  
hold on;  
h2 = plot(tblnew.Acceleration,yCI,'g-.');
```

Display the degrees of freedom.

```
DF(1)
```

```
ans = 389
```

Compute and plot the simultaneous confidence bounds.

```
[ypred,yCI,DF] = predict(lme,tblnew,'Simultaneous',true);  
h3 = plot(tblnew.Acceleration,yCI,'r--');
```

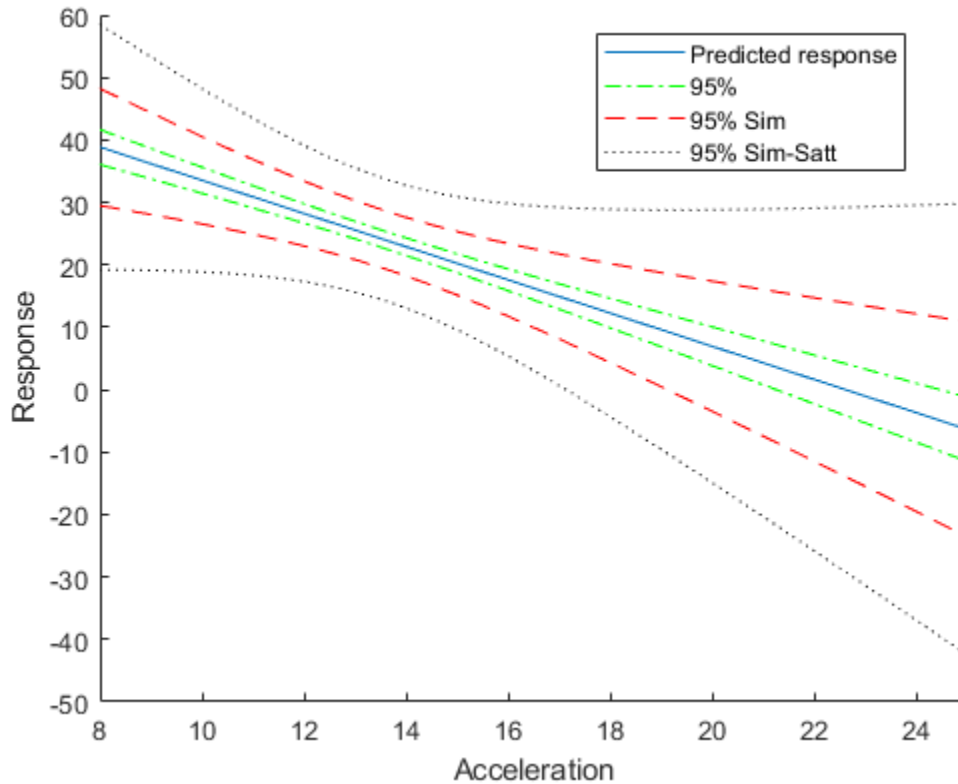

Display the degrees of freedom.

```
DF
```

```
DF = 389
```

Compute the simultaneous confidence bounds using the Satterthwaite method to compute the degrees of freedom.

```
[ypred,yCI,DF] = predict(lme,tblnew,'Simultaneous',true,'DFMethod','satterthwaite');
h4 = plot(tblnew.Acceleration,yCI,'k:');
hold off
xlabel('Acceleration')
ylabel('Response')
ylim([-50,60])
xlim([8,25])
legend([h1,h2(1),h3(1),h4(1)],'Predicted response','95%','95% Sim',...
'95% Sim-Satt','Location','Best')
```

Display the degrees of freedom.

DF

DF = 3.6001

Definitions

Conditional and Marginal Predictions

A conditional prediction includes contributions from both fixed and random effects, whereas a marginal model includes contribution from only fixed effects.

Suppose the linear mixed-effects model `lme` has an n -by- p fixed-effects design matrix X and an n -by- q random-effects design matrix Z . Also, suppose the estimated p -by-1 fixed-effects vector is $\hat{\beta}$, and the q -by-1 estimated best linear unbiased predictor (BLUP) vector of random effects is \hat{b} . The predicted conditional response is

$$\hat{y}_{Cond} = X\hat{\beta} + Z\hat{b},$$

which corresponds to the 'Conditional', 'true' name-value pair argument.

The predicted marginal response is

$$\hat{y}_{Mar} = X\hat{\beta},$$

which corresponds to the 'Conditional', 'false' name-value pair argument.

When making predictions, if a particular grouping variable has new levels (1s that were not in the original data), then the random effects for the grouping variable do not contribute to the 'Conditional' prediction at observations where the grouping variable has new levels.

`LinearMixedModel` | `fitted` | `random`

predict

Class: FeatureSelectionNCAClassification

Predict responses using neighborhood component analysis (NCA) classifier

Syntax

```
[labels,postprobs,classnames] = predict mdl,X)
```

Description

`[labels,postprobs,classnames] = predict(mdl,X)` computes the predicted labels, `labels`, corresponding to the rows of `X`, using the model `mdl`.

Input Arguments

mdl — Neighborhood component analysis model for classification

FeatureSelectionNCAClassification object

Neighborhood component analysis model for classification, specified as a FeatureSelectionNCAClassification object.

X — Predictor variable values

n-by-*p* matrix

Predictor variable values, specified as an *n*-by-*p* matrix, where *n* is the number of observations and *p* is the number of predictor variables.

Data Types: single | double

Output Arguments

labels — Predicted class labels

categorical vector | logical vector | numeric vector | cell array of character vectors | character array

Predicted class labels corresponding to the rows of X , returned as a categorical, logical, or numeric vector, a cell array of character vectors of length n , or a character array with n rows. n is the number of observations. The type of `labels` is the same as Y used in training.

postprobs — Posterior probabilities

n -by- c matrix

Posterior probabilities, returned as an n -by- c matrix, where n is the number of observations and c is the number of classes. A posterior probability, `postprobs(i, :)`, represents the membership of an observation in $X(i, :)$ in classes 1 through c .

classnames — Class names

cell array of character vectors

Class names corresponding to posterior probabilities, returned as a cell array of character vectors. Each character vector is the class name corresponding to a column of `postprobs`.

Examples

Tune NCA Model for Classification

Load the sample data.

```
load(fullfile(matlabroot, 'examples', 'stats', 'twodimclassdata.mat'));
```

This data set is simulated using the scheme described in [1]. This is a two-class classification problem in two dimensions. Data from the first class (class -1) are drawn from two bivariate normal distributions $N(\mu_1, \Sigma)$ or $N(\mu_2, \Sigma)$ with equal probability, where $\mu_1 = [-0.75, -1.5]$, $\mu_2 = [0.75, 1.5]$, and $\Sigma = I_2$. Similarly, data from the second class (class 1) are drawn from two bivariate normal distributions $N(\mu_3, \Sigma)$ or $N(\mu_4, \Sigma)$

with equal probability, where $\mu_3 = [1.5, -1.5]$, $\mu_4 = [-1.5, 1.5]$, and $\Sigma = I_2$. The normal distribution parameters used to create this data set result in tighter clusters in data than the data used in [1].

Create a scatter plot of the data grouped by the class.

```
figure
gscatter(X(:,1),X(:,2),y)
xlabel('x1')
ylabel('x2')
```

Add 100 irrelevant features to X . First generate data from a Normal distribution with a mean of 0 and a variance of 20.

```
n = size(X,1);
rng('default')
XwithBadFeatures = [X,randn(n,100)*sqrt(20)];
```

Normalize the data so that all points are between 0 and 1.

```
XwithBadFeatures = bsxfun(@rdivide,...
    bsxfun(@minus,XwithBadFeatures,min(XwithBadFeatures,[],1)), ...
    range(XwithBadFeatures,1));
X = XwithBadFeatures;
```

Fit a neighborhood component analysis (NCA) model to the data using the default Lambda (regularization parameter, λ) value. Use the LBFGS solver and display the convergence information.

```
ncaMdl = fscnca(X,y,'FitMethod','exact','Verbose',1, ...
    'Solver','lbfgs');
```

```
o Solver = LBFGS, HessianHistorySize = 15, LineSearchMethod = weakwolfe
```

10	-4.974874e-01	9.404e-08	8.947e-04	OK	1.670e+02	1.000

```
Infinity norm of the final gradient = 9.404e-08
```

```
Two norm of the final step = 8.947e-04, TolX = 1.000e-06
```

```
Relative infinity norm of the final gradient = 9.404e-08, TolFun = 1.000e-06
```

```
EXIT: Local minimum found.
```

Plot the feature weights. The weights of the irrelevant features should be very close to zero.

```
figure
semilogx(ncaMdl.FeatureWeights,'ro')
```

```
xlabel('Feature index')
ylabel('Feature weight')
grid on
```

Predict the classes using the NCA model and compute the confusion matrix.

```
ypred = predict(ncaMdl,X);
confusionchart(y,ypred);
```

Confusion matrix shows that 40 of the data that are in class -1 are predicted as belonging to class -1. 60 of the data from class -1 are predicted to be in class 1. Similarly, 94 of the data from class 1 are predicted to be from class 1 and 6 of them are predicted to be from class -1. The prediction accuracy for class -1 is not good.

All weights are very close to zero, which indicates that the value of λ used in training the model is too large. When $\lambda \rightarrow \infty$, all features weights approach to zero. Hence, it is important to tune the regularization parameter in most cases to detect the relevant features.

Use five-fold cross-validation to tune λ for feature selection by using `fscnca`. Tuning λ means finding the λ value that will produce the minimum classification loss. To tune λ using cross-validation:

1. Partition the data into five folds. For each fold, `cvpartition` assigns four-fifths of the data as a training set and one-fifth of the data as a test set. Again for each fold, `cvpartition` creates a stratified partition, where each partition has roughly the same proportion of classes.

```
cvp = cvpartition(y, 'kfold', 5);  
numtestsets = cvp.NumTestSets;  
lambdavalues = linspace(0, 2, 20)/length(y);  
lossvalues = zeros(length(lambdavalues), numtestsets);
```

2. Train the neighborhood component analysis (nca) model for each λ value using the training set in each fold.

3. Compute the classification loss for the corresponding test set in the fold using the nca model. Record the loss value.

4. Repeat this process for all folds and all λ values.

```
for i = 1:length(lambdavalues)  
    for k = 1:numtestsets  
  
        % Extract the training set from the partition object  
        Xtrain = X(cvp.training(k), :);  
        ytrain = y(cvp.training(k), :);  
  
        % Extract the test set from the partition object  
        Xtest = X(cvp.test(k), :);  
        ytest = y(cvp.test(k), :);  
  
        % Train an NCA model for classification using the training set  
        ncaMdl = fscnca(Xtrain, ytrain, 'FitMethod', 'exact', ...  
            'Solver', 'lbfgs', 'Lambda', lambdavalues(i));  
  
        % Compute the classification loss for the test set using the NCA  
        % model  
        lossvalues(i, k) = loss(ncaMdl, Xtest, ytest, ...  
            'LossFunction', 'quadratic');  
  
    end  
end
```

Plot the average loss values of the folds versus the λ values. If the λ value that corresponds to the minimum loss falls on the boundary of the tested λ values, the range of λ values should be reconsidered.

```
figure
plot(lambdavalues,mean(lossvalues,2),'ro-')
xlabel('Lambda values')
ylabel('Loss values')
grid on
```

Find the λ value that corresponds to the minimum average loss.

```
[~,idx] = min(mean(lossvalues,2)); % Find the index
bestlambda = lambdavalues(idx) % Find the best lambda value
```

```
bestlambda =
```

0.0037

Fit the NCA model to all of the data using the best λ value. Use the LBFGS solver and display the convergence information.

```
ncaMdl = fscnca(X,y,'FitMethod','exact','Verbose',1, ...
               'Solver','lbfgs','Lambda',bestlambda);
```

o Solver = LBFGS, HessianHistorySize = 15, LineSearchMethod = weakwolfe

18	-6.149997e-01	3.250e-06	5.114e-03	OK	1.225e+02	1.000
19	-6.149997e-01	1.574e-06	1.275e-03	OK	1.808e+02	1.000

ITER	FUN VALUE	NORM GRAD	NORM STEP	CURV	GAMMA	ALPH
20	-6.149997e-01	5.764e-07	6.765e-04	OK	2.905e+02	1.000

```

Infinity norm of the final gradient = 5.764e-07
Two norm of the final step = 6.765e-04, TolX = 1.000e-06
Relative infinity norm of the final gradient = 5.764e-07, TolFun = 1.000e-06
EXIT: Local minimum found.
```

Plot the feature weights.

```
figure
semilogx(ncaMdl.FeatureWeights,'ro')
xlabel('Feature index')
ylabel('Feature weight')
grid on
```

fscnca correctly figures out that the first two features are relevant and that the rest are not. The first two features are not individually informative, but when taken together result in an accurate classification model.

Predict the classes using the new model and compute the accuracy.

```
ypred = predict(ncaMdl,X);  
confusionchart(y,ypred);
```

Confusion matrix shows that prediction accuracy for class -1 has improved. 88 of the data from class -1 are predicted to be from -1, and 12 of them are predicted to be from class 1. 92 of the data from class 1 are predicted to be from class 1 and 8 of them are predicted to be from class -1.

`FeatureSelectionNCAClassification` | `fscnca` | `loss` | `refit`

Introduced in R2016b

predict

Class: FeatureSelectionNCARegression

Predict responses using neighborhood component analysis (NCA) regression model

Syntax

```
ypred = predict mdl, X
```

Description

`ypred = predict(mdl, X)` computes the predicted response values, `ypred`, corresponding to rows of `X`, using the model `mdl`.

Input Arguments

mdl — Neighborhood component analysis model for regression

FeatureSelectionNCARegression object

Neighborhood component analysis model for regression, specified as a FeatureSelectionNCARegression object.

X — Predictor variable values

n-by-*p* matrix

Predictor variable values, specified as an *n*-by-*p* matrix, where *n* is the number of observations and *p* is the number of predictor variables.

Data Types: single | double

Output Arguments

ypred — Predicted response values

n-by-1 vector

Predicted response values, specified as an n -by-1 vector, where n is the number of observations.

Examples

Tune NCA Model for Regression Using `loss` and `predict`

Load the sample data.

Download the housing data [1], from the UCI Machine Learning Repository [2]. The dataset has 506 observations. The first 13 columns contain the predictor values and the last column contains the response values. The goal is to predict the median value of owner-occupied homes in suburban Boston as a function of 13 predictors.

Load the data and define the response vector and the predictor matrix.

```
load('housing.data');  
X = housing(:,1:13);  
y = housing(:,end);
```

Divide the data into training and test sets using the 4th predictor as the grouping variable for a stratified partitioning. This ensures that each partition includes similar amount of observations from each group.

```
rng(1) % For reproducibility  
cvp = cvpartition(X(:,4), 'Holdout', 56);  
Xtrain = X(cvp.training,:);  
ytrain = y(cvp.training,:);  
Xtest = X(cvp.test,:);  
ytest = y(cvp.test,:);
```

`cvpartition` randomly assigns 56 observations into a test set and the rest of the data into a training set.

Perform Feature Selection Using Default Settings

Perform feature selection using NCA model for regression. Standardize the predictor values.

```
nca = fsrnca(Xtrain,ytrain, 'Standardize', 1);
```

Plot the feature weights.

```
figure()  
plot(nca.FeatureWeights, 'ro')
```

The weights of irrelevant features are expected to approach zero. `fsrnca` identifies two features as irrelevant.

Compute the regression loss.

```
L = loss(nca,Xtest,ytest,'LossFunction','mad')
```

```
L = 2.5394
```

Compute the predicted response values for the test set and plot them versus the actual response.

```
ypred = predict(nca,Xtest);  
figure()  
plot(ypred,ytest,'bo')  
xlabel('Predicted response')  
ylabel('Actual response')
```

A perfect fit versus the actual values forms a 45 degree straight line. In this plot, the predicted and actual response values seem to be scattered around this line. Tuning λ (regularization parameter) value usually helps improve the performance.

Tune the regularization parameter using 10-fold cross-validation

Tuning λ means finding the λ value that will produce the minimum regression loss. Here are the steps for tuning λ using 10-fold cross-validation:

1. First partition the data into 10 folds. For each fold, `cvpartition` assigns 1/10th of the data as a training set, and 9/10th of the data as a test set.

```
n = length(ytrain);
cvp = cvpartition(Xtrain(:,4), 'kfold', 10);
numvalidsets = cvp.NumTestSets;
```

Assign the λ values for the search. Create an array to store the loss values.

```
lambdaval = linspace(0, 2, 30) * std(ytrain) / n;
lossvals = zeros(length(lambdaval), numvalidsets);
```

2. Train the neighborhood component analysis (nca) model for each λ value using the training set in each fold.

3. Fit a Gaussian process regression (gpr) model using the selected features. Next, compute the regression loss for the corresponding test set in the fold using the gpr model. Record the loss value.

4. Repeat this for each λ value and each fold.

```
for i = 1:length(lambdaval)
    for k = 1:numvalidsets
        X = Xtrain(cvp.training(k), :);
        y = ytrain(cvp.training(k), :);
        Xvalid = Xtrain(cvp.test(k), :);
        yvalid = ytrain(cvp.test(k), :);

        nca = fsrnca(X, y, 'FitMethod', 'exact', ...
                    'Lambda', lambdaval(i), ...
                    'Standardize', 1, 'LossFunction', 'mad');

        % Select features using the feature weights and a relative
        % threshold.
        tol = 1e-3;
        selidx = nca.FeatureWeights > tol * max(1, max(nca.FeatureWeights));

        % Fit a non-ARD GPR model using selected features.
        gpr = fitrgp(X(:, selidx), y, 'Standardize', 1, ...
                    'KernelFunction', 'squareexponential', 'Verbose', 0);

        lossvals(i, k) = loss(gpr, Xvalid(:, selidx), yvalid);
    end
end
```

```
end  
end
```

Compute the average loss obtained from the folds for each λ value. Plot the mean loss versus the λ values.

```
meanloss = mean(lossvals,2);  
figure;  
plot(lambdaval,meanloss,'ro-');  
xlabel('Lambda');  
ylabel('Loss (MSE)');  
grid on;
```

Find the λ value that produces the minimum loss value.

```
[~,idx] = min(meanloss);  
bestlambda = lambdaval(idx)
```

```
bestlambda = 0.0251
```

Perform feature selection for regression using the best λ value. Standardize the predictor values.

```
nca2 = fsrnca(Xtrain,ytrain,'Standardize',1,'Lambda',bestlambda,...  
             'LossFunction','mad');
```

Plot the feature weights.

```
figure()  
plot(nca.FeatureWeights,'ro')
```

Compute the loss using the new nca model on the test data, which is not used to select the features.

```
L2 = loss(nca2,Xtest,ytest,'LossFunction','mad')
```

```
L2 = 2.0560
```

Tuning the regularization parameter helps identify the relevant features and reduces the loss.

Plot the predicted versus the actual response values in the test set.

```
ypred = predict(nca2,Xtest);  
figure;  
plot(ypred,ytest,'bo');
```

The predicted response values seem to be closer to the actual values as well.

`FeatureSelectionNCARegression` | `fsrcna` | `loss` | `refit`

Introduced in R2016b

predict

Class: NonLinearModel

Predict response of nonlinear regression model

Syntax

```
ypred = predict(mdl, Xnew)  
[ypred, yci] = predict(mdl, Xnew)  
[ypred, yci] = predict(mdl, Xnew, Name, Value)
```

Description

`ypred = predict(mdl, Xnew)` returns the predicted response of the `mdl` nonlinear regression model to the points in `Xnew`.

`[ypred, yci] = predict(mdl, Xnew)` returns confidence intervals for the true mean responses.

`[ypred, yci] = predict(mdl, Xnew, Name, Value)` predicts responses with additional options specified by one or more `Name, Value` pair arguments.

Input Arguments

mdl

Nonlinear regression model, constructed by `fitnlm`.

X_{new}

Points at which `mdl` predicts responses.

- If `Xnew` is a table or dataset array, it must contain the predictor names in `mdl`.

- If `Xnew` is a numeric matrix, it must have the same number of variables (columns) as was used to create `mdl`. Furthermore, all variables used in creating `mdl` must be numeric.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Alpha

Positive scalar from 0 to 1. Confidence level of `yci` is $100(1 - \text{alpha})\%$.

Default: 0.05, meaning a 95% confidence interval.

Prediction

Type of prediction:

- `'curve'` — `predict` predicts confidence bounds for the fitted mean values.
- `'observation'` — `predict` predicts confidence bounds for the new observations. This results in wider bounds because the error in a new observation is equal to the error in the estimated mean value, plus the variability in the observation from the true mean.

For details, see `polyconf`.

Default: `'curve'`

Simultaneous

Logical value specifying whether the confidence bounds are for all predictor values simultaneously (`true`), or hold for each individual predictor value (`false`). Simultaneous bounds are wider than separate bounds, because it is more stringent to require that the entire curve be within the bounds than to require that the curve at a single predictor value be within the bounds.

For details, see `polyconf`.

Default: `false`

Weights

Vector of real, positive value weights or a function handle.

- If you specify a vector, then it must have the same number of elements as the number of observations (or rows) in `Xnew`.
- If you specify a function handle, then the function must accept a vector of predicted response values as input, and return a vector of real positive weights as output.

Given weights, `W`, `predict` estimates the error variance at observation `i` by $MSE * (1/W(i))$, where `MSE` is the mean squared error.

Default: No weights

Output Arguments

`ypred`

Predicted mean values at `Xnew`. `ypred` is the same size as each component of `Xnew`.

`yci`

Confidence intervals, a two-column matrix with each row providing one interval. The meaning of the confidence interval depends on the settings of the name-value pairs.

Examples

Predict Responses

Create a nonlinear model of car mileage as a function of weight, and predict the response.

Create an exponential model of car mileage as a function of weight from the `carsmall` data. Scale the weight by a factor of 1000 so all the variables are roughly equal in size.

```
load carsmall
X = Weight;
y = MPG;
modelfun = 'y ~ b1 + b2*exp(-b3*x/1000)';
```

```
beta0 = [1 1 1];  
mdl = fitnlm(X,y,modelfun,beta0);
```

Create predicted responses to the data.

```
Xnew = X;  
ypred = predict(mdl,Xnew);
```

Plot the original responses and the predicted responses to see how they differ.

```
plot(X,y,'o',X,ypred,'x')  
legend('Data','Predicted')
```

Confidence Intervals for Predictions

Create a nonlinear model of car mileage as a function of weight, and examine confidence intervals of some responses.

Create an exponential model of car mileage as a function of weight from the `carsmall` data. Scale the weight by a factor of 1000 so all the variables are roughly equal in size.

```
load carsmall
X = Weight;
y = MPG;
modelfun = 'y ~ b1 + b2*exp(-b3*x/1000)';
beta0 = [1 1 1];
mdl = fitnlm(X,y,modelfun,beta0);
```

Create predicted responses to the smallest, mean, and largest data points.

```
Xnew = [min(X);mean(X);max(X)];
[ypred,yci] = predict(mdl,Xnew)
```

```
ypred = 3×1
```

```
34.9469
22.6868
10.0617
```

```
yci = 3×2
```

```
32.5212 37.3726
21.4061 23.9674
7.0148 13.1086
```

Simultaneous Confidence Intervals for Robust Fit Curve

Generate sample data from the nonlinear regression model

$$y = b_1 + b_2 \exp(-b_3 x) + \epsilon$$

where b_1 , b_2 , and b_3 are coefficients, and the error term ϵ is normally distributed with mean 0 and standard deviation 0.5.

```
modelfun = @(b,x)(b(1)+b(2)*exp(-b(3)*x));
```

```
rng('default') % For reproducibility  
b = [1;3;2];  
x = exprnd(2,100,1);  
y = modelfun(b,x) + normrnd(0,0.5,100,1);
```

Fit the nonlinear model using robust fitting options.

```
opts = statset('nlinfit');  
opts.RobustWgtFun = 'bisquare';  
b0 = [2;2;2];  
mdl = fitnlm(x,y,modelfun,b0,'Options',opts);
```

Plot the fitted regression model and simultaneous 95% confidence bounds.

```
xrange = [min(x):.01:max(x)]';  
[ypred,yci] = predict(mdl,xrange,'Simultaneous',true);  
  
figure()  
plot(x,y,'ko') % observed data  
hold on  
plot(xrange,ypred,'k','LineWidth',2)  
plot(xrange,yci,'r--','LineWidth',1.5)
```

Confidence Interval Using Observation Weights

Load sample data.

```
S = load('reaction');  
X = S.reactants;  
y = S.rate;  
beta0 = S.beta;
```

Specify a function handle for observation weights, then fit the Hougen-Watson model to the rate data using the specified observation weights function.

```
a = 1; b = 1;
weights = @(yhat) 1./((a + b*abs(yhat)).^2);
mdl = fitnlm(X,y,@hougen,beta0,'Weights',weights);
```

Compute the 95% prediction interval for a new observation with reactant levels [100,100,100] using the observation weight function.

```
[ypred,yci] = predict(mdl,[100,100,100],'Prediction','observation', ...
    'Weights',weights)
```

```
ypred = 1.8149
```

```
yci = 1×2
```

```
    1.5264    2.1033
```

Tips

- For predictions with added noise, use `random`.
- For a syntax that can be easier to use with models created from tables or dataset arrays, try `feval`.

predict

Class: RepeatedMeasuresModel

Compute predicted values given predictor values

Syntax

```
yPred = predict(rm,tnew)
yPred = predict(rm,tnew,Name,Value)
[yPred,yci] = predict( ___ )
```

Description

`yPred = predict(rm,tnew)` returns the predicted values from the repeated measures model `rm` using the predictor values from the table `t`.

`yPred = predict(rm,tnew,Name,Value)` returns the predicted values from the repeated measures model `rm` with additional options specified by one or more `Name,Value` pair arguments.

For example, you can specify the within-subjects design matrix.

`[yPred,yci] = predict(___)` also returns the 95% confidence interval for the predicted values.

Input Arguments

rm — Repeated measures model

RepeatedMeasuresModel object

Repeated measures model, returned as a RepeatedMeasuresModel object.

For properties and methods of this object, see RepeatedMeasuresModel.

tnew — New data

table used to create `rm` (default) | table

New data including the values of the response variables and the between-subject factors used as predictors in the repeated measures model, `rm`, specified as a table. `tnew` must contain all of the between-subject factors used to create `rm`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Alpha — Significance level

0.05 (default) | scalar value in the range of 0 through 1

Significance level of the confidence intervals for the predicted values, specified as the comma-separated pair consisting of `'alpha'` and a scalar value in the range of 0 to 1. The confidence level is $100*(1-\alpha)\%$.

Example: `'alpha', 0.01`

Data Types: `double` | `single`

WithinModel — Model for within-subject factors

`'separatemeans'` | `'orthogonalcontrasts'` | character vector | string scalar

Model for the within-subject factors, specified as the comma-separated pair consisting of `'WithinModel'` and one of the following:

- `'separatemeans'` — Compute a separate mean for each group.
- `'orthogonalcontrasts'` — Valid when the within-subject design consists of a single numeric factor T . This specifies a model consisting of orthogonal polynomials up to order $T^{(r-1)}$, where r is the number of repeated measures.
- A character vector or string scalar that defines a model specification in the within-subject factors.

Example: `'WithinModel', 'orthogonalcontrasts'`

Data Types: `char` | `string`

WithinDesign — Design for within-subject factors

vector | matrix | table

Design for within-subject factors, specified as the comma-separated pair consisting of 'WithinDesign' and a vector, matrix, or a table. It provides the values of the within-subject factors in the same form as the `RM.WithinDesign` property.

Example: 'WithinDesign', 'Time'

Data Types: single | double | table

Output Arguments

ypred — Predicted values*n*-by-*r* matrix

Predicted values from the repeated measures model `rm`, returned as an *n*-by-*r* matrix, where *n* is the number of rows in `tnew` and *r* is the number of repeated measures in `rm`.

yci — Confidence intervals for predicted values*n*-by-*r*-by-2 matrix

Confidence intervals for predicted values from the repeated measures model `rm`, returned as an *n*-by-*r*-by-2 matrix.

These are nonsimultaneous intervals for predicting the mean response at the specified predictor values. For predicted value `ypred(i, j)`, the lower limit of the interval is `yci(i, j, 1)` and the upper limit is `yci(i, j, 2)`.

Examples

Predict Response Values

Load the sample data.

```
load fisheriris
```

The column vector, `species` consists of iris flowers of three different species: `setosa`, `versicolor`, and `virginica`. The double matrix `meas` consists of four types of measurements on the flowers: the length and width of sepals and petals in centimeters, respectively.

Store the data in a table array.

```
t = table(species,meas(:,1),meas(:,2),meas(:,3),meas(:,4), ...
    'VariableNames',{'species','meas1','meas2','meas3','meas4'});
Meas = dataset([1 2 3 4'],'VarNames',{'Measurements'});
```

Fit a repeated measures model, where the measurements are the responses and the species is the predictor variable.

```
rm = fitrm(t,'meas1-meas4~species','WithinDesign',Meas);
```

Predict responses for the three species.

```
Y = predict(rm,t([1 51 101],:))
```

Y = 3×4

5.0060	3.4280	1.4620	0.2460
5.9360	2.7700	4.2600	1.3260
6.5880	2.9740	5.5520	2.0260

Predict Response Values and Plot Predictions

Load the sample data.

```
load longitudinalData
```

The matrix Y contains response data for 16 individuals. The response is the blood level of a drug measured at five time points (time = 0, 2, 4, 6, and 8). Each row of Y corresponds to an individual, and each column corresponds to a time point. The first eight subjects are female, and the second eight subjects are male. This is simulated data.

Define a variable that stores gender information.

```
Gender = ['F' 'F' 'F' 'F' 'F' 'F' 'F' 'F' 'M' 'M' 'M' 'M' 'M' 'M' 'M'];
```

Store the data in a proper table array format to perform repeated measures analysis.

```
t = table(Gender,Y(:,1),Y(:,2),Y(:,3),Y(:,4),Y(:,5), ...
    'VariableNames',{'Gender','t0','t2','t4','t6','t8'});
```

Define the within-subjects variable.

```
Time = [0 2 4 6 8]';
```

Fit a repeated measures model, where the blood levels are the responses and gender is the predictor variable.

```
rm = fitrm(t, 't0-t8 ~ Gender', 'WithinDesign', Time);
```

Predict the responses at intermediate times.

```
time = linspace(0,8)';  
Y = predict(rm, t([1 5 8 12],:), ...  
    'WithinModel', 'orthogonalcontrasts', 'WithinDesign', time);
```

Plot the predictions along with the estimated marginal means.

```
plotprofile(rm, 'Time', 'Group', {'Gender'})  
hold on;  
plot(time, Y, 'Color', 'k', 'LineStyle', ':');  
legend('Gender=F', 'Gender=M', 'Predictions')  
hold off
```

Compute and Plot Confidence Intervals

Load the sample data.

```
load longitudinalData
```

The matrix Y contains response data for 16 individuals. The response is the blood level of a drug measured at five time points (time = 0, 2, 4, 6, and 8). Each row of Y corresponds to an individual, and each column corresponds to a time point. The first eight subjects are female, and the second eight subjects are male. This is simulated data.

Define a variable that stores gender information.

```
Gender = ['F' 'F' 'F' 'F' 'F' 'F' 'F' 'F' 'M' 'M' 'M' 'M' 'M' 'M' 'M' 'M'];
```

Store the data in a proper table array format to perform repeated measures analysis.

```
t = table(Gender,Y(:,1),Y(:,2),Y(:,3),Y(:,4),Y(:,5), ...  
         'VariableNames',{'Gender','t0','t2','t4','t6','t8'});
```

Define the within-subjects variable.

```
Time = [0 2 4 6 8]';
```

Fit a repeated measures model, where the blood levels are the responses and gender is the predictor variable.

```
rm = fitrm(t,'t0-t8 ~ Gender','WithinDesign',Time);
```

Predict the responses at intermediate times.

```
time = linspace(0,8)';  
[ypred,ypredci] = predict(rm,t([1 5 8 12],:), ...  
                        'WithinModel','orthogonalcontrasts','WithinDesign',time);
```

Plot the predictions and the confidence intervals for predictions along with the estimated marginal means.

```
p1 = plotprofile(rm,'Time','Group',{'Gender'});  
hold on;  
p2 = plot(time,ypred,'Color','k','LineStyle',':');  
p3 = plot(time,ypredci(:,1),'k--');  
p4 = plot(time,ypredci(:,2),'k--');  
legend([p1;p2(1);p3(1)],'Gender=F','Gender=M','Predictions','Confidence Intervals')  
hold off
```

`fitrm` | `random`

predict

Class: TreeBagger

Predict responses using ensemble of bagged decision trees

Syntax

```
Yfit = predict(B,X)
Yfit = predict(B,X,Name,Value)
[Yfit,stdevs] = predict( ___ )
[Yfit,scores] = predict( ___ )
[Yfit,scores,stdevs] = predict( ___ )
```

Description

`Yfit = predict(B,X)` returns a vector of predicted responses for the predictor data in the table or matrix `X`, based on the ensemble of bagged decision trees `B`. `Yfit` is a cell array of character vectors for classification and a numeric array for regression. By default, `predict` takes a democratic (nonweighted) average vote from all trees in the ensemble.

`B` is a trained `TreeBagger` model object, that is, a model returned by `TreeBagger`.

`X` is a table or matrix of predictor data used to generate responses. Rows represent observations and columns represent variables.

- If `X` is a numeric matrix:
 - The variables making up the columns of `X` must have the same order as the predictor variables that trained `B`.
 - If you trained `B` using a table (for example, `Tbl`), then `X` can be a numeric matrix if `Tbl` contains all numeric predictor variables. To treat numeric predictors in `Tbl` as categorical during training, identify categorical predictors using the `CategoricalPredictors` name-value pair argument of `TreeBagger`. If `Tbl` contains heterogeneous predictor variables (for example, numeric and categorical data types) and `X` is a numeric matrix, then `predict` throws an error.

- If `X` is a table:
 - `predict` does not support multi-column variables and cell arrays other than cell arrays of character vectors.
 - If you trained `B` using a table (for example, `Tbl`), then all predictor variables in `X` must have the same variable names and be of the same data types as those that trained `B` (stored in `B.PredictorNames`). However, the column order of `X` does not need to correspond to the column order of `Tbl`. `Tbl` and `X` can contain additional variables (response variables, observation weights, etc.), but `predict` ignores them.
 - If you trained `B` using a numeric matrix, then the predictor names in `B.PredictorNames` and corresponding predictor variable names in `X` must be the same. To specify predictor names during training, see the `PredictorNames` name-value pair argument of `TreeBagger`. All predictor variables in `X` must be numeric vectors. `X` can contain additional variables (response variables, observation weights, etc.), but `predict` ignores them.

`Yfit = predict(B,X,Name,Value)` specifies additional options using one or more name-value pair arguments:

- `'Trees'` — Array of tree indices to use for computation of responses. The default is `'all'`.
- `'TreeWeights'` — Array of `NTrees` weights for weighting votes from the specified trees, where `NTrees` is the number of trees in the ensemble.
- `'UseInstanceForTree'` — Logical matrix of size `Nobs-by-NTrees` indicating which trees to use to make predictions for each observation, where `Nobs` is the number of observations. By default all trees are used for all observations.

For regression, `[Yfit,stdevs] = predict(____)` also returns standard deviations of the computed responses over the ensemble of the grown trees using any of the input argument combinations in previous syntaxes.

For classification, `[Yfit,scores] = predict(____)` also returns scores for all classes. `scores` is a matrix with one row per observation and one column per class. For each observation and each class, the score generated by each tree is the probability of the observation originating from the class, computed as the fraction of observations of the class in a tree leaf. `predict` averages these scores over all trees in the ensemble.

`[Yfit,scores,stdevs] = predict(____)` also returns standard deviations of the computed scores for classification. `stdevs` is a matrix with one row per observation and

one column per class, with standard deviations taken over the ensemble of the grown trees.

Algorithms

- For regression problems, the predicted response for an observation is the weighted average of the predictions using selected trees only. That is,

$$\hat{y}_{\text{bag}} = \frac{1}{\sum_{t=1}^T \alpha_t I(t \in S)} \sum_{t=1}^T \alpha_t \hat{y}_t I(t \in S).$$

- \hat{y}_t is the prediction from tree t in the ensemble.
 - S is the set of indices of selected trees that comprise the prediction (see 'Trees' and 'UseInstanceForTree'). $I(t \in S)$ is 1 if t is in the set S , and 0 otherwise.
 - α_t is the weight of tree t (see 'TreeWeights').
- For classification problems, the predicted class for an observation is the class that yields the largest weighted average of the class posterior probabilities (i.e., classification scores) computed using selected trees only. That is,
 - 1 For each class $c \in C$ and each tree $t = 1, \dots, T$, `predict` computes $\hat{P}_t(c|x)$, which is the estimated posterior probability of class c given observation x using tree t . C is the set of all distinct classes in the training data. For more details on classification tree posterior probabilities, see `fitctree` and `predict`.
 - 2 `predict` computes the weighted average of the class posterior probabilities over the selected trees.

$$\hat{P}_{\text{bag}}(c|x) = \frac{1}{\sum_{t=1}^T \alpha_t I(t \in S)} \sum_{t=1}^T \alpha_t \hat{P}_t(c|x) I(t \in S).$$

- 3 The predicted class is the class that yields the largest weighted average.

$$\hat{y}_{\text{bag}} = \operatorname{argmax}_{c \in C} \{ \hat{P}_{\text{bag}}(c|x) \}.$$

predictConstraints

Predict coupled constraint violations at a set of points

Syntax

```
ConstraintViolations = predictConstraints(results,XTable)
[ConstraintViolations,sigma] = predictConstraints(results,XTable)
```

Description

`ConstraintViolations = predictConstraints(results,XTable)` returns the coupled constraint function violations at the points in `XTable`.

`[ConstraintViolations,sigma] = predictConstraints(results,XTable)` also returns the standard deviations of the coupled constraint functions.

Examples

Predict Coupled Constraints

This example shows how to predict the coupled constraints of an optimized SVM model. For details of this model, see “Optimize a Cross-Validated SVM Classifier Using `bayesopt`” on page 10-54.

```
rng default
grnpop = mvnrnd([1,0],eye(2),10);
redpop = mvnrnd([0,1],eye(2),10);
redpts = zeros(100,2);
grnpts = redpts;
for i = 1:100
    grnpts(i,:) = mvnrnd(grnpop(randi(10),:),eye(2)*0.02);
    redpts(i,:) = mvnrnd(redpop(randi(10),:),eye(2)*0.02);
end
cdata = [grnpts;redpts];
```

```

grp = ones(200,1);
grp(101:200) = -1;
c = cvpartition(200,'KFold',10);
sigma = optimizableVariable('sigma',[1e-5,1e5],'Transform','log');
box = optimizableVariable('box',[1e-5,1e5],'Transform','log');

```

The objective function is the cross-validation loss of the SVM model for the partition `c`. The coupled constraint is the number of support vectors in the model minus 100. The model has 200 data points, so the coupled constraint values range from -100 to 100. Positive values mean the constraint is not satisfied.

```

function [objective,constraint] = mysvmfun(x,cdata,grp,c)
SVMModel = fitcsvm(cdata,grp,'KernelFunction','rbf',...
    'BoxConstraint',x.box,...
    'KernelScale',x.sigma);
cvModel = crossval(SVMModel,'CVPartition',c);
objective = kfoldLoss(cvModel);
constraint = sum(SVMModel.IsSupportVector)-100.5;

```

Call the optimizer using this function and its one coupled constraint.

```

fun = @(x)mysvmfun(x,cdata,grp,c);
results = bayesopt(fun,[sigma,box],'IsObjectiveDeterministic',true,...
    'NumCoupledConstraints',1,'PlotFcn',...
    {@plotMinObjective,@plotConstraintModels,@plotObjectiveModel},...
    'AcquisitionFunctionName','expected-improvement-plus','Verbose',0);

```

Constraint 1 model

The constraint model plot shows that most parameters in the range are infeasible, and are feasible only for relatively high values of the `box` parameter and a small range of the `sigma` parameter. Predict the coupled constraint values for several values of the control variables `box` and `sigma`.

```
sigma = logspace(-2,2,11)';  
box = logspace(0,5,11)';
```

```
XTable = table(sigma,box);  
cons = predictConstraints(results,XTable);  
[XTable,table(cons)]
```

```
ans =
```

```
11x3 table
```

sigma	box	cons
0.01	1	99.443
0.025119	3.1623	106.49
0.063096	10	94.468
0.15849	31.623	25.134
0.39811	100	-38.732
1	316.23	-55.156
2.5119	1000	-34.181
6.3096	3162.3	5.0153
15.849	10000	39.465
39.811	31623	60.9
100	1e+05	71.906

Input Arguments

results — Bayesian optimization results

BayesianOptimization object

Bayesian optimization results, specified as a BayesianOptimization object.

XTable — Prediction points

table with D columns

Prediction points, specified as a table with D columns, where D is the number of variables in the problem. The function performs its predictions on these points.

Data Types: table

Output Arguments

ConstraintViolations — Constraint violations

N-by-K matrix

Constraint violations, returned as an N-by-K matrix, where there are N rows in `XTable` and K coupled constraints. The constraint violations are the posterior means of the Gaussian process model of the coupled constraints at the points in `XTable`.

sigma — Constraint standard deviations

N-by-K matrix

Constraint standard deviations, returned as an N-by-K matrix, where there are N rows in `XTable` and K coupled constraints. The standard deviations represent those of the posterior distribution at the points in `XTable`.

See Also

`BayesianOptimization` | `bayesopt`

Introduced in R2016b

predictError

Predict error value at a set of points

Syntax

```
error = predictError(results,XTable)
[error,sigma] = predictError(results,XTable)
```

Description

`error = predictError(results,XTable)` returns the posterior mean of the error coupled constraint at the points in `XTable`.

`[error,sigma] = predictError(results,XTable)` also returns the posterior standard deviations.

Examples

Error Prediction

This example shows optimizing a function that throws an error when the evaluation point has norm larger than 2. The error model for the objective function learns this behavior.

Create variables named `x1` and `x2` that range from -5 to 5.

```
var1 = optimizableVariable('x1',[-5,5]);
var2 = optimizableVariable('x2',[-5,5]);
vars = [var1,var2];
```

The following objective function throws an error when the norm of `x = [x1,x2]` exceeds 2:

```
function f = makeanerror(x)
```

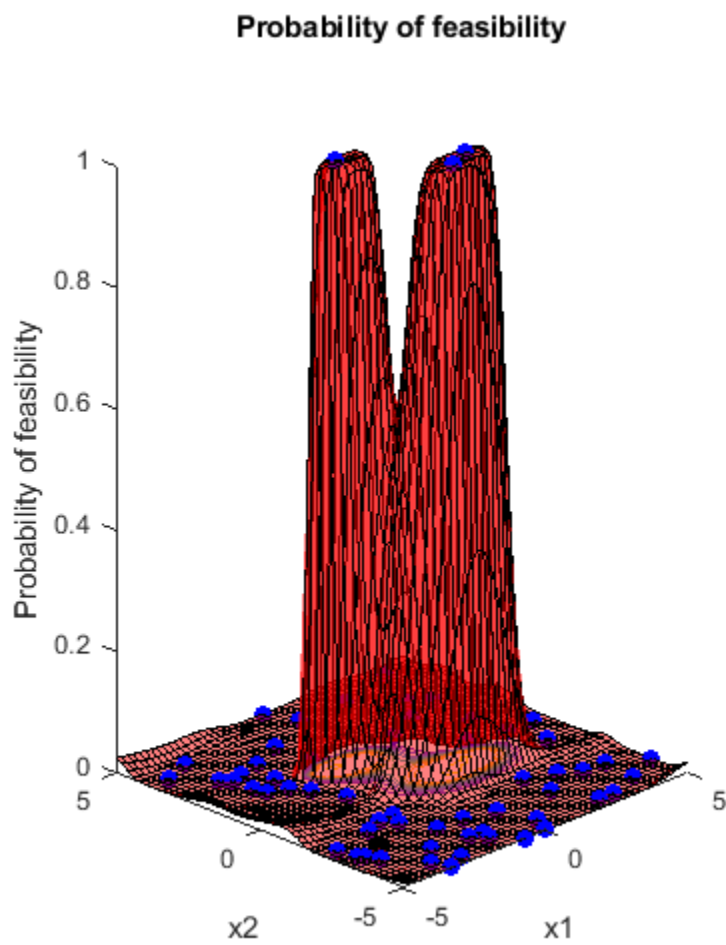

```
f = x.x1 - x.x2 - sqrt(4-x.x1^2-x.x2^2);
```

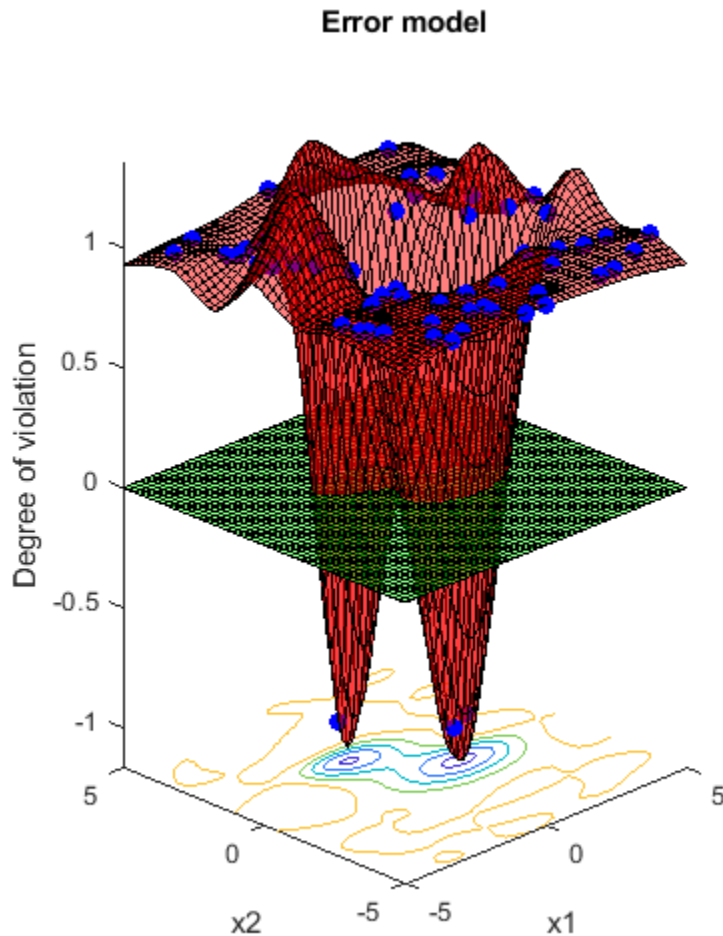

```
fun = @makeanerror;
```

Plot the error model and minimum objective as the optimization proceeds. Optimize for 60 iterations so the error model becomes well-trained. For reproducibility, set the random seed and use the 'expected-improvement-plus' acquisition function.

```
rng default
results = bayesopt(fun,vars,'Verbose',0,'MaxObjectiveEvaluations',60,...
    'AcquisitionFunctionName','expected-improvement-plus',...
    'PlotFcn',{@plotMinObjective,@plotConstraintModels});
```

Predict the error at points on the line $x_1 = x_2$. If the error model were perfect, it would have value -1 at every point where the norm of x is no more than 2, and value 1 at all other points.

```
x1 = (-5:0.5:5)';  
x2 = x1;  
XTable = table(x1,x2);
```

```
error = predictError(results,XTable);  
normx = sqrt(x1.^2 + x2.^2);  
[XTable,table(normx,error)]
```

```
ans =
```

```
21x4 table
```

x1	x2	normx	error
-5	-5	7.0711	0.94663

4.5	4.5	6.364	0.98956
5	5	7.0711	0.95549

Input Arguments

results — Bayesian optimization results

BayesianOptimization object

Bayesian optimization results, specified as a BayesianOptimization object.

XTable — Prediction points

table with D columns

Prediction points, specified as a table with D columns, where D is the number of variables in the problem. The function performs its predictions on these points.

Data Types: table

Output Arguments

error — Mean of error coupled constraint

N-by-1 vector

Mean of error coupled constraint, returned as an N-by-1 vector, where N is the number of rows of XTable. The mean is the posterior mean of the error coupled constraint at the points in XTable.

bayesopt deems your objective function to return an error if it returns anything other than a finite real scalar. See “Objective Function Errors” on page 10-43.

sigma — Standard deviation of error coupled constraint

N-by-1 vector

Standard deviation of error coupled constraint, returned as an N-by-1 vector, where N is the number of rows of XTable.

BayesianOptimization | bayesopt

Introduced in R2016b

predictObjective

Predict objective function at a set of points

Syntax

```
objective = predictObjective(results,XTable)
[objective,sigma] = predictObjective(results,XTable)
```

Description

`objective = predictObjective(results,XTable)` returns the estimated objective function value at the points in `XTable`.

`[objective,sigma] = predictObjective(results,XTable)` also returns estimated standard deviations.

Examples

Predict Cross-Validation Loss of an Optimized Classifier

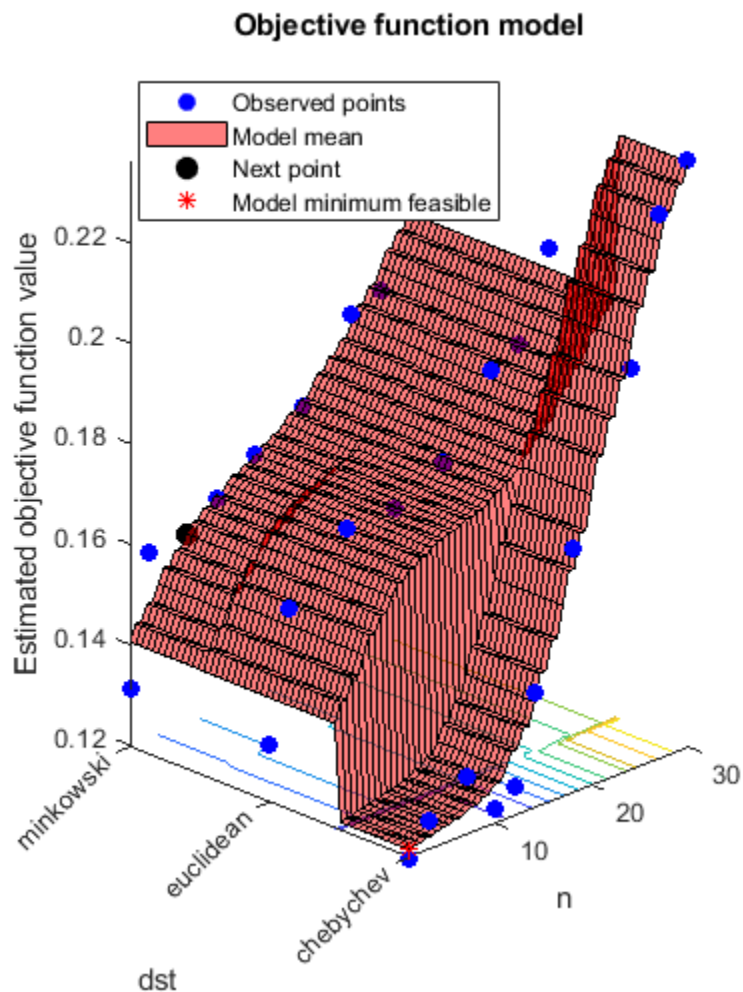

This example shows how to estimate the cross-validation loss of an optimized classifier.

Optimize a KNN classifier for the `ionosphere` data, meaning find parameters that minimize the cross-validation loss. Minimize over nearest-neighborhood sizes from 1 to 30, and over the distance functions `'chebychev'`, `'euclidean'`, and `'minkowski'`.

For reproducibility, set the random seed, and set the `AcquisitionFunctionName` option to `'expected-improvement-plus'`.

```
load ionosphere
rng default
num = optimizableVariable('n',[1,30],'Type','integer');
dst = optimizableVariable('dst',{'chebychev','euclidean','minkowski'},'Type','categorical');
c = cvpartition(351,'Kfold',5);
```

```
fun = @(x)kfoldLoss(fitcknn(X,Y,'CVPartition',c,'NumNeighbors',x.n,...  
'Distance',char(x.dst),'NSMethod','exhaustive'));  
results = bayesopt(fun,[num,dst],'Verbose',0,...  
'AcquisitionFunctionName','expected-improvement-plus');
```

Create a table of points to estimate.

```
b = categorical({'chebychev','euclidean','minkowski'});
n = [1;1;1;4;2;2];
dst = [b(1);b(2);b(3);b(1);b(1);b(3)];
XTable = table(n,dst);
```

Estimate the objective and standard deviation of the objective at these points.

```
[objective,sigma] = predictObjective(results,XTable);
[XTable,table(objective,sigma)]
```

```
ans=6x4 table
      n      dst      objective      sigma
      -      -      -      -
```

1	chebychev	0.12132	0.0068029
1	euclidean	0.14052	0.0079128
1	minkowski	0.14057	0.0079117
4	chebychev	0.1227	0.0068805
2	chebychev	0.12176	0.0066739
2	minkowski	0.1437	0.0075448

Input Arguments

results — Bayesian optimization results

BayesianOptimization object

Bayesian optimization results, specified as a BayesianOptimization object.

XTable — Prediction points

table with D columns

Prediction points, specified as a table with D columns, where D is the number of variables in the problem. The function performs its predictions on these points.

Data Types: table

Output Arguments

objective — Objective estimates

N-by-1 vector

Objective estimates, returned as an N-by-1 vector, where N is the number of rows of XTable. The estimates are the mean values of the posterior distribution of the Gaussian process model of the objective function.

sigma — Standard deviations of objective function

N-by-1 vector

Standard deviations of objective function, returned as an N-by-1 vector, where N is the number of rows of XTable. The standard deviations are those of the posterior distribution of the Gaussian process model of the objective function.

predictObjectiveEvaluationTime

Predict objective function run times at a set of points

Syntax

```
time = predictObjectiveEvaluationTime(results,XTable)
```

Description

`time = predictObjectiveEvaluationTime(results,XTable)` returns estimated objective evaluation times at the points in `XTable`.

Examples

Predict Evaluation Time of Objective In an Optimized Model

This example shows how to estimate the objective function evaluation time in an optimized Bayesian model of SVM classification.

Create an optimized SVM model. For details of this model, see “Optimize a Cross-Validated SVM Classifier Using `bayesopt`” on page 10-54.

```
rng default
grpnpop = mvnrnd([1,0],eye(2),10);
redpop = mvnrnd([0,1],eye(2),10);
redpts = zeros(100,2);
grppts = redpts;
for i = 1:100
    grppts(i,:) = mvnrnd(grnpop(randi(10),:),eye(2)*0.02);
    redpts(i,:) = mvnrnd(redpop(randi(10),:),eye(2)*0.02);
end
cdata = [grppts;redpts];
grp = ones(200,1);
grp(101:200) = -1;
c = cvpartition(200,'KFold',10);
```

```

sigma = optimizableVariable('sigma',[1e-5,1e5],'Transform','log');
box = optimizableVariable('box',[1e-5,1e5],'Transform','log');
minfn = @(z)kfoldLoss(fitcsvm(cdata,grp,'CVPartition',c,...
    'KernelFunction','rbf','BoxConstraint',z.box,...
    'KernelScale',z.sigma));
results = bayesopt(minfn,[sigma,box],'IsObjectiveDeterministic',true,...
    'AcquisitionFunctionName','expected-improvement-plus','Verbose',0);

```

Predict the evaluation time for various points.

```
sigma = logspace(-5,5,11)';
box = 1e5*ones(size(sigma));
XTable = table(sigma,box);
time = predictObjectiveEvaluationTime(results,XTable);
[XTable,table(time)]
```

```
ans=11x3 table
    sigma    box    time
    -----
    1e-05    1e+05    0.44304
    0.0001    1e+05    0.49003
```

0.001	1e+05	0.43487
0.01	1e+05	0.42909
0.1	1e+05	0.31202
1	1e+05	0.53908
10	1e+05	4.8849
100	1e+05	0.91161
1000	1e+05	0.28705
10000	1e+05	0.32398
1e+05	1e+05	0.28783

Input Arguments

results — Bayesian optimization results

BayesianOptimization object

Bayesian optimization results, specified as a BayesianOptimization object.

XTable — Prediction points

table with D columns

Prediction points, specified as a table with D columns, where D is the number of variables in the problem. The function performs its predictions on these points.

Data Types: table

Output Arguments

time — Estimated objective evaluation times

N-by-1 vector

Estimated objective evaluation times, returned as an N-by-1 vector, where N is the number of rows of XTable. The estimated values are the means of the posterior distribution of the Gaussian process model of the evaluation times of the objective function.

predictorImportance

Estimates of predictor importance

Syntax

```
imp = predictorImportance(ens)  
[imp,ma] = predictorImportance(ens)
```

Description

`imp = predictorImportance(ens)` computes estimates of predictor importance for `ens` by summing these estimates over all weak learners in the ensemble. `imp` has one element for each input predictor in the data used to train this ensemble. A high value indicates that this predictor is important for `ens`.

`[imp,ma] = predictorImportance(ens)` returns a P-by-P matrix with predictive measures of association for P predictors, when the learners in `ens` contain surrogate splits. See “Definitions” on page 32-5436.

Input Arguments

ens

A classification ensemble created by `fitcensemble`, or by the compact method.

Output Arguments

imp

A row vector with the same number of elements as the number of predictors (columns) in `ens.X`. The entries are the estimates of predictor importance, with 0 representing the smallest possible importance.

ma

A P-by-P matrix of predictive measures of association for P predictors. Element $ma(I, J)$ is the predictive measure of association averaged over surrogate splits on predictor J for which predictor I is the optimal split predictor. `predictorImportance` averages this predictive measure of association over all trees in the ensemble.

Examples

Estimate Predictor Importance

Estimate the predictor importance for all variables in the Fisher iris data.

Load Fisher's iris data set.

```
load fisheriris
```

Train a classification ensemble using AdaBoostM2. Specify tree stumps as the weak learners.

```
t = templateTree('MaxNumSplits',1);
ens = fitcensemble(meas,species,'Method','AdaBoostM2','Learners',t);
```

Estimate the predictor importance for all predictor variables.

```
imp = predictorImportance(ens)

imp = 1x4

    0.0004    0.0016    0.1266    0.0324
```

The first two predictors are not very important in the ensemble.

Predictor Importance and Surrogate Splits

Estimate the predictor importance for all variables in the Fisher iris data for an ensemble where the trees contain surrogate splits.

Load Fisher's iris data set.

```
load fisheriris
```

Grow an ensemble of 100 classification trees using AdaBoostM2. Specify tree stumps as the weak learners, and also identify surrogate splits.

```
t = templateTree('MaxNumSplits',1,'Surrogate','on');  
ens = fitensemble(meas,species,'Method','AdaBoostM2','Learners',t);
```

Estimate the predictor importance and predictive measures of association for all predictor variables.

```
[imp,ma] = predictorImportance(ens)  
  
imp = 1×4  
    0.0674    0.0417    0.1582    0.1537  
  
ma = 4×4  
    1.0000         0         0         0  
    0.0115    1.0000    0.0022    0.0054  
    0.3186    0.2137    1.0000    0.6391  
    0.0392    0.0073    0.1137    1.0000
```

The first two predictors show much more importance than the analysis in “Estimate Predictor Importance” on page 32-5435.

Definitions

Predictor Importance

`predictorImportance` computes estimates of predictor importance for `ens` by summing changes in the risk due to splits on every predictor and dividing the sum by the number of branch nodes. If `ens` is grown without surrogate splits, this sum is taken over best splits found at each branch node. If `ens` is grown with surrogate splits, this sum is taken over all splits at each branch node including surrogate splits. `imp` has one element for each input predictor in the data used to train `ens`. Predictor importance associated

with this split is computed as the difference between the risk for the parent node and the total risk for the two children.

Impurity and Node Error

`ClassificationTree` splits nodes based on either impurity or node error.

Impurity means one of several things, depending on your choice of the `SplitCriterion` name-value pair argument:

- Gini's Diversity Index (`gdi`) — The Gini index of a node is

$$1 - \sum_i p^2(i),$$

where the sum is over the classes i at the node, and $p(i)$ is the observed fraction of classes with class i that reach the node. A node with just one class (a pure node) has Gini index 0; otherwise the Gini index is positive. So the Gini index is a measure of node impurity.

- Deviance ('`deviance`') — With $p(i)$ defined the same as for the Gini index, the deviance of a node is

$$- \sum_i p(i) \log_2 p(i).$$

A pure node has deviance 0; otherwise, the deviance is positive.

- Twoing rule ('`twoing`') — Twoing is not a purity measure of a node, but is a different measure for deciding how to split a node. Let $L(i)$ denote the fraction of members of class i in the left child node after a split, and $R(i)$ denote the fraction of members of class i in the right child node after a split. Choose the split criterion to maximize

$$P(L)P(R) \left(\sum_i |L(i) - R(i)| \right)^2,$$

where $P(L)$ and $P(R)$ are the fractions of observations that split to the left and right respectively. If the expression is large, the split made each child node purer. Similarly, if the expression is small, the split made each child node similar to each other, and therefore similar to the parent node. The split did not increase node purity.

- Node error — The node error is the fraction of misclassified classes at a node. If j is the class with the largest number of training samples at a node, the node error is

1

-

 $p(j)$.

Predictive Measure of Association

The predictive measure of association is a value that indicates the similarity between decision rules that split observations. Among all possible decision splits that are compared to the optimal split (found by growing the tree), the best surrogate decision split on page 32-2176 yields the maximum predictive measure of association. The second-best surrogate split has the second-largest predictive measure of association.

Suppose x_j and x_k are predictor variables j and k , respectively, and $j \neq k$. At node t , the predictive measure of association between the optimal split $x_j < u$ and a surrogate split $x_k < v$ is

$$\lambda_{jk} = \frac{\min(P_L, P_R) - (1 - P_{L_j L_k} - P_{R_j R_k})}{\min(P_L, P_R)}.$$

- P_L is the proportion of observations in node t , such that $x_j < u$. The subscript L stands for the left child of node t .
- P_R is the proportion of observations in node t , such that $x_j \geq u$. The subscript R stands for the right child of node t .
- $P_{L_j L_k}$ is the proportion of observations at node t , such that $x_j < u$ and $x_k < v$.
- $P_{R_j R_k}$ is the proportion of observations at node t , such that $x_j \geq u$ and $x_k \geq v$.
- Observations with missing values for x_j or x_k do not contribute to the proportion calculations.

λ_{jk} is a value in $(-\infty, 1]$. If $\lambda_{jk} > 0$, then $x_k < v$ is a worthwhile surrogate split for $x_j < u$.

Algorithms

Element $\text{ma}(i, j)$ is the predictive measure of association averaged over surrogate splits on predictor j for which predictor i is the optimal split predictor. This average is computed by summing positive values of the predictive measure of association over optimal splits on predictor i and surrogate splits on predictor j and dividing by the total number of optimal splits on predictor i , including splits for which the predictive measure of association between predictors i and j is negative.

predictorImportance

Estimates of predictor importance

Syntax

```
imp = predictorImportance(tree)
```

Description

`imp = predictorImportance(tree)` computes estimates of predictor importance for `tree` by summing changes in the risk due to splits on every predictor and dividing the sum by the number of branch nodes.

Input Arguments

tree

A classification tree created by `fitctree`, or by the `compact` method.

Output Arguments

imp

A row vector with the same number of elements as the number of predictors (columns) in `tree.X`. The entries are the estimates of predictor importance, with `0` representing the smallest possible importance.

Examples

Estimate Predictor Importance Values

Load Fisher's iris data set.

```
load fisheriris
```

Grow a classification tree.

```
Mdl = fitctree(meas,species);
```

Compute predictor importance estimates for all predictor variables.

```
imp = predictorImportance(Mdl)
```

```
imp = 1×4
      0      0  0.0907  0.0682
```

The first two elements of `imp` are zero. Therefore, the first two predictors do not enter into `Mdl` calculations for classifying irises.

Estimates of predictor importance do not depend on the order of predictors if you use surrogate splits, but do depend on the order if you do not use surrogate splits.

Permute the order of the data columns in the previous example, grow another classification tree, and then compute predictor importance estimates.

```
measPerm = meas(:,[4 1 3 2]);
MdlPerm = fitctree(measPerm,species);
impPerm = predictorImportance(MdlPerm)
```

```
impPerm = 1×4
  0.1515      0  0.0074      0
```

The estimates of predictor importance are not a permutation of `imp`.

Surrogate Splits and Predictor Importance

Load Fisher's iris data set.

```
load fisheriris
```

Grow a classification tree. Specify usage of surrogate splits.

```
Mdl = fitctree(meas,species,'Surrogate','on');
```

Compute predictor importance estimates for all predictor variables.

```
imp = predictorImportance(Mdl)
```

```
imp = 1×4
```

```
    0.0791    0.0374    0.1530    0.1529
```

All predictors have some importance. The first two predictors are less important than the final two.

Permute the order of the data columns in the previous example, grow another classification tree specifying usage of surrogate splits, and then compute predictor importance estimates.

```
measPerm = meas(:,[4 1 3 2]);
```

```
MdlPerm = fitctree(measPerm,species,'Surrogate','on');
```

```
impPerm = predictorImportance(MdlPerm)
```

```
impPerm = 1×4
```

```
    0.1529    0.0791    0.1530    0.0374
```

The estimates of predictor importance are a permutation of `imp`.

Unbiased Predictor Importance Estimates

Load the census1994 data set. Consider a model that predicts a person's salary category given their age, working class, education level, marital status, race, sex, capital gain and loss, and number of working hours per week.

```
load census1994
```

```
X = adultdata(:,{'age','workClass','education_num','marital_status','race',...  
               'sex','capital_gain','capital_loss','hours_per_week','salary'});
```

Display the number of categories represented in the categorical variables using `summary`.

```
summary(X)
```

```
Variables:
```

```
age: 32561x1 double
```

```
Values:
```

Min	17
Median	37
Max	90

```
workClass: 32561x1 categorical
```

```
Values:
```

Federal-gov	960
Local-gov	2093
Never-worked	7
Private	22696
Self-emp-inc	1116
Self-emp-not-inc	2541
State-gov	1298
Without-pay	14
NumMissing	1836

```
education_num: 32561x1 double
```

```
Values:
```

Min	1
Median	10
Max	16

```
marital_status: 32561x1 categorical
```

```
Values:
```

Divorced	4443
Married-AF-spouse	23
Married-civ-spouse	14976
Married-spouse-absent	418
Never-married	10683

Separated	1025
Widowed	993

race: 32561x1 categorical

Values:

Amer-Indian-Eskimo	311
Asian-Pac-Islander	1039
Black	3124
Other	271
White	27816

sex: 32561x1 categorical

Values:

Female	10771
Male	21790

capital_gain: 32561x1 double

Values:

Min	0
Median	0
Max	99999

capital_loss: 32561x1 double

Values:

Min	0
Median	0
Max	4356

hours_per_week: 32561x1 double

Values:

Min	1
Median	40
Max	99

```
salary: 32561x1 categorical
```

```
Values:
```

```

    <=50K    24720
    >50K     7841

```

Because there are few categories represented in the categorical variables compared to levels in the continuous variables, the standard CART, predictor-splitting algorithm prefers splitting a continuous predictor over the categorical variables.

Train a classification tree using the entire data set. To grow unbiased trees, specify usage of the curvature test for splitting predictors. Because there are missing observations in the data, specify usage of surrogate splits.

```
Mdl = fitctree(X,'salary','PredictorSelection','curvature',...
    'Surrogate','on');
```

Estimate predictor importance values by summing changes in the risk due to splits on every predictor and dividing the sum by the number of branch nodes. Compare the estimates using a bar graph.

```
imp = predictorImportance(Mdl);

figure;
bar(imp);
title('Predictor Importance Estimates');
ylabel('Estimates');
xlabel('Predictors');
h = gca;
h.XTickLabel = Mdl.PredictorNames;
h.XTickLabelRotation = 45;
h.TickLabelInterpreter = 'none';
```

In this case, `capital_gain` is the most important predictor, followed by `education_num`.

Definitions

Predictor Importance

`predictorImportance` computes estimates of predictor importance for `tree` by summing changes in the risk due to splits on every predictor and dividing the sum by the number of branch nodes. If `tree` is grown without surrogate splits, this sum is taken over

best splits found at each branch node. If `tree` is grown with surrogate splits, this sum is taken over all splits at each branch node including surrogate splits. `imp` has one element for each input predictor in the data used to train `tree`. Predictor importance associated with this split is computed as the difference between the risk for the parent node and the total risk for the two children.

Estimates of predictor importance do not depend on the order of predictors if you use surrogate splits, but do depend on the order if you do not use surrogate splits.

If you use surrogate splits, `predictorImportance` computes estimates before the tree is reduced by pruning or merging leaves. If you do not use surrogate splits, `predictorImportance` computes estimates after the tree is reduced by pruning or merging leaves. Therefore, reducing the tree by pruning affects the predictor importance for a tree grown without surrogate splits, and does not affect the predictor importance for a tree grown with surrogate splits.

Impurity and Node Error

`ClassificationTree` splits nodes based on either impurity or node error.

Impurity means one of several things, depending on your choice of the `SplitCriterion` name-value pair argument:

- Gini's Diversity Index (`gdi`) — The Gini index of a node is

$$1 - \sum_i p^2(i),$$

where the sum is over the classes i at the node, and $p(i)$ is the observed fraction of classes with class i that reach the node. A node with just one class (a pure node) has Gini index 0; otherwise the Gini index is positive. So the Gini index is a measure of node impurity.

- Deviance (`'deviance'`) — With $p(i)$ defined the same as for the Gini index, the deviance of a node is

$$- \sum_i p(i) \log_2 p(i).$$

A pure node has deviance 0; otherwise, the deviance is positive.

- Twoing rule (`'twoing'`) — Twoing is not a purity measure of a node, but is a different measure for deciding how to split a node. Let $L(i)$ denote the fraction of members of

class i in the left child node after a split, and $R(i)$ denote the fraction of members of class i in the right child node after a split. Choose the split criterion to maximize

$$P(L)P(R)\left(\sum_i |L(i) - R(i)|\right)^2,$$

where $P(L)$ and $P(R)$ are the fractions of observations that split to the left and right respectively. If the expression is large, the split made each child node purer. Similarly, if the expression is small, the split made each child node similar to each other, and therefore similar to the parent node. The split did not increase node purity.

- Node error — The node error is the fraction of misclassified classes at a node. If j is the class with the largest number of training samples at a node, the node error is

1

-

 $p(j)$.

Topics

“Choose Split Predictor Selection Technique” on page 19-19

predictorImportance

Estimates of predictor importance

Syntax

```
imp = predictorImportance(ens)  
[imp,ma] = predictorImportance(ens)
```

Description

`imp = predictorImportance(ens)` computes estimates of predictor importance for `ens` by summing these estimates over all weak learners in the ensemble. `imp` has one element for each input predictor in the data used to train this ensemble. A high value indicates that this predictor is important for `ens`.

`[imp,ma] = predictorImportance(ens)` returns a P-by-P matrix with predictive measures of association for P predictors.

Input Arguments

ens

A regression ensemble created by `fitrensemble`, or by the `compact` method.

Output Arguments

imp

A row vector with the same number of elements as the number of predictors (columns) in `ens.X`. The entries are the estimates of predictor importance, with 0 representing the smallest possible importance.

ma

A P-by-P matrix of predictive measures of association for P predictors. Element `ma(I, J)` is the predictive measure of association averaged over surrogate splits on predictor J for which predictor I is the optimal split predictor. `predictorImportance` averages this predictive measure of association over all trees in the ensemble.

Examples

Estimate Predictor Importance

Estimate the predictor importance for all predictor variables in the data.

Load the `carsmall` data set.

```
load carsmall
```

Grow an ensemble of 100 regression trees for MPG using Acceleration, Cylinders, Displacement, Horsepower, Model_Year, and Weight as predictors. Specify tree stumps as the weak learners.

```
X = [Acceleration Cylinders Displacement Horsepower Model_Year Weight];  
t = templateTree('MaxNumSplits',1);  
ens = fitrensemble(X,MPG,'Method','LSBoost','Learners',t);
```

Estimate the predictor importance for all predictor variables.

```
imp = predictorImportance(ens)
```

```
imp = 1×6
```

```
    0.0150         0    0.0066    0.1111    0.0437    0.5181
```

Weight, the last predictor, has the most impact on mileage. The second predictor has importance 0, which means that the number of cylinders has no impact on predictions made with `ens`.

Predictor Importance and Surrogate Splits

Estimate the predictor importance for all variables in the data and where the regression tree ensemble contains surrogate splits.

Load the `carsmall` data set.

```
load carsmall
```

Grow an ensemble of 100 regression trees for MPG using Acceleration, Cylinders, Displacement, Horsepower, Model_Year, and Weight as predictors. Specify tree stumps as the weak learners, and also identify surrogate splits.

```
X = [Acceleration Cylinders Displacement Horsepower Model_Year Weight];
t = templateTree('MaxNumSplits',1,'Surrogate','on');
ens = fitensemble(X,MPG,'Method','LSBoost','Learners',t);
```

Estimate the predictor importance and predictive measures of association for all predictor variables.

```
[imp,ma] = predictorImportance(ens)
```

```
imp = 1×6
```

```
    0.2065    0.3799    0.4100    0.6190    0.3670    0.5476
```

```
ma = 6×6
```

```
    1.0000    0.0098    0.0102    0.0098    0.0033    0.0067
         0     1.0000         0         0         0         0
    0.0056    0.0084    1.0000    0.0078    0.0022    0.0084
    0.2232    0.1574    0.2066    1.0000    0.0580    0.2059
    0.0061    0.0070    0.0063    0.0064    1.0000    0.0056
    0.0200    0.0368    0.0620    0.0521    0.0098    1.0000
```

Comparing `imp` to the results in “Estimate Predictor Importance” on page 32-5450, Horsepower has the greatest impact on mileage, with Weight having the second greatest impact.

Definitions

Predictor Importance

`predictorImportance` computes estimates of predictor importance for `tree` by summing changes in the mean squared error (MSE) due to splits on every predictor and dividing the sum by the number of branch nodes. If the tree is grown without surrogate splits, this sum is taken over best splits found at each branch node. If the tree is grown with surrogate splits, this sum is taken over all splits at each branch node including surrogate splits. `imp` has one element for each input predictor in the data used to train this tree. At each node, MSE is estimated as node error weighted by the node probability. Variable importance associated with this split is computed as the difference between MSE for the parent node and the total MSE for the two children.

Predictive Measure of Association

The predictive measure of association is a value that indicates the similarity between decision rules that split observations. Among all possible decision splits that are compared to the optimal split (found by growing the tree), the best surrogate decision split on page 32-2176 yields the maximum predictive measure of association. The second-best surrogate split has the second-largest predictive measure of association.

Suppose x_j and x_k are predictor variables j and k , respectively, and $j \neq k$. At node t , the predictive measure of association between the optimal split $x_j < u$ and a surrogate split $x_k < v$ is

$$\lambda_{jk} = \frac{\min(P_L, P_R) - (1 - P_{L_j L_k} - P_{R_j R_k})}{\min(P_L, P_R)}.$$

- P_L is the proportion of observations in node t , such that $x_j < u$. The subscript L stands for the left child of node t .
- P_R is the proportion of observations in node t , such that $x_j \geq u$. The subscript R stands for the right child of node t .
- $P_{L_j L_k}$ is the proportion of observations at node t , such that $x_j < u$ and $x_k < v$.
- $P_{R_j R_k}$ is the proportion of observations at node t , such that $x_j \geq u$ and $x_k \geq v$.
- Observations with missing values for x_j or x_k do not contribute to the proportion calculations.

λ_{jk} is a value in $(-\infty, 1]$. If $\lambda_{jk} > 0$, then $x_k < v$ is a worthwhile surrogate split for $x_j < u$.

Algorithms

Element $ma(i, j)$ is the predictive measure of association averaged over surrogate splits on predictor j for which predictor i is the optimal split predictor. This average is computed by summing positive values of the predictive measure of association over optimal splits on predictor i and surrogate splits on predictor j and dividing by the total number of optimal splits on predictor i , including splits for which the predictive measure of association between predictors i and j is negative.

predictorImportance

Estimates of predictor importance

Syntax

```
imp = predictorImportance(tree)
```

Description

`imp = predictorImportance(tree)` computes estimates of predictor importance for `tree` by summing changes in the mean squared error due to splits on every predictor and dividing the sum by the number of branch nodes.

Input Arguments

tree

A regression tree created by `fitrtree`, or by the `compact` method.

Output Arguments

imp

A row vector with the same number of elements as the number of predictors (columns) in `tree.X`. The entries are the estimates of predictor importance, with `0` representing the smallest possible importance.

Examples

Estimate Predictor Importance

Estimate the predictor importance for all predictor variables in the data.

Load the `carsmall` data set.

```
load carsmall
```

Grow a regression tree for MPG using Acceleration, Cylinders, Displacement, Horsepower, Model_Year, and Weight as predictors.

```
X = [Acceleration Cylinders Displacement Horsepower Model_Year Weight];  
tree = fitrtree(X,MPG);
```

Estimate the predictor importance for all predictor variables.

```
imp = predictorImportance(tree)
```

```
imp = 1×6
```

```
    0.0647    0.1068    0.1155    0.1411    0.3348    2.6565
```

Weight, the last predictor, has the most impact on mileage. The predictor with the minimal impact on making predictions is the first variable, which is Acceleration.

Predictor Importance and Surrogate Splits

Estimate the predictor importance for all variables in the data and where the regression tree contains surrogate splits.

Load the `carsmall` data set.

```
load carsmall
```

Grow a regression tree for MPG using Acceleration, Cylinders, Displacement, Horsepower, Model_Year, and Weight as predictors. Specify to identify surrogate splits.

```
X = [Acceleration Cylinders Displacement Horsepower Model_Year Weight];  
tree = fitrtree(X,MPG, 'Surrogate', 'on');
```

Estimate the predictor importance for all predictor variables.

```
imp = predictorImportance(tree)
```

```
imp = 1×6
```

```
    1.0449    2.4560    2.5570    2.5788    2.0832    2.8938
```

Comparing `imp` to the results in “Estimate Predictor Importance” on page 32-5454, `Weight` still has the most impact on mileage, but `Cylinders` is the fourth most important predictor.

Unbiased Predictor Importance Estimates

Load the `carsmall` data set. Consider a model that predicts the mean fuel economy of a car given its acceleration, number of cylinders, engine displacement, horsepower, manufacturer, model year, and weight. Consider `Cylinders`, `Mfg`, and `Model_Year` as categorical variables.

```
load carsmall
Cylinders = categorical(Cylinders);
Mfg = categorical(cellstr(Mfg));
Model_Year = categorical(Model_Year);
X = table(Acceleration,Cylinders,Displacement,Horsepower,Mfg,...
          Model_Year,Weight,MPG);
```

Display the number of categories represented in the categorical variables.

```
numCylinders = numel(categories(Cylinders))
```

```
numCylinders = 3
```

```
numMfg = numel(categories(Mfg))
```

```
numMfg = 28
```

```
numModelYear = numel(categories(Model_Year))
```

```
numModelYear = 3
```

Because there are 3 categories only in `Cylinders` and `Model_Year`, the standard CART, predictor-splitting algorithm prefers splitting a continuous predictor over these two variables.

Train a regression tree using the entire data set. To grow unbiased trees, specify usage of the curvature test for splitting predictors. Because there are missing values in the data, specify usage of surrogate splits.

```
Mdl = fitrtree(X, 'MPG', 'PredictorSelection', 'curvature', 'Surrogate', 'on');
```

Estimate predictor importance values by summing changes in the risk due to splits on every predictor and dividing the sum by the number of branch nodes. Compare the estimates using a bar graph.

```
imp = predictorImportance(Mdl);  
  
figure;  
bar(imp);  
title('Predictor Importance Estimates');  
ylabel('Estimates');  
xlabel('Predictors');  
h = gca;  
h.XTickLabel = Mdl.PredictorNames;  
h.XTickLabelRotation = 45;  
h.TickLabelInterpreter = 'none';
```

In this case, `Displacement` is the most important predictor, followed by `Horsepower`.

Definitions

Predictor Importance

`predictorImportance` computes estimates of predictor importance for `tree` by summing changes in the mean squared error (MSE) due to splits on every predictor and dividing the sum by the number of branch nodes. If the tree is grown without surrogate splits, this sum is taken over best splits found at each branch node. If the tree is grown

with surrogate splits, this sum is taken over all splits at each branch node including surrogate splits. `imp` has one element for each input predictor in the data used to train this tree. At each node, MSE is estimated as node error weighted by the node probability. Variable importance associated with this split is computed as the difference between MSE for the parent node and the total MSE for the two children.

Estimates of predictor importance do not depend on the order of predictors if you use surrogate splits, but do depend on the order if you do not use surrogate splits.

If you use surrogate splits, `predictorImportance` computes estimates before the tree is reduced by pruning or merging leaves. If you do not use surrogate splits, `predictorImportance` computes estimates after the tree is reduced by pruning or merging leaves. Therefore, reducing the tree by pruning affects the predictor importance for a tree grown without surrogate splits, and does not affect the predictor importance for a tree grown with surrogate splits.

“Choose Split Predictor Selection Technique” on page 19-19

probplot

Probability plots

Syntax

```
probplot(y)
probplot(y, cens)
probplot(y, cens, freq)
probplot(dist, ___ )

probplot(ax, ___ )
probplot(ax, pd)
probplot(ax, fun, params)

probplot( ___ , 'noref' )

h = probplot( ___ )
```

Description

`probplot(y)` creates a normal probability plot comparing the distribution of the data in `y` to the normal distribution.

`probplot` plots each data point in `y` using marker symbols and draws a reference line that represents the theoretical distribution. If the sample data has a normal distribution, then the data points appear along the reference line. The reference line connects the first and third quartiles of the data and extends to the ends of the data. A distribution other than normal introduces curvature in the data plot.

`probplot(y, cens)` creates a probability plot using the censoring data in `cens`.

`probplot(y, cens, freq)` creates a probability plot using the censoring data in `cens` and the frequency data in `freq`.

`probplot(dist, ___)` creates a probability plot for the distribution specified by `dist`, using any of the input arguments in the previous syntaxes.

`probplot(ax, ___)` adds a probability plot into the existing probability plot axes specified by `ax`, using any of the input arguments in the previous syntaxes.

`probplot(ax, pd)` adds a fitted line on the existing probability plot axes specified by `ax` to represent the probability distribution `pd`.

`probplot(ax, fun, params)` adds a fitted line on the existing probability plot axes specified by `ax` to represent the function `fun` with the parameters `params`.

`probplot(___, 'noref')` omits the reference line from the plot.

`h = probplot(___)` returns graphics handles corresponding to the plotted lines.

Examples

Create Weibull Probability Plot

Generate sample data and create a probability plot.

Generate sample data. The sample `x1` contains 500 random numbers from a Weibull distribution with scale parameter $A = 3$ and shape parameter $B = 3$. The sample `x2` contains 500 random numbers from a Rayleigh distribution with scale parameter $B = 3$.

```
rng('default'); % For reproducibility
x1 = wblrnd(3,3,[500,1]);
x2 = raylrnd(3,[500,1]);
```

Create a probability plot to assess whether the data in `x1` and `x2` comes from a Weibull distribution.

```
figure
probplot('weibull',[x1 x2])
legend('Weibull Sample','Rayleigh Sample','Location','best')
```

The probability plot shows that the data in x1 comes from a Weibull distribution, while the data in x2 does not.

Alternatively, you can use `wblplot` to create a Weibull probability plot.

Add Fitted Line to Probability Plot

Create a probability plot and an additional fitted line on the same figure.

Generate sample data containing about 20% outliers in the tails. The left tail of the sample data contains 10 values randomly generated from an exponential distribution with

parameter $\mu = 1$. The right tail contains 10 values randomly generated from an exponential distribution with parameter $\mu = 5$. The center of the sample data contains 80 values randomly generated from a standard normal distribution.

```
rng('default') % For reproducibility
left_tail = -exprnd(1,10,1);
right_tail = exprnd(5,10,1);
center = randn(80,1);
data = [left_tail;center;right_tail];
```

Create a probability plot to assess whether the sample data comes from a normal distribution.

```
probplot(data)
```

Plot a t location-scale curve on the same figure to compare with data.

```
p = mle(data, 'distribution', 'tLocationScale');
t = @(data,mu,sig,df)cdf('tLocationScale',data,mu,sig,df);
h = probplot(gca,t,p);
h.Color = 'r';
h.LineStyle = '-';
title('\bf Probability Plot')
legend('Normal','Data','t','Location','NW')
```

The plot shows that neither the normal line nor the t location-scale curve fits the tails very well because of the outliers.

Identify Significant Effects with Half-Normal Probability Plot

Create a half-normal probability distribution plot to identify significant effects in an experiment to study factors that might influence flow rate in a chemical manufacturing process. The four factors are reactants A, B, C, and D. Each factor is present at two levels (high and low concentration). The experiment contains only one replication at each factor level.

Load the sample data.

```
load flowrate
```

The first four columns of the table `flowrate` contain the design matrix for the factors and their interactions. The design matrix is coded to use 1 for the high factor level and -1 for the low factor level. The fifth column of `flowrate` contains the measured flow rate.

Fit a linear regression model using `rate` as the response variable. Use predictor variables A, B, C, D, and all of their interaction terms.

```
mdl = fitlm(flowrate,'rate ~ A*B*C*D');
```

Calculate and store the absolute value of the factor effect estimates. To obtain the factor effect estimates, multiply the coefficient estimates obtained during the model fitting by two. This step is necessary because the regression coefficients measure the effect of a one-unit change in x on the mean of y . However, the effects estimates measure a two-unit change in x due to the design matrix coding of -1 and 1. Exclude the baseline measurement. Note that the factor order in `mdl` may be different from the order in the original design matrix.

```
effects = abs(mdl.Coefficients{2:end,1}*2);
```

Create a half-normal probability plot using the absolute value of the effects estimates, excluding the baseline.

```
figure  
h = probplot('halfnormal',effects);
```

Label the points and format the plot. First, return the index values for the sorted effects estimates (from lowest to highest). Then use these index values to sort the probability values stored in the graphics handle (`h(1).YData`).

```
[b,i] = sort(effects);
prob(i) = h(1).YData;
```

Add text labels to the plot at each point. For each point, the x-value is the effects estimate and the y-value is the corresponding probability.

```
text(effects,prob,mdl.CoefficientNames(2:end),'FontSize',8,...
     'VerticalAlignment','top')
h(1).Color = 'r';
```

The points located far from the reference line represent the significant effects.

Create a Normal Probability Plot Using Frequency Data

Generate simulated frequency data.

```
y = 1:10;
freq = [2 4 6 7 9 8 7 7 6 5];
```

Create a normal probability plot using the frequency data.

```
probplot(y, [], freq)
```

The normal probability plot shows that the data do not have a normal distribution.

Input Arguments

y — Sample data

numeric vector | numeric matrix

Sample data, specified as a numeric vector or numeric matrix. `probplot` displays each value in `y` using marker symbols including 'x' and 'o'. If `y` is a matrix, then `probplot` displays a separate line for each column of `y`.

Not all distributions are appropriate for all data sets. `probplot` errors if the data set is inappropriate for a specified distribution. See `dist` for appropriate data ranges for each distribution.

dist – Distribution for probability plot

probability distribution object | 'normal' | 'exponential' | 'extreme value' | 'half normal' | 'lognormal' | ...

Distribution for probability plot, specified as a probability distribution object or one of the following distribution names:

Name	Plot Type	Data Range
'normal'	Normal probability plot	All values
'exponential'	Exponential probability plot	Nonnegative values
'extreme value'	Extreme value probability plot	All values
'half normal'	Half-normal probability plot	All values
'lognormal'	Lognormal probability plot	Positive values
'logistic'	Logistic probability plot	All values
'loglogistic'	Loglogistic probability plot	Positive values
'rayleigh'	Rayleigh probability plot	Positive values
'weibull'	Weibull probability plot	Positive values

The default is 'normal' if you create a probability plot in a new figure. If you add a probability plot to a figure that already includes one by using the `ax` input argument, then the default is the plot type of the existing probability plot.

You can create a probability distribution object with specified parameter values using `makedist`. Alternatively, fit a probability distribution object to sample data using `fitdist`. For more information on probability distribution objects, see “Working with Probability Distributions” on page 5-3.

The y-axis scale is based on the selected distribution. The x-axis has a log scale for the Weibull, loglogistic, and lognormal distributions, and a linear scale for the others.

Not all distributions are appropriate for all data sets. `probplot` errors if the data set is inappropriate for a specified distribution.

Example: 'weibull'

cens — Censoring data

numeric vector

Censoring data, specified as a numeric vector. `cens` must be the same length as `y`, and contain a 1 value for observations that are right-censored and a 0 value for observations that are measured exactly.

Data Types: `single` | `double`

freq — Frequency data

vector of integer values

Frequency data, specified as a vector of integer values. `freq` must be the same length as `y`. `freq` contains the integer frequencies for the corresponding elements in `y`.

To create a probability plot using frequency data but not censoring data, specify empty brackets (`[]`) for `cens`.

Data Types: `single` | `double`

ax — Target axes

Axes object | UIAxes object

Target axes, specified as an Axes object or a UIAxes object. `probplot` adds an additional plot into the axes specified by `ax`. For details, see Axes Properties and UIAxes Properties.

Use `gca` to return the current axes for the current figure.

pd — Probability distribution for reference line

probability distribution object

Probability distribution for reference line, specified as a probability distribution object. `probplot` adds a fitted line to the axes specified by `ax` to represent the probability distribution specified by `pd`.

Create a probability distribution object with specified parameter values using `makedist`. Alternatively, fit a probability distribution object to sample data using `fitdist`. For more information on probability distribution objects, see “Working with Probability Distributions” on page 5-3.

fun — Function for reference line

function handle

Function for reference line, specified as a function handle. `probplot` adds a fitted line to the axes specified by `ax` to represent the function specified by `fun`, evaluated at the parameters specified by `params`.

`fun` is a function handle to a cdf function, specified using the function handle operator `@`. The function must accept a vector of input values as its first argument, and return a vector containing the cdf evaluated at each input value. Specify the parameter values required to evaluate `fun` using the `params` argument. For more information on function handles, see “Create Function Handle” (MATLAB).

Example: `@wblpdf`

Data Types: `function_handle`

params — Reference line function parameters

vector of numeric values | cell array

Reference line function parameters, specified as a vector of numeric values or a cell array. `probplot` adds a fitted line to the axes specified by `ax` to represent the function specified by `fun`, evaluated at the parameters specified by `params`.

`fun` is a function handle to a cdf function, specified using the function handle operator `@`. The function must accept a vector of values as its first argument, and return a vector of cdf values evaluated at each value. Specify the parameter values required to evaluate `fun` using the `params` argument. For more information on function handles, see “Create Function Handle” (MATLAB).

Output Arguments

h — Graphic handles for line objects

vector of Line graphic handles

Graphic handles for line objects, returned as a vector of Line graphic handles. Graphic handles are unique identifiers that you can use to query and modify the properties of a specific line on the plot. For each column of `y`, `probplot` returns two handles:

- The line representing the data points. `probplot` represents each data point in `y` using marker symbols such as `'+'` and `'o'`.

- The line showing the theoretical distribution for the probability plot, represented as a dashed line.

To view and set properties of line objects, use dot notation. For information on using dot notation, see “Access Property Values” (MATLAB). For information on the Line properties that you can set, see Primitive Line.

Algorithms

`probplot` matches the quantiles of sample data to the quantiles of a given probability distribution. The sample data is sorted, scaled according to the choice of `dist`, and plotted on the x-axis. When `dist` is `'lognormal'`, `'loglogistic'`, or `'weibull'`, the scaling is logarithmic. Otherwise, the scaling is linear. The y-axis represents the quantiles of the distribution specified in `dist`, converted into probability values. The scaling depends on the given distribution and is not linear.

Where the x-axis value is the i th sorted value from a sample of size N , the y-axis value is the midpoint between evaluation points of the empirical cumulative distribution function of the data. In the case of uncensored data, the midpoint is equal to $\frac{(i - 0.5)}{N}$.

`probplot` superimposes a reference line to assess the linearity of the plot. If the data is uncensored, then the line goes through the first and third quartiles of the data. If the data is censored, then the line shifts accordingly. If the data is uncensored and `dist` is `'half normal'`, then `probplot` uses the zeroth and second quartiles instead.

Introduced before R2006a

procrustes

Procrustes analysis

Syntax

```
d = procrustes(X,Y)
[d,Z] = procrustes(X,Y)
[d,Z,transform] = procrustes(X,Y)
[...] = procrustes(...,'scaling',flag)
[...] = procrustes(...,'reflection',flag)
```

Description

`d = procrustes(X,Y)` determines a linear transformation (translation, reflection, orthogonal rotation, and scaling) of the points in matrix `Y` to best conform them to the points in matrix `X`. The goodness-of-fit criterion is the sum of squared errors.

`procrustes` returns the minimized value of this dissimilarity measure in `d`. `d` is standardized by a measure of the scale of `X`, given by:

$$\text{sum}(\text{sum}((X - \text{repmat}(\text{mean}(X,1), \text{size}(X,1), 1)) .^2, 1))$$

That is, the sum of squared elements of a centered version of `X`. However, if `X` comprises repetitions of the same point, the sum of squared errors is not standardized.

`X` and `Y` must have the same number of points (rows), and `procrustes` matches `Y(i)` to `X(i)`. Points in `Y` can have smaller dimension (number of columns) than those in `X`. In this case, `procrustes` adds columns of zeros to `Y` as necessary.

`[d,Z] = procrustes(X,Y)` also returns the transformed `Y` values.

`[d,Z,transform] = procrustes(X,Y)` also returns the transformation that maps `Y` to `Z`. `transform` is a structure array with fields:

- `c` — Translation component
- `T` — Orthogonal rotation and reflection component

- `b` — Scale component

That is:

```
c = transform.c;  
T = transform.T;  
b = transform.b;
```

```
Z = b*Y*T + c;
```

`[...] = procrustes(..., 'scaling', flag)`, when *flag* is `false`, allows you to compute the transformation without a scale component (that is, with `b` equal to 1). The default *flag* is `true`.

`[...] = procrustes(..., 'reflection', flag)`, when *flag* is `false`, allows you to compute the transformation without a reflection component (that is, with `det(T)` equal to 1). The default *flag* is `'best'`, which computes the best-fitting transformation, whether or not it includes a reflection component. A *flag* of `true` forces the transformation to be computed with a reflection component (that is, with `det(T)` equal to -1)

Examples

Procrustes Analysis

Generate the sample data in two dimensions.

```
rng('default')  
n = 10;  
X = normrnd(0,1,[n 2]);
```

Rotate, scale, translate, and add some noise to sample points.

```
S = [0.5 -sqrt(3)/2; sqrt(3)/2 0.5];  
Y = normrnd(0.5*X*S+2,0.05,n,2);
```

Conform Y to X using procrustes analysis.

```
[d,Z,tr] = procrustes(X,Y);
```

Plot the original X and Y with the transformed Y.

```
plot(X(:,1),X(:,2), 'rx',Y(:,1),Y(:,2), 'b.',Z(:,1),Z(:,2), 'bx');
```

Introduced before R2006a

proflik

Package: prob

Profile likelihood function for probability distribution

Syntax

```
[ll,param] = proflik(pd,pnum)
[ll,param] = proflik(pd,pnum,'Display',display)
[ll,param] = proflik(pd,pnum,setparam)
[ll,param] = proflik(pd,pnum,setparam,'Display',display)
[ll,param,other] = proflik( ___ )
```

Description

[ll,param] = proflik(pd,pnum) returns a vector ll of loglikelihood values and a vector param of corresponding parameter values for the parameter in the position indicated by pnum.

[ll,param] = proflik(pd,pnum,'Display',display) returns the loglikelihood values and corresponding parameter values, and plots the profile likelihood overlaid on an approximation of the loglikelihood.

[ll,param] = proflik(pd,pnum,setparam) returns the loglikelihood values and corresponding parameter values as specified by setparam.

[ll,param] = proflik(pd,pnum,setparam,'Display',display) returns the loglikelihood values and corresponding parameter values as specified by setparam, and plots the profile likelihood overlaid on an approximation of the loglikelihood.

[ll,param,other] = proflik(___) also returns a matrix other containing the values of the other parameters that maximize the likelihood, using any of the input arguments from the previous syntaxes.

Examples

Profile Likelihood of a Distribution Parameter

Load the sample data. Create a probability distribution object by fitting a Weibull distribution to the miles per gallon (MPG) data.

```
load carsmall
pd = fitdist(MPG,'Weibull')

pd =
  WeibullDistribution

  Weibull distribution
  A = 26.5079 [24.8333, 28.2954]
  B = 3.27193 [2.79441, 3.83104]
```

View the parameter names for the distribution.

```
pd.ParameterNames

ans = 1x2 cell array
    {'A'}    {'B'}
```

For the Weibull distribution, A is in position 1, and B is in position 2.

Compute the profile likelihood for B, which is in position `pnum = 2`.

```
[ll,param] = proflik(pd,2);
```

Display the loglikelihood values for the estimated values of B.

```
[ll',param']

ans = 21x2

-329.9688    2.7132
-329.4312    2.7748
-328.9645    2.8365
-328.5661    2.8981
-328.2340    2.9597
-327.9658    3.0213
```

```
-327.7596    3.0830
-327.6135    3.1446
-327.5256    3.2062
-327.4943    3.2678
  :
```

These results show that the profile log likelihood is maximized between the estimated B values of 3.2678 and 3.3295, which correspond to loglikelihood values -327.4943 and -327.5178. From the earlier fit, the MLE of B is 3.27193, which is in this interval as expected.

Profile Likelihood With Restricted Parameter Values

Load the sample data. Create a probability distribution object by fitting a generalized extreme value distribution to the miles per gallon (MPG) data.

```
load carsmall
pd = fitdist(MPG, 'GeneralizedExtremeValue')

pd =
  GeneralizedExtremeValueDistribution

  Generalized Extreme Value distribution
      k = -0.207765    [-0.381674, -0.0338564]
  sigma =  7.49674    [6.31755, 8.89603]
      mu = 20.6233    [18.8859, 22.3606]
```

View the parameter names for the distribution.

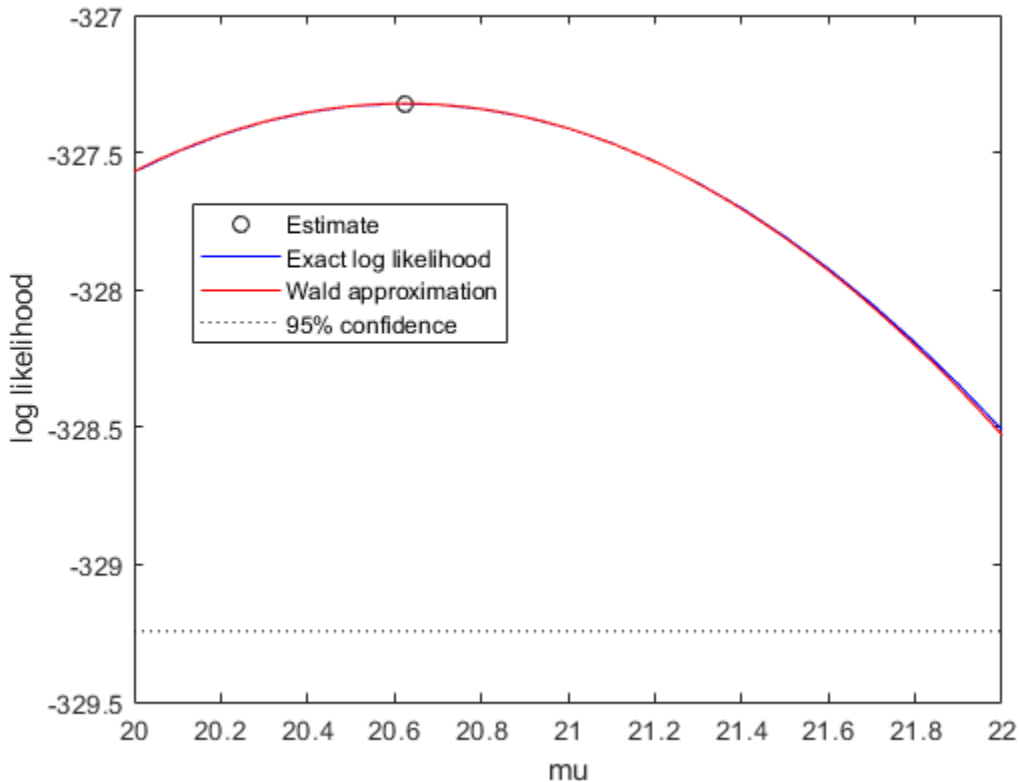

```
pd.ParameterNames

ans = 1x3 cell array
      {'k'}      {'sigma'}      {'mu'}
```

For the generalized extreme value distribution, k is in position 1, sigma is in position 2, and mu is in position 3.

Compute the profile likelihood for mu, which is in position pnun = 3. Restrict the computation to parameter values from 20 to 22, and display the plot.

```
[ll,param,other] = proflik(pd,3,20:.1:22,'display','on');
```

The plot shows the estimated value for the parameter μ that maximizes the loglikelihood.

Display the loglikelihood values for the estimated values of μ , and the values of the other distribution parameters that maximize the corresponding loglikelihood.

```
[ll',param',other]
```

```
ans = 21×4
```

```
-327.5706    20.0000   -0.1803    7.4087
-327.4971    20.1000   -0.1846    7.4218
```

```

-327.4364    20.2000    -0.1890    7.4354
-327.3887    20.3000    -0.1934    7.4493
-327.3538    20.4000    -0.1978    7.4636
-327.3317    20.5000    -0.2023    7.4783
-327.3223    20.6000    -0.2067    7.4932
-327.3257    20.7000    -0.2112    7.5084
-327.3418    20.8000    -0.2156    7.5240
-327.3706    20.9000    -0.2201    7.5399
    :
```

The first column contains the log likelihood value that corresponds to the estimate of μ in the second column. The log likelihood is maximized between the parameter values 20.6000 and 20.7000, corresponding to log likelihood values -327.3223 and -327.3257. The third column contains the value of k that maximizes the corresponding log likelihood for μ . The fourth column contains the value of σ that maximizes the corresponding log likelihood for μ .

Input Arguments

pd — Probability distribution

probability distribution object

Probability distribution, specified as a probability distribution object created using one of the following.

Function or App	Description
fitdist	Fit a probability distribution object to sample data.
Distribution Fitter	Fit a probability distribution to sample data using the interactive Distribution Fitter app and export the fitted object to the workspace.

pnum — Parameter number

positive integer value

Parameter number for which to compute the profile likelihood, specified as a positive integer value corresponding to the position of the desired parameter in the parameter name vector. For example, a Weibull distribution has a parameter name vector `{ 'A' , 'B' }`, so specify `pnum` as 2 to compute the profile likelihood for B.

Data Types: `single` | `double`

setparam — Parameter value restriction

scalar value | vector of scalar values

Parameter value restriction, specified as a scalar value or a vector of such values. If you do not specify `setparam`, `proflik` chooses the values for output vector `param` based on the default confidence interval method for the probability distribution `pd`. If the parameter can take only restricted values, and if the confidence interval violates that restriction, you can use `setparam` to specify valid values.

Example: `[3,3.5,4]`

display — Display toggle

'off' (default) | 'on'

Display toggle, specified as either 'on' or 'off'. Specify 'on' to display the profile of the exact loglikelihood overlaid on the Wald approximation of the loglikelihood. Specify 'off' to omit the display. The Wald approximation is based on a Taylor series expansion around the estimated parameter value, as a function of the parameter in position `pnum` or its logarithm. The intersection of the curves with the horizontal dotted line marks the endpoints of 95% confidence intervals.

Output Arguments

ll — Loglikelihood values

vector

Loglikelihood values, returned as a vector. The loglikelihood is the value of the likelihood with the parameter in position `pnum` set to the values in `param`, maximized over the remaining parameters.

param — Parameter values

vector

Parameter values corresponding to the loglikelihood values in `ll`, returned as a vector. If you specify parameter values using `setparam`, then `param` is equal to `setparam`.

other — Other parameter values

matrix

Other parameter values that maximize the likelihood, returned as a matrix. Each row of other contains the values for all parameters except the parameter in position pnum.

Introduced in R2013a

proximity

Class: CompactTreeBagger

Proximity matrix for data

Syntax

```
prox = proximity(B,X)
```

Description

`prox = proximity(B,X)` computes a numeric matrix of size **Nobs**-by-**Nobs** of proximities for data **X**, where **Nobs** is the number of observations (rows) in **X**. Proximity between any two observations in the input data is defined as a fraction of trees in the ensemble **B** for which these two observations land on the same leaf. This is a symmetric matrix with ones on the diagonal and off-diagonal elements ranging from 0 to 1.

prune

Class: ClassificationTree

Produce sequence of subtrees by pruning

Syntax

```
tree1 = prune(tree)
tree1 = prune(tree,Name,Value)
```

Description

`tree1 = prune(tree)` creates a copy of the classification tree `tree` with its optimal pruning sequence filled in.

`tree1 = prune(tree,Name,Value)` creates a pruned tree with additional options specified by one `Name,Value` pair argument. You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Input Arguments

tree

A classification tree created with `fitctree`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Alpha

A numeric scalar. `prune` prunes `tree` to the specified value of the pruning cost.

Level

A numeric scalar from 0 (no pruning) to the largest pruning level of this tree `max(tree.PruneList)`. `prune` returns the tree pruned to this level.

Nodes

A numeric vector with elements from 1 to `tree.NumNodes`. Any tree branch nodes listed in `nodes` become leaf nodes in `tree1`, unless their parent nodes are also pruned.

Output Arguments

tree1

A classification tree.

Examples

Prune and Display a Classification Tree

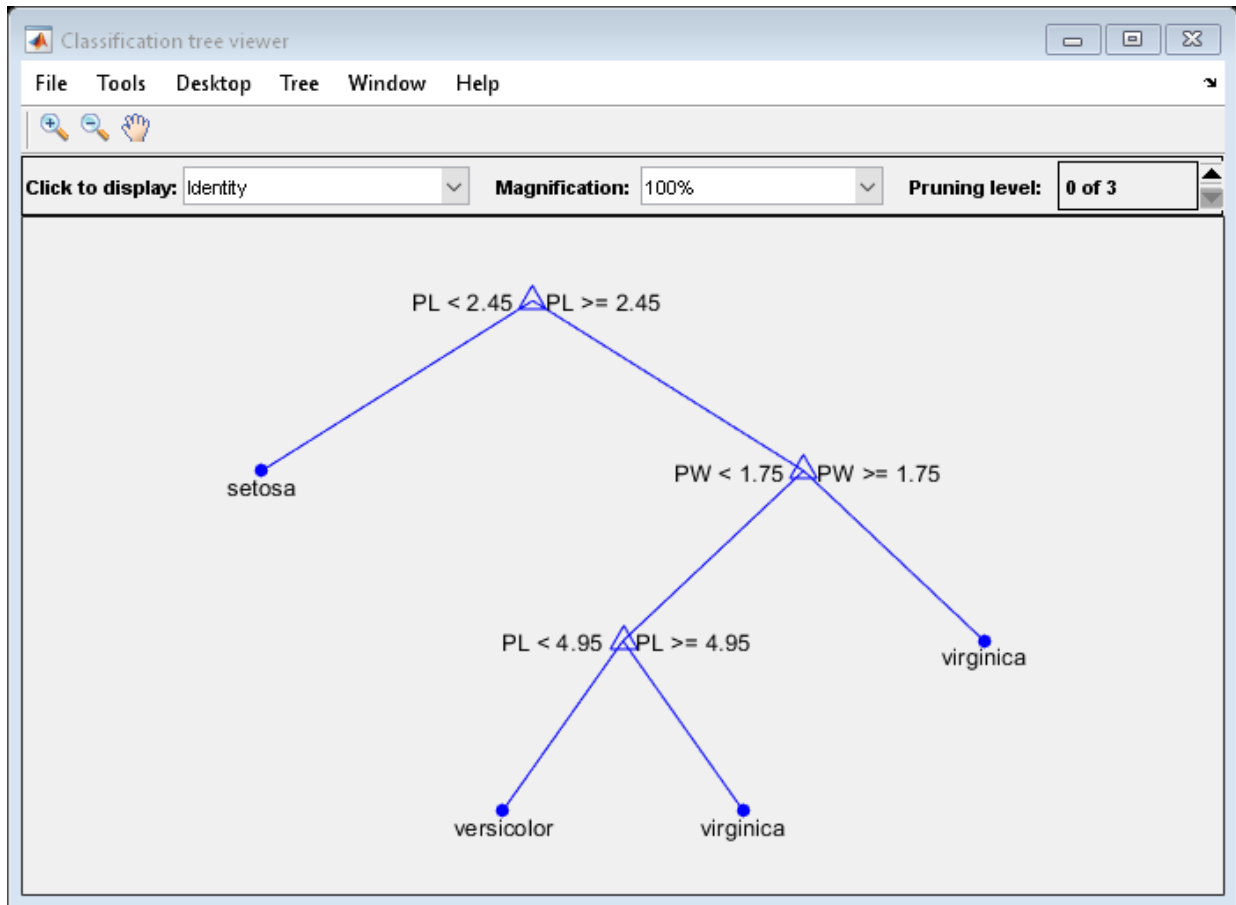

Construct and display a full classification tree for Fisher's iris data.

```
load fisheriris;
varnames = {'SL', 'SW', 'PL', 'PW'};
t1 = fitctree(meas, species, 'MinParentSize', 5, 'PredictorNames', varnames);
view(t1, 'Mode', 'graph');
```

Construct and display the next largest tree from the optimal pruning sequence.

```
t2 = prune(t1, 'Level', 1);
view(t2, 'Mode', 'graph');
```

Tips

- `tree1 = prune(tree)` returns the decision tree `tree1` that is the full, unpruned tree, but with optimal pruning information added. This is useful only if you created `tree` by pruning another tree, or by using the `fitctree` function with pruning set 'off'. If you plan to prune a tree multiple times along the optimal pruning sequence, it is more efficient to create the optimal pruning sequence first.

See Also

fitctree

prune

Class: RegressionTree

Produce sequence of subtrees by pruning

Syntax

```
tree1 = prune(tree)
tree1 = prune(tree, Name, Value)
```

Description

`tree1 = prune(tree)` creates a copy of the regression tree `tree` with its optimal pruning sequence filled in.

`tree1 = prune(tree, Name, Value)` creates a pruned tree with additional options specified by one `Name, Value` pair argument. You can specify several name-value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Input Arguments

tree

A regression tree created with `fitrtree`.

Name-Value Pair Arguments

Optional comma-separated pair of `Name, Value` arguments, where `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside single quotes (' '). You can specify only one name-value pair argument.

Alpha

A numeric scalar from 0 (no pruning) to 1 (prune to one node). Prunes to minimize the sum of (`Alpha` times the number of leaf nodes) and a cost (mean squared error).

Level

A numeric scalar from 0 (no pruning) to the largest pruning level of this tree `max(tree.PruneList)`. `prune` returns the tree pruned to this level.

Nodes

A numeric vector with elements from 1 to `tree.NumNodes`. Any tree branch nodes listed in `Nodes` become leaf nodes in `tree1`, unless their parent nodes are also pruned.

Output Arguments

`tree1`

A regression tree.

Examples

Prune Regression Tree

Load the `carsmall` data set. Consider `Horsepower` and `Weight` as predictor variables.

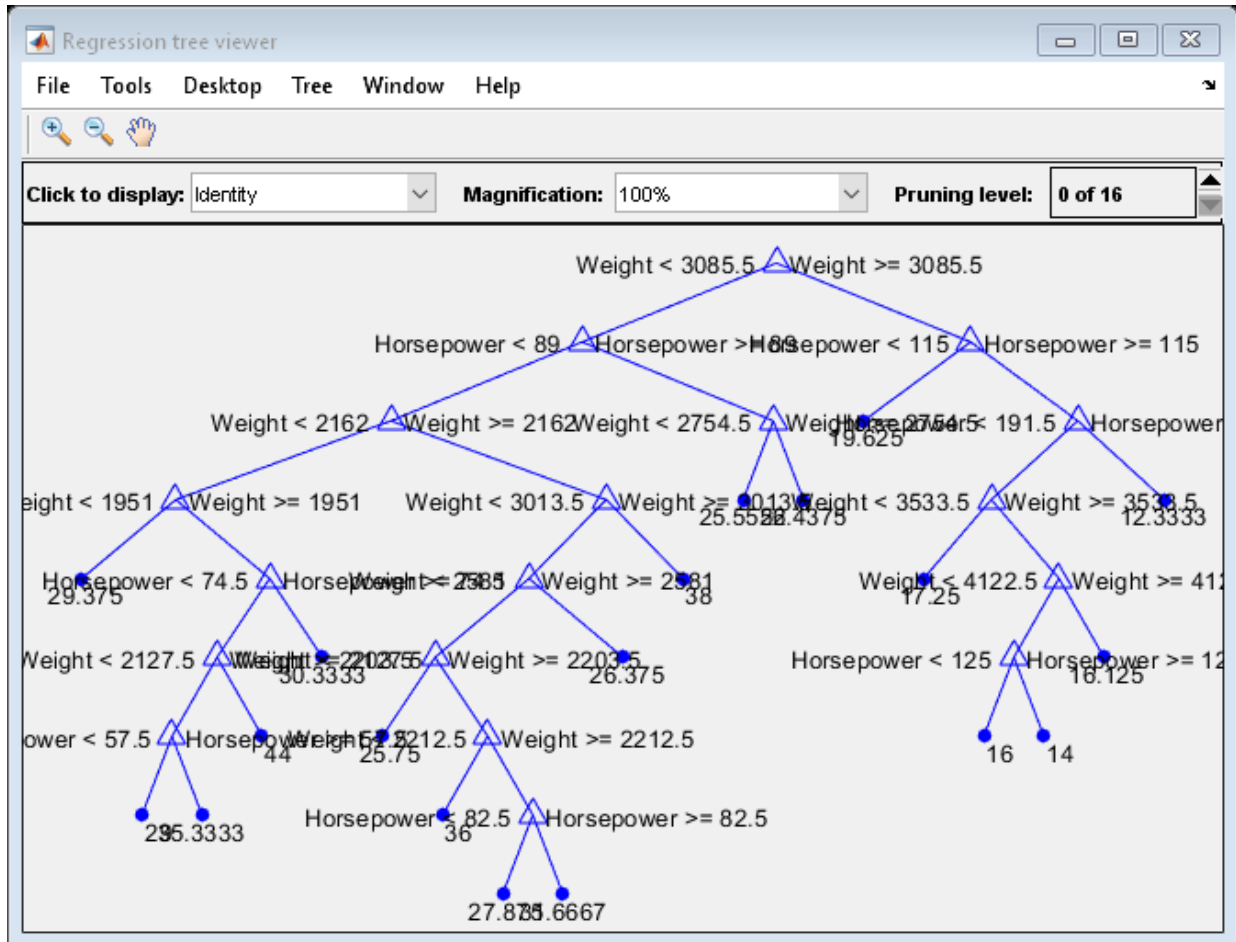

```
load carsmall;  
X = [Weight Horsepower];  
varNames = {'Weight' 'Horsepower'};
```

Grow a regression tree using the entire data set. View the tree.

```
Mdl = fitrtree(X,MPG,'PredictorNames',varNames)  
  
Mdl =  
    RegressionTree  
        PredictorNames: {'Weight' 'Horsepower'}  
        ResponseName: 'Y'  
        CategoricalPredictors: []  
        ResponseTransform: 'none'  
        NumObservations: 94
```

Properties, Methods

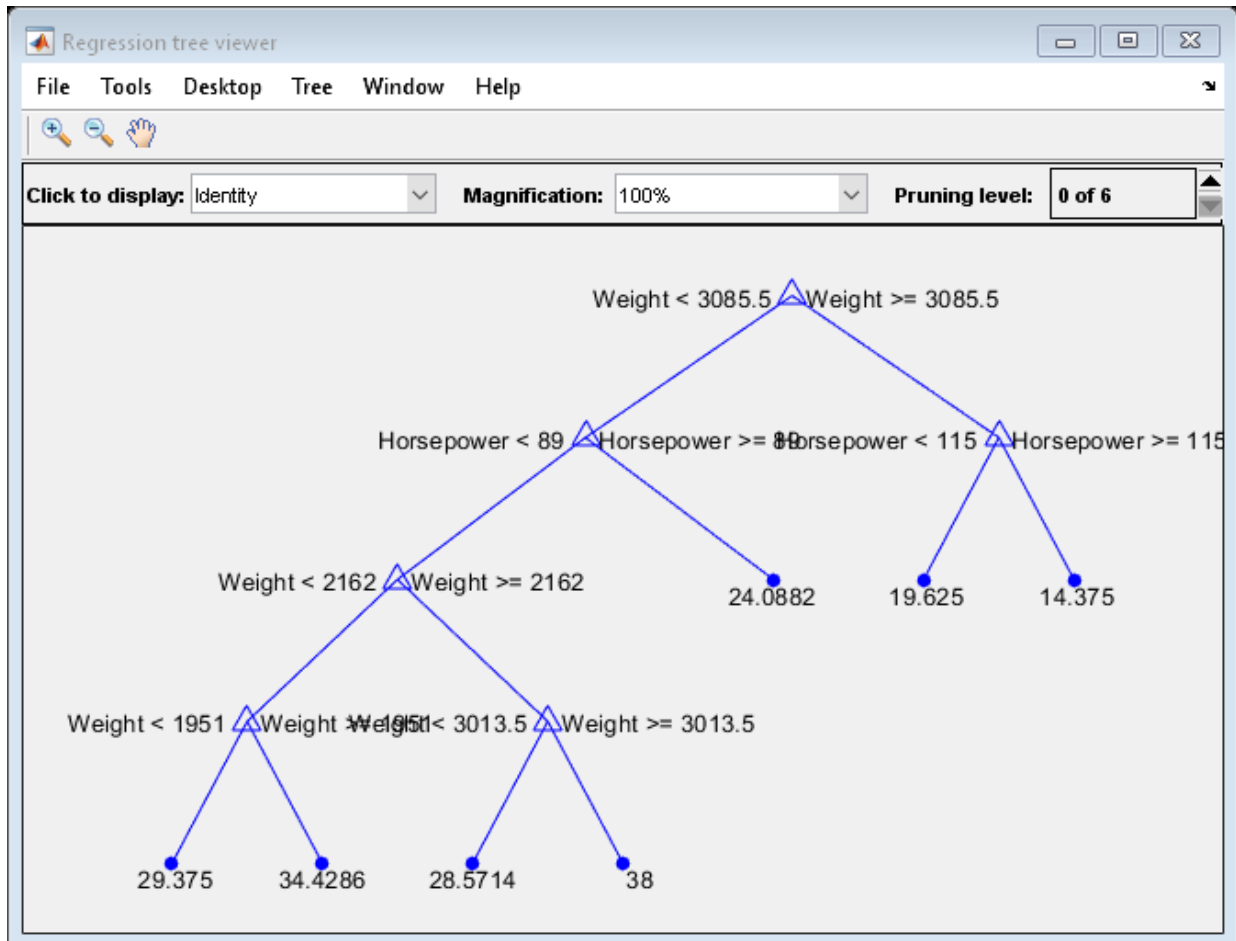

```
view(Mdl, 'Mode', 'graph');
```

The regression tree has 16 pruning levels.

Prune the regression tree to pruning-level 10. View the pruned tree.

```
MdlPruned = prune(Mdl, 'Level', 10);  
view(MdlPruned, 'Mode', 'graph');
```

The pruned tree has six pruning levels.

Alternatively, you can use the pruning-level field in the Regression tree viewer to prune the tree.

Tips

- `tree1 = prune(tree)` returns the decision tree `tree1` that is the full, unpruned tree, but with optimal pruning information added. This is useful only if you created `tree` by pruning another tree, or by using `fitrtree` with pruning set `'off'`. If you plan to prune a tree multiple times along the optimal pruning sequence, it is more efficient to create the optimal pruning sequence first.

`fitrtree`

grand

Class: grandstream

Generate quasi-random points from stream

Syntax

```
x = grand(q)
X = grand(q,n)
```

Description

`x = grand(q)` returns the next value x in the quasi-random number stream q of the `grandstream` on page 32-5498 class. x is a 1-by- d vector, where d is the dimension of the stream. The command sets `q.State` to the index in the underlying point set of the next value to be returned.

`X = grand(q,n)` returns the next n values X in an n -by- d matrix.

Objects `q` of the `grandstream` class encapsulate properties of a specified quasi-random number stream. Values of the stream are not generated and stored in memory until `q` is accessed using `grand`.

Examples

Use `grandstream` to construct a 3-D Halton stream, based on a point set that skips the first 1000 values and then retains every 101st point:

```
q = grandstream('halton',3,'Skip',1e3,'Leap',1e2)
q =
  Halton quasi-random stream in 3 dimensions
  Point set properties:
      Skip : 1000
      Leap : 100
  ScrambleMethod : none
```

```
nextIdx = q.State
nextIdx =
    1
```

Use `qrand` to generate two samples of size four:

```
X1 = qrand(q,4)
X1 =
    0.0928    0.3475    0.0051
    0.6958    0.2035    0.2371
    0.3013    0.8496    0.4307
    0.9087    0.5629    0.6166
nextIdx = q.State
nextIdx =
    5
```

```
X2 = qrand(q,4)
X2 =
    0.2446    0.0238    0.8102
    0.5298    0.7540    0.0438
    0.3843    0.5112    0.2758
    0.8335    0.2245    0.4694
nextIdx = q.State
nextIdx =
    9
```

Use `reset` to reset the stream, then generate another sample:

```
reset(q)
nextIdx = q.State
nextIdx =
    1

X = qrand(q,4)
X =
    0.0928    0.3475    0.0051
    0.6958    0.2035    0.2371
    0.3013    0.8496    0.4307
    0.9087    0.5629    0.6166
```

grandstream

Class: grandstream

Construct quasi-random number stream

Syntax

```
q = grandstream(type,d)  
q = grandstream(type,d,prop1,val1,prop2,val2,...)   
q = grandstream(p)
```

Description

`q = grandstream(type,d)` constructs a *d*-dimensional quasi-random number stream *q* of the `grandstream` on page 32-5498 class, of type specified by *type*. *type* is either 'halton' or 'sobol', and *q* is based on a point set from either the `haltonset` class or `sobolset` class, respectively, with default property settings.

`q = grandstream(type,d,prop1,val1,prop2,val2,...)` specifies property name/value pairs for the point set on which the stream is based. Applicable properties depend on *type*.

`q = grandstream(p)` constructs a stream based on the specified point set *p*. *p* must be a point set from either the `haltonset` class or `sobolset` class.

Examples

Construct a 3-D Halton stream, based on a point set that skips the first 1000 values and then retains every 101st point:

```
q = grandstream('halton',3,'Skip',1e3,'Leap',1e2)  
q =  
  Halton quasi-random stream in 3 dimensions  
  Point set properties:  
    Skip : 1000
```

```
Leap : 100
ScrambleMethod : none
```

```
nextIdx = q.State
nextIdx =
  1
```

Use `qrand` to generate two samples of size four:

```
X1 = qrand(q,4)
X1 =
    0.0928    0.3475    0.0051
    0.6958    0.2035    0.2371
    0.3013    0.8496    0.4307
    0.9087    0.5629    0.6166
nextIdx = q.State
nextIdx =
  5
```

```
X2 = qrand(q,4)
X2 =
    0.2446    0.0238    0.8102
    0.5298    0.7540    0.0438
    0.3843    0.5112    0.2758
    0.8335    0.2245    0.4694
nextIdx = q.State
nextIdx =
  9
```

Use `reset` to reset the stream, and then generate another sample:

```
reset(q)
nextIdx = q.State
nextIdx =
  1
```

```
X = qrand(q,4)
X =
    0.0928    0.3475    0.0051
    0.6958    0.2035    0.2371
    0.3013    0.8496    0.4307
    0.9087    0.5629    0.6166
```

Introduced in R2008a

qqplot

Quantile-quantile plot

Syntax

```
qqplot(x)
```

```
qqplot(x, pd)
```

```
qqplot(x, y)
```

```
qqplot( ____, pvec)
```

```
h = qqplot( ____, )
```

Description

`qqplot(x)` displays a quantile-quantile plot of the quantiles of the sample data `x` versus the theoretical quantile values from a normal distribution. If the distribution of `x` is normal, then the data plot appears linear.

`qqplot` plots each data point in `x` using plus sign ('+') markers and draws two reference lines that represent the theoretical distribution. A solid reference line connects the first and third quartiles of the data, and a dashed reference line extends the solid line to the ends of the data.

`qqplot(x, pd)` displays a quantile-quantile plot of the quantiles of the sample data `x` versus the theoretical quantiles of the distribution specified by the probability distribution object `pd`. If the distribution of `x` is the same as the distribution specified by `pd`, then the plot appears linear.

`qqplot(x, y)` displays a quantile-quantile plot of the quantiles of the sample data `x` versus the quantiles of the sample data `y`. If the samples come from the same distribution, then the plot appears linear.

`qqplot(____, pvec)` displays a quantile-quantile plot with the quantiles specified in the vector `pvec`, using any of the previous syntaxes.

`h = qqplot(___)` returns the handles (`h`) to the lines in the quantile-quantile plot.

Examples

Quantile-Quantile Plot for Normal Distribution

Use a quantile-quantile plot to determine whether gas prices in Massachusetts follow a normal distribution.

Load the sample data.

```
load gas
```

The sample data in `price1` and `price2` represent gasoline prices at 20 different gas stations in Massachusetts. The samples were collected during two different months.

Create a quantile-quantile plot to determine if the gas prices in `price1` follow a normal distribution.

```
figure  
qqplot(price1)
```

The plot produces an approximately straight line, suggesting that the gas prices follow a normal distribution.

Quantile-Quantile Plot With Two Samples

Use a quantile-quantile plot to determine whether two sets of sample data come from the same distribution.

Load the sample data.

```
load gas
```

The sample data in `price1` and `price2` represent gasoline prices at 20 different gas stations in Massachusetts. The samples were collected during two different months.

Create a quantile-quantile plot using both sets of sample data, to assess whether prices at different times have the same distribution.

```
qqplot(price1,price2);
```

The plot produces an approximately straight line, suggesting that the two sets of sample data have the same distribution.

Quantile-Quantile Plot for Weibull Distribution

Use a quantile-quantile plot to determine whether sample data comes from a Weibull distribution.

Load the sample data.

```
load lightbulb
```

The first column of the data has the lifetime (in hours) of two types of light bulbs. The second column has information about the type of light bulb. 1 indicates fluorescent bulbs whereas 0 indicates the incandescent bulbs. The third column has censoring information. 1 indicates censored data, and 0 indicates the exact failure time. This is simulated data.

Remove the censored data.

```
lightbulb = [lightbulb(lightbulb(:,3)==0,1), ...  
            lightbulb(lightbulb(:,3)==0,2)];
```

Create a variable for each light bulb type. Include only uncensored data.

```
fluo = [lightbulb(lightbulb(:,2)==0,1)];  
insc = [lightbulb(lightbulb(:,2)==1,1)];
```

Create a Weibull probability distribution object using the default parameters of $A = 1$ and $B = 1$.

```
pd = makedist('Weibull');
```

Create a q-q plot to determine whether the lifetime of fluorescent bulbs has a Weibull distribution.

```
figure  
qqplot(fluo,pd)
```

The plot is not a straight line, suggesting that the lifetime data for fluorescent bulbs does not follow a Weibull distribution.

Input Arguments

x — Sample data

numeric vector | numeric matrix

Sample data, specified as a numeric vector or numeric matrix. If **x** is a matrix, then `qqplot` displays a separate line for each column.

`qqplot` displays the sample data using the plot symbol '+' . A line joining the first and third quartiles of each distribution is superimposed on the plot. The line represents a robust linear fit of the order statistics for the data in `x`. This line is extrapolated out to the minimum and maximum values in `x` to help evaluate the linearity of the data.

Data Types: `single` | `double`

y — Second set of sample data

numeric vector | numeric matrix

Second set of sample data, specified as a numeric vector or numeric matrix. `x` and `y` do not need to be the same length. However, if `x` and `y` are matrices, they must contain the same number of columns. If `x` and `y` are matrices, then `qqplot` displays a separate line for each pair of columns.

`qqplot` selects the quantiles to plot based on the size of the smaller data set.

Data Types: `single` | `double`

pd — Hypothesized probability distribution

probability distribution object

Hypothesized probability distribution, specified as a probability distribution object. `qqplot` plots the quantiles of the input data `x` versus the theoretical quantiles of the distribution specified by `pd`.

Create a probability distribution object with specified parameter values using `makedist`, or fit a probability distribution object to data using `fitdist`.

pvec — Quantiles for plot

numeric value in the range [0,100] | vector of numeric values in the range [0,100]

Quantiles for plot, specified as a numeric value, or vector of numeric values, in the range [0,100].

For a single set of sample data (`x`), `qqplot` uses the quantiles in `x`. For two sets of sample data (`x` and `y`), `qqplot` uses the quantiles in the smaller of the two data sets.

Data Types: `single` | `double`

Output Arguments

h — Graphics handles for line objects

vector of `Line` graphics handles

Graphics handles for line objects, returned as a vector of `Line` graphics handles. Graphics handles are unique identifiers that you can use to query and modify the properties of a specific line on the plot. For each column of `x`, `qqplot` returns three handles:

- The line representing the data points. `qqplot` represents each data point in `x` using plus sign ('+') markers.
- The line joining the first and third quartiles of each column of `x`, represented as a solid line.
- The extrapolation of the quartile line, extended to the minimum and maximum values of `x`, represented as a dashed line.

To view and set properties of line objects, use dot notation. For information on using dot notation, see “Access Property Values” (MATLAB). For information on the `Line` properties that you can set, see `Primitive Line`.

Definitions

Quantile-Quantile Plot

A *quantile-quantile plot* (also called a *q-q plot*) visually assesses whether sample data comes from a specified distribution. Alternatively, a q-q plot assesses whether two sets of sample data come from the same distribution.

A q-q plot orders the sample data values from smallest to largest, then plots these values against the expected value for the specified distribution at each quantile in the sample data. The quantile values of the input sample appear along the *y*-axis, and the theoretical values of the specified distribution at the same quantiles appear along the *x*-axis. If the resulting plot is linear, then the sample data likely comes from the specified distribution.

The q-q plot selects quantiles based on the number of values in the sample data. If the sample data contains *n* values, then the plot uses *n* quantiles. Plot the *i*th ordered value

(also called the *i*th *order statistic*) against the $\frac{i - 0.5}{n}$ th quantile of the specified distribution.

A q-q plot can also assess whether two sets of sample data have the same distribution, even if you do not know the underlying distribution. The quantile values for the first data set appear on the x-axis and the corresponding quantile values for the second data set appear on the y-axis. Since q-q plots rely on quantiles, the number of data points in the two samples does not need to be equal. If the sample sizes are unequal, the q-q plot chooses the quantiles based on the smaller data set. If the resulting plot is linear, then the two sets of sample data likely come from the same distribution.

Introduced before R2006a

quantile

Quantiles of a data set

Syntax

```
Y = quantile(X,p)
```

```
Y = quantile(X,N)
```

```
Y = quantile( ____, 'all' )
```

```
Y = quantile( ____, dim )
```

```
Y = quantile( ____, vecdim )
```

```
Y = quantile( ____, 'Method', method )
```

Description

`Y = quantile(X,p)` returns quantiles of the elements in data vector or array `X` for the cumulative probability or probabilities `p` in the interval `[0,1]`.

- If `X` is a vector, then `Y` is a scalar or a vector having the same length as `p`.
- If `X` is a matrix, then `Y` is a row vector or a matrix where the number of rows of `Y` is equal to the length of `p`.
- For multidimensional arrays on page 32-5530, `quantile` operates along the first nonsingleton dimension on page 32-5530 of `X`.

`Y = quantile(X,N)` returns quantiles for `N` evenly spaced cumulative probabilities $(1/(N + 1), 2/(N + 1), \dots, N/(N + 1))$ for integer `N`>1.

- If `X` is a vector, then `Y` is a scalar or a vector with length `N`.
- If `X` is a matrix, then `Y` is a matrix where the number of rows of `Y` is equal to `N`.
- For multidimensional arrays on page 32-5530, `quantile` operates along the first nonsingleton dimension on page 32-5530 of `X`.

`Y = quantile(____, 'all')` returns quantiles of all the elements of `X` for either of the first two syntaxes.

`Y = quantile(___,dim)` returns quantiles along the operating dimension `dim` for either of the first two syntaxes.

`Y = quantile(___,vecdim)` returns quantiles over the dimensions specified in the vector `vecdim` for either of the first two syntaxes. For example, if `X` is a matrix, then `quantile(X,0.5,[1 2])` returns the 0.5 quantile of all the elements of `X` because every element of a matrix is contained in the array slice defined by dimensions 1 and 2.

`Y = quantile(___, 'Method', method)` returns either exact or approximate quantiles based on the value of `method`, using any of the input argument combinations in the previous syntaxes.

Examples

Quantiles for Given Probabilities

Calculate the quantiles of a data set for specified probabilities.

Generate a data set of size 10.

```
rng('default'); % for reproducibility
x = normrnd(0,1,1,10)
```

```
x = 1×10
```

```
    0.5377    1.8339   -2.2588    0.8622    0.3188   -1.3077   -0.4336    0.3426    3.5
```

Calculate the 0.3 quantile.

```
y = quantile(x,0.30)
```

```
y = -0.0574
```

Calculate the quantiles for the cumulative probabilities 0.025, 0.25, 0.5, 0.75, and 0.975.

```
y = quantile(x,[0.025 0.25 0.50 0.75 0.975])
```

```
y = 1×5
```

```
   -2.2588   -0.4336    0.4401    1.8339    3.5784
```

Quantiles for N Evenly Spaced Cumulative Probabilities

Calculate the quantiles of a data set for a given number of quantiles.

Generate a data set of size 10.

```
rng('default'); % for reproducibility
x = normrnd(0,1,1,10)
```

```
x = 1×10
```

```
    0.5377    1.8339   -2.2588    0.8622    0.3188   -1.3077   -0.4336    0.3426    3.5
```

Calculate four evenly spaced quantiles.

```
y = quantile(x,4)
```

```
y = 1×4
```

```
   -0.8706    0.3307    0.6999    2.3017
```

Using `y = quantile(x,[0.2,0.4,0.6,0.8])` is another way to return the four evenly spaced quantiles.

Quantiles of a Matrix for Given Probabilities

Calculate the quantiles along the columns and rows of a data matrix for specified probabilities.

Generate a 4-by-6 data matrix.

```
rng default % For reproducibility
X = normrnd(0,1,4,6)
```

```
X = 4×6
```

```
    0.5377    0.3188    3.5784    0.7254   -0.1241    0.6715
```

```

1.8339   -1.3077   2.7694   -0.0631   1.4897   -1.2075
-2.2588  -0.4336   -1.3499   0.7147   1.4090   0.7172
0.8622   0.3426    3.0349   -0.2050   1.4172   1.6302

```

Calculate the 0.3 quantile for each column of X ($\text{dim} = 1$).

```
y = quantile(X,0.3,1)
```

```
y = 1×6
```

```
-0.3013   -0.6958    1.5336   -0.1056    0.9491    0.1078
```

`quantile` returns a row vector y when calculating one quantile for each column of a matrix. For example, -0.3013 is the 0.3 quantile of the first column of X with elements (0.5377, 1.8339, -2.2588, 0.8622). Because the default value of dim is 1, you can return the same result with $y = \text{quantile}(X,0.3)$.

Calculate the 0.3 quantile for each row of X ($\text{dim} = 2$).

```
y = quantile(X,0.3,2)
```

```
y = 4×1
```

```
0.3844
-0.8642
-1.0750
0.4985
```

`quantile` returns a column vector y when calculating one quantile for each row of a matrix. For example 0.3844 is the 0.3 quantile of the first row of X with elements (0.5377, 0.3188, 3.5784, 0.7254, -0.1241, 0.6715).

Quantiles of a Matrix for Given Number of Quantiles

Calculate the N evenly spaced quantiles along the columns and rows of a data matrix.

Generate a 6-by-10 data matrix.

```
rng('default'); % for reproducibility
X = unidrnd(10,6,7)
```

```
X = 6×7
```

```
     9     3    10     8     7     8     7
    10     6     5    10     8     1     4
     2    10     9     7     8     3    10
    10    10     2     1     4     1     1
     7     2     5     9     7     1     5
     1    10    10    10     2     9     4
```

Calculate three evenly spaced quantiles for each column of X (`dim = 1`).

```
y = quantile(X,3,1)
```

```
y = 3×7
```

```
    2.0000    3.0000    5.0000    7.0000    4.0000    1.0000    4.0000
    8.0000    8.0000    7.0000    8.5000    7.0000    2.0000    4.5000
   10.0000   10.0000   10.0000   10.0000    8.0000    8.0000    7.0000
```

Each column of matrix `y` corresponds to the three evenly spaced quantiles of each column of matrix `X`. For example, the first column of `y` with elements (2, 8, 10) has the quantiles for the first column of `X` with elements (9, 10, 2, 10, 7, 1). `y = quantile(X,3)` returns the same answer because the default value of `dim` is 1.

Calculate three evenly spaced quantiles for each row of X (`dim = 2`).

```
y = quantile(X,3,2)
```

```
y = 6×3
```

```
    7.0000    8.0000    8.7500
    4.2500    6.0000    9.5000
    4.0000    8.0000    9.7500
    1.0000    2.0000    8.5000
    2.7500    5.0000    7.0000
    2.5000    9.0000   10.0000
```

Each row of matrix `y` corresponds to the three evenly spaced quantiles of each row of matrix `X`. For example, the first row of `y` with elements (7, 8, 8.75) has the quantiles for the first row of `X` with elements (9, 3, 10, 8, 7, 8, 7).

Quantiles of Multidimensional Array for Given Probabilities

Calculate the quantiles of a multidimensional array for specified probabilities by using the 'all' and `vecdim` input arguments.

Create a 3-by-5-by-2 array `X`. Specify the vector of probabilities `p`.

```
X = reshape(1:30,[3 5 2])
```

```
X =  
X(:,:,1) =
```

```
     1     4     7    10    13  
     2     5     8    11    14  
     3     6     9    12    15
```

```
X(:,:,2) =
```

```
    16    19    22    25    28  
    17    20    23    26    29  
    18    21    24    27    30
```

```
p = [0.25 0.75];
```

Calculate the 0.25 and 0.75 quantiles of all the elements in `X`.

```
Yall = quantile(X,p,'all')
```

```
Yall = 2×1
```

```
     8  
    23
```

`Yall(1)` is the 0.25 quantile of `X`, and `Yall(2)` is the 0.75 quantile of `X`.

Calculate the 0.25 and 0.75 quantiles for each page of X by specifying dimensions 1 and 2 as the operating dimensions.

```
Ypage = quantile(X,p,[1 2])
```

```
Ypage =  
Ypage(:,:,1) =
```

```
    4.2500  
   11.7500
```

```
Ypage(:,:,2) =
```

```
   19.2500  
   26.7500
```

For example, $Y_{\text{page}}(1,1,1)$ is the 0.25 quantile of the first page of X , and $Y_{\text{page}}(2,1,1)$ is the 0.75 quantile of the first page of X .

Calculate the 0.25 and 0.75 quantiles of the elements in each $X(i, :, :)$ slice by specifying dimensions 2 and 3 as the operating dimensions.

```
Yrow = quantile(X,p,[2 3])
```

```
Yrow = 3×2
```

```
    7    22  
    8    23  
    9    24
```

For example, $Y_{\text{row}}(3,1)$ is the 0.25 quantile of the elements in $X(3, :, :)$, and $Y_{\text{row}}(3,2)$ is the 0.75 quantile of the elements in $X(3, :, :)$.

Median and Quartiles for Even Number of Data Elements

Find median and quartiles of a vector, x , with even number of elements.

Enter the data.

```
x = [2 5 6 10 11 13]
x = 1×6
     2     5     6    10    11    13
```

Calculate the median of x .

```
y = quantile(x,0.50)
```

```
y = 8
```

Calculate the quartiles of x .

```
y = quantile(x,[0.25, 0.5, 0.75])
```

```
y = 1×3
     5     8    11
```

Using `y = quantile(x,3)` is another way to compute the quartiles of x .

These results might be different than the textbook definitions because `quantile` uses “Linear Interpolation” on page 32-5530 to find the median and quartiles.

Median and Quartiles for Odd Number of Data Elements

Find median and quartiles of a vector, x , with odd number of elements.

Enter the data.

```
x = [2 4 6 8 10 12 14]
x = 1×7
     2     4     6     8    10    12    14
```

Find the median of x .

```
y = quantile(x,0.50)
```

```
y = 8
```

Find the quartiles of x .

```
y = quantile(x,[0.25, 0.5, 0.75])
```

```
y = 1×3
```

```
    4.5000    8.0000   11.5000
```

Using `y = quantile(x,3)` is another way to compute the quartiles of x .

These results might be different than the textbook definitions because `quantile` uses “Linear Interpolation” on page 32-5530 to find the median and quartiles.

Quantiles of Tall Vector for Given Probability

Calculate exact and approximate quantiles of a tall column vector for a given probability.

Create a datastore for the `airlinesmall` data set. Treat 'NA' values as missing data so that `datastore` replaces them with NaN values. Specify to work with the `ArrTime` variable.

```
ds = datastore('airlinesmall.csv','TreatAsMissing','NA',...  
             'SelectedVariableNames','ArrTime');
```

Create a tall table on top of the datastore, and extract the data from the tall table into a tall vector.

```
t = tall(ds) % Tall table
```

Starting parallel pool (`parpool`) using the 'local' profile ...
connected to 6 workers.

```
t =
```

```
M×1 tall table
```

```
    ArrTime
```

    1134
    :
    :

```

Calculate the exact quantile of x for $p = 0.5$. Because X is a tall column vector and p is a scalar, `quantile` returns the exact quantile value by default.

```

p = 0.5; % Cumulative probability
yExact = quantile(x,p)
yExact =
MxNx... tall double array
? ? ? ...
? ? ? ...
? ? ? ...
: : :
: : :

```

Preview deferred. [Learn more.](#)

Calculate the approximate quantile of x for $p = 0.5$. Specify 'Method', 'approximate' to use an approximation algorithm based on “T-Digest” on page 32-5531 for computing the quantiles.

```
yApprox = quantile(x,p,'Method','approximate')
```

```
yApprox =
```

```
M×N×... tall double array
```

```
? ? ? ...  
? ? ? ...  
? ? ? ...

: : :
```

Preview deferred. [Learn more.](#)

Evaluate the tall arrays and bring the results into memory by using `gather`.

```
[yExact,yApprox] = gather(yExact,yApprox)
```

```
Evaluating tall expression using the Parallel Pool 'local':
```

```
- Pass 1 of 4: Completed in 8.7 sec  
- Pass 2 of 4: Completed in 4.7 sec  
- Pass 3 of 4: Completed in 1.8 sec  
- Pass 4 of 4: Completed in 1.5 sec  
Evaluation completed in 19 sec
```

```
yExact = 1522
```

```
yApprox = 1.5220e+03
```

The values of the approximate quantile and the exact quantile are the same to the four digits shown.

Quantiles of Tall Matrix Along Different Dimensions

Calculate exact and approximate quantiles of a tall matrix for specified cumulative probabilities along different dimensions.

Create a tall matrix `X` containing a subset of variables from the `airlinesmall` data set. See “Quantiles of Tall Vector for Given Probability” on page 32-5520 for details about the steps to extract data from a tall array.

```
varnames = {'ArrDelay','ArrTime','DepTime','ActualElapsedTime'}; % Subset of variables
ds = datastore('airlinesmall.csv','TreatAsMissing','NA',...
    'SelectedVariableNames',varnames); % Datastore
t = tall(ds); % Tall table
```

Starting parallel pool (`parpool`) using the 'local' profile ...
Connected to the parallel pool (number of workers: 6).

```
X = t{:,varnames} % Tall matrix
```

`X =`

Preview deferred. [Learn more.](#)

When the function operates along the first dimension and `p` is a vector of cumulative probabilities, you must use the approximation algorithm based on `t-digest` to compute the quantiles. Using the sorting-based algorithm to find the quantiles along the first dimension of a tall array is computationally intensive.

Calculate the approximate quantiles of `X` along the first dimension for the cumulative probabilities 0.25, 0.5, and 0.75. Because the default dimension is 1, you do not need to specify a value for `dim`.

```
Yapprox = quantile(X,p,'Method','approximate')
```

```
Yapprox =
```

```
M×N×... tall double array
```

    0.0405    0.3530    0.6875
```

Each row of the matrix `Yexact` contains the three evenly spaced quantiles of the corresponding row in X . For example, `30.5`, `347.5`, and `688.5` are the 0.25, 0.5, and 0.75 quantiles, respectively, of the first row in X .

Input Arguments

X — Input data

vector | array

Input data, specified as a vector or array.

Data Types: double | single

p — Cumulative probabilities

scalar | vector

Cumulative probabilities for which to compute the quantiles, specified as a scalar or vector of scalars from 0 to 1.

Example: 0.3

Example: [0.25, 0.5, 0.75]

Example: (0:0.25:1)

Data Types: double | single

N — Number of quantiles

positive integer

Number of quantiles to compute, specified as a positive integer. `quantile` returns `N` quantiles that divide the data set into evenly distributed `N+1` segments.

Data Types: `double` | `single`**dim — Dimension**

positive integer

Dimension along which the quantiles of a matrix `X` are requested, specified as a positive integer. For example, for a matrix `X`, when `dim = 1`, `quantile` returns the quantile(s) of the columns of `X`; when `dim = 2`, `quantile` returns the quantile(s) of the rows of `X`. For a multidimensional array `X`, the length of the `dim`th dimension of `Y` is the same as the length of `p`.

Data Types: `single` | `double`**vecdim — Vector of dimensions**

positive integer vector

Vector of dimensions, specified as a positive integer vector. Each element of `vecdim` represents a dimension of the input array `X`. In the smallest specified operating dimension (that is, dimension `min(vecdim)`), the output `Y` has length equal to the number of quantiles requested (either `N` or `length(p)`). In each of the remaining operating dimensions, `Y` has length 1. The other dimension lengths are the same for `X` and `Y`.

For example, consider a 2-by-3-by-3 array `X` with `p = [0.2 0.4 0.6 0.8]`. In this case, `quantile(X,p,[1 2])` returns an array, where each page of the array contains the 0.2, 0.4, 0.6, and 0.8 quantiles of the elements on the corresponding page of `X`. Because 1 and 2 are the operating dimensions, with `min([1 2]) = 1` and `length(p) = 4`, the output is a 4-by-1-by-3 array.

Data Types: `single` | `double`**method — Method for calculating quantiles**

'exact' (default) | 'approximate'

Method for calculating quantiles, specified as 'exact' or 'approximate'. By default, `quantile` returns the exact quantiles by implementing an algorithm on page 32-5533 that uses sorting. You can specify 'method', 'approximate' for `quantile` to return approximate quantiles by implementing an algorithm that uses T-Digest on page 32-5531.

Data Types: `char` | `string`

Output Arguments

Y — Quantiles

scalar | array

Quantiles of a data vector or array, returned as a scalar or array for one or multiple values of cumulative probabilities.

- If X is a vector, then Y is a scalar or a vector with the same length as the number of quantiles requested (N or `length(p)`). $Y(i)$ contains the $p(i)$ quantile.
- If X is an array of dimension d , then Y is an array with the length of the smallest operating dimension equal to the number of quantiles requested (N or `length(p)`).

Definitions

Multidimensional Array

A *multidimensional array* is an array with more than two dimensions. For example, if X is a 1-by-3-by-4 array, then X is a 3-D array.

First Nonsingleton Dimension

A *first nonsingleton dimension* is the first dimension of an array whose size is not equal to 1. For example, if X is a 1-by-2-by-3-by-4 array, then the second dimension is the first nonsingleton dimension of X .

Linear Interpolation

Linear interpolation uses linear polynomials to find $y_i = f(x_i)$, the values of the underlying function $Y = f(X)$ at the points in the vector or array x . Given the data points (x_1, y_1) and (x_2, y_2) , where $y_1 = f(x_1)$ and $y_2 = f(x_2)$, linear interpolation finds $y = f(x)$ for a given x between x_1 and x_2 as follows:

$$y = f(x) = y_1 + \frac{(x - x_1)}{(x_2 - x_1)}(y_2 - y_1).$$

Similarly, if the $1.5/n$ quantile is $y_{1.5/n}$ and the $2.5/n$ quantile is $y_{2.5/n}$, then linear interpolation finds the $2.3/n$ quantile $y_{2.3/n}$ as

$$y_{\frac{2.3}{n}} = y_{\frac{1.5}{n}} + \left(\frac{\frac{2.3}{n} - \frac{1.5}{n}}{\frac{2.5}{n} - \frac{1.5}{n}} \right) \left(y_{\frac{2.5}{n}} - y_{\frac{1.5}{n}} \right).$$

T-Digest

T-digest[2] on page 32-5533 is a probabilistic data structure that is a sparse representation of the empirical cumulative distribution function (CDF) of a data set. T-digest is useful for computing approximations of rank-based statistics (such as percentiles and quantiles) from online or distributed data in a way that allows for controllable accuracy, particularly near the tails of the data distribution.

For data that is distributed in different partitions, t-digest computes quantile estimates (and percentile estimates) for each data partition separately, and then combines the estimates while maintaining a constant-memory bound and constant relative accuracy of computation ($q(1 - q)$ for the q th quantile). For these reasons, t-digest is practical for working with tall arrays.

To estimate quantiles of an array that is distributed in different partitions, first build a t-digest in each partition of the data. A t-digest clusters the data in the partition and summarizes each cluster by a centroid value and an accumulated weight that represents the number of samples contributing to the cluster. T-digest uses large clusters (widely spaced centroids) to represent areas of the CDF that are near $q = 0.5$ and uses small clusters (tightly spaced centroids) to represent areas of the CDF that are near $q = 0$ or $q = 1$.

T-digest controls the cluster size by using a scaling function that maps a quantile q to an index k with a compression parameter δ . That is,

$$k(q, \delta) = \delta \cdot \left(\frac{\sin^{-1}(2q - 1)}{\pi} + \frac{1}{2} \right),$$

where the mapping k is monotonic with minimum value $k(0, \delta) = 0$ and maximum value $k(1, \delta) = \delta$.

Scaling Function for $\delta = 10$

The scaling function translates the quantile q to the scaling factor k in order to give variable size steps in q . As a result, cluster sizes are unequal (larger around the center quantiles and smaller near $q = 0$ or $q = 1$). The smaller clusters allow for better accuracy near the edges of the data.

To update a t-digest with a new observation that has a weight and location, find the cluster closest to the new observation. Then, add the weight and update the centroid of the cluster based on the weighted average, provided that the updated weight of the cluster does not exceed the size limitation.

You can combine independent t-digests from each partition of the data by taking a union of the t-digests and merging their centroids. To combine t-digests, first sort the clusters from all the independent t-digests in decreasing order of cluster weights. Then, merge neighboring clusters, when they meet the size limitation, to form a new t-digest.

Once you form a t-digest that represents the complete data set, you can estimate the end-points (or boundaries) of each cluster in the t-digest and then use interpolation between the end-points of each cluster to find accurate quantile estimates.

Algorithms

For an n -element vector X , `quantile` computes quantiles by using a sorting-based algorithm as follows:

- 1 The sorted elements in X are taken as the $(0.5/n)$, $(1.5/n)$, ..., $([n - 0.5]/n)$ quantiles. For example:
 - For a data vector of five elements such as $\{6, 3, 2, 10, 1\}$, the sorted elements $\{1, 2, 3, 6, 10\}$ respectively correspond to the 0.1, 0.3, 0.5, 0.7, 0.9 quantiles.
 - For a data vector of six elements such as $\{6, 3, 2, 10, 8, 1\}$, the sorted elements $\{1, 2, 3, 6, 8, 10\}$ respectively correspond to the $(0.5/6)$, $(1.5/6)$, $(2.5/6)$, $(3.5/6)$, $(4.5/6)$, $(5.5/6)$ quantiles.
- 2 `quantile` uses “Linear Interpolation” on page 32-5530 to compute quantiles for probabilities between $(0.5/n)$ and $([n - 0.5]/n)$.
- 3 For the quantiles corresponding to the probabilities outside that range, `quantile` assigns the minimum or maximum values of the elements in X .

`quantile` treats NaNs as missing values and removes them.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

Usage notes and limitations:

- `Y = quantile(X,p)` and `Y = quantile(X,p,dim)` return the exact quantiles (using a sorting-based algorithm on page 32-5533) under these conditions:
 - `X` is a tall column vector and `p` is a scalar. In this case, `dim` is 1.
 - `X` is a tall array and `dim` is not 1.

If `p` is a vector and `dim` is 1, then you must specify `'Method'`, `'approximate'` to use an approximation algorithm based on T-Digest on page 32-5531 for computing the quantiles.

- `Y = quantile(X,N)` returns the exact quantiles only when `quantile` is operating along a dimension other than the first dimension. If `dim` is 1, then you must specify `'Method'`, `'approximate'` to use the approximation algorithm.
- `Y = quantile(__, 'all')` returns the exact quantiles when `p` is a scalar. If `p` is a vector, then you must specify `'Method'`, `'approximate'` to use the approximation algorithm.
- `Y = quantile(__, vecdim)` returns the exact quantiles if `vecdim` does not include the first dimension. If `vecdim` includes the first dimension, then you must specify `'Method'`, `'approximate'` to use the approximation algorithm.

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The `'all'` and `vecdim` input arguments are not supported.
- The `'Method'` name-value pair argument is not supported.
- The `dim` input argument must be a compile-time constant.

- If you do not specify the `dim` input argument, the working (or operating) dimension can be different in the generated code. As a result, run-time errors can occur. For more details, see “Automatic dimension restriction” (MATLAB Coder).
- If the output `Y` is a vector, the orientation of `Y` differs from MATLAB when all of the following are true:
 - You do not supply `dim`.
 - `X` is a variable-size array, and not a variable-size vector, at compile time, but `X` is a vector at run time.
 - The orientation of the vector `X` does not match the orientation of the vector `p`.

In this case, the output `Y` matches the orientation of `X`, not the orientation of `p`.

For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “General Code Generation Workflow” on page 31-5.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Usage notes and limitations:

- The `'all'` and `vecdim` input arguments are not supported.
- The `'Method'` name-value pair argument is not supported.

For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

Topics

“Quantiles and Percentiles” on page 3-6

Introduced before R2006a

rand

Class: grandstream

Generate quasi-random points from stream

Syntax

```
rand
rand(q, n)
rand(q)
rand(q, m, n)
rand(q, [m, n])
rand(q, m, n, p, ...)
rand(q, [m, n, p, ...])
```

Description

rand returns a matrix of quasi-random values and is intended to allow objects of the grandstream on page 32-5498 class to be used in code that contains calls to the rand method of the MATLAB pseudo-random randstream class. Due to the multidimensional nature of quasi-random numbers, only some syntaxes of rand are supported by the grandstream class.

rand(q, n) returns an n-by-n matrix only when n is equal to the number of dimensions. Any other value of n produces an error.

rand(q) returns a scalar only when the stream is in one dimension. Having more than one dimension in q produces an error.

rand(q, m, n) or rand(q, [m, n]) returns an m-by-n matrix only when n is equal to the number of dimensions in the stream. Any other value of n produces an error.

rand(q, m, n, p, ...) or rand(q, [m, n, p, ...]) produces an error unless p and all following dimensions sizes are equal to one.

Examples

Generate the first 256 points from a 5-D Sobol sequence:

```
q = grandstream('sobol',5);  
X = rand(q,256,5);
```

[grand](#) | [grandstream](#) | [rand](#)

quantileError

Class: TreeBagger

Quantile loss using bag of regression trees

Syntax

```
err = quantileError(Mdl,X)
err = quantileError(Mdl,X,ResponseVarName)
err = quantileError(Mdl,X,Y)
err = quantileError( ____,Name,Value)
```

Description

`err = quantileError(Mdl,X)` returns half of the mean absolute deviation (MAD) from comparing the true responses in the table `X` to the predicted medians resulting from applying the bag of regression trees `Mdl` to the observations of the predictor data in `X`.

- `Mdl` must be a `TreeBagger` model object.
- The response variable name in `X` must have the same name as the response variable in the table containing the training data.

`err = quantileError(Mdl,X,ResponseVarName)` uses the true response and predictor variables contained in the table `X`. `ResponseVarName` is the name of the response variable and `Mdl.PredictorNames` contain the names of the predictor variables.

`err = quantileError(Mdl,X,Y)` uses the predictor data in the table or matrix `X` and the response data in the vector `Y`.

`err = quantileError(____,Name,Value)` uses any of the previous syntaxes and additional options specified by one or more `Name, Value` pair arguments. For example, specify quantile probabilities, the error type, or which trees to include in the quantile-regression-error estimation.

Input Arguments

Mdl — Bag of regression trees

TreeBagger model object (default)

Bag of regression trees, specified as a TreeBagger model object created by TreeBagger. The value of Mdl.Method must be regression.

X — Sample data

numeric matrix | table

Sample data used to estimate quantiles, specified as a numeric matrix or table.

Each row of X corresponds to one observation, and each column corresponds to one variable. If you specify Y, then the number of rows in X must be equal to the length of Y.

- For a numeric matrix:
 - The variables making up the columns of X must have the same order as the predictor variables that trained Mdl (stored in Mdl.PredictorNames).
 - If you trained Mdl using a table (for example, Tbl), then X can be a numeric matrix if Tbl contains all numeric predictor variables. If Tbl contains heterogeneous predictor variables (for example, numeric and categorical data types), then quantileError throws an error.
 - Specify Y for the true responses.
- For a table:
 - quantileError does not support multi-column variables and cell arrays other than cell arrays of character vectors.
 - If you trained Mdl using a table (for example, Tbl), then all predictor variables in X must have the same variable names and data types as those variables that trained Mdl (stored in Mdl.PredictorNames). However, the column order of X does not need to correspond to the column order of Tbl. Tbl and X can contain additional variables (response variables, observation weights, etc.).
 - If you trained Mdl using a numeric matrix, then the predictor names in Mdl.PredictorNames and corresponding predictor variable names in X must be the same. To specify predictor names during training, see the PredictorNames name-value pair argument of TreeBagger. All predictor variables in X must be numeric vectors. X can contain additional variables (response variables, observation weights, etc.).

- If `X` contains the response variable:
 - If the response variable has the same name as the response variable that trained `Mdl`, then you do not have to supply the response variable name or vector of true responses. `quantileError` uses that variable for the true responses by default.
 - You can specify `ResponseVarName` or `Y` for the true responses.

Data Types: `table` | `double` | `single`

ResponseVarName — Response variable name

character vector | string scalar

Response variable name, specified as a character vector or string scalar.

`ResponseVarName` must be the name of the response variable in the table of sample data `X`.

If the table `X` contains the response variable, and it has the same name as the response variable used to train `Mdl`, then you do not have to specify `ResponseVarName`. `quantileError` uses that variable for the true responses by default.

Data Types: `char` | `string`

Y — True responses

numeric vector

True responses, specified as a numeric vector. The number of rows in `X` must be equal to the length of `Y`.

Data Types: `double` | `single`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Mode — Ensemble error type

'ensemble' (default) | 'cumulative' | 'individual'

Ensemble error type, specified as the comma-separated pair consisting of 'Mode' and a value in this table. Suppose `tau` is the value of `Quantile`.

Value	Description
'cumulative'	err is a <code>Mdl.NumTrees</code> -by- <code>numel(tau)</code> numeric matrix of cumulative quantile regression errors. <code>err(j,k)</code> is the $\tau(k)$ quantile regression error using the learners in <code>Mdl.Trees(1:j)</code> only.
'ensemble'	err is a 1-by- <code>numel(tau)</code> numeric vector of cumulative quantile regression errors for the entire ensemble. <code>err(k)</code> is the $\tau(k)$ ensemble quantile regression error.
'individual'	err is a <code>Mdl.NumTrees</code> -by- <code>numel(tau)</code> numeric matrix of quantile regression errors from individual learners. <code>err(j,k)</code> is the $\tau(k)$ quantile regression error using the learner in <code>Mdl.Trees(j)</code> only.

For 'cumulative' and 'individual', if you include fewer trees in quantile estimation using `Trees` or `UseInstanceForTree`, then the number of rows in `err` decreases from `Mdl.NumTrees`.

Example: 'Mode', 'cumulative'

Weights — Observation weights

`ones(size(X,1),1)` (default) | numeric vector of positive values

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a numeric vector of positive values with length equal to `size(X,1)`. `quantileError` uses `Weights` to compute the weighted average of the deviations when estimating the quantile regression error.

By default, `quantileError` attributes a weight of 1 to each observation, which yields an unweighted average of the deviations.

Quantile — Quantile probability

0.5 (default) | numeric vector containing values in [0,1]

Quantile probability, specified as the comma-separated pair consisting of 'Quantile' and a numeric vector containing values in the interval [0,1]. For each element in `Quantile`, `quantileError` returns corresponding quantile regression errors for all probabilities in `Quantile`.

Example: 'Quantile',[0 0.25 0.5 0.75 1]

Data Types: single | double

Trees — Indices of trees to use in response estimation

'all' (default) | numeric vector of positive integers

Indices of trees to use in response estimation, specified as the comma-separated pair consisting of 'Trees' and 'all' or a numeric vector of positive integers. Indices correspond to the cells of `Mdl.Trees`; each cell therein contains a tree in the ensemble. The maximum value of `Trees` must be less than or equal to the number of trees in the ensemble (`Mdl.NumTrees`).

For 'all', `quantileError` uses all trees in the ensemble (that is, the indices `1:Mdl.NumTrees`).

Values other than the default can affect the number of rows in `err`.

Example: 'Trees', [1 10 Mdl.NumTrees]

Data Types: char | string | single | double

TreeWeights — Weights to attribute to responses from individual trees

`ones(Mdl.NumTrees, 1)` (default) | numeric vector of nonnegative values

Weights to attribute to responses from individual trees, specified as the comma-separated pair consisting of 'TreeWeights' and a numeric vector of `numel(trees)` nonnegative values. `trees` is the value of `Trees`.

If you specify 'Mode', 'individual', then `quantileError` ignores `TreeWeights`.

Data Types: single | double

UseInstanceForTree — Indicators specifying which trees to use to make predictions for each observation

'all' (default) | logical matrix

Indicators specifying which trees to use to make predictions for each observation, specified as the comma-separated pair consisting of 'UseInstanceForTree' and an n -by-`Mdl.Trees` logical matrix. n is the number of observations (rows) in `X`. Rows of `UseInstanceForTree` correspond to observations and columns correspond to learners in `Mdl.Trees`. 'all' indicates to use all trees for all observations when estimating the quantiles.

If `UseInstanceForTree(j, k) = true`, then `quantileError` uses the tree in `Mdl.Trees(k)` when it predicts the response for the observation `X(j, :)`.

You can estimate quantiles using the response data in `Mdl.Y` directly instead of using the predictions from the random forest by specifying a row composed entirely of `false` values. For example, to estimate the quantile for observation j using the response data,

and to use the predictions from the random forest for all other observations, specify this matrix:

```
UseInstanceForTree = true(size(Mdl.X,2),Mdl.NumTrees);
UseInstanceForTree(j,:) = false(1,Mdl.NumTrees);
```

Values other than the default can affect the number of rows in `err`. Also, the value of `Trees` affects the value of `UseInstanceForTree`. Suppose that U is the value of `UseInstanceForTree`. `quantileError` ignores the columns of U corresponding to trees not being used in estimation from the specification of `Trees`. That is, `quantileError` resets the value of `'UseInstanceForTree'` to $U(:, trees)$, where $trees$ is the value of `'Trees'`.

Data Types: char | string | logical

Output Arguments

err — Half of quantile regression error

numeric scalar | numeric matrix

Half of the quantile regression error on page 32-5546, returned as a numeric scalar or T -by- $\text{numel}(\tau)$ matrix. τ is the value of `Quantile`.

T depends on the values of `Mode`, `Trees`, `UseInstanceForTree`, and `Quantile`. Suppose that you specify `'Trees'`, $trees$ and you use the default value of `'UseInstanceForTree'`.

- For `'Mode'`, `'cumulative'`, `err` is a $\text{numel}(trees)$ -by- $\text{numel}(\tau)$ numeric matrix. `err(j,k)` is the $\tau(k)$ cumulative quantile regression error using the learners in `Mdl.Trees(trees(1:j))`.
- For `'Mode'`, `'ensemble'`, `err` is a 1-by- $\text{numel}(\tau)$ numeric vector. `err(k)` is the $\tau(k)$ cumulative quantile regression error using the learners in `Mdl.Trees(trees)`.
- For `'Mode'`, `'individual'`, `err` is a $\text{numel}(trees)$ -by- $\text{numel}(\tau)$ numeric matrix. `err(j,k)` is the $\tau(k)$ quantile regression error using the learner in `Mdl.Trees(trees(j))`.

Examples

Estimate In-Sample Quantile Regression Error

Load the `carsmall` data set. Consider a model that predicts the fuel economy of a car given its engine displacement, weight, and number of cylinders. Consider `Cylinders` a categorical variable.

```
load carsmall
Cylinders = categorical(Cylinders);
X = table(Displacement,Weight,Cylinders,MPG);
```

Train an ensemble of bagged regression trees using the entire data set. Specify 100 weak learners.

```
rng(1); % For reproducibility
Mdl = TreeBagger(100,X,'MPG','Method','regression');
```

`Mdl` is a `TreeBagger` ensemble.

Perform quantile regression, and estimate the MAD of the entire ensemble using the predicted conditional medians.

```
err = quantileError(Mdl,X)
```

```
err = 1.2586
```

Because `X` is a table containing the response and commensurate variable names, you do not have to specify the response variable name or data. However, you can specify the response using this syntax.

```
err = quantileError(Mdl,X,'MPG')
```

```
err = 1.2586
```

Find Appropriate Ensemble Size Using Quantile Regression Error

Load the `carsmall` data set. Consider a model that predicts the fuel economy of a car given its engine displacement, weight, and number of cylinders.

```
load carsmall
X = table(Displacement,Weight,Cylinders,MPG);
```

Randomly split the data into two sets: 75% training and 25% testing. Extract the subset indices.

```
rng(1); % For reproducibility
cvp = cvpartition(size(X,1),'Holdout',0.25);
idxTrn = training(cvp);
idxTest = test(cvp);
```

Train an ensemble of bagged regression trees using the training set. Specify 250 weak learners.

```
Mdl = TreeBagger(250,X(idxTrn,:), 'MPG', 'Method', 'regression');
```

Estimate the cumulative 0.25, 0.5, and 0.75 quantile regression errors for the test set. Pass the predictor data in as a numeric matrix, and the response data in as a vector.

```
err = quantileError(Mdl,X{idxTest,1:3},MPG(idxTest), 'Quantile',[0.25 0.5 0.75],...
    'Mode', 'cumulative');
```

`err` is a 250-by-3 matrix of cumulative quantile regression errors. Columns correspond to quantile probabilities and rows correspond to trees in the ensemble. The errors are cumulative, so they incorporate aggregated predictions from previous trees. Although, `Mdl` was trained using a table, if all predictor variables in the table are numeric, then you can supply a matrix of predictor data instead.

Plot the cumulative quantile errors on the same plot.

```
figure;
plot(err);
legend('0.25 quantile error', '0.5 quantile error', '0.75 quantile error');
ylabel('Quantile error');
xlabel('Tree index');
title('Cumulative Quantile Regression Error')
```

Training using about 60 trees appears to be enough for the first two quartiles, but the third quartile requires about 150 trees.

Definitions

Quantile Regression Error

The quantile regression error of a model given observed predictor data and responses is the weighted mean absolute deviation (MAD). If the model under-predicts the response, then deviation weights are τ , the quantile probability. If the model over-predicts, then deviation weights are $1 - \tau$.

That is, the τ quantile regression error is

$$L_\tau = \tau \frac{\sum_{\{j: y_j \geq \hat{y}_{\tau, j}\}} w_j (y_j - \hat{y}_{\tau, j})}{\sum_{j=1}^n w_j} + (1 - \tau) \frac{\sum_{\{j: y_j < \hat{y}_{\tau, j}\}} w_j (\hat{y}_{\tau, j} - y_j)}{\sum_{j=1}^n w_j}.$$

y_j is true response j , $\hat{y}_{\tau, j}$ is the τ quantile that the model predicts, and w_j is observation weight j .

Tips

- To tune the number of trees in the ensemble, set 'Mode', 'cumulative' and plot the quantile regression errors with respect to tree indices. The maximal number of required trees is the tree index where the quantile regression error appears to level off.
- To investigate the performance of a model when the training sample is small, use `oobQuantileError` instead.

`TreeBagger` | `error` | `oobQuantileError` | `quantilePredict`

Introduced in R2016b

quantilePredict

Class: TreeBagger

Predict response quantile using bag of regression trees

Syntax

```
YFit = quantilePredict(Mdl,X)
YFit = quantilePredict(Mdl,X,Name,Value)
[YFit,YW] = quantilePredict( ___ )
```

Description

`YFit = quantilePredict(Mdl,X)` returns a vector of medians of the predicted responses at `X`, a table or matrix of predictor data, and using the bag of regression trees `Mdl`. `Mdl` must be a `TreeBagger` model object.

`YFit = quantilePredict(Mdl,X,Name,Value)` uses additional options specified by one or more `Name,Value` pair arguments. For example, specify quantile probabilities or which trees to include for quantile estimation.

`[YFit,YW] = quantilePredict(___)` also returns a sparse matrix of response weights on page 32-5559.

Input Arguments

Mdl — Bag of regression trees

`TreeBagger` model object (default)

Bag of regression trees, specified as a `TreeBagger` model object created by `TreeBagger`. The value of `Mdl.Method` must be `regression`.

X — Predictor data

numeric matrix | table

Predictor data used to estimate quantiles, specified as a numeric matrix or table.

Each row of `X` corresponds to one observation, and each column corresponds to one variable.

- For a numeric matrix:
 - The variables making up the columns of `X` must have the same order as the predictor variables that trained `Mdl`.
 - If you trained `Mdl` using a table (for example, `Tbl`), then `X` can be a numeric matrix if `Tbl` contains all numeric predictor variables. If `Tbl` contains heterogeneous predictor variables (for example, numeric and categorical data types) and `X` is a numeric matrix, then `quantilePredict` throws an error.
- For a table:
 - `quantilePredict` does not support multi-column variables and cell arrays other than cell arrays of character vectors.
 - If you trained `Mdl` using a table (for example, `Tbl`), then all predictor variables in `X` must have the same variable names and data types as those variables that trained `Mdl` (stored in `Mdl.PredictorNames`). However, the column order of `X` does not need to correspond to the column order of `Tbl`. `Tbl` and `X` can contain additional variables (response variables, observation weights, etc.), but `quantilePredict` ignores them.
 - If you trained `Mdl` using a numeric matrix, then the predictor names in `Mdl.PredictorNames` and corresponding predictor variable names in `X` must be the same. To specify predictor names during training, see the `PredictorNames` name-value pair argument of `TreeBagger`. All predictor variables in `X` must be numeric vectors. `X` can contain additional variables (response variables, observation weights, etc.), but `quantilePredict` ignores them.

Data Types: `table` | `double` | `single`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Quantile — Quantile probability

0.5 (default) | numeric vector containing values in [0,1]

Quantile probability, specified as the comma-separated pair consisting of 'Quantile' and a numeric vector containing values in the interval [0,1]. For each observation (row) in *X*, `quantilePredict` returns corresponding quantiles for all probabilities in *Quantile*.

Example: 'Quantile',[0 0.25 0.5 0.75 1]

Data Types: single | double

Trees — Indices of trees to use in response estimation

'all' (default) | numeric vector of positive integers

Indices of trees to use in response estimation, specified as the comma-separated pair consisting of 'Trees' and 'all' or a numeric vector of positive integers. Indices correspond to the cells of `Mdl.Trees`; each cell therein contains a tree in the ensemble. The maximum value of *Trees* must be less than or equal to the number of trees in the ensemble (`Mdl.NumTrees`).

For 'all', `quantilePredict` uses the indices `1:Mdl.NumTrees`.

Example: 'Trees',[1 10 `Mdl.NumTrees`]

Data Types: char | string | single | double

TreeWeights — Weights to attribute to responses from individual trees

numeric vector of nonnegative values

Weights to attribute to responses from individual trees, specified as the comma-separated pair consisting of 'TreeWeights' and a numeric vector of `numel(trees)` nonnegative values. *trees* is the value of the *Trees* name-value pair argument.

The default is `ones(size(trees))`.

Data Types: single | double

UseInstanceForTree — Indicators specifying which trees to use to make predictions for each observation

'all' (default) | logical matrix

Indicators specifying which trees to use to make predictions for each observation, specified as the comma-separated pair consisting of 'UseInstanceForTree' and an *n*-by-`Mdl.Trees` logical matrix. *n* is the number of observations (rows) in *X*. Rows of

`UseInstanceForTree` correspond to observations and columns correspond to learners in `Mdl.Trees`. 'all' indicates to use all trees for all observations when estimating the quantiles.

If `UseInstanceForTree(j,k) = true`, then `quantilePredict` uses the tree in `Mdl.Trees(trees(k))` when it predicts the response for the observation `X(j,:)`.

You can estimate the quantile using the response data in `Mdl.Y` directly instead of using the predictions from the random forest by specifying a row composed entirely of `false` values. For example, to estimate the quantile for observation `j` using the response data, and to use the predictions from the random forest for all other observations, specify this matrix:

```
UseInstanceForTree = true(size(Mdl.X,2),Mdl.NumTrees);
UseInstanceForTree(j,:) = false(1,Mdl.NumTrees);
```

Data Types: char | string | logical

Output Arguments

YFit — Estimated quantiles

numeric matrix

Estimated quantiles, returned as an n -by-`numel(tau)` numeric matrix. n is the number of observations in `X` (`size(X,1)`) and `tau` is the value of `Quantile`. That is, `YFit(j,k)` is the estimated $100*tau(k)\%$ percentile of the response distribution given `X(j,:)` and using `Mdl`.

YW — Response weights

sparse matrix

Response weights on page 32-5559, returned as an n_{train} -by- n sparse matrix. n_{train} is the number of responses in the training data (`numel(Mdl.Y)`) and n is the number of observations in `X` (`size(X,1)`).

`quantilePredict` predicts quantiles using linear interpolation of the empirical cumulative distribution function (C.D.F.). For a particular observation, you can use its response weights to estimate quantiles using alternative methods, such as approximating the C.D.F. using kernel smoothing.

Note `quantilePredict` derives response weights by passing an observation through the trees in the ensemble. If you specify `UseInstanceForTree` and you compose row j entirely of false values, then $YW(:, j) = \text{Mdl}.W$ instead, that is, the observation weights.

Examples

Predict Training Sample Medians

Load the `carsmall` data set. Consider a model that predicts the fuel economy of a car given its engine displacement.

```
load carsmall
```

Train an ensemble of bagged regression trees using the entire data set. Specify 100 weak learners.

```
rng(1); % For reproducibility
Mdl = TreeBagger(100, Displacement, MPG, 'Method', 'regression');
```

`Mdl` is a `TreeBagger` ensemble.

Perform quantile regression to predict the median MPG for all sorted training observations.

```
medianMPG = quantilePredict(Mdl, sort(Displacement));
```

`medianMPG` is an n -by-1 numeric vector of medians corresponding to the conditional distribution of the response given the sorted observations in `Displacement`. n is the number of observations in `Displacement`.

Plot the observations and the estimated medians on the same figure. Compare the median and mean responses.

```
meanMPG = predict(Mdl, sort(Displacement));

figure;
plot(Displacement, MPG, 'k. ');
hold on
plot(sort(Displacement), medianMPG);
plot(sort(Displacement), meanMPG, 'r--');
```

```
ylabel('Fuel economy');  
xlabel('Engine displacement');  
legend('Data', 'Median', 'Mean');  
hold off;
```

Estimate Prediction Intervals Using Percentiles

Load the `carsmall` data set. Consider a model that predicts the fuel economy of a car given its engine displacement.

```
load carsmall
```

Train an ensemble of bagged regression trees using the entire data set. Specify 100 weak learners.

```
rng(1); % For reproducibility
Mdl = TreeBagger(100,Displacement,MPG,'Method','regression');
```

Perform quantile regression to predict the 2.5% and 97.5% percentiles for ten equally-spaced engine displacements between the minimum and maximum in-sample displacement.

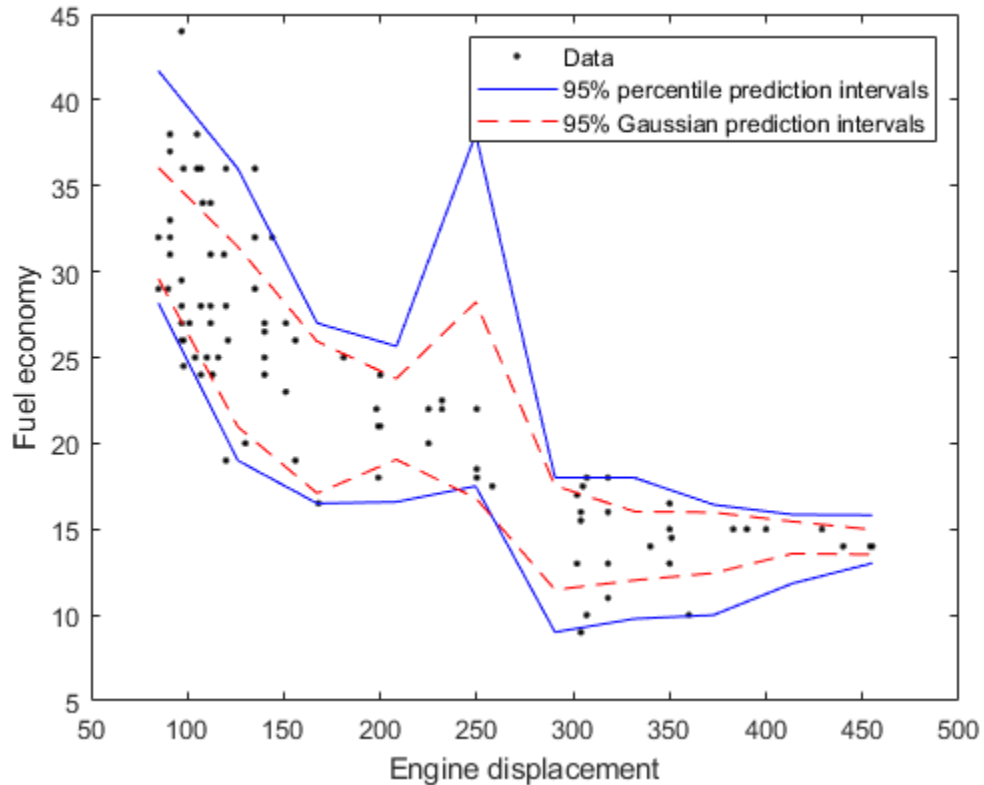

```
predX = linspace(min(Displacement),max(Displacement),10)';
quantPredInts = quantilePredict(Mdl,predX,'Quantile',[0.025,0.975]);
```

`quantPredInts` is a 10-by-2 numeric matrix of prediction intervals corresponding to the observations in `predX`. The first column contains the 2.5% percentiles and the second column contains the 97.5% percentiles.

Plot the observations and the estimated medians on the same figure. Compare the percentile prediction intervals and the 95% prediction intervals assuming the conditional distribution of MPG is Gaussian.

```
[meanMPG,steMeanMPG] = predict(Mdl,predX);
stndPredInts = meanMPG + [-1 1]*norminv(0.975).*steMeanMPG;

figure;
h1 = plot(Displacement,MPG,'k. ');
hold on
h2 = plot(predX,quantPredInts,'b');
h3 = plot(predX,stndPredInts,'r--');
ylabel('Fuel economy');
xlabel('Engine displacement');
legend([h1,h2(1),h3(1)],{'Data','95% percentile prediction intervals',...
'95% Gaussian prediction intervals'});
hold off;
```

Estimate Conditional Cumulative Distribution Using Quantile Regression

Load the `carsmall` data set. Consider a model that predicts the fuel economy of a car given its engine displacement.

```
load carsmall
```

Train an ensemble of bagged regression trees using the entire data set. Specify 100 weak learners.

```
rng(1); % For reproducibility
Mdl = TreeBagger(100, Displacement, MPG, 'Method', 'regression');
```

Estimate the response weights for a random sample of four training observations. Plot the training sample and identify the chosen observations.

```
[predX,idx] = datasample(Mdl.X,4);
[~,YW] = quantilePredict(Mdl,predX);
n = numel(Mdl.Y);

figure;
plot(Mdl.X,Mdl.Y,'o');
hold on
plot(predX,Mdl.Y(idx),'*', 'MarkerSize',10);
text(predX-10,Mdl.Y(idx)+1.5,{'obs. 1' 'obs. 2' 'obs. 3' 'obs. 4'});
legend('Training Data', 'Chosen Observations');
xlabel('Engine displacement')
ylabel('Fuel economy')
hold off
```

YW is an n -by- 4 sparse matrix containing the response weights. Columns correspond to test observations and rows correspond to responses in the training sample. Response weights are independent of the specified quantile probability.

Estimate the conditional cumulative distribution function (C.C.D.F.) of the responses by:

- 1 Sorting the responses in ascending order, and then sorting the response weights using the indices induced by sorting the responses.
- 2 Computing the cumulative sums over each column of the sorted response weights.

```
[sortY,sortIdx] = sort(Mdl.Y);
cpdf = full(YW(sortIdx,:));
ccdf = cumsum(cpdf);
```

`ccdf(:, j)` is the empirical C.C.D.F. of the response given test observation j .

Plot the four empirical C.C.D.F. in the same figure.

```
figure;
plot(sortY,ccdf);
legend('C.C.D.F. given test obs. 1','C.C.D.F. given test obs. 2',...
      'C.C.D.F. given test obs. 3','C.C.D.F. given test obs. 4',...
      'Location','SouthEast')
title('Conditional Cumulative Distribution Functions')
xlabel('Fuel economy')
ylabel('Empirical CDF')
```

Definitions

Response Weights

Response weights are scalars that represent the conditional distribution of the response given a value in the predictor space. The observations in the bootstrap samples and the leaves that the training and test observations share induce response weights.

Given the observation x , the response weight for observation j in the training sample using tree t in the ensemble is

$$w_{tj}(x) = \frac{I\{X_j \in S_t(x)\}}{\sum_{k=1}^{n_{\text{train}}} I\{X_k \in S_t(x)\}},$$

where:

- $I\{h\}$ is the indicator function.
- $S_t(x)$ is the leaf of tree t containing x .
- n_{train} is the number of training observations.

In other words, the response weights of a particular tree form the conditional relative frequency distribution of the response.

The response weights for the entire ensemble are averaged over the trees:

$$w_j^*(x) = \frac{1}{T} \sum_{t=1}^T w_{tj}(x).$$

Quantile Random Forest

Quantile random forest [2] is a quantile-regression method that uses a random forest [1] of regression trees to model the conditional distribution of a response variable, given the value of predictor variables. You can use a fitted model to estimate quantiles in the conditional distribution of the response.

Besides quantile estimation, you can use quantile regression to estimate prediction intervals or detect outliers. For example:

- To estimate 95% quantile prediction intervals, estimate the 0.025 and 0.975 quantiles.
- To detect outliers, estimate the 0.01 and 0.99 quantiles. All observations smaller than the 0.01 quantile and larger than the 0.99 quantile are outliers. All observations that are outside the interval $[L,U]$ can be considered outliers:

$$L = Q_1 - 1.5 * IQR$$

and

$$U = Q_3 + 1.5 * IQR,$$

where:

- Q_1 is the 0.25 quantile.
- Q_3 is the 0.75 quantile.
- $IQR = Q_3 - Q_1$ (the interquartile range).

Tip

`quantilePredict` estimates the conditional distribution of the response using the training data every time you call it. To predict many quantiles efficiently, or quantiles for many observations efficiently, you should pass X as a matrix or table of observations and specify all quantiles in a vector using the `Quantile` name-value pair argument. That is, avoid calling `quantilePredict` within a loop.

Algorithms

- `TreeBagger` grows a random forest of regression trees using the training data. Then, to implement quantile random forest on page 32-5559, `quantilePredict` predicts quantiles using the empirical conditional distribution of the response given an observation from the predictor variables. To obtain the empirical conditional distribution of the response:
 - 1 `quantilePredict` passes all the training observations in `Mdl.X` through all the trees in the ensemble, and stores the leaf nodes of which the training observations are members.
 - 2 `quantilePredict` similarly passes each observation in X through all the trees in the ensemble.

- 3 For each observation in X , `quantilePredict`:
 - a Estimates the conditional distribution of the response by computing response weights on page 32-5559 for each tree.
 - b For observation k in X , aggregates the conditional distributions for the entire ensemble:

$$\widehat{F}(y|X = x_k) = \sum_{j=1}^n \sum_{t=1}^T \frac{1}{T} w_{tj}(x_k) I\{Y_j \leq y\}.$$

n is the number of training observations (`size(Y, 1)`) and T is the number of trees in the ensemble (`Mdl.NumTrees`).

- 4 For observation k in X , the τ quantile or, equivalently, the $100\tau\%$ percentile, is $Q_\tau(x_k) = \inf\{y: \widehat{F}(y|X = x_k) \geq \tau\}$.
- This process describes how `quantilePredict` uses all specified weights.
 - 1 For all training observations $j = 1, \dots, n$ and all chosen trees $t = 1, \dots, T$,

`quantilePredict` attributes the product $v_{tj} = b_{tj}w_{j,\text{obs}}$ to training observation j (stored in `Mdl.X(j, :)` and `Mdl.Y(j)`). b_{tj} is the number of times observation j is in the bootstrap sample for tree t . $w_{j,\text{obs}}$ is the observation weight in `Mdl.W(j)`.
 - 2 For each chosen tree, `quantilePredict` identifies the leaves in which each training observation falls. Let $S_t(x_j)$ be the set of all observations contained in the leaf of tree t of which observation j is a member.
 - 3 For each chosen tree, `quantilePredict` normalizes all weights within a particular leaf to sum to 1, that is,

$$v_{tj}^* = \frac{v_{tj}}{\sum_{i \in S_t(x_j)} v_{ti}}.$$

- 4 For each training observation and tree, `quantilePredict` incorporates tree weights ($w_{t,\text{tree}}$) specified by `TreeWeights`, that is, $w_{tj,\text{tree}}^* = w_{t,\text{tree}} v_{tj}^*$. Trees not chosen for prediction have 0 weight.
- 5 For all test observations $k = 1, \dots, K$ in X and all chosen trees $t = 1, \dots, T$, `quantilePredict` predicts the unique leaves in which the observations fall, and then identifies all training observations within the predicted leaves. `quantilePredict` attributes the weight u_{tj} such that

$$u_{tj} = \begin{cases} w_{tj, \text{tree}}^* & \text{if } x_k \in S_t(x_j) \\ 0 & \text{otherwise} \end{cases}.$$

6 `quantilePredict` sums the weights over all chosen trees, that is,

$$u_j = \sum_{t=1}^T u_{tj}.$$

7 `quantilePredict` creates response weights by normalizing the weights so that they sum to 1, that is,

$$w_j^* = \frac{u_j}{\sum_{j=1}^n u_j}.$$

“Detect Outliers Using Quantile Regression” on page 18-173

Introduced in R2016b

randg

Gamma random numbers with unit scale

Syntax

```
Y = randg
Y = randg(A)
Y = randg(A,m)
Y = randg(A,m,n,p,...)
Y = randg(A,[m,n,p,...])
```

Description

`Y = randg` returns a scalar random value chosen from a gamma distribution with unit scale and shape.

`Y = randg(A)` returns a matrix of random values chosen from gamma distributions with unit scale. `Y` is the same size as `A`, and `randg` generates each element of `Y` using a shape parameter equal to the corresponding element of `A`.

`Y = randg(A,m)` returns an `m`-by-`m` matrix of random values chosen from gamma distributions with shape parameters `A`. `A` is either an `m`-by-`m` matrix or a scalar. If `A` is a scalar, `randg` uses that single shape parameter value to generate all elements of `Y`.

`Y = randg(A,m,n,p,...)` or `Y = randg(A,[m,n,p,...])` returns an `m`-by-`n`-by-`p`-by-... array of random values chosen from gamma distributions with shape parameters `A`. `A` is either an `m`-by-`n`-by-`p`-by-... array or a scalar.

`randg` produces pseudo-random numbers using the MATLAB functions `rand` and `randn`. The sequence of numbers generated is determined by the settings of the uniform random number generator that underlies `rand` and `randn`. Control that shared random number generator using `rng`. See the `rng` documentation for more information.

Note To generate gamma random numbers and specify both the scale and shape parameters, you should call `gamrnd`.

Examples

Example 1

Generate a 100-by-1 array of values drawn from a gamma distribution with shape parameter 3.

```
r = randg(3,100,1);
```

Example 2

Generate a 100-by-2 array of values drawn from gamma distributions with shape parameters 3 and 2.

```
A = [ones(100,1)*3,ones(100,1)*2];  
r = randg(A,[100,2]);
```

Example 3

To create reproducible output from `randg`, reset the random number generator used by `rand` and `randn` to its default startup settings. This way `randg` produces the same random numbers as if you restarted MATLAB.

```
rng('default')  
randg(3,1,5)
```

```
ans =
```

```
    6.9223    4.3369    1.0505    3.2662   11.3269
```

Example 4

Save the settings for the random number generator used by `rand` and `randn`, generate 5 values from `randg`, restore the settings, and repeat those values.

```
s = rng; % Obtain the current state of the random stream  
r1 = randg(10,1,5)
```

```
r1 =
```

```
    9.4719    9.0433    15.0774    14.7763    6.3775
rng(s); % Reset the stream to the previous state
r2 = randg(10,1,5)

r2 =
    9.4719    9.0433    15.0774    14.7763    6.3775
```

r2 contains exactly the same values as r1.

Example 5

Reinitialize the random number generator used by `rand` and `randn` with a seed based on the current time. `randg` returns different values each time you do this. Note that it is usually not necessary to do this more than once per MATLAB session.

```
rng('shuffle');
randg(2,1,5);
```

gamrnd

Introduced before R2006a

random

Package: prob

Random numbers

Syntax

```
R = random('name', A)
R = random('name', A, B)
R = random('name', A, B, C)
R = random('name', A, B, C, D)

R = random(pd)

R = random( ____, sz1, ..., szN)
R = random( ____, [sz1, ..., szN])
```

Description

`R = random('name', A)` returns a random number from the one-parameter distribution family specified by 'name' and the distribution parameter A.

`R = random('name', A, B)` returns a random number from the two-parameter distribution family specified by 'name' and the distribution parameters A and B.

`R = random('name', A, B, C)` returns a random number from the three-parameter distribution family specified by 'name' and the distribution parameters A, B, and C.

`R = random('name', A, B, C, D)` returns a random number from the four-parameter distribution family specified by 'name' and the distribution parameters A, B, C, and D.

`R = random(pd)` returns a random number from the probability distribution object `pd`.

`R = random(____, sz1, ..., szN)` or `R = random(____, [sz1, ..., szN])` generates a `sz1-by-...-by-szN` array of random numbers from the specified probability distribution using input arguments from any of the previous syntaxes.

Examples

Generate One Random Number

Create a standard normal probability distribution object.

```
pd = makedist('Normal')

pd =
  NormalDistribution

  Normal distribution
      mu = 0
      sigma = 1
```

Generate one random number from the distribution.

```
rng('default') % For reproducibility
r1 = random(pd)

r1 = 0.5377
```

Alternatively, you can generate a standard normal random number by specifying its name and parameters.

```
r2 = random('Normal',0,1)

r2 = 1.8339
```

Reset Random Number Generator

Save the current state of the random number generator. Then generate a random number from the Poisson distribution with rate parameter 5.

```
s = rng;
r = random('Poisson',5)

r = 5
```

Restore the state of the random number generator to `s`, and then create a new random number. The value is the same as before.

```
rng(s);  
r1 = random('Poisson',5)  
  
r1 = 5
```

Clone Size from Existing Array

Create a matrix of random numbers with the same size as an existing array. Use the stable distribution with shape parameters 2 and 0, scale parameter 1, and location parameter 0.

```
A = [3 2; -2 1];  
sz = size(A);  
R = random('Stable',2,0,1,0,sz)  
  
R = 2×2  
  
    0.7604    -3.1945  
    2.5935     1.2193
```

You can combine the previous two lines of code into a single line.

```
R = random('Stable',2,0,1,0,size(A))  
  
R = 2×2  
  
    0.4508    -0.6132  
   -1.8494     0.4845
```

Generate Multiple Random Numbers

Create a Weibull probability distribution object using the default parameter values.

```
pd = makedist('Weibull')
```

```
pd =  
    WeibullDistribution  
  
    Weibull distribution  
    A = 1  
    B = 1
```

Generate random numbers from the distribution.

```
rng('default') % For reproducibility  
r = random(pd,10000,1);
```

Construct a histogram using 100 bins with a Weibull distribution fit.

```
histfit(r,100,'weibull')
```

Generate Multidimensional Array of Random Numbers

Create a standard normal probability distribution object.

```
pd = makedist('Normal')
```

```
pd =  
NormalDistribution  
  
Normal distribution  
mu = 0
```

```
sigma = 1
```

Generate a 2-by-3-by-2 array of random numbers from the distribution.

```
r = random(pd, [2,3,2])
```

```
r =
r(:,:,1) =
    0.5377    -2.2588    0.3188
    1.8339     0.8622   -1.3077
```

```
r(:,:,2) =
   -0.4336    3.5784   -1.3499
    0.3426    2.7694    3.0349
```

Input Arguments

'name' — Probability distribution name

character vector or string scalar of probability distribution name

Probability distribution name, specified as one of the probability distribution names in this table.

'name'	Distribution	Input Parameter A	Input Parameter B	Input Parameter C	Input Parameter D
'Beta'	"Beta Distribution" on page B-4	a first shape parameter	b second shape parameter	—	—
'Binomial'	"Binomial Distribution" on page B-9	n number of trials	p probability of success for each trial	—	—

'Weibull'	"Weibull Distribution" on page B-199	<i>a</i> scale parameter	<i>b</i> shape parameter	—	—

Example: 'Normal'

A — First probability distribution parameter

scalar value | array of scalar values

First probability distribution parameter, specified as a scalar value or an array of scalar values.

If one or more of the input arguments A, B, C, and D are arrays, then the array sizes must be the same. In this case, `random` expands each scalar input into a constant array of the same size as the array inputs. See 'name' for the definitions of A, B, C, and D for each distribution.

Data Types: single | double

B — Second probability distribution parameter

scalar value | array of scalar values

Second probability distribution parameter, specified as a scalar value or an array of scalar values.

If one or more of the input arguments A, B, C, and D are arrays, then the array sizes must be the same. In this case, `random` expands each scalar input into a constant array of the same size as the array inputs. See 'name' for the definitions of A, B, C, and D for each distribution.

Data Types: single | double

C — Third probability distribution parameter

scalar value | array of scalar values

Third probability distribution parameter, specified as a scalar value or an array of scalar values.

If one or more of the input arguments A, B, C, and D are arrays, then the array sizes must be the same. In this case, `random` expands each scalar input into a constant array of the

same size as the array inputs. See 'name' for the definitions of A, B, C, and D for each distribution.

Data Types: `single` | `double`

D — Fourth probability distribution parameter

scalar value | array of scalar values

Fourth probability distribution parameter, specified as a scalar value or an array of scalar values.

If one or more of the input arguments A, B, C, and D are arrays, then the array sizes must be the same. In this case, `random` expands each scalar input into a constant array of the same size as the array inputs. See 'name' for the definitions of A, B, C, and D for each distribution.

Data Types: `single` | `double`

pd — Probability distribution

probability distribution object

Probability distribution, specified as a probability distribution object created with a function or app in this table.

Function or App	Description
<code>makedist</code>	Create a probability distribution object using specified parameter values.
<code>fitdist</code>	Fit a probability distribution object to sample data.
Distribution Fitter	Fit a probability distribution to sample data using the interactive Distribution Fitter app and export the fitted object to the workspace.
<code>paretotails</code>	Create a piecewise distribution object that has generalized Pareto distributions in the tails.

sz1, ..., szN — Size of each dimension

integer values | row vector of integer values

Size of each dimension, specified as integer values or a row vector of integer values. For example, specifying `5, 3, 2` or `[5, 3, 2]` generates a 5-by-3-by-2 array of random numbers from the specified probability distribution.

If one or more of the input arguments *A*, *B*, *C*, and *D* are arrays, then the specified dimensions *sz1*, . . . , *szN* must match the common dimensions of *A*, *B*, *C*, and *D* after any necessary scalar expansion. The default values of *sz1*, . . . , *szN* are the common dimensions.

- If you specify a single value *sz1*, then *R* is a square matrix of size *sz1*.
- If the size of any dimension is 0 or negative, then *R* is an empty array.
- Beyond the second dimension, `random` ignores trailing dimensions with a size of 1. For example, `random(3,1,1,1)` produces a 3-by-1 vector of random numbers.

Data Types: `single` | `double`

Output Arguments

R — Random number

scalar value | array of scalar values

Random number generated from the specified probability distribution, returned as a scalar value or an array of scalar values with the dimensions specified by *sz1*, . . . , *szN*.

If you specify distribution parameters *A*, *B*, *C*, or *D*, then each element in *R* is the random number generated from the distribution specified by the corresponding elements in *A*, *B*, *C*, and *D*.

Alternative Functionality

- `random` is a generic function that accepts either a distribution by its name 'name' or a probability distribution object *pd*. It is faster to use a distribution-specific function, such as `randn` and `normrnd` for the normal distribution and `binornd` for the binomial distribution. For a list of distribution-specific functions, see “Supported Distributions” on page 5-20.
- To generate random numbers interactively, use `randtool`, a random number generation user interface.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The input argument 'name' must be a compile-time constant. For example, to use the normal distribution, include `coder.Constant('Normal')` in the `-args` value of `codegen`.
- Code generation does not support the probability distribution object (pd) input argument.

For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “General Code Generation Workflow” on page 31-5.

Introduced before R2006a

random

Simulate responses for generalized linear regression model

Syntax

```
ysim = random mdl, Xnew  
ysim = random mdl, Xnew, Name, Value
```

Description

`ysim = random(mdl, Xnew)` simulates responses from the `mdl` generalized linear model to the data in `Xnew`.

`ysim = random(mdl, Xnew, Name, Value)` simulates responses with additional options specified by one or more `Name, Value` pair arguments.

Input Arguments

`mdl`

Generalized linear model, specified as a full `GeneralizedLinearModel` object constructed using `fitglm` or `stepwiseglm`, or a compacted `CompactGeneralizedLinearModel` object constructed using `compact`.

`Xnew`

Points at which `mdl` predicts responses.

- If `Xnew` is a table or dataset array, it must contain the predictor names in `mdl`.
- If `Xnew` is a numeric matrix, it must have the same number of variables (columns) as was used to create `mdl`. Furthermore, all variables used in creating `mdl` must be numeric.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

BinomialSize

The value of the binomial n parameter for each row in the training data. `BinomialSize` can be a vector the same length as `Xnew`, or a scalar that applies to each row. The default value 1 produces `ysim` values that are predicted proportions. Use `BinomialSize` only if `mdl` is fit to a binomial distribution.

Default: 1

Offset

Value of the offset for each row in `Xnew`. `Offset` can be a vector the same length as `Xnew`, or a scalar that applies to each row. The offset is used as an additional predictor with a coefficient value fixed at 1. In other words, if \mathbf{b} is the fitted coefficient vector, and `link` is the link function,

$$\text{link}(\text{ysim}) = \text{Offset} + \text{Xnew} * \mathbf{b}.$$

Default: `zeros(size(Xnew,1))`

Output Arguments

`ysim`

Vector of simulated values at `Xnew`.

`random` generates `ysim` using random values with mean given by the fitted model, and with the distribution used in `mdl`. The values in `ysim` are independent conditional on the predictors. For binomial and Poisson fits, `random` generates `ysim` with the specified distribution with no adjustment for any estimated dispersion.

Examples

Generalized Linear Model Simulation

Create a generalized linear model, and simulate its response to new data.

Generate artificial data for the model, Poisson random numbers with one underlying predictors X .

```
rng('default') % reproducible
X = rand(20,1);
mu = exp(1 + 2*X);
y = poissrnd(mu);
```

Create a generalized linear regression model of Poisson data.

```
mdl = fitglm(X,y,'y ~ x1','distr','poisson');
```

Create points for prediction.

```
Xnew = (0:.05:1)';
```

Simulate responses at the new points.

```
ysim = random(mdl,Xnew);
```

Plot the simulated values along with the original values.

```
plot(X,y,'rx',Xnew,ysim,'bo',...
      Xnew,feval(mdl,Xnew),'g-')
legend('Data','Simulated','Fitted Mean',...
       'Location','best')
```

Generate Code From Function That Simulates Responses Given New Data

Train a generalized linear model, and then generate code from a function that draws random responses from the model given new predictor data.

Generate artificial data, specifically:

- $x \sim N(1, 0.5^2)$.
- $\beta_0 = 1$ and $\beta = -2$.

- $y \sim \text{Binomial}\left(10, \frac{\exp(1+x\beta)}{1+\exp(1+x\beta)}\right)$.

```
rng('default') % For reproducibility
x = 1 + randn(100,1)*0.5;
beta = -2;
p = exp(1 + x*beta)./(1 + exp(1 + x*beta)); % Inverse logit
n = 10;
y = binornd(n,p,100,1);
```

Create a generalized linear regression model of binomial data. Specify a binomial sample size of 10.

```
mdl = fitglm(x,y,'y ~ x1','Distribution','Binomial','BinomialSize',n);
```

Save the fitted generalized linear model to the file `GLMMdl.mat`.

```
saveCompactModel(mdl,'GLMMdl');
```

In your current folder, define a function called `myrandomGLM.m` that:

- Accepts measurements with columns corresponding to those in `X` and valid name-value pair arguments
- Loads the fitted generalized linear model in `GLMMdl.mat`
- Simulates responses from the loaded GLM model

```
function y = myrandomGLM(x,varargin) %#codegen
%MYRANDOMGLM Simulate response using GLM model
% MYRANDOMGLM simulates responses for the n observations in the n-by-1
% vector x using the GLM model stored in the MAT-file GLMMdl.mat, and
% then returns the simulations in the n-by-1 vector y.
CompactMdl = loadCompactModel('GLMMdl');
narginchk(1,Inf);
y = random(CompactMdl,x,varargin{:});
end
```

Generate a MEX function from `myrandomGLM.m`. Specify the in-sample predictor data `X` and 10 for the binomial parameter `n`. Because C uses static typing, `codegen` must determine the properties of all variables in MATLAB® files at compile time. To designate arguments as compile-time constants, use `coder.Constant`.

```
codegen -config:mex myrandomGLM -args {x,coder.Constant('BinomialSize'),coder.Constant
```

codegen generates the MEX file `myrandomGLM_mex.mexw64` in your current folder. The file extension depends on your platform.

Simulate responses using the MEX function.

```
ysim = myrandomGLM_mex(x, 'BinomialSize', n);
```

Plot the simulated values and the data in the same figure.

```
figure;  
plot(x,y, 'bo', x, ysim, 'r*');  
legend('Observed responses', 'Simulated responses');  
xlabel('x');  
ylabel('y');
```

The observed and simulated responses appear to be similarly distributed.

Alternatives

For predictions without random noise, use `predict` or `feval`.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Use `saveCompactModel`, `loadCompactModel`, and `codegen` to generate code for the `random` function. Save a trained model by using `saveCompactModel`. Define an entry-point function that loads the saved model by using `loadCompactModel` and calls the `random` function. Then use `codegen` to generate code for the entry-point function.
- `random` can return a different sequence of numbers than MATLAB if either of the following is true:
 - The output is nonscalar.
 - An input parameter is invalid for the distribution.
- This table contains notes about the arguments of `random`. Arguments not included in this table are fully supported.

Argument	Notes and Limitations
<code>mdl</code>	For the usage notes and limitations of the model object, see “Code Generation” on page 32-907 of the <code>CompactGeneralizedLinearModel</code> object.
<code>Xnew</code>	<ul style="list-style-type: none"> • Must be a single-precision or double-precision matrix and can be variable-size. However, the number of columns in <code>Xnew</code> must be <code>numel(mdl.PredictorNames)</code>. • Rows and columns must correspond to observations and predictors, respectively.
Name-value pair arguments	Names in name-value pair arguments must be compile-time constants. For example, to use the <code>'BinomialSize'</code> name-value pair argument in the generated code, include <code>{coder.Constant('BinomialSize'),0}</code> in the <code>-args</code> value of <code>codegen</code> .

For more information, see “Introduction to Code Generation” on page 31-2.

“Generalized Linear Models” on page 12-12

Introduced in R2012a

random

Class: GeneralizedLinearMixedModel

Generate random responses from fitted generalized linear mixed-effects model

Syntax

```
ysim = random(glme)
ysim = random(glme, tblnew)
ysim = random( ____, Name, Value)
```

Description

`ysim = random(glme)` returns simulated responses, `ysim`, from the fitted generalized linear mixed-effects model `glme`, at the original design points.

`ysim = random(glme, tblnew)` returns simulated responses using new input values specified in the table or dataset array, `tblnew`.

`ysim = random(____, Name, Value)` returns simulated responses using additional options specified by one or more `Name, Value` pair arguments, using any of the previous syntaxes. For example, you can specify observation weights, binomial sizes, or offsets for the model.

Input Arguments

glme — Generalized linear mixed-effects model

GeneralizedLinearMixedModel object

Generalized linear mixed-effects model, specified as a GeneralizedLinearMixedModel object. For properties and methods of this object, see GeneralizedLinearMixedModel.

tblnew — New input data

table | dataset array

New input data, which includes the response variable, predictor variables, and grouping variables on page 2-57, specified as a table or dataset array. The predictor variables can be continuous or grouping variables. `tblnew` must contain the same variables as the original table or dataset array, `tbl`, used to fit the generalized linear mixed-effects model `glme`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

BinomialSize — Number of trials for binomial distribution

`ones(m, 1)` (default) | m -by-1 vector of positive integer values

Number of trials for binomial distribution, specified as the comma-separated pair consisting of 'BinomialSize' and an m -by-1 vector of positive integer values, where m is the number of rows in `tblnew`. The 'BinomialSize' name-value pair applies only to the binomial distribution. The value specifies the number of binomial trials when generating the random response values.

Data Types: `single` | `double`

Offset — Model offset

`zeros(m, 1)` (default) | vector of scalar values

Model offset, specified as a vector of scalar values of length m , where m is the number of rows in `tblnew`. The offset is used as an additional predictor and has a coefficient value fixed at 1.

Weights — Observation weights

m -by-1 vector of nonnegative scalar values

Observation weights, specified as the comma-separated pair consisting of 'Weights' and an m -by-1 vector of nonnegative scalar values, where m is the number of rows in `tblnew`. If the response distribution is binomial or Poisson, then 'Weights' must be a vector of positive integers.

Data Types: `single` | `double`

Output Arguments

ysim — Simulated response values

m-by-1 vector

Simulated response values, returned as an *m*-by-1 vector, where *m* is the number of rows in `tblnew`. `random` creates `ysim` by first generating the random-effects vector based on its fitted prior distribution. `random` then generates `ysim` from its fitted conditional distribution given the random effects. `random` takes into account the effect of observation weights specified when fitting the model using `fitglm`, if any.

Examples

Simulate Random Responses From a GLME Model

Load the sample data.

```
load mfr
```

This simulated data is from a manufacturing company that operates 50 factories across the world, with each factory running a batch process to create a finished product. The company wants to decrease the number of defects in each batch, so it developed a new manufacturing process. To test the effectiveness of the new process, the company selected 20 of its factories at random to participate in an experiment: Ten factories implemented the new process, while the other ten continued to run the old process. In each of the 20 factories, the company ran five batches (for a total of 100 batches) and recorded the following data:

- Flag to indicate whether the batch used the new process (`newprocess`)
- Processing time for each batch, in hours (`time`)
- Temperature of the batch, in degrees Celsius (`temp`)
- Categorical variable indicating the supplier (A, B, or C) of the chemical used in the batch (`supplier`)
- Number of defects in the batch (`defects`)

The data also includes `time_dev` and `temp_dev`, which represent the absolute deviation of time and temperature, respectively, from the process standard of 3 hours at 20 degrees Celsius.

Fit a generalized linear mixed-effects model using `newprocess`, `time_dev`, `temp_dev`, and `supplier` as fixed-effects predictors. Include a random-effects term for intercept grouped by `factory`, to account for quality differences that might exist due to factory-specific variations. The response variable `defects` has a Poisson distribution, and the appropriate link function for this model is `log`. Use the Laplace fit method to estimate the coefficients. Specify the dummy variable encoding as `'effects'`, so the dummy variable coefficients sum to 0.

The number of defects can be modeled using a Poisson distribution

$$\text{defects}_{ij} \sim \text{Poisson}(\mu_{ij})$$

This corresponds to the generalized linear mixed-effects model

$$\log(\mu_{ij}) = \beta_0 + \beta_1 \text{newprocess}_{ij} + \beta_2 \text{time_dev}_{ij} + \beta_3 \text{temp_dev}_{ij} + \beta_4 \text{supplier_C}_{ij} + \beta_5 \text{supplier_B}_{ij} + b_i,$$

where

- `defectsij` is the number of defects observed in the batch produced by factory *i* during batch *j*.
- `μij` is the mean number of defects corresponding to factory *i* (where *i* = 1, 2, . . . , 20) during batch *j* (where *j* = 1, 2, . . . , 5).
- `newprocessij`, `time_devij`, and `temp_devij` are the measurements for each variable that correspond to factory *i* during batch *j*. For example, `newprocessij` indicates whether the batch produced by factory *i* during batch *j* used the new process.
- `supplier_Cij` and `supplier_Bij` are dummy variables that use effects (sum-to-zero) coding to indicate whether company C or B, respectively, supplied the process chemicals for the batch produced by factory *i* during batch *j*.
- `bi ~ N(0, σb2)` is a random-effects intercept for each factory *i* that accounts for factory-specific variation in quality.

```
glme = fitglme(mfr, 'defects ~ 1 + newprocess + time_dev + temp_dev + supplier + (1|factory)')
```

Use `random` to simulate a new response vector from the fitted model.

```
rng(0, 'twister'); % For reproducibility
ynew = random(glme);
```

Display the first 10 rows of the simulated response vector.

```
ynew(1:10)
```

```
ans = 10×1
```

```
3
3
1
7
5
8
7
9
5
9
```

Simulate a new response vector using new input values. Create a new table by copying the first 10 rows of `mfr` into `tblnew`.

```
tblnew = mfr(1:10,:);
```

The first 10 rows of `mfr` include data collected from trials 1 through 5 for factories 1 and 2. Both factories used the old process for all of their trials during the experiment, so `newprocess = 0` for all 10 observations.

Change the value of `newprocess` to 1 for the observations in `tblnew`.

```
tblnew.newprocess = ones(height(tblnew),1);
```

Simulate new responses using the new input values in `tblnew`.

```
ynew2 = random(glme,tblnew)
```

```
ynew2 = 10×1
```

```
2
3
5
4
2
2
2
1
2
0
```

Definitions

Conditional Distribution Method

random generates random data from the fitted generalized linear mixed-effects model as follows:

- Sample $b_{sim} \sim P(b | \hat{\theta}, \hat{\sigma}^2)$, where $P(b | \hat{\theta}, \hat{\sigma}^2)$ is the estimated prior distribution of random effects, and $\hat{\theta}$ is a vector of estimated covariance parameters, and $\hat{\sigma}^2$ is the estimated dispersion parameter.
- Given b_{sim} , for $i = 1$ to m , sample $y_{sim_i} \sim P(y_{new_i} | b_{sim}, \hat{\beta}, \hat{\theta}, \hat{\sigma}^2)$, where $P(y_{new_i} | b_{sim}, \hat{\beta}, \hat{\theta}, \hat{\sigma}^2)$ is the conditional distribution of the i th new response y_{new_i} given b_{sim} and the model parameters.

GeneralizedLinearMixedModel | fitglm | fitted | predict

random

Random variate from Gaussian mixture distribution

Syntax

```
Y = random(gm)
Y = random(gm,n)
[Y,compIdx] = random( ___ )
```

Description

`Y = random(gm)` generates a 1-by- m random variate from the m -dimensional Gaussian mixture distribution `gm`.

`Y = random(gm,n)` returns n random variates. Each row of `Y` is a random variate generated from the m -dimensional Gaussian mixture distribution `gm`.

`[Y,compIdx] = random(___)` also returns an n -by-1 index vector `compIdx` for any of the input arguments in previous syntaxes. `compIdx(i)` indicates the mixture component used to generate the i th random variate `Y(i, :)`.

Examples

Generate Random Variates

Create a `gmdistribution` object and generate random variates.

Define the distribution parameters (means and covariances) of a two-component bivariate Gaussian mixture distribution.

```
mu = [1 2;-3 -5];
sigma = [1 1]; % shared diagonal covariance matrix
```

Create a `gmdistribution` object by using the `gmdistribution` function. By default, the function creates an equal proportion mixture.

```
gm = gmdistribution(mu,sigma)
```

```
gm =
```

```
Gaussian mixture distribution with 2 components in 2 dimensions
```

```
Component 1:
```

```
Mixing proportion: 0.500000
```

```
Mean:      1      2
```

```
Component 2:
```

```
Mixing proportion: 0.500000
```

```
Mean:     -3     -5
```

Generate 1000 random variates.

```
rng('default'); % For reproducibility
```

```
[Y,compIdx] = random(gm,1000);
```

`compIdx(i)` indicates the mixture component used to generate the *i*th random variate `Y(i,:)`. Count the number of random variates generated by Component 1.

```
numIdx1 = sum(compIdx == 1)
```

```
numIdx1 = 512
```

`random` generates about half of the random variates using Component 1 because `gm` has equal mixing proportions.

Plot the generated random variates by using `scatter`.

```
scatter(Y(:,1),Y(:,2),10, '.') % Scatter plot with points of size 10
```

Reset Random Number Generator

Reset the random number generator to generate the same random variate.

Define the distribution parameters (means, covariances, and mixing proportions) of two bivariate Gaussian mixture components.

```
p = [0.4 0.6];           % Mixing proportions
mu = [1 2;-3 -5];       % Means
sigma = cat(3,[2 .5],[1 1]) % Covariances 1-by-2-by-2 array
```

```
sigma =  
sigma(:,:,1) =  
    2.0000    0.5000  
  
sigma(:,:,2) =  
    1    1
```

The `cat` function concatenates the covariances along the third array dimension. The defined covariance matrices are diagonal matrices. `sigma(1,:,i)` contains the diagonal elements of the covariance matrix of component `i`.

Create a `gmdistribution` object by using the `gmdistribution` function.

```
gm = gmdistribution(mu,sigma);
```

Save the current state of the random number generator, and then generate a random variate using `gm`.

```
s = rng;  
r = random(gm)  
  
r = 1×2  
    -1.1661    -7.2588
```

Restore the state of the random number generator to `s`, and then generate a random variate using `gm`. The values are the same as before.

```
rng(s);  
r1 = random(gm)  
  
r1 = 1×2  
    -1.1661    -7.2588
```

Input Arguments

gm — Gaussian mixture distribution

`gmdistribution` object

Gaussian mixture distribution, also called Gaussian mixture model (GMM), specified as a `gmdistribution` object.

You can create a `gmdistribution` object using `gmdistribution` or `fitgmdist`. Use the `gmdistribution` function to create a `gmdistribution` object by specifying the distribution parameters. Use the `fitgmdist` function to fit a `gmdistribution` model to data given a fixed number of components.

n — Number of random variates

1 (default) | positive integer

Number of random variates to generate, specified as a positive integer.

Data Types: `single` | `double`

Output Arguments

Y — Random variate

1-by-*m* numeric vector | *n*-by-*m* numeric matrix

Random variate, returned as a 1-by-*m* numeric vector or an *n*-by-*m* numeric matrix. Each row of *Y* is a random variate generated from the *m*-dimensional Gaussian mixture distribution `gm`.

compIdx — Component index

positive integer | *n*-by-1 numeric vector

Component index, returned as a positive integer or an *n*-by-1 index vector, where `compIdx(i)` indicates the mixture component used to generate the *i*th random variate `Y(i,:)`.

Introduced in R2007b

random

Package:

Simulate responses with random noise for linear regression model

Syntax

```
ysim = random mdl, Xnew)
```

Description

`ysim = random(mdl, Xnew)` simulates responses to the predictor data in `Xnew` using the linear model `mdl`, adding random noise.

Examples

Simulate Response Data with Random Noise

Create a quadratic model of car mileage as a function of weight from the `carsmall` data set.

```
load carsmall
X = Weight;
y = MPG;
mdl = fitlm(X,y,'quadratic');
```

Create simulated responses to the data with random noise.

```
ysim = random(mdl,X);
```

Plot the original responses and the simulated responses to see how they differ.

```
plot(X,y,'o',X,ysim,'x')
legend('Data','Simulated')
```

Input Arguments

mdl — Linear regression model object

LinearModel object | CompactLinearModel object

Linear regression model object, specified as a LinearModel object created by using fitlm or stepwiselm, or a CompactLinearModel object created by using compact.

Xnew — New predictor input values

table | dataset array | matrix

New predictor input values, specified as a table, dataset array, or matrix. Each row of `Xnew` corresponds to one observation, and each column corresponds to one variable.

- If `Xnew` is a table or dataset array, it must contain predictors that have the same predictor names as in the `PredictorNames` property of `mdl`.
- If `Xnew` is a matrix, it must have the same number of variables (columns) in the same order as the predictor input used to create `mdl`. Note that `Xnew` must also contain any predictor variables that are not used as predictors in the fitted model. Also, all variables used in creating `mdl` must be numeric or logical. To treat numerical predictors as categorical, identify the predictors using the `'CategoricalVars'` name-value pair argument when you create `mdl`.

Data Types: `single` | `double` | `table`

Output Arguments

`ysim` — Simulated response values

numeric vector

Simulated response value, returned as a numeric vector. The simulated value is the predicted response values at `Xnew` perturbed by random noise. The noise is independent and normally distributed, with mean equal to zero and variance equal to the estimated error variance of the model.

Alternative Functionality

For predictions without random noise, use `predict` or `feval`. These two functions give the same predictions.

- `predict` uses a single input argument with one observation in each row, and gives confidence intervals on its predictions.
- `feval` uses multiple input arguments with one input for each predictor variable.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Use `saveCompactModel`, `loadCompactModel`, and `codegen` to generate code for the `random` function. Save a trained model by using `saveCompactModel`. Define an entry-point function that loads the saved model by using `loadCompactModel` and calls the `random` function. Then use `codegen` to generate code for the entry-point function.
- `random` can return a different sequence of numbers than MATLAB if either of the following is true:
 - The output is nonscalar.
 - An input parameter is invalid for the distribution.
- This table contains notes about the arguments of `random`. Arguments not included in this table are fully supported.

Argument	Notes and Limitations
<code>mdl</code>	<ul style="list-style-type: none"> • Suppose you train a linear model by using <code>fitlm</code> and specifying <code>'RobustOpts'</code> as a structure with an anonymous function handle for the <code>RobustWgtFun</code> field, use <code>saveCompactModel</code> to save the model, and then use <code>loadCompactModel</code> to load the model. In this case, <code>loadCompactModel</code> cannot restore the <code>Robust</code> property into the MATLAB Workspace. However, <code>loadCompactModel</code> can load the model at compile time within an entry-point function for code generation. • For the usage notes and limitations of the model object, see “Code Generation” on page 32-893 of the <code>CompactLinearModel</code> object.

Argument	Notes and Limitations
Xnew	<ul style="list-style-type: none">• Must be a single-precision or double-precision matrix and can be variable-size. However, the number of columns in Xnew must be <code>numel mdl.PredictorNames</code>.• Rows and columns must correspond to observations and predictors, respectively.

For more information, see “Introduction to Code Generation” on page 31-2.

random

Class: LinearMixedModel

Generate random responses from fitted linear mixed-effects model

Syntax

```
ysim = random(lme)
ysim = random(lme, tblnew)
ysim = random(lme, Xnew, Znew)
ysim = random(lme, Xnew, Znew, Gnew)
```

Description

`ysim = random(lme)` returns a vector of simulated responses `ysim` from the fitted linear mixed-effects model `lme` at the original fixed- and random-effects design points, used to fit `lme`.

`random` simulates new random-effects vector and new observation errors. So, the simulated response is

$$y_{sim} = X\hat{\beta} + Z\hat{b} + \varepsilon,$$

where $\hat{\beta}$ is the estimated fixed-effects coefficients, \hat{b} is the new random effects, and ε is the new observation error.

`random` also accounts for the effect of observation weights, if you use any when fitting the model.

`ysim = random(lme, tblnew)` returns a vector of simulated responses `ysim` from the fitted linear mixed-effects model `lme` at the values in the new table or dataset array `tblnew`. Use a table or dataset array for `random` if you use a table or dataset array for fitting the model `lme`.

`ysim = random(lme, Xnew, Znew)` returns a vector of simulated responses `ysim` from the fitted linear mixed-effects model `lme` at the values in the new fixed- and random-

effects design matrices, X_{new} and Z_{new} , respectively. Z_{new} can also be a cell array of matrices. Use the matrix format for `random` if you use design matrices for fitting the model `lme`.

`ysim = random(lme, Xnew, Znew, Gnew)` returns a vector of simulated responses `ysim` from the fitted linear mixed-effects model `lme` at the values in the new fixed- and random-effects design matrices, X_{new} and Z_{new} , respectively, and the grouping variable `Gnew`.

Z_{new} and `Gnew` can also be cell arrays of matrices and grouping variables, respectively.

Input Arguments

lme — Linear mixed-effects model

`LinearMixedModel` object

Linear mixed-effects model, specified as a `LinearMixedModel` object constructed using `fitlme` or `fitlmematrix`.

tblnew — New input data

table | dataset array

New input data, which includes the response variable, predictor variables, and grouping variables on page 2-57, specified as a table or dataset array. The predictor variables can be continuous or grouping variables. `tblnew` must have the same variables as in the original table or dataset array used to fit the linear mixed-effects model `lme`.

Xnew — New fixed-effects design matrix

n -by- p matrix

New fixed-effects design matrix, specified as an n -by- p matrix, where n is the number of observations and p is the number of fixed predictor variables. Each row of X corresponds to one observation and each column of X corresponds to one variable.

Data Types: `single` | `double`

Znew — New random-effects design

n -by- q matrix | cell array of length R

New random-effects design, specified as an n -by- q matrix or a cell array of R design matrices $Z\{r\}$, where $r = 1, 2, \dots, R$. If Z_{new} is a cell array, then each $Z\{r\}$ is an n -by- $q(r)$

matrix, where n is the number of observations, and $q(r)$ is the number of random predictor variables.

Data Types: `single` | `double` | `cell`

gnew — New grouping variable or variables

vector | cell array of grouping variables of length R

New grouping variable or variables on page 2-57, specified as a vector or a cell array, of length R , of grouping variables used to fit the linear mixed-effects model, `lme`.

`random` treats all levels of each grouping variable as new levels. It draws an independent random effects vector for each level of each grouping variable.

Data Types: `single` | `double` | `categorical` | `logical` | `char` | `string` | `cell`

Output Arguments

ysim — Simulated response values

n -by-1 vector

Simulated response values, returned as an n -by-1 vector, where n is the number of observations.

Examples

Generate Random Responses at the Original Design Values

Load the sample data.

```
load(fullfile(matlabroot, 'examples', 'stats', 'fertilizer.mat'));
```

The dataset array includes data from a split-plot experiment, where soil is divided into three blocks based on the soil type: sandy, silty, and loamy. Each block is divided into five plots, where five different types of tomato plants (cherry, heirloom, grape, vine, and plum) are randomly assigned to these plots. The tomato plants in the plots are then divided into subplots, where each subplot is treated by one of four fertilizers. This is simulated data.

Store the data in a dataset array called `ds`, for practical purposes, and define `Tomato`, `Soil`, and `Fertilizer` as categorical variables.

```
ds = fertilizer;
ds.Tomato = nominal(ds.Tomato);
ds.Soil = nominal(ds.Soil);
ds.Fertilizer = nominal(ds.Fertilizer);
```

Fit a linear mixed-effects model, where Fertilizer and Tomato are the fixed-effects variables, and the mean yield varies by the block (soil type), and the plots within blocks (tomato types within soil types) independently.

```
lme = fitlme(ds, 'Yield ~ Fertilizer * Tomato + (1|Soil) + (1|Soil:Tomato)');
```

Generate random response values at the original design points. Display the first five values.

```
rng(123, 'twister') % For reproducibility
ysim = random(lme);
ysim(1:5)
```

```
ans = 5×1
```

```
114.8785
134.2018
154.2818
169.7554
84.6089
```

Plot Randomly Generated vs. Observed Response Values

Load the sample data.

```
load carsmall
```

Fit a linear mixed-effects model, with a fixed-effects for Weight, and a random intercept grouped by Model_Year. First, store the data in a table.

```
tbl = table(MPG, Weight, Model_Year);
lme = fitlme(tbl, 'MPG ~ Weight + (1|Model_Year)');
```

Randomly generate responses using the original data.

```
rng(123, 'twister') % For reproducibility
ysim = random(lme, tbl);
```

Plot the original and the randomly generated responses to see how they differ. Group them by model year.

```
figure()
gscatter(Weight,MPG,Model_Year)
hold on
gscatter(Weight,ysim,Model_Year,[],'o+x')
legend('70-data','76-data','82-data','70-sim','76-sim','82-sim')
hold off
```

Note that the simulated random response values for year 82 are lower than the original data for that year. This might be due to a lower simulated random effect for year 82 than the estimated random effect in the original data.

Generate Responses Using a New Dataset Array

Load the sample data.

```
load(fullfile(matlabroot, 'examples', 'stats', 'fertilizer.mat'));
```

The dataset array includes data from a split-plot experiment, where soil is divided into three blocks based on the soil type: sandy, silty, and loamy. Each block is divided into five plots, where five different types of tomato plants (cherry, heirloom, grape, vine, and plum) are randomly assigned to these plots. The tomato plants in the plots are then divided into subplots, where each subplot is treated by one of four fertilizers. This is simulated data.

Store the data in a dataset array called `ds`, for practical purposes, and define `Tomato`, `Soil`, and `Fertilizer` as categorical variables.

```
ds = fertilizer;
ds.Tomato = nominal(ds.Tomato);
ds.Soil = nominal(ds.Soil);
ds.Fertilizer = nominal(ds.Fertilizer);
```

Fit a linear mixed-effects model, where `Fertilizer` and `Tomato` are the fixed-effects variables, and the mean yield varies by the block (soil type), and the plots within blocks (tomato types within soil types) independently.

```
lme = fitlme(ds, 'Yield ~ Fertilizer * Tomato + (1|Soil) + (1|Soil:Tomato)');
```

Create a new dataset array with design values. The new dataset array must have the same variables as the original dataset array you use for fitting the model `lme`.

```
dsnew = dataset();
dsnew.Soil = nominal({'Sandy'; 'Silty'; 'Silty'});
dsnew.Tomato = nominal({'Cherry'; 'Vine'; 'Plum'});
dsnew.Fertilizer = nominal([2;2;4]);
```

Generate random responses at the new points.

```
rng(123, 'twister') % For reproducibility
ysim = random(lme, dsnew)
```

```
ysim = 3×1
```

```
99.6006
```

```
101.9911
161.4026
```

Generate Random Responses Using New Design Matrices

Load the sample data.

```
load carbig
```

Fit a linear mixed-effects model for miles per gallon (MPG), with fixed effects for acceleration, horsepower, and cylinders, and potentially correlated random effect for intercept and acceleration grouped by model year.

First, prepare the design matrices for fitting the linear mixed-effects model.

```
X = [ones(406,1) Acceleration Horsepower];
Z = [ones(406,1) Acceleration];
Model_Year = nominal(Model_Year);
G = Model_Year;
```

Now, fit the model using `fitlmematrix` with the defined design matrices and grouping variables.

```
lme = fitlmematrix(X,MPG,Z,G,'FixedEffectPredictors',...
{'Intercept','Acceleration','Horsepower'},'RandomEffectPredictors',...
{{'Intercept','Acceleration'}},'RandomEffectGroups',{'Model_Year'});
```

Create the design matrices that contain the data at which to predict the response values. `Xnew` must have three columns as in `X`. The first column must be a column of 1s. And the values in the last two columns must correspond to `Acceleration` and `Horsepower`, respectively. The first column of `Znew` must be a column of 1s, and the second column must contain the same `Acceleration` values as in `Xnew`. The original grouping variable in `G` is the model year. So, `Gnew` must contain values for the model year. Note that `Gnew` must contain nominal values.

```
Xnew = [1,13.5,185; 1,17,205; 1,21.2,193];
Znew = [1,13.5; 1,17; 1,21.2];
Gnew = nominal([73 77 82]);
```

Generate random responses for the data in the new design matrices.

```

rng(123,'twister') % For reproducibility
ysim = random(lme,Xnew,Znew,Gnew)

ysim = 3×1

    15.7416
    10.6085
     6.8796

```

Now, repeat the same for a linear mixed-effects model with uncorrelated random-effects terms for intercept and acceleration. First, change the original random effects design and the random effects grouping variables. Then, fit the model.

```

Z = {ones(406,1),Acceleration};
G = {Model_Year,Model_Year};

lme = fitlmematrix(X,MPG,Z,G,'FixedEffectPredictors',....
{'Intercept','Acceleration','Horsepower'},'RandomEffectPredictors',...
{'Intercept'},{'Acceleration'}},'RandomEffectGroups',{'Model_Year','Model_Year'});

```

Now, recreate the new random effects design, Znew, and the grouping variable design, Gnew, using which to predict the response values.

```

Znew = {[1;1;1],[13.5;17;21.2]};
MY = nominal([73 77 82]);
Gnew = {MY,MY};

```

Generate random responses using the new design matrices.

```

rng(123,'twister') % For reproducibility
ysim = random(lme,Xnew,Znew,Gnew)

ysim = 3×1

    16.8280
    10.4375
     4.1027

```

random

Class: NonLinearModel

Simulate responses for nonlinear regression model

Syntax

```
ysim = random mdl
ysim = random mdl, Xnew
ysim = random mdl, Xnew, 'Weights', W
```

Description

`ysim = random(mdl)` simulates responses from the fitted nonlinear model `mdl` at the original design points.

`ysim = random(mdl, Xnew)` simulates responses from the fitted nonlinear model `mdl` to the data in `Xnew`, adding random noise.

`ysim = random(mdl, Xnew, 'Weights', W)` simulates responses using the observation weights, `W`.

Input Arguments

mdl

Nonlinear regression model, constructed by `fitnlm`.

Xnew

Points at which `mdl` predicts responses.

- If `Xnew` is a table or dataset array, it must contain the predictor names in `mdl`.

- If X_{new} is a numeric matrix, it must have the same number of variables (columns) as was used to create `mdl`. Furthermore, all variables used in creating `mdl` must be numeric.

W

Vector of real, positive value weights or a function handle.

- If you specify a vector, then it must have the same number of elements as the number of observations (or rows) in X_{new} .
- If you specify a function handle, the function must accept a vector of predicted response values as input, and returns a vector of real positive weights as output.

Given weights, W , `random` estimates the error variance at observation i by $MSE \cdot (1/W(i))$, where MSE is the mean squared error.

Default: No weights

Output Arguments

`ysim`

Vector of predicted mean values at X_{new} , perturbed by random noise. The noise is independent, normally distributed, with mean zero, and variance equal to the estimated error variance of the model.

Examples

Simulate Responses

Create a nonlinear model of car mileage as a function of weight, and simulate the response.

Create an exponential model of car mileage as a function of weight from the `carsmall` data. Scale the weight by a factor of 1000 so all the variables are roughly equal in size.

```
load carsmall
X = Weight;
```

```
y = MPG;
modelfun = 'y ~ b1 + b2*exp(-b3*x/1000)';
beta0 = [1 1 1];
mdl = fitnlm(X,y,modelfun,beta0);
```

Create simulated responses to the data.

```
Xnew = X;
ysim = random(mdl,Xnew);
```

Plot the original responses and the simulated responses to see how they differ.

```
plot(X,y,'o',X,ysim,'x')
legend('Data','Simulated')
```

Alternatives

For predictions without added noise, use `predict`.

random

Class: RepeatedMeasuresModel

Generate new random response values given predictor values

Syntax

```
ysim = random(rm, tnew)
```

Description

`ysim = random(rm, tnew)` generates random response values from the repeated measures model `rm` using the predictor variables from table `tnew`.

Input Arguments

rm — Repeated measures model

RepeatedMeasuresModel object

Repeated measures model, returned as a RepeatedMeasuresModel object.

For properties and methods of this object, see RepeatedMeasuresModel.

tnew — New data

table used to create `rm` (default) | table

New data including the values of the response variables and the between-subject factors used as predictors in the repeated measures model, `rm`, specified as a table. `tnew` must contain all of the between-subject factors used to create `rm`.

Output Arguments

ysim — Random response values

n-by-*r* matrix

Random response values `random` generates, returned as an n -by- r matrix, where n is the number of rows in `tnew`, and r is the number of repeated measures in `rm`.

Examples

Randomly Generate New Response Values

Load the sample data.

```
load fisheriris
```

The column vector `species` consists of iris flowers of three different species: `setosa`, `versicolor`, and `virginica`. The double matrix `meas` consists of four types of measurements on the flowers: the length and width of sepals and petals in centimeters, respectively.

Store the data in a table array.

```
t = table(species,meas(:,1),meas(:,2),meas(:,3),meas(:,4),...  
'VariableNames',{'species','meas1','meas2','meas3','meas4'});  
Meas = dataset([1 2 3 4]','VarNames',{'Measurements'});
```

Fit a repeated measures model, where the measurements are the responses and the `species` is the predictor variable.

```
rm = fitrm(t,'meas1-meas4~species','WithinDesign',Meas);
```

Randomly generate new response values.

```
ysim = random(rm);
```

`random` uses the predictor values in the original sample data you use to fit the repeated measures model `rm` in table `t`.

Randomly Generate Response Values Using New Data

Load the sample data.

```
load repeatedmeas
```

The table `between` includes the between-subject variables `age`, `IQ`, `group`, `gender`, and eight repeated measures `y1` through `y8` as responses. The table `within` includes the within-subject variables `w1` and `w2`. This is simulated data.

Fit a repeated measures model, where the repeated measures `y1` through `y8` are the responses, and `age`, `IQ`, `group`, `gender`, and the group-gender interaction are the predictor variables. Also specify the within-subject design matrix.

```
rm = fitrm(between, 'y1-y8 ~ Group*Gender + Age + IQ', 'WithinDesign', within);
```

Define a table with new values for the predictor variables.

```
tnew = table(16, 93, {'B'}, {'Male'}, 'VariableNames', {'Age', 'IQ', 'Group', 'Gender'})
```

```
tnew=1x4 table
  Age    IQ    Group    Gender
  ---    ---    ---      ---
  16     93     'B'     'Male'
```

Randomly generate new response values using the values in the new table `tnew`.

```
ysim = random(rm, tnew)
```

```
ysim = 1x8
```

```
46.2252    66.8003   -40.4987   -1.9930    27.5213   -37.9809    4.8905   -3.7568
```

Algorithms

`random` computes `ysim` by creating predicted values and adding random noise values. For each row, the noise has a multivariate normal distribution with covariance the same as `rm.Covariance`.

`fitrm` | `predict`

randomEffects

Class: GeneralizedLinearMixedModel

Estimates of random effects and related statistics

Syntax

```
B = randomEffects(glme)
[B, BNames] = randomEffects(glme)
[B, BNames, stats] = randomEffects(glme)
[B, BNames, stats] = randomEffects(glme, Name, Value)
```

Description

`B = randomEffects(glme)` returns the estimates of the empirical Bayes predictors (EPBs) of random effects in the generalized linear mixed-effects model `glme` conditional on the estimated covariance parameters and the observed response.

`[B, BNames] = randomEffects(glme)` also returns the names of the coefficients, `BNames`. Each name corresponds to a coefficient in `B`.

`[B, BNames, stats] = randomEffects(glme)` also returns related statistics, `stats`, for the estimated EPBs of random effects in `glme`.

`[B, BNames, stats] = randomEffects(glme, Name, Value)` returns any of the above output arguments using additional options specified by one or more `Name, Value` pair arguments. For example, you can specify the confidence interval level, or the method for computing the approximate degrees of freedom.

Input Arguments

glme — Generalized linear mixed-effects model

GeneralizedLinearMixedModel object

Generalized linear mixed-effects model, specified as a `GeneralizedLinearMixedModel` object. For properties and methods of this object, see `GeneralizedLinearMixedModel`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Alpha — Significance level

0.05 (default) | scalar value in the range [0,1]

Significance level, specified as the comma-separated pair consisting of `'Alpha'` and a scalar value in the range [0,1]. For a value α , the confidence level is $100 \times (1 - \alpha)\%$.

For example, for 99% confidence intervals, you can specify the confidence level as follows.

Example: `'Alpha', 0.01`

Data Types: `single` | `double`

DFMethod — Method for computing approximate degrees of freedom

`'residual'` (default) | `'none'`

Method for computing approximate degrees of freedom, specified as the comma-separated pair consisting of `'DFMethod'` and one of the following.

Value	Description
<code>'residual'</code>	The degrees of freedom value is assumed to be constant and equal to $n - p$, where n is the number of observations and p is the number of fixed effects.
<code>'none'</code>	The degrees of freedom is set to infinity.

Example: `'DFMethod', 'none'`

Output Arguments

B — Estimated empirical Bayes predictors for the random effects

column vector

Estimated empirical Bayes predictors (EBPs) for the random effects in the generalized linear mixed-effects model `glme`, returned as a column vector. The EBPs in `B` are approximated by the mode of the empirical posterior distribution of the random effects given the estimated covariance parameters and the observed response.

Suppose `glme` has R grouping variables g_1, g_2, \dots, g_R , with levels m_1, m_2, \dots, m_R , respectively. Also suppose q_1, q_2, \dots, q_R are the lengths of the random-effects vectors that are associated with g_1, g_2, \dots, g_R , respectively. Then, `B` is a column vector of length $q_1*m_1 + q_2*m_2 + \dots + q_R*m_R$.

`randomEffects` creates `B` by concatenating the empirical Bayes predictors of random-effects vectors corresponding to each level of each grouping variable as `[g1level1; g1level2; ...; g1levelm1; g2level1; g2level2; ...; g2levelm2; ...; gRlevel1; gRlevel2; ...; gRlevelmR]`'.

BNames — Names of random-effects coefficients

table

Names of random-effects coefficients in `B`, returned as a table.

stats — Estimated empirical Bayes predictors and related statistics

table

Estimated empirical Bayes predictors (EBPs) and related statistics for the random effects in the generalized linear mixed-effects model `glme`, returned as a table. `stats` has one row for each of the random effects, and one column for each of the following statistics.

Column Name	Description
Group	Grouping variable associated with the random effect
Level	Level within the grouping variable corresponding to the random effect
Name	Name of the random-effect coefficient

Column Name	Description
Estimate	Empirical Bayes predictor (EBP) of random effect
SEPred	Square root of the conditional mean squared error of prediction (CMSEP) given covariance parameters and response
tStat	<i>t</i> -statistic for a test that the random-effects coefficient is equal to 0
DF	Estimated degrees of freedom for the <i>t</i> -statistic
pValue	<i>p</i> -value for the <i>t</i> -statistic
Lower	Lower limit of a 95% confidence interval for the random-effects coefficient
Upper	Upper limit of a 95% confidence interval for the random-effects coefficient

`randomEffects` computes the confidence intervals using the conditional mean squared error of prediction (CMSEP) approach conditional on the estimated covariance parameters and the observed response. An alternative interpretation of the confidence intervals is that they are approximate Bayesian credible intervals conditional on the estimated covariance parameters and the observed response.

When fitting a GLME model using `fitglme` and one of the pseudo likelihood fit methods ('MPL' or 'REMP'), `randomEffects` computes confidence intervals and related statistics based on the fitted linear mixed-effects model from the final pseudo likelihood iteration.

Examples

Compute and Plot Estimated Random Effects

Load the sample data.

```
load mfr
```

This simulated data is from a manufacturing company that operates 50 factories across the world, with each factory running a batch process to create a finished product. The

company wants to decrease the number of defects in each batch, so it developed a new manufacturing process. To test the effectiveness of the new process, the company selected 20 of its factories at random to participate in an experiment: Ten factories implemented the new process, while the other ten continued to run the old process. In each of the 20 factories, the company ran five batches (for a total of 100 batches) and recorded the following data:

- Flag to indicate whether the batch used the new process (`newprocess`)
- Processing time for each batch, in hours (`time`)
- Temperature of the batch, in degrees Celsius (`temp`)
- Categorical variable indicating the supplier (A, B, or C) of the chemical used in the batch (`supplier`)
- Number of defects in the batch (`defects`)

The data also includes `time_dev` and `temp_dev`, which represent the absolute deviation of time and temperature, respectively, from the process standard of 3 hours at 20 degrees Celsius.

Fit a generalized linear mixed-effects model using `newprocess`, `time_dev`, `temp_dev`, and `supplier` as fixed-effects predictors. Include a random-effects term for intercept grouped by `factory`, to account for quality differences that might exist due to factory-specific variations. The response variable `defects` has a Poisson distribution, and the appropriate link function for this model is log. Use the Laplace fit method to estimate the coefficients. Specify the dummy variable encoding as `'effects'`, so the dummy variable coefficients sum to 0.

The number of defects can be modeled using a Poisson distribution

$$\text{defects}_{ij} \sim \text{Poisson}(\mu_{ij})$$

This corresponds to the generalized linear mixed-effects model

$$\log(\mu_{ij}) = \beta_0 + \beta_1 \text{newprocess}_{ij} + \beta_2 \text{time_dev}_{ij} + \beta_3 \text{temp_dev}_{ij} + \beta_4 \text{supplier_C}_{ij} + \beta_5 \text{supplier_B}_{ij} + b_i,$$

where

- defects_{ij} is the number of defects observed in the batch produced by factory i during batch j .

- μ_{ij} is the mean number of defects corresponding to factory i (where $i = 1, 2, \dots, 20$) during batch j (where $j = 1, 2, \dots, 5$).
- `newprocessij`, `time_devij`, and `temp_devij` are the measurements for each variable that correspond to factory i during batch j . For example, `newprocessij` indicates whether the batch produced by factory i during batch j used the new process.
- `supplier_Cij` and `supplier_Bij` are dummy variables that use effects (sum-to-zero) coding to indicate whether company C or B, respectively, supplied the process chemicals for the batch produced by factory i during batch j .
- $b_i \sim N(0, \sigma_b^2)$ is a random-effects intercept for each factory i that accounts for factory-specific variation in quality.

```
glme = fitglme(mfr, 'defects ~ 1 + newprocess + time_dev + temp_dev + supplier + (1|factory)')
```

Compute and display the names and estimated values of the empirical Bayes predictors (EBPs) for the random effects.

```
[B, BNames] = randomEffects(glme)
```

```
B = 20×1
```

```

'factory'    '14'     '(Intercept)'
'factory'    '15'     '(Intercept)'
'factory'    '16'     '(Intercept)'
  ⋮

```

Each row of **B** contains the estimated EPB for the random-effects coefficient named in the corresponding row of **Bnames**. For example, the value -0.2633 in row 3 of **B** is the estimated EPB for '(Intercept)' for level '3' of factory.

Compute 99% Confidence Intervals for Random Effects

Load the sample data.

```
load mfr
```

This simulated data is from a manufacturing company that operates 50 factories across the world, with each factory running a batch process to create a finished product. The company wants to decrease the number of defects in each batch, so it developed a new manufacturing process. To test the effectiveness of the new process, the company selected 20 of its factories at random to participate in an experiment: Ten factories implemented the new process, while the other ten continued to run the old process. In each of the 20 factories, the company ran five batches (for a total of 100 batches) and recorded the following data:

- Flag to indicate whether the batch used the new process (**newprocess**)
- Processing time for each batch, in hours (**time**)
- Temperature of the batch, in degrees Celsius (**temp**)
- Categorical variable indicating the supplier (A, B, or C) of the chemical used in the batch (**supplier**)

- Number of defects in the batch (`defects`)

The data also includes `time_dev` and `temp_dev`, which represent the absolute deviation of time and temperature, respectively, from the process standard of 3 hours at 20 degrees Celsius.

Fit a generalized linear mixed-effects model using `newprocess`, `time_dev`, `temp_dev`, and `supplier` as fixed-effects predictors. Include a random-effects term for intercept grouped by `factory`, to account for quality differences that might exist due to factory-specific variations. The response variable `defects` has a Poisson distribution, and the appropriate link function for this model is `log`. Use the Laplace fit method to estimate the coefficients. Specify the dummy variable encoding as `'effects'`, so the dummy variable coefficients sum to 0.

The number of defects can be modeled using a Poisson distribution

$$\text{defects}_{ij} \sim \text{Poisson}(\mu_{ij})$$

This corresponds to the generalized linear mixed-effects model

$$\log(\mu_{ij}) = \beta_0 + \beta_1 \text{newprocess}_{ij} + \beta_2 \text{time_dev}_{ij} + \beta_3 \text{temp_dev}_{ij} + \beta_4 \text{supplier_C}_{ij} + \beta_5 \text{supplier_B}_{ij} + b_i,$$

where

- `defectsij` is the number of defects observed in the batch produced by factory i during batch j .
- μ_{ij} is the mean number of defects corresponding to factory i (where $i = 1, 2, \dots, 20$) during batch j (where $j = 1, 2, \dots, 5$).
- `newprocessij`, `time_devij`, and `temp_devij` are the measurements for each variable that correspond to factory i during batch j . For example, `newprocessij` indicates whether the batch produced by factory i during batch j used the new process.
- `supplier_Cij` and `supplier_Bij` are dummy variables that use effects (sum-to-zero) coding to indicate whether company C or B, respectively, supplied the process chemicals for the batch produced by factory i during batch j .
- $b_i \sim N(0, \sigma_b^2)$ is a random-effects intercept for each factory i that accounts for factory-specific variation in quality.

```
glme = fitglm(mfr, 'defects ~ 1 + newprocess + time_dev + temp_dev + supplier + (1|factory)
               'Distribution', 'Poisson', 'Link', 'log', 'FitMethod', 'Laplace', 'DummyVarCoding', 'effects')
```

Compute and display the 99% confidence intervals for the random-effects coefficients.

```
[B,BNames,stats] = randomEffects(glme, 'Alpha', 0.01);
stats
```

```
stats =
  Random effect coefficients: DFMethod = 'residual', Alpha = 0.01

-0.73061	94	0.46684	-0.74817	0.42278
-1.3773	94	0.17168	-0.93325	0.29159
0.27195	94	0.78626	-0.50635	0.62319

The first three columns of `stats` contain the group name, level, and random-effects coefficient name. Column 4 contains the estimated EBP of the random-effects coefficient. The last two columns of `stats`, `Lower` and `Upper`, contain the lower and upper bounds of the 99% confidence interval, respectively. For example, for the coefficient for '(Intercept)' for level 3 of `factory`, the estimated EBP is -0.26325, and the 99% confidence interval is [-0.82191,0.29541].

randomEffects

Class: LinearMixedModel

Estimates of random effects and related statistics

Syntax

```
B = randomEffects(lme)
[B, Bnames] = randomEffects(lme)
[B, Bnames, stats] = randomEffects(lme)
[B, Bnames, stats] = randomEffects(lme, Name, Value)
```

Description

`B = randomEffects(lme)` returns the estimates of the best linear unbiased predictors (BLUPs) of random effects in the linear mixed-effects model `lme`.

`[B, Bnames] = randomEffects(lme)` also returns the names of the coefficients in `Bnames`. Each name corresponds to a coefficient in `B`.

`[B, Bnames, stats] = randomEffects(lme)` also returns the estimated BLUPs of random effects in the linear mixed-effects model `lme` and related statistics.

`[B, Bnames, stats] = randomEffects(lme, Name, Value)` also returns the BLUPs of random effects in the linear mixed-effects model `lme` and related statistics with additional options specified by one or more `Name, Value` pair arguments.

Input Arguments

lme — Linear mixed-effects model

LinearMixedModel object

Linear mixed-effects model, specified as a LinearMixedModel object constructed using `fitlme` or `fitlmematrix`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Alpha — Significance level

0.05 (default) | scalar value in the range 0 to 1

Significance level, specified as the comma-separated pair consisting of `'Alpha'` and a scalar value in the range 0 to 1. For a value α , the confidence level is $100*(1-\alpha)\%$.

For example, for 99% confidence intervals, you can specify the confidence level as follows.

Example: `'Alpha', 0.01`

Data Types: `single` | `double`

DFMethod — Method for computing approximate degrees of freedom

`'residual'` (default) | `'satterthwaite'` | `'none'`

Method for computing approximate degrees of freedom for the t -statistics that test the random-effects coefficients against 0, specified as the comma-separated pair consisting of `'DFMethod'` and one of the following.

<code>'residual'</code>	Default. The degrees of freedom are assumed to be constant and equal to $n - p$, where n is the number of observations and p is the number of fixed effects.
<code>'satterthwaite'</code>	Satterthwaite approximation.
<code>'none'</code>	All degrees of freedom are set to infinity.

For example, you can specify the Satterthwaite approximation as follows.

Example: `'DFMethod', 'satterthwaite'`

Output Arguments

B — Estimated best linear unbiased predictors of random effects

column vector

Estimated best linear unbiased predictors of random effects of linear mixed-effects model `lme`, returned as a column vector.

Suppose `lme` has R grouping variables g_1, g_2, \dots, g_R , with levels m_1, m_2, \dots, m_R , respectively. Also suppose q_1, q_2, \dots, q_R are the lengths of the random-effects vectors that are associated with g_1, g_2, \dots, g_R , respectively. Then, `B` is a column vector of length $q_1*m_1 + q_2*m_2 + \dots + q_R*m_R$.

`randomEffects` creates `B` by concatenating the best linear unbiased predictors of random-effects vectors corresponding to each level of each grouping variable as `[g1level1; g1level2; ...; g1levelm1; g2level1; g2level2; ...; g2levelm2; ...; gRlevel1; gRlevel2; ...; gRlevelmR]`'.

Bnames — Names of random-effects coefficients

table

Names of random-effects coefficients in `B`, returned as a table.

stats — Estimates of random effects BLUPs and related statistics

dataset array

Estimates of random effects BLUPs and related statistics, returned as a dataset array that has one row for each of the fixed effects and one column for each of the following statistics.

Group	Grouping variable associated with the random effect
Level	Level within the grouping variable corresponding to the random effect
Name	Name of the random-effect coefficient
Estimate	Best linear unbiased predictor (BLUP) of random effect
SEPred	Standard error of the estimate (BLUP minus random effect)

tStat	<i>t</i> -statistic for a test that the random effect is zero
DF	Estimated degrees of freedom for the <i>t</i> -statistic
pValue	<i>p</i> -value for the <i>t</i> -statistic
Lower	Lower limit of a 95% confidence interval for the random effect
Upper	Upper limit of a 95% confidence interval for the random effect

Examples

Display Random-Effects Estimates and Coefficient Names

Load the sample data.

```
load carbig
```

Fit a linear mixed-effects model for miles per gallon (MPG), with fixed effects for acceleration and horsepower, and potentially correlated random effects for intercept and acceleration, grouped by the model year. First, store the data in a table.

```
tbl = table(Acceleration,Horsepower,Model_Year,MPG);
```

Fit the model.

```
lme = fitlme(tbl, 'MPG ~ Acceleration + Horsepower + (Acceleration|Model_Year)');
```

Compute the BLUPs of the random-effects coefficients and display the names of the corresponding random effects.

```
[B,Bnames] = randomEffects(lme)
```

```
B = 26×1
```

```

0.33789    0.1825     0.62558
```

The correlation value suggests that random effects seem negatively correlated. Plot the random effects for intercept versus acceleration to confirm this.

```
plot(B(1:2:end),B(2:2:end), 'r*')
```

Compute Random-Effects Estimates and Related Statistics

Load the sample data.

```
load(fullfile(matlabroot, 'examples', 'stats', 'fertilizer.mat'));
```

The dataset array includes data from a split-plot experiment, where soil is divided into three blocks based on the soil type: sandy, silty, and loamy. Each block is divided into five plots, where five different types of tomato plants (cherry, heirloom, grape, vine, and plum) are randomly assigned to these plots. The tomato plants in the plots are then divided into subplots, where each subplot is treated by one of four fertilizers. This is simulated data.

Store the data in a dataset array called `ds`, for practical purposes, and define `Tomato`, `Soil`, and `Fertilizer` as categorical variables.

```
ds = fertilizer;
ds.Tomato = nominal(ds.Tomato);
ds.Soil = nominal(ds.Soil);
ds.Fertilizer = nominal(ds.Fertilizer);
```

Fit a linear mixed-effects model, where `Fertilizer` and `Tomato` are the fixed-effects variables, and the mean yield varies by the block (soil type), and the plots within blocks (tomato types within soil types) independently.

```
lme = fitlme(ds, 'Yield ~ Fertilizer * Tomato + (1|Soil) + (1|Soil:Tomato)');
```

Compute the BLUPs and related statistics for random effects.

```
[~,~,stats] = randomEffects(lme)
```

```
stats =
```

```
Random effect coefficients: DFMethod = 'Residual', Alpha = 0.05
```

7.1765	-1.1231	40	0.2681	-22.564	6.4444
7.1765	-0.36952	40	0.71369	-17.156	11.852
7.1765	0.6138	40	0.54282	-10.099	18.909

The first three rows contain the random-effects estimates and the statistics for the three levels, *Loamy*, *Sandy*, and *Silty* of the grouping variable *Soil*. The corresponding p -values 0.66918, 0.51825, and 0.82593 indicate that these random-effects are not significantly different from 0. The following 15 rows include the BLUPS of random-effects estimates for the intercept, grouped by the variable *Tomato* nested in *Soil*, i.e. interaction of *Tomato* and *Soil*.

Compute Confidence Intervals with Specified Options

Load the sample data.

```
load shift
```

Fit a linear mixed-effects model with a random intercept grouped by operator, to assess if there is a significant difference in the performance according to the time of the shift. Use the restricted maximum likelihood method.

```
lme = fitlme(shift, 'QCDev ~ Shift + (1|Operator)');
```

Compute the 99% confidence intervals for random effects using the residuals option to compute the degrees of freedom. This is the default method.

```
[~,~,stats] = randomEffects(lme, 'Alpha',0.01)
```

```
stats =
  Random effect coefficients: DFMethod = 'Residual', Alpha = 0.01
```

Group	Level	Name	Estimate	SEPred
'Operator'	'1'	'(Intercept)'	0.57753	0.90378
'Operator'	'2'	'(Intercept)'	1.1757	0.90378
'Operator'	'3'	'(Intercept)'	-2.1715	0.90378
'Operator'	'4'	'(Intercept)'	2.3655	0.90378
'Operator'	'5'	'(Intercept)'	-1.9472	0.90378

tStat	DF	pValue	Lower	Upper
0.63902	12	0.53482	-2.1831	3.3382
1.3009	12	0.21772	-1.5849	3.9364
-2.4027	12	0.033352	-4.9322	0.58909
2.6174	12	0.022494	-0.39511	5.1261
-2.1546	12	0.052216	-4.7079	0.81337

Compute the 99% confidence intervals for random effects using the Satterthwaite approximation to compute the degrees of freedom.

```
[~,~,stats] = randomEffects(lme, 'DFMethod', 'satterthwaite', 'Alpha', 0.01)
```

```
stats =
  Random effect coefficients: DFMethod = 'Satterthwaite', Alpha = 0.01
```

Group	Level	Name	Estimate	SEPred
'Operator'	'1'	'(Intercept)'	0.57753	0.90378
'Operator'	'2'	'(Intercept)'	1.1757	0.90378
'Operator'	'3'	'(Intercept)'	-2.1715	0.90378
'Operator'	'4'	'(Intercept)'	2.3655	0.90378
'Operator'	'5'	'(Intercept)'	-1.9472	0.90378

tStat	DF	pValue	Lower	Upper
0.63902	6.4253	0.5449	-2.684	3.839
1.3009	6.4253	0.23799	-2.0858	4.4372
-2.4027	6.4253	0.050386	-5.433	1.09
2.6174	6.4253	0.037302	-0.89598	5.627
-2.1546	6.4253	0.071626	-5.2087	1.3142

The Satterhwaite method usually produces smaller values for the degrees of freedom (DF), which results in larger p-values (pValue) and larger confidence intervals (Lower and Upper) for the random-effects estimates.

randsample

Random sample

Syntax

```
y = randsample(n,k)
y = randsample(population,k)
y = randsample( ____, replacement)
y = randsample(n,k,true,w)
y = randsample(population,k,true,w)
y = randsample(s, ____)
```

Description

`y = randsample(n,k)` returns `k` values sampled uniformly at random, without replacement, from the integers 1 to `n`.

`y = randsample(population,k)` returns a vector of `k` values sampled uniformly at random, without replacement, from the values in the vector `population`.

`y = randsample(____, replacement)` returns a sample taken with replacement if `replacement` is `true`, or without replacement if `replacement` is `false`. Specify `replacement` following any of the input argument combinations in the previous syntaxes.

`y = randsample(n,k,true,w)` uses a vector of non-negative weights, `w`, whose length is `n`, to determine the probability that an integer `i` is selected as an entry for `y`.

`y = randsample(population,k,true,w)` uses a vector of nonnegative weights, `w`, of the same length as the vector `population`, to determine the probability that a value `population(i)` is selected as an entry for `y`.

`y = randsample(s, ____)` uses the stream `s` for random number generation. The option `s` can precede any of the input arguments in the previous syntaxes. `s` is a member of the `RandStream` class.

Examples

Sample Unique Value from Range

Draw a single value from the integers 1 through 10.

```
n = 10;
x = randsample(n,1)

x = 9
```

Sample from Population Vector

Create the random seed for reproducibility of the results.

```
s = RandStream('mlfg6331_64');
```

Draw a single value from the vector [10:20].

```
population = 10:20;
y = randsample(s,population,1)

y = 17
```

Generate Random Sequence for Specified Probabilities

Create the random number stream for reproducibility.

```
s = RandStream('mlfg6331_64');
```

Choose 48 characters randomly and with replacement from the sequence ACGT, according to the specified probabilities.

```
R = randsample(s, 'ACGT',48,true,[0.15 0.35 0.35 0.15])

R =
'GGCGGCGCAAGGCGCCGGACCTGGCTGCACGCCGTTCCCTGCTACTCG'
```

Set Random Number Stream

Create the random number stream for reproducibility.

```
s = RandStream('mlfg6331_64');
```

Draw five values with replacement from the integers 1:10.

```
y = randsample(s,10,5,true)
```

```
y = 5×1
```

```
    7  
    8  
    5  
    7  
    8
```

Input Arguments

n — Upper limit of range

positive integer

Upper limit of the range (1 to n) from which to sample, specified as a positive integer. By default, `randsample` samples uniformly at random, without replacement, from the values in the range 1 to n.

Data Types: `single` | `double`

population — Input data

vector

Input data from which to sample, specified as a vector. By default, `randsample` samples uniformly at random, without replacement, from the values in `population`. The orientation of `y` (row or column) is the same as that of `population`.

If `population` is a numeric vector containing only nonnegative integer values, and `population` can have the length 1, then use `y =`

`population(randsample(length(population),k))` instead of `y = randsample(population,k)`.

Example: `y = randsample([50:100],20)` returns a vector of 20 values sampled uniformly at random, without replacement, from the population vector consisting of integers from 50 to 100.

Data Types: `single` | `double` | `logical` | `char` | `string` | `categorical`

k — Number of samples

positive integer

Number of samples, specified as a positive integer.

Example: `randsample(20,10)` returns a vector of 10 values sampled uniformly at random, without replacement, from the integers 1 to 20.

Data Types: `single` | `double`

replacement — Indicator for sampling with replacement

`false` (default) | `true`

Indicator for sampling with replacement, specified as either `false` or `true`.

Example: `randsample(10,2,true)` returns two values with replacement from the integers 1 to 10.

Data Types: `logical`

w — Sampling weights

`ones(n,1)` (default) | vector of nonnegative scalar values

Sampling weights, specified as a vector of nonnegative scalar values. The length of `w` must be equal to the range of integers to sample or the length of `population`. The vector `w` must have at least one positive value. If `w` contains negative values or NaN values, `randsample` displays an error message. The `randsample` function samples with probability proportional to $w(i)/\text{sum}(w)$. Usually, `w` is a vector of probabilities. The `randsample` function supports specifying weights only for sampling with replacement.

Example: `[0.1 0.5 0.35 0.46]`

Data Types: `single` | `double`

s — Random number stream

MATLAB default random number stream (default) | `RandStream`

Random number stream, specified as the MATLAB default random number stream or `RandStream`. For details, see “Creating and Controlling a Random Number Stream” (MATLAB).

Example: `s = RandStream('mlfg6331_64')` creates a random number stream that uses the multiplicative lagged Fibonacci generator algorithm.

Output Arguments

y — Sample

vector | scalar

Sample, returned as a vector or scalar.

- If $k = 1$, then y is a scalar.
- If $k > 1$, then y is a k -by-1 vector.

Tips

To sample data randomly, with or without replacement, use `datasample`.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- When you sample without replacement, the order of the output values might not match the order in MATLAB.
- Code generation does not support the random number stream input argument s .

For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “General Code Generation Workflow” on page 31-5.

RandStream | datasample | rand | randperm

Introduced before R2006a

randtool

Interactive random number generation

Syntax

```
randtool
```

Description

randtool opens the Random Number Generation Tool.

The Random Number Generation Tool is a graphical user interface that generates random samples from specified probability distributions and displays the samples as histograms. Use the tool to explore the effects of changing parameters and sample size on the distributions.

Start by selecting a distribution, then enter the desired sample size.

You can also

- Use the controls at the bottom of the window to set parameter values for the distribution and to change their upper and lower bounds.
- Draw another sample from the same distribution, with the same size and parameters.
- Export the current sample to your workspace. A dialog box enables you to provide a name for the sample.

`randttool` does not provide printing functionality in MATLAB Online.

Introduced before R2006a

range

Range of values

Syntax

```
y = range(X)
y = range(X, 'all')
y = range(X, dim)
y = range(X, vecdim)
```

Description

`y = range(X)` returns the difference between the maximum and minimum values of sample data in `X`.

- If `X` is a vector, then `range(X)` is the range of the values in `X`.
- If `X` is a matrix, then `range(X)` is a row vector containing the range of each column in `X`.
- If `X` is a multidimensional array, then `range` operates along the first nonsingleton dimension of `X`, treating the values as vectors. The size of this dimension becomes 1 while the sizes of all other dimensions remain the same. If `X` is an empty array with first dimension 0, then `range(X)` returns an empty array with the same size as `X`.

`y = range(X, 'all')` returns the range of all elements in `X`.

`y = range(X, dim)` returns the range along the operating dimension `dim` of `X`. For example, if `X` is a matrix, then `range(X, 2)` is a column vector containing the range value of each row.

`y = range(X, vecdim)` returns the range over the dimensions specified in the vector `vecdim`. For example, if `X` is a matrix, then `range(X, [1 2])` is the range of all elements in `X` because every element of a matrix is contained in the array slice defined by dimensions 1 and 2.

Examples

Range of Standard Normal Random Numbers

Generate five large samples of standard normal random numbers.

```
rng('default') % For reproducibility  
rv = normrnd(0,1,1000,5);
```

Find the range values of the samples.

```
near6 = range(rv)
```

```
near6 = 1×5
```

```
    6.8104    6.6420    6.9578    6.0860    6.8165
```

The range value is approximately 6 for each sample.

Range of Exam Scores

Find the range of exam scores over the course of five exams.

Load the examgrades data set.

```
load examgrades
```

Find the range of all exam scores.

```
y = range(grades, 'all')
```

```
y = 46
```

Range of Exam Scores by Student

Find the range of exam scores for each student over the course of five exams.

Load the examgrades data set.

```
load examgrades
```

Find the range of exam scores for the first 10 students. For example, the difference between the eighth student's best and worst exam scores is 7 points.

```
X = grades(1:10,:);
y = range(X,2)
```

```
y = 10×1
```

```
12
13
10
12
8
16
14
7
12
10
```

Range Along Vector Dimension

Find the range of a multidimensional array over multiple dimensions.

Create a 3-by-5-by-2 array of normal random numbers with mean $\mu = 2$ and standard deviation $\sigma = 7$.

```
rng('default') % For reproducibility
mu = 2;
sigma = 7;
X = normrnd(mu,sigma,[3 5 2])
```

```
X =
X(:,:,1) =
```

```
5.7637    8.0352   -1.0351   21.3861    7.0778
14.8372    4.2314    4.3984   -7.4492    1.5586
-13.8119   -7.1538   27.0488   23.2445    7.0032
```

```
X(:,:,2) =  
    0.5652    11.8632   -6.4524    5.4223   -0.1241  
    1.1310    11.9203    7.0207    9.2429    4.0571  
   12.4279    6.7005   13.4116    7.0882   -3.5110
```

Find the range of each page of X by specifying dimensions 1 and 2 as the operating dimensions.

```
ypage = range(X,[1 2])
```

```
ypage =  
ypage(:,:,1) =
```

```
    40.8607
```

```
ypage(:,:,2) =
```

```
    19.8641
```

For example, `ypage(1,1,2)` is the range of all the elements in `X(:,:,2)`.

Find the range of the elements in each `X(i,:,:)` slice by specifying dimensions 2 and 3 as the operating dimensions.

```
yrow = range(X,[2 3])
```

```
yrow = 3×1
```

```
    27.8385  
    22.2864  
    40.8607
```

For example, `yrow(3)` is the range of all the elements in `X(3,:,:)`.

Input Arguments

X — Data sample

scalar | vector | matrix | multidimensional array

Data sample, specified as a scalar, vector, matrix, or multidimensional array.

- If X is a scalar, then `range(X)` is 0.
- If X is a 0-by-0 empty array, then `range(X)` is also an empty array.

Data Types: `single` | `double` | `logical` | `datetime` | `duration`

dim — Dimension to operate along

positive integer scalar

Dimension to operate along, specified as a positive integer scalar. If you do not specify a value, then the default value is the first array dimension whose size does not equal 1.

`dim` indicates the dimension whose length reduces to 1. `size(y, dim)` is 1, while the sizes of all other dimensions remain the same unless `size(X, dim)` is 0. If `size(X, dim)` is 0, then `range(X, dim)` returns an empty array of the same size as X .

Consider a two-dimensional data sample X :

- If `dim` is equal to 1, then `range(X, 1)` returns a row vector containing the range for each column.
- If `dim` is equal to 2, then `range(X, 2)` returns a column vector containing the range for each row.

If `dim` is greater than `ndims(X)`, `range` returns an array of zeros with the same dimensions and missing values as X .

Data Types: `single` | `double`

vecdim — Vector of dimensions

positive integer vector

Vector of dimensions, specified as a positive integer vector. Each element of `vecdim` represents a dimension of the input array X . The output y has length 1 in the specified operating dimensions. The other dimension lengths are the same for X and y .

For example, if X is a 2-by-3-by-3 array, then `range(X, [1 2])` returns a 1-by-1-by-3 array. Each element of the output array is the range of the elements on the corresponding page of X .

Data Types: `single` | `double`

Output Arguments

y — Difference between maximum and minimum values

`scalar` | `vector` | `matrix` | `multidimensional array`

Difference between the maximum and minimum values, returned as a scalar, vector, matrix, or multidimensional array.

Tips

- `range` treats NaNs as missing values and ignores them.
- `range` provides an easily calculated estimate of the spread of a sample. Avoid using `range` with data that has outliers because they have an undue influence on this statistic.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. For more information, see “Tall Arrays” (MATLAB).

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Usage notes and limitations:

- The 'all' and vecdim input arguments are not supported.

For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

`iqr` | `mad` | `std`

Introduced before R2006a

rangesearch

Find all neighbors within specified distance using searcher object

Syntax

```
Idx = rangesearch(Mdl, Y, r)
Idx = rangesearch(Mdl, Y, r, Name, Value)
[Idx, D] = rangesearch( ___ )
```

Description

`Idx = rangesearch(Mdl, Y, r)` searches for all neighbors (i.e., points, rows, or observations) in `Mdl.X` within radius `r` of each point (i.e., row or observation) in the query data `Y` using an exhaustive search or a *Kd-tree*. `rangesearch` returns `Idx`, which is a column vector of the indices of `Mdl.X` within `r` units.

`Idx = rangesearch(Mdl, Y, r, Name, Value)` returns the indices of the observation in `Mdl.X` within radius `r` of each observation in `Y` with additional options specified by one or more `Name, Value` pair arguments. For example, you can specify to use a different distance metric than is stored in `Mdl.Distance` or a different distance metric parameter than is stored in `Mdl.DistanceParameter`.

`[Idx, D] = rangesearch(___)` additionally returns the matrix `D` using any of the input arguments in the previous syntaxes. `D` contains the distances between the observations in `Mdl.X` within radius `r` of each observation in `Y`. By default, the function arranges the columns of `D` in ascending order by closeness, with respect to the distance metric.

Examples

Search for Neighbors Within a Radius Using *Kd-tree* and Exhaustive Search

`rangesearch` accepts `ExhaustiveSearcher` or `KDTreeSearcher` model objects to search the training data for the nearest neighbors to the query data. An

ExhaustiveSearcher model invokes the exhaustive searcher algorithm, and a KDTreeSearcher model defines a Kd-tree, which rangesearch uses to search for nearest neighbors.

Load Fisher's iris data set. Randomly reserve five observations from the data for query data. Focus on the petal dimensions.

```
load fisheriris
rng(1); % For reproducibility
n = size(meas,1);
idx = randsample(n,5);
X = meas(~ismember(1:n,idx),3:4); % Training data
Y = meas(idx,3:4); % Query data
```

Grow a default two-dimensional Kd-tree.

```
MdlKDT = KDTreeSearcher(X)
```

```
MdlKDT =
  KDTreeSearcher with properties:
    BucketSize: 50
    Distance: 'euclidean'
    DistParameter: []
    X: [145x2 double]
```

MdlKDT is a KDTreeSearcher model object. You can alter its writable properties using dot notation.

Prepare an exhaustive nearest neighbor searcher.

```
MdlES = ExhaustiveSearcher(X)
```

```
MdlES =
  ExhaustiveSearcher with properties:
    Distance: 'euclidean'
    DistParameter: []
    X: [145x2 double]
```

MdlES is an ExhaustiveSearcher model object. It contains the options, such as the distance metric, to use to find nearest neighbors.

Alternatively, you can grow a *Kd*-tree or prepare an exhaustive nearest neighbor searcher using `createns`.

Search training data for the nearest neighbor indices that correspond to each query observation that are within a 0.5 cm radius. Conduct both types of searches and use the default settings.

```
r = 0.15; % Search radius
IdxKDT = rangesearch(MdlKDT,Y,r);
IdxES = rangesearch(MdlES,Y,r);
[IdxKDT IdxES]

ans = 5x2 cell array
    {1x27 double}    {1x27 double}
    {[          13]} {[          13]}
    {1x27 double}    {1x27 double}
    {1x2  double}    {1x2  double}
    {1x0  double}    {1x0  double}
```

`IdxKDT` and `IdxES` are cell arrays of vectors corresponding to the indices of `X` that are within 0.15 cm of the observations in `Y`. Each row of the index matrices corresponds to a query observation.

Compare the results between the methods.

```
cellfun(@isequal,IdxKDT,IdxES)

ans = 5x1 logical array

     1
     1
     1
     1
     1
```

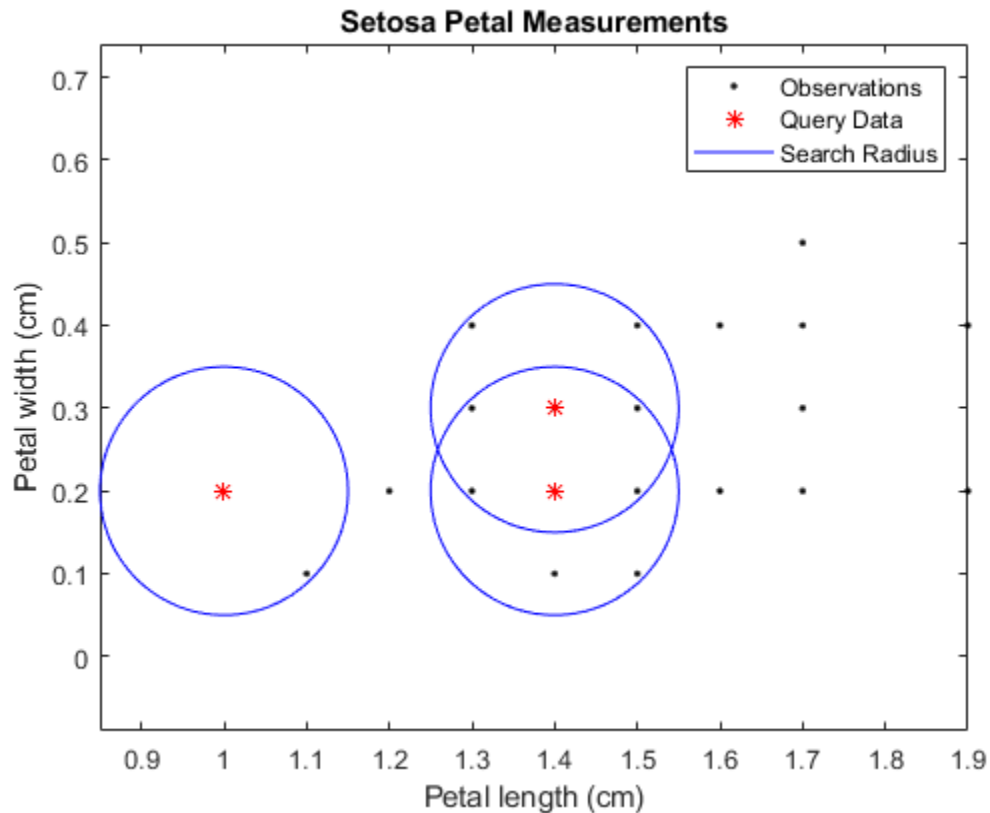

In this case, the results are the same.

Plot the results for the setosa irises.

```
setosaIdx = strcmp(species(~ismember(1:n,idx)),'setosa');
XSetosa = X(setosaIdx,:);
ySetosaIdx = strcmp(species(idx),'setosa');
YSetosa = Y(ySetosaIdx,:);
```

```
figure;
plot(XSetosa(:,1),XSetosa(:,2),'.k');
hold on;
plot(YSetosa(:,1),YSetosa(:,2),'*r');
for j = 1:sum(ySetosaIdx)
    c = YSetosa(j,:);
    circleFun = @(x1,x2)r^2 - (x1 - c(1)).^2 - (x2 - c(2)).^2;
    fimplicit(circleFun,[c(1) + [-1 1]*r, c(2) + [-1 1]*r],'b-')
end
xlabel 'Petal length (cm)';
ylabel 'Petal width (cm)';
title 'Setosa Petal Measurements';
legend('Observations','Query Data','Search Radius');
axis equal
hold off
```

Search for Neighbors Within a Radius Using the Mahalanobis Distance

Load Fisher's iris data set.

```
load fisheriris
```

Remove five irises randomly from the predictor data to use as a query set.

```
rng(1); % For reproducibility
n = size(meas,1); % Sample size
qIdx = randsample(n,5); % Indices of query data
```

```
X = meas(~ismember(1:n,qIdx),:);
Y = meas(qIdx,:);
```

Prepare a default exhaustive nearest neighbor searcher.

```
Mdl = ExhaustiveSearcher(X)
```

```
Mdl =
  ExhaustiveSearcher with properties:
    Distance: 'euclidean'
  DistParameter: []
    X: [145x4 double]
```

Mdl is an ExhaustiveSearcher model.

Find the indices of the training data (X) that are within 0.15 cm of each point in the query data (Y). Specify that the distances are with respect to the Mahalanobis metric.

```
r = 1;
Idx = rangesearch(Mdl,Y,r,'Distance','mahalanobis')
```

```
Idx = 5x1 cell array
    {1x15 double}
    {1x5 double}
    {1x6 double}
    {[      84]}
    {[      69]}
```

```
Idx{3}
```

```
ans = 1x6
     1    34    33    22    24     2
```

Each cell of `Idx` corresponds to a query data observation and contains in `X` a vector of indices of the neighbors within 0.15cm of the query data. `rangesearch` arranges the indices in ascending order by distance. For example, using the Mahalanobis distance, the second nearest neighbor of `Y(3, :)` is `X(34, :)`.

Compute Distances of Neighbors Within a Radius

Load Fisher's iris data set.

```
load fisheriris
```

Remove five irises randomly from the predictor data to use as a query set.

```
rng(4); % For reproducibility
n = size(meas,1); % Sample size
qIdx = randsample(n,5); % Indices of query data
X = meas(~ismember(1:n,qIdx),:);
Y = meas(qIdx,:);
```

Grow a four-dimensional Kd-tree using the training data. Specify to use the Minkowski distance for finding nearest neighbors.

```
Mdl = KDTreeSearcher(X);
```

Mdl is a KDTreeSearcher model. By default, the distance metric for finding nearest neighbors is the Euclidean metric.

Find the indices of the training data (X) that are within 0.5 cm from each point in the query data (Y).

```
r = 0.5;
[Idx,D] = rangesearch(Mdl,Y,r);
```

Idx and D are five-element cell arrays of vectors. The vector values in Idx are the indices in X. The X indices represent the observations that are within 0.5 cm of the query data, Y. D contains the distances that correspond to the observations.

Display the results for query observation 3.

```
Idx{3}
```

```
ans = 1×2
```

```
127 122
```

```
D{3}
```

```
ans = 1×2
```

0.2646 0.4359

The closest observation to $Y(3, :)$ is $X(127, :)$, which is 0.2646 cm away. The next closest is $X(122, :)$, which is 0.4359 cm away. All other observations are greater than 0.5 cm away from $Y(5, :)$.

Input Arguments

Mdl — Nearest neighbor searcher

`ExhaustiveSearcher` model object | `KDTreeSearcher` model object

Nearest neighbor searcher, specified as an `ExhaustiveSearcher` or `KDTreeSearcher` model object, respectively.

If `Mdl` is an `ExhaustiveSearcher` model, then `rangesearch` searches for nearest neighbors using an exhaustive search. Otherwise, `rangesearch` uses the grown Kd-tree to search for nearest neighbors.

Y — Query data

numeric matrix

Query data, specified as a numeric matrix.

Y is an m -by- K matrix. Rows of Y correspond to observations (i.e., examples), and columns correspond to predictors (i.e., variables or features). Y must have the same number of columns as the training data stored in `Mdl.X`.

Data Types: `single` | `double`

r — Search radius

nonnegative scalar

Search radius around each point in the query data, specified as a nonnegative scalar.

`rangesearch` finds all observations in `Mdl.X` that are within distance r of each observation in Y . The property `Mdl.Distance` stores the distance.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'Distance', 'minkowski', 'P', 3` specifies to find all observations in `Mdl.X` within distance `r` of each observation in `Y`, using the Minkowski distance metric with exponent 3.

For Both Nearest Neighbor Searchers

Distance — Distance metric

`Mdl.Distance` (default) | `'cityblock'` | `'euclidean'` | `'mahalanobis'` | `'minkowski'` | `'seuclidean'` | function handle | ...

Distance metric used to find neighbors of the training data to the query observations, specified as the comma-separated pair consisting of `'Distance'` and a character vector, string scalar, or function handle.

For both types of nearest neighbor searchers, `rangesearch` supports these distance metrics.

Value	Description
<code>'chebychev'</code>	Chebychev distance (maximum coordinate difference).
<code>'cityblock'</code>	City block distance.
<code>'euclidean'</code>	Euclidean distance.
<code>'minkowski'</code>	Minkowski distance. The default exponent is 2. To specify a different exponent, use the <code>'P'</code> name-value pair argument.

If `Mdl` is an `ExhaustiveSearcher` model object, then `rangesearch` also supports these distance metrics.

Value	Description
<code>'correlation'</code>	One minus the sample linear correlation between observations (treated as sequences of values).

Value	Description
'cosine'	One minus the cosine of the included angle between observations (treated as row vectors).
'hamming'	Hamming distance, which is the percentage of coordinates that differ.
'jaccard'	One minus the Jaccard coefficient, which is the percentage of nonzero coordinates that differ.
'mahalanobis'	Mahalanobis distance, computed using a positive definite covariance matrix. To change the value of the covariance matrix, use the 'Cov' name-value pair argument.
'seuclidean'	Standardized Euclidean distance. Each coordinate difference between rows in <code>Mdl.X</code> and the query matrix is scaled by dividing by the corresponding element of the standard deviation computed from <code>Mdl.X</code> . To specify another scaling, use the 'Scale' name-value pair argument.
'spearman'	One minus the sample Spearman's rank correlation between observations (treated as sequences of values).

If `Mdl` is an `ExhaustiveSearcher` model object, then you can also specify a function handle for a custom distance metric by using `@` (for example, `@distfun`). The custom distance function must:

- Have the form `function D2 = distfun(ZI,ZJ)`.
- Take as arguments:
 - A 1-by- K vector `ZI` containing a single row from `Mdl.X` or `Y`, where K is the number of columns of `Mdl.X`.
 - An m -by- K matrix `ZJ` containing multiple rows of `Mdl.X` or `Y`, where m is a positive integer.
- Return an m -by-1 vector of distances `D2`, where `D2(j)` is the distance between the observations `ZI` and `ZJ(j,:)`.

For more details, see “Distance Metrics” on page 18-16.

Example: 'Distance', 'minkowski'

P — Exponent for Minkowski distance metric

2 (default) | positive scalar

Exponent for the Minkowski distance metric, specified as the comma-separated pair consisting of 'P' and a positive scalar. This argument is valid only if 'Distance' is 'minkowski'.

Example: 'P', 3

Data Types: single | double

SortIndices — Flag to sort returned indices according to distance

true (1) (default) | false (0)

Flag to sort returned indices according to distance, specified as the comma-separated pair consisting of 'SortIndices' and either true (1) or false (0).

For faster performance when Y contains many observations that have many nearest points, you can set SortIndices to false. In this case, rangearch returns the indices of the nearest points in no particular order. When SortIndices is true, the function arranges the indices of the nearest points in ascending order by distance.

Example: 'SortIndices', false

Data Types: logical

For Exhaustive Nearest Neighbor Searchers

Cov — Covariance matrix for Mahalanobis distance metric

nancov(Mdl.X) (default) | positive definite matrix

Covariance matrix for the Mahalanobis distance metric, specified as the comma-separated pair consisting of 'Cov' and a positive definite matrix. Cov is a K -by- K matrix, where K is the number of columns of Mdl.X. If you specify Cov and do not specify 'Distance', 'mahalanobis', then rangearch returns an error message.

Example: 'Cov', eye(3)

Data Types: single | double

Scale — Scale parameter value for standardized Euclidean distance metric

nanstd(Mdl.X) (default) | nonnegative numeric vector

Scale parameter value for the standardized Euclidean distance metric, specified as the comma-separated pair consisting of 'Scale' and a nonnegative numeric vector. Scale has length K , where K is the number of columns of `Mdl.X`.

The software scales each difference between the training and query data using the corresponding element of Scale. If you specify Scale and do not specify 'Distance', 'seuclidean', then rangesearch returns an error message.

Example: 'Scale', quantile(Mdl.X,0.75) - quantile(Mdl.X,0.25)

Data Types: single | double

Note If you specify 'Distance', 'Cov', 'P', or 'Scale', then `Mdl.Distance` and `Mdl.DistanceParameter` do not change value.

Output Arguments

Idx — Training data indices of nearest neighbors

cell array of numeric vectors

Training data indices of nearest neighbors, returned as a cell array of numeric vectors.

Idx is an m -by-1 cell array such that cell j (`Idx{j}`) contains an m_j -dimensional vector of indices of the observations in `Mdl.X` that are within r units to the query observation `Y(j, :)`. If `SortIndices` is true, then rangesearch arranges the elements of the vectors in ascending order by distance.

D — Distances of nearest neighbors to the query data

cell array of numeric vectors

Distances of the neighbors to the query data, returned as a numeric matrix or cell array of numeric vectors.

D is an m -by-1 cell array such that cell j (`D{j}`) contains an m_j -dimensional vector of the distances that the observations in `Mdl.X` are from the query observation `Y(j, :)`. All elements of the vector are less than r . If `SortIndices` is true, then rangesearch arranges the elements of the vectors in ascending order.

Tips

`knnsearch` finds the k (positive integer) points in `Mdl.X` that are k -nearest for each `Y` point. In contrast, `rangesearch` finds all the points in `Mdl.X` that are within distance `r` (positive scalar) of each `Y` point.

Alternative Functionality

`rangesearch` is an object function that requires an `ExhaustiveSearcher` or a `KDTreeSearcher` model object, query data, and a distance. Under equivalent conditions, `rangesearch` returns the same results as `rangesearch` when you specify the name-value pair argument `'NSMethod','exhaustive'` or `'NSMethod','kdtree'`, respectively.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- This table contains notes about the arguments of `rangesearch`. Arguments not included in this table are fully supported.

Argument	Notes and Limitations
Mdl	<p>There are two ways to use Mdl in code generation. For an example, see “Code Generation for Nearest Neighbor Searcher” on page 31-15.</p> <ul style="list-style-type: none"> • Use <code>saveCompactModel</code>, <code>loadCompactModel</code>, and <code>codegen</code> to generate code for the <code>rangesearch</code> function. Save a trained model by using <code>saveCompactModel</code>. Define an entry-point function that loads the saved model by using <code>loadCompactModel</code> and calls the <code>rangesearch</code> function. Then use <code>codegen</code> to generate code for the entry-point function. • Include <code>coder.Constant(Mdl)</code> in the <code>-args</code> value of <code>codegen</code>. <p>If Mdl is a <code>KDTreeSearcher</code> object, and the code generation build type is a MEX function, then <code>codegen</code> generates a MEX function using Intel Threading Building Blocks (TBB) for parallel computation. Otherwise, <code>codegen</code> generates code using <code>parfor</code>.</p> <ul style="list-style-type: none"> • MEX function for the kd-tree search algorithm — <code>codegen</code> generates an optimized MEX function using Intel TBB for parallel computation on multicore platforms. You can use the MEX function to accelerate MATLAB algorithms. For details on Intel TBB, see https://software.intel.com/en-us/intel-tbb. <p>If you generate the MEX function to test the generated code of the <code>parfor</code> version, you can disable the usage of Intel TBB. Set the <code>ExtrinsicCalls</code> property of the MEX configuration object to <code>false</code>. For details, see <code>coder.MexCodeConfig</code>.</p> <ul style="list-style-type: none"> • MEX function for the exhaustive search algorithm and standalone C/C++ code for both algorithms — The generated code of <code>rangesearch</code> uses <code>parfor</code> to create loops that run in parallel on supported shared-memory multicore platforms in the generated code. If your compiler does not support the Open Multiprocessing (OpenMP) application interface or you disable OpenMP

Argument	Notes and Limitations
	library, MATLAB Coder treats the <code>parfor</code> -loops as <code>for</code> -loops. To find supported compilers, see https://www.mathworks.com/support/compilers/current_release/ . To disable OpenMP library, set the <code>EnableOpenMP</code> property of the configuration object to <code>false</code> . For details, see <code>coder.CodeConfig</code> .
'Distance'	<ul style="list-style-type: none"> • Cannot be a custom distance function. • Must be a compile-time constant; its value cannot change in the generated code.
'SortIndices'	Not supported. The output arguments are always sorted.
Name-value pair arguments	Names in name-value pair arguments must be compile-time constants. For example, to allow a user-defined exponent for the Minkowski distance in the generated code, include <code>{coder.Constant('Distance'), coder.Constant('Minkowski'), coder.Constant('P'), 0}</code> in the <code>-args</code> value of <code>codegen</code> .
Idx	The sorted order of tied distances in the generated code can be different from the order in MATLAB due to numerical precision.

Topics

“k-Nearest Neighbor Search and Radius Search” on page 18-18

“Distance Metrics” on page 18-16

Introduced in R2011b

rangesearch

Find all neighbors within specified distance using input data

Syntax

```
Idx = rangesearch(X,Y,r)  
[Idx,D] = rangesearch(X,Y,r)  
[Idx,D] = rangesearch(X,Y,r,Name,Value)
```

Description

`Idx = rangesearch(X,Y,r)` finds all the X points that are within distance `r` of the Y points. The rows of X and Y correspond to observations, and the columns correspond to variables.

`[Idx,D] = rangesearch(X,Y,r)` also returns the distances between the Y points and the X points that are within a distance of `r`.

`[Idx,D] = rangesearch(X,Y,r,Name,Value)` specifies additional options using one or more name-value pair arguments. For example, you can specify the nearest neighbor search method and the distance metric used in the search.

Examples

Find All Points Within Specified Distance

Find the X points that are within a Euclidean distance 1.5 of each Y point. Both X and Y are samples of five-dimensional normally distributed variables.

```
rng('default') % For reproducibility  
X = randn(100,5);  
Y = randn(10,5);  
[Idx,D] = rangesearch(X,Y,1.5)
```

```
Idx = 10x1 cell array
    {1x7 double}
    {1x2 double}
    {1x11 double}
    {1x2 double}
    {1x12 double}
    {1x9 double}
    {[      89]}
    {1x0 double}
    {1x0 double}
    {1x0 double}
```

```
D = 10x1 cell array
    {1x7 double}
    {1x2 double}
    {1x11 double}
    {1x2 double}
    {1x12 double}
    {1x9 double}
    {[  1.1739]}
    {1x0 double}
    {1x0 double}
    {1x0 double}
```

In this case, the last three Y points are more than 1.5 distance away from any X point. X(89, :) is 1.1739 distance away from Y(7, :), and no other X point is within distance 1.5 of Y(7, :). X contains 12 points within distance 1.5 of Y(5, :).

Find Nearest Points in Clustered Data

Generate 5000 random points from each of three distinct multivariate normal distributions. Shift the means of the distributions so that the randomly generated points are likely to form three separate clusters.

```
rng('default') % For reproducibility
N = 5000;
dist = 10;
X = [mvnrnd([0 0],eye(2),N);
     mvnrnd(dist*[1 1],eye(2),N);
     mvnrnd(dist*[-1 -1],eye(2),N)];
```

For each point in X , find the points in X that are within a radius `dist` away from the point. For faster computation, specify to keep the indices of the nearest neighbors unsorted. Select the first point in X , and find its nearest neighbors.

```
Idx = rangesearch(X,X,dist,'SortIndices',false);  
x = X(1,:);  
nearestPoints = X(Idx{1},:);
```

Find the values in X that are not the nearest neighbors of x . Display those points in one color and the nearest neighbors of x in a different color. Label the point x with a black, filled circle.

```
nonNearestIdx = true(size(X,1),1);  
nonNearestIdx(Idx{1}) = false;  
  
scatter(X(nonNearestIdx,1),X(nonNearestIdx,2))  
hold on  
scatter(nearestPoints(:,1),nearestPoints(:,2))  
scatter(x(1),x(2),'black','filled')  
hold off
```

Find Nearest Points Using Custom Distance Function

Find the patients in the `patients` data set that are within a certain age and weight range of the patients in `Y`.

Load the `patients` data set. The `Age` values are in years, and the `Weight` values are in pounds.

```
load patients
X = [Age Weight];
Y = [20 162; 30 169; 40 168]; % New patients
```

Create a custom distance function `distfun` that determines the distance between patients in terms of age and weight. For example, according to `distfun`, two patients that are one year apart in age and have the same weight are one distance unit apart. Similarly, two patients that have the same age and are five pounds apart in weight are also one distance unit apart.

```
type distfun.m % Display contents of distfun.m file
```

```
function D2 = distfun(ZI,ZJ)
ageDifference = abs(ZI(1)-ZJ(:,1));
weightDifference = abs(ZI(2)-ZJ(:,2));
D2 = ageDifference + 0.2*weightDifference;
end
```

Note: If you click the button located in the upper-right section of this example and open the example in MATLAB®, then MATLAB opens the example folder. This folder includes the function file `distfun.m`.

Find the patients in `X` that are within the distance 2 of the patients in `Y`.

```
[Idx,D] = rangesearch(X,Y,2,'Distance',@distfun)
```

```
Idx = 3x1 cell array
    {1x0 double}
    {1x0 double}
    {[      41]}
```

```
D = 3x1 cell array
    {1x0 double}
    {1x0 double}
    {[  1.8000]}
```

The third patient in `Y` is the only one to have a patient in `X` within a distance of 2.

Display the `Age` and `Weight` values for the nearest patient in `X` to the patient with age 40 and weight 168.

```
X(Idx{3}, :)
```

```
ans = 1x2
```

```
    39    164
```

Input Arguments

X — Input data

numeric matrix

Input data, specified as an $m \times n$ numeric matrix, where each row represents one n -dimensional point. The number of columns n must equal the number of columns in `Y`.

Data Types: `single` | `double`

Y — Query points

numeric matrix

Query points, specified as an $m \times n$ numeric matrix, where each row represents one n -dimensional point. The number of columns n must equal the number of columns in `X`.

Data Types: `single` | `double`

r — Search radius

nonnegative scalar

Search radius around each query point, specified as a nonnegative scalar. `rangesearch` finds all `X` points (rows) that are within distance `r` of each `Y` point. The meaning of distance depends on the 'Distance' name-value pair argument.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `rangesearch(X,Y,1.4,'Distance','seuclidean','Scale',iqr(X))` specifies to find all the observations in `X` within distance 1.4 of each observation in `Y`, using a standardized Euclidean distance scaled by the interquartile range of `X`.

NSMethod — Nearest neighbor search method

'kdtree' | 'exhaustive'

Nearest neighbor search method, specified as the comma-separated pair consisting of 'NSMethod' and one of these values.

Value	Description
'kdtree'	Create and use a <i>Kd</i> -tree to find nearest neighbors. 'kdtree' is valid only when the distance metric is one of these options: <ul style="list-style-type: none"> 'chebychev' 'cityblock' 'euclidean' 'minkowski'
'exhaustive'	Use the exhaustive search algorithm. The software computes the distances from all X points to each Y point to find nearest neighbors.

'kdtree' is the default value when the number of columns in X is less than or equal to 10, X is not sparse, and the distance metric is one of the valid 'kdtree' metrics. Otherwise, the default value is 'exhaustive'.

Example: 'NSMethod', 'exhaustive'

Distance — Distance metric

'euclidean' (default) | 'seuclidean' | 'mahalanobis' | 'cityblock' | 'minkowski' | 'chebychev' | function handle | ...

Distance metric that rangesearch uses, specified as the comma-separated pair consisting of 'Distance' and one of the values in this table.

Value	Description
'euclidean'	Euclidean distance.
'seuclidean'	Standardized Euclidean distance. Each coordinate difference between a row in X and a query point is scaled by dividing by the corresponding element of the standard deviation computed from X, <code>nanstd(X)</code> . To specify another scaling, use the 'Scale' name-value pair argument.

Value	Description
'mahalanobis'	Mahalanobis distance, computed using a positive definite covariance matrix C . The default value of C is the sample covariance matrix of X , as computed by <code>nancov(X)</code> . To specify a different value for C , use the 'Cov' name-value pair argument.
'cityblock'	City block distance.
'minkowski'	Minkowski distance. The default exponent is 2. To specify a different exponent, use the 'P' name-value pair argument.
'chebychev'	Chebychev distance (maximum coordinate difference).
'cosine'	One minus the cosine of the included angle between observations (treated as vectors).
'correlation'	One minus the sample linear correlation between observations (treated as sequences of values).
'hamming'	Hamming distance, the percentage of coordinates that differ.
'jaccard'	One minus the Jaccard coefficient, the percentage of nonzero coordinates that differ.
'spearman'	One minus the sample Spearman's rank correlation between observations (treated as sequences of values).
@ <i>distfun</i>	<p>Custom distance function handle. A distance function has the form</p> <pre>function D2 = distfun(ZI,ZJ) % calculation of distance ...</pre> <p>where</p> <ul style="list-style-type: none"> • ZI is a 1-by-n vector containing one row of X or Y. • ZJ is an m-by-n matrix containing multiple rows of X or Y. • $D2$ is an m-by-1 vector of distances, and $D2(j)$ is the distance between the observations ZI and $ZJ(j, :)$.

For more information, see “Distance Metrics” on page 18-16.

Example: 'Distance', 'minkowski'

P — Exponent for Minkowski distance metric

2 (default) | positive scalar

Exponent for the Minkowski distance metric, specified as the comma-separated pair consisting of 'P' and a positive scalar. This argument is valid only if 'Distance' is 'minkowski'.

Example: 'P', 4

Data Types: single | double

Cov — Covariance matrix for Mahalanobis distance metric

nancov(X) (default) | positive definite matrix

Covariance matrix for the Mahalanobis distance metric, specified as the comma-separated pair consisting of 'Cov' and a positive definite matrix. This argument is valid only when 'Distance' is 'mahalanobis'.

Example: 'Cov', eye(4)

Data Types: single | double

Scale — Scale parameter value for standardized Euclidean distance metric

nanstd(X) (default) | nonnegative vector

Scale parameter value for the standardized Euclidean distance metric, specified as the comma-separated pair consisting of 'Scale' and a nonnegative vector. Scale has length equal to the number of columns in X. Each coordinate difference between a row in X and a query point is scaled by the corresponding element of Scale. This argument is valid only when 'Distance' is 'seuclidean'.

Example: 'Scale', iqr(X)

Data Types: single | double

BucketSize — Maximum number of data points in leaf node of Kd-tree

50 (default) | positive integer scalar

Maximum number of data points in the leaf node of the Kd-tree, specified as the comma-separated pair consisting of 'BucketSize' and a positive integer scalar. This argument is valid only when NSMethod is 'kdtree'.

Example: 'BucketSize', 20

Data Types: `single` | `double`

SortIndices — Flag to sort returned indices according to distance

`true` (1) (default) | `false` (0)

Flag to sort returned indices according to distance, specified as the comma-separated pair consisting of 'SortIndices' and either `true` (1) or `false` (0).

For faster performance when *Y* contains many observations that have many nearest points in *X*, you can set `SortIndices` to `false`. In this case, `rangesearch` returns the indices of the nearest points in no particular order. When `SortIndices` is `true`, the function arranges the indices of the nearest points in ascending order by distance.

Example: 'SortIndices', `false`

Data Types: `logical`

Output Arguments

Idx — Indices of nearest points

cell array of numeric vectors

Indices of nearest points, returned as a cell array of numeric vectors.

`Idx` is an *my*-by-1 cell array, where *my* is the number of rows in *Y*. The vector `Idx{j}` contains the indices of points (rows) in *X* whose distances to `Y(j, :)` are not greater than *r*. If `SortIndices` is `true`, then `rangesearch` arranges the indices in ascending order by distance.

D — Distances of nearest points to query points

cell array of numeric vectors

Distances of the nearest points to the query points, returned as a cell array of numeric vectors.

`D` is an *my*-by-1 cell array, where *my* is the number of rows in *Y*. `D{j}` contains the distance values between `Y(j, :)` and the points (rows) in `X(Idx{j}, :)`. If `SortIndices` is `true`, then `rangesearch` arranges the distances in ascending order.

Tips

- For a fixed positive real value r , `rangesearch` finds all the X points that are within a distance r of each Y point. To find the k points in X that are nearest to each Y point, for a fixed positive integer k , use `knnsearch`.
- `rangesearch` does not save a search object. To create a search object, use `createns`.

Algorithms

- For an overview of the kd -tree algorithm, see “ k -Nearest Neighbor Search Using a Kd -Tree” on page 18-20.
- The exhaustive search algorithm finds the distance from each point in X to each point in Y .

Alternative Functionality

If you set the `rangesearch` function 'NSMethod' name-value pair argument to the appropriate value ('`exhaustive`' for an exhaustive search algorithm or '`kdtree`' for a Kd -tree algorithm), then the search results are equivalent to the results obtained by conducting a distance search using the `rangesearch` object function. Unlike the `rangesearch` function, the `rangesearch` object function requires an `ExhaustiveSearcher` or `KDTreeSearcher` model object.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- For code generation, the default value of the 'NSMethod' name-value pair argument is '`exhaustive`' when the number of columns in X is greater than 7.

- The value of the 'Distance' name-value pair argument must be a compile-time constant and cannot be a custom distance function.
- The 'SortIndices' name-value pair argument is not supported. The output arguments are always sorted.
- Names in name-value pair arguments must be compile-time constants. For example, to allow a user-defined exponent for the Minkowski distance in the generated code, include `{coder.Constant('Distance'),coder.Constant('Minkowski'),coder.Constant('P'),0}` in the `-args` value of `codegen`.
- The sorted order of tied distances in the generated code can be different from the order in MATLAB due to numerical precision.
- When `rangesearch` uses the kd-tree search algorithm, and the code generation build type is a MEX function, `codegen` generates a MEX function using Intel Threading Building Blocks (TBB) for parallel computation. Otherwise, `codegen` generates code using `parfor`.
 - MEX function for the kd-tree search algorithm — `codegen` generates an optimized MEX function using Intel TBB for parallel computation on multicore platforms. You can use the MEX function to accelerate MATLAB algorithms. For details on Intel TBB, see <https://software.intel.com/en-us/intel-tbb>.

If you generate the MEX function to test the generated code of the `parfor` version, you can disable the usage of Intel TBB. Set the `ExtrinsicCalls` property of the MEX configuration object to `false`. For details, see `coder.MexCodeConfig`.

- MEX function for the exhaustive search algorithm and standalone C/C++ code for both algorithms — The generated code of `rangesearch` uses `parfor` to create loops that run in parallel on supported shared-memory multicore platforms in the generated code. If your compiler does not support the Open Multiprocessing (OpenMP) application interface or you disable OpenMP library, MATLAB Coder treats the `parfor`-loops as `for`-loops. To find supported compilers, see https://www.mathworks.com/support/compilers/current_release/. To disable OpenMP library, set the `EnableOpenMP` property of the configuration object to `false`. For details, see `coder.CodeConfig`.

For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “General Code Generation Workflow” on page 31-5.

Topics

“k-Nearest Neighbor Search and Radius Search” on page 18-18

“Distance Metrics” on page 18-16

Introduced in R2011b

ranksum

Wilcoxon rank sum test

Syntax

```
p = ranksum(x,y)
[p,h] = ranksum(x,y)
[p,h,stats] = ranksum(x,y)
[ ___ ] = ranksum(x,y,Name,Value)
```

Description

`p = ranksum(x,y)` returns the p -value of a two-sided Wilcoxon rank sum test on page 32-5691. `ranksum` tests the null hypothesis that data in `x` and `y` are samples from continuous distributions with equal medians, against the alternative that they are not. The test assumes that the two samples are independent. `x` and `y` can have different lengths.

This test is equivalent to a Mann-Whitney U-test.

`[p,h] = ranksum(x,y)` also returns a logical value indicating the test decision. The result `h = 1` indicates a rejection of the null hypothesis, and `h = 0` indicates a failure to reject the null hypothesis at the 5% significance level.

`[p,h,stats] = ranksum(x,y)` also returns the structure `stats` with information about the test statistic.

`[___] = ranksum(x,y,Name,Value)` returns any of the output arguments in the previous syntaxes, for a rank sum test with additional options specified by one or more `Name,Value` pair arguments.

Examples

Test for Equal Median of Two Populations

Test the hypothesis of equal medians for two independent unequal-sized samples.

Generate sample data.

```
rng('default') % for reproducibility
x = unifrnd(0,1,10,1);
y = unifrnd(0.25,1.25,15,1);
```

These samples come from populations with identical distributions except for a shift of 0.25 in the location.

Test the equality of medians of x and y .

```
p = ranksum(x,y)
```

```
p = 0.0375
```

The p -value of 0.0375 indicates that ranksum rejects the null hypothesis of equal medians at the default 5% significance level.

Statistics of the Test for Two Population Medians

Obtain the statistics of the test for the equality of two population medians.

Load the sample data.

```
load mileage
```

Test if the mileage per gallon is the same for the first and second type of cars.

```
[p,h,stats] = ranksum(mileage(:,1),mileage(:,2))
```

```
p = 0.0043
```

```
h = logical
    1
```

```
stats = struct with fields:
    ranksum: 21.5000
```

Both the p -value, 0.043, and $h = 1$ indicate the rejection of the null hypothesis of equal medians at the default 5% significance level. Because the sample sizes are small (six each), `ranksum` calculates the p -value using the exact method. The structure `stats` includes only the value of the rank sum test statistic.

Increase in the Median

Test the hypothesis of an increase in the population median.

Load the sample data.

```
load(fullfile(matlabroot, 'examples', 'stats', 'weather.mat'));
```

The weather data shows the daily high temperatures taken in the same month in two consecutive years.

Perform a left-sided test to assess the increase in the median at the 1% significance level.

```
[p,h,stats] = ranksum(year1,year2,'alpha',0.01,...  
'tail','left')
```

```
p = 0.1271
```

```
h = logical  
    0
```

```
stats = struct with fields:  
    zval: -1.1403  
    ranksum: 837.5000
```

Both the p -value of 0.1271 and $h = 0$ indicate that there is not enough evidence to reject the null hypothesis and conclude that there is a positive shift in the median of observed high temperatures in the same month from year 1 to year 2 at the 1% significance level. Notice that `ranksum` uses the approximate method to calculate the p -value due to the large sample sizes.

Use the exact method to calculate the p -value.

```
[p,h,stats] = ranksum(year1,year2,'alpha',0.01,...  
'tail','left','method','exact')
```

```
p = 0.1273
h = logical
    0

stats = struct with fields:
    ranksum: 837.5000
```

The results of the approximate and exact methods are consistent with each other.

Input Arguments

x — Sample data

vector

Sample data, specified as a vector.

Data Types: `single` | `double`

y — Sample data

vector

Sample data, specified as a vector. The length of `y` does not have to be the same as the length of `x`.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'alpha', 0.01, 'method', 'approximate', 'tail', 'right'` specifies a right-tailed rank sum test with 1% significance level, which returns the approximate p-value.

alpha — Significance level

0.05 (default) | scalar value in the range 0 to 1

Significance level of the decision of a hypothesis test, specified as the comma-separated pair consisting of 'alpha' and a scalar value in the range 0 to 1. The significance level of h is $100 * \alpha\%$.

Example: 'alpha', 0.01

Data Types: double | single

method — Computation method of the p -value

'exact' | 'approximate'

Computation method of the p -value, p , specified as the comma-separated pair consisting of 'method' and one of the following:

'exact'	Exact computation of the p -value, p .
'approximate'	Normal approximation while computing the p -value, p .

When 'method' is unspecified, the default is:

- 'exact' if $\min(n_x, n_y) < 10$ and $n_x + n_y < 20$
- 'approximate' otherwise

n_x and n_y are the sizes of the samples in x and y , respectively.

Example: 'method', 'exact'

tail — Type of test

'both' (default) | 'right' | 'left'

Type of test, specified as the comma-separated pair consisting of 'tail' and one of the following:

'both'	Two-sided hypothesis test, where the alternative hypothesis states that x and y have different medians. Default test type if 'tail' is not specified.
'right'	Right-tailed hypothesis test, where the alternative hypothesis states that the median of x is greater than the median of y .
'left'	Left-tailed hypothesis test, where the alternative hypothesis states that the median of x is less than the median of y .

Example: 'tail', 'left'

Output Arguments

p — *p*-value of the test

nonnegative scalar

p-value of the test, returned as a positive scalar from 0 to 1. *p* is the probability of observing a test statistic as or more extreme than the observed value under the null hypothesis. `ranksum` computes the two-sided *p*-value by doubling the most significant one-sided value.

h — Result of the hypothesis test

1 | 0

Result of the hypothesis test, returned as a logical value.

- If $h = 1$, this indicates rejection of the null hypothesis at the $100 * \alpha\%$ significance level.
- If $h = 0$, this indicates a failure to reject the null hypothesis at the $100 * \alpha\%$ significance level.

stats — Test statistics

structure

Test statistics, returned as a structure. The test statistics stored in `stats` are:

- `ranksum`: Value of the rank sum test statistic
- `zval`: Value of the z-statistic on page 32-5692 (computed when 'method' is 'approximate')

Definitions

Wilcoxon Rank Sum Test

The Wilcoxon rank sum test is a nonparametric test for two populations when samples are independent. If *X* and *Y* are independent samples with different sample sizes, the test statistic which `ranksum` returns is the rank sum of the first sample.

The Wilcoxon rank sum test is equivalent to the Mann-Whitney U-test. The Mann-Whitney U-test is a nonparametric test for equality of population medians of two independent samples X and Y.

The Mann-Whitney U-test statistic, U , is the number of times a y precedes an x in an ordered arrangement of the elements in the two independent samples X and Y. It is related to the Wilcoxon rank sum statistic in the following way: If X is a sample of size n_X , then

$$U = W - \frac{n_X(n_X + 1)}{2}.$$

z-Statistic

For large samples, `ranksum` uses a z -statistic to compute the approximate p -value of the test.

If X and Y are two independent samples of size n_X and n_Y , where $n_X < n_Y$ the z -statistic is

$$z = \frac{W - E(W)}{\sqrt{V(W)}} = \frac{W - \left[\frac{n_X n_Y + n_X(n_X + 1)}{2} \right] - 0.5 * \text{sign}(W - E(W))}{\sqrt{\frac{n_X n_Y (n_X + n_Y + 1) - \text{tiescor}}{12}}},$$

with continuity correction and tie adjustment. Here *tiescor* is given by

$$\text{tiescor} = \frac{2 * \text{tiedj}}{(n_X + n_Y)(n_X + n_Y - 1)},$$

where `ranksum` uses `[ranks,tiedj] = tiedrank(x,y)` to obtain tie adjustments. The standard normal distribution gives the p -value for this z -statistic.

Algorithms

`ranksum` treats NaNs in x and y as missing values and ignores them.

For a two-sided test of medians with unequal sample sizes, the test statistic that `ranksum` returns is the rank sum of the first sample.

Introduced before R2006a

ranova

Class: RepeatedMeasuresModel

Repeated measures analysis of variance

Syntax

```
ranovatbl = ranova(rm)
ranovatbl = ranova(rm, 'WithinModel', WM)
[ranovatbl, A, C, D] = ranova( ___ )
```

Description

`ranovatbl = ranova(rm)` returns the results of repeated measures analysis of variance for a repeated measures model `rm` in table `ranovatbl`.

`ranovatbl = ranova(rm, 'WithinModel', WM)` returns the results of repeated measures analysis of variance using the responses specified by the within-subject model `WM`.

`[ranovatbl, A, C, D] = ranova(___)` also returns arrays `A`, `C`, and `D` for the hypotheses tests of the form $A*B*C = D$, where `D` is zero.

Input Arguments

rm — Repeated measures model

RepeatedMeasuresModel object

Repeated measures model, returned as a RepeatedMeasuresModel object.

For properties and methods of this object, see RepeatedMeasuresModel.

WM — Model specifying responses

'separatemeans' (default) | *r*-by-*nc* contrast matrix | character vector or string scalar that defines a model specification

Model specifying the responses, specified as one of the following:

- `'separatemeans'` — Compute a separate mean for each group.
- `C` — r -by- nc contrast matrix specifying the nc contrasts among the r repeated measures. If Y represents a matrix of repeated measures, `ranova` tests the hypothesis that the means of $Y*C$ are zero.
- A character vector or string scalar that defines a model specification in the within-subject factors. You can define the model based on the rules for the `terms` in the `modelspec` argument of `fitrm`. Also see “Model Specification for Repeated Measures Models” on page 9-77.

For example, if there are three within-subject factors `w1`, `w2`, and `w3`, then you can specify a model for the within-subject factors as follows.

Example: `'WithinModel', 'w1+w2+w2*w3'`

Data Types: `single` | `double` | `char` | `string`

Output Arguments

ranovatbl — Results of repeated measures anova

table

Results of repeated measures anova, returned as a table.

`ranovatbl` includes a term representing all differences across the within-subjects factors. This term has either the name of the within-subjects factor if specified while fitting the model, or the name `Time` if the name of the within-subjects factor is not specified while fitting the model or there are more than one within-subjects factors. `ranovatbl` also includes all interactions between the terms in the within-subject model and all between-subject model terms. It contains the following columns.

Column Name	Definition
SumSq	Sum of squares.
DF	Degrees of freedom.
MeanSq	Mean squared error.
F	F -statistic.

Column Name	Definition
pValue	p -value for the corresponding F -statistic. A small p -value indicates significant term effect.
pValueGG	p -value with Greenhouse-Geisser adjustment.
pValueHF	p -value with Huynh-Feldt adjustment.
pValueLB	p -value with Lower bound adjustment.

The last three p -values are the adjusted p -values for use when the compound symmetry assumption is not satisfied. For details, see “Compound Symmetry Assumption and Epsilon Corrections” on page 9-79. The `mauchy` method tests for sphericity (hence, compound symmetry) and `epsilon` method returns the epsilon adjustment values.

A — Specification based on between-subjects model

matrix | cell array

Specification based on the between-subjects model, returned as a matrix or a cell array. It permits the hypothesis on the elements within given columns of `B` (within time hypothesis). If `ranovatbl` contains multiple hypothesis tests, `A` might be a cell array.

Data Types: `single` | `double` | `cell`

C — Specification based on within-subjects model

matrix | cell array

Specification based on the within-subjects model, returned as a matrix or a cell array. It permits the hypotheses on the elements within given rows of `B` (between time hypotheses). If `ranovatbl` contains multiple hypothesis tests, `C` might be a cell array.

Data Types: `single` | `double` | `cell`

D — Hypothesis value

0

Hypothesis value, returned as 0.

Examples

Repeated Measures Analysis of Variance

Load the sample data.

```
load fisheriris
```

The column vector `species` consists of iris flowers of three different species: `setosa`, `versicolor`, `virginica`. The double matrix `meas` consists of four types of measurements on the flowers: the length and width of sepals and petals in centimeters, respectively.

Store the data in a table array.

```
t = table(species,meas(:,1),meas(:,2),meas(:,3),meas(:,4),...
'VariableNames',{'species','meas1','meas2','meas3','meas4'});
Meas = table([1 2 3 4]','VariableNames',{'Measurements'});
```

Fit a repeated measures model, where the measurements are the responses and the species is the predictor variable.

```
rm = fitrm(t,'meas1-meas4~species','WithinDesign',Meas);
```

Perform repeated measures analysis of variance.

```
ranovatbl = ranova(rm)
```

```
ranovatbl=3x8 table
```

	SumSq	DF	MeanSq	F	pValue
(Intercept):Measurements	1656.3	3	552.09	6873.3	0
species:Measurements	282.47	6	47.078	586.1	1.4271e-206
Error(Measurements)	35.423	441	0.080324		

There are four measurements, three types of species, and 150 observations. So, degrees of freedom for measurements is $(4-1) = 3$, for species-measurements interaction it is $(4-1)*(3-1) = 6$, and for error it is $(150-4)*(3-1) = 441$. `ranova` computes the last three *p*-values using Greenhouse-Geisser, Huynh-Feldt, and Lower bound corrections, respectively. You can check the compound symmetry (sphericity) assumption using the `mauchly` method, and display the epsilon corrections using the `epsilon` method.

Longitudinal Data

Load the sample data.

```
load(fullfile(matlabroot, 'examples', 'stats', 'longitudinalData.mat'));
```

The matrix *Y* contains response data for 16 individuals. The response is the blood level of a drug measured at five time points (time = 0, 2, 4, 6, and 8). Each row of *Y* corresponds to an individual, and each column corresponds to a time point. The first eight subjects are female, and the second eight subjects are male. This is simulated data.

Define a variable that stores gender information.

```
Gender = ['F' 'F' 'F' 'F' 'F' 'F' 'F' 'F' 'M' 'M' 'M' 'M' 'M' 'M' 'M'];
```

Store the data in a proper table array format to do repeated measures analysis.

```
t = table(Gender, Y(:,1), Y(:,2), Y(:,3), Y(:,4), Y(:,5), ...
'VariableNames', {'Gender', 't0', 't2', 't4', 't6', 't8'});
```

Define the within-subjects variable.

```
Time = [0 2 4 6 8]';
```

Fit a repeated measures model, where the blood levels are the responses and gender is the predictor variable.

```
rm = fitrm(t, 't0-t8 ~ Gender', 'WithinDesign', Time);
```

Perform repeated measures analysis of variance.

```
ranovatbl = anova(rm)
```

```
ranovatbl=3×8 table
```

	SumSq	DF	MeanSq	F	pValue	pValueGG
(Intercept):Time	881.7	4	220.43	37.539	3.0348e-15	4.7325e-09
Gender:Time	17.65	4	4.4125	0.75146	0.56126	0.4877
Error(Time)	328.83	56	5.872			

There are 5 time points, 2 genders, and 16 observations. So, the degrees of freedom for time is $(5-1) = 4$, for gender-time interaction it is $(5-1)*(2-1) = 4$, and for error it is $(16-2)*(5-1) = 56$. The small *p*-value of 2.6198e-05 indicates that there is a significant effect

of time on blood pressure. The p -value of 0.40063 indicates that there is no significant gender-time interaction.

Specify the Within-Subjects Model

Load the sample data.

```
load repeatedmeas
```

The table `between` includes the between-subject variables `age`, `IQ`, `group`, `gender`, and eight repeated measures `y1` through `y8` as responses. The table `within` includes the within-subject variables `w1` and `w2`. This is simulated data.

Fit a repeated measures model, where the repeated measures `y1` through `y8` are the responses, and `age`, `IQ`, `group`, `gender`, and the group-gender interaction are the predictor variables. Also specify the within-subject design matrix.

```
rm = fitrm(between, 'y1-y8 ~ Group*Gender + Age + IQ', 'WithinDesign', within);
```

Perform repeated measures analysis of variance.

```
ranovatbl = ranova(rm)
```

ranovatbl=7×8 table

	SumSq	DF	MeanSq	F	pValue	pValueGG
(Intercept):Time	6645.2	7	949.31	2.2689	0.031674	0.071235
Age:Time	5824.3	7	832.05	1.9887	0.059978	0.10651
IQ:Time	5188.3	7	741.18	1.7715	0.096749	0.14492
Group:Time	15800	14	1128.6	2.6975	0.0014425	0.011884
Gender:Time	4455.8	7	636.55	1.5214	0.16381	0.20533
Group:Gender:Time	4247.3	14	303.38	0.72511	0.74677	0.663
Error(Time)	64433	154	418.39			

Specify the model for the within-subject factors. Also display the matrices used in the hypothesis test.

```
[ranovatbl,A,C,D] = ranova(rm, 'WithinModel', 'w1+w2')
```

ranovatbl=21×8 table

Algorithms

ranova computes the regular p -value (in the `pValue` column of the `rmanova` table) using the F -statistic cumulative distribution function:

$$p\text{-value} = 1 - \text{fcdf}(F, v_1, v_2).$$

When the compound symmetry assumption is not satisfied, ranova uses a correction factor ϵ , to compute the corrected p -values as follows:

$$p\text{-value_corrected} = 1 - \text{fcdf}(F, \epsilon * v_1, \epsilon * v_2).$$

The `mauchly` method tests for sphericity (hence, compound symmetry) and `epsilon` method returns the epsilon adjustment values.

raylcdf

Rayleigh cumulative distribution function

Syntax

```
p = raylcdf(x,b)
p = raylcdf(x,b,'upper')
```

Description

`p = raylcdf(x,b)` returns the Rayleigh cdf at each value in `x` using the corresponding scale parameter, `b`. `x` and `b` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input for `x` or `b` is expanded to a constant array with the same dimensions as the other input.

`p = raylcdf(x,b,'upper')` returns the complement of the Rayleigh cdf at each value in `x`, using an algorithm that more accurately computes the extreme upper tail probabilities.

The Rayleigh cdf is

$$y = F(x|b) = \int_0^x \frac{t}{b^2} e^{\left(\frac{-t^2}{2b^2}\right)} dt$$

Examples

Compute and Plot Rayleigh Distribution cdf

Compute the cdf of a Rayleigh distribution with parameter `B = 1`.

```
x = 0:0.1:3;
p = raylcdf(x,1);
```

Plot the cdf.

```
figure;  
plot(x,p)
```

Introduced before R2006a

raylfit

Rayleigh parameter estimates

Syntax

```
raylfit(data,alpha)  
[phat,pci] = raylfit(data,alpha)
```

Description

`raylfit(data,alpha)` returns the maximum likelihood estimates of the parameter of the Rayleigh distribution given the data in the vector `data`.

`[phat,pci] = raylfit(data,alpha)` returns the maximum likelihood estimate and $100(1 - \alpha)\%$ confidence interval given the data. The default value of the optional parameter `alpha` is 0.05, corresponding to 95% confidence intervals.

Introduced before R2006a

raylinv

Rayleigh inverse cumulative distribution function

Syntax

```
X = raylinv(P,B)
```

Description

`X = raylinv(P,B)` returns the inverse of the Rayleigh cumulative distribution function using the corresponding scale parameter, `B` at the corresponding probabilities in `P`. `P` and `B` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input for `P` or `B` is expanded to a constant array with the same dimensions as the other input.

Examples

```
x = raylinv(0.9,1)
x =
    2.1460
```

Extended Capabilities

Introduced before R2006a

raylpdf

Rayleigh probability density function

Syntax

```
Y = raylpdf(X,B)
```

Description

`Y = raylpdf(X,B)` computes the Rayleigh pdf at each of the values in `X` using the corresponding scale parameter, `B`. `X` and `B` can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of `Y`. A scalar input for `X` or `B` is expanded to a constant array with the same dimensions as the other input.

The Rayleigh pdf is

$$y = f(x|b) = \frac{x}{b^2} e^{\left(\frac{-x^2}{2b^2}\right)}$$

Examples

Compute and Plot Rayleigh Distribution pdf

Compute the pdf of a Rayleigh distribution with parameter `B = 0.5`.

```
x = [0:0.01:2];  
p = raylpdf(x,0.5);
```

Plot the pdf.

```
figure;  
plot(x,p)
```

Extended Capabilities

raylrnd

Rayleigh random numbers

Syntax

```
R = raylrnd(B)
R = raylrnd(B,v)
R = raylrnd(B,m,n)
```

Description

`R = raylrnd(B)` returns a matrix of random numbers chosen from the Rayleigh distribution with scale parameter, `B`. `B` can be a vector, a matrix, or a multidimensional array. The size of `R` is the size of `B`.

`R = raylrnd(B,v)` returns a matrix of random numbers chosen from the Rayleigh distribution with parameter `B`, where `v` is a row vector. If `v` is a 1-by-2 vector, `R` is a matrix with `v(1)` rows and `v(2)` columns. If `v` is 1-by-`n`, `R` is an `n`-dimensional array.

`R = raylrnd(B,m,n)` returns a matrix of random numbers chosen from the Rayleigh distribution with parameter `B`, where scalars `m` and `n` are the row and column dimensions of `R`.

Examples

```
r = raylrnd(1:5)
r =
    1.7986    0.8795    3.3473    8.9159    3.5182
```

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

The generated code can return a different sequence of numbers than MATLAB if either of the following is true:

- The output is nonscalar.
- An input parameter is invalid for the distribution.

For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “General Code Generation Workflow” on page 31-5.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU arrays. For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

Introduced before R2006a

raylstat

Rayleigh mean and variance

Syntax

```
[M,V] = raylstat(B)
```

Description

`[M,V] = raylstat(B)` returns the mean of and variance for the Rayleigh distribution with scale parameter `B`.

The mean of the Rayleigh distribution with parameter b is $b\sqrt{\pi/2}$ and the variance is

$$\frac{4 - \pi}{2} b^2$$

Examples

```
[mn,v] = raylstat(1)
mn =
    1.2533
v =
    0.4292
```

Extended Capabilities

rcoplot

Residual case order plot

Syntax

```
rcoplot(r,rint)
```

Description

`rcoplot(r,rint)` displays an errorbar plot of the confidence intervals on the residuals from a regression. The residuals appear in the plot in case order. Inputs `r` and `rint` are outputs from the `regress` function.

Examples

The following plots residuals and prediction intervals from a regression of a linearly additive model to the data in `moore.mat`:

```
load moore
X = [ones(size(moore,1),1) moore(:,1:5)];
y = moore(:,6);
alpha = 0.05;
[betahat,Ibeta,Ires,stats] = regress(y,X,alpha);
rcoplot(res,Ires)
```

The interval around the first residual, shown in red, does not contain zero. This indicates that the residual is larger than expected in 95% of new observations, and suggests the data point is an outlier.

`regress`

Introduced before R2006a

ReconstructionICA

Feature extraction by reconstruction ICA

Description

`ReconstructionICA` applies reconstruction independent component analysis (RICA) to learn a transformation that maps input predictors to new predictors.

Creation

Create a `ReconstructionICA` object by using the `rica` function.

Properties

FitInfo — Fitting history

structure

This property is read-only.

Fitting history, returned as a structure with two fields:

- **Iteration** — Iteration numbers from 0 through the final iteration.
- **Objective** — Objective function value at each corresponding iteration. Iteration 0 corresponds to the initial values, before any fitting.

Data Types: `struct`

InitialTransformWeights — Initial feature transformation weights

p-by-q matrix

This property is read-only.

Initial feature transformation weights, returned as a p-by-q matrix, where p is the number of predictors passed in X and q is the number of features that you want. These weights

are the initial weights passed to the creation function. The data type is single when the training data X is single.

Data Types: `single` | `double`

ModelParameters — Parameters for training model

structure

This property is read-only.

Parameters for training the model, returned as a structure. The structure contains a subset of the fields that correspond to the `rica` name-value pairs that were in effect during model creation:

- `IterationLimit`
- `VerbosityLevel`
- `Lambda`
- `Standardize`
- `ContrastFcn`
- `GradientTolerance`
- `StepTolerance`

For details, see the `rica Name, Value` on page 32-6229 pairs.

Data Types: `struct`

Mu — Predictor means when standardizing

p -by-1 vector

This property is read-only.

Predictor means when standardizing, returned as a p -by-1 vector. This property is nonempty when the `Standardize` name-value pair is `true` at model creation. The value is the vector of predictor means in the training data. The data type is single when the training data X is single.

Data Types: `single` | `double`

NonGaussianityIndicator — Non-Gaussianity of sources

length- q vector of ± 1

This property is read-only.

Non-Gaussianity of sources, returned as a length- q vector of ± 1 .

- `NonGaussianityIndicator(k) = 1` means `rica` models the k th source as sub-Gaussian.
- `NonGaussianityIndicator(k) = -1` means `rica` models the k th source as super-Gaussian, with a sharp peak at 0.

Data Types: `double`

NumLearnedFeatures — Number of output features

positive integer

This property is read-only.

Number of output features, returned as a positive integer. This value is the q argument passed to the creation function, which is the requested number of features to learn.

Data Types: `double`

NumPredictors — Number of input predictors

positive integer

This property is read-only.

Number of input predictors, returned as a positive integer. This value is the number of predictors passed in X to the creation function.

Data Types: `double`

Sigma — Predictor standard deviations when standardizing

p -by-1 vector

This property is read-only.

Predictor standard deviations when standardizing, returned as a p -by-1 vector. This property is nonempty when the `Standardize` name-value pair is `true` at model creation. The value is the vector of predictor standard deviations in the training data. The data type is `single` when the training data X is `single`.

Data Types: `single` | `double`

TransformWeights — Feature transformation weights

p -by- q matrix

This property is read-only.

Feature transformation weights, returned as a p -by- q matrix, where p is the number of predictors passed in X and q is the number of features that you want. The data type is single when the training data X is single.

Data Types: single | double

Object Functions

`transform` Transform predictors into extracted features

Examples

Create Reconstruction ICA Object

Create a ReconstructionICA object by using the `rica` function.

Load the caltech101 image patches.

```
data = load('caltech101patches');
size(data.X)
```

```
ans = 1×2
```

```
    100000    363
```

There are 100,000 image patches, each containing 363 features.

Extract 100 features from the data.

```
rng default % For reproducibility
q = 100;
Mdl = rica(data.X,q,'IterationLimit',100)
```

Warning: Solver LBFGS was not able to converge to a solution.

```
Mdl =
  ReconstructionICA
    ModelParameters: [1x1 struct]
```

```
    NumPredictors: 363
  NumLearnedFeatures: 100
        Mu: []
        Sigma: []
    FitInfo: [1x1 struct]
  TransformWeights: [363x100 double]
InitialTransformWeights: []
NonGaussianityIndicator: [100x1 double]
```

Properties, Methods

`rica` issues a warning because it stopped due to reaching the iteration limit, instead of reaching a step-size limit or a gradient-size limit. You can still use the learned features in the returned object by calling the `transform` function.

“Feature Extraction” on page 15-157

Introduced in R2017a

refcurve

Add reference curve to plot

Syntax

```
refcurve(p)
refcurve
hcurve = refcurve(...)
```

Description

`refcurve(p)` adds a polynomial reference curve with coefficients `p` to the current axes. If `p` is a vector with `n+1` elements, the curve is:

$$y = p(1)*x^n + p(2)*x^{(n-1)} + \dots + p(n)*x + p(n+1)$$

`refcurve` with no input arguments adds a line along the `x` axis.

`hcurve = refcurve(...)` returns the handle `hcurve` to the curve.

Examples

Add Population and Fitted Mean Functions

Generate data with a polynomial trend.

```
p = [1 -2 -1 0];
t = 0:0.1:3;
rng default % For reproducibility
y = polyval(p,t) + 0.5*randn(size(t));
```

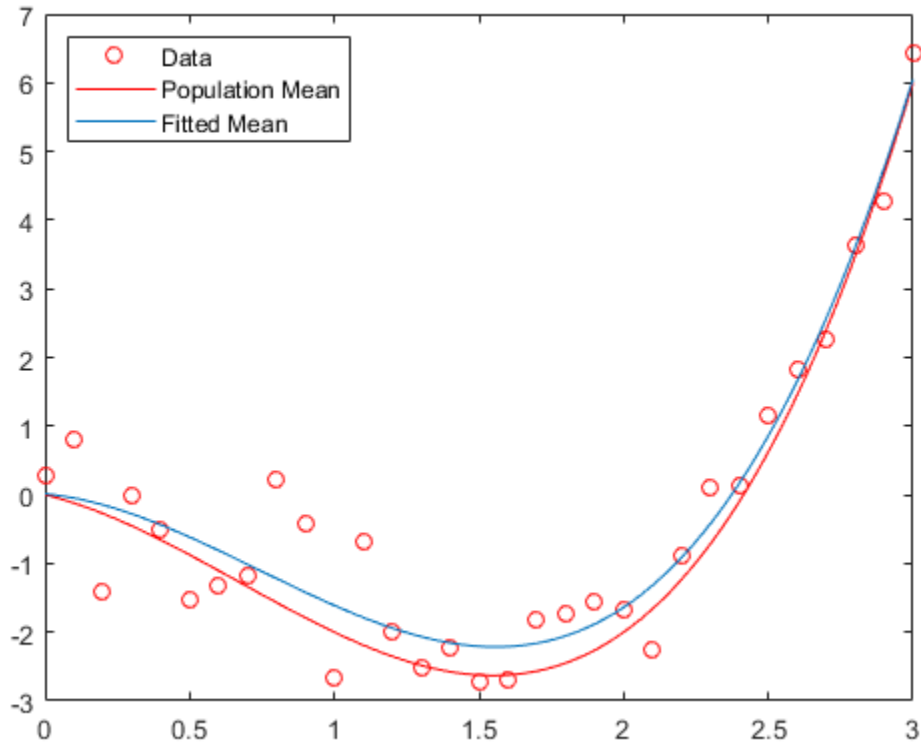

Plot data and add the population mean function using `refcurve`.

```
plot(t,y,'ro')  
h = refcurve(p);  
h.Color = 'r';
```

Also add the fitted mean function.

```
q = polyfit(t,y,3);  
refcurve(q)  
legend('Data', 'Population Mean', 'Fitted Mean', ...  
       'Location', 'NW')
```

Plot Trajectories of a Batted Baseball Using refcurve

Introduce the relevant physical constants.

```

M = 0.145;      % Mass (kg)
R = 0.0366;    % Radius (m)
A = pi*R^2;    % Area (m^2)
rho = 1.2;     % Density of air (kg/m^3)
C = 0.5;      % Drag coefficient
D = rho*C*A/2; % Drag proportional to the square of the speed
g = 9.8;      % Acceleration due to gravity (m/s^2)

```

Simulate the trajectory with drag proportional to the square of the speed, assuming constant acceleration in each time interval.

```
dt = 1e-2;      % Simulation time interval (s)
r0 = [0 1];    % Initial position (m)
s0 = 50;      % Initial speed (m/s)
alpha0 = 35;  % Initial angle (deg)
v0 = s0*[cosd(alpha0) sind(alpha0)]; % Initial velocity (m/s)

r = r0;
v = v0;
trajectory = r0;
while r(2) > 0
    a = [0 -g] - (D/M)*norm(v)*v;
    v = v + a*dt;
    r = r + v*dt + (1/2)*a*(dt^2);
    trajectory = [trajectory;r];
end
```

Plot trajectory and use `refcurve` to add the drag-free parabolic trajectory (found analytically) to the plot of trajectory.

```
figure
plot(trajectory(:,1),trajectory(:,2),'m','LineWidth',2)
xlim([0,250])
h = refcurve([-g/(2*v0(1)^2),...
    (g*r0(1)/v0(1)^2) + (v0(2)/v0(1)),...
    (-g*r0(1)^2/(2*v0(1)^2) - (v0(2)*r0(1)/v0(1)) + r0(2)]);
h.Color = 'c';
h.LineWidth = 2;
axis equal
ylim([0,50])
grid on
xlabel('Distance (m)')
ylabel('Height (m)')
title('\bf Baseball Trajectories')
legend('With Drag','Without Drag')
```

`gline` | `lsline` | `polyfit` | `refline`

Introduced before R2006a

refit

Class: GeneralizedLinearMixedModel

Refit generalized linear mixed-effects model

Syntax

```
glmenew = refit(glme, ynew)
```

Description

`glmenew = refit(glme, ynew)` returns a refitted generalized linear mixed-effects model, `glmenew`, based on the input model `glme`, using a new response vector, `ynew`.

Input Arguments

glme — Generalized linear mixed-effects model

GeneralizedLinearMixedModel object

Generalized linear mixed-effects model, specified as a GeneralizedLinearMixedModel object. For properties and methods of this object, see GeneralizedLinearMixedModel.

ynew — New response vector

n -by-1 vector of scalar values

New response vector, specified as an n -by-1 vector of scalar values, where n is the number of observations used to fit `glme`.

For an observation i with prior weights w_i^p and binomial size n_i (when applicable), the response values y_i contained in `ynew` can have the following values.

Distribution	Permitted Values	Notes
Binomial	$\left\{0, \frac{1}{w_i^p n_i}, \frac{2}{w_i^p n_i}, \dots, 1\right\}$	w_i^p and n_i are integer values > 0
Poisson	$\left\{0, \frac{1}{w_i^p}, \frac{2}{w_i^p}, \dots, 1\right\}$	w_i^p is an integer value > 0
Gamma	$(0, \infty)$	$w_i^p \geq 0$
InverseGaussian	$(0, \infty)$	$w_i^p \geq 0$
Normal	$(-\infty, \infty)$	$w_i^p \geq 0$

You can access the prior weights property w_i^p using dot notation.

```
glme.ObservationInfo.Weights
```

Data Types: `single` | `double`

Output Arguments

glmenew — Generalized linear mixed-effects model

GeneralizedLinearMixedModel object

Generalized linear mixed-effects model, returned as a GeneralizedLinearMixedModel object. `glmenew` is an updated version of the generalized linear mixed-effects model `glme`, refit to the values in the response vector `ynew`.

For properties and methods of this object, see GeneralizedLinearMixedModel.

Examples

Refit Model to New Response Vector

Load the sample data.

```
load mfr
```

This simulated data is from a manufacturing company that operates 50 factories across the world, with each factory running a batch process to create a finished product. The company wants to decrease the number of defects in each batch, so it developed a new manufacturing process. To test the effectiveness of the new process, the company selected 20 of its factories at random to participate in an experiment: Ten factories implemented the new process, while the other ten continued to run the old process. In each of the 20 factories, the company ran five batches (for a total of 100 batches) and recorded the following data:

- Flag to indicate whether the batch used the new process (`newprocess`)
- Processing time for each batch, in hours (`time`)
- Temperature of the batch, in degrees Celsius (`temp`)
- Categorical variable indicating the supplier (A, B, or C) of the chemical used in the batch (`supplier`)
- Number of defects in the batch (`defects`)

The data also includes `time_dev` and `temp_dev`, which represent the absolute deviation of time and temperature, respectively, from the process standard of 3 hours at 20 degrees Celsius.

Fit a generalized linear mixed-effects model using `newprocess`, `time_dev`, `temp_dev`, and `supplier` as fixed-effects predictors. Include a random-effects term for intercept grouped by `factory`, to account for quality differences that might exist due to factory-specific variations. The response variable `defects` has a Poisson distribution, and the appropriate link function for this model is `log`. Use the Laplace fit method to estimate the coefficients. Specify the dummy variable encoding as `'effects'`, so the dummy variable coefficients sum to 0.

The number of defects can be modeled using a Poisson distribution

$$\text{defects}_{ij} \sim \text{Poisson}(\mu_{ij})$$

This corresponds to the generalized linear mixed-effects model

$$\log(\mu_{ij}) = \beta_0 + \beta_1 \text{newprocess}_{ij} + \beta_2 \text{time_dev}_{ij} + \beta_3 \text{temp_dev}_{ij} + \beta_4 \text{supplier_C}_{ij} + \beta_5 \text{supplier_B}_{ij} + b_i,$$

where

- `defectsij` is the number of defects observed in the batch produced by factory *i* during batch *j*.

- μ_{ij} is the mean number of defects corresponding to factory i (where $i = 1, 2, \dots, 20$) during batch j (where $j = 1, 2, \dots, 5$).
- `newprocessij`, `time_devij`, and `temp_devij` are the measurements for each variable that correspond to factory i during batch j . For example, `newprocessij` indicates whether the batch produced by factory i during batch j used the new process.
- `supplier_Cij` and `supplier_Bij` are dummy variables that use effects (sum-to-zero) coding to indicate whether company C or B, respectively, supplied the process chemicals for the batch produced by factory i during batch j .
- $b_i \sim N(0, \sigma_b^2)$ is a random-effects intercept for each factory i that accounts for factory-specific variation in quality.

```
glme = fitglme(mfr, 'defects ~ 1 + newprocess + time_dev + temp_dev + supplier + (1|factory)')
```

Use `random` to simulate a new response vector from the fitted model.

```
rng(0, 'twister'); % For reproducibility
ynew = random(glme);
```

Refit the model using the new response vector.

```
glme = refit(glme, ynew)
```

```
glme =
Generalized linear mixed-effects model fit by ML
```

Model information:

Number of observations	100
Fixed effects coefficients	6
Random effects coefficients	20
Covariance parameters	1
Distribution	Poisson
Link	Log
FitMethod	Laplace

Formula:

```
defects ~ 1 + newprocess + time_dev + temp_dev + supplier + (1 | factory)
```

Model fit statistics:

AIC	BIC	LogLikelihood	Deviance
469.24	487.48	-227.62	455.24

Fixed effects coefficients (95% CIs):

Name	Estimate	SE	tStat	DF	pValue

refit

Class: FeatureSelectionNCAClassification

Refit neighborhood component analysis (NCA) model for classification

Syntax

```
mdlrefit = refit(mdl,Name,Value)
```

Description

`mdlrefit = refit(mdl,Name,Value)` refits the model `mdl`, with modified parameters specified by one or more `Name,Value` pair arguments.

Input Arguments

mdl — Neighborhood component analysis model for classification

FeatureSelectionNCAClassification object

Neighborhood component analysis model or classification, specified as a FeatureSelectionNCAClassification object.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Fitting Options

FitMethod — Method for fitting the model

`mdl.FitMethod` (default) | 'exact' | 'none' | 'average'

Method for fitting the model, specified as the comma-separated pair consisting of 'FitMethod' and one of the following.

- 'exact' — Performs fitting using all of the data.
- 'none' — No fitting. Use this option to evaluate the generalization error of the NCA model using the initial feature weights supplied in the call to `fscnca`.
- 'average' — The function divides the data into partitions (subsets), fits each partition using the `exact` method, and returns the average of the feature weights. You can specify the number of partitions using the `NumPartitions` name-value pair argument.

Example: 'FitMethod', 'none'

Lambda — Regularization parameter

`mdl.Lambda` (default) | non-negative scalar value

Regularization parameter, specified as the comma-separated pair consisting of 'Lambda' and a non-negative scalar value.

For n observations, the best Lambda value that minimizes the generalization error of the NCA model is expected to be a multiple of $1/n$

Example: 'Lambda', 0.01

Data Types: `double` | `single`

Solver — Solver type

`mdl.Solver` (default) | 'lbfgs' | 'sgd' | 'minibatch-lbfgs'

Solver type for estimating feature weights, specified as the comma-separated pair consisting of 'Solver' and one of the following.

- 'lbfgs' — Limited memory BFGS (Broyden-Fletcher-Goldfarb-Shanno) algorithm (LBFGS algorithm)
- 'sgd' — Stochastic gradient descent
- 'minibatch-lbfgs' — Stochastic gradient descent with LBFGS algorithm applied to mini-batches

Example: 'solver', 'minibatch-lbfgs'

InitialFeatureWeights — Initial feature weights

`mdl.InitialFeatureWeights` (default) | p -by-1 vector of real positive scalar values

Initial feature weights, specified as the comma-separated pair consisting of 'InitialFeatureWeights' and a p -by-1 vector of real positive scalar values.

Data Types: double | single

Verbose — Indicator for verbosity level

`mdl.Verbose` (default) | 0 | 1 | >1

Indicator for verbosity level for the convergence summary display, specified as the comma-separated pair consisting of 'Verbose' and one of the following.

- 0 — No convergence summary
- 1 — Convergence summary including iteration number, norm of the gradient, and objective function value.
- >1 — More convergence information depending on the fitting algorithm

When using solver 'minibatch-lbfgs' and verbosity level >1, the convergence information includes iteration log from intermediate minibatch LBFGS fits.

Example: 'Verbose',2

Data Types: double | single

LBFGS or Mini-Batch LBFGS Options

GradientTolerance — Relative convergence tolerance

`mdl.GradientTolerance` (default) | positive real scalar value

Relative convergence tolerance on the gradient norm for solver lbfgs, specified as the comma-separated pair consisting of 'GradientTolerance' and a positive real scalar value.

Example: 'GradientTolerance',0.00001

Data Types: double | single

SGD or Mini-Batch LBFGS Options

InitialLearningRate — Initial learning rate for solver sgd

`mdl.InitialLearningRate` (default) | positive real scalar value

Initial learning rate for solver sgd, specified as the comma-separated pair consisting of 'InitialLearningRate' and a positive scalar value.

When using solver type 'sgd', the learning rate decays over iterations starting with the value specified for 'InitialLearningRate'.

Example: 'InitialLearningRate',0.8

Data Types: double | single

PassLimit — Maximum number of passes for solver 'sgd'

`mdl.PassLimit` (default) | positive integer value

Maximum number of passes for solver 'sgd' (stochastic gradient descent), specified as the comma-separated pair consisting of 'PassLimit' and a positive integer. Every pass processes `size(mdl.X,1)` observations.

Example: 'PassLimit',10

Data Types: double | single

SGD or LBFGS or Mini-Batch LBFGS Options

IterationLimit — Maximum number of iterations

`mdl.IterationLimit` (default) | positive integer value

Maximum number of iterations, specified as the comma-separated pair consisting of 'IterationLimit' and a positive integer.

Example: 'IterationLimit',250

Data Types: double | single

Output Arguments

mdlrefit — Neighborhood component analysis model for classification

`FeatureSelectionNCAClassification` object

Neighborhood component analysis model for classification, returned as a `FeatureSelectionNCAClassification` object. You can either save the results as a new model or update the existing model as `mdl = refit(mdl,Name,Value)`.

Examples

Refit NCA Model for Classification with Modified Settings

Generate checkerboard data using the `generateCheckerBoardData.m` function.

```
rng(2016, 'twister'); % For reproducibility
pps = 1375;
[X,y] = generateCheckerBoardData(pps);
X = X + 2;
```

Plot the data.

```
figure
plot(X(y==1,1),X(y==1,2), 'rx')
hold on
plot(X(y==-1,1),X(y==-1,2), 'bx')
```

```
[n,p] = size(X)
```

```
n =
```

```
22000
```

```
p =
```

```
2
```

Add irrelevant predictors to the data.

```
Q = 98;  
Xrnd = unifrnd(0,4,n,Q);  
Xobs = [X,Xrnd];
```

This piece of code creates 98 additional predictors, all uniformly distributed between 0 and 4.

Partition the data into training and test sets. To create stratified partitions, so that each partition has similar proportion of classes, use `y` instead of `length(y)` as the partitioning criteria.

```
cvp = cvpartition(y, 'holdout', 2000);
```

cvpartition randomly chooses 2000 of the observations to add to the test set and the rest of the data to add to the training set. Create the training and validation sets using the assignments stored in the cvpartition object cvp .

```
Xtrain = Xobs(cvp.training(1),:);
ytrain = y(cvp.training(1),:);
```

```
Xval = Xobs(cvp.test(1),:);
yval = y(cvp.test(1),:);
```

Compute the misclassification error without feature selection.

```
nca = fscnca(Xtrain,ytrain,'FitMethod','none','Standardize',true, ...
    'Solver','lbfgs');
loss_nofs = loss(nca,Xval,yval)
```

```
loss_nofs =
    0.5165
```

'FitMethod','none' option uses the default weights (all 1s), which means all features are equally important.

This time, perform feature selection using neighborhood component analysis for classification, with $\lambda = 1/n$.

```
w0 = rand(100,1);
n = length(ytrain)
lambda = 1/n;
nca = refit(nca,'InitialFeatureWeights',w0,'FitMethod','exact', ...
    'Lambda',lambda,'solver','sgd');
```

```
n =
    20000
```

Plot the objective function value versus the iteration number.

```
figure()
plot(nca.FitInfo.Iteration,nca.FitInfo.Objective,'ro')
hold on
```

```
plot(nca.FitInfo.Iteration,movmean(nca.FitInfo.Objective,10),'k.-')
xlabel('Iteration number')
ylabel('Objective value')
```

Compute the misclassification error with feature selection.

```
loss_withfs = loss(nca,Xval,yval)
```

```
loss_withfs =
```

```
0.0115
```

Plot the selected features.

```
figure
semilogx(nca.FeatureWeights,'ro')
xlabel('Feature index')
ylabel('Feature weight')
grid on
```

Select features using the feature weights and a relative threshold.

```
tol = 0.15;
selidx = find(nca.FeatureWeights > tol*max(1,max(nca.FeatureWeights)))
```

```
selidx =
```

```
1
```

2

Feature selection improves the results and `fscnca` detects the correct two features as relevant.

`FeatureSelectionNCAClassification` | `fscnca` | `loss` | `predict`

Introduced in R2016b

refit

Class: FeatureSelectionNCARRegression

Refit neighborhood component analysis (NCA) model for regression

Syntax

```
mdlrefit = refit(mdl,Name,Value)
```

Description

`mdlrefit = refit(mdl,Name,Value)` refits the model `mdl`, with modified parameters specified by one or more `Name,Value` pair arguments.

Input Arguments

mdl — Neighborhood component analysis model for regression

FeatureSelectionNCARRegression object

Neighborhood component analysis model or classification, specified as a FeatureSelectionNCARRegression object.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Fitting Options

FitMethod — Method for fitting the model

`mdl.FitMethod` (default) | 'exact' | 'none' | 'average'

Method for fitting the model, specified as the comma-separated pair consisting of 'FitMethod' and one of the following.

- 'exact' — Performs fitting using all of the data.
- 'none' — No fitting. Use this option to evaluate the generalization error of the NCA model using the initial feature weights supplied in the call to `fsrnca`.
- 'average' — The function divides the data into partitions (subsets), fits each partition using the `exact` method, and returns the average of the feature weights. You can specify the number of partitions using the `NumPartitions` name-value pair argument.

Example: 'FitMethod', 'none'

Lambda — Regularization parameter

`mdl.Lambda` (default) | non-negative scalar value

Regularization parameter, specified as the comma-separated pair consisting of 'Lambda' and a non-negative scalar value.

For n observations, the best Lambda value that minimizes the generalization error of the NCA model is expected to be a multiple of $1/n$

Example: 'Lambda', 0.01

Data Types: `double` | `single`

Solver — Solver type

`mdl.Solver` (default) | 'lbfgs' | 'sgd' | 'minibatch-lbfgs'

Solver type for estimating feature weights, specified as the comma-separated pair consisting of 'Solver' and one of the following.

- 'lbfgs' — Limited memory BFGS (Broyden-Fletcher-Goldfarb-Shanno) algorithm (LBFGS algorithm)
- 'sgd' — Stochastic gradient descent
- 'minibatch-lbfgs' — Stochastic gradient descent with LBFGS algorithm applied to mini-batches

Example: 'solver', 'minibatch-lbfgs'

InitialFeatureWeights — Initial feature weights

`mdl.InitialFeatureWeights` (default) | p -by-1 vector of real positive scalar values

Initial feature weights, specified as the comma-separated pair consisting of 'InitialFeatureWeights' and a p -by-1 vector of real positive scalar values.

Data Types: double | single

Verbose — Indicator for verbosity level

`mdl.Verbose` (default) | 0 | 1 | >1

Indicator for verbosity level for the convergence summary display, specified as the comma-separated pair consisting of 'Verbose' and one of the following.

- 0 — No convergence summary
- 1 — Convergence summary including iteration number, norm of the gradient, and objective function value.
- >1 — More convergence information depending on the fitting algorithm

When using solver 'minibatch-lbfgs' and verbosity level >1, the convergence information includes iteration log from intermediate minibatch LBFGS fits.

Example: 'Verbose',2

Data Types: double | single

LBFGS or Mini-Batch LBFGS Options

GradientTolerance — Relative convergence tolerance

`mdl.GradientTolerance` (default) | positive real scalar value

Relative convergence tolerance on the gradient norm for solver lbfgs, specified as the comma-separated pair consisting of 'GradientTolerance' and a positive real scalar value.

Example: 'GradientTolerance',0.00001

Data Types: double | single

SGD or Mini-Batch LBFGS Options

InitialLearningRate — Initial learning rate for solver sgd

`mdl.InitialLearningRate` (default) | positive real scalar value

Initial learning rate for solver sgd, specified as the comma-separated pair consisting of 'InitialLearningRate' and a positive scalar value.

When using solver type 'sgd', the learning rate decays over iterations starting with the value specified for 'InitialLearningRate'.

Example: 'InitialLearningRate',0.8

Data Types: double | single

PassLimit — Maximum number of passes for solver 'sgd'

`mdl.PassLimit` (default) | positive integer value

Maximum number of passes for solver 'sgd' (stochastic gradient descent), specified as the comma-separated pair consisting of 'PassLimit' and a positive integer. Every pass processes `size(mdl.X,1)` observations.

Example: 'PassLimit',10

Data Types: double | single

SGD or LBFGS or Mini-Batch LBFGS Options

IterationLimit — Maximum number of iterations

`mdl.IterationLimit` (default) | positive integer value

Maximum number of iterations, specified as the comma-separated pair consisting of 'IterationLimit' and a positive integer.

Example: 'IterationLimit',250

Data Types: double | single

Output Arguments

mdlrefit — Neighborhood component analysis model for regression

`FeatureSelectionNCARegression` object

Neighborhood component analysis model or classification, returned as a `FeatureSelectionNCARegression` object. You can either save the results as a new model or update the existing model as `mdl = refit(mdl,Name,Value)`.

Examples

Refit NCA Model for Regression with Modified Settings

Load the sample data.

```
load(fullfile(matlabroot, 'examples', 'stats', 'robotarm.mat'))
```

The robotarm (pumadyn32nm) dataset is created using a robot arm simulator with 7168 training and 1024 test observations with 32 features [1], [2]. This is a preprocessed version of the original data set. Data are preprocessed by subtracting off a linear regression fit followed by normalization of all features to unit variance.

Compute the generalization error without feature selection.

```
nca = fsrnca(Xtrain,ytrain, 'FitMethod', 'none', 'Standardize', 1);  
L = loss(nca,Xtest,ytest)  
  
L = 0.9017
```

Now, refit the model and compute the prediction loss with feature selection, with $\lambda = 0$ (no regularization term) and compare to the previous loss value, to determine feature selection seems necessary for this problem. For the settings that you do not change, `refit` uses the settings of the initial model `nca`. For example, it uses the feature weights found in `nca` as the initial feature weights.

```
nca2 = refit(nca, 'FitMethod', 'exact', 'Lambda', 0);  
L2 = loss(nca2,Xtest,ytest)  
  
L2 = 0.1088
```

The decrease in the loss suggests that feature selection is necessary.

Plot the feature weights.

```
figure()  
plot(nca2.FeatureWeights, 'ro')
```

Tuning the regularization parameter usually improves the results. Suppose that, after tuning λ using cross-validation as in “Tune Regularization Parameter in NCA for Regression” on page 32-2772, the best λ value found is 0.0035. Refit the nca model using this λ value and stochastic gradient descent as the solver. Compute the prediction loss.

```
nca3 = refit(nca2, 'FitMethod', 'exact', 'Lambda', 0.0035, ...
            'Solver', 'sgd');
L3 = loss(nca3, Xtest, ytest)

L3 = 0.0573
```

Plot the feature weights.

```
figure()
plot(nca3.FeatureWeights, 'ro')
```

After tuning the regularization parameter, the loss decreased even more and the software identified four of the features as relevant.

`FeatureSelectionNCARegression` | `fsrnca` | `loss` | `predict`

Introduced in R2016b

reduceDimensions

Reduce dimensions of Sobol point set

Syntax

```
pr = reduceDimensions(p,d)
```

Description

`pr = reduceDimensions(p,d)` reduces the Sobol quasirandom point set `p` to the first `d` dimensions. `d` must be less than or equal to the number of dimensions in `p`.

The reduced point set `pr` is a `sobolset` object.

Examples

Reduce Dimensions of Sobol Point Set

Generate a seven-dimensional Sobol point set and scramble the points.

```
p = sobolset(7);  
ps = scramble(p, 'MatousekAffineOwen')
```

```
ps =  
Sobol point set in 7 dimensions (9007199254740992 points)
```

Properties:

```
        Skip : 0  
        Leap : 0  
ScrambleMethod : MatousekAffineOwen  
        PointOrder : standard
```

Split the first 7186 points in `ps` into seven levels of 1024 points each. Reduce the first 1024 points to be one-dimensional, the second 1024 points to be two-dimensional, and so on. For each level, compute the variance of the point values in each dimension.

```
variance = NaN(7);
for level = 1:7
    pr = reduceDimensions(ps,level);
    pr.Skip = (level-1)*1024;
    pts = pr(1:1024,:);
    variance(level,1:level) = var(pts);
end
```

Plot the variances. The dark blue bars show the variance of the points in the first dimension, the dark orange bars show the variance of the points in the second dimension, and so on.

```
bar(variance)
xlabel('Level')
ylabel('Variances')
```

Input Arguments

p — Sobol point set

sobolset object

Sobol point set, specified as a `sobolset` object.

d — Number of dimensions to retain

positive integer scalar

Number of dimensions to retain from the point set p , specified as a positive integer scalar between 1 and the number of dimensions in p . The function always retains the first d dimensions of p .

Data Types: `single` | `double`

See Also

`net` | `scramble` | `sobolset`

Introduced in R2019a

refline

Add reference line to plot

Syntax

```
refline(m,b)
refline(coeffs)
refline
refline(ax, ___)
hline = refline( ___ )
```

Description

`refline(m,b)` adds a reference line with slope `m` and intercept `b` to the current axes.

`refline(coeffs)` adds the line defined by the elements of the vector `coeffs` to the figure.

`refline` with no input arguments is equivalent to `lsline`.

`refline(ax, ___)` adds a reference line to the plot in the axis specified by `ax`, using any of the input arguments in the previous syntaxes.

`hline = refline(___)` returns the reference line object `hline` using any of the input arguments in the previous syntaxes. Use `hline` to modify properties of a specific reference line after you create it. For a list of properties, see [Line Properties](#).

Examples

Add Reference Line at the Mean

Generate sample data for an independent variable `x` and a dependent variable `y`.

```
x = 1:10;  
y = x + randn(1,10);
```

Create a scatter plot of x and y .

```
scatter(x,y,25,'b','*')
```

Superimpose a least-squares line on the scatter plot.

```
refline
```

Add a reference line at the mean of the scatter plot.

```
mu = mean(y);  
hline = refline([0 mu]);  
hline.Color = 'r';
```

The red line is the reference line at the mean of the data.

Specify Axes for Least-Squares and Reference Lines

Define the x-variable and two different y-variables to use for the plots.

```
rng default % For reproducibility
x = 1:10;
y1 = x + randn(1,10);
y2 = 2*x + randn(1,10);
```

Define `ax1` as the top half of the figure, and `ax2` as the bottom half of the figure. Create the first scatter plot on the top axis using `y1`, and the second scatter plot on the bottom axis using `y2`.

```
figure
ax1 = subplot(2,1,1);
ax2 = subplot(2,1,2);

scatter(ax1,x,y1)
scatter(ax2,x,y2)
```

Superimpose a least-squares line on the top plot, and a reference line at the mean of the `y2` values in the bottom plot.

```
lsline(ax1) % This is equivalent to reffline(ax1)
```

```
mu = mean(y2);  
reffline(ax2,[0 mu])
```

Input Arguments

m — Slope of reference line

numeric scalar

Slope of the reference line, specified as a numeric scalar. The function uses `m` to define the line

$$y = m*x + b.$$

Example: `refline(-1,1)`

Data Types: `single` | `double`

b — Intercept of reference line

numeric scalar

Intercept of the reference line, specified as a numeric scalar. The function uses `b` to define the line

$$y = m*x + b.$$

Example: `refline(2,-10)`

Data Types: `single` | `double`

coeffs — Linear coefficients

length-two numeric vector

Linear coefficients, specified as a length-two numeric vector. `coeffs` contains the coefficients of a line defined as

$$y = coeffs(1)*x + coeffs(2).$$

Example: `refline([-1,2])`

Data Types: `single` | `double`

ax — Target axes

`gca` (default) | axes object

Target axes, specified as an axes object. If you do not specify the axes and if the current axes are Cartesian axes, then the `refline` function uses the current axes.

Output Arguments

hline — One or more reference line objects

scalar | vector

One or more reference line objects, returned as a scalar or a vector. These objects are unique identifiers, which you can use to query and modify properties of a specific reference line. For a list of properties, see Chart Line.

See Also

`gline` | `lsline` | `refcurve`

Introduced before R2006a

regress

Multiple linear regression

Syntax

```
b = regress(y,X)
[b,bint] = regress(y,X)
[b,bint,r] = regress(y,X)
[b,bint,r,rint] = regress(y,X)
[b,bint,r,rint,stats] = regress(y,X)
[___] = regress(y,X,alpha)
```

Description

`b = regress(y,X)` returns a vector `b` of coefficient estimates for a multiple linear regression of the responses in vector `y` on the predictors in matrix `X`. The matrix `X` must include a column of ones.

`[b,bint] = regress(y,X)` also returns a matrix `bint` of 95% confidence intervals for the coefficient estimates.

`[b,bint,r] = regress(y,X)` also returns an additional vector `r` of residuals.

`[b,bint,r,rint] = regress(y,X)` also returns a matrix `rint` of intervals that can be used to diagnose outliers.

`[b,bint,r,rint,stats] = regress(y,X)` also returns a vector `stats` that contains the R^2 statistic, the F -statistic and its p -value, and an estimate of the error variance.

`[___] = regress(y,X,alpha)` uses a $100*(1-\alpha)\%$ confidence level to compute `bint` and `rint`. Specify any of the output argument combinations in the previous syntaxes.

Examples

Estimate Multiple Linear Regression Coefficients

Load the `carsmall` data set. Identify weight and horsepower as predictors and mileage as the response.

```
load carsmall
x1 = Weight;
x2 = Horsepower;    % Contains NaN data
y = MPG;
```

Compute the regression coefficients for a linear model with an interaction term.

```
X = [ones(size(x1)) x1 x2 x1.*x2];
b = regress(y,X)    % Removes NaN data
```

```
b = 4×1

    60.7104
   -0.0102
   -0.1882
    0.0000
```

Plot the data and the model.

```
scatter3(x1,x2,y,'filled')
hold on
x1fit = min(x1):100:max(x1);
x2fit = min(x2):10:max(x2);
[X1FIT,X2FIT] = meshgrid(x1fit,x2fit);
YFIT = b(1) + b(2)*X1FIT + b(3)*X2FIT + b(4)*X1FIT.*X2FIT;
mesh(X1FIT,X2FIT,YFIT)
xlabel('Weight')
ylabel('Horsepower')
zlabel('MPG')
view(50,10)
hold off
```

Diagnose Outliers Using Residuals

Load the examgrades data set.

```
load examgrades
```

Use the last exam scores as response data and the first two exam scores as predictor data.

```
y = grades(:,5);  
X = [ones(size(grades(:,1))) grades(:,1:2)];
```

Perform multiple linear regression with $\alpha = 0.01$.

```
[~,~,r,rint] = regress(y,X,0.01);
```

Diagnose outliers by finding the residual intervals `rint` that do not contain 0.

```
contain0 = (rint(:,1)<0 & rint(:,2)>0);  
idx = find(contain0==false)
```

```
idx = 2×1
```

```
53
```

```
54
```

Observations 53 and 54 are possible outliers.

Create a scatter plot of the residuals. Fill in the points corresponding to the outliers.

```
hold on  
scatter(y,r)  
scatter(y(idx),r(idx),'b','filled')  
xlabel("Last Exam Grades")  
ylabel("Residuals")  
hold off
```

Determine Significance of Linear Regression Relationship

Load the `hald` data set. Use `heat` as the response variable and `ingredients` as the predictor data.

```
load hald
y = heat;
X1 = ingredients;
x1 = ones(size(X1,1),1);
X = [x1 X1]; % Includes column of ones
```

Perform multiple linear regression and generate model statistics.

```
[~,~,~,~,stats] = regress(y,X)
stats = 1×4
    0.9824    111.4792    0.0000    5.9830
```

Because the R^2 value of 0.9824 is close to 1, and the p -value of 0.0000 is less than the default significance level of 0.05, a significant linear regression relationship exists between the response y and the predictor variables in X .

Input Arguments

y — Response data

numeric vector

Response data, specified as an n -by-1 numeric vector. Rows of y correspond to different observations. y must have the same number of rows as X .

Data Types: `single` | `double`

X — Predictor data

numeric matrix

Predictor data, specified as an n -by- p numeric matrix. Rows of X correspond to observations, and columns correspond to predictor variables. X must have the same number of rows as y .

Data Types: `single` | `double`

alpha — Significance level

0.05 (default) | positive scalar

Significance level, specified as a positive scalar. α must be between 0 and 1.

Data Types: `single` | `double`

Output Arguments

b — Coefficient estimates for multiple linear regression

numeric vector

Coefficient estimates for multiple linear regression, returned as a numeric vector. **b** is a p -by-1 vector, where p is the number of predictors in X . If the columns of X are linearly dependent, `regress` sets the maximum number of elements of **b** to zero.

Data Types: double

bint — Lower and upper confidence bounds for coefficient estimates

numeric matrix

Lower and upper confidence bounds for coefficient estimates, returned as a numeric matrix. **bint** is a p -by-2 matrix, where p is the number of predictors in X . The first column of **bint** contains lower confidence bounds for each of the coefficient estimates; the second column contains upper confidence bounds. If the columns of X are linearly dependent, `regress` returns zeros in elements of **bint** corresponding to the zero elements of **b**.

Data Types: double

r — Residuals

numeric vector

Residuals, returned as a numeric vector. **r** is a p -by-1 vector, where p is the number of predictors in X .

Data Types: single | double

rint — Intervals to diagnose outliers

numeric matrix

Intervals to diagnose outliers, returned as a numeric matrix. **rint** is a p -by-2 matrix, where p is the number of predictors in X . If the interval `rint(i, :)` for observation i does not contain zero, the corresponding residual is larger than expected in $100*(1-\alpha)\%$ of new observations, suggesting an outlier. For more information, see “Algorithms” on page 32-5770.

Data Types: single | double

stats — Model statistics

numeric vector

Model statistics, returned as a numeric vector including the R^2 statistic, the F -statistic and its p -value, and an estimate of the error variance.

- X must include a column of ones so that the model contains a constant term. The F -statistic and its p -value are computed under this assumption and are not correct for models without a constant.
- The F -statistic is the test statistic of the F -test on the regression model. The F -test looks for a significant linear regression relationship between the response variable and the predictor variables.
- The R^2 statistic can be negative for models without a constant, indicating that the model is not appropriate for the data.

Data Types: `single` | `double`

Tips

- `regress` treats NaN values in X or y as missing values. `regress` omits observations with missing values from the regression fit.

Algorithms

Residual Intervals

In a linear model, observed values of y and their residuals are random variables. Residuals have normal distributions with zero mean but with different variances at different values of the predictors. To put residuals on a comparable scale, `regress` “Studentizes” the residuals. That is, `regress` divides the residuals by an estimate of their standard deviation that is independent of their value. Studentized residuals have t -distributions with known degrees of freedom. The intervals returned in `rint` are shifts of the $100*(1-\alpha)\%$ confidence intervals of these t -distributions, centered at the residuals.

Alternative Functionality

`regress` is useful when you simply need the output arguments of the function and when you want to repeat fitting a model multiple times in a loop. If you need to investigate a

fitted regression model further, create a linear regression model object `LinearModel` by using `fitlm` or `stepwiselm`. A `LinearModel` object provides more features than `regress`.

- Use the properties of `LinearModel` to investigate a fitted linear regression model. The object properties include information about coefficient estimates, summary statistics, fitting method, and input data.
- Use the object functions of `LinearModel` to predict responses and to modify, evaluate, and visualize the linear regression model.
- Unlike `regress`, the `fitlm` function does not require a column of ones in the input data. A model created by `fitlm` always includes an intercept term unless you specify not to include it by using the 'Intercept' name-value pair argument.
- You can find the information in the output of `regress` using the properties and object functions of `LinearModel`.

Output of <code>regress</code>	Equivalent Values in <code>LinearModel</code>
<code>b</code>	See the Estimate column of the Coefficients property.
<code>bint</code>	Use the <code>coefCI</code> function.
<code>r</code>	See the Raw column of the Residuals property.
<code>rint</code>	Not supported. Instead, use studentized residuals (<code>Residuals</code> property) and observation diagnostics (<code>Diagnostics</code> property) to find outliers.
<code>stats</code>	See the model display in the Command Window. You can find the statistics in the model properties (MSE and <code>Rsquared</code>) and by using the <code>anova</code> function.

Introduced before R2006a

RegressionBaggedEnsemble

Package: classreg.learning.regr

Superclasses:

Regression ensemble grown by resampling

Description

RegressionBaggedEnsemble combines a set of trained weak learner models and data on which these learners were trained. It can predict ensemble response for new data by aggregating predictions from its weak learners.

Construction

Create a bagged regression ensemble object using `fitrensemble`. Set the name-value pair argument 'Method' of `fitrensemble` to 'Bag' to use bootstrap aggregation (bagging, for example, random forest).

Properties

BinEdges

Bin edges for numeric predictors, specified as a cell array of p numeric vectors, where p is the number of predictors. Each vector includes the bin edges for a numeric predictor. The element in the cell array for a categorical predictor is empty because the software does not bin categorical predictors.

The software bins numeric predictors only if you specify the 'NumBins' name-value pair argument as a positive integer scalar when training a model with tree learners. The `BinEdges` property is empty if the 'NumBins' value is empty (default).

You can reproduce the binned predictor data `Xbinned` by using the `BinEdges` property of the trained model `mdl`.

```
X = mdl.X; % Predictor data
Xbinned = zeros(size(X));
```

```
edges = mdl.BinEdges;
% Find indices of binned predictors.
idxNumeric = find(~cellfun(@isempty,edges));
if iscolumn(idxNumeric)
    idxNumeric = idxNumeric';
end
for j = idxNumeric
    x = X(:,j);
    % Convert x to array if x is a table.
    if istable(x)
        x = table2array(x);
    end
    % Group x into bins by using the discretize function.
    xbinned = discretize(x,[-inf; edges{j}; inf]);
    Xbinned(:,j) = xbinned;
end
```

Xbinned contains the bin indices, ranging from 1 to the number of bins, for numeric predictors. Xbinned values are 0 for categorical predictors. If X contains NaNs, then the corresponding Xbinned values are NaNs.

CategoricalPredictors

Categorical predictor indices, specified as a vector of positive integers. **CategoricalPredictors** contains index values corresponding to the columns of the predictor data that contain categorical predictors. If none of the predictors are categorical, then this property is empty ([]).

CombineWeights

A character vector describing how the ensemble combines learner predictions.

ExpandedPredictorNames

Expanded predictor names, stored as a cell array of character vectors.

If the model uses encoding for categorical variables, then **ExpandedPredictorNames** includes the names that describe the expanded variables. Otherwise, **ExpandedPredictorNames** is the same as **PredictorNames**.

FitInfo

A numeric array of fit information. The **FitInfoDescription** property describes the content of this array.

FitInfoDescription

Character vector describing the meaning of the `FitInfo` array.

FResample

A numeric scalar between 0 and 1. `FResample` is the fraction of training data `fitrensemble` resampled at random for every weak learner when constructing the ensemble.

HyperparameterOptimizationResults

Description of the cross-validation optimization of hyperparameters, stored as a `BayesianOptimization` object or a table of hyperparameters and associated values. Nonempty when the `OptimizeHyperparameters` name-value pair is nonempty at creation. Value depends on the setting of the `HyperparameterOptimizationOptions` name-value pair at creation:

- `'bayesopt'` (default) — Object of class `BayesianOptimization`
- `'gridsearch'` or `'randomsearch'` — Table of hyperparameters used, observed objective function values (cross-validation loss), and rank of observations from lowest (best) to highest (worst)

LearnerNames

Cell array of character vectors with names of the weak learners in the ensemble. The name of each learner appears just once. For example, if you have an ensemble of 100 trees, `LearnerNames` is `{ 'Tree' }`.

Method

A character vector with the name of the algorithm `fitrensemble` used for training the ensemble.

ModelParameters

Parameters used in training `ens`.

NumObservations

Numeric scalar containing the number of observations in the training data.

NumTrained

Number of trained learners in the ensemble, a positive scalar.

PredictorNames

A cell array of names for the predictor variables, in the order in which they appear in X .

ReasonForTermination

A character vector describing the reason `fitensemble` stopped adding weak learners to the ensemble.

Regularization

A structure containing the result of the `regularize` method. Use `Regularization` with `shrink` to lower resubstitution error and shrink the ensemble.

Replace

Boolean flag indicating if training data for weak learners in this ensemble were sampled with replacement. `Replace` is `true` for sampling with replacement, `false` otherwise.

ResponseName

A character vector with the name of the response variable Y .

ResponseTransform

Function handle for transforming scores, or character vector representing a built-in transformation function. 'none' means no transformation; equivalently, 'none' means $@(x)x$.

Add or change a `ResponseTransform` function using dot notation:

```
ens.ResponseTransform = @function
```

Trained

The trained learners, a cell array of compact regression models.

TrainedWeights

A numeric vector of weights the ensemble assigns to its learners. The ensemble computes predicted response by aggregating weighted predictions from its learners.

UseObsForLearner

A logical matrix of size N -by- NumTrained , where N is the number of rows (observations) in the training data X , and NumTrained is the number of trained weak learners. $\text{UseObsForLearner}(I, J)$ is `true` if observation I was used for training learner J , and is `false` otherwise.

W

The scaled weights, a vector with length n , the number of rows in X . The sum of the elements of W is 1.

X

The matrix or table of predictor values that trained the ensemble. Each column of X represents one variable, and each row represents one observation.

Y

The numeric column vector with the same number of rows as X that trained the ensemble. Each entry in Y is the response to the data in the corresponding row of X .

Methods

<code>oobLoss</code>	Out-of-bag regression error
<code>oobPermutedPredictorImportance</code>	Predictor importance estimates by permutation of out-of-bag predictor observations for random forest of regression trees
<code>oobPredict</code>	Predict out-of-bag response of ensemble

Inherited Methods

<code>compact</code>	Create compact regression ensemble
<code>crossval</code>	Cross validate ensemble
<code>cvshrink</code>	Cross validate shrinking (pruning) ensemble
<code>regularize</code>	Find weights to minimize resubstitution error plus penalty term
<code>resubLoss</code>	Regression error by resubstitution
<code>resubPredict</code>	Predict response of ensemble by resubstitution
<code>resume</code>	Resume training ensemble
<code>shrink</code>	Prune ensemble
<code>loss</code>	Regression error
<code>predict</code>	Predict responses using ensemble of regression models
<code>predictorImportance</code>	Estimates of predictor importance
<code>removeLearners</code>	Remove members of compact regression ensemble

Copy Semantics

Value. To learn how value classes affect copy operations, see [Copying Objects \(MATLAB\)](#).

Examples

Train Bagged Ensemble of Regression Trees

Load the `carsmall` data set. Consider a model that explains a car's fuel economy (MPG) using its weight (`Weight`) and number of cylinders (`Cylinders`).

```
load carsmall
X = [Weight Cylinders];
Y = MPG;
```

Train a bagged ensemble of 100 regression trees using all measurements.

```
Mdl = fitensemble(X,Y,'Method','bag')
```

```
Mdl =
  classreg.learning.regr.RegressionBaggedEnsemble
    ResponseName: 'Y'
    CategoricalPredictors: []
    ResponseTransform: 'none'
    NumObservations: 94
    NumTrained: 100
    Method: 'Bag'
    LearnerNames: {'Tree'}
    ReasonForTermination: 'Terminated normally after completing the requested number of iterations'
    FitInfo: []
    FitInfoDescription: 'None'
    Regularization: []
    FResample: 1
    Replace: 1
    UseObsForLearner: [94x100 logical]
```

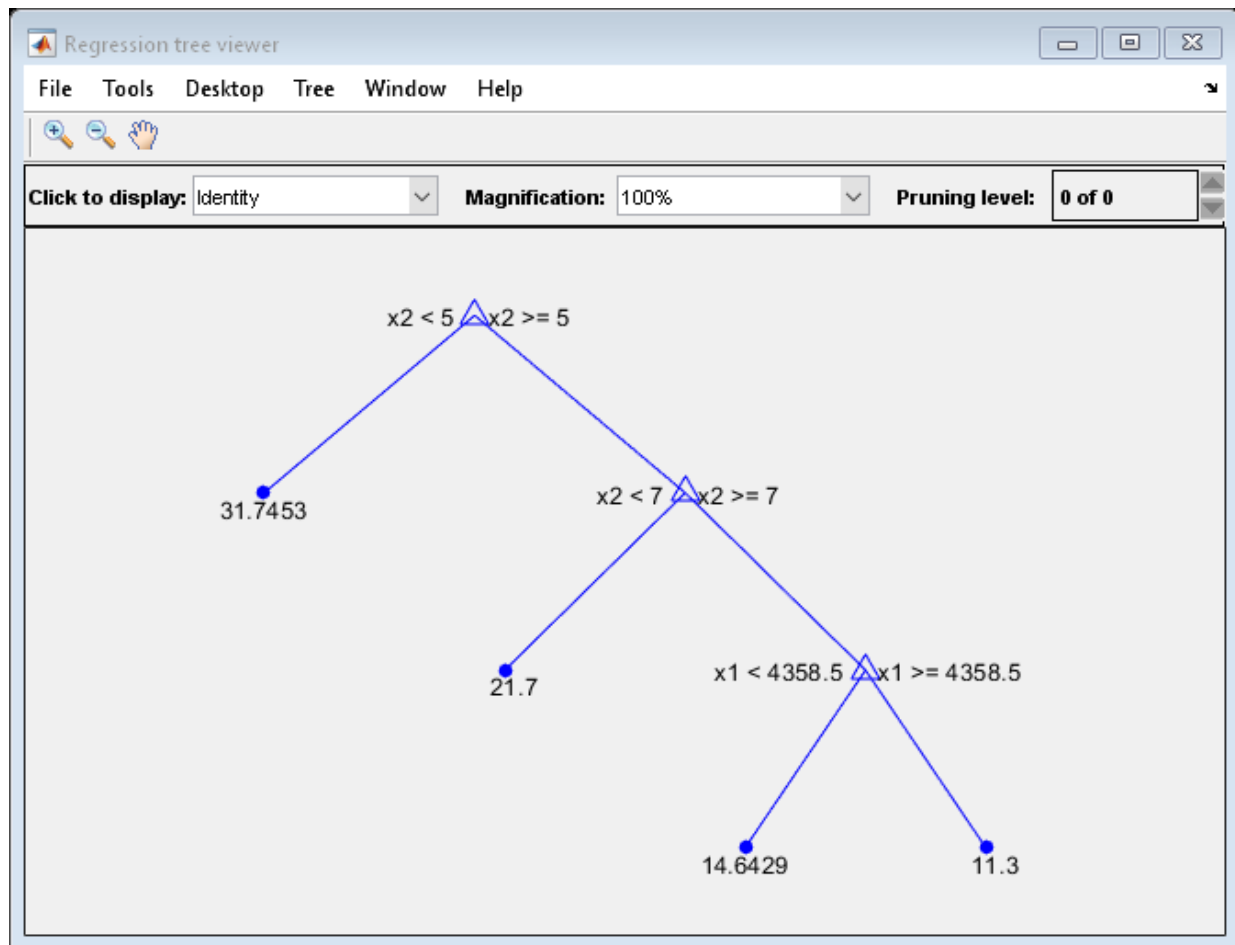

Properties, Methods

Mdl is a RegressionBaggedEnsemble model object.

Mdl.Trained is the property that stores a 100-by-1 cell vector of the trained, compact regression trees (CompactRegressionTree model objects) that compose the ensemble.

Plot a graph of the first trained regression tree.

```
view(Mdl.Trained{1}, 'Mode', 'graph')
```

By default, `fitrenssemble` grows deep trees for bags of trees.

Estimate the in-sample mean-squared error (MSE).

```
L = resubLoss(Mdl)
```

```
L = 18.7591
```

Tip

For a bagged ensemble of regression trees, the `Trained` property of `ens` stores a cell vector of `ens.NumTrained CompactRegressionTree` model objects. For a textual or graphical display of tree `t` in the cell vector, enter

```
view(ens.Trained{t})
```

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The `predict` function supports code generation.
- When you train an ensemble by using `fitensemble`, code generation limitations for regression trees also apply to ensembles of regression trees. For more details, see “Code Generation” on page 32-938 of the `CompactRegressionTree` class.

For more information, see “Introduction to Code Generation” on page 31-2.

Introduced in R2011a

RegressionEnsemble

Package: classreg.learning.regr

Superclasses:

Ensemble regression

Description

RegressionEnsemble combines a set of trained weak learner models and data on which these learners were trained. It can predict ensemble response for new data by aggregating predictions from its weak learners.

Construction

Create a regression ensemble object using `fitrensemble`.

Properties

BinEdges

Bin edges for numeric predictors, specified as a cell array of p numeric vectors, where p is the number of predictors. Each vector includes the bin edges for a numeric predictor. The element in the cell array for a categorical predictor is empty because the software does not bin categorical predictors.

The software bins numeric predictors only if you specify the 'NumBins' name-value pair argument as a positive integer scalar when training a model with tree learners. The BinEdges property is empty if the 'NumBins' value is empty (default).

You can reproduce the binned predictor data `Xbinned` by using the BinEdges property of the trained model `mdl`.

```
X = mdl.X; % Predictor data
Xbinned = zeros(size(X));
edges = mdl.BinEdges;
```

```

% Find indices of binned predictors.
idxNumeric = find(~cellfun(@isempty,edges));
if iscolumn(idxNumeric)
    idxNumeric = idxNumeric';
end
for j = idxNumeric
    x = X(:,j);
    % Convert x to array if x is a table.
    if istable(x)
        x = table2array(x);
    end
    % Group x into bins by using the discretize function.
    xbinned = discretize(x,[-inf; edges{j}; inf]);
    Xbinned(:,j) = xbinned;
end

```

Xbinned contains the bin indices, ranging from 1 to the number of bins, for numeric predictors. Xbinned values are 0 for categorical predictors. If X contains NaNs, then the corresponding Xbinned values are NaNs.

CategoricalPredictors

Categorical predictor indices, specified as a vector of positive integers. CategoricalPredictors contains index values corresponding to the columns of the predictor data that contain categorical predictors. If none of the predictors are categorical, then this property is empty ([]).

CombineWeights

A character vector describing how the ensemble combines learner predictions.

ExpandedPredictorNames

Expanded predictor names, stored as a cell array of character vectors.

If the model uses encoding for categorical variables, then ExpandedPredictorNames includes the names that describe the expanded variables. Otherwise, ExpandedPredictorNames is the same as PredictorNames.

FitInfo

A numeric array of fit information. The FitInfoDescription property describes the content of this array.

FitInfoDescription

Character vector describing the meaning of the `FitInfo` array.

LearnerNames

Cell array of character vectors with names of the weak learners in the ensemble. The name of each learner appears just once. For example, if you have an ensemble of 100 trees, `LearnerNames` is `{ 'Tree' }`.

HyperparameterOptimizationResults

Description of the cross-validation optimization of hyperparameters, stored as a `BayesianOptimization` object or a table of hyperparameters and associated values. Nonempty when the `OptimizeHyperparameters` name-value pair is nonempty at creation. Value depends on the setting of the `HyperparameterOptimizationOptions` name-value pair at creation:

- `'bayesopt'` (default) — Object of class `BayesianOptimization`
- `'gridsearch'` or `'randomsearch'` — Table of hyperparameters used, observed objective function values (cross-validation loss), and rank of observations from lowest (best) to highest (worst)

Method

A character vector with the name of the algorithm `fitensemble` used for training the ensemble.

ModelParameters

Parameters used in training `ens`.

NumObservations

Numeric scalar containing the number of observations in the training data.

NumTrained

Number of trained learners in the ensemble, a positive scalar.

PredictorNames

A cell array of names for the predictor variables, in the order in which they appear in `X`.

ReasonForTermination

A character vector describing the reason `fitensemble` stopped adding weak learners to the ensemble.

Regularization

A structure containing the result of the `regularize` method. Use `Regularization` with `shrink` to lower resubstitution error and shrink the ensemble.

ResponseName

A character vector with the name of the response variable Y .

ResponseTransform

Function handle for transforming scores, or character vector representing a built-in transformation function. 'none' means no transformation; equivalently, 'none' means $@(x)x$.

Add or change a `ResponseTransform` function using dot notation:

```
ens.ResponseTransform = @function
```

Trained

The trained learners, a cell array of compact regression models.

TrainedWeights

A numeric vector of weights the ensemble assigns to its learners. The ensemble computes predicted response by aggregating weighted predictions from its learners.

W

The scaled `weights`, a vector with length n , the number of rows in X . The sum of the elements of W is 1.

X

The matrix or table of predictor values that trained the ensemble. Each column of X represents one variable, and each row represents one observation.

Y

The numeric column vector with the same number of rows as X that trained the ensemble. Each entry in Y is the response to the data in the corresponding row of X.

Methods

compact	Create compact regression ensemble
crossval	Cross validate ensemble
cvshrink	Cross validate shrinking (pruning) ensemble
regularize	Find weights to minimize resubstitution error plus penalty term
resubLoss	Regression error by resubstitution
resubPredict	Predict response of ensemble by resubstitution
resume	Resume training ensemble
shrink	Prune ensemble

Inherited Methods

loss	Regression error
predict	Predict responses using ensemble of regression models
predictorImportance	Estimates of predictor importance
removeLearners	Remove members of compact regression ensemble

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects (MATLAB).

Examples

Train Boosted Regression Ensemble

Load the `carsmall` data set. Consider a model that explains a car's fuel economy (MPG) using its weight (Weight) and number of cylinders (Cylinders).

```
load carsmall
X = [Weight Cylinders];
Y = MPG;
```

Train a boosted ensemble of 100 regression trees using the `LSBoost` method. Specify that `Cylinders` is a categorical variable.

```
Mdl = fitrensemble(X,Y,'Method','LSBoost',...
    'PredictorNames',{'W','C'},'CategoricalPredictors',2)
```

```
Mdl =
    classreg.learning.regr.RegistrationEnsemble
        PredictorNames: {'W' 'C'}
        ResponseName: 'Y'
    CategoricalPredictors: 2
        ResponseTransform: 'none'
        NumObservations: 94
        NumTrained: 100
            Method: 'LSBoost'
        LearnerNames: {'Tree'}
    ReasonForTermination: 'Terminated normally after completing the requested number of
        FitInfo: [100x1 double]
    FitInfoDescription: {2x1 cell}
        Regularization: []
```

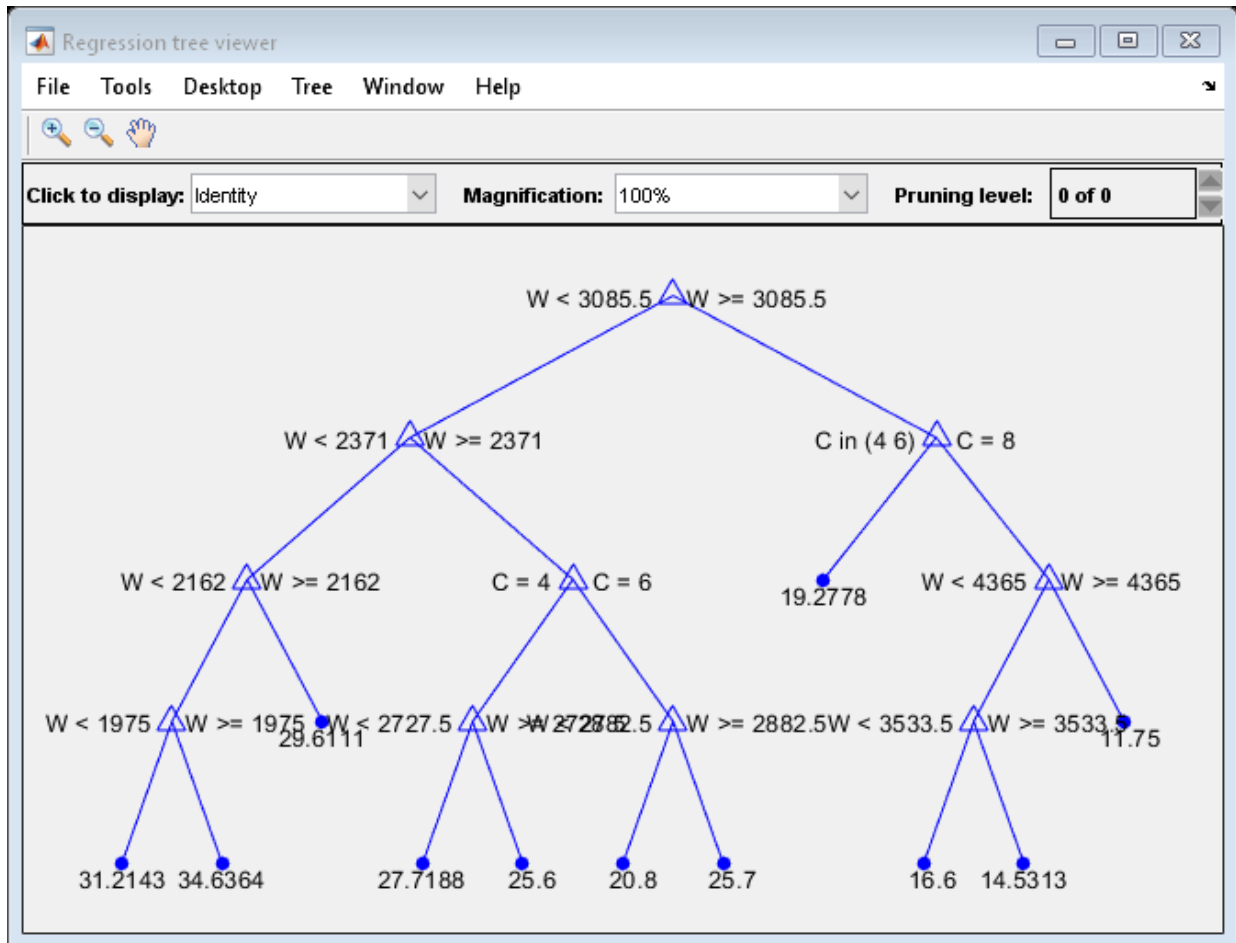

Properties, Methods

`Mdl` is a `RegressionEnsemble` model object that contains the training data, among other things.

`Mdl.Trained` is the property that stores a 100-by-1 cell vector of the trained regression trees (`CompactRegressionTree` model objects) that compose the ensemble.

Plot a graph of the first trained regression tree.

```
view(Mdl.Trained{1}, 'Mode', 'graph')
```

By default, `fitrenssemble` grows shallow trees for boosted ensembles of trees.

Predict the fuel economy of 4,000 pound cars with 4, 6, and 8 cylinders.

```
XNew = [4000*ones(3,1) [4; 6; 8]];
mpgNew = predict(Mdl,XNew)
```

```
mpgNew = 3×1
```

```
19.5926
18.6388
```

15.4810

Tip

For an ensemble of regression trees, the `Trained` property contains a cell vector of `ens.NumTrained CompactRegressionTree` model objects. For a textual or graphical display of tree `t` in the cell vector, enter

```
view(ens.Trained{t})
```

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The `predict` function supports code generation.
- When you train an ensemble by using `fitrensemble`, code generation limitations for regression trees also apply to ensembles of regression trees. For more details, see “Code Generation” on page 32-938 of the `CompactRegressionTree` class.

For more information, see “Introduction to Code Generation” on page 31-2.

Introduced in R2011a

RegressionGP class

Superclasses:

Gaussian process regression model class

Description

RegressionGP is a Gaussian process regression (GPR) model. You can train a GPR model, using `fitrgp`. Using the trained model, you can

- Predict responses for training data using `resubPredict` or new predictor data using `predict`. You can also compute the prediction intervals.
- Compute the regression loss for training data using `resubLoss` or new data using `loss`.

Construction

Create a RegressionGP object by using `fitrgp`.

Properties

Fitting

FitMethod — Method used to estimate the parameters

'none' | 'exact' | 'sd' | 'sr' | 'fic'

Method used to estimate the basis function coefficients, β ; noise standard deviation, σ ; and kernel parameters, θ , of the GPR model, stored as a character vector. It can be one of the following.

Fit Method	Description
'none'	No estimation. <code>fitrgp</code> uses the initial parameter values as the parameter values.

Fit Method	Description
'exact'	Exact Gaussian process regression.
'sd'	Subset of data points approximation.
'sr'	Subset of regressors approximation.
'fic'	Fully independent conditional approximation.

BasisFunction – Explicit basis function

'none' | 'constant' | 'linear' | 'pureQuadratic' | function handle

Explicit basis function used in the GPR model, stored as a character vector or a function handle. It can be one of the following. If n is the number of observations, the basis function adds the term $\mathbf{H}\boldsymbol{\beta}$ to the model, where \mathbf{H} is the basis matrix and $\boldsymbol{\beta}$ is a p -by-1 vector of basis coefficients.

Explicit Basis	Basis Matrix
'none'	Empty matrix.
'constant'	$H = \mathbf{1}$ <p>(n-by-1 vector of 1s, where n is the number of observations)</p>
'linear'	$H = [1, X]$
'pureQuadratic'	$H = [1, X, X_2],$ <p>where</p> $X_2 = \begin{bmatrix} x_{11}^2 & x_{12}^2 & \dots & x_{1d}^2 \\ x_{21}^2 & x_{22}^2 & \dots & x_{2d}^2 \\ \vdots & \vdots & \vdots & \vdots \\ x_{n1}^2 & x_{n2}^2 & \dots & x_{nd}^2 \end{bmatrix}.$

Explicit Basis	Basis Matrix
Function handle	Function handle, <code>hfcn</code> , that <code>fitrgp</code> calls as: $H = hfcn(X),$ where X is an n -by- d matrix of predictors and H is an n -by- p matrix of basis functions.

Data Types: `char` | `function_handle`

Beta — Estimated coefficients

vector

Estimated coefficients for the explicit basis functions, stored as a vector. You can define the explicit basis function by using the `BasisFunction` name-value pair argument in `fitrgp`.

Data Types: `double`

Sigma — Estimated noise standard deviation

scalar value

Estimated noise standard deviation of the GPR model, stored as a scalar value.

Data Types: `double`

CategoricalPredictors — Indices of categorical predictors

vector of positive integers

Categorical predictor indices, specified as a vector of positive integers. `CategoricalPredictors` contains index values corresponding to the columns of the predictor data that contain categorical predictors. If none of the predictors are categorical, then this property is empty (`[]`).

Data Types: `single` | `double`

HyperparameterOptimizationResults — Description of cross-validation optimization of hyperparameters

`BayesianOptimization` object | table

Description of the cross-validation optimization of hyperparameters, specified as a `BayesianOptimization` object or a table of hyperparameters and associated values.

This property is nonempty if the 'OptimizeHyperparameters' name-value pair argument is nonempty when you create the model. The value of `HyperparameterOptimizationResults` depends on the setting of the `Optimizer` field in the `HyperparameterOptimizationOptions` structure when you create the model, as described in this table.

Value of <code>Optimizer</code> Field	Value of <code>HyperparameterOptimizationResults</code>
'bayesopt' (default)	Object of class <code>BayesianOptimization</code>
'gridsearch' or 'randomsearch'	Table of hyperparameters used, observed objective function values (cross-validation loss), and rank of observations from lowest (best) to highest (worst)

LogLikelihood — Maximized marginal log likelihood

scalar value | []

Maximized marginal log likelihood of the GPR model, stored as a scalar value if the `FitMethod` is different from 'none'. If `FitMethod` is 'none', then `LogLikelihood` is empty.

If `FitMethod` is 'sd', 'sr', or 'fic', then `LogLikelihood` is the maximized approximation of the marginal log likelihood of the GPR model.

Data Types: double

ModelParameters — Parameters used for training

GPParams object

Parameters used for training the GPR model, stored as a GPParams object.

Kernel Function

KernelFunction — Form of the covariance function

'squaredExponential' | 'matern32' | 'matern52' | 'ardsquaredexponential' | 'ardmatern32' | 'ardmatern52' | function handle

Form of the covariance function used in the GPR model, stored as a character vector containing the name of the built-in covariance function or a function handle. It can be one of the following.

Function	Description
'squaredexponential'	Squared exponential kernel.
'matern32'	Matern kernel with parameter 3/2.
'matern52'	Matern kernel with parameter 5/2.
'ardsquaredexponential'	Squared exponential kernel with a separate length scale per predictor.
'ardmatern32'	Matern kernel with parameter 3/2 and a separate length scale per predictor.
'ardmatern52'	Matern kernel with parameter 5/2 and a separate length scale per predictor.
Function handle	A function handle that <code>fitrgp</code> can call like this: $K_{mn} = \text{kfcn}(X_m, X_n, \theta)$ where X_m is an m -by- d matrix, X_n is an n -by- d matrix and K_{mn} is an m -by- n matrix of kernel products such that $K_{mn}(i,j)$ is the kernel product between $X_m(i,:)$ and $X_n(j,:)$. θ is the r -by-1 unconstrained parameter vector for <code>kfcn</code> .

Data Types: char | function_handle

KernelInformation — Information about the parameters of the kernel function structure

Information about the parameters of the kernel function used in the GPR model, stored as a structure with the following fields.

Field Name	Description
Name	Name of the kernel function
KernelParameters	Vector of the estimated kernel parameters
KernelParameterNames	Names associated with the elements of KernelParameters.

Data Types: struct

Prediction**PredictMethod — Method used to make predictions**

'exact' | 'bcd' | 'sd' | 'sr' | 'fic'

Method that `predict` uses to make predictions from the GPR model, stored as a character vector. It can be one of the following.

PredictMethod	Description
'exact'	Exact Gaussian process regression
'bcd'	Block Coordinate Descent
'sd'	Subset of Data points approximation
'sr'	Subset of Regressors approximation
'fic'	Fully Independent Conditional approximation

Alpha — Weights

numeric vector

Weights used to make predictions from the trained GPR model, stored as a numeric vector. `predict` computes the predictions for a new predictor matrix X_{new} by using the product

$$K(X_{new}, A) * \alpha .$$

$K(X_{new}, A)$ is the matrix of kernel products between X_{new} and active set vector A and α is a vector of weights.

Data Types: double

BCDInformation — Information on BCD-based computation of Alpha

structure | []

Information on block coordinate descent (BCD)-based computation of `Alpha` when `PredictMethod` is 'bcd', stored as a structure containing the following fields.

Field Name	Description
Gradient	n -by-1 vector containing the gradient of the BCD objective function at convergence.

Field Name	Description
Objective	Scalar containing the BCD objective function at convergence.
SelectionCounts	n -by-1 integer vector indicating the number of times each point was selected into a block during BCD.

Alpha property contains the Alpha vector computed from BCD.

If PredictMethod is not 'bcd', then BCDInformation is empty.

Data Types: struct

ResponseTransform — Transformation applied to predicted response

'none' (default)

Transformation applied to the predicted response, stored as a character vector describing how the response values predicted by the model are transformed. In RegressionGP, ResponseTransform is 'none' by default, and RegressionGP does not use ResponseTransform when making predictions.

Active Set Selection

ActiveSetVectors — Subset of training data

matrix

Subset of training data used to make predictions from the GPR model, stored as a matrix.

predict computes the predictions for a new predictor matrix X_{new} by using the product

$$K(X_{new}, A) * \alpha .$$

$K(X_{new}, A)$ is the matrix of kernel products between X_{new} and active set vector \mathbf{A} and α is a vector of weights.

ActiveSetVectors is equal to the training data X for exact GPR fitting and a subset of the training data X for sparse GPR methods. When there are categorical predictors in the model, ActiveSetVectors contains dummy variables for the corresponding predictors.

Data Types: double

ActiveSetHistory — History of active set selection and parameter estimation

structure

History of interleaved active set selection and parameter estimation on page 32-5801 for `FitMethod` equal to 'sd', 'sr', or 'fic', stored as a structure with the following fields.

Field Name	Description
ParameterVector	Cell array containing the parameter vectors: basis function coefficients, β , kernel function parameters θ , and noise standard deviation σ .
ActiveSetIndices	Cell array containing the active set indices.
Loglikelihood	Vector containing the maximized log likelihoods.
CriterionProfile	Cell array containing the active set selection criterion values as the active set grows from size 0 to its final size.

Data Types: struct

ActiveSetMethod — Method used to select the active set

'sgma' | 'entropy' | 'likelihood' | 'random'

Method used to select the active set for sparse methods ('sd', 'sr', or 'fic'), stored as a character vector. It can be one of the following.

ActiveSetMethod	Description
'sgma'	Sparse greedy matrix approximation
'entropy'	Differential entropy-based selection
'likelihood'	Subset of regressors log likelihood-based selection
'random'	Random selection

The selected active set is used in parameter estimation or prediction, depending on the choice of `FitMethod` and `PredictMethod` in `fitrgp`.

ActiveSetSize — Size of the active set

integer value

Size of the active set for sparse methods ('sd', 'sr', or 'fic'), stored as an integer value.

Data Types: `double`

IsActiveSetVector — Indicators for selected active set

logical vector

Indicators for selected active set for making predictions from the trained GPR model, stored as a logical vector. These indicators mark the subset of training data that `fitrgp` selects as the active set. For example, if `X` is the original training data, then `ActiveSetVectors = X(IsActiveSetVector, :)`.

Data Types: `logical`

Training Data**NumObservations — Number of observations in training data**

scalar value

Number of observations in training data, stored as a scalar value.

Data Types: `double`

X — Training data

n-by-*d* table | *n*-by-*d* matrix

Training data, stored as an *n*-by-*d* table or matrix, where *n* is the number of observations and *d* is the number of predictor variables (columns) in the training data. If the GPR model is trained on a table, then `X` is a table. Otherwise, `X` is a matrix.

Data Types: `double` | `table`

Y — Observed response values

n-by-1 vector

Observed response values used to train the GPR model, stored as an *n*-by-1 vector, where *n* is the number of observations.

Data Types: `double`

PredictorNames — Names of predictors

cell array of character vectors

Names of predictors used in the GPR model, stored as a cell array of character vectors. Each name (cell) corresponds to a column in `X`.

Data Types: `cell`

ExpandedPredictorNames — Names of expanded predictors

cell array of character vectors

Names of expanded predictors for the GPR model, stored as a cell array of character vectors. Each name (cell) corresponds to a column in `ActiveSetVectors`.

If the model uses dummy variables for categorical variables, then `ExpandedPredictorNames` includes the names that describe the expanded variables. Otherwise, `ExpandedPredictorNames` is the same as `PredictorNames`.

Data Types: cell

ResponseName — Name of the response variable

character vector

Name of the response variable in the GPR model, stored as a character vector.

Data Types: char

PredictorLocation — Means of predictors

1-by- d vector | []

Means of predictors used for training the GPR model if the training data is standardized, stored as a 1-by- d vector. If the training data is not standardized, `PredictorLocation` is empty.

If `PredictorLocation` is not empty, then the `predict` method centers the predictor values by subtracting the respective element of `PredictorLocation` from every column of X .

If there are categorical predictors, then `PredictorLocation` includes a 0 for each dummy variable corresponding to those predictors. The dummy variables are not centered or scaled.

Data Types: double

PredictorScale — Standard deviations of predictors

1-by- d vector | []

Standard deviations of predictors used for training the GPR model if the training data is standardized, stored as a 1-by- d vector. If the training data is not standardized, `PredictorScale` is empty.

If `PredictorScale` is not empty, the `predict` method scales the predictors by dividing every column of `X` by the respective element of `PredictorScale` (after centering using `PredictorLocation`).

If there are categorical predictors, then `PredictorLocation` includes a 1 for each dummy variable corresponding to those predictors. The dummy variables are not centered or scaled.

Data Types: `double`

RowsUsed — Indicators for rows used in training

logical vector | []

Indicators for rows used in training the GPR model, stored as a logical vector. If all rows are used in training the model, then `RowsUsed` is empty.

Data Types: `logical`

Methods

<code>compact</code>	Create compact Gaussian process regression model
<code>crossval</code>	Cross-validate Gaussian process regression model
<code>postFitStatistics</code>	Compute post-fit statistics for the exact Gaussian process regression model
<code>resubLoss</code>	Resubstitution loss for a trained Gaussian process regression model
<code>resubPredict</code>	Resubstitution prediction from a trained Gaussian process regression model

Inherited Methods

<code>loss</code>	Regression error for Gaussian process regression model
<code>predict</code>	Predict response of Gaussian process regression model

Definitions

Active Set Selection and Parameter Estimation

For subset of data, subset of regressors, or fully independent conditional approximation fitting methods (FitMethod equal to 'sd', 'sr', or 'fic'), if you do not provide the active set, `fitrgp` selects the active set and computes the parameter estimates in a series of iterations.

In the first iteration, the software uses the initial parameter values in vector $\eta_0 = [\beta_0, \sigma_0, \theta_0]$ to select an active set A_1 . It maximizes the GPR marginal log likelihood or its approximation using η_0 as the initial values and A_1 to compute the new parameter estimates η_1 . Next, it computes the new log likelihood L_1 using η_1 and A_1 .

In the second iteration, the software selects the active set A_2 using the parameter values in η_1 . Then, using η_1 as the initial values and A_2 , it maximizes the GPR marginal log likelihood or its approximation and estimates the new parameter values η_2 . Then using η_2 and A_2 , computes the new log likelihood value L_2 .

The following table summarizes the iterations and what is computed at each iteration.

Iteration Number	Active Set	Parameter Vector	Log Likelihood
1	A_1	η_1	L_1
2	A_2	η_2	L_2
3	A_3	η_3	L_3
...

The software iterates similarly for a specified number of repetitions. You can specify the number of replications for active set selection using the `NumActiveSetRepeats` name-value pair argument.

Tips

- You can access the properties of this class using dot notation. For example, `KernelInformation` is a structure holding the kernel parameters and their names. Hence, to access the kernel function parameters of the trained model `gprMdl`, use `gprMdl.KernelInformation.KernelParameters`.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The `predict` function supports code generation.
- When you train a Gaussian process regression model by using `fitrgp`, you cannot supply training data in a table that contains a logical vector, character array, categorical array, string array, or cell array of character vectors. Also, you cannot use the `'CategoricalPredictors'` name-value pair argument. Code generation does not support categorical predictors. To include categorical predictors in a model, preprocess the categorical predictors by using `dummyvar` before fitting the model.

For more information, see “Introduction to Code Generation” on page 31-2.

RegressionLinear class

Linear regression model for high-dimensional data

Description

RegressionLinear is a trained linear model object for regression; the linear model is a support vector machine regression (SVM) or linear regression model. `fitrlinear` fits a RegressionLinear model by minimizing the objective function using techniques that reduce computation time for high-dimensional data sets (e.g., stochastic gradient descent). The regression loss plus the regularization term compose the objective function.

Unlike other regression models, and for economical memory usage, RegressionLinear model objects do not store the training data. However, they do store, for example, the estimated linear model coefficients, estimated coefficients, and the regularization strength.

You can use trained RegressionLinear models to predict responses for new data. For details, see `predict`.

Construction

Create a RegressionLinear object by using `fitrlinear`.

Properties

Linear Regression Properties

Epsilon — Half of width of epsilon-insensitive band

nonnegative scalar

Half of the width of the epsilon-insensitive-band, specified as a nonnegative scalar.

If `Learner` is not `'svm'`, then `Epsilon` is an empty array (`[]`).

Data Types: `single` | `double`

Lambda — Regularization term strength

nonnegative scalar | vector of nonnegative values

Regularization term strength, specified as a nonnegative scalar or vector of nonnegative values.

Data Types: double | single

Learner — Linear regression model type

'leastsquares' | 'svm'

Linear regression model type, specified as 'leastsquares' or 'svm'.

In this table, $f(x) = x\beta + b$.

- β is a vector of p coefficients.
- x is an observation from p predictor variables.
- b is the scalar bias.

Value	Algorithm	Loss function	FittedLoss Value
'leastsquares'	Linear regression via ordinary least squares	Mean squared error (MSE): $\ell[y, f(x)]$ $= \frac{1}{2}[y - f(x)]^2$	'mse'
'svm'	Support vector machine regression	Epsilon-insensitive: $\ell[y, f(x)] = \max$ $[0, y - f(x) - \varepsilon]$	'epsiloninsensitive'

Beta — Linear coefficient estimates

numeric vector

Linear coefficient estimates, specified as a numeric vector with length equal to the number of predictors.

Data Types: double

Bias — Estimated bias term

numeric scalar

Estimated bias term or model intercept, specified as a numeric scalar.

Data Types: double

FittedLoss — Loss function used to fit the linear model

'epsiloninsensitive' | 'mse'

Loss function used to fit the model, specified as 'epsiloninsensitive' or 'mse'.

Value	Algorithm	Loss function	Learner Value
'epsiloninsensitive'	Support vector machine regression	Epsilon-insensitive: $\ell[y, f(x)] = \max[0, y - f(x) - \varepsilon]$	'svm'
'mse'	Linear regression via ordinary least squares	Mean squared error (MSE): $\ell[y, f(x)] = \frac{1}{2}[y - f(x)]^2$	'leastquares'

Regularization — Complexity penalty type

'lasso (L1)' | 'ridge (L2)'

Complexity penalty type, specified as 'lasso (L1)' or 'ridge (L2)'.

The software composes the objective function for minimization from the sum of the average loss function (see FittedLoss) and a regularization value from this table.

Value	Description
'lasso (L1)'	Lasso (L_1) penalty: $\lambda \sum_{j=1}^p \beta_j $
'ridge (L2)'	Ridge (L_2) penalty: $\frac{\lambda}{2} \sum_{j=1}^p \beta_j^2$

λ specifies the regularization term strength (see Lambda).

The software excludes the bias term (β_0) from the regularization penalty.

Other Regression Properties

ModelParameters — Parameters used for training model

structure

Parameters used for training the `RegressionLinear` model, specified as a structure.

Access fields of `ModelParameters` using dot notation. For example, access the relative tolerance on the linear coefficients and the bias term by using `Mdl.ModelParameters.BetaTolerance`.

Data Types: `struct`

PredictorNames — Predictor names

cell array of character vectors

Predictor names in order of their appearance in the predictor data `X`, specified as a cell array of character vectors. The length of `PredictorNames` is equal to the number of columns in `X`.

Data Types: `cell`

ExpandedPredictorNames — Expanded predictor names

cell array of character vectors

Expanded predictor names, specified as a cell array of character vectors.

Because a `RegressionLinear` model does not support categorical predictors, `ExpandedPredictorNames` and `PredictorNames` are equal.

Data Types: `cell`

ResponseName — Response variable name

character vector

Response variable name, specified as a character vector.

Data Types: `char`

ResponseTransform — Response transformation function

'none' | function handle

Response transformation function, specified as 'none' or a function handle. `ResponseTransform` describes how the software transforms raw response values.

For a MATLAB function, or a function that you define, enter its function handle. For example, you can enter `Mdl.ResponseTransform = @function`, where *function* accepts a numeric vector of the original responses and returns a numeric vector of the same size containing the transformed responses.

Data Types: char | function_handle

Methods

loss	Regression loss for linear regression models
predict	Predict response of linear regression model
selectModels	Select fitted regularized linear regression models

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects (MATLAB).

Examples

Train Linear Regression Model

Train a linear regression model using SVM, dual SGD, and ridge regularization.

Simulate 10000 observations from this model

$$y = x_{100} + 2x_{200} + e.$$

- $X = x_1, \dots, x_{1000}$ is a 10000-by-1000 sparse matrix with 10% nonzero standard normal elements.
- e is random normal error with mean 0 and standard deviation 0.3.

```
rng(1) % For reproducibility
n = 1e4;
d = 1e3;
nz = 0.1;
X = sprandn(n,d,nz);
Y = X(:,100) + 2*X(:,200) + 0.3*randn(n,1);
```

Train a linear regression model. By default, `fitrlinear` uses support vector machines with a ridge penalty, and optimizes using dual SGD for SVM. Determine how well the optimization algorithm fit the model to the data by extracting a fit summary.

```
[Mdl,FitInfo] = fitrlinear(X,Y)
```

```
Mdl =  
  RegressionLinear  
    ResponseName: 'Y'  
    ResponseTransform: 'none'  
        Beta: [1000x1 double]  
        Bias: -0.0056  
    Lambda: 1.0000e-04  
    Learner: 'svm'
```

Properties, Methods

```
FitInfo = struct with fields:  
    Lambda: 1.0000e-04  
    Objective: 0.2725  
    PassLimit: 10  
    NumPasses: 10  
    BatchLimit: []  
    NumIterations: 100000  
    GradientNorm: NaN  
    GradientTolerance: 0  
    RelativeChangeInBeta: 0.4907  
    BetaTolerance: 1.0000e-04  
    DeltaGradient: 1.5816  
    DeltaGradientTolerance: 0.1000  
    TerminationCode: 0  
    TerminationStatus: {'Iteration limit exceeded.'}  
    Alpha: [10000x1 double]  
    History: []  
    FitTime: 0.0912  
    Solver: {'dual'}
```

`Mdl` is a `RegressionLinear` model. You can pass `Mdl` and the training or new data to `loss` to inspect the in-sample mean-squared error. Or, you can pass `Mdl` and new predictor data to `predict` to predict responses for new observations.

`FitInfo` is a structure array containing, among other things, the termination status (`TerminationStatus`) and how long the solver took to fit the model to the data (`FitTime`). It is good practice to use `FitInfo` to determine whether optimization-termination measurements are satisfactory. In this case, `fitrlinear` reached the

maximum number of iterations. Because training time is fast, you can retrain the model, but increase the number of passes through the data. Or, try another solver, such as LBFGS.

Predict Responses Using Linear Regression Model

Simulate 10000 observations from this model

$$y = x_{100} + 2x_{200} + e.$$

- $X = \{x_1, \dots, x_{1000}\}$ is a 10000-by-1000 sparse matrix with 10% nonzero standard normal elements.
- e is random normal error with mean 0 and standard deviation 0.3.

```
rng(1) % For reproducibility
n = 1e4;
d = 1e3;
nz = 0.1;
X = sprandn(n,d,nz);
Y = X(:,100) + 2*X(:,200) + 0.3*randn(n,1);
```

Hold out 5% of the data.

```
rng(1); % For reproducibility
cvp = cvpartition(n,'Holdout',0.05)
```

```
cvp =
Hold-out cross validation partition
  NumObservations: 10000
   NumTestSets: 1
   TrainSize: 9500
   TestSize: 500
```

`cvp` is a `CVPARTITION` object that defines the random partition of n data into training and test sets.

Train a linear regression model using the training set. For faster training time, orient the predictor data matrix so that the observations are in columns.

```
idxTrain = training(cvp); % Extract training set indices
X = X';
Mdl = fitrlinear(X(:,idxTrain),Y(idxTrain),'ObservationsIn','columns');
```

Predict observations and the mean squared error (MSE) for the hold out sample.

```
idxTest = test(cvp); % Extract test set indices
yHat = predict(Mdl,X(:,idxTest),'ObservationsIn','columns');
L = loss(Mdl,X(:,idxTest),Y(idxTest),'ObservationsIn','columns')
```

```
L = 0.1851
```

The hold-out sample MSE is 0.1852.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The `predict` function supports code generation.
- When you train a linear regression model by using `fitrlinear`, the following restrictions apply.
 - The predictor data input argument value (`X`) must be a full numeric matrix.
 - You can specify only one regularization strength, either `'auto'` or a nonnegative scalar for the `'Lambda'` name-value pair argument.
 - The value of the `'ResponseTransform'` name-value pair argument cannot be an anonymous function.

For more information, see “Introduction to Code Generation” on page 31-2.

Introduced in R2016a

RegressionPartitionedEnsemble

Package: `classreg.learning.partition`

Superclasses:

Cross-validated regression ensemble

Description

`RegressionPartitionedEnsemble` is a set of regression ensembles trained on cross-validated folds. Estimate the quality of classification by cross validation using one or more “kfold” methods: `kfoldfun`, `kfoldLoss`, or `kfoldPredict`. Every “kfold” method uses models trained on in-fold observations to predict response for out-of-fold observations. For example, suppose you cross validate using five folds. In this case, every training fold contains roughly 4/5 of the data and every test fold contains roughly 1/5 of the data. The first model stored in `Trained{1}` was trained on X and Y with the first 1/5 excluded, the second model stored in `Trained{2}` was trained on X and Y with the second 1/5 excluded, and so on. When you call `kfoldPredict`, it computes predictions for the first 1/5 of the data using the first model, for the second 1/5 of data using the second model and so on. In short, response for every observation is computed by `kfoldPredict` using the model trained without this observation.

Construction

`cvens = crossval(ens)` creates a cross-validated ensemble from `ens`, a regression ensemble. For syntax details, see the `crossval` method reference page.

`cvens = fitrensemble(X,Y,Name,Value)` creates a cross-validated ensemble when `Name` is one of `'crossval'`, `'kfold'`, `'holdout'`, `'leaveout'`, or `'cvpartition'`. For syntax details, see the `fitrensemble` function reference page.

Input Arguments

ens

A regression ensemble constructed with `fitrensemble`.

Properties

BinEdges

Bin edges for numeric predictors, specified as a cell array of p numeric vectors, where p is the number of predictors. Each vector includes the bin edges for a numeric predictor. The element in the cell array for a categorical predictor is empty because the software does not bin categorical predictors.

The software bins numeric predictors only if you specify the 'NumBins' name-value pair argument as a positive integer scalar when training a model with tree learners. The BinEdges property is empty if the 'NumBins' value is empty (default).

You can reproduce the binned predictor data `Xbinned` by using the `BinEdges` property of the trained model `mdl`.

```
X = mdl.X; % Predictor data
Xbinned = zeros(size(X));
edges = mdl.BinEdges;
% Find indices of binned predictors.
idxNumeric = find(~cellfun(@isempty,edges));
if iscolumn(idxNumeric)
    idxNumeric = idxNumeric';
end
for j = idxNumeric
    x = X(:,j);
    % Convert x to array if x is a table.
    if istable(x)
        x = table2array(x);
    end
    % Group x into bins by using the discretize function.
    xbinned = discretize(x,[-inf; edges{j}; inf]);
    Xbinned(:,j) = xbinned;
end
```

`Xbinned` contains the bin indices, ranging from 1 to the number of bins, for numeric predictors. `Xbinned` values are 0 for categorical predictors. If `X` contains NaNs, then the corresponding `Xbinned` values are NaNs.

CategoricalPredictors

Categorical predictor indices, specified as a vector of positive integers. `CategoricalPredictors` contains index values corresponding to the columns of the

predictor data that contain categorical predictors. If none of the predictors are categorical, then this property is empty (`[]`).

CrossValidatedModel

Name of the cross-validated model, a character vector.

Kfold

Number of folds used in a cross-validated tree, a positive integer.

ModelParameters

Object holding parameters of `tree`.

NumObservations

Numeric scalar containing the number of observations in the training data.

NTrainedPerFold

Vector of `Kfold` elements. Each entry contains the number of trained learners in this cross-validation fold.

Partition

The partition of class `cvpartition` used in creating the cross-validated ensemble.

PredictorNames

A cell array of names for the predictor variables, in the order in which they appear in `X`.

ResponseName

Name of the response variable `Y`, a character vector.

ResponseTransform

Function handle for transforming scores, or character vector representing a built-in transformation function. 'none' means no transformation; equivalently, '`none`' means $@(x)x$.

Add or change a `ResponseTransform` function using dot notation:

```
ens.ResponseTransform = @function
```

Trainable

Cell array of ensembles trained on cross-validation folds. Every ensemble is full, meaning it contains its training data and weights.

Trained

Cell array of compact ensembles trained on cross-validation folds.

W

The scaled `weights`, a vector with length `n`, the number of rows in `X`.

X

A matrix or table of predictor values. Each column of `X` represents one variable, and each row represents one observation.

Y

A numeric column vector with the same number of rows as `X`. Each entry in `Y` is the response to the data in the corresponding row of `X`.

Methods

<code>kfoldLoss</code>	Cross-validation loss of partitioned regression ensemble
<code>resume</code>	Resume training ensemble

Inherited Methods

<code>kfoldfun</code>	Cross validate function
<code>kfoldLoss</code>	Cross-validation loss of partitioned regression model
<code>kfoldPredict</code>	Predict response for observations not used for training

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects (MATLAB).

Examples

Construct Partitioned Regression Ensemble

Construct a partitioned regression ensemble, and examine the cross-validation losses for the folds.

Load the `carsmall` data set.

```
load carsmall;
```

Create a subset of variables.

```
XX = [Cylinders Displacement Horsepower Weight];  
YY = MPG;
```

Construct the ensemble model.

```
rens = fitensemble(XX,YY);
```

Create a cross-validated ensemble from `rens`.

```
rng(10,'twister') % For reproducibility  
cvrens = crossval(rens);
```

Examine the cross-validation losses.

```
L = kfoldLoss(cvrens,'mode','individual')
```

```
L = 10×1
```

```
21.4489  
48.4388  
28.2223  
17.5354  
29.9441  
49.5254  
43.8872  
31.0152
```

31.6388
8.9607

L is a vector containing the cross-validation loss for each trained learner in the ensemble.

RegressionPartitionedLinear

Package: `classreg.learning.partition`

Superclasses:

Cross-validated linear regression model for high-dimensional data

Description

`RegressionPartitionedLinear` is a set of linear regression models trained on cross-validated folds. To obtain a cross-validated, linear regression model, use `fitrlinear` and specify one of the cross-validation options. You can estimate the predictive quality of the model, or how well the linear regression model generalizes, using one or more of these “kfold” methods: `kfoldPredict` and `kfoldLoss`.

Every “kfold” method uses models trained on in-fold observations to predict the response for out-of-fold observations. For example, suppose that you cross-validate using five folds. In this case, the software randomly assigns each observation into five roughly equally sized groups. The training fold contains four of the groups (that is, roughly 4/5 of the data) and the test fold contains the other group (that is, roughly 1/5 of the data). In this case, cross-validation proceeds as follows:

- 1 The software trains the first model (stored in `CVMdl.Trained{1}`) using the observations in the last four groups and reserves the observations in the first group for validation.
- 2 The software trains the second model (stored in `CVMdl.Trained{2}`) using the observations in the first group and last three groups. The software reserves the observations in the second group for validation.
- 3 The software proceeds in a similar fashion for the third through fifth models.

If you validate by calling `kfoldPredict`, it computes predictions for the observations in group 1 using the first model, group 2 for the second model, and so on. In short, the software estimates a response for every observation using the model trained without that observation.

Note Unlike other cross-validated, regression models, `RegressionPartitionedLinear` model objects do not store the predictor data set.

Construction

`CVMdl = fitrlinear(X,Y,Name,Value)` creates a cross-validated, linear regression model when `Name` is either `'CrossVal'`, `'CVPartition'`, `'Holdout'`, or `'KFold'`. For more details, see `fitrlinear`.

Properties

Cross-Validation Properties

CrossValidatedModel — Cross-validated model name

character vector

Cross-validated model name, specified as a character vector.

For example, `'Linear'` specifies a cross-validated linear model for binary classification or regression.

Data Types: `char`

KFold — Number of cross-validated folds

positive integer

Number of cross-validated folds, specified as a positive integer.

Data Types: `double`

ModelParameters — Cross-validation parameter values

object

Cross-validation parameter values, e.g., the name-value pair argument values used to cross-validate the linear model, specified as an object. `ModelParameters` does not contain estimated parameters.

Access properties of `ModelParameters` using dot notation.

NumObservations — Number of observations

positive numeric scalar

Number of observations in the training data, specified as a positive numeric scalar.

Data Types: `double`

Partition — Data partition`cvpartition` model

Data partition indicating how the software splits the data into cross-validation folds, specified as a `cvpartition` model.

Trained — Linear regression models trained on cross-validation foldscell array of `RegressionLinear` model objects

Linear regression models trained on cross-validation folds, specified as a cell array of `RegressionLinear` models. `Trained` has k cells, where k is the number of folds.

Data Types: `cell`**W — Observation weights**

numeric vector

Observation weights used to cross-validate the model, specified as a numeric vector. `W` has `NumObservations` elements.

The software normalizes the weights used for training so that `nansum(W)` is 1.

Data Types: `single` | `double`**Y — Observed responses**

numeric vector

Observed responses used to cross-validate the model, specified as a numeric vector containing `NumObservations` elements.

Each row of `Y` represents the observed response of the corresponding observation in the predictor data.

Data Types: `single` | `double`**Other Regression Properties****CategoricalPredictors — Categorical predictor indices**vector of positive integers | `[]`

Categorical predictor indices, specified as a vector of positive integers. `CategoricalPredictors` contains index values corresponding to the columns of the predictor data that contain categorical predictors. If none of the predictors are categorical, then this property is empty (`[]`).

Data Types: `single` | `double`

PredictorNames — Predictor names

cell array of character vectors

Predictor names in their order of appearance in predictor data used to train `CVMDL`, specified as a cell array of character vectors. `PredictorNames` has length equal to the number of predictor variables in the predictor data.

Data Types: `cell`

ResponseName — Response variable name

character vector

Response variable name, specified as a character vector.

Data Types: `char`

ResponseTransform — Response transformation function

'none' | function handle

Response transformation function, specified as 'none' or a function handle. `ResponseTransform` describes how the software transforms raw response values.

For a MATLAB function, or a function that you define, enter its function handle. For example, you can enter `Mdl.ResponseTransform = @function`, where *function* accepts a numeric vector of the original responses and returns a numeric vector of the same size containing the transformed responses.

Data Types: `char` | `function_handle`

Methods

<code>kfoldLoss</code>	Regression loss for observations not used in training
<code>kfoldPredict</code>	Predict responses for observations not used for training

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects (MATLAB).

Examples

Create Cross-Validated Linear Regression Model

Simulate 10000 observations from this model

$$y = x_{100} + 2x_{200} + e.$$

- $X = \{x_1, \dots, x_{1000}\}$ is a 10000-by-1000 sparse matrix with 10% nonzero standard normal elements.
- e is random normal error with mean 0 and standard deviation 0.3.

```
rng(1) % For reproducibility
n = 1e4;
d = 1e3;
nz = 0.1;
X = sprandn(n,d,nz);
Y = X(:,100) + 2*X(:,200) + 0.3*randn(n,1);
```

Cross-validate a linear regression model. To increase execution speed, transpose the predictor data and specify that the observations are in columns.

```
X = X';
CVMdl = fitrlinear(X,Y,'CrossVal','on','ObservationsIn','columns');
```

CVMdl is a `RegressionPartitionedLinear` cross-validated model. Because `fitrlinear` implements 10-fold cross-validation by default, `CVMdl.Trained` contains a cell vector of ten `RegressionLinear` models. Each cell contains a linear regression model trained on nine folds, and then tested on the remaining fold.

Predict responses for out-of-fold observations and estimate the generalization error by passing CVMdl to `kfoldPredict` and `kfoldLoss`, respectively.

```
oofYHat = kfoldPredict(CVMdl);
ge = kfoldLoss(CVMdl)
```

```
ge = 0.1748
```

The estimated, generalization, mean squared error is 0.1748.

Find Good Lasso Penalty Using Cross-Validation

To determine a good lasso-penalty strength for a linear regression model that uses least squares, implement 5-fold cross-validation.

Simulate 10000 observations from this model

$$y = x_{100} + 2x_{200} + e.$$

- $X = \{x_1, \dots, x_{1000}\}$ is a 10000-by-1000 sparse matrix with 10% nonzero standard normal elements.
- e is random normal error with mean 0 and standard deviation 0.3.

```
rng(1) % For reproducibility
n = 1e4;
d = 1e3;
nz = 0.1;
X = sprandn(n,d,nz);
Y = X(:,100) + 2*X(:,200) + 0.3*randn(n,1);
```

Create a set of 15 logarithmically-spaced regularization strengths from 10^{-5} through 10^{-1} .

```
Lambda = logspace(-5, -1, 15);
```

Cross-validate the models. To increase execution speed, transpose the predictor data and specify that the observations are in columns. Optimize the objective function using SpARSA.

```
X = X';
CVMdl = fitrlinear(X,Y,'ObservationsIn','columns','KFold',5,'Lambda',Lambda,...
    'Learner','leastsquares','Solver','sparsa','Regularization','lasso');
```

```
numCLModels = numel(CVMdl.Trained)
```

```
numCLModels = 5
```

CVMdl is a RegressionPartitionedLinear model. Because fitrlinear implements 5-fold cross-validation, CVMdl contains 5 RegressionLinear models that the software trains on each fold.

Display the first trained linear regression model.

```
Mdl1 = CVMdl.Trained{1}

Mdl1 =
  RegressionLinear
    ResponseName: 'Y'
    ResponseTransform: 'none'
    Beta: [1000x15 double]
    Bias: [1x15 double]
    Lambda: [1x15 double]
    Learner: 'leastsquares'
```

Properties, Methods

Mdl1 is a `RegressionLinear` model object. `fitrlinear` constructed Mdl1 by training on the first four folds. Because `Lambda` is a sequence of regularization strengths, you can think of Mdl1 as 15 models, one for each regularization strength in `Lambda`.

Estimate the cross-validated MSE.

```
mse = kfoldLoss(CVMdl);
```

Higher values of `Lambda` lead to predictor variable sparsity, which is a good quality of a regression model. For each regularization strength, train a linear regression model using the entire data set and the same options as when you cross-validated the models.

Determine the number of nonzero coefficients per model.

```
Mdl = fitrlinear(X,Y,'ObservationsIn','columns','Lambda',Lambda,...
    'Learner','leastsquares','Solver','sparsa','Regularization','lasso');
numNZCoeff = sum(Mdl.Beta~=0);
```

In the same figure, plot the cross-validated MSE and frequency of nonzero coefficients for each regularization strength. Plot all variables on the log scale.

```
figure
[h,hL1,hL2] = plotyy(log10(Lambda),log10(mse),...
    log10(Lambda),log10(numNZCoeff));
hL1.Marker = 'o';
hL2.Marker = 'o';
ylabel(h(1),'log10 MSE')
ylabel(h(2),'log10 nonzero-coefficient frequency')
xlabel('log10 Lambda')
hold off
```

Choose the index of the regularization strength that balances predictor variable sparsity and low MSE (for example, $\text{Lambda}(10)$).

```
idxFinal = 10;
```

Extract the model with corresponding to the minimal MSE.

```
MdlFinal = selectModels(Mdl,idxFinal)
```

```
MdlFinal =
  RegressionLinear
    ResponseName: 'Y'
    ResponseTransform: 'none'
    Beta: [1000x1 double]
```

```
Bias: -0.0050  
Lambda: 0.0037  
Learner: 'leastsquares'
```

Properties, Methods

```
idxNZCoeff = find(MdlFinal.Beta~=0)
```

```
idxNZCoeff = 2×1
```

```
100  
200
```

```
EstCoeff = Mdl.Beta(idxNZCoeff)
```

```
EstCoeff = 2×1
```

```
1.0051  
1.9965
```

`MdlFinal` is a `RegressionLinear` model with one regularization strength. The nonzero coefficients `EstCoeff` are close to the coefficients that simulated the data.

Introduced in R2016a

RegressionPartitionedModel

Package: classreg.learning.partition

Cross-validated regression model

Description

`RegressionPartitionedModel` is a set of regression models trained on cross-validated folds. Estimate the quality of regression by cross validation using one or more “kfold” methods: `kfoldPredict`, `kfoldLoss`, and `kfoldfun`. Every “kfold” method uses models trained on in-fold observations to predict response for out-of-fold observations. For example, suppose you cross validate using five folds. In this case, every training fold contains roughly 4/5 of the data and every test fold contains roughly 1/5 of the data. The first model stored in `Trained{1}` was trained on X and Y with the first 1/5 excluded, the second model stored in `Trained{2}` was trained on X and Y with the second 1/5 excluded, and so on. When you call `kfoldPredict`, it computes predictions for the first 1/5 of the data using the first model, for the second 1/5 of data using the second model and so on. In short, response for every observation is computed by `kfoldPredict` using the model trained without this observation.

Construction

`cvmodel = crossval(tree)` creates a cross-validated classification model from a regression tree. For syntax details, see the `crossval` method reference page.

`cvmodel = fitrtree(X,Y,Name,Value)` creates a cross-validated model when name is one of 'CrossVal', 'KFold', 'Holdout', 'Leaveout', or 'CVPartition'. For syntax details, see the `fitrtree` function reference page.

Input Arguments

tree

A regression tree constructed with `fitrtree`.

Properties

BinEdges

Bin edges for numeric predictors, specified as a cell array of p numeric vectors, where p is the number of predictors. Each vector includes the bin edges for a numeric predictor. The element in the cell array for a categorical predictor is empty because the software does not bin categorical predictors.

The software bins numeric predictors only if you specify the 'NumBins' name-value pair argument as a positive integer scalar when training a model with tree learners. The BinEdges property is empty if the 'NumBins' value is empty (default).

You can reproduce the binned predictor data `Xbinned` by using the BinEdges property of the trained model `mdl`.

```
X = mdl.X; % Predictor data
Xbinned = zeros(size(X));
edges = mdl.BinEdges;
% Find indices of binned predictors.
idxNumeric = find(~cellfun(@isempty,edges));
if iscolumn(idxNumeric)
    idxNumeric = idxNumeric';
end
for j = idxNumeric
    x = X(:,j);
    % Convert x to array if x is a table.
    if istable(x)
        x = table2array(x);
    end
    % Group x into bins by using the discretize function.
    xbinned = discretize(x,[-inf; edges{j}; inf]);
    Xbinned(:,j) = xbinned;
end
```

`Xbinned` contains the bin indices, ranging from 1 to the number of bins, for numeric predictors. `Xbinned` values are 0 for categorical predictors. If `X` contains NaNs, then the corresponding `Xbinned` values are NaNs.

CategoricalPredictors

Categorical predictor indices, specified as a vector of positive integers. `CategoricalPredictors` contains index values corresponding to the columns of the

predictor data that contain categorical predictors. If none of the predictors are categorical, then this property is empty (`[]`).

CrossValidatedModel

Name of the cross-validated model, a character vector.

Kfold

Number of folds used in a cross-validated tree, a positive integer.

ModelParameters

Object holding parameters of `tree`.

Partition

The partition of class `cvpartition` used in the cross-validated model.

PredictorNames

A cell array of names for the predictor variables, in the order in which they appear in X .

ResponseName

Name of the response variable Y , a character vector.

ResponseTransform

Function handle for transforming the raw response values (mean squared error). The function handle should accept a matrix of response values and return a matrix of the same size. The default character vector `'none'` means $@(x)x$, or no transformation.

Add or change a `ResponseTransform` function using dot notation:

```
ctree.ResponseTransform = @function
```

Trained

The trained learners, a cell array of compact regression models.

W

The scaled `weights`, a vector with length n , the number of rows in X .

X

A matrix or table of predictor values. Each column of X represents one variable, and each row represents one observation.

Y

A numeric column vector with the same number of rows as X. Each entry in Y is the response to the data in the corresponding row of X.

Methods

<code>kfoldfun</code>	Cross validate function
<code>kfoldLoss</code>	Cross-validation loss of partitioned regression model
<code>kfoldPredict</code>	Predict response for observations not used for training

Copy Semantics

Value. To learn how value classes affect copy operations, see [Copying Objects \(MATLAB\)](#).

Examples

Evaluate Cross-Validation Error

Load the sample data. Create a variable X containing the Horsepower and Weight data.

```
load carsmall
X = [Horsepower Weight];
```

Construct a regression tree using the sample data.

```
cvtree = fitrtree(X,MPG,'crossval','on');
```

Evaluate the cross-validation error of the `carsmall` data using Horsepower and Weight as predictor variables for mileage (MPG).

```
L = kfoldLoss(cvtree)
```

L = 25.5338

RegressionPartitionedSVM

Package: `classreg.learning.partition`

Superclasses:

Cross-validated support vector machine regression model

Description

`RegressionPartitionedSVM` is a set of support vector machine (SVM) regression models trained on cross-validated folds.

Construction

`CVMDL = crossval mdl` returns a cross-validated (partitioned) support vector machine regression model, `CVMDL`, from a trained SVM regression model, `mdl`.

`CVMDL = crossval mdl, Name, Value` returns a cross-validated model with additional options specified by one or more `Name, Value` pair arguments. `Name` can also be a property name on page 32-5832 and `Value` is the corresponding value. `Name` must appear inside single quotes (`'`). You can specify several name-value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Input Arguments

mdl — Full, trained SVM regression model

`RegressionSVM` model

Full, trained SVM regression model, specified as a `RegressionSVM` model returned by `fitrsvm`.

Properties

CategoricalPredictors — Indices of categorical predictors

vector of positive integers

Categorical predictor indices, specified as a vector of positive integers. `CategoricalPredictors` contains index values corresponding to the columns of the predictor data that contain categorical predictors. If none of the predictors are categorical, then this property is empty (`[]`).

Data Types: `single` | `double`

CrossValidatedModel — Name of the cross-validated model

character vector

Name of the cross-validated model, stored as a character vector.

Data Types: `char`

KFold — Number of cross-validation folds

positive integer value

Number of cross-validation folds, stored as a positive integer value.

Data Types: `single` | `double`

ModelParameters — Cross-validation parameters

object

Cross-validation parameters, stored as an object.

NumObservations — Number of observations

positive integer value

Number of observations in the training data, stored as a positive integer value.

Data Types: `single` | `double`

Partition — Data partition for cross-validation

`cvpartition` object

Data partition for cross-validation, stored as a `cvpartition` object.

PredictorNames — Predictor names

cell array of character vectors

Predictor names, stored as a cell array of character vectors containing the name of each predictor in the order in which they appear in X . `PredictorNames` has a length equal to the number of columns in X .

Data Types: cell

ResponseName — Response variable name

character vector

Response variable name, stored as a character vector.

Data Types: char

ResponseTransform — Response transformation function

'none' | function handle

Response transformation function, specified as 'none' or a function handle. ResponseTransform describes how the software transforms raw response values.

For a MATLAB function, or a function that you define, enter its function handle. For example, you can enter `Mdl.ResponseTransform = @function`, where *function* accepts a numeric vector of the original responses and returns a numeric vector of the same size containing the transformed responses.

Data Types: char | function_handle

Trained — Trained, compact regression models

cell array of CompactRegressionSVM models

Trained, compact regression models, stored as a cell array of CompactRegressionSVM models.

Data Types: cell

W — Observation weights

vector of numeric values

Observation weights used to train the model, stored as a numeric vector containing NumObservation number of elements. `fitrsvm` normalizes the weights used for training so that they sum to 1.

Data Types: single | double

X — Predictor values

matrix of numeric values | table of numeric values

Predictor values used to train the model, stored as a matrix of numeric values if the model is trained on a matrix, or a table if the model is trained on a table. X has size *n*-by-*p*,

where n is the number of rows and p is the number of predictor variables or columns in the training data.

Data Types: `single` | `double` | `table`

Y — Observed responses

numeric vector

Observed responses used to cross-validate the model, specified as a numeric vector containing `NumObservations` elements.

Each row of Y represents the observed classification of the corresponding row of X.

Data Types: `single` | `double`

Methods

Inherited Methods

<code>kfoldfun</code>	Cross validate function
<code>kfoldLoss</code>	Cross-validation loss of partitioned regression model
<code>kfoldPredict</code>	Predict response for observations not used for training

Examples

Train Cross-Validated SVM Regression Model Using `crossval`

This example shows how to train a cross-validated SVM regression model using `crossval`.

This example uses the abalone data from the UCI Machine Learning Repository. Download the data and save it in your current directory with the name `'abalone.data'`. Read the data into a `table`.

```
tbl = readtable('abalone.data', 'Filetype', 'text', 'ReadVariableNames', false);  
rng default % for reproducibility
```

The sample data contains 4177 observations. All of the predictor variables are continuous except for `sex`, which is a categorical variable with possible values 'M' (for males), 'F' (for females), and 'I' (for infants). The goal is to predict the number of rings on the abalone, and thereby determine its age, using physical measurements.

Train an SVM regression model, using a Gaussian kernel function with a kernel scale equal to 2.2. Standardize the data.

```
mdl = fitrsvm(tbl, 'Var9', 'KernelFunction', 'gaussian', 'KernelScale', 2.2, 'Standardize', t
```

`mdl` is a trained `RegressionSVM` regression model.

Cross validate the model using 10-fold cross validation.

```
CVMDl = crossval(mdl)
```

```
CVMDl =
```

```
classreg.learning.partition.RegistrationPartitionedSVM
  CrossValidatedModel: 'SVM'
  PredictorNames: {1x8 cell}
  CategoricalPredictors: 1
  ResponseName: 'Var9'
  NumObservations: 4177
  KFold: 10
  Partition: [1x1 cvpartition]
  ResponseTransform: 'none'
```

Properties, Methods

`CVMDl` is a `RegistrationPartitionedSVM` cross-validated regression model. The software:

1. Randomly partitions the data into ten equally-sized sets.
2. Trains an SVM regression model on nine of the ten sets.
3. Repeats steps 1 and 2 $k = 10$ times. It leaves out one of the partitions each time, and trains on the other nine partitions.
4. Combines generalization statistics for each fold.

Display the first of the 10 trained models.

```

FirstModel = CVMdl.Trained{1}
FirstModel =
    classreg.learning.regr.CompactRegressionSVM
        PredictorNames: {1x8 cell}
        ResponseName: 'Var9'
        ResponseTransform: 'none'
        Alpha: [3553x1 double]
        Bias: 11.0623
        KernelParameters: [1x1 struct]
            Mu: [0 0 0 0.5242 0.4080 0.1393 0.8300 0.3599 0.1811 0.2392]
            Sigma: [1 1 1 0.1205 0.0995 0.0392 0.4907 0.2217 0.1103 0.1392]
        SupportVectors: [3553x10 double]

```

Properties, Methods

FirstModel is the first of the 10 trained CompactRegressionSVM models.

Specify Cross-Validation Holdout Proportion for SVM Regression

This example shows how to specify a holdout proportion for training a cross-validated SVM regression model.

This example uses the abalone data from the UCI Machine Learning Repository. Download the data and save it in your current directory with the name 'abalone.data'. Read the data into a table.

```
tbl = readtable('abalone.data', 'Filetype', 'text', 'ReadVariableNames', false);
rng default % for reproducibility
```

The sample data contains 4177 observations. All of the predictor variables are continuous except for sex, which is a categorical variable with possible values 'M' (for males), 'F' (for females), and 'I' (for infants). The goal is to predict the number of rings on the abalone, and thereby determine its age, using physical measurements.

Train an SVM regression model, using a Gaussian kernel function with a kernel scale equal to 2.2. Standardize the data.

```
mdl = fitsvm(tbl, 'Var9', 'KernelFunction', 'gaussian', 'KernelScale', 2.2, 'Standardize', true);
```

mdl is a trained RegressionSVM regression model.

Cross validate the regression model by specifying a 10% holdout sample.

```
CVMDL = crossval mdl, 'Holdout', 0.1)
```

```
CVMDL =
```

```
classreg.learning.partition.RegistrationPartitionedSVM
  CrossValidatedModel: 'SVM'
  PredictorNames: {1x8 cell}
  CategoricalPredictors: 1
  ResponseName: 'Var9'
  NumObservations: 4177
  KFold: 1
  Partition: [1x1 cvpartition]
  ResponseTransform: 'none'
```

Properties, Methods

CVMDL is a `RegistrationPartitionedSVM` model object.

Extract and display the trained, compact SVM regression model from CVMDL.

```
CVMDL.Trained{1}
```

```
TrainedModel =
```

```
classreg.learning.regr.CompactRegressionSVM
  PredictorNames: {1x8 cell}
  ResponseName: 'Var9'
  ResponseTransform: 'none'
  Alpha: [3530x1 double]
  Bias: 11.2646
  KernelParameters: [1x1 struct]
  Mu: [0 0 0 0.5244 0.4080 0.1393 0.8282 0.3595 0.1805 0.2386]
  Sigma: [1 1 1 0.1198 0.0989 0.0388 0.4891 0.2218 0.1093 0.1390]
  SupportVectors: [3530x10 double]
```

Properties, Methods

TrainedModel is a CompactRegressionSVM regression model that was trained using 90% of the data.

Alternatives

You can create a RegressionPartitionedSVM model using the following techniques:

- Use the training function `fitrsvm` and specify one of the 'CrossVal', 'Holdout', 'KFold', or 'Leaveout' name-value pairs.
- Train a model using `fitrsvm`, then cross validate the model using the `crossval` method.
- Create a cross validation partition using `cvpartition`, then pass the resulting partition object to `fitrsvm` during training using the 'CVPartition' name-value pair.

Introduced in R2015b

RegressionSVM class

Superclasses:

Support vector machine regression model

Description

RegressionSVM is a support vector machine (SVM) regression model. Train a RegressionSVM model using `fitrsvm` and the sample data.

RegressionSVM models store data, parameter values, support vectors, and algorithmic implementation information. You can use these models to:

- Estimate resubstitution predictions. For details, see `resubPredict`.
- Predict values for new data. For details, see `predict`.
- Compute resubstitution loss. For details, see `resubLoss`.
- Compute the mean square error or epsilon-insensitive loss. For details, see `loss`.

Construction

Create a RegressionSVM object by using `fitrsvm`.

Properties

Alpha — Dual problem coefficients

vector of numeric values

Dual problem coefficients, specified as a vector of numeric values. Alpha contains m elements, where m is the number of support vectors in the trained SVM regression model. The dual problem introduces two Lagrange multipliers for each support vector. The values of Alpha are the differences between the two estimated Lagrange multipliers for the support vectors. For more details, see “Understanding Support Vector Machine Regression” on page 25-2.

If you specified to remove duplicates using `RemoveDuplicates`, then, for a particular set of duplicate observations that are support vectors, `Alpha` contains one coefficient corresponding to the entire set. That is, MATLAB attributes a nonzero coefficient to one observation from the set of duplicates and a coefficient of 0 to all other duplicate observations in the set.

Data Types: `single` | `double`

Beta — Primal linear problem coefficients

vector of numeric values | ' [] '

Primal linear problem coefficients, stored as a numeric vector of length p , where p is the number of predictors in the SVM regression model.

The values in `Beta` are the linear coefficients for the primal optimization problem.

If the model is obtained using a kernel function other than `'linear'`, this property is empty (`' [] '`).

The `predict` method computes predicted response values for the model as $YFIT = (X/S) \times \text{Beta} + \text{Bias}$, where S is the value of the kernel scale stored in the `KernelParameters.Scale` property.

Data Types: `single` | `double`

Bias — Bias term

scalar value

Bias term in the SVM regression model, stored as a scalar value.

Data Types: `single` | `double`

BoxConstraints — Box constraints for dual problem coefficients

vector of numeric values

Box constraints for dual problem alpha coefficients, stored as a numeric vector containing n elements, where n is the number of observations in X (`Mdl.NumObservations`).

The absolute value of the dual coefficient `Alpha` for observation i cannot exceed `BoxConstraints(i)`.

If you specify removing duplicates using `'RemoveDuplicates'`, then for a given set of duplicate observations, MATLAB sums the box constraints, and then attributes the sum to one observation and box constraints of 0 to all other observations in the set.

Data Types: single | double

CacheInfo — Caching information

structure

Caching information, stored as a structure with the following fields.

Field	Description
'Size'	Positive scalar value indicating the cache size (in MB) that the software reserves to store entries of the Gram matrix. Set the cache size by using the 'CacheSize' name-value pair argument in <code>fitrsvm</code> .
'Algorithm'	Character vector containing the name of the algorithm used to remove entries from the cache when its capacity is exceeded. Currently, the only available caching algorithm is 'Queue'. You cannot set the caching algorithm.

Data Types: struct

CategoricalPredictors — Indices of categorical predictors

vector of positive integers

Categorical predictor indices, specified as a vector of positive integers. `CategoricalPredictors` contains index values corresponding to the columns of the predictor data that contain categorical predictors. If none of the predictors are categorical, then this property is empty (`[]`).

Data Types: single | double

ConvergenceInfo — Convergence information

structure

Convergence information, stored as a structure with the following fields.

Field	Description
Converged	Logical flag indicating whether the algorithm converged. A value of 1 indicates convergence.
ReasonForConvergence	Character vector indicating the criterion the software used to detect convergence.
Gap	Scalar feasibility gap between the dual and primal objective functions.
GapTolerance	Scalar tolerance for the feasibility gap. You can set this tolerance using the 'GapTolerance' name-value pair argument in <code>fitrsvm</code> .
DeltaGradient	Scalar gradient difference between upper and lower violators.
DeltaGradientTolerance	Scalar tolerance for the gradient difference. You can set this tolerance using the <code>DeltaGradientTolerance</code> name-value pair argument in <code>fitrsvm</code> .
LargestKKTViolation	Maximal scalar Karush-Kuhn-Tucker (KKT) violation value.
KKTTolerance	Scalar tolerance for the largest KKT violation. You can set this tolerance using the 'KKTTolerance' name-value pair argument in <code>fitrsvm</code> .

Field	Description
History	<p>Structure containing convergence information recorded at periodic intervals during the model training process. This structure contains the following fields:</p> <ul style="list-style-type: none"> • NumIterations — Array of iteration indices at which the software recorded convergence criteria. • Gap — Gap values at these iterations. • DeltaGradient — DeltaGradient values at these iterations. • LargestKKTViolation — LargestKKTViolation values at these iterations. • NumSupportVectors — Number of support vectors at these iterations. • Objective — Objective values at these iterations.
Objective	Numeric value of the dual objective.

Data Types: struct

Epsilon — Half the width of the epsilon-insensitive band

nonnegative scalar value

Half the width of the epsilon-insensitive band, stored as a nonnegative scalar value.

Data Types: single | double

ExpandedPredictorNames — Expanded predictor names

cell array of character vectors

Expanded predictor names, stored as a cell array of character vectors.

If the model uses encoding for categorical variables, then ExpandedPredictorNames includes the names that describe the expanded variables. Otherwise, ExpandedPredictorNames is the same as PredictorNames.

Data Types: cell

Gradient — Gradient values in training data

vector of numeric values

Gradient values in training data, stored as a numeric vector containing $2n$ elements, where n is the number of observations in the training data.

Element i of `Gradient` contains the gradient value for the Alpha coefficient that corresponds to the upper boundary of the epsilon-insensitive band at observation i at the end of the optimization.

Element $i + \text{NumObservations}$ of `Gradient` contains the gradient value for the Alpha coefficient that corresponds to the lower boundary of the epsilon-insensitive band at observation i at the end of the optimization.

Data Types: `single` | `double`**HyperparameterOptimizationResults — Description of cross-validation optimization of hyperparameters**

BayesianOptimization object | table

Description of the cross-validation optimization of hyperparameters, specified as a `BayesianOptimization` object or a table of hyperparameters and associated values. This property is nonempty if the `'OptimizeHyperparameters'` name-value pair argument is nonempty when you create the model. The value of `HyperparameterOptimizationResults` depends on the setting of the `Optimizer` field in the `HyperparameterOptimizationOptions` structure when you create the model, as described in this table.

Value of Optimizer Field	Value of HyperparameterOptimizationResults
'bayesopt' (default)	Object of class <code>BayesianOptimization</code>
'gridsearch' or 'randomsearch'	Table of hyperparameters used, observed objective function values (cross-validation loss), and rank of observations from lowest (best) to highest (worst)

IsSupportVector — Flag indicating whether observation is support vector

logical vector

Flag indicating whether an observation is a support vector, stored as an n -by-1 logical vector. n is the number of observations in X (see `NumObservations`). A value of 1 indicates that the corresponding observation in the training data is a support vector.

If you specify removing duplicates using `RemoveDuplicates`, then for a given set of duplicate observations that are support vectors, `IsSupportVector` flags only one as a support vector.

Data Types: logical

KernelParameters — Kernel function parameters structure

Kernel function parameters, stored as a structure with the following fields.

Field	Description
Function	Kernel function name (a character vector).
Scale	Numeric scale factor used to divide predictor values.

You can specify values for `KernelParameters.Function` and `KernelParameters.Scale` by using the `KernelFunction` and `KernelScale` name-value pair arguments in `fitrsvm`, respectively.

Data Types: struct

ModelParameters — Parameter values model parameter object

Parameter values used to train the SVM regression model, stored as a model parameter object. Access the properties of `ModelParameters` using dot notation. For example, access the value of `Epsilon` used to train the model as `Mdl.ModelParameters.Epsilon`.

Mu — Predictor means

vector of numeric values | ' [] '

Predictor means, stored as a vector of numeric values.

If the predictors are standardized, then `Mu` is a numeric vector of length p , where p is the number of predictors used to train the model. In this case, the `predict` method centers predictor matrix X by subtracting the corresponding element of `Mu` from each column.

If the predictors are not standardized, then `Mu` is empty (' []).

If the data contains categorical predictors, then `Mu` includes elements for the dummy variables for those predictors. The corresponding entries in `Mu` are 0 because dummy variables are not centered or scaled.

Data Types: `single` | `double`

NumIterations — Number of iterations required for convergence

positive integer value

Number of iterations required for the optimization routine to reach convergence, stored as a positive integer value.

To set a limit on the number of iterations, use the 'IterationLimit' name-value pair argument of `fitrsvm`.

Data Types: `single` | `double`

NumObservations — Number of observations

positive integer value

Number of observations in the training data, stored as a positive integer value.

Data Types: `single` | `double`

PredictorNames — Predictor names

cell array of character vectors

Predictor names, stored as a cell array of character vectors containing the name of each predictor in the order they appear in `X`. `PredictorNames` has a length equal to the number of columns in `X`.

Data Types: `cell`

OutlierFraction — Expected fraction of outliers

scalar value in the range [0,1]

Expected fraction of outliers in the training set, stored as a scalar value in the range [0,1]. You can specify the expected fraction of outliers using the 'OutlierFraction' name-value pair argument in `fitrsvm`.

Data Types: `double`

ResponseName — Response variable name

character vector

Response variable name, stored as a character vector.

Data Types: char

ResponseTransform — Response transformation function

'none' | function handle

Response transformation function, specified as 'none' or a function handle. ResponseTransform describes how the software transforms raw response values.

For a MATLAB function, or a function that you define, enter its function handle. For example, you can enter `Mdl.ResponseTransform = @function`, where *function* accepts a numeric vector of the original responses and returns a numeric vector of the same size containing the transformed responses.

Data Types: char | function_handle

ShrinkagePeriod — Number of iterations between reductions of active set

nonnegative integer value

Number of iterations between reductions of the active set during optimization, stored as a nonnegative integer value.

You can set the shrinkage period by using the 'ShrinkagePeriod' name-value pair argument in `fitrsvm`.

Data Types: single | double

Sigma — Predictor standard deviations

vector of numeric values | '[]'

Predictor standard deviations, stored as a vector of numeric values.

If the predictors are standardized, then Sigma is a numeric vector of length p , where p is the number of predictors used to train the model. In this case, the `predict` method scales the predictor matrix X by dividing each column by the corresponding element of Sigma, after centering each element using Mu.

If the predictors are not standardized, then Sigma is empty ('[]').

If the data contains categorical predictors, `Sigma` includes elements for the dummy variables for those predictors. The corresponding entries in `Sigma` are 1, because dummy variables are not centered or scaled.

Data Types: `single` | `double`

Solver — Name of solver algorithm

character vector

Name of the solver algorithm used to solve the optimization problem, stored as a value in this table.

Value	Description
'SMO'	Sequential Minimal Optimization
'ISDA'	Iterative Single Data Algorithm
'L1QP'	L1 soft-margin minimization by quadratic programming (requires an Optimization Toolbox license).

SupportVectors — Support vectors

matrix of numeric values

Support vectors, stored as an m -by- p matrix of numeric values. m is the number of support vectors (`sum(Mdl.IsSupportVector)`), and p is the number of predictors in `X`.

If you specified to remove duplicates using `RemoveDuplicates`, then for a given set of duplicate observations that are support vectors, `SupportVectors` contains one unique support vector.

Data Types: `single` | `double`

W — Observation weights

vector of numeric values

Observation weights used to train the model, stored as a numeric vector containing `NumObservation` number of elements. `fitrsvm` normalizes the weights used for training so that they sum to 1.

Data Types: `single` | `double`

X — Predictor values

matrix of numeric values | table of numeric values

Predictor values used to train the model, stored as a matrix of numeric values if the model is trained on a matrix, or a table if the model is trained on a table. X has size n -by- p , where n is the number of rows and p is the number of predictor variables or columns in the training data.

Data Types: `single` | `double` | `table`

Y — Observed response values

vector of numeric values

Observed response values, stored as a numeric vector containing `NumObservations` number of elements.

Data Types: `single` | `double`

Methods

<code>compact</code>	Compact support vector machine regression model

Examples

Train Linear Support Vector Machine Regression Model

This example shows how to train a linear support vector machine (SVM) regression model using sample data stored in matrices.

Load the `carsmall` data set.

```
load carsmall
rng default % for reproducibility
```

Specify Horsepower and Weight as the predictor variables (X) and MPG as the response variable (Y).

```
X = [Horsepower,Weight];
Y = MPG;
```

Train a linear SVM regression model.

```
Mdl = fitrsvm(X,Y)
```

```
Mdl =
  RegressionSVM
      ResponseName: 'Y'
  CategoricalPredictors: []
      ResponseTransform: 'none'
                Alpha: [76x1 double]
                Bias: 43.1920
  KernelParameters: [1x1 struct]
      NumObservations: 93
      BoxConstraints: [93x1 double]
      ConvergenceInfo: [1x1 struct]
      IsSupportVector: [93x1 logical]
                Solver: 'SMO'
```

Properties, Methods

The Command Window shows that `Mdl` is a trained `RegressionSVM` model and a list of its properties.

Check the model for convergence.

```
Mdl.ConvergenceInfo.Converged
```

```
ans = logical
      0
```

0 indicates that the model did not converge.

```
MdlStd = fitrsvm(X,Y,'Standardize',true)
```

```
MdlStd =
  RegressionSVM
      ResponseName: 'Y'
  CategoricalPredictors: []
      ResponseTransform: 'none'
              Alpha: [77x1 double]
              Bias: 22.9131
  KernelParameters: [1x1 struct]
              Mu: [109.3441 2.9625e+03]
              Sigma: [45.3545 805.9668]
  NumObservations: 93
      BoxConstraints: [93x1 double]
  ConvergenceInfo: [1x1 struct]
  IsSupportVector: [93x1 logical]
      Solver: 'SMO'
```

Properties, Methods

Check the model for convergence.

```
MdlStd.ConvergenceInfo.Converged
```

```
ans = logical
      1
```

1 indicates that the model did converge.

Compute the resubstitution mean squared error for the new model.

```
lStd = resubLoss(MdlStd)
```

```
lStd = 17.0256
```

Train Support Vector Machine Regression Model

Train a support vector machine regression model using the abalone data from the UCI Machine Learning Repository.

Download the data and save it in your current folder with the name 'abalone.csv'.

```
url = 'https://archive.ics.uci.edu/ml/machine-learning-databases/abalone/abalone.data';  
websave('abalone.csv',url);
```

Read the data into a table. Specify the variable names.

```
varnames = {'Sex'; 'Length'; 'Diameter'; 'Height'; 'Whole_weight';...  
           'Shucked_weight'; 'Viscera_weight'; 'Shell_weight'; 'Rings'};  
Tbl = readtable('abalone.csv','Filetype','text','ReadVariableNames',false);  
Tbl.Properties.VariableNames = varnames;
```

The sample data contains 4177 observations. All the predictor variables are continuous except for Sex, which is a categorical variable with possible values 'M' (for males), 'F' (for females), and 'I' (for infants). The goal is to predict the number of rings (stored in Rings) on the abalone and determine its age using physical measurements.

Train an SVM regression model, using a Gaussian kernel function with an automatic kernel scale. Standardize the data.

```
rng default % For reproducibility  
Mdl = fitrsvm(Tbl,'Rings','KernelFunction','gaussian','KernelScale','auto',...  
             'Standardize',true)
```

```
Mdl =
```

```
RegressionSVM  
    PredictorNames: {1×8 cell}  
    ResponseName: 'Rings'  
    CategoricalPredictors: 1  
    ResponseTransform: 'none'  
                Alpha: [3635×1 double]  
                Bias: 10.8144  
    KernelParameters: [1×1 struct]
```

```
          Mu: [1×10 double]
          Sigma: [1×10 double]
NumObservations: 4177
  BoxConstraints: [4177×1 double]
ConvergenceInfo: [1×1 struct]
IsSupportVector: [4177×1 logical]
          Solver: 'SMO'
```

The Command Window shows that `Mdl` is a trained `RegressionSVM` model and displays a property list.

Display the properties of `Mdl` using dot notation. For example, check to confirm whether the model converged and how many iterations it completed.

```
conv = Mdl.ConvergenceInfo.Converged
iter = Mdl.NumIterations
```

```
conv =
    logical
     1

iter =
    2759
```

The returned results indicate that the model converged after 2759 iterations.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The `predict` and `update` functions support code generation.
- When you train an SVM regression model by using `fitrsvm`, the following restrictions apply.
 - Code generation does not support categorical predictors. You cannot supply training data in a table that contains a logical vector, character array, categorical array, string array, or cell array of character vectors. Also, you cannot use the 'CategoricalPredictors' name-value pair argument. To include categorical predictors in a model, preprocess the categorical predictors by using `dummyvar` before fitting the model.
 - The value of the 'ResponseTransform' name-value pair argument cannot be an anonymous function.

For more information, see “Introduction to Code Generation” on page 31-2.

Introduced in R2015b

RegressionSVMCoderConfigurer

Coder configurer for support vector machine (SVM) regression model

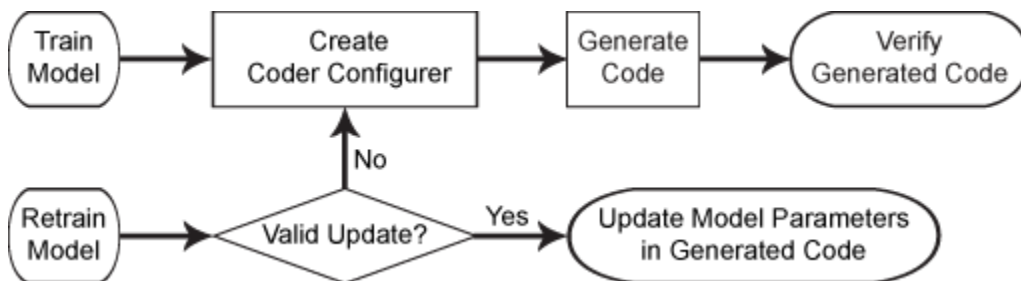

Description

A `RegressionSVMCoderConfigurer` object is a coder configurer of an SVM regression model (`RegressionSVM` or `CompactRegressionSVM`).

A coder configurer offers convenient features to configure code generation options, generate C/C++ code, and update model parameters in the generated code.

- Configure code generation options and specify the coder attributes for SVM model parameters using object properties.
- Generate C/C++ code for the `predict` and `update` functions of the SVM regression model by using `generateCode`. Generating C/C++ code requires MATLAB Coder.
- Update model parameters in the generated C/C++ code without having to regenerate the code. This feature reduces the effort required to regenerate, redeploy, and reverify C/C++ code when you retrain the SVM model with new data or settings. Before updating model parameters, use `validatedUpdateInputs` to validate and extract the model parameters to update.

This flow chart shows the code generation workflow using a coder configurer.

For the code generation usage notes and limitations of an SVM regression model, see the Code Generation sections of `CompactRegressionSVM`, `predict`, and `update`.

Creation

After training an SVM regression model by using `fitrsvm`, create a coder configurer for the model by using `learnerCoderConfigurer`. Use the properties of a coder configurer to specify the coder attributes of `predict` and `update` arguments. Then, use `generateCode` to generate C/C++ code based on the specified coder attributes.

Properties

predict Arguments

The properties listed in this section specify the coder attributes of the `predict` function arguments in the generated code.

X — Coder attributes of predictor data

LearnerCoderInput object

Coder attributes of predictor data to pass to the generated C/C++ code for the `predict` function of the SVM regression model, specified as a `LearnerCoderInput` on page 32-5874 object.

When you create a coder configurer by using the `learnerCoderConfigurer` function, the input argument `X` determines the default values of the `LearnerCoderInput` coder attributes:

- `SizeVector` — The default value is the array size of the input `X`.
- `VariableDimensions` — This value is `[0,0]` (default) or `[1,0]`.
 - `[0,0]` indicates that the array size is fixed as specified in `SizeVector`.
 - `[1,0]` indicates that the array has variable-size rows and fixed-size columns. In this case, the first value of `SizeVector` is the upper bound for the number of rows, and the second value of `SizeVector` is the number of columns.
- `DataType` — This value is `single` or `double`. The default data type depends on the data type of the input `X`.
- `Tunability` — This value must be `true`, meaning that `predict` in the generated C/C++ code always includes predictor data as an input.

You can modify the coder attributes by using dot notation. For example, if you want to generate C/C++ code that accepts predictor data with 100 observations of three

predictor variables, specify the coder attributes of X of the coder configurer `configurer` as follows:

```
configurer.X.SizeVector = [100 3];  
configurer.X.DataType = 'double';  
configurer.X.VariableDimensions = [0 0];
```

[0 0] indicates that the first and second dimensions of X (number of observations and number of predictor variables, respectively) have fixed sizes.

To allow the generated C/C++ code to accept predictor data with up to 100 observations, specify the coder attributes of X as follows:

```
configurer.X.SizeVector = [100 3];  
configurer.X.DataType = 'double';  
configurer.X.VariableDimensions = [1 0];
```

[1 0] indicates that the first dimension of X (number of observations) has a variable size and the second dimension of X (number of predictor variables) has a fixed size. The specified number of observations, 100 in this example, becomes the maximum allowed number of observations in the generated C/C++ code. To allow any number of observations, specify the bound as `Inf`.

NumOutputs — Number of outputs in predict

1 (default)

Number of output arguments to return from the generated C/C++ code for the `predict` function of the SVM regression model, specified as 1. `predict` returns `yfit` (predicted responses) in the generated C/C++ code.

The `NumOutputs` property is equivalent to the `'-nargout'` compiler option of `codegen`. This option specifies the number of output arguments in the entry-point function of code generation. The object function `generateCode` generates two entry-point functions—`predict.m` and `update.m` for the `predict` and `update` functions of an SVM regression model, respectively—and generates C/C++ code for the two entry-point functions. The specified value for the `NumOutputs` property corresponds to the number of output arguments in the entry-point function `predict.m`.

Data Types: `single` | `double`

update Arguments

The properties listed in this section specify the coder attributes of the `update` function arguments in the generated code. The `update` function takes a trained model and new

model parameters as input arguments, and returns an updated version of the model that contains the new parameters. To enable updating the parameters in the generated code, you need to specify the coder attributes of the parameters before generating code. Use a `LearnerCoderInput` on page 32-5874 object to specify the coder attributes of each parameter. The default attribute values are based on the model parameters in the input argument `Mdl` of `learnerCoderConfigurer`.

Alpha — Coder attributes of dual problem coefficients

`LearnerCoderInput` object

Coder attributes of the dual problem coefficients (Alpha of an SVM regression model), specified as a `LearnerCoderInput` on page 32-5874 object.

The default attribute values of the `LearnerCoderInput` object are based on the input argument `Mdl` of `learnerCoderConfigurer`:

- `SizeVector` — The default value is $[s, 1]$, where s is the number of support vectors in `Mdl`.
- `VariableDimensions` — This value is $[0, 0]$ (default) or $[1, 0]$.
 - $[0, 0]$ indicates that the array size is fixed as specified in `SizeVector`.
 - $[1, 0]$ indicates that the array has variable-size rows and fixed-size columns. In this case, the first value of `SizeVector` is the upper bound for the number of rows, and the second value of `SizeVector` is the number of columns.
- `DataType` — This value is `single` or `double`. The default data type is consistent with the data type of the training data you use to train `Mdl`.
- `Tunability` — If you train a model with a linear kernel function and discard support vectors by using `discardSupportVectors`, this value must be `false`. Otherwise, this value must be `true`.

Beta — Coder attributes of primal linear problem coefficients

`LearnerCoderInput` object

Coder attributes of the primal linear problem coefficients (Beta of an SVM regression model), specified as a `LearnerCoderInput` on page 32-5874 object.

The default attribute values of the `LearnerCoderInput` object are based on the input argument `Mdl` of `learnerCoderConfigurer`:

- `SizeVector` — This value must be $[p, 1]$, where p is the number of predictors in `Mdl`.

- **VariableDimensions** — This value must be `[0,0]`, indicating that the array size is fixed as specified in `SizeVector`.
- **DataType** — This value is `single` or `double`. The default data type is consistent with the data type of the training data you use to train `Mdl`.
- **Tunability** — If you train a model with a linear kernel function and discard support vectors by using `discardSupportVectors`, this value must be `true`. Otherwise, this value must be `false`.

Bias — Coder attributes of bias term

`LearnerCoderInput` object

Coder attributes of the bias term (Bias of an SVM regression model), specified as a `LearnerCoderInput` on page 32-5874 object.

The default attribute values of the `LearnerCoderInput` object are based on the input argument `Mdl` of `learnerCoderConfigurer`:

- **SizeVector** — This value must be `[1,1]`.
- **VariableDimensions** — This value must be `[0,0]`, indicating that the array size is fixed as specified in `SizeVector`.
- **DataType** — This value is `single` or `double`. The default data type is consistent with the data type of the training data you use to train `Mdl`.
- **Tunability** — This value must be `true`.

Mu — Coder attributes of predictor means

`LearnerCoderInput` object

Coder attributes of the predictor means (Mu of an SVM regression model), specified as a `LearnerCoderInput` on page 32-5874 object.

The default attribute values of the `LearnerCoderInput` object are based on the input argument `Mdl` of `learnerCoderConfigurer`:

- **SizeVector** — If you train `Mdl` using standardized predictor data by specifying `'Standardize', true`, this value must be `[1,p]`, where `p` is the number of predictors in `Mdl`. Otherwise, this value must be `[0,0]`.
- **VariableDimensions** — This value must be `[0,0]`, indicating that the array size is fixed as specified in `SizeVector`.
- **DataType** — This value is `single` or `double`. The default data type is consistent with the data type of the training data you use to train `Mdl`.

- **Tunability** — If you train Mdl using standardized predictor data by specifying 'Standardize', true, the default value is true. Otherwise, this value must be false.

Scale — Coder attributes of kernel scale parameter

LearnerCoderInput object

Coder attributes of the kernel scale parameter (KernelParameters.Scale of an SVM regression model), specified as a LearnerCoderInput on page 32-5874 object.

The default attribute values of the LearnerCoderInput object are based on the input argument Mdl of learnerCoderConfigurer:

- **SizeVector** — This value must be [1,1].
- **VariableDimensions** — This value must be [0,0], indicating that the array size is fixed as specified in SizeVector.
- **DataType** — This value is single or double. The default data type is consistent with the data type of the training data you use to train Mdl.
- **Tunability** — The default value is true.

Sigma — Coder attributes of predictor standard deviations

LearnerCoderInput object

Coder attributes of the predictor standard deviations (Sigma of an SVM regression model), specified as a LearnerCoderInput on page 32-5874 object.

The default attribute values of the LearnerCoderInput object are based on the input argument Mdl of learnerCoderConfigurer:

- **SizeVector** — If you train Mdl using standardized predictor data by specifying 'Standardize', true, this value must be [1,p], where p is the number of predictors in Mdl. Otherwise, this value must be [0,0].
- **VariableDimensions** — This value must be [0,0], indicating that the array size is fixed as specified in SizeVector.
- **DataType** — This value is single or double. The default data type is consistent with the data type of the training data you use to train Mdl.
- **Tunability** — If you train Mdl using standardized predictor data by specifying 'Standardize', true, the default value is true. Otherwise, this value must be false.

SupportVectors — Coder attributes of support vectors

LearnerCoderInput object

Coder attributes of the support vectors (SupportVectors of an SVM regression model), specified as a LearnerCoderInput on page 32-5874 object.

The default attribute values of the LearnerCoderInput object are based on the input argument Mdl of learnerCoderConfigurer:

- **SizeVector** — The default value is [s, p], where s is the number of support vectors, and p is the number of predictors in Mdl.
- **VariableDimensions** — This value is [0, 0] (default) or [1, 0].
 - [0, 0] indicates that the array size is fixed as specified in SizeVector.
 - [1, 0] indicates that the array has variable-size rows and fixed-size columns. In this case, the first value of SizeVector is the upper bound for the number of rows, and the second value of SizeVector is the number of columns.
- **DataType** — This value is single or double. The default data type is consistent with the data type of the training data you use to train Mdl.
- **Tunability** — If you train a model with a linear kernel function and discard support vectors by using discardSupportVectors, this value must be false. Otherwise, this value must be true.

Other Configurer Options

OutputFileName — File name of generated C/C++ code

'RegressionSVMModel' (default) | character vector

File name of the generated C/C++ code, specified as a character vector.

The object function generateCode of RegressionSVMCoderConfigurer generates C/C++ code using this file name.

The file name must not contain spaces because they can lead to code generation failures in certain operating system configurations. Also, the name must be a valid MATLAB function name.

After creating the coder configurer configurer, you can specify the file name by using dot notation.

```
configurer.OutputFileName = 'myModel';
```

Data Types: `char`

Verbose — Verbosity level

`true` (logical 1) (default) | `false` (logical 0)

Verbosity level, specified as `true` (logical 1) or `false` (logical 0). The verbosity level controls the display of notification messages at the command line.

Value	Description
<code>true</code> (logical 1)	The software displays notification messages when your changes to the coder attributes of a parameter result in changes for other dependent parameters.
<code>false</code> (logical 0)	The software does not display notification messages.

To enable updating machine learning model parameters in the generated code, you need to configure the coder attributes of the parameters before generating code. The coder attributes of parameters are dependent on each other, so the software stores the dependencies as configuration constraints. If you modify the coder attributes of a parameter by using a coder configurer, and the modification requires subsequent changes to other dependent parameters to satisfy configuration constraints, then the software changes the coder attributes of the dependent parameters. The verbosity level determines whether or not the software displays notification messages for these subsequent changes.

After creating the coder configurer `configurer`, you can modify the verbosity level by using dot notation.

```
configurer.Verbose = false;
```

Data Types: `logical`

Options for Code Generation Customization

To customize the code generation workflow, use the `generateFiles` function and the following three properties with `codegen`, instead of using the `generateCode` function.

After generating the two entry-point function files (`predict.m` and `update.m`) by using the `generateFiles` function, you can modify these files according to your code generation workflow. For example, you can modify the `predict.m` file to include data preprocessing, or you can add these entry-point functions to another code generation project. Then, you can generate C/C++ code by using the `codegen` function and the

codegen arguments appropriate for the modified entry-point functions or code generation project. Use the three properties described in this section as a starting point to set the codegen arguments.

CodeGenerationArguments — codegen arguments

cell array

This property is read-only.

codegen arguments, specified as a cell array.

This property enables you to customize the code generation workflow. Use the `generateCode` function if you do not need to customize your workflow.

Instead of using `generateCode` with the coder configurer `configurer`, you can generate C/C++ code as follows:

```
generateFiles(configurer)
cgArgs = configurer.CodeGenerationArguments;
codegen(cgArgs{:})
```

If you customize the code generation workflow, modify `cgArgs` accordingly before calling `codegen`.

If you modify other properties of `configurer`, the software updates the `CodeGenerationArguments` property accordingly.

Data Types: `cell`

PredictInputs — Input argument of predict

cell array of a `coder.PrimitiveType` object

This property is read-only.

Input argument of the entry-point function `predict.m` for code generation, specified as a cell array of a `coder.PrimitiveType` object. The `coder.PrimitiveType` object includes the coder attributes of predictor data stored in the `X` property.

If you modify the coder attributes of predictor data, then the software updates the `coder.PrimitiveType` object accordingly.

The `coder.PrimitiveType` object in `PredictInputs` is equivalent to `configurer.CodeGenerationArguments{6}` for the coder configurer `configurer`.

Data Types: cell

UpdateInputs — List of tunable input arguments of update

cell array of a structure including `coder.PrimitiveType` objects

This property is read-only.

List of the tunable input arguments of the entry-point function `update.m` for code generation, specified as a cell array of a structure including `coder.PrimitiveType` objects. Each `coder.PrimitiveType` object includes the coder attributes of a tunable machine learning model parameter.

If you modify the coder attributes of a model parameter by using the coder configurer properties (update Arguments on page 32-5860 properties), then the software updates the corresponding `coder.PrimitiveType` object accordingly. If you specify the `Tunability` attribute of a machine learning model parameter as `false`, then the software removes the corresponding `coder.PrimitiveType` object from the `UpdateInputs` list.

The structure in `UpdateInputs` is equivalent to `configurer.CodeGenerationArguments{3}` for the coder configurer `configurer`.

Data Types: cell

Object Functions

<code>generateCode</code>	Generate C/C++ code using coder configurer
<code>generateFiles</code>	Generate MATLAB files for code generation using coder configurer
<code>validatedUpdateInputs</code>	Validate and extract machine learning model parameters to update

Examples

Generate Code Using Coder Configurer

Train a machine learning model, and then generate code for the `predict` and `update` functions of the model by using a coder configurer.

Load the `carsmall` data set and train a support vector machine (SVM) regression model.

```
load carsmall
X = [Horsepower,Weight];
Y = MPG;
Mdl = fitrsvm(X,Y);
```

Mdl is a RegressionSVM object.

Create a coder configurer for the RegressionSVM model by using learnerCoderConfigurer. Specify the predictor data X. The learnerCoderConfigurer function uses the input X to configure the coder attributes of the predict function input.

```
configurer = learnerCoderConfigurer(Mdl,X)
```

```
configurer =
  RegressionSVMCoderConfigurer with properties:
```

```
  Update Inputs:
```

```
    Alpha: [1x1 LearnerCoderInput]
  SupportVectors: [1x1 LearnerCoderInput]
    Scale: [1x1 LearnerCoderInput]
    Bias: [1x1 LearnerCoderInput]
```

```
  Predict Inputs:
```

```
    X: [1x1 LearnerCoderInput]
```

```
  Code Generation Parameters:
```

```
    NumOutputs: 1
  OutputFileName: 'RegressionSVMModel'
```

```
  Properties, Methods
```

configurer is a RegressionSVMCoderConfigurer object, which is a coder configurer of a RegressionSVM object.

To generate C/C++ code, you must have access to a C/C++ compiler that is configured properly. MATLAB Coder locates and uses a supported, installed compiler. You can use `mex -setup` to view and change the default compiler. For more details, see “Change Default Compiler” (MATLAB).

Generate code for the `predict` and `update` functions of the SVM regression model (Mdl) with default settings.

```
generateCode(configurer)
```

generateCode creates these files in output folder:
'initialize.m', 'predict.m', 'update.m', 'RegressionSVMModel.mat'

The generateCode function completes these actions:

- Generate the MATLAB files required to generate code, including the two entry-point functions `predict.m` and `update.m` for the `predict` and `update` functions of `Mdl`, respectively.
- Create a MEX function named `RegressionSVMModel` for the two entry-point functions.
- Create the code for the MEX function in the `codegen\mex\RegressionSVMModel` folder.
- Copy the MEX function to the current folder.

Display the contents of the `predict.m`, `update.m`, and `initialize.m` files by using the `type` function.

type `predict.m`

```
function varargout = predict(X,varargin) %#codegen
% Autogenerated by MATLAB, 03-Mar-2019 15:58:37
[varargout{1:nargout}] = initialize('predict',X,varargin{:});
end
```

type `update.m`

```
function update(varargin) %#codegen
% Autogenerated by MATLAB, 03-Mar-2019 15:58:37
initialize('update',varargin{:});
end
```

type `initialize.m`

```
function [varargout] = initialize(command,varargin) %#codegen
% Autogenerated by MATLAB, 03-Mar-2019 15:58:37
coder.inline('always');
persistent model;
if isempty(model)
    model = loadCompactModel('RegressionSVMModel.mat');
end
switch(command)
    case 'update'
```

```
        % Update struct fields: Alpha
        %                               SupportVectors
        %                               Scale
        %                               Bias

        model = update(model,varargin{:});
    case 'predict'
        % Predict Inputs: X

        X = varargin{1};
        if nargin == 2
            [varargout{1:nargout}] = predict(model,X);
        else
            PVPairs = cell(1,nargin-2);
            for i = 1:nargin-2
                PVPairs{1,i} = varargin{i+1};
            end
            [varargout{1:nargout}] = predict(model,X,PVPairs{:});
        end
    end
end
end
```

Update Parameters of SVM Regression Model in Generated Code

Train a support vector machine (SVM) model using a partial data set and create a coder configurer for the model. Use the properties of the coder configurer to specify coder attributes of the SVM model parameters. Use the object function of the coder configurer to generate C code that predicts responses for new predictor data. Then retrain the model using the whole data set and update parameters in the generated code without regenerating the code.

Train Model

Load the `carsmall` data set and train an SVM regression model using the first 50 observations.

```
load carsmall
X = [Horsepower,Weight];
Y = MPG;
Mdl = fitsvm(X(1:50,:),Y(1:50));
```

Mdl is a `RegressionSVM` object.

Create Coder Configurer

Create a coder configurer for the `RegressionSVM` model by using `learnerCoderConfigurer`. Specify the predictor data `X`. The `learnerCoderConfigurer` function uses the input `X` to configure the coder attributes of the `predict` function input.

```
configurer = learnerCoderConfigurer(Mdl,X(1:50,:));
```

`configurer` is a `RegressionSVMCoderConfigurer` object, which is a coder configurer of a `RegressionSVM` object.

Specify Coder Attributes of Parameters

Specify the coder attributes of the SVM regression model parameters so that you can update the parameters in the generated code after retraining the model. This example specifies the coder attributes of predictor data that you want to pass to the generated code and the coder attributes of the support vectors of the SVM regression model.

First, specify the coder attributes of `X` so that the generated code accepts any number of observations. Modify the `SizeVector` and `VariableDimensions` attributes. The `SizeVector` attribute specifies the upper bound of the predictor data size, and the `VariableDimensions` attribute specifies whether each dimension of the predictor data has a variable size or fixed size.

```
configurer.X.SizeVector = [Inf 2];  
configurer.X.VariableDimensions = [true false];
```

The size of the first dimension is the number of observations. In this case, the code specifies that the upper bound of the size is `Inf` and the size is variable, meaning that `X` can have any number of observations. This specification is convenient if you do not know the number of observations when generating code.

The size of the second dimension is the number of predictor variables. This value must be fixed for a machine learning model. `X` contains two predictors, so the value of the `SizeVector` attribute must be two and the value of the `VariableDimensions` attribute must be `false`.

If you retrain the SVM model using new data or different settings, the number of support vectors can vary. Therefore, specify the coder attributes of `SupportVectors` so that you can update the support vectors in the generated code.

```
configurer.SupportVectors.SizeVector = [250 2];
```

SizeVector attribute for Alpha has been modified to satisfy configuration constraints.

```
configurer.SupportVectors.VariableDimensions = [true false];
```

VariableDimensions attribute for Alpha has been modified to satisfy configuration constraints.

If you modify the coder attributes of `SupportVectors`, then the software modifies the coder attributes of `Alpha` to satisfy configuration constraints. If the modification of the coder attributes of one parameter requires subsequent changes to other dependent parameters to satisfy configuration constraints, then the software changes the coder attributes of the dependent parameters.

Generate Code

To generate C/C++ code, you must have access to a C/C++ compiler that is configured properly. MATLAB Coder locates and uses a supported, installed compiler. You can use `mex -setup` to view and change the default compiler. For more details, see “Change Default Compiler” (MATLAB).

Use `generateCode` to generate code for the `predict` and `update` functions of the SVM regression model (`Mdl`) with default settings.

```
generateCode(configurer)
```

`generateCode` creates these files in output folder:
'initialize.m', 'predict.m', 'update.m', 'RegressionSVMModel.mat'

`generateCode` generates the MATLAB files required to generate code, including the two entry-point functions `predict.m` and `update.m` for the `predict` and `update` functions of `Mdl`, respectively. Then `generateCode` creates a MEX function named `RegressionSVMModel` for the two entry-point functions in the `codegen\mex\RegressionSVMModel` folder and copies the MEX function to the current folder.

Verify Generated Code

Pass some predictor data to verify whether the `predict` function of `Mdl` and the `predict` function in the MEX function return the same predicted responses. To call an entry-point function in a MEX function that has more than one entry point, specify the function name as the first input argument.

```
yfit = predict(Mdl,X);  
yfit_mex = RegressionSVMModel('predict',X);
```

`yfit_mex` might include round-off differences compared with `yfit`. In this case, compare `yfit` and `yfit_mex`, allowing a small tolerance.

```
find(abs(yfit-yfit_mex) > 1e-6)
```

```
ans =
```

```
0x1 empty double column vector
```

The comparison confirms that `yfit` and `yfit_mex` are equal within the tolerance $1e-6$.

Retrain Model and Update Parameters in Generated Code

Retrain the model using the entire data set.

```
retrainedMdl = fitrsvm(X,Y);
```

Extract parameters to update by using `validatedUpdateInputs`. This function detects the modified model parameters in `retrainedMdl` and validates whether the modified parameter values satisfy the coder attributes of the parameters.

```
params = validatedUpdateInputs(configurer,retrainedMdl);
```

Update parameters in the generated code.

```
RegressionSVMModel('update',params)
```

Verify Generated Code

Compare the outputs from the `predict` function of `retrainedMdl` and the `predict` function in the updated MEX function.

```
yfit = predict(retrainedMdl,X);  
yfit_mex = RegressionSVMModel('predict',X);  
find(abs(yfit-yfit_mex) > 1e-6)
```

```
ans =
```

```
0x1 empty double column vector
```

The comparison confirms that `yfit` and `yfit_mex` are equal within the tolerance $1e-6$.

Definitions

LearnerCoderInput Object

A coder configurer uses a `LearnerCoderInput` object to specify the coder attributes of `predict` and `update` input arguments.

A `LearnerCoderInput` object has the following attributes to specify the properties of an input argument array in the generated code.

Attribute Name	Description
<code>SizeVector</code>	<ul style="list-style-type: none"> Array size if the corresponding <code>VariableDimensions</code> value is <code>false</code>. Upper bound of the array size if the corresponding <code>VariableDimensions</code> value is <code>true</code>. To allow an unbounded array, specify the bound as <code>Inf</code>.
<code>VariableDimensions</code>	<p>Indicator specifying whether each dimension of the array has a variable size or fixed size, specified as <code>true</code> (logical 1) or <code>false</code> (logical 0):</p> <ul style="list-style-type: none"> A value of <code>true</code> (logical 1) means that the corresponding dimension has a variable size. A value of <code>false</code> (logical 0) means that the corresponding dimension has a fixed size.
<code>DataType</code>	Data type of the array
<code>Tunability</code>	<p>Indicator specifying whether or not <code>predict</code> or <code>update</code> includes the argument as an input in the generated code, specified as <code>true</code> (logical 1) or <code>false</code> (logical 0).</p> <p>If you specify other attribute values when <code>Tunability</code> is <code>false</code>, the software sets <code>Tunability</code> to <code>true</code>.</p>

After creating a coder configurer, you can modify the coder attributes by using dot notation. For example, specify the coder attributes of the coefficients `Alpha` of the coder configurer `configurer` as follows:

```
configurer.Alpha.SizeVector = [100 1];  
configurer.Alpha.VariableDimensions = [1 0];  
configurer.Alpha.DataType = 'double';
```

If you specify the verbosity level (`Verbose`) as `true` (default), then the software displays notification messages when you modify the coder attributes of a machine learning model parameter and the modification changes the coder attributes of other dependent parameters.

Topics

“Introduction to Code Generation” on page 31-2

“Code Generation for Prediction and Update Using Coder Configurer” on page 31-96

Introduced in R2018b

RegressionTree class

Superclasses:

Regression tree

Description

A decision tree with binary splits for regression. An object of class `RegressionTree` can predict responses for new data with the `predict` method. The object contains the data used for training, so can compute resubstitution predictions.

Construction

Create a `RegressionTree` object by using `fitrtree`.

Properties

BinEdges

Bin edges for numeric predictors, specified as a cell array of p numeric vectors, where p is the number of predictors. Each vector includes the bin edges for a numeric predictor. The element in the cell array for a categorical predictor is empty because the software does not bin categorical predictors.

The software bins numeric predictors only if you specify the `'NumBins'` name-value pair argument as a positive integer scalar when training a model with tree learners. The `BinEdges` property is empty if the `'NumBins'` value is empty (default).

You can reproduce the binned predictor data `Xbinned` by using the `BinEdges` property of the trained model `mdl`.

```
X = mdl.X; % Predictor data
Xbinned = zeros(size(X));
edges = mdl.BinEdges;
% Find indices of binned predictors.
```

```

idxNumeric = find(~cellfun(@isempty,edges));
if iscolumn(idxNumeric)
    idxNumeric = idxNumeric';
end
for j = idxNumeric
    x = X(:,j);
    % Convert x to array if x is a table.
    if istable(x)
        x = table2array(x);
    end
    % Group x into bins by using the discretize function.
    xbinned = discretize(x,[-inf; edges{j}; inf]);
    Xbinned(:,j) = xbinned;
end

```

Xbinned contains the bin indices, ranging from 1 to the number of bins, for numeric predictors. Xbinned values are 0 for categorical predictors. If X contains NaNs, then the corresponding Xbinned values are NaNs.

CategoricalPredictors

Categorical predictor indices, specified as a vector of positive integers. CategoricalPredictors contains index values corresponding to the columns of the predictor data that contain categorical predictors. If none of the predictors are categorical, then this property is empty ([]).

CategoricalSplits

An n -by-2 cell array, where n is the number of categorical splits in `tree`. Each row in CategoricalSplits gives left and right values for a categorical split. For each branch node with categorical split j based on a categorical predictor variable z , the left child is chosen if z is in CategoricalSplits(j ,1) and the right child is chosen if z is in CategoricalSplits(j ,2). The splits are in the same order as nodes of the tree. Nodes for these splits can be found by running `cuttype` and selecting 'categorical' cuts from top to bottom.

Children

An n -by-2 array containing the numbers of the child nodes for each node in `tree`, where n is the number of nodes. Leaf nodes have child node 0.

CutCategories

An n -by-2 cell array of the categories used at branches in `tree`, where n is the number of nodes. For each branch node i based on a categorical predictor variable x , the left child is chosen if x is among the categories listed in `CutCategories{i,1}`, and the right child is chosen if x is among those listed in `CutCategories{i,2}`. Both columns of `CutCategories` are empty for branch nodes based on continuous predictors and for leaf nodes.

`CutPoint` contains the cut points for 'continuous' cuts, and `CutCategories` contains the set of categories.

CutPoint

An n -element vector of the values used as cut points in `tree`, where n is the number of nodes. For each branch node i based on a continuous predictor variable x , the left child is chosen if $x < \text{CutPoint}(i)$ and the right child is chosen if $x \geq \text{CutPoint}(i)$. `CutPoint` is NaN for branch nodes based on categorical predictors and for leaf nodes.

CutType

An n -element cell array indicating the type of cut at each node in `tree`, where n is the number of nodes. For each node i , `CutType{i}` is:

- 'continuous' — If the cut is defined in the form $x < v$ for a variable x and cut point v .
- 'categorical' — If the cut is defined by whether a variable x takes a value in a set of categories.
- '' — If i is a leaf node.

`CutPoint` contains the cut points for 'continuous' cuts, and `CutCategories` contains the set of categories.

CutPredictor

An n -element cell array of the names of the variables used for branching in each node in `tree`, where n is the number of nodes. These variables are sometimes known as *cut variables*. For leaf nodes, `CutPredictor` contains an empty character vector.

`CutPoint` contains the cut points for 'continuous' cuts, and `CutCategories` contains the set of categories.

ExpandedPredictorNames

Expanded predictor names, stored as a cell array of character vectors.

If the model uses encoding for categorical variables, then `ExpandedPredictorNames` includes the names that describe the expanded variables. Otherwise, `ExpandedPredictorNames` is the same as `PredictorNames`.

HyperparameterOptimizationResults

Description of the cross-validation optimization of hyperparameters, stored as a `BayesianOptimization` object or a table of hyperparameters and associated values. Nonempty when the `OptimizeHyperparameters` name-value pair is nonempty at creation. Value depends on the setting of the `HyperparameterOptimizationOptions` name-value pair at creation:

- 'bayesopt' (default) — Object of class `BayesianOptimization`
- 'gridsearch' or 'randomsearch' — Table of hyperparameters used, observed objective function values (cross-validation loss), and rank of observations from lowest (best) to highest (worst)

IsBranchNode

An n -element logical vector `ib` that is `true` for each branch node and `false` for each leaf node of `tree`.

ModelParameters

Object holding parameters of `tree`.

NumObservations

Number of observations in the training data, a numeric scalar. `NumObservations` can be less than the number of rows of input data `X` when there are missing values in `X` or response `Y`.

NodeError

An n -element vector `e` of the errors of the nodes in `tree`, where n is the number of nodes. `e(i)` is the misclassification probability for node `i`.

NodeMean

An n -element numeric array with mean values in each node of `tree`, where n is the number of nodes in the tree. Every element in `NodeMean` is the average of the true Y values over all observations in the node.

NodeProbability

An n -element vector `p` of the probabilities of the nodes in `tree`, where n is the number of nodes. The probability of a node is computed as the proportion of observations from the original data that satisfy the conditions for the node. This proportion is adjusted for any prior probabilities assigned to each class.

NodeRisk

An n -element vector of the risk of the nodes in the tree, where n is the number of nodes. The risk for each node is the node error weighted by the node probability.

NodeSize

An n -element vector `sizes` of the sizes of the nodes in `tree`, where n is the number of nodes. The size of a node is defined as the number of observations from the data used to create the tree that satisfy the conditions for the node.

NumNodes

The number of nodes n in `tree`.

Parent

An n -element vector `p` containing the number of the parent node for each node in `tree`, where n is the number of nodes. The parent of the root node is θ .

PredictorNames

A cell array of names for the predictor variables, in the order in which they appear in X .

PruneAlpha

Numeric vector with one element per pruning level. If the pruning level ranges from 0 to M , then `PruneAlpha` has $M + 1$ elements sorted in ascending order. `PruneAlpha(1)` is for pruning level 0 (no pruning), `PruneAlpha(2)` is for pruning level 1, and so on.

PruneList

An n -element numeric vector with the pruning levels in each node of `tree`, where n is the number of nodes. The pruning levels range from 0 (no pruning) to M , where M is the distance between the deepest leaf and the root node.

ResponseName

A character vector that specifies the name of the response variable (Y).

ResponseTransform

Function handle for transforming the raw response values (mean squared error). The function handle must accept a matrix of response values and return a matrix of the same size. The default 'none' means $@(x)x$, or no transformation.

Add or change a `ResponseTransform` function using dot notation:

```
tree.ResponseTransform = @function
```

RowsUsed

An n -element logical vector indicating which rows of the original predictor data (X) were used in fitting. If the software uses all rows of X , then `RowsUsed` is an empty array (`[]`).

SurrogateCutCategories

An n -element cell array of the categories used for surrogate splits in `tree`, where n is the number of nodes in `tree`. For each node k , `SurrogateCutCategories{k}` is a cell array. The length of `SurrogateCutCategories{k}` is equal to the number of surrogate predictors found at this node. Every element of `SurrogateCutCategories{k}` is either an empty character vector for a continuous surrogate predictor, or is a two-element cell array with categories for a categorical surrogate predictor. The first element of this two-element cell array lists categories assigned to the left child by this surrogate split, and the second element of this two-element cell array lists categories assigned to the right child by this surrogate split. The order of the surrogate split variables at each node is matched to the order of variables in `SurrogateCutPredictor`. The optimal-split variable at this node does not appear. For nonbranch (leaf) nodes, `SurrogateCutCategories` contains an empty cell.

SurrogateCutFlip

An n -element cell array of the numeric cut assignments used for surrogate splits in `tree`, where n is the number of nodes in `tree`. For each node k , `SurrogateCutFlip{k}` is a

numeric vector. The length of `SurrogateCutFlip{k}` is equal to the number of surrogate predictors found at this node. Every element of `SurrogateCutFlip{k}` is either zero for a categorical surrogate predictor, or a numeric cut assignment for a continuous surrogate predictor. The numeric cut assignment can be either -1 or $+1$. For every surrogate split with a numeric cut C based on a continuous predictor variable Z , the left child is chosen if $Z < C$ and the cut assignment for this surrogate split is $+1$, or if $Z \geq C$ and the cut assignment for this surrogate split is -1 . Similarly, the right child is chosen if $Z \geq C$ and the cut assignment for this surrogate split is $+1$, or if $Z < C$ and the cut assignment for this surrogate split is -1 . The order of the surrogate split variables at each node is matched to the order of variables in `SurrogateCutPredictor`. The optimal-split variable at this node does not appear. For nonbranch (leaf) nodes, `SurrogateCutFlip` contains an empty array.

SurrogateCutPoint

An n -element cell array of the numeric values used for surrogate splits in `tree`, where n is the number of nodes in `tree`. For each node k , `SurrogateCutPoint{k}` is a numeric vector. The length of `SurrogateCutPoint{k}` is equal to the number of surrogate predictors found at this node. Every element of `SurrogateCutPoint{k}` is either NaN for a categorical surrogate predictor, or a numeric cut for a continuous surrogate predictor. For every surrogate split with a numeric cut C based on a continuous predictor variable Z , the left child is chosen if $Z < C$ and `SurrogateCutFlip` for this surrogate split is $+1$, or if $Z \geq C$ and `SurrogateCutFlip` for this surrogate split is -1 . Similarly, the right child is chosen if $Z \geq C$ and `SurrogateCutFlip` for this surrogate split is $+1$, or if $Z < C$ and `SurrogateCutFlip` for this surrogate split is -1 . The order of the surrogate split variables at each node is matched to the order of variables returned by `SurrCutPredictor`. The optimal-split variable at this node does not appear. For nonbranch (leaf) nodes, `SurrogateCutPoint` contains an empty cell.

SurrogateCutType

An n -element cell array indicating types of surrogate splits at each node in `tree`, where n is the number of nodes in `tree`. For each node k , `SurrogateCutType{k}` is a cell array with the types of the surrogate split variables at this node. The variables are sorted by the predictive measure of association with the optimal predictor in the descending order, and only variables with the positive predictive measure are included. The order of the surrogate split variables at each node is matched to the order of variables in `SurrogateCutPredictor`. The optimal-split variable at this node does not appear. For nonbranch (leaf) nodes, `SurrogateCutType` contains an empty cell. A surrogate split type can be either 'continuous' if the cut is defined in the form $Z < V$ for a variable Z

and cut point V or 'categorical' if the cut is defined by whether Z takes a value in a set of categories.

SurrogateCutPredictor

An n -element cell array of the names of the variables used for surrogate splits in each node in `tree`, where n is the number of nodes in `tree`. Every element of `SurrogateCutPredictor` is a cell array with the names of the surrogate split variables at this node. The variables are sorted by the predictive measure of association with the optimal predictor in the descending order, and only variables with the positive predictive measure are included. The optimal-split variable at this node does not appear. For nonbranch (leaf) nodes, `SurrogateCutPredictor` contains an empty cell.

SurrogatePredictorAssociation

An n -element cell array of the predictive measures of association for surrogate splits in `tree`, where n is the number of nodes in `tree`. For each node k , `SurrogatePredictorAssociation{k}` is a numeric vector. The length of `SurrogatePredictorAssociation{k}` is equal to the number of surrogate predictors found at this node. Every element of `SurrogatePredictorAssociation{k}` gives the predictive measure of association between the optimal split and this surrogate split. The order of the surrogate split variables at each node is the order of variables in `SurrogateCutPredictor`. The optimal-split variable at this node does not appear. For nonbranch (leaf) nodes, `SurrogatePredictorAssociation` contains an empty cell.

W

The scaled weights, a vector with length n , the number of rows in X .

X

A matrix or table of predictor values. Each column of X represents one variable, and each row represents one observation.

Y

A numeric column vector with the same number of rows as X . Each entry in Y is the response to the data in the corresponding row of X .

Methods

compact	Compact regression tree
crossval	Cross-validated decision tree
cvloss	Regression error by cross validation
prune	Produce sequence of subtrees by pruning
resubLoss	Regression error by resubstitution
resubPredict	Predict resubstitution response of tree

Inherited Methods

loss	Regression error
surrogateAssociation	Mean predictive measure of association for surrogate splits in decision tree
predict	Predict responses using regression tree
predictorImportance	Estimates of predictor importance
view	View tree

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects (MATLAB).

Examples

Construct Regression Tree

Load the sample data.

```
load carsmall
```

Construct a regression tree using the sample data. The response variable is miles per gallon, MPG.

```
tree = fitrtree([Weight, Cylinders],MPG,...
               'CategoricalPredictors',2,'MinParentSize',20,...
               'PredictorNames',{'W','C'})

tree =
    RegressionTree
        PredictorNames: {'W' 'C'}
        ResponseName: 'Y'
        CategoricalPredictors: 2
        ResponseTransform: 'none'
        NumObservations: 94
```

Properties, Methods

Predict the mileage of 4,000-pound cars with 4, 6, and 8 cylinders.

```
MPG4Kpred = predict(tree,[4000 4; 4000 6; 4000 8])
```

```
MPG4Kpred = 3×1
```

```
19.2778
19.2778
14.3889
```

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The `predict` function supports code generation.
- When you train a regression tree model by using `fitrtree`, the following restrictions apply.
 - Code generation does not support categorical predictors. You cannot supply training data in a table that contains a logical vector, character array, categorical array, string array, or cell array of character vectors. Also, you cannot use the 'CategoricalPredictors' name-value pair argument. To include categorical predictors in a model, preprocess the categorical predictors by using `dummyvar` before fitting the model.
 - The value of the 'ResponseTransform' name-value pair argument cannot be an anonymous function.
 - You cannot use surrogate splits, that is, the value of the 'Surrogate' name-value pair argument must be 'off'.

For more information, see “Introduction to Code Generation” on page 31-2.

Introduced in R2011a

regstats

Regression diagnostics

Syntax

```
regstats(y,X,model)
stats = regstats(...)
stats = regstats(y,X,model,whichstats)
```

Description

`regstats(y,X,model)` performs a multilinear regression of the responses in `y` on the predictors in `X`. `X` is an n -by- p matrix of p predictors at each of n observations. `y` is an n -by-1 vector of observed responses.

Note By default, `regstats` adds a first column of 1s to `X`, corresponding to a constant term in the model. Do not enter a column of 1s directly into `X`.

The optional input `model` controls the regression model. By default, `regstats` uses a linear additive model with a constant term. `model` can be any one of the following:

- 'linear' — Constant and linear terms (the default)
- 'interaction' — Constant, linear, and interaction terms
- 'quadratic' — Constant, linear, interaction, and squared terms
- 'purequadratic' — Constant, linear, and squared terms

Alternatively, `model` can be a matrix of model terms accepted by the `x2fx` function. See `x2fx` for a description of this matrix and for a description of the order in which terms appear. You can use this matrix to specify other models including ones without a constant term.

With this syntax, the function displays a graphical user interface (GUI) with a list of diagnostic statistics, as shown in the following figure.

When you select check boxes corresponding to the statistics you want to compute and click **OK**, `regstats` returns the selected statistics to the MATLAB workspace. The names

of the workspace variables are displayed on the right-hand side of the interface. You can change the name of the workspace variable to any valid MATLAB variable name.

`stats = regstats(...)` creates the structure `stats`, whose fields contain all of the diagnostic statistics for the regression. This syntax does not open the GUI. The fields of `stats` are listed in the following table.

Field	Description
Q	Q from the QR decomposition of the design matrix
R	R from the QR decomposition of the design matrix
beta	Regression coefficients
covb	Covariance of regression coefficients
yhat	Fitted values of the response data
r	Residuals
mse	Mean squared error
rsquare	R^2 statistic
adjrsquare	Adjusted R^2 statistic
leverage	Leverage
hatmat	Hat matrix
s2_i	Delete-1 variance
beta_i	Delete-1 coefficients
standres	Standardized residuals
studres	Studentized residuals
dfbetas	Scaled change in regression coefficients
dffit	Change in fitted values
dffits	Scaled change in fitted values
covratio	Change in covariance
cookd	Cook's distance
tstat	t statistics and p -values for coefficients
fstat	F statistic and p -value
dwstat	Durbin-Watson statistic and p -value

Note that the fields names of `stats` correspond to the names of the variables returned to the MATLAB workspace when you use the GUI. For example, `stats.beta` corresponds to the variable `beta` that is returned when you select **Coefficients** in the GUI and click **OK**.

`stats = regstats(y,X,model,whichstats)` returns only the statistics that you specify in `whichstats`. `whichstats` can be a single character vector such as `'leverage'`, a string array such as `["leverage", "standres", "studres"]`, or a cell array of character vectors such as `{'leverage', 'standres', 'studres'}`. Set `whichstats` to `'all'` to return all of the statistics.

Note The F statistic is computed under the assumption that the model contains a constant term. It is not correct for models without a constant. The R^2 statistic can be negative for models without a constant, which indicates that the model is not appropriate for the data.

Examples

Open the `regstats` GUI using data from `hald.mat`:

```
load hald
regstats(heat,ingredients,'linear');
```

Select **Fitted Values** and **Residuals** in the GUI:

Click **OK** to export the fitted values and residuals to the MATLAB workspace in variables named `yhat` and `r`, respectively.

You can create the same variables using the `stats` output, without opening the GUI:

```
whichstats = {'yhat','r'};
stats = regstats(heat,ingredients,'linear',whichstats);
yhat = stats.yhat;
r = stats.r;
```

Introduced before R2006a

regularize

Find weights to minimize resubstitution error plus penalty term

Syntax

```
ens1 = regularize(ens)
ens1 = regularize(ens,Name,Value)
```

Description

`ens1 = regularize(ens)` finds optimal weights for learners in `ens` by lasso regularization. `regularize` returns a regression ensemble identical to `ens`, but with a populated `Regularization` property.

`ens1 = regularize(ens,Name,Value)` computes optimal weights with additional options specified by one or more `Name,Value` pair arguments. You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Input Arguments

`ens`

A regression ensemble, created by `fitrensemble`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`Lambda`

Vector of nonnegative regularization parameter values for lasso. For the default setting of `lambda`, `regularize` calculates the smallest value `lambda_max` for which all optimal

weights for learners are 0. The default value of `lambda` is a vector including 0 and nine exponentially-spaced numbers from `lambda_max/1000` to `lambda_max`.

Default: `[0 logspace(log10(lambda_max/1000), log10(lambda_max), 9)]`

MaxIter

Maximum number of iterations allowed, specified as a positive integer. If the algorithm executes `MaxIter` iterations before reaching the convergence tolerance, then the function stops iterating and returns a warning message. The function can return more than one warning when either `npass` or the number of `lambda` values is greater than 1.

Default: `1e3`

npass

Maximal number of passes for lasso optimization, a positive integer.

Default: `10`

reltol

Relative tolerance on the regularized loss for lasso, a numeric positive scalar.

Default: `1e-3`

verbose

Verbosity level, either 0 or 1. When set to 1, `regularize` displays more information as it runs.

Default: `0`

Output Arguments

ens1

A regression ensemble. Usually you set `ens1` to the same name as `ens`.

Examples

Regularize Ensemble of Bagged Trees

Regularize an ensemble of bagged trees.

Generate sample data.

```
rng(10, 'twister') % For reproducibility
X = rand(2000,20);
Y = repmat(-1,2000,1);
Y(sum(X(:,1:5),2)>2.5) = 1;
```

You can create a bagged classification ensemble of 300 trees from the sample data.

```
bag = fitensemble(X,Y, 'Method', 'Bag', 'NumLearningCycles', 300);
```

`fitensemble` uses a default template tree object `templateTree()` as a weak learner when 'Method' is 'Bag'. In this example, for reproducibility, specify 'Reproducible', true when you create a tree template object, and then use the object as a weak learner.

```
t = templateTree('Reproducible', true); % For reproducibility of random predictor selection
bag = fitensemble(X,Y, 'Method', 'Bag', 'NumLearningCycles', 300, 'Learners', t);
```

Regularize the ensemble of bagged regression trees.

```
bag = regularize(bag, 'lambda', [0.001 0.1], 'verbose', 1);
```

Starting lasso minimization for Lambda=0.001. Initial MSE=0.110607.

```

regularize reports on its progress.

Inspect the resulting regularization structure.

bag.Regularization

```
ans = struct with fields:
    Method: 'Lasso'
    TrainedWeights: [300x2 double]
    Lambda: [1.0000e-03 0.1000]
    ResubstitutionMSE: [0.0599 0.0788]
    CombineWeights: @classreg.learning.combiner.WeightedSum
```

Check how many learners in the regularized ensemble have positive weights. These are the learners included in a shrunken ensemble.

```
sum(bag.Regularization.TrainedWeights > 0)
```

```
ans = 1x2
```

```
113    87
```

Shrink the ensemble using the weights from $\text{Lambda} = 0.1$.

```
cmp = shrink(bag, 'weightcolumn', 2)

cmp =
  classreg.learning.regr.CompactRegressionEnsemble
      ResponseName: 'Y'
  CategoricalPredictors: []
      ResponseTransform: 'none'
      NumTrained: 87
```

Properties, Methods

The compact ensemble contains **87** members, less than 1/3 of the original **300**.

Definitions

Lasso

The lasso algorithm finds an optimal set of learner weights α_t that minimize

$$\sum_{n=1}^N w_n g\left(\left(\sum_{t=1}^T \alpha_t h_t(x_n)\right), y_n\right) + \lambda \sum_{t=1}^T |\alpha_t|.$$

Here

- $\lambda \geq 0$ is a parameter you provide, called the lasso parameter.
- h_t is a weak learner in the ensemble trained on N observations with predictors x_n , responses y_n , and weights w_n .
- $g(f, y) = (f - y)^2$ is the squared error.

Topics

“Ensemble Regularization” on page 18-93

relieff

Rank importance of predictors using ReliefF or RReliefF algorithm

Syntax

```
[ranks,weights] = relieff(X,y,k)  
[ranks,weights] = relieff(X,y,k,Name,Value)
```

Description

[ranks,weights] = relieff(X,y,k) returns the ranks and weights of predictors for the input data matrix X and response vector y, using either the ReliefF or RReliefF algorithm with k nearest neighbors.

If y is numeric, relieff performs RReliefF analysis for regression by default. Otherwise, relieff performs ReliefF analysis for classification using k nearest neighbors per class. For more information on ReliefF and RReliefF, see “Algorithms” on page 32-5906.

[ranks,weights] = relieff(X,y,k,Name,Value) specifies additional options using one or more name-value pair arguments. For example, 'updates',10 sets the number of observations randomly selected for computing weights to 10.

Examples

Determine Important Predictors

Load the sample data.

```
load fisheriris
```

Find the important predictors using 10 nearest neighbors.

```
[ranks,weights] = relieff(meas,species,10)
```

```
ranks = 1×4
      4   3   1   2

weights = 1×4
      0.1399   0.1226   0.3590   0.3754
```

`ranks` shows the predictor numbers listed according to their ranking. The fourth predictor is the most important, and the second predictor is the least important. `weights` gives the weight values in the same order as the predictors. The first predictor has a weight of 0.1399, and the fourth predictor has a weight of 0.3754.

Rank Predictors by Importance

Load the sample data.

```
load ionosphere
```

Rank the predictors based on importance using 10 nearest neighbors.

```
[ranks,weights] = relieff(X,Y,10);
```

Create a bar plot of predictor importance weights.

```
bar(weights(ranks))
xlabel('Predictor rank')
ylabel('Predictor importance weight')
```

Select the top 5 most important predictors. Find the columns of these predictors in X.

```
ranks(1:5)
```

```
ans = 1x5
```

```
    24     3     8     5    14
```

The 24th column of X is the most important predictor of Y.

Determine Important Categorical Predictors

Rank categorical predictors using `relieff`.

Load the sample data.

```
load carbig
```

Convert the categorical predictor variables `Mfg`, `Model`, and `Origin` to numerical values, and combine them into an input matrix. Specify the response variable `MPG`.

```
X = [grp2idx(Mfg) grp2idx(Model) grp2idx(Origin)];  
y = MPG;
```

Find the ranks and weights of the predictor variables using 10 nearest neighbors and treating the data in `X` as categorical.

```
[ranks,weights] = relieff(X,y,10,'categoricalx','on')
```

```
ranks = 1×3
```

```
    2    3    1
```

```
weights = 1×3
```

```
 -0.0019    0.0501    0.0114
```

The `Model` predictor is the most important in predicting `MPG`. The `Mfg` variable has a negative weight, indicating it is not a good predictor of `MPG`.

Input Arguments

X — Predictor data

numeric matrix

Predictor data, specified as a numeric matrix. Each row of `X` corresponds to one observation, and each column corresponds to one variable.

Data Types: `single` | `double`

y — Response data

numeric vector | categorical vector | logical vector | character array | string array | cell array of character vectors

Response data, specified as a numeric vector, categorical vector, logical vector, character array, string array, or cell array of character vectors.

Data Types: `single` | `double` | `categorical` | `logical` | `char` | `string` | `cell`

k — Number of nearest neighbors

positive integer scalar

Number of nearest neighbors, specified as a positive integer scalar.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `relieff(X,y,5,'method','classification','categoricalx','on')` specifies 5 nearest neighbors and treats the response variable and predictor data as categorical.

method — Method for computing weights

`'regression'` | `'classification'`

Method for computing weights, specified as the comma-separated pair consisting of `'method'` and either `'regression'` or `'classification'`. If `y` is numeric, `'regression'` is the default method. Otherwise, `'classification'` is the default.

Example: `'method','classification'`

prior — Prior probabilities for each class

`'empirical'` (default) | `'uniform'` | numeric vector | structure

Prior probabilities for each class, specified as the comma-separated pair consisting of `'prior'` and a value in this table.

Value	Description
'empirical'	The class probabilities are determined from class frequencies in y .
'uniform'	All class probabilities are equal.
numeric vector	One value exists for each distinct group name.
structure	A structure S with two fields: <ul style="list-style-type: none"> • S.group contains the group names as a variable of the same type as y. • S.prob contains a vector of corresponding probabilities.

Example: 'prior', 'uniform'

Data Types: single | double | char | string | struct

updates — Number of observations for computing weights

'all' (default) | positive integer scalar

Number of observations to select at random for computing weights, specified as the comma-separated pair consisting of 'updates' and either 'all' or a positive integer scalar. By default, `relieff` uses all observations.

Example: 'updates', 25

Data Types: single | double | char | string

categoricalx — Categorical predictors flag

'off' (default) | 'on'

Categorical predictors flag, specified as the comma-separated pair consisting of 'categoricalx' and either 'on' or 'off'. If you specify 'on', then `relieff` treats all predictors in X as categorical. Otherwise, it treats all predictors in X as numeric. You cannot mix numeric and categorical predictors.

Example: 'categoricalx', 'on'

sigma — Distance scaling factor

numeric positive scalar

Distance scaling factor, specified as the comma-separated pair consisting of 'sigma' and a numeric positive scalar. For observation i , influence on the predictor weight from its nearest neighbor j is multiplied by $e^{-(\text{rank}(i,j)/\text{sigma})^2}$. $\text{rank}(i,j)$ is the position of the j th observation among the nearest neighbors of the i th observation, sorted by distance. The default is `Inf` for classification (all nearest neighbors have the same influence) and 50 for regression.

Example: 'sigma',20

Data Types: single | double

Output Arguments

ranks — Indices of most important predictors

numeric vector

Indices of the most important predictors, returned as a numeric vector. `ranks` are the indices of the columns in X ordered by predictor importance. For example, if `ranks(3)` is 5, then the third most important predictor is the fifth column in X .

Data Types: double

weights — Weights of predictors

numeric vector

Weights of the predictors, returned as a numeric vector. `weights` range from -1 to 1 with large positive weights assigned to important predictors.

Data Types: double

Tips

- Predictor ranks and weights usually depend on k . If you set k to 1, then the estimates can be unreliable for noisy data. If you set k to a value comparable with the number of observations (rows) in X , `relieff` can fail to find important predictors. You can start with $k = 10$ and investigate the stability and reliability of `relieff` ranks and weights for various values of k .
- `relieff` removes observations with NaN values.

Algorithms

ReliefF

ReliefF finds the weights of predictors in the case where y is a multiclass categorical variable. The algorithm penalizes the predictors that give different values to neighbors of the same class, and rewards predictors that give different values to neighbors of different classes.

ReliefF first sets all predictor weights W_j to 0. Then, the algorithm iteratively selects a random observation x_r , finds the k -nearest observations to x_r for each class, and updates, for each nearest neighbor x_q , all the weights for the predictors F_j as follows:

If x_r and x_q are in the same class,

$$W_j^i = W_j^{i-1} - \frac{\Delta_j(x_r, x_q)}{m} \cdot d_{rq}.$$

If x_r and x_q are in different classes,

$$W_j^i = W_j^{i-1} + \frac{p_{y_q}}{1 - p_{y_r}} \cdot \frac{\Delta_j(x_r, x_q)}{m} \cdot d_{rq}.$$

- W_j^i is the weight of the predictor F_j at the i th iteration step.
- p_{y_r} is the prior probability of the class to which x_r belongs, and p_{y_q} is the prior probability of the class to which x_q belongs.
- m is the number of iterations specified by 'updates'.
- $\Delta_j(x_r, x_q)$ is the difference in the value of the predictor F_j between observations x_r and x_q . Let x_{rj} denote the value of the j th predictor for observation x_r , and let x_{qj} denote the value of the j th predictor for observation x_q .

- For discrete F_j ,

$$\Delta_j(x_r, x_q) = \begin{cases} 0, & x_{rj} = x_{qj} \\ 1, & x_{rj} \neq x_{qj} \end{cases}.$$

- For continuous F_j ,

$$\Delta_j(x_r, x_q) = \frac{|x_{rj} - x_{qj}|}{\max(F_j) - \min(F_j)}.$$

- d_{rq} is a distance function of the form

$$d_{rq} = \frac{\tilde{d}_{rq}}{\sum_{l=1}^k \tilde{d}_{rl}}.$$

The distance is subject to the scaling

$$\tilde{d}_{rq} = e^{-(\text{rank}(r, q)/\text{sigma})^2}$$

where $\text{rank}(r, q)$ is the position of the q th observation among the nearest neighbors of the r th observation, sorted by distance. k is the number of nearest neighbors, specified by k . You can change the scaling by specifying 'sigma'.

RRelieff

RRelieff works with continuous y . Similar to ReliefF, RRelieff also penalizes the predictors that give different values to neighbors with the same response values, and rewards predictors that give different values to neighbors with different response values. However, RRelieff uses intermediate weights to compute the final predictor weights.

Given two nearest neighbors, assume the following:

- W_{dy} is the weight of having different values for the response y .
- W_{dj} is the weight of having different values for the predictor F_j .
- $W_{dy \wedge dj}$ is the weight of having different response values and different values for the predictor F_j .

RRelieff first sets the weights W_{dy} , W_{dj} , $W_{dy \wedge dj}$, and W_j equal to 0. Then, the algorithm iteratively selects a random observation x_r , finds the k -nearest observations to x_r , and updates, for each nearest neighbor x_q , all the intermediate weights as follows:

$$W_{dy}^i = W_{dy}^{i-1} + \Delta_y(x_r, x_q) \cdot d_{rq}.$$

$$W_{dj}^i = W_{dj}^{i-1} + \Delta_j(x_r, x_q) \cdot d_{rq}.$$

$$W_{dy \wedge dj}^i = W_{dy \wedge dj}^{i-1} + \Delta_y(x_r, x_q) \cdot \Delta_j(x_r, x_q) \cdot d_{rq}.$$

- The i and $i-1$ superscripts denote the iteration step number. m is the number of iterations specified by 'updates'.

- $\Delta_y(x_r, x_q)$ is the difference in the value of the continuous response y between observations x_r and x_q . Let y_r denote the value of the response for observation x_r , and let y_q denote the value of the response for observation x_q .

$$\Delta_y(x_r, x_q) = \frac{|y_r - y_q|}{\max(y) - \min(y)}.$$

- The $\Delta_j(x_r, x_q)$ and $d_{r,q}$ functions are the same as for “ReliefF” on page 32-5906.

RReliefF calculates the predictor weights W_j after fully updating all the intermediate weights.

$$W_j = \frac{W_{dy \wedge dj}}{W_{dy}} - \frac{W_{dj} - W_{dy \wedge dj}}{m - W_{dy}}.$$

For more information, see [2].

Introduced in R2010b

removeLearners

Remove members of compact classification ensemble

Syntax

```
cens1 = removeLearners(cens,idx)
```

Description

`cens1 = removeLearners(cens,idx)` creates a compact classification ensemble identical to `cens` only without the ensemble members in the `idx` vector.

Input Arguments

cens

Compact classification ensemble, constructed with `compact`.

idx

Vector of positive integers with entries from 1 to `cens.NumTrained`, where `cens.NumTrained` is the number of members in `cens`. `cens1` contains all members of `cens` except those with indices in `idx`.

Typically, you set `idx = j:cens.NumTrained` for some positive integer `j`.

Output Arguments

cens1

Compact classification ensemble, identical to `cens` except `cens1` does not contain those members of `cens` with indices in `idx`.

Examples

Remove Learners from an Ensemble

Create a compact classification ensemble. Compact it further by removing members of the ensemble.

Load the `ionosphere` data set.

```
load ionosphere
```

Train a classification ensemble for the `ionosphere` data using `AdaBoostM1`. Specify tree stumps as the weak learners.

```
t = templateTree('MaxNumSplits',1);  
ens = fitcensemble(X,Y,'Method','AdaBoostM1','Learners',t);
```

Create a compact classification ensemble `cens` from `ens`.

```
cens = compact(ens);
```

Remove the last 50 members of the ensemble.

```
idx = cens.NumTrained-49:cens.NumTrained;  
cens1 = removeLearners(cens,idx);
```

Tips

- Typically, set `cens1` equal to `cens` to retain just one ensemble.
- Removing learners reduces the memory used by the ensemble and speeds up its predictions.

removeLearners

Remove members of compact regression ensemble

Syntax

```
cens1 = removeLearners(cens,idx)
```

Description

`cens1 = removeLearners(cens,idx)` creates a compact regression ensemble identical to `cens` only without the ensemble members in the `idx` vector.

Input Arguments

cens

Compact regression ensemble, constructed with `compact`.

idx

Vector of positive integers with entries from 1 to `cens.NumTrained`, where `cens.NumTrained` is the number of members in `cens`. `cens1` contains the members of `cens` except those with indices in `idx`.

Typically, you set `idx = j:cens.NumTrained` for some positive integer `j`.

Output Arguments

cens1

Compact regression ensemble, identical to `cens` except `cens1` does not contain members of `cens` with indices in `idx`.

Examples

Remove Learners from an Ensemble

Create a compact regression ensemble. Compact it further by removing members of the ensemble.

Load the `carsmall` data set and select `Weight` and `Cylinders` as predictors.

```
load carsmall
X = [Weight Cylinders];
```

Train a regression ensemble using `LSBoost`. Specify tree stumps as the weak learners.

```
t = templateTree('MaxNumSplits',1);
ens = fitensemble(X,MPG,'Method','LSBoost','Learners',t,...
    'CategoricalPredictors',2);
```

Create a compact classification ensemble `cens` from `ens`.

```
cens = compact(ens);
```

Remove the last 50 members of the ensemble.

```
idx = cens.NumTrained-49:cens.NumTrained;
cens1 = removeLearners(cens,idx);
```

Tips

- Typically, set `cens1` equal to `cens` to retain just one ensemble.
- Removing learners reduces the memory used by the ensemble and speeds up its predictions.

`CompactRegressionEnsemble`

removeTerms

Class: GeneralizedLinearModel

Remove terms from generalized linear model

Syntax

```
mdl1 = removeTerms(mdl, terms)
```

Description

`mdl1 = removeTerms(mdl, terms)` returns a linear model the same as `mdl` but with fewer terms.

Input Arguments

mdl

Generalized linear model, as constructed by `fitglm` or `stepwiseglm`.

terms

Terms to remove from the `mdl` regression model. Specify as either a:

- Text representing one or more terms to remove. For details, see “Wilkinson Notation” on page 32-5916.
- Row or rows in the terms matrix (see `modelspec` in `fitglm`). For example, if there are three variables A, B, and C:

```
[0 0 0] represents a constant term or intercept  
[0 1 0] represents B; equivalently, A^0 * B^1 * C^0  
[1 0 1] represents A*C  
[2 0 0] represents A^2  
[0 1 2] represents B*(C^2)
```

Output Arguments

mdl1

Generalized linear model, the same as `mdl` but without the terms given in `terms`. You can set `mdl1` equal to `mdl` to overwrite `mdl`.

Examples

Remove a Term from a Generalized Linear Regression Model

This example makes a model using two predictors, then removes one.

Generate artificial data for the model, Poisson random numbers with two underlying predictors `X(1)` and `X(2)`.

```
rng('default') % for reproducibility
rndvars = randn(100,2);
X = [2+rndvars(:,1),rndvars(:,2)];
mu = exp(1 + X*[1;2]);
y = poissrnd(mu);
```

Create a generalized linear regression model of Poisson data.

```
mdl = fitglm(X,y,'y ~ x1 + x2','distr','poisson')
```

```
mdl =
Generalized linear regression model:
    log(y) ~ 1 + x1 + x2
    Distribution = Poisson
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	1.0405	0.022122	47.034	0
x1	0.9968	0.003362	296.49	0
x2	1.987	0.0063433	313.24	0

100 observations, 97 error degrees of freedom

```
Dispersion: 1  
Chi^2-statistic vs. constant model: 2.95e+05, p-value = 0
```

Remove the second predictor from the model.

```
mdl1 = removeTerms(mdl, 'x2')
```

```
mdl1 =  
Generalized linear regression model:  
log(y) ~ 1 + x1  
Distribution = Poisson
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	2.7784	0.014043	197.85	0
x1	1.1732	0.0033653	348.6	0

```
100 observations, 98 error degrees of freedom  
Dispersion: 1  
Chi^2-statistic vs. constant model: 1.25e+05, p-value = 0
```

Definitions

Wilkinson Notation

Wilkinson notation describes the terms present in a model. The notation relates to the terms present in a model, not to the multipliers (coefficients) of those terms.

Wilkinson notation uses these symbols:

- + means include the next variable.
- – means do not include the next variable.
- : defines an interaction, which is a product of terms.
- * defines an interaction and all lower-order terms.
- ^ raises the predictor to a power, exactly as in * repeated, so ^ includes lower-order terms as well.

- `()` groups terms.

This table shows typical examples of Wilkinson notation.

Wilkinson Notation	Term in Standard Notation
1	Constant (intercept) term
A^k , where k is a positive integer	A, A^2, \dots, A^k
$A + B$	A, B
$A*B$	$A, B, A*B$
$A:B$	$A*B$ only
$-B$	Do not include B
$A*B + C$	$A, B, C, A*B$
$A + B + C + A:B$	$A, B, C, A*B$
$A*B*C - A:B:C$	$A, B, C, A*B, A*C, B*C$
$A*(B + C)$	$A, B, C, A*B, A*C$

Statistics and Machine Learning Toolbox notation always includes a constant term unless you explicitly remove the term using `-1`.

For more details, see “Wilkinson Notation” on page 11-117.

For details, see Wilkinson and Rogers [1].

Algorithms

- `removeTerms` treats a categorical predictor as follows:
 - A model with a categorical predictor that has L levels (categories) includes $L - 1$ indicator variables. The model uses the first category as a reference level, so it does not include the indicator variable for the reference level. If the data type of the categorical predictor is `categorical`, then you can check the order of categories by using `categories` and reorder the categories by using `reordercats` to customize the reference level.
 - `removeTerms` treats the group of $L - 1$ indicator variables as a single variable. If you want to treat the indicator variables as distinct predictor variables, create indicator variables manually by using `dummyvar`. Then use the indicator variables,

except the one corresponding to the reference level of the categorical variable, when you fit a model. For the categorical predictor X , if you specify all columns of `dummyvar(X)` and an intercept term as predictors, then the design matrix becomes rank deficient.

- Interaction terms between a continuous predictor and a categorical predictor with L levels consist of the element-wise product of the $L - 1$ indicator variables with the continuous predictor.
- Interaction terms between two categorical predictors with L and M levels consist of the $(L - 1) * (M - 1)$ indicator variables to include all possible combinations of the two categorical predictor levels.
- You cannot specify higher-order terms for a categorical predictor because the square of an indicator is equal to itself.

Alternatives

`step` adds or removes terms from a model using a greedy one-step algorithm.

removeTerms

Remove terms from linear regression model

Syntax

```
NewMdl = removeTerms(mdl, terms)
```

Description

`NewMdl = removeTerms(mdl, terms)` returns a linear regression model fitted using the input data and settings in `mdl` with the terms `terms` removed.

Examples

Remove Terms from Linear Regression Model

Create a linear regression model using the `hald` data set. Remove terms that have high p -values.

Load the data set.

```
load hald
X = ingredients; % predictor variables
y = heat; % response variable
```

Fit a linear regression model to the data.

```
mdl = fitlm(X,y)
```

```
mdl =
Linear regression model:
    y ~ 1 + x1 + x2 + x3 + x4
```

Estimated Coefficients:

Estimate	SE	tStat	pValue
----------	----	-------	--------

	Estimate	SE	tStat	pValue
(Intercept)	62.405	70.071	0.8906	0.39913
x1	1.5511	0.74477	2.0827	0.070822
x2	0.51017	0.72379	0.70486	0.5009
x3	0.10191	0.75471	0.13503	0.89592
x4	-0.14406	0.70905	-0.20317	0.84407

Number of observations: 13, Error degrees of freedom: 8
 Root Mean Squared Error: 2.45
 R-squared: 0.982, Adjusted R-Squared: 0.974
 F-statistic vs. constant model: 111, p-value = 4.76e-07

Remove the x3 and x4 terms because their p -values are high.

```
terms = 'x3 + x4'; % terms to remove
NewMdl = removeTerms mdl, terms)
```

```
NewMdl =
Linear regression model:
y ~ 1 + x1 + x2
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	52.577	2.2862	22.998	5.4566e-10
x1	1.4683	0.1213	12.105	2.6922e-07
x2	0.66225	0.045855	14.442	5.029e-08

Number of observations: 13, Error degrees of freedom: 10
 Root Mean Squared Error: 2.41
 R-squared: 0.979, Adjusted R-Squared: 0.974
 F-statistic vs. constant model: 230, p-value = 4.41e-09

`NewMdl` has the same adjusted R-squared value (0.974) as the previous model, meaning the fit is as good in the new model. All the terms in the new model have extremely low p -values.

Input Arguments

mdl — Linear regression model

LinearModel object

Linear regression model, specified as a LinearModel object created using fitlm or stepwiselm.

terms — Terms to remove from regression model

formula in Wilkinson notation | terms matrix

Terms to remove from the regression model mdl, specified as one of the following:

- Formula in “Wilkinson Notation” on page 32-5922 representing one or more terms.
- Terms matrix of size t -by- p , where t is the number of terms and p is the number of predictor variables in mdl. The value of $T(i, j)$ is the exponent of variable j in term i .

For example, suppose mdl has three variables A, B, and C in that order. Each row of T represents one term:

- [0 0 0] — Constant term or intercept
- [0 1 0] — B; equivalently, $A^0 * B^1 * C^0$
- [1 0 1] — $A * C$
- [2 0 0] — A^2
- [0 1 2] — $B * (C^2)$

removeTerms treats a group of indicator variables for a categorical predictor as a single variable. Therefore, you cannot specify an indicator variable to remove from the model. If you specify a categorical predictor to remove from the model, removeTerms removes a group of indicator variables for the predictor in one step. See “Modify Linear Regression Model Using step” on page 32-6518 for an example that describes how to create indicator variables manually and treat each one as a separate variable.

Output Arguments

NewMdl — Linear regression model with fewer terms

LinearModel object

Linear regression model with fewer terms, returned as a `LinearModel` object. `NewMdl` is a newly fitted model that uses the input data and settings in `mdl` with the terms specified in `terms` removed from `mdl`.

To overwrite the input argument `mdl`, assign the newly fitted model to `mdl`:

```
mdl = removeTerms(mdl, terms);
```

Definitions

Wilkinson Notation

Wilkinson notation describes the terms present in a model. The notation relates to the terms present in a model, not to the multipliers (coefficients) of those terms.

Wilkinson notation uses these symbols:

- `+` means include the next variable.
- `-` means do not include the next variable.
- `:` defines an interaction, which is a product of terms.
- `*` defines an interaction and all lower-order terms.
- `^` raises the predictor to a power, exactly as in `*` repeated, so `^` includes lower-order terms as well.
- `()` groups terms.

This table shows typical examples of Wilkinson notation.

Wilkinson Notation	Term in Standard Notation
1	Constant (intercept) term
A^k , where k is a positive integer	A, A^2, \dots, A^k
$A + B$	A, B
$A*B$	$A, B, A*B$
$A:B$	$A*B$ only
$-B$	Do not include B

Wilkinson Notation	Term in Standard Notation
$A*B + C$	A, B, C, A*B
$A + B + C + A:B$	A, B, C, A*B
$A*B*C - A:B:C$	A, B, C, A*B, A*C, B*C
$A*(B + C)$	A, B, C, A*B, A*C

Statistics and Machine Learning Toolbox notation always includes a constant term unless you explicitly remove the term using `-1`.

For more details, see “Wilkinson Notation” on page 11-117.

Algorithms

- `removeTerms` treats a categorical predictor as follows:
 - A model with a categorical predictor that has L levels (categories) includes $L - 1$ indicator variables. The model uses the first category as a reference level, so it does not include the indicator variable for the reference level. If the data type of the categorical predictor is `categorical`, then you can check the order of categories by using `categories` and reorder the categories by using `reordercats` to customize the reference level.
 - `removeTerms` treats the group of $L - 1$ indicator variables as a single variable. If you want to treat the indicator variables as distinct predictor variables, create indicator variables manually by using `dummyvar`. Then use the indicator variables, except the one corresponding to the reference level of the categorical variable, when you fit a model. For the categorical predictor X , if you specify all columns of `dummyvar(X)` and an intercept term as predictors, then the design matrix becomes rank deficient.
 - Interaction terms between a continuous predictor and a categorical predictor with L levels consist of the element-wise product of the $L - 1$ indicator variables with the continuous predictor.
 - Interaction terms between two categorical predictors with L and M levels consist of the $(L - 1)*(M - 1)$ indicator variables to include all possible combinations of the two categorical predictor levels.
 - You cannot specify higher-order terms for a categorical predictor because the square of an indicator is equal to itself.

Alternative Functionality

- Use `stepwiselm` to specify terms in a starting model and continue improving the model until no single step of adding or removing a term is beneficial.
- Use `addTerms` to add specific terms to a model.
- Use `step` to optimally improve a model by adding or removing terms.

Introduced in R2012a

reorderlevels

Reorder levels of nominal or ordinal arrays

Note The `nominal` and `ordinal` array data types might be removed in a future release. To represent ordered and unordered discrete, nonnumeric data, use the “Categorical Arrays” (MATLAB) data type instead.

Syntax

`B = reorderlevels(A,newlevels)`

Description

`B = reorderlevels(A,newlevels)` returns a `nominal` or `ordinal` array object of the same type as `A`, but with levels in the new order specified by `newlevels`.

For ordinal arrays, the order of the levels has significance for relational operators, finding minimum and maximum values, and sorting.

Input Arguments

A — Nominal or ordinal array

`nominal` array | `ordinal` array

Nominal or ordinal array, specified as a `nominal` or `ordinal` array object created with `nominal` or `ordinal`.

newlevels — New order of levels

string array | cell array of character vectors | 2-D character matrix

New order of levels, specified as a string array, cell array of character vectors, or 2-D character matrix. `newlevels` must be a reordering of the labels returned by `getlabels`.

Data Types: `char` | `string` | `cell`

Output Arguments

B — Nominal or ordinal array

`nominal` array | `ordinal` array

Nominal or ordinal array, returned as a `nominal` or `ordinal` array object.

Introduced in R2007a

repartition

Class: cvpartition

Repartition data for cross-validation

Syntax

```
cnew = repartition(c)
```

Description

`cnew = repartition(c)` constructs an object `cnew` of the `cvpartition` on page 32-1237 class defining a random partition of the same type as `c`, where `c` is also an object of the `cvpartition` on page 32-1237 class.

Repartitioning is useful for Monte-Carlo repetitions of cross-validation analyses. `repartition` is called by `crossval` when the `'mcreps'` parameter is specified.

Examples

Partition and repartition 100 observations for 3-fold cross-validation:

```
c = cvpartition(100,'kfold',3)
c =
K-fold cross validation partition
      N: 100
  NumTestSets: 3
   TrainSize: 67 66 67
   TestSize: 33 34 33

cnew = repartition(c)
cnew =
K-fold cross validation partition
      N: 100
  NumTestSets: 3
```

```
TrainSize: 67 66 67
TestSize: 33 34 33
```

Check for equality of the test data in the first fold:

```
isequal(test(c,1),test(cnew,1))
ans =
    0
```

`cvpartition`

RepeatedMeasuresModel class

Repeated measures model class

Description

A `RepeatedMeasuresModel` object represents a model fitted to data with multiple measurements per subject. The object comprises data, fitted coefficients, covariance parameters, design matrix, error degrees of freedom, and between- and within-subjects factor names for a repeated measures model. You can predict model responses using the `predict` method and generate random data at new design points using the `random` method.

Construction

You can fit a repeated measures model using `fitrm(t,modelspec)`.

Input Arguments

t — Input data

table

Input data, which includes the values of the response variables and the between-subject factors to use as predictors in the repeated measures model, specified as a table.

Data Types: table

modelspec — Formula for model specification

character vector or string scalar of the form 'y1-yk ~ terms'

Formula for model specification, specified as a character vector or string scalar of the form 'y1-yk ~ terms'. Specify the terms using Wilkinson notation. `fitrm` treats the variables used in model terms as categorical if they are categorical (nominal or ordinal), logical, character arrays, string arrays, or a cell array of character vectors.

Example: 'y1-y4 ~ x1 + x2 * x3'

Data Types: `char` | `string`

Properties

BetweenDesign — Design for between-subject factors

table

Design for between-subject factors and values of repeated measures, stored as a table.

Data Types: `table`

BetweenModel — Model for between-subjects factors

character vector

Model for between-subjects factors, stored as a character vector. This character vector is the text representation to the right of the tilde in the model specification you provide when fitting the repeated measures model using `fitrm`.

Data Types: `char`

BetweenFactorNames — Names of variables used as between-subject factors

cell array of character vectors

Names of variables used as between-subject factors in the repeated measures model, `rm`, stored as a cell array of character vectors.

Data Types: `cell`

ResponseNames — Names of variables used as response variables

cell array of character vectors

Names of variables used as response variables in the repeated measures model, `rm`, stored as a cell array of character vectors.

Data Types: `cell`

WithinDesign — Values of within-subject factors

table

Values of the within-subject factors, stored as a table.

Data Types: `table`

WithinModel — Model for within-subjects factors

character vector

Model for within-subjects factors, stored as a character vector.

You can specify `WithinModel` as a character vector or a string scalar using dot notation:
`Mdl.WithinModel = newWithinModelValue.`

WithinFactorNames — Names of within-subject factors

cell array of character vectors

Names of the within-subject factors, stored as a cell array of character vectors.

Data Types: cell

Coefficients — Values of estimated coefficients

table

Values of the estimated coefficients for fitting the repeated measures as a function of the terms in the between-subjects model, stored as a table.

`fitrm` defines the coefficients for a categorical term using 'effects' coding, which means coefficients sum to 0. There is one coefficient for each level except the first. The implied coefficient for the first level is the sum of the other coefficients for the term.

You can display the coefficient values as a matrix rather than a table using `coef = r.Coefficients{:, :}`.

You can display marginal means for all levels using the `marginmean` method.

Data Types: table

Covariance — Estimated response covariances

table

Estimated response covariances, that is, covariance of the repeated measures, stored as a table. `fitrm` computes the covariances around the mean returned by the fitted repeated measures model `rm`.

You can display the covariance values as a matrix rather than a table using `coef = r.Covariance{:, :}`.

Data Types: table

DFE — Error degrees of freedom

scalar value

Error degrees of freedom, stored as a scalar value. DFE is the number of observations minus the number of estimated coefficients in the between-subjects model.

Data Types: double

Methods

anova	Analysis of variance for between-subject effects
epsilon	Epsilon adjustment for repeated measures anova
grpstats	Compute descriptive statistics of repeated measures data by group
manova	Multivariate analysis of variance
margmean	Estimate marginal means
mauchly	Mauchly's test for sphericity
multcompare	Multiple comparison of estimated marginal means
plot	Plot data with optional grouping
plotprofile	Plot expected marginal means with optional grouping
predict	Compute predicted values given predictor values
random	Generate new random response values given predictor values
ranova	Repeated measures analysis of variance

Examples**Fit a Repeated Measures Model**

Load the sample data.

```
load fisheriris
```

The column vector, `species`, consists of iris flowers of three different species: `setosa`, `versicolor`, `virginica`. The double matrix `meas` consists of four types of measurements on the flowers: the length and width of sepals and petals in centimeters, respectively.

Store the data in a table array.

```
t = table(species,meas(:,1),meas(:,2),meas(:,3),meas(:,4),...
'VariableNames',{'species','meas1','meas2','meas3','meas4'});
Meas = table([1 2 3 4]','VariableNames',{'Measurements'});
```

Fit a repeated measures model, where the measurements are the responses and the species is the predictor variable.

```
rm = fitrm(t,'meas1-meas4~species','WithinDesign',Meas)
```

```
rm =
```

```
RepeatedMeasuresModel with properties:
```

```
Between Subjects:
```

```
    BetweenDesign: [150x5 table]
```

```
    ResponseNames: {'meas1' 'meas2' 'meas3' 'meas4'}
```

```
    BetweenFactorNames: {'species'}
```

```
    BetweenModel: '1 + species'
```

```
Within Subjects:
```

```
    WithinDesign: [4x1 table]
```

```
    WithinFactorNames: {'Measurements'}
```

```
    WithinModel: 'separatemeans'
```

```
Estimates:
```

```
    Coefficients: [3x4 table]
```

```
    Covariance: [4x4 table]
```

Display the coefficients.

```
rm.Coefficients
```

```
ans=3x4 table
```

	meas1	meas2	meas3	meas4
(Intercept)	5.8433	3.0573	3.758	1.1993
species_setosa	-0.83733	0.37067	-2.296	-0.95333
species_versicolor	0.092667	-0.28733	0.502	0.12667

`fitrm` uses the 'effects' contrasts, which means that the coefficients sum to 0. The `rm.DesignMatrix` has one column of 1s for the intercept, and two other columns `species_setosa` and `species_versicolor`, which are as follows:

$$\text{species_setosa} = \begin{cases} 1, & \text{if } \textit{setosa} \\ 0, & \text{if } \textit{versicolor} \\ -1, & \text{if } \textit{virginica} \end{cases}$$

and

$$\text{species_versicolor} = \begin{cases} 0, & \text{if } \textit{setosa} \\ 1, & \text{if } \textit{versicolor} \\ -1, & \text{if } \textit{virginica} \end{cases} .$$

Display the covariance matrix.

```
rm.Covariance
```

```
ans=4x4 table
```

	meas1	meas2	meas3	meas4
meas1	0.26501	0.092721	0.16751	0.038401
meas2	0.092721	0.11539	0.055244	0.03271
meas3	0.16751	0.055244	0.18519	0.042665
meas4	0.038401	0.03271	0.042665	0.041882

Display the error degrees of freedom.

```
rm.DFE
```

```
ans = 147
```

The error degrees of freedom is the number of observations minus the number of estimated coefficients in the between-subjects model, e.g. $150 - 3 = 147$.

Definitions

Wilkinson Notation

Wilkinson notation describes the factors present in models. It does not describe the multipliers (coefficients) of those factors.

Use these rules to specify the responses in `modelspec`.

Wilkinson Notation	Description
Y1, Y2, Y3	Specific list of variables
Y1-Y5	All table variables from Y1 through Y5

Use these rules to specify terms in `modelspec`.

Wilkinson Notation	Factors in Standard Notation
1	Constant (intercept) term
X^k , where k is a positive integer	X, X^2, \dots, X^k
$X1 + X2$	$X1, X2$
$X1 * X2$	$X1, X2, X1 * X2$
$X1 : X2$	$X1 * X2$ only
$-X2$	Do not include $X2$
$X1 * X2 + X3$	$X1, X2, X3, X1 * X2$
$X1 + X2 + X3 + X1 : X2$	$X1, X2, X3, X1 * X2$
$X1 * X2 * X3 - X1 : X2 : X3$	$X1, X2, X3, X1 * X2, X1 * X3, X2 * X3$
$X1 * (X2 + X3)$	$X1, X2, X3, X1 * X2, X1 * X3$

Statistics and Machine Learning Toolbox notation always includes a constant term unless you explicitly remove the term using `-1`.

Class Attributes (MATLAB)

Property Attributes (MATLAB)

replacedata

Class: dataset

Replace dataset variables

Note The dataset data type might be removed in a future release. To work with heterogeneous data, use the MATLAB® table data type instead. See MATLAB table documentation for more information.

Syntax

`B = replacedata(A,X)`
`B = replacedata(A,X,vars)`
`B = replacedata(A,fun)`
`B = replacedata(A,fun,vars)`

Description

`B = replacedata(A,X)` creates a dataset array **B** with the same variables as the dataset array **A**, but with the data for those variables replaced by the data in the array **X**. `replacedata` creates each variable in **B** using one or more columns from **X**, in order. **X** must have as many columns as the total number of columns in all of the variables in **A**, and as many rows as **A** has observations.

`B = replacedata(A,X,vars)` creates a dataset array **B** with the same variables as the dataset array **A**, but with the data for the variables specified in **vars** replaced by the data in the array **X**. The remaining variables in **B** are copies of the corresponding variables in **A**. **vars** is a positive integer, a vector of positive integers, a character vector, a string array, a cell array of character vectors, or a logical vector. Each variable in **B** has as many columns as the corresponding variable in **A**. **X** must have as many columns as the total number of columns in all the variables specified in **vars**.

`B = replacedata(A,fun)` or `B = replacedata(A,fun,vars)` creates a dataset array **B** by applying the function **fun** to the values in **A**'s variables. `replacedata` first horizontally concatenates **A**'s variables into a single array, then applies the function **fun**.

The specified variables in A must have types and sizes compatible with the concatenation. fun is a function handle that accepts a single input array and returns an array with the same number of rows and columns as the input.

Examples

```
data = dataset({rand(3,3),'Var1','Var2','Var3'})
```

```
% Use ZSCORE to normalize each variable in a dataset array  
% separately, by explicitly extracting and transforming the  
% data, and then replacing it.
```

```
X = double(data);
```

```
X = zscore(X);
```

```
data = replacedata(data,X)
```

```
% Equivalently, provide a handle to ZSCORE.
```

```
data = replacedata(data,@zscore)
```

```
% Use ZSCORE to normalize each observation in a dataset  
% array separately by creating an anonymous function.
```

```
data = replacedata(data,@(x) zscore(x,[],2))
```

dataset

replaceWithMissing

Class: dataset

Insert missing data indicators into a dataset array

Note The dataset data type might be removed in a future release. To work with heterogeneous data, use the MATLAB® table data type instead. See MATLAB table documentation for more information.

Syntax

```
ds2 = replaceWithMissing(ds,Name,Value)
```

Description

`ds2 = replaceWithMissing(ds,Name,Value)` replaces specified values in a dataset array with standard missing data indicators using options specified by one or more `Name,Value` pair arguments. Use `replaceWithMissing` to specify:

- Which numeric missing value indicators to replace with NaN.
- Which character missing value indicators to replace with ' '.
- Which categorical levels to replace with <undefined>.

Input Arguments

ds

dataset array.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes.

You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

NumericValues

Vector of numeric values that `replaceWithMissing` replaces with `NaN`.

CategoricalLevels

Character vector or cell array of character vectors naming the categorical levels that `replaceWithMissing` replaces with `<undefined>`.

Strings

Character vector or cell array of character vectors containing the text that `replaceWithMissing` replaces with `' '`.

DataVars

Specified set of variables in `ds` for which `replaceWithMissing` replaces values. You can specify a positive integer or vector of positive integers indicating the variable column numbers, a variable name or a cell array of variables names, or a logical vector indicating which variables to replace missing values in.

Default: All variables in `ds`.

Output Arguments

ds2

dataset array that has the specified missing value indicators, in the specified variables of `ds`, replaced with standard missing value indicators.

Examples

Replace Nonstandard Missing Value Indicators

Replace nonstandard missing value indicators with standard missing value indicators.

Replace numeric missing values coded 99 with NaN, and character missing values coded '.' with ''.

```
ds = replaceWithMissing(ds, 'NumericValues', 99, 'Strings', '.');
```

Topics

“Clean Messy and Missing Data” on page 2-118

“Dataset Arrays” on page 2-137

reset

Class: grandstream

Reset state

Syntax

```
reset(q)
```

Description

`reset(q)` resets the state of the quasi-random number stream `q` of the `grandstream` on page 32-5498 class back to its initial state, 1. Subsequent points drawn from the stream will be the same as those drawn from a new stream. The command is equivalent to `q.State = 1`.

Examples

Use `grandstream` to construct a 3-D Halton stream, based on a point set that skips the first 1000 values and then retains every 101st point:

```
q = grandstream('halton',3,'Skip',1e3,'Leap',1e2)
q =
    Halton quasi-random stream in 3 dimensions
    Point set properties:
        Skip : 1000
        Leap : 100
        ScrambleMethod : none

nextIdx = q.State
nextIdx =
     1
```

Use `grand` to generate two samples of size four:

```
X1 = grand(q,4)
X1 =
```

```
    0.0928    0.3475    0.0051
    0.6958    0.2035    0.2371
    0.3013    0.8496    0.4307
    0.9087    0.5629    0.6166
nextIdx = q.State
nextIdx =
    5
```

```
X2 = grand(q,4)
X2 =
    0.2446    0.0238    0.8102
    0.5298    0.7540    0.0438
    0.3843    0.5112    0.2758
    0.8335    0.2245    0.4694
nextIdx = q.State
nextIdx =
    9
```

Use `reset` to reset the stream, then generate another sample:

```
reset(q)
nextIdx = q.State
nextIdx =
    1

X = grand(q,4)
X =
    0.0928    0.3475    0.0051
    0.6958    0.2035    0.2371
    0.3013    0.8496    0.4307
    0.9087    0.5629    0.6166
```

See Also

`grand` | `grandstream`

residuals

Class: GeneralizedLinearMixedModel

Residuals of fitted generalized linear mixed-effects model

Syntax

```
r = residuals(glme)
r = residuals(glme, Name, Value)
```

Description

`r = residuals(glme)` returns the raw conditional residuals from a fitted generalized linear mixed-effects model `glme`.

`r = residuals(glme, Name, Value)` returns the residuals using additional options specified by one or more `Name, Value` pair arguments. For example, you can specify to return Pearson residuals for the model.

Input Arguments

glme — Generalized linear mixed-effects model

GeneralizedLinearMixedModel object

Generalized linear mixed-effects model, specified as a GeneralizedLinearMixedModel object. For properties and methods of this object, see GeneralizedLinearMixedModel.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Conditional — Indicator for conditional residuals

true (default) | false

Indicator for conditional residuals, specified as the comma-separated pair consisting of 'Conditional' and one of the following.

Value	Description
true	Contributions from both fixed effects and random effects (conditional)
false	Contribution from only fixed effects (marginal)

Conditional residuals include contributions from both fixed- and random-effects predictors. Marginal residuals include contribution from only fixed effects. To obtain marginal residual values, `residuals` computes the conditional mean of the response with the empirical Bayes predictor vector of random effects, `b`, set to 0.

Example: 'Conditional', false

ResidualType — Residual type

'raw' (default) | 'Pearson'

Residual type, specified as the comma-separated pair consisting of 'ResidualType' and one of the following.

Residual Type	Conditional	Marginal
'raw'	$r_{ci} = y_i - g^{-1} \left(x_i^T \widehat{\beta} + z_i^T \widehat{b} + \delta_i \right)$	$r_{mi} = y_i - g^{-1} \left(x_i^T \widehat{\beta} + \delta_i \right)$
'Pearson'	$r_{ci}^{pearson} = \frac{r_{ci}}{\sqrt{\frac{\sigma^2}{w_i} v_i(\mu_i(\widehat{\beta}, \widehat{b}))}}$	$r_{mi}^{pearson} = \frac{r_{mi}}{\sqrt{\frac{\sigma^2}{w_i} v_i(\mu_i(\widehat{\beta}, 0))}}$

In each of these equations:

- y_i is the i th element of the n -by-1 response vector, y , where $i = 1, \dots, n$.

- g^{-1} is the inverse link function for the model.
- x_i^T is the i th row of the fixed-effects design matrix X .
- z_i^T is the i th row of the random-effects design matrix Z .
- δ_i is the i th offset value.
- σ^2 is the dispersion parameter.
- w_i is the i th observation weight.
- v_i is the variance term for the i th observation.
- μ_i is the mean of the response for the i th observation.
- $\hat{\beta}$ and \hat{b} are estimated values of β and b .

Raw residuals from a generalized linear mixed-effects model have nonconstant variance. Pearson residuals are expected to have an approximately constant variance, and are generally used for analysis.

Example: 'ResidualType', 'Pearson'

Output Arguments

r — Residuals

n -by-1 vector

Residuals of the fitted generalized linear mixed-effects model `glme` returned as an n -by-1 vector, where n is the number of observations.

Examples

Plot Residuals Versus Fitted Values

Load the sample data.

```
load mfr
```

This simulated data is from a manufacturing company that operates 50 factories across the world, with each factory running a batch process to create a finished product. The company wants to decrease the number of defects in each batch, so it developed a new

manufacturing process. To test the effectiveness of the new process, the company selected 20 of its factories at random to participate in an experiment: Ten factories implemented the new process, while the other ten continued to run the old process. In each of the 20 factories, the company ran five batches (for a total of 100 batches) and recorded the following data:

- Flag to indicate whether the batch used the new process (`newprocess`)
- Processing time for each batch, in hours (`time`)
- Temperature of the batch, in degrees Celsius (`temp`)
- Categorical variable indicating the supplier (A, B, or C) of the chemical used in the batch (`supplier`)
- Number of defects in the batch (`defects`)

The data also includes `time_dev` and `temp_dev`, which represent the absolute deviation of time and temperature, respectively, from the process standard of 3 hours at 20 degrees Celsius.

Fit a generalized linear mixed-effects model using `newprocess`, `time_dev`, `temp_dev`, and `supplier` as fixed-effects predictors. Include a random-effects term for intercept grouped by `factory`, to account for quality differences that might exist due to factory-specific variations. The response variable `defects` has a Poisson distribution, and the appropriate link function for this model is log. Use the Laplace fit method to estimate the coefficients. Specify the dummy variable encoding as `'effects'`, so the dummy variable coefficients sum to 0.

The number of defects can be modeled using a Poisson distribution

$$\text{defects}_{ij} \sim \text{Poisson}(\mu_{ij})$$

This corresponds to the generalized linear mixed-effects model

$$\log(\mu_{ij}) = \beta_0 + \beta_1 \text{newprocess}_{ij} + \beta_2 \text{time_dev}_{ij} + \beta_3 \text{temp_dev}_{ij} + \beta_4 \text{supplier_C}_{ij} + \beta_5 \text{supplier_B}_{ij} + b_i,$$

where

- defects_{ij} is the number of defects observed in the batch produced by factory i during batch j .
- μ_{ij} is the mean number of defects corresponding to factory i (where $i = 1, 2, \dots, 20$) during batch j (where $j = 1, 2, \dots, 5$).

- newprocess_{ij} , time_dev_{ij} , and temp_dev_{ij} are the measurements for each variable that correspond to factory i during batch j . For example, newprocess_{ij} indicates whether the batch produced by factory i during batch j used the new process.
- supplier_C_{ij} and supplier_B_{ij} are dummy variables that use effects (sum-to-zero) coding to indicate whether company C or B, respectively, supplied the process chemicals for the batch produced by factory i during batch j .
- $b_i \sim N(0, \sigma_b^2)$ is a random-effects intercept for each factory i that accounts for factory-specific variation in quality.

```
glme = fitglme(mfr, 'defects ~ 1 + newprocess + time_dev + temp_dev + supplier + (1|factory)
  'Distribution', 'Poisson', 'Link', 'log', 'FitMethod', 'Laplace', 'DummyVarCoding', 'effects')
```

Generate the conditional Pearson residuals and the conditional fitted values from the model.

```
r = residuals(glme, 'ResidualType', 'Pearson');
mufit = fitted(glme);
```

Display the first ten rows of the Pearson residuals.

```
r(1:10)
ans = 10×1
    0.4530
    0.4339
    0.3833
   -0.2653
    0.2811
   -0.0935
   -0.2984
   -0.2509
    1.5547
   -0.3027
```

Plot the Pearson residuals versus the fitted values, to check for signs of nonconstant variance among the residuals (heteroscedasticity).

```
figure
scatter(mufit, r)
title('Residuals versus Fitted Values')
```

```
xlabel('Fitted Values')  
ylabel('Residuals')
```

The plot does not show a systematic dependence on the fitted values, so there are no signs of nonconstant variance among the residuals.

`GeneralizedLinearMixedModel` | `designMatrix` | `fitted` | `response`

residuals

Class: LinearMixedModel

Residuals of fitted linear mixed-effects model

Syntax

```
R = residuals(lme)
R = residuals(lme, Name, Value)
```

Description

`R = residuals(lme)` returns the raw conditional residuals from a fitted linear mixed-effects model `lme`.

`R = residuals(lme, Name, Value)` returns the residuals from the linear mixed-effects model `lme` with additional options specified by one or more `Name, Value` pair arguments.

For example, you can specify Pearson or standardized residuals, or residuals with contributions from only fixed effects.

Input Arguments

lme — Linear mixed-effects model

LinearMixedModel object

Linear mixed-effects model, specified as a LinearMixedModel object constructed using `fitlme` or `fitlmematrix`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes.

You can specify several name and value pair arguments in any order as Name1, Value1, . . . , NameN, ValueN.

Conditional — Indicator for conditional residuals

True (default) | False

Indicator for conditional residuals, specified as the comma-separated pair consisting of 'Conditional' and one of the following.

- True Contribution from both fixed effects and random effects (conditional)
- False Contribution from only fixed effects (marginal)

Example: 'Conditional', 'False'

ResidualType — Residual type

'Raw' (default) | 'Pearson' | 'Standardized'

Residual type, specified by the comma-separated pair consisting of ResidualType and one of the following.

Residual Type	Conditional	Marginal
'Raw'	$r_i^C = [y - X\hat{\beta} - Z\hat{b}]_i$	$r_i^M = [y - X\hat{\beta}]_i$
'Pearson'	$pr_i^C = \frac{r_i^C}{\sqrt{[\widehat{\text{Var}}_{y,b}(y - X\hat{\beta} - Z\hat{b})]_{ii}}}$	$pr_i^M = \frac{r_i^M}{\sqrt{[\widehat{\text{Var}}_y(y - X\hat{\beta})]_{ii}}}$
'Standardized'	$st_i^C = \frac{r_i^C}{\sqrt{[\widehat{\text{Var}}_y(r^C)]_{ii}}}$	$st_i^M = \frac{r_i^M}{\sqrt{[\widehat{\text{Var}}_y(r^M)]_{ii}}}$

For more information on the conditional and marginal residuals and residual variances, see Definitions at the end of this page.

Example: 'ResidualType', 'Standardized'

Output Arguments

R — Residuals

n-by-1 vector

Residuals of the fitted linear mixed-effects model `lme` returned as an *n*-by-1 vector, where *n* is the number of observations.

Examples

Plot Residuals vs. Fitted Values

Load the sample data.

```
load(fullfile(matlabroot, 'examples', 'stats', 'weight.mat'));
```

`weight` contains data from a longitudinal study, where 20 subjects are randomly assigned to 4 exercise programs, and their weight loss is recorded over six 2-week time periods. This is simulated data.

Store the data in a table. Define `Subject` and `Program` as categorical variables.

```
tbl = table(InitialWeight, Program, Subject, Week, y);  
tbl.Subject = nominal(tbl.Subject);  
tbl.Program = nominal(tbl.Program);
```

Fit a linear mixed-effects model where the initial weight, type of program, week, and the interaction between the week and type of program are the fixed effects. The intercept and week vary by subject.

```
lme = fitlme(tbl, 'y ~ InitialWeight + Program*Week + (Week|Subject)');
```

Compute the fitted values and raw residuals.

```
F = fitted(lme);  
R = residuals(lme);
```

Plot the residuals versus the fitted values.

```
plot(F,R,'bx')
xlabel('Fitted Values')
ylabel('Residuals')
```

Now, plot the residuals versus the fitted values, grouped by program.

```
figure();
gscatter(F,R,Program)
```

The residuals seem to behave similarly across levels of the program as expected.

Compute Conditional and Marginal Pearson Residuals

Load the sample data.

```
load carbig
```

Store the variables for miles per gallon (MPG), acceleration, horsepower, cylinders, and model year in a table.

```
tbl = table(MPG,Acceleration,Horsepower,Cylinders,Model_Year);
```

Fit a linear mixed-effects model for miles per gallon (MPG), with fixed effects for acceleration, horsepower, and the cylinders, and potentially correlated random effects for intercept and acceleration grouped by model year.

```
lme = fitlme(tbl, 'MPG ~ Acceleration + Horsepower + Cylinders + (Acceleration|Model_Year)')
```

Compute the conditional Pearson residuals and display the first five residuals.

```
PR = residuals(lme, 'ResidualType', 'Pearson');  
PR(1:5)
```

```
ans = 5×1  
  
-0.0533  
0.0652  
0.3655  
-0.0106  
-0.3340
```

Compute the marginal Pearson residuals and display the first five residuals.

```
PRM = residuals(lme, 'ResidualType', 'Pearson', 'Conditional', false);  
PRM(1:5)
```

```
ans = 5×1  
  
-0.1250  
0.0130  
0.3242  
-0.0861  
-0.3006
```

Examine Residuals

Load the sample data.

```
load carbig
```

Store the variables for miles per gallon (MPG), acceleration, horsepower, cylinders, and model year in a table.

```
tbl = table(MPG,Acceleration,Horsepower,Cylinders,Model_Year);
```

Fit a linear mixed-effects model for miles per gallon (MPG), with fixed effects for acceleration, horsepower, and the cylinders, and potentially correlated random effects for intercept and acceleration grouped by model year.

```
lme = fitlme(tbl, 'MPG ~ Acceleration + Horsepower + Cylinders + (Acceleration|Model_Year)');
```

Draw a histogram of the raw residuals with a normal fit.

```
r = residuals(lme);  
histfit(r)
```

Normal distribution seems to be a good fit for the residuals.

Compute the conditional Pearson and standardized residuals and create box plots of all three types of residuals.

```
pr = residuals(lme, 'ResidualType', 'Pearson');
st = residuals(lme, 'ResidualType', 'Standardized');
X = [r pr st];
figure();
boxplot(X)
```

Red plus signs show the observations with residuals above or below $q_3 + 1.5(q_3 - q_1)$ and $q_1 - 1.5(q_3 - q_1)$, where q_1 and q_3 are the 25th and 75th percentiles, respectively.

Find the observations with residuals that are 2.5 standard deviations above and below the mean.

```
find(r > nanmean(r) + 2.5*nanstd(r))
```

```
ans = 7×1
```

```

```

```
find(r < nanmean(r) - 2.5*nanstd(r))
```

```
ans = 3×1
```

```
119
324
375
```

Definitions

Conditional and Marginal Residuals

Conditional residuals include contributions from both fixed and random effects, whereas marginal residuals include contribution from only fixed effects.

Suppose the linear mixed-effects model `lme` has an n -by- p fixed-effects design matrix X and an n -by- q random-effects design matrix Z . Also, suppose the p -by-1 estimated fixed-effects vector is $\widehat{\beta}$, and the q -by-1 estimated best linear unbiased predictor (BLUP) vector of random effects is \widehat{b} . The fitted conditional response is

$$\widehat{y}_{Cond} = X\widehat{\beta} + Z\widehat{b},$$

and the fitted marginal response is

$$\widehat{y}_{Mar} = X\widehat{\beta},$$

`residuals` can return three types of residuals: raw, Pearson, and standardized. For any type, you can compute the conditional or the marginal residuals. For example, the conditional raw residual is

$$r_{Cond} = y - X\hat{\beta} - Z\hat{b},$$

and the marginal raw residual is

$$r_{Mar} = y - X\hat{\beta}.$$

For more information on other types of residuals, see the `ResidualType` name-value pair argument.

See Also

`LinearMixedModel` | `fitted` | `plotResiduals` | `response`

response

Class: GeneralizedLinearMixedModel

Response vector of generalized linear mixed-effects model

Syntax

```
y = response(glme)
[y,binomialsizes] = response(glme)
```

Description

`y = response(glme)` returns the response vector `y` used to fit the generalized linear mixed effects model `glme`.

`[y,binomialsizes] = response(glme)` also returns the binomial size associated with each element of `y` if the conditional distribution of response given the random effects is binomial.

Input Arguments

glme — Generalized linear mixed-effects model

GeneralizedLinearMixedModel object

Generalized linear mixed-effects model, specified as a GeneralizedLinearMixedModel object. For properties and methods of this object, see GeneralizedLinearMixedModel.

Output Arguments

y — Response values

n-by-1 vector

Response values, specified as an *n*-by-1 vector, where *n* is the number of observations.

For an observation i with prior weights w_i^p and binomial size n_i (when applicable), the response values y_i can have the following values.

Distribution	Permitted Values	Notes
Binomial	$\left\{0, \frac{1}{w_i^p n_i}, \frac{2}{w_i^p n_i}, \dots, 1\right\}$	w_i^p and n_i are integer values > 0
Poisson	$\left\{0, \frac{1}{w_i^p}, \frac{2}{w_i^p}, \dots\right\}$	w_i^p is an integer value > 0
Gamma	$(0, \infty)$	$w_i^p \geq 0$
InverseGaussian	$(0, \infty)$	$w_i^p \geq 0$
normal	$(-\infty, \infty)$	$w_i^p \geq 0$

You can access the prior weights property w_i^p using dot notation. For example, to access the prior weights property for a model `glme`:

```
glme.ObservationInfo.Weights
```

binomialsize — Binomial size

vector

Binomial size associated with each element of y , returned as an n -by-1 vector, where n is the number of observations. `response` only returns `binomialsize` if the conditional distribution of response given the random effects is binomial. `binomialsize` is empty for other distributions.

Examples

Plot Response Versus Fitted Values

Load the sample data.

```
load mfr
```

This simulated data is from a manufacturing company that operates 50 factories across the world, with each factory running a batch process to create a finished product. The company wants to decrease the number of defects in each batch, so it developed a new

manufacturing process. To test the effectiveness of the new process, the company selected 20 of its factories at random to participate in an experiment: Ten factories implemented the new process, while the other ten continued to run the old process. In each of the 20 factories, the company ran five batches (for a total of 100 batches) and recorded the following data:

- Flag to indicate whether the batch used the new process (`newprocess`)
- Processing time for each batch, in hours (`time`)
- Temperature of the batch, in degrees Celsius (`temp`)
- Categorical variable indicating the supplier (A, B, or C) of the chemical used in the batch (`supplier`)
- Number of defects in the batch (`defects`)

The data also includes `time_dev` and `temp_dev`, which represent the absolute deviation of time and temperature, respectively, from the process standard of 3 hours at 20 degrees Celsius.

Fit a generalized linear mixed-effects model using `newprocess`, `time_dev`, `temp_dev`, and `supplier` as fixed-effects predictors. Include a random-effects term for intercept grouped by `factory`, to account for quality differences that might exist due to factory-specific variations. The response variable `defects` has a Poisson distribution, and the appropriate link function for this model is log. Use the Laplace fit method to estimate the coefficients. Specify the dummy variable encoding as `'effects'`, so the dummy variable coefficients sum to 0.

The number of defects can be modeled using a Poisson distribution

$$\text{defects}_{ij} \sim \text{Poisson}(\mu_{ij})$$

This corresponds to the generalized linear mixed-effects model

$$\log(\mu_{ij}) = \beta_0 + \beta_1 \text{newprocess}_{ij} + \beta_2 \text{time_dev}_{ij} + \beta_3 \text{temp_dev}_{ij} + \beta_4 \text{supplier_C}_{ij} + \beta_5 \text{supplier_B}_{ij} + b_i,$$

where

- defects_{ij} is the number of defects observed in the batch produced by factory i during batch j .
- μ_{ij} is the mean number of defects corresponding to factory i (where $i = 1, 2, \dots, 20$) during batch j (where $j = 1, 2, \dots, 5$).

- newprocess_{ij} , time_dev_{ij} , and temp_dev_{ij} are the measurements for each variable that correspond to factory i during batch j . For example, newprocess_{ij} indicates whether the batch produced by factory i during batch j used the new process.
- supplier_C_{ij} and supplier_B_{ij} are dummy variables that use effects (sum-to-zero) coding to indicate whether company C or B, respectively, supplied the process chemicals for the batch produced by factory i during batch j .
- $b_i \sim N(0, \sigma_b^2)$ is a random-effects intercept for each factory i that accounts for factory-specific variation in quality.

```
glme = fitglm(mfr, 'defects ~ 1 + newprocess + time_dev + temp_dev + supplier + (1|factory)  
'Distribution', 'Poisson', 'Link', 'log', 'FitMethod', 'Laplace', 'DummyVarCoding', 'effects')
```

Extract the observed response values for the model, then use `fitted` to generate the fitted conditional mean values.

```
y = response(glme); % Observed response values  
yfit = fitted(glme); % Fitted response values
```

Create a scatterplot of the observed response values versus fitted values. Add a reference line to improve the visualization.

```
figure  
scatter(yfit, y)  
xlim([0, 12])  
ylim([0, 12])  
refline(1, 0)  
title('Response versus Fitted Values')  
xlabel('Fitted Values')  
ylabel('Response')
```

The plot shows a positive correlation between the fitted values and the observed response values.

GeneralizedLinearMixedModel | fitted | residuals

response

Class: LinearMixedModel

Response vector of the linear mixed-effects model

Syntax

```
y = response(lme)
```

Description

`y = response(lme)` returns the response vector `y` used to fit the linear mixed-effects model `lme`.

Input Arguments

lme — Linear mixed-effects model

LinearMixedModel object

Linear mixed-effects model, specified as a LinearMixedModel object constructed using `fitlme` or `fitlmematrix`.

Output Arguments

y — Response values

n-by-1 vector

Response values, specified as an *n*-by-1 vector, where *n* is the number of observations.

Data Types: `single` | `double`

Examples

Plot Response versus Fitted Values

Load the sample data.

```
load(fullfile(matlabroot, 'examples', 'stats', 'weight.mat'));
```

`weight` contains data from a longitudinal study, where 20 subjects are randomly assigned to 4 exercise programs, and their weight loss is recorded over two-week time periods. This is simulated data.

Store the data in a table. Define `Subject` and `Program` as categorical variables.

```
tbl = table(InitialWeight, Program, Subject, Week, y);  
tbl.Subject = nominal(tbl.Subject);  
tbl.Program = nominal(tbl.Program);
```

Fit a linear mixed-effects model where the initial weight, type of program, week, and the interaction between the week and type of program are the fixed effects. The intercept and week vary by subject.

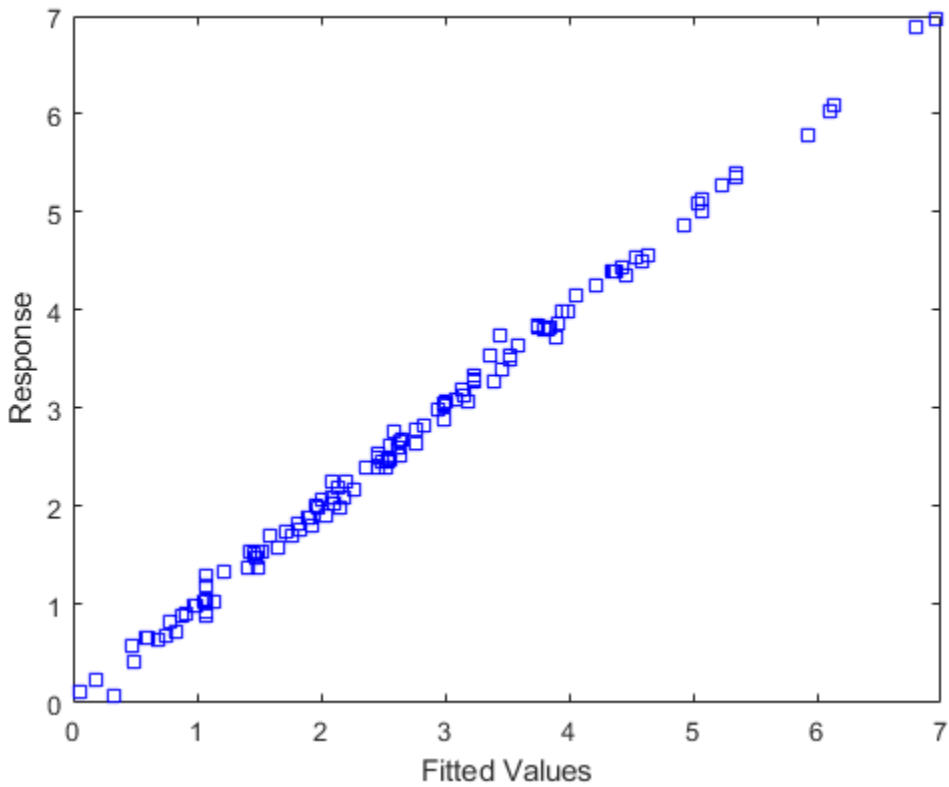

```
lme = fitlme(tbl, 'y ~ InitialWeight + Program*Week + (Week|Subject)');
```

Compute the fitted values and the response.

```
F = fitted(lme);  
y = response(lme);
```

Plot the response versus the fitted values.

```
plot(F, y, 'bs')  
xlabel('Fitted Values')  
ylabel('Response')
```

`LinearMixedModel` | `fitted` | `residuals`

resubEdge

Class: ClassificationDiscriminant

Classification edge by resubstitution

Syntax

```
edge = resubEdge(obj)
```

Description

`edge = resubEdge(obj)` returns the classification edge obtained by `obj` on its training data.

Input Arguments

obj

Discriminant analysis classifier, produced using `fitcdiscr`.

Output Arguments

edge

Classification edge obtained by resubstituting the training data into the calculation of `edge`.

Examples

Estimate the Resubstitution Edge of Discriminant Analysis Classifiers

Estimate the quality of a discriminant analysis classifier for Fisher's iris data by resubstitution.

Load Fisher's iris data set.

```
load fisheriris
```

Train a discriminant analysis classifier.

```
Mdl = fitcdiscr(meas, species);
```

Compute the resubstitution edge.

```
redge = resubEdge(Mdl)
```

```
redge = 0.9454
```

Definitions

Edge

The edge is the weighted mean value of the classification margin. The weights are class prior probabilities. If you supply additional weights, those weights are normalized to sum to the prior probabilities in the respective classes, and are then used to compute the weighted average.

Margin

The classification margin is the difference between the classification score for the true class and maximal classification score for the false classes.

The classification margin is a column vector with the same number of rows as in the matrix X . A high value of margin indicates a more reliable prediction than a low value.

Score

For discriminant analysis, the score of a classification is the posterior probability of the classification. For the definition of posterior probability in discriminant analysis, see “Posterior Probability” on page 20-6.

resubEdge

Resubstitution classification edge for multiclass error-correcting output codes (ECOC) model

Syntax

```
e = resubEdge(Mdl)
e = resubEdge(Mdl, Name, Value)
```

Description

`e = resubEdge(Mdl)` returns the resubstitution classification edge on page 32-5975 (`e`) for the multiclass error-correcting output codes (ECOC) model `Mdl` using the training data stored in `Mdl.X` and the corresponding class labels stored in `Mdl.Y`.

The classification edge is a scalar value that represents the weighted mean of the classification margins on page 32-5976.

`e = resubEdge(Mdl, Name, Value)` computes the resubstitution classification edge with additional options specified by one or more name-value pair arguments. For example, you can specify a decoding scheme, binary learner loss function, and verbosity level.

Examples

Resubstitution Edge of ECOC Model

Compute the resubstitution edge for an ECOC model with SVM binary learners.

Load Fisher's iris data set. Specify the predictor data `X` and the response data `Y`.

```
load fisheriris
X = meas;
Y = species;
```

Train an ECOC model using SVM binary classifiers. Standardize the predictors using an SVM template, and specify the class order.

```
t = templateSVM('Standardize',true);
classOrder = unique(Y)
```

```
classOrder = 3x1 cell array
    {'setosa'   }
    {'versicolor'}
    {'virginica' }
```

```
Mdl = fitcecoc(X,Y,'Learners',t,'ClassNames',classOrder);
```

t is an SVM template object. During training, the software uses default values for empty properties in t. Mdl is a ClassificationECOC model.

Compute the resubstitution edge, which is the mean of the training-sample margins.

```
e = resubEdge(Mdl)
```

```
e = 0.4961
```

Select ECOC Model Features by Comparing Training-Sample Edges

Perform feature selection by comparing training-sample edges from multiple models. Based solely on this comparison, the classifier with the greatest edge is the best classifier.

Load Fisher's iris data set. Define two data sets:

- fullX contains all four predictors.
- partX contains the sepal measurements only.

```
load fisheriris
X = meas;
fullX = X;
partX = X(:,1:2);
Y = species;
```

Train an ECOC model using SVM binary learners for each predictor set. Standardize the predictors using an SVM template, specify the class order, and compute the posterior probabilities.

```
t = templateSVM('Standardize',true);
classOrder = unique(Y)

classOrder = 3x1 cell array
    {'setosa'   }
    {'versicolor'}
    {'virginica' }
```

```
FullMdl = fitcecoc(fullX,Y,'Learners',t,'ClassNames',classOrder,...
    'FitPosterior',true);
PartMdl = fitcecoc(partX,Y,'Learners',t,'ClassNames',classOrder,...
    'FitPosterior',true);
```

The default SVM score is the distance from the decision boundary. If you specify to compute posterior probabilities, then the software uses posterior probabilities as scores.

Compute the resubstitution edge for each classifier. The quadratic loss function operates on scores in the domain [0,1]. Specify to use quadratic loss when aggregating the binary learners for both models.

```
fullEdge = resubEdge(FullMdl,'BinaryLoss','quadratic')

fullEdge = 0.9896

partEdge = resubEdge(PartMdl,'BinaryLoss','quadratic')

partEdge = 0.5058
```

The edge for the classifier trained on the complete data set is greater, suggesting that the classifier trained with all the predictors has a better training-sample fit.

Input Arguments

Mdl — Full, trained multiclass ECOC model

ClassificationECOC model

Full, trained multiclass ECOC model, specified as a ClassificationECOC model trained with `fitcecoc`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `resubEdge(Mdl, 'BinaryLoss', 'quadratic')` specifies a quadratic binary learner loss function.

BinaryLoss — Binary learner loss function

'hamming' | 'linear' | 'logit' | 'exponential' | 'binodeviance' | 'hinge' | 'quadratic' | function handle

Binary learner loss function, specified as the comma-separated pair consisting of 'BinaryLoss' and a built-in loss function name or function handle.

- This table describes the built-in functions, where y_j is a class label for a particular binary learner (in the set $\{-1, 1, 0\}$), s_j is the score for observation j , and $g(y_j, s_j)$ is the binary loss formula.

Value	Description	Score Domain	$g(y_j, s_j)$
'binodeviance'	Binomial deviance	$(-\infty, \infty)$	$\log[1 + \exp(-2y_j s_j)] / [2\log(2)]$
'exponential'	Exponential	$(-\infty, \infty)$	$\exp(-y_j s_j) / 2$
'hamming'	Hamming	$[0, 1]$ or $(-\infty, \infty)$	$[1 - \text{sign}(y_j s_j)] / 2$
'hinge'	Hinge	$(-\infty, \infty)$	$\max(0, 1 - y_j s_j) / 2$
'linear'	Linear	$(-\infty, \infty)$	$(1 - y_j s_j) / 2$
'logit'	Logistic	$(-\infty, \infty)$	$\log[1 + \exp(-y_j s_j)] / [2\log(2)]$
'quadratic'	Quadratic	$[0, 1]$	$[1 - y_j(2s_j - 1)]^2 / 2$

The software normalizes binary losses so that the loss is 0.5 when $y_j = 0$. Also, the software calculates the mean binary loss for each class.

- For a custom binary loss function, for example `customFunction`, specify its function handle 'BinaryLoss', @customFunction.

`customFunction` has this form:

```
bLoss = customFunction(M,s)
```

where:

- M is the K -by- L coding matrix stored in `Mdl.CodingMatrix`.
- s is the 1-by- L row vector of classification scores.
- `bLoss` is the classification loss. This scalar aggregates the binary losses for every learner in a particular class. For example, you can use the mean binary loss to aggregate the loss over the learners for each class.
- K is the number of classes.
- L is the number of binary learners.

For an example of passing a custom binary loss function, see “Predict Test-Sample Labels of ECOC Model Using Custom Binary Loss Function” on page 32-5219.

The default `BinaryLoss` value depends on the score ranges returned by the binary learners. This table describes some default `BinaryLoss` values based on the given assumptions.

Assumption	Default Value
All binary learners are SVMs or either linear or kernel classification models of SVM learners.	'hinge'
All binary learners are ensembles trained by <code>AdaboostM1</code> or <code>GentleBoost</code> .	'exponential'
All binary learners are ensembles trained by <code>LogitBoost</code> .	'binodeviance'
All binary learners are linear or kernel classification models of logistic regression learners. Or, you specify to predict class posterior probabilities by setting ' <code>FitPosterior</code> ', <code>true</code> in <code>fitcecoc</code> .	'quadratic'

To check the default value, use dot notation to display the `BinaryLoss` property of the trained model at the command line.

```
Example: 'BinaryLoss', 'binodeviance'
```

```
Data Types: char | string | function_handle
```

Decoding — Decoding scheme

```
'lossweighted' (default) | 'lossbased'
```

Decoding scheme that aggregates the binary losses, specified as the comma-separated pair consisting of 'Decoding' and 'lossweighted' or 'lossbased'. For more information, see “Binary Loss” on page 32-5976.

Example: 'Decoding', 'lossbased'

Options — Estimation options

[] (default) | structure array returned by `statset`

Estimation options, specified as the comma-separated pair consisting of 'Options' and a structure array returned by `statset`.

To invoke parallel computing:

- You need a Parallel Computing Toolbox license.
- Specify 'Options', `statset('UseParallel', true)`.

Verbose — Verbosity level

0 (default) | 1

Verbosity level, specified as the comma-separated pair consisting of 'Verbose' and 0 or 1. Verbose controls the number of diagnostic messages that the software displays in the Command Window.

If Verbose is 0, then the software does not display diagnostic messages. Otherwise, the software displays diagnostic messages.

Example: 'Verbose', 1

Data Types: `single` | `double`

Definitions

Classification Edge

The classification edge is the weighted mean of the classification margins.

One way to choose among multiple classifiers, for example to perform feature selection, is to choose the classifier that yields the greatest edge.

Classification Margin

The classification margin is, for each observation, the difference between the negative loss for the true class and the maximal negative loss among the false classes. If the margins are on the same scale, then they serve as a classification confidence measure. Among multiple classifiers, those that yield greater margins are better.

Binary Loss

A binary loss is a function of the class and classification score that determines how well a binary learner classifies an observation into the class.

Suppose the following:

- m_{kj} is element (k,j) of the coding design matrix M (that is, the code corresponding to class k of binary learner j).
- s_j is the score of binary learner j for an observation.
- g is the binary loss function.
- \hat{k} is the predicted class for the observation.

In loss-based decoding [Escalera et al.] on page 18-228, the class producing the minimum sum of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \operatorname{argmin}_k \sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j).$$

In loss-weighted decoding [Escalera et al.] on page 18-228, the class producing the minimum average of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \operatorname{argmin}_k \frac{\sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j)}{\sum_{j=1}^L |m_{kj}|}.$$

Allwein et al. on page 18-227 suggest that loss-weighted decoding improves classification accuracy by keeping loss values for all classes in the same dynamic range.

This table summarizes the supported loss functions, where y_j is a class label for a particular binary learner (in the set $\{-1,1,0\}$), s_j is the score for observation j , and $g(y_j, s_j)$.

Value	Description	Score Domain	$g(y_j, s_j)$
'binodeviance'	Binomial deviance	$(-\infty, \infty)$	$\log[1 + \exp(-2y_j s_j)] / [2\log(2)]$
'exponential'	Exponential	$(-\infty, \infty)$	$\exp(-y_j s_j) / 2$
'hamming'	Hamming	$[0,1]$ or $(-\infty, \infty)$	$[1 - \text{sign}(y_j s_j)] / 2$
'hinge'	Hinge	$(-\infty, \infty)$	$\max(0, 1 - y_j s_j) / 2$
'linear'	Linear	$(-\infty, \infty)$	$(1 - y_j s_j) / 2$
'logit'	Logistic	$(-\infty, \infty)$	$\log[1 + \exp(-y_j s_j)] / [2\log(2)]$
'quadratic'	Quadratic	$[0,1]$	$[1 - y_j(2s_j - 1)]^2 / 2$

The software normalizes binary losses such that the loss is 0.5 when $y_j = 0$, and aggregates using the average of the binary learners [Allwein et al.] on page 18-227.

Do not confuse the binary loss with the overall classification loss (specified by the 'LossFun' name-value pair argument of the `loss` and `predict` object functions), which measures how well an ECOC classifier performs as a whole.

Tips

- To compare the margins or edges of several ECOC classifiers, use template objects to specify a common score transform function among the classifiers during training.

Extended Capabilities

Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the 'UseParallel' option to true.

Set the 'UseParallel' field of the options structure to true using `statset` and specify the 'Options' name-value pair argument in the call to this function.

For example: `'Options',statset('UseParallel',true)`

For more information, see the 'Options' name-value pair argument.

For more general information about parallel computing, see "Run MATLAB Functions with Automatic Parallel Support" (Parallel Computing Toolbox).

resubEdge

Classification edge by resubstitution

Syntax

```
edge = resubEdge(ens)
edge = resubEdge(ens,Name,Value)
```

Description

`edge = resubEdge(ens)` returns the classification edge obtained by `ens` on its training data.

`edge = resubEdge(ens,Name,Value)` calculates edge with additional options specified by one or more `Name,Value` pair arguments. You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Input Arguments

`ens`

A classification ensemble created with `fitcensemble`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Learners

Indices of weak learners in the ensemble ranging from 1 to `NumTrained`. `resubEdge` uses only these learners for calculating edge.

Default: 1:NumTrained

mode

Character vector or string scalar representing the meaning of the output `edge`:

- 'ensemble' — `edge` is a scalar value, the loss for the entire ensemble.
- 'individual' — `edge` is a vector with one element per trained learner.
- 'cumulative' — `edge` is a vector in which element `J` is obtained by using learners `1:J` from the input list of learners.

Default: 'ensemble'

Output Arguments

edge

Classification edge obtained by `ens` by resubstituting the training data into the calculation of `edge`. Classification edge is classification margin averaged over the entire data. `edge` can be a scalar or vector, depending on the setting of the `mode` name-value pair.

Examples

Find Classification Edge by Resubstitution of Training Data

Find the resubstitution edge for an ensemble that classifies the Fisher iris data.

Load the sample data set.

```
load fisheriris
```

Train an ensemble of 100 boosted classification trees using `AdaBoostM2`.

```
t = templateTree('MaxNumSplits',1); % Weak learner template tree object
ens = fitensemble(meas,species,'Method','AdaBoostM2','Learners',t);
```

Find the resubstitution edge.

```
edge = resubEdge(ens)
```

edge = 3.2486

Definitions

Edge

The edge is the weighted mean value of the classification margin. The weights are the class probabilities in `ens.Prior`.

Margin

The classification margin is the difference between the classification score for the true class and maximal classification score for the false classes. Margin is a column vector with the same number of rows as in the matrix `ens.X`.

Score (ensemble)

For ensembles, a classification score represents the confidence of a classification into a class. The higher the score, the higher the confidence.

Different ensemble algorithms have different definitions for their scores. Furthermore, the range of scores depends on ensemble type. For example:

- AdaBoostM1 scores range from $-\infty$ to ∞ .
- Bag scores range from 0 to 1.

resubEdge

Edge of k -nearest neighbor classifier by resubstitution

Syntax

```
E = resubEdge(md1)
```

Description

`E = resubEdge(md1)` returns the classification edge for `md1` with the data used to train `md1`.

The classification edge (`E`) is a scalar value that represents the mean of the classification margins on page 32-5983.

Examples

Resubstitution Edge Calculation

Create a k -nearest neighbor classifier for the Fisher iris data, where $k = 5$.

Load the Fisher iris data set.

```
load fisheriris  
X = meas;  
Y = species;
```

Create a classifier for five nearest neighbors.

```
mdl = fitcknn(X,Y,'NumNeighbors',5);
```

Examine the resubstitution edge of the classifier.

```
E = resubEdge(mdl)
```

$$E = 0.9253$$

E is the mean of the training sample margins.

Input Arguments

mdl — *k*-nearest neighbor classifier model

ClassificationKNN object

k-nearest neighbor classifier model, specified as a ClassificationKNN object.

Definitions

Margin

The classification margin for each observation is the difference between the classification score for the true class and the maximal classification score for the false classes.

The classification margins form a column vector with the same number of rows as in the training data.

Score

The score of a classification is the posterior probability of the classification. The posterior probability is the number of neighbors with that classification divided by the number of neighbors. For a more detailed definition that includes weights and prior probabilities, see “Posterior Probability” on page 32-5188.

Introduced in R2012a

resubEdge

Class: ClassificationNaiveBayes

Classification edge for naive Bayes classifiers by resubstitution

Syntax

```
e = resubEdge(Mdl)
```

Description

`e = resubEdge(Mdl)` returns the resubstitution classification edge on page 32-5987 (`e`) for the naive Bayes classifier `Mdl` using the training data stored in `Mdl.X` and corresponding class labels stored in `Mdl.Y`.

Input Arguments

Mdl — Fully trained naive Bayes classifier

ClassificationNaiveBayes model

A fully trained naive Bayes classifier, specified as a ClassificationNaiveBayes model trained by `fitcnb`.

Output Arguments

e — Classification edge

scalar

Classification edge on page 32-5987, returned as a scalar. If you passed in weights when training the classifier, then `e` is the weighted classification edge. The software normalizes the weights so that they sum to the prior probability of their respective class.

Examples

Estimate the Resubstitution Edge of Naive Bayes Classifiers

Load Fisher's iris data set.

```
load fisheriris
X = meas;    % Predictors
Y = species; % Response
rng(1);
```

Train a naive Bayes classifier. It is good practice to specify the class order. Assume that each predictor is conditionally, normally distributed given its label.

```
Mdl = fitcnb(X,Y,'ClassNames',{'setosa','versicolor','virginica'});
```

Mdl is a trained `ClassificationNaiveBayes` classifier.

Estimate the resubstitution edge.

```
e = resubEdge(Mdl)

e = 0.8944
```

The mean of the training sample margins is approximately 0.9, which indicates that the classifier classifies in-sample observations with high confidence.

Select Naive Bayes Classifier Features by Comparing In-Sample Edges

The classifier edge measures the average of the classifier margins. One way to perform feature selection is to compare training sample edges from multiple models. Based solely on this criterion, the classifier with the highest edge is the best classifier.

Load Fisher's iris data set. Define two data sets:

- `fullX` contains all predictors.
- `partX` contains the last two predictors.

```
load fisheriris
X = meas;    % Predictors
```

```
Y = species; % Response
fullX = X;
partX = X(:,3:4);
```

Train naive Bayes classifiers for each predictor set.

```
FullMdl = fitcnb(fullX,Y);
PartMdl = fitcnb(partX,Y);
```

Estimate the training sample edge for each classifier.

```
fullEdge = resubEdge(FullMdl)
fullEdge = 0.8944
partEdge = resubEdge(PartMdl)
partEdge = 0.9169
```

The edge for the classifier trained on predictors 3 and 4 is greater, suggesting that the classifier trained using only those predictors has a better in-sample fit.

Definitions

Classification Edge

The classification edge is the weighted mean of the classification margins.

If you supply weights, then the software normalizes them to sum to the prior probability of their respective class. The software uses the normalized weights to compute the weighted mean.

One way to choose among multiple classifiers, e.g., to perform feature selection, is to choose the classifier that yields the highest edge.

Classification Margins

The classification margins are, for each observation, the difference between the score for the true class and maximal score for the false classes. Provided that they are on the same scale, margins serve as a classification confidence measure, i.e., among multiple classifiers, those that yield larger margins are better.

Posterior Probability

The posterior probability is the probability that an observation belongs in a particular class, given the data.

For naive Bayes, the posterior probability that a classification is k for a given observation (x_1, \dots, x_p) is

$$\widehat{P}(Y = k | x_1, \dots, x_p) = \frac{P(X_1, \dots, X_p | y = k)\pi(Y = k)}{P(X_1, \dots, X_p)},$$

where:

- $P(X_1, \dots, X_p | y = k)$ is the conditional joint density of the predictors given they are in class k . `Mdl.DistributionNames` stores the distribution names of the predictors.
- $\pi(Y = k)$ is the class prior probability distribution. `Mdl.Prior` stores the prior distribution.
- $P(X_1, \dots, X_p)$ is the joint density of the predictors. The classes are discrete, so

$$P(X_1, \dots, X_p) = \sum_{k=1}^K P(X_1, \dots, X_p | y = k)\pi(Y = k).$$

Prior Probability

The prior probability of a class is the believed relative frequency with which observations from that class occur in a population.

Score

The naive Bayes score is the class posterior probability given the observation.

resubEdge

Find classification edge for support vector machine (SVM) classifier by resubstitution

Syntax

```
e = resubEdge(SVMModel)
```

Description

`e = resubEdge(SVMModel)` returns the resubstitution “Classification Edge” on page 32-5992 (e) for the support vector machine (SVM) classifier `SVMModel` using the training data stored in `SVMModel.X` and the corresponding class labels stored in `SVMModel.Y`.

The classification edge is a scalar value that represents the weighted mean of the classification margins on page 32-5992.

Examples

Estimate Resubstitution Edge of SVM Classifiers

Load the ionosphere data set.

```
load ionosphere
```

Train an SVM classifier. Standardize the data and specify that 'g' is the positive class.

```
SVMModel = fitcsvm(X,Y,'Standardize',true,'ClassNames',{'b','g'});
```

`SVMModel` is a trained `ClassificationSVM` classifier.

Estimate the resubstitution edge. This is the mean of the training sample margins.

```
e = resubEdge(SVMModel)
```

```
e = 5.0998
```

Select SVM Classifier Features by Comparing In-Sample Edges

Perform feature selection by comparing training sample edges from multiple models. Based solely on this comparison, the classifier with the highest edge is the best classifier.

Load the `ionosphere` data set. Define two data sets:

- `fullX` contains all predictors (except the removed column of 0s).
- `partX` contains the last 20 predictors.

```
load ionosphere
fullX = X;
partX = X(:,end-20:end);
```

Train SVM classifiers for each predictor set.

```
FullSVMModel = fitcsvm(fullX,Y);
PartSVMModel = fitcsvm(partX,Y);
```

Estimate the training sample edge for each classifier.

```
fullEdge = resubEdge(FullSVMModel)
fullEdge = 3.3653
partEdge = resubEdge(PartSVMModel)
partEdge = 2.0471
```

The edge for the classifier trained on the complete data set is greater, suggesting that the classifier trained with all the predictors has a better in-sample fit.

Input Arguments

SVMModel — Full, trained SVM classifier

ClassificationSVM classifier

Full, trained SVM classifier, specified as a `ClassificationSVM` model trained with `fitcsvm`.

Definitions

Classification Edge

The edge is the weighted mean of the classification margins.

The weights are the prior class probabilities. If you supply weights, then the software normalizes them to sum to the prior probabilities in the respective classes. The software uses the renormalized weights to compute the weighted mean.

One way to choose among multiple classifiers, for example, to perform feature selection, is to choose the classifier that yields the highest edge.

Classification Margin

The classification margin for binary classification is, for each observation, the difference between the classification score for the true class and the classification score for the false class.

The software defines the classification margin for binary classification as

$$m = 2yf(x).$$

x is an observation. If the true label of x is the positive class, then y is 1, and -1 otherwise. $f(x)$ is the positive-class classification score for the observation x . The classification margin is commonly defined as $m = yf(x)$.

If the margins are on the same scale, then they serve as a classification confidence measure. Among multiple classifiers, those that yield greater margins are better.

Classification Score

The SVM classification score for classifying observation x is the signed distance from x to the decision boundary ranging from $-\infty$ to $+\infty$. A positive score for a class indicates that x is predicted to be in that class. A negative score indicates otherwise.

The positive class classification score $f(x)$ is the trained SVM classification function. $f(x)$ is also the numerical, predicted response for x , or the score for predicting x into the positive class.

$$f(x) = \sum_{j=1}^n \alpha_j y_j G(x_j, x) + b,$$

where $(\alpha_1, \dots, \alpha_n, b)$ are the estimated SVM parameters, $G(x_j, x)$ is the dot product in the predictor space between x and the support vectors, and the sum includes the training set observations. The negative class classification score for x , or the score for predicting x into the negative class, is $-f(x)$.

If $G(x_j, x) = x_j'x$ (the linear kernel), then the score function reduces to

$$f(x) = (x/s)' \beta + b.$$

s is the kernel scale and β is the vector of fitted linear coefficients.

For more details, see “Understanding Support Vector Machines” on page 18-189.

Algorithms

For binary classification, the software defines the margin for observation j , m_j , as

$$m_j = 2y_j f(x_j),$$

where $y_j \in \{-1, 1\}$, and $f(x_j)$ is the predicted score of observation j for the positive class. However, $m_j = y_j f(x_j)$ is commonly used to define the margin.

Introduced in R2014a

resubEdge

Class: ClassificationTree

Classification edge by resubstitution

Syntax

```
edge = resubEdge(tree)
```

Description

`edge = resubEdge(tree)` returns the classification edge obtained by `tree` on its training data.

Input Arguments

tree

A classification tree created using `fitctree`.

Output Arguments

edge

Classification edge obtained by resubstituting the training data into the calculation of `edge`.

Examples

Estimate the quality of a classification tree for the Fisher iris data by resubstitution.

```
load fisheriris
tree = fitctree(meas,species);
redge = resubEdge(tree)

redge =
    0.9384
```

Definitions

Edge

The edge is the weighted mean value of the classification margin. The weights are the class probabilities in `tree.Prior`.

Margin

The classification margin is the difference between the classification score for the true class and maximal classification score for the false classes. Margin is a column vector with the same number of rows as in the matrix `X`.

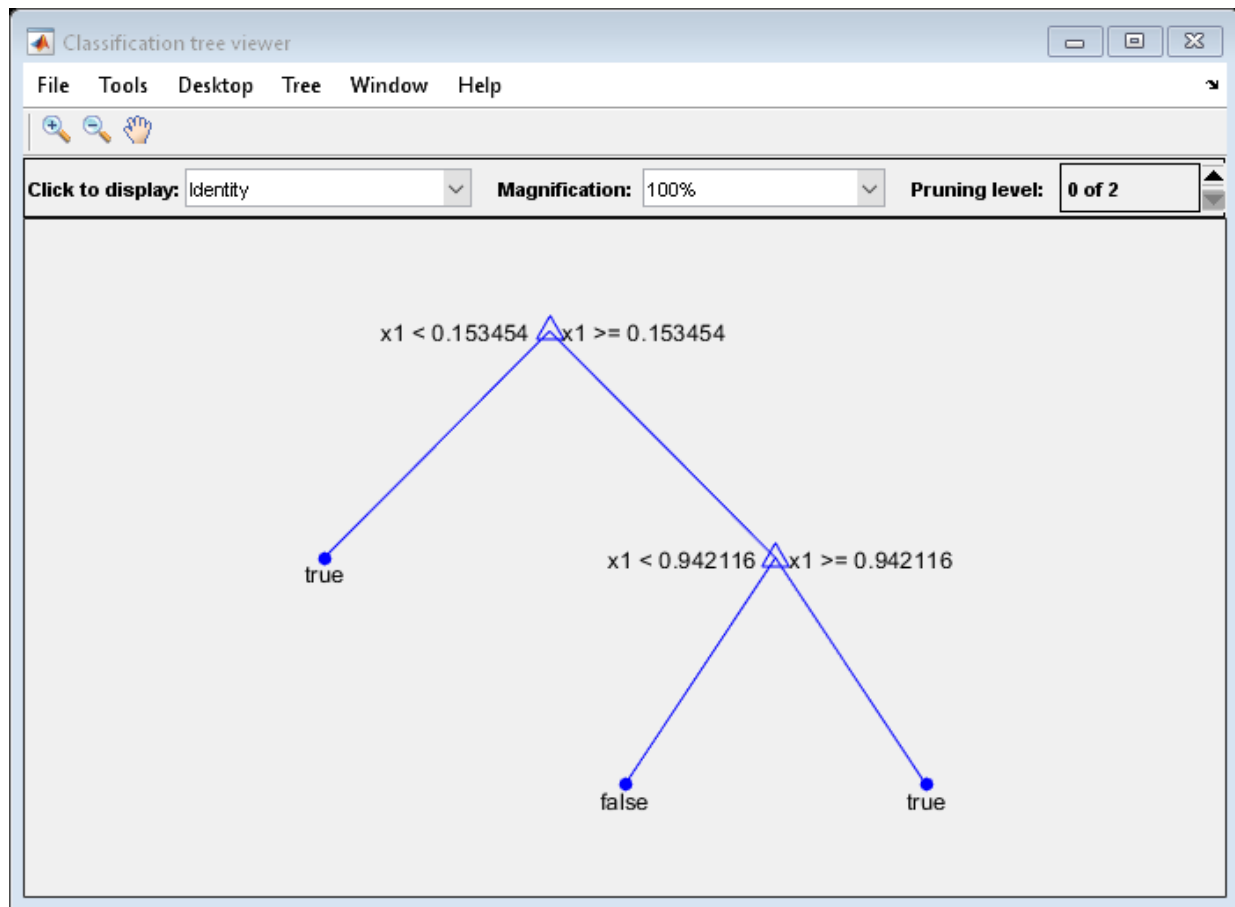

Score (tree)

For trees, the score of a classification of a leaf node is the posterior probability of the classification at that node. The posterior probability of the classification at a node is the number of training sequences that lead to that node with the classification, divided by the number of training sequences that lead to that node.

For example, consider classifying a predictor `X` as true when $X < 0.15$ or $X > 0.95$, and `X` is false otherwise.

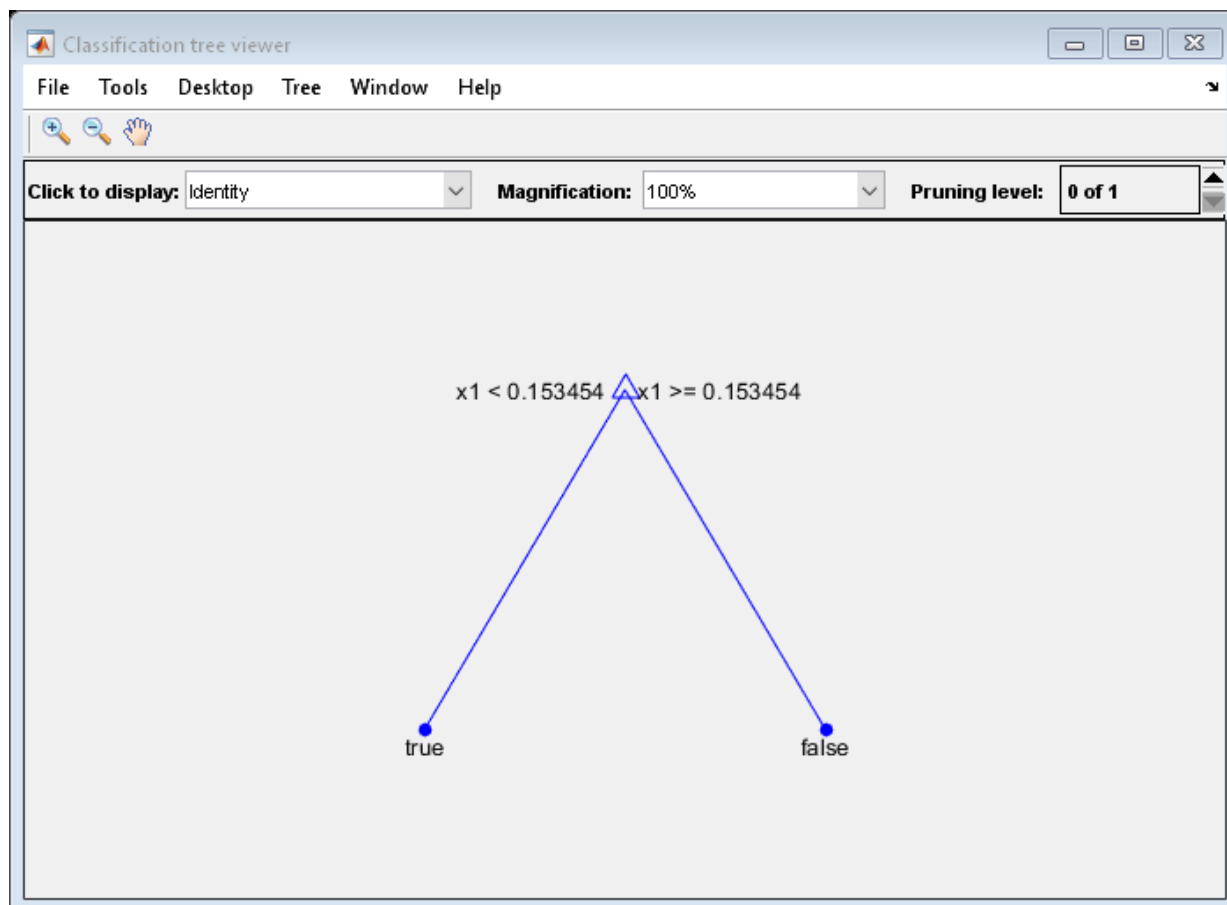

Generate 100 random points and classify them:

```
rng(0, 'twister') % for reproducibility
X = rand(100,1);
Y = (abs(X - .55) > .4);
tree = fitctree(X,Y);
view(tree, 'Mode', 'Graph')
```

Prune the tree:

```
tree1 = prune(tree, 'Level', 1);  
view(tree1, 'Mode', 'Graph')
```

The pruned tree correctly classifies observations that are less than 0.15 as `true`. It also correctly classifies observations from .15 to .94 as `false`. However, it incorrectly classifies observations that are greater than .94 as `false`. Therefore, the score for observations that are greater than .15 should be about $.05/.85=.06$ for `true`, and about $.8/.85=.94$ for `false`.

Compute the prediction scores for the first 10 rows of `X`:

```
[~,score] = predict(tree1,X(1:10));
[score X(1:10,:)]
```

```
ans = 10x3
    0.9059    0.0941    0.8147
    0.9059    0.0941    0.9058
         0     1.0000    0.1270
    0.9059    0.0941    0.9134
    0.9059    0.0941    0.6324
         0     1.0000    0.0975
    0.9059    0.0941    0.2785
    0.9059    0.0941    0.5469
    0.9059    0.0941    0.9575
    0.9059    0.0941    0.9649
```

Indeed, every value of X (the right-most column) that is less than 0.15 has associated scores (the left and center columns) of 0 and 1, while the other values of X have associated scores of 0.91 and 0.09. The difference (score 0.09 instead of the expected .06) is due to a statistical fluctuation: there are 8 observations in X in the range (.95, 1) instead of the expected 5 observations.

resubLoss

Class: ClassificationDiscriminant

Classification error by resubstitution

Syntax

```
L = resubLoss(obj)
L = resubLoss(obj,Name,Value)
```

Description

`L = resubLoss(obj)` returns the resubstitution loss, meaning the loss computed for the data that `fitcdiscr` used to create `obj`.

`L = resubLoss(obj,Name,Value)` returns loss statistics with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

obj

Discriminant analysis classifier, produced using `fitcdiscr`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

LossFun — Loss function

'classiferror' (default) | 'binodeviance' | 'exponential' | 'hinge' | 'logit' | 'mincost' | 'quadratic' | function handle

Loss function, specified as the comma-separated pair consisting of 'LossFun' and a built-in, loss-function name or function handle.

- The following table lists the available loss functions. Specify one using the corresponding character vector or string scalar.

Value	Description
'binodeviance'	Binomial deviance
'classiferror'	Classification error
'exponential'	Exponential
'hinge'	Hinge
'logit'	Logistic
'mincost'	Minimal expected misclassification cost (for classification scores that are posterior probabilities)
'quadratic'	Quadratic

'mincost' is appropriate for classification scores that are posterior probabilities. Discriminant analysis models return posterior probabilities as classification scores by default (see `predict`).

- Specify your own function using function handle notation.

Suppose that n be the number of observations in X and K be the number of distinct classes (`numel(obj.ClassNames)`). Your function must have this signature

```
lossvalue = lossfun(C,S,W,Cost)
```

where:

- The output argument `lossvalue` is a scalar.
- You choose the function name (`lossfun`).
- C is an n -by- K logical matrix with rows indicating which class the corresponding observation belongs. The column order corresponds to the class order in `obj.ClassNames`.

Construct C by setting $C(p, q) = 1$ if observation p is in class q , for each row. Set all other elements of row p to 0 .

- *S* is an *n*-by-*K* numeric matrix of classification scores. The column order corresponds to the class order in `obj.ClassNames`. *S* is a matrix of classification scores, similar to the output of `predict`.
- *W* is an *n*-by-1 numeric vector of observation weights. If you pass *W*, the software normalizes them to sum to 1.
- *Cost* is a *K*-by-*K* numeric matrix of misclassification costs. For example, `Cost = ones(K) - eye(K)` specifies a cost of 0 for correct classification, and 1 for misclassification.

Specify your function using `'LossFun',@lossfun`.

For more details on loss functions, see “Classification Loss” on page 32-6002.

Data Types: `char` | `string` | `function_handle`

Output Arguments

L

Classification error, a scalar. The meaning of the error depends on the values in `weights` and `lossfun`. See “Classification Loss” on page 32-6002.

Examples

Compute the resubstituted classification error for the Fisher iris data:

```
load fisheriris
obj = fitcdiscr(meas,species);
L = resubLoss(obj)
```

```
L =
    0.0200
```

Definitions

Classification Loss

Classification loss functions measure the predictive inaccuracy of classification models. When you compare the same type of loss among many models, a lower loss indicates a better predictive model.

Consider the following scenario.

- L is the weighted average classification loss.
- n is the sample size.
- For binary classification:
 - y_j is the observed class label. The software codes it as -1 or 1 , indicating the negative or positive class, respectively.
 - $f(X_j)$ is the raw classification score for observation (row) j of the predictor data X .
 - $m_j = y_j f(X_j)$ is the classification score for classifying observation j into the class corresponding to y_j . Positive values of m_j indicate correct classification and do not contribute much to the average loss. Negative values of m_j indicate incorrect classification and contribute significantly to the average loss.
- For algorithms that support multiclass classification (that is, $K \geq 3$):
 - y_j^* is a vector of $K - 1$ zeros, with 1 in the position corresponding to the true, observed class y_j . For example, if the true class of the second observation is the third class and $K = 4$, then $y_2^* = [0 \ 0 \ 1 \ 0]$. The order of the classes corresponds to the order in the `ClassNames` property of the input model.
 - $f(X_j)$ is the length K vector of class scores for observation j of the predictor data X . The order of the scores corresponds to the order of the classes in the `ClassNames` property of the input model.
 - $m_j = y_j^* f(X_j)$. Therefore, m_j is the scalar classification score that the model predicts for the true, observed class.
- The weight for observation j is w_j . The software normalizes the observation weights so that they sum to the corresponding prior class probability. The software also normalizes the prior probabilities so they sum to 1 . Therefore,

$$\sum_{j=1}^n w_j = 1.$$

Given this scenario, the following table describes the supported loss functions that you can specify by using the 'LossFun' name-value pair argument.

Loss Function	Value of LossFun	Equation
Binomial deviance	'binodeviance'	$L = \sum_{j=1}^n w_j \log\{1 + \exp[-2m_j]\}.$
Exponential loss	'exponential'	$L = \sum_{j=1}^n w_j \exp(-m_j).$
Classification error	'classiferror'	$L = \sum_{j=1}^n w_j I\{\hat{y}_j \neq y_j\}.$ <p>It is the weighted fraction of misclassified observations where \hat{y}_j is the class label corresponding to the class with the maximal posterior probability. $I\{x\}$ is the indicator function.</p>
Hinge loss	'hinge'	$L = \sum_{j=1}^n w_j \max\{0, 1 - m_j\}.$
Logit loss	'logit'	$L = \sum_{j=1}^n w_j \log(1 + \exp(-m_j)).$

Loss Function	Value of LossFun	Equation
Minimal cost	'mincost'	<p>Minimal cost. The software computes the weighted minimal cost using this procedure for observations $j = 1, \dots, n$.</p> <ol style="list-style-type: none"> 1 Estimate the 1-by-K vector of expected classification costs for observation j: $v_j = f(X_j)'C.$ <p>$f(X_j)$ is the column vector of class posterior probabilities for binary and multiclass classification. C is the cost matrix that the input model stores in the <code>Cost</code> property.</p> 2 For observation j, predict the class label corresponding to the minimum expected classification cost: $\hat{y}_j = \min_{j = 1, \dots, K} (v_j).$ 3 Using C, identify the cost incurred (c_j) for making the prediction. <p>The weighted, average, minimum cost loss is</p> $L = \sum_{j=1}^n w_j c_j.$
Quadratic loss	'quadratic'	$L = \sum_{j=1}^n w_j (1 - m_j)^2.$

This figure compares the loss functions (except 'mincost') for one observation over m . Some functions are normalized to pass through [0,1].

Posterior Probability

The posterior probability that a point z belongs to class j is the product of the prior probability and the multivariate normal density. The density function of the multivariate normal with mean μ_j and covariance Σ_j at a point z is

$$P(x|k) = \frac{1}{(2\pi|\Sigma_k|)^{1/2}} \exp\left(-\frac{1}{2}(x - \mu_k)^T \Sigma_k^{-1} (x - \mu_k)\right),$$

where $|\Sigma_k|$ is the determinant of Σ_k , and Σ_k^{-1} is the inverse matrix.

Let $P(k)$ represent the prior probability of class k . Then the posterior probability that an observation x is of class k is

$$\hat{P}(k|x) = \frac{P(x|k)P(k)}{P(x)},$$

where $P(x)$ is a normalization constant, the sum over k of $P(x|k)P(k)$.

Prior Probability

The prior probability is one of three choices:

- 'uniform' — The prior probability of class k is one over the total number of classes.
- 'empirical' — The prior probability of class k is the number of training samples of class k divided by the total number of training samples.
- Custom — The prior probability of class k is the k th element of the prior vector. See `fitcdiscr`.

After creating a classification model (`Mdl`) you can set the prior using dot notation:

```
Mdl.Prior = v;
```

where v is a vector of positive elements representing the frequency with which each element occurs. You do not need to retrain the classifier when you set a new prior.

Cost

The matrix of expected costs per observation is defined in “Cost” on page 20-7.

resubLoss

Resubstitution classification loss for multiclass error-correcting output codes (ECOC) model

Syntax

```
L = resubLoss(Mdl)
L = resubLoss(Mdl, Name, Value)
```

Description

`L = resubLoss(Mdl)` returns the classification loss by resubstitution (L) for the multiclass error-correcting output codes (ECOC) model `Mdl` using the training data stored in `Mdl.X` and the corresponding class labels stored in `Mdl.Y`. By default, `resubLoss` uses the classification error on page 32-6013 to compute L .

The classification loss (L) is a generalization or resubstitution quality measure. Its interpretation depends on the loss function and weighting scheme, but in general, better classifiers yield smaller classification loss values.

`L = resubLoss(Mdl, Name, Value)` returns the classification loss with additional options specified by one or more name-value pair arguments. For example, you can specify the loss function, decoding scheme, and verbosity level.

Examples

Resubstitution Loss of ECOC Model

Compute the resubstitution loss for an ECOC model with SVM binary learners.

Load Fisher's iris data set. Specify the predictor data X and the response data Y .

```
load fisheriris
X = meas;
Y = species;
```

Train an ECOC model using SVM binary classifiers. Standardize the predictors using an SVM template, and specify the class order.

```
t = templateSVM('Standardize',true);
classOrder = unique(Y)
```

```
classOrder = 3x1 cell array
    {'setosa'   }
    {'versicolor'}
    {'virginica' }
```

```
Mdl = fitcecoc(X,Y,'Learners',t,'ClassNames',classOrder);
```

t is an SVM template object. During training, the software uses default values for empty properties in t. Mdl is a ClassificationECOC model.

Estimate the resubstitution classification error, which is the default classification loss.

```
L = resubLoss(Mdl)
```

```
L = 0.0267
```

The ECOC model misclassifies 2.67% of the training-sample irises.

Determine ECOC Model Quality Using Custom Resubstitution Loss

Determine the quality of an ECOC model by using a custom loss function that considers the minimal binary loss for each observation.

Load Fisher's iris data set. Specify the predictor data X, the response data Y, and the order of the classes in Y.

```
load fisheriris
X = meas;
Y = categorical(species);
classOrder = unique(Y) % Class order
```

```
classOrder = 3x1 categorical array
    setosa
    versicolor
    virginica
```

```
rng(1); % For reproducibility
```

Train an ECOC model using SVM binary classifiers. Standardize the predictors using an SVM template, and specify the class order.

```
t = templateSVM('Standardize',true);
Mdl = fitcecoc(X,Y,'Learners',t,'ClassNames',classOrder);
```

t is an SVM template object. During training, the software uses default values for empty properties in t. Mdl is a ClassificationECOC model.

Create a function that takes the minimal loss for each observation, then averages the minimal losses for all observations. S corresponds to the NegLoss output of resubPredict.

```
lossfun = @(~,S,~,~)mean(min(-S,[],2));
```

Compute the custom classification loss for the training data.

```
resubLoss(Mdl,'LossFun',lossfun)
```

```
ans = 0.0065
```

The average minimal binary loss for the training data is 0.0065.

Input Arguments

Mdl — Full, trained multiclass ECOC model

ClassificationECOC model

Full, trained multiclass ECOC model, specified as a ClassificationECOC model trained with fitcecoc.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example: `resubLoss(Mdl, 'BinaryLoss', 'hamming', 'LossFun', @lossfun)` specifies 'hamming' as the binary learner loss function and the custom function handle `@lossfun` as the overall loss function.

BinaryLoss — Binary learner loss function

'hamming' | 'linear' | 'logit' | 'exponential' | 'binodeviance' | 'hinge' | 'quadratic' | function handle

Binary learner loss function, specified as the comma-separated pair consisting of 'BinaryLoss' and a built-in loss function name or function handle.

- This table describes the built-in functions, where y_j is a class label for a particular binary learner (in the set $\{-1, 1, 0\}$), s_j is the score for observation j , and $g(y_j, s_j)$ is the binary loss formula.

Value	Description	Score Domain	$g(y_j, s_j)$
'binodeviance'	Binomial deviance	$(-\infty, \infty)$	$\log[1 + \exp(-2y_j s_j)] / [2\log(2)]$
'exponential'	Exponential	$(-\infty, \infty)$	$\exp(-y_j s_j) / 2$
'hamming'	Hamming	$[0, 1]$ or $(-\infty, \infty)$	$[1 - \text{sign}(y_j s_j)] / 2$
'hinge'	Hinge	$(-\infty, \infty)$	$\max(0, 1 - y_j s_j) / 2$
'linear'	Linear	$(-\infty, \infty)$	$(1 - y_j s_j) / 2$
'logit'	Logistic	$(-\infty, \infty)$	$\log[1 + \exp(-y_j s_j)] / [2\log(2)]$
'quadratic'	Quadratic	$[0, 1]$	$[1 - y_j(2s_j - 1)]^2 / 2$

The software normalizes binary losses so that the loss is 0.5 when $y_j = 0$. Also, the software calculates the mean binary loss for each class.

- For a custom binary loss function, for example `customFunction`, specify its function handle 'BinaryLoss', `@customFunction`.

`customFunction` has this form:

```
bLoss = customFunction(M,s)
```

where:

- M is the K -by- L coding matrix stored in `Mdl.CodingMatrix`.
- s is the 1-by- L row vector of classification scores.
- `bLoss` is the classification loss. This scalar aggregates the binary losses for every learner in a particular class. For example, you can use the mean binary loss to aggregate the loss over the learners for each class.
- K is the number of classes.
- L is the number of binary learners.

For an example of passing a custom binary loss function, see “Predict Test-Sample Labels of ECOC Model Using Custom Binary Loss Function” on page 32-5219.

The default `BinaryLoss` value depends on the score ranges returned by the binary learners. This table describes some default `BinaryLoss` values based on the given assumptions.

Assumption	Default Value
All binary learners are SVMs or either linear or kernel classification models of SVM learners.	'hinge'
All binary learners are ensembles trained by <code>AdaboostM1</code> or <code>GentleBoost</code> .	'exponential'
All binary learners are ensembles trained by <code>LogitBoost</code> .	'binodeviance'
All binary learners are linear or kernel classification models of logistic regression learners. Or, you specify to predict class posterior probabilities by setting ' <code>FitPosterior</code> ', <code>true</code> in <code>fitcecoc</code> .	'quadratic'

To check the default value, use dot notation to display the `BinaryLoss` property of the trained model at the command line.

```
Example: 'BinaryLoss', 'binodeviance'
```

```
Data Types: char | string | function_handle
```

Decoding — Decoding scheme

```
'lossweighted' (default) | 'lossbased'
```

Decoding scheme that aggregates the binary losses, specified as the comma-separated pair consisting of 'Decoding' and 'lossweighted' or 'lossbased'. For more information, see “Binary Loss” on page 32-6014.

Example: 'Decoding', 'lossbased'

LossFun — Loss function

'classiferror' (default) | function handle

Loss function, specified as the comma-separated pair consisting of 'LossFun' and 'classiferror' or a function handle.

- Specify the built-in function 'classiferror'. In this case, the loss function is the classification error on page 32-6013, which is the proportion of misclassified observations.
- Or, specify your own function using function handle notation.

Assume that $n = \text{size}(X, 1)$ is the sample size and K is the number of classes. Your function must have the signature `lossvalue = lossfun(C, S, W, Cost)`, where:

- The output argument `lossvalue` is a scalar.
- You specify the function name (*lossfun*).
- C is an n -by- K logical matrix with rows indicating the class to which the corresponding observation belongs. The column order corresponds to the class order in `Mdl.ClassNames`.

Construct C by setting $C(p, q) = 1$ if observation p is in class q , for each row. Set all other elements of row p to 0 .

- S is an n -by- K numeric matrix of negated loss values for the classes. Each row corresponds to an observation. The column order corresponds to the class order in `Mdl.ClassNames`. The input S resembles the output argument `NegLoss` of `resubPredict`.
- W is an n -by-1 numeric vector of observation weights. If you pass W , the software normalizes its elements to sum to 1.
- $Cost$ is a K -by- K numeric matrix of misclassification costs. For example, `Cost = ones(K) - eye(K)` specifies a cost of 0 for correct classification and 1 for misclassification.

Specify your function using 'LossFun', @`lossfun`.

Data Types: char | string | function_handle

Options — Estimation options

[] (default) | structure array returned by `statset`

Estimation options, specified as the comma-separated pair consisting of 'Options' and a structure array returned by `statset`.

To invoke parallel computing:

- You need a Parallel Computing Toolbox license.
- Specify 'Options', `statset('UseParallel',true)`.

Verbose — Verbosity level

0 (default) | 1

Verbosity level, specified as the comma-separated pair consisting of 'Verbose' and 0 or 1. Verbose controls the number of diagnostic messages that the software displays in the Command Window.

If Verbose is 0, then the software does not display diagnostic messages. Otherwise, the software displays diagnostic messages.

Example: 'Verbose', 1

Data Types: single | double

Definitions

Classification Error

The classification error is a binary classification error measure that has the form

$$L = \frac{\sum_{j=1}^n w_j e_j}{\sum_{j=1}^n w_j},$$

where:

- w_j is the weight for observation j . The software renormalizes the weights to sum to 1.

- $e_j = 1$ if the predicted class of observation j differs from its true class, and 0 otherwise.

In other words, the classification error is the proportion of observations misclassified by the classifier.

Binary Loss

A binary loss is a function of the class and classification score that determines how well a binary learner classifies an observation into the class.

Suppose the following:

- m_{kj} is element (k,j) of the coding design matrix M (that is, the code corresponding to class k of binary learner j).
- s_j is the score of binary learner j for an observation.
- g is the binary loss function.
- \hat{k} is the predicted class for the observation.

In loss-based decoding [Escalera et al.] on page 18-228, the class producing the minimum sum of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \operatorname{argmin}_k \sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j).$$

In loss-weighted decoding [Escalera et al.] on page 18-228, the class producing the minimum average of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \operatorname{argmin}_k \frac{\sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j)}{\sum_{j=1}^L |m_{kj}|}.$$

Allwein et al. on page 18-227 suggest that loss-weighted decoding improves classification accuracy by keeping loss values for all classes in the same dynamic range.

This table summarizes the supported loss functions, where y_j is a class label for a particular binary learner (in the set $\{-1,1,0\}$), s_j is the score for observation j , and $g(y_j, s_j)$.

Value	Description	Score Domain	$g(y_j, s_j)$
'binodeviance'	Binomial deviance	$(-\infty, \infty)$	$\log[1 + \exp(-2y_j s_j)] / [2\log(2)]$
'exponential'	Exponential	$(-\infty, \infty)$	$\exp(-y_j s_j) / 2$
'hamming'	Hamming	$[0, 1]$ or $(-\infty, \infty)$	$[1 - \text{sign}(y_j s_j)] / 2$
'hinge'	Hinge	$(-\infty, \infty)$	$\max(0, 1 - y_j s_j) / 2$
'linear'	Linear	$(-\infty, \infty)$	$(1 - y_j s_j) / 2$
'logit'	Logistic	$(-\infty, \infty)$	$\log[1 + \exp(-y_j s_j)] / [2\log(2)]$
'quadratic'	Quadratic	$[0, 1]$	$[1 - y_j(2s_j - 1)]^2 / 2$

The software normalizes binary losses such that the loss is 0.5 when $y_j = 0$, and aggregates using the average of the binary learners [Allwein et al.] on page 18-227.

Do not confuse the binary loss with the overall classification loss (specified by the 'LossFun' name-value pair argument of the `loss` and `predict` object functions), which measures how well an ECOC classifier performs as a whole.

Extended Capabilities

Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the 'UseParallel' option to true.

Set the 'UseParallel' field of the options structure to true using `statset` and specify the 'Options' name-value pair argument in the call to this function.

For example: `'Options',statset('UseParallel',true)`

For more information, see the 'Options' name-value pair argument.

For more general information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

Introduced in R2014b

resubLoss

Classification error by resubstitution

Syntax

```
L = resubLoss(ens)
L = resubLoss(ens,Name,Value)
```

Description

`L = resubLoss(ens)` returns the resubstitution loss, meaning the loss computed for the data that `fitcensemble` used to create `ens`.

`L = resubLoss(ens,Name,Value)` calculates loss with additional options specified by one or more `Name,Value` pair arguments. You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Input Arguments

`ens`

A classification ensemble created with `fitcensemble`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Learners

Indices of weak learners in the ensemble ranging from 1 to `NumTrained`. `resubLoss` uses only these learners for calculating loss.

Default: 1:NumTrained

lossfun

Loss function, specified as the comma-separated pair consisting of 'LossFun' and a built-in, loss-function name or function handle.

- The following table lists the available loss functions. Specify one using its corresponding character vector or string scalar.

Value	Description
'binodeviance'	Binomial deviance
'classiferror'	Classification error
'exponential'	Exponential
'hinge'	Hinge
'logit'	Logistic
'mincost'	Minimal expected misclassification cost (for classification scores that are posterior probabilities)
'quadratic'	Quadratic

'mincost' is appropriate for classification scores that are posterior probabilities.

- Bagged and subspace ensembles return posterior probabilities by default (ens.Method is 'Bag' or 'Subspace').
- If the ensemble method is 'AdaBoostM1', 'AdaBoostM2', GentleBoost, or 'LogitBoost', then, to use posterior probabilities as classification scores, you must specify the double-logit score transform by entering

```
ens.ScoreTransform = 'doublelogit';
```
- For all other ensemble methods, the software does not support posterior probabilities as classification scores.
- Specify your own function using function handle notation.

Suppose that n be the number of observations in X and K be the number of distinct classes (`numel(ens.ClassNames)`, `ens` is the input model). Your function must have this signature

```
lossvalue = lossfun(C,S,W,Cost)
```

where:

- The output argument `lossvalue` is a scalar.
- You choose the function name (*lossfun*).
- `C` is an n -by- K logical matrix with rows indicating which class the corresponding observation belongs. The column order corresponds to the class order in `ens.ClassNames`.

Construct `C` by setting $C(p, q) = 1$ if observation p is in class q , for each row. Set all other elements of row p to 0 .

- `S` is an n -by- K numeric matrix of classification scores. The column order corresponds to the class order in `ens.ClassNames`. `S` is a matrix of classification scores, similar to the output of `predict`.
- `W` is an n -by-1 numeric vector of observation weights. If you pass `W`, the software normalizes them to sum to 1.
- `Cost` is a K -by- K numeric matrix of misclassification costs. For example, `Cost = ones(K) - eye(K)` specifies a cost of 0 for correct classification, and 1 for misclassification.

Specify your function using `'LossFun', @lossfun`.

For more details on loss functions, see “Classification Loss” on page 32-6020.

Default: `'classiferror'`

mode

Character vector or string scalar representing the meaning of the output `L`:

- `'ensemble'` — `L` is a scalar value, the loss for the entire ensemble.
- `'individual'` — `L` is a vector with one element per trained learner.
- `'cumulative'` — `L` is a vector in which element J is obtained by using learners $1:J$ from the input list of learners.

Default: `'ensemble'`

Output Arguments

L

Classification loss on page 32-6020, by default the fraction of misclassified data. L can be a vector, and can mean different things, depending on the name-value pair settings.

Examples

Estimate Classification Error for Training Observations

Load Fisher's iris data set.

```
load fisheriris
```

Train a classification ensemble of 100 decision trees using AdaBoostM2. Specify tree stumps as the weak learners.

```
t = templateTree('MaxNumSplits',1);  
ens = fitcensemble(meas,species,'Method','AdaBoostM2','Learners',t);
```

Estimate the resubstitution classification error.

```
loss = resubLoss(ens)
```

```
loss = 0.0333
```

Definitions

Classification Loss

Classification loss functions measure the predictive inaccuracy of classification models. When you compare the same type of loss among many models, a lower loss indicates a better predictive model.

Consider the following scenario.

- L is the weighted average classification loss.
- n is the sample size.
- For binary classification:
 - y_j is the observed class label. The software codes it as -1 or 1, indicating the negative or positive class, respectively.
 - $f(X_j)$ is the raw classification score for observation (row) j of the predictor data X .
 - $m_j = y_j f(X_j)$ is the classification score for classifying observation j into the class corresponding to y_j . Positive values of m_j indicate correct classification and do not contribute much to the average loss. Negative values of m_j indicate incorrect classification and contribute significantly to the average loss.
- For algorithms that support multiclass classification (that is, $K \geq 3$):
 - y_j^* is a vector of $K - 1$ zeros, with 1 in the position corresponding to the true, observed class y_j . For example, if the true class of the second observation is the third class and $K = 4$, then $y_2^* = [0 \ 0 \ 1 \ 0]$. The order of the classes corresponds to the order in the `ClassNames` property of the input model.
 - $f(X_j)$ is the length K vector of class scores for observation j of the predictor data X . The order of the scores corresponds to the order of the classes in the `ClassNames` property of the input model.
 - $m_j = y_j^* f(X_j)$. Therefore, m_j is the scalar classification score that the model predicts for the true, observed class.
- The weight for observation j is w_j . The software normalizes the observation weights so that they sum to the corresponding prior class probability. The software also normalizes the prior probabilities so they sum to 1. Therefore,

$$\sum_{j=1}^n w_j = 1.$$

Given this scenario, the following table describes the supported loss functions that you can specify by using the 'LossFun' name-value pair argument.

Loss Function	Value of LossFun	Equation
Binomial deviance	'binodeviance'	$L = \sum_{j=1}^n w_j \log\{1 + \exp[-2m_j]\}.$

Loss Function	Value of LossFun	Equation
Exponential loss	'exponential'	$L = \sum_{j=1}^n w_j \exp(-m_j).$
Classification error	'classiferror'	$L = \sum_{j=1}^n w_j I\{\hat{y}_j \neq y_j\}.$ <p>It is the weighted fraction of misclassified observations where \hat{y}_j is the class label corresponding to the class with the maximal posterior probability. $I\{x\}$ is the indicator function.</p>
Hinge loss	'hinge'	$L = \sum_{j=1}^n w_j \max\{0, 1 - m_j\}.$
Logit loss	'logit'	$L = \sum_{j=1}^n w_j \log(1 + \exp(-m_j)).$

Loss Function	Value of LossFun	Equation
Minimal cost	'mincost'	<p>Minimal cost. The software computes the weighted minimal cost using this procedure for observations $j = 1, \dots, n$.</p> <ol style="list-style-type: none"> 1 Estimate the 1-by-K vector of expected classification costs for observation j: $v_j = f(X_j)'C.$ <p>$f(X_j)$ is the column vector of class posterior probabilities for binary and multiclass classification. C is the cost matrix that the input model stores in the <code>Cost</code> property.</p> 2 For observation j, predict the class label corresponding to the minimum expected classification cost: $\hat{y}_j = \min_{j = 1, \dots, K} (v_j).$ 3 Using C, identify the cost incurred (c_j) for making the prediction. <p>The weighted, average, minimum cost loss is</p> $L = \sum_{j=1}^n w_j c_j.$
Quadratic loss	'quadratic'	$L = \sum_{j=1}^n w_j (1 - m_j)^2.$

This figure compares the loss functions (except 'mincost') for one observation over m . Some functions are normalized to pass through [0,1].

resubLoss

Loss of k -nearest neighbor classifier by resubstitution

Syntax

```
L = resubLoss mdl  
L = resubLoss(mdl, 'LossFun', lossfun)
```

Description

`L = resubLoss(mdl)` returns the classification loss on page 32-6027 by resubstitution, which is the loss computed for the data used by `fitcknn` to create `mdl`.

The classification loss (L) is a numeric scalar, whose interpretation depends on the loss function and the observation weights in `mdl`.

`L = resubLoss(mdl, 'LossFun', lossfun)` returns the resubstitution loss for the loss function `lossfun`, specified as a name-value pair argument.

Examples

Loss Calculation

Create a k -nearest neighbor classifier for the Fisher iris data, where $k = 5$.

Load the Fisher iris data set.

```
load fisheriris
```

Create a classifier for five nearest neighbors.

```
mdl = fitcknn(meas, species, 'NumNeighbors', 5);
```

Examine the resubstitution loss of the classifier.

```
L = resubLoss mdl
```

```
L = 0.0333
```

The classifier predicts incorrect classifications for 1/30 of its training data.

Input Arguments

mdl — *k*-nearest neighbor classifier model

ClassificationKNN object

k-nearest neighbor classifier model, specified as a ClassificationKNN object.

lossfun — Loss function

'mincost' (default) | 'binodeviance' | 'classiferror' | 'exponential' | 'hinge' | 'logit' | 'quadratic' | function handle

Loss function, specified as a built-in loss function name or a function handle.

- The following table lists the available loss functions.

Value	Description
'binodeviance'	Binomial deviance
'classiferror'	Classification error
'exponential'	Exponential
'hinge'	Hinge
'logit'	Logistic
'mincost'	Minimal expected misclassification cost (for classification scores that are posterior probabilities)
'quadratic'	Quadratic

'mincost' is appropriate for classification scores that are posterior probabilities. By default, *k*-nearest neighbor models return posterior probabilities as classification scores (see `predict`).

- You can specify a function handle for a custom loss function using @ (for example, @lossfun). Let n be the number of observations in X and K be the number of distinct classes (`numel mdl.ClassNames`). Your custom loss function must have this form:

```
function lossvalue = lossfun(C,S,W,Cost)
```

- C is an n -by- K logical matrix with rows indicating the class to which the corresponding observation belongs. The column order corresponds to the class order in `mdl.ClassNames`. Construct C by setting $C(p,q) = 1$, if observation p is in class q , for each row. Set all other elements of row p to 0.
- S is an n -by- K numeric matrix of classification scores. The column order corresponds to the class order in `mdl.ClassNames`. The argument S is a matrix of classification scores, similar to the output of `predict`.
- W is an n -by-1 numeric vector of observation weights. If you pass W , the software normalizes the weights to sum to 1.
- $Cost$ is a K -by- K numeric matrix of misclassification costs. For example, $Cost = \text{ones}(K) - \text{eye}(K)$ specifies a cost of 0 for correct classification and 1 for misclassification.
- The output argument `lossvalue` is a scalar.

For more details on loss functions, see “Classification Loss” on page 32-3868.

Data Types: `char` | `string` | `function_handle`

Algorithms

Classification Loss

Classification loss functions measure the predictive inaccuracy of classification models. When you compare the same type of loss among many models, a lower loss indicates a better predictive model.

Consider the following scenario.

- L is the weighted average classification loss.
- n is the sample size.
- For binary classification:

- y_j is the observed class label. The software codes it as -1 or 1, indicating the negative or positive class, respectively.
- $f(X_j)$ is the raw classification score for observation (row) j of the predictor data X .
- $m_j = y_j f(X_j)$ is the classification score for classifying observation j into the class corresponding to y_j . Positive values of m_j indicate correct classification and do not contribute much to the average loss. Negative values of m_j indicate incorrect classification and contribute significantly to the average loss.
- For algorithms that support multiclass classification (that is, $K \geq 3$):
 - y_j^* is a vector of $K - 1$ zeros, with 1 in the position corresponding to the true, observed class y_j . For example, if the true class of the second observation is the third class and $K = 4$, then $y_2^* = [0 \ 0 \ 1 \ 0]$. The order of the classes corresponds to the order in the `ClassNames` property of the input model.
 - $f(X_j)$ is the length K vector of class scores for observation j of the predictor data X . The order of the scores corresponds to the order of the classes in the `ClassNames` property of the input model.
 - $m_j = y_j^* f(X_j)$. Therefore, m_j is the scalar classification score that the model predicts for the true, observed class.
- The weight for observation j is w_j . The software normalizes the observation weights so that they sum to the corresponding prior class probability. The software also normalizes the prior probabilities so they sum to 1. Therefore,

$$\sum_{j=1}^n w_j = 1.$$

Given this scenario, the following table describes the supported loss functions that you can specify by using the 'LossFun' name-value pair argument.

Loss Function	Value of LossFun	Equation
Binomial deviance	'binodeviance'	$L = \sum_{j=1}^n w_j \log\{1 + \exp[-2m_j]\}$.
Exponential loss	'exponential'	$L = \sum_{j=1}^n w_j \exp(-m_j)$.

Loss Function	Value of LossFun	Equation
Classification error	'classiferror'	$L = \sum_{j=1}^n w_j I\{\hat{y}_j \neq y_j\}.$ <p>It is the weighted fraction of misclassified observations where \hat{y}_j is the class label corresponding to the class with the maximal posterior probability. $I\{x\}$ is the indicator function.</p>
Hinge loss	'hinge'	$L = \sum_{j=1}^n w_j \max\{0, 1 - m_j\}.$
Logit loss	'logit'	$L = \sum_{j=1}^n w_j \log(1 + \exp(-m_j)).$

Loss Function	Value of LossFun	Equation
Minimal cost	'mincost'	<p>Minimal cost. The software computes the weighted minimal cost using this procedure for observations $j = 1, \dots, n$.</p> <ol style="list-style-type: none"> Estimate the 1-by-K vector of expected classification costs for observation j: $\nu_j = f(X_j)'C.$ <p>$f(X_j)$ is the column vector of class posterior probabilities for binary and multiclass classification. C is the cost matrix that the input model stores in the <code>Cost</code> property.</p> For observation j, predict the class label corresponding to the minimum expected classification cost: $\hat{y}_j = \min_{j = 1, \dots, K} (\nu_j).$ Using C, identify the cost incurred (c_j) for making the prediction. <p>The weighted, average, minimum cost loss is</p> $L = \sum_{j=1}^n w_j c_j.$
Quadratic loss	'quadratic'	$L = \sum_{j=1}^n w_j (1 - m_j)^2.$

This figure compares the loss functions (except 'mincost') for one observation over m . Some functions are normalized to pass through [0,1].

True Misclassification Cost

Two costs are associated with KNN classification: the true misclassification cost per class and the expected misclassification cost per observation.

You can set the true misclassification cost per class by using the 'Cost' name-value pair argument when you run `fitcknn`. The value `Cost(i, j)` is the cost of classifying an observation into class `j` if its true class is `i`. By default, `Cost(i, j) = 1` if `i ~= j`, and `Cost(i, j) = 0` if `i = j`. In other words, the cost is 0 for correct classification and 1 for incorrect classification.

Expected Cost

Two costs are associated with KNN classification: the true misclassification cost per class and the expected misclassification cost per observation. The third output of `resubPredict` is the expected misclassification cost per observation.

Suppose you have `Nobs` observations that you classified with a trained classifier `mdl`, and you have `K` classes. The command

```
[label,score,cost] = resubPredict(mdl)
```

returns a matrix `cost` of size `Nobs-by-K`, among other outputs. Each row of the `cost` matrix contains the expected (average) cost of classifying the observation into each of the `K` classes. `cost(n, j)` is

$$\sum_{i=1}^K \widehat{P}(i|X(n))C(j|i),$$

where

- K is the number of classes.
- $\widehat{P}(i|X(n))$ is the posterior probability on page 32-6153 of class i for observation $X(n)$.
- $C(j|i)$ is the true misclassification cost of classifying an observation as j when its true class is i .

resubLoss

Class: ClassificationNaiveBayes

Classification loss for naive Bayes classifiers by resubstitution

Syntax

```
L = resubLoss(Mdl)
L = resubLoss(Mdl,Name,Value)
```

Description

`L = resubLoss(Mdl)` returns the in-sample minimum misclassification cost loss (L), which is a scalar representing how well the trained naive Bayes classifier `Mdl` classifies the predictor data stored in `Mdl.X` as compared to the true class labels stored in `Mdl.Y`.

`L = resubLoss(Mdl,Name,Value)` returns the in-sample classification loss with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

Mdl — Fully trained naive Bayes classifier

ClassificationNaiveBayes model

A fully trained naive Bayes classifier, specified as a `ClassificationNaiveBayes` model trained by `fitcnb`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

LossFun — Loss function

'classiferror' (default) | 'binodeviance' | 'exponential' | 'hinge' | 'logit' | 'mincost' | 'quadratic' | function handle

Loss function, specified as the comma-separated pair consisting of 'LossFun' and a built-in, loss-function name or function handle.

- The following table lists the available loss functions. Specify one using its corresponding character vector or string scalar.

Value	Description
'binodeviance'	Binomial deviance
'classiferror'	Classification error
'exponential'	Exponential
'hinge'	Hinge
'logit'	Logistic
'mincost'	Minimal expected misclassification cost (for classification scores that are posterior probabilities)
'quadratic'	Quadratic

'mincost' is appropriate for classification scores that are posterior probabilities. Naive Bayes models return posterior probabilities as classification scores by default (see `predict`).

- Specify your own function using function handle notation.

Suppose that n be the number of observations in X and K be the number of distinct classes (`numel(Mdl.ClassNames)`, Mdl is the input model). Your function must have this signature

```
lossvalue = lossfun(C,S,W,Cost)
```

where:

- The output argument `lossvalue` is a scalar.
- You choose the function name (`lossfun`).
- C is an n -by- K logical matrix with rows indicating which class the corresponding observation belongs. The column order corresponds to the class order in `Mdl.ClassNames`.

Construct C by setting $C(p, q) = 1$ if observation p is in class q , for each row. Set all other elements of row p to 0 .

- S is an n -by- K numeric matrix of classification scores. The column order corresponds to the class order in `Mdl.ClassNames`. S is a matrix of classification scores, similar to the output of `predict`.
- W is an n -by-1 numeric vector of observation weights. If you pass W , the software normalizes them to sum to 1.
- $Cost$ is a K -by- K numeric matrix of misclassification costs. For example, $Cost = ones(K) - eye(K)$ specifies a cost of 0 for correct classification, and 1 for misclassification.

Specify your function using `'LossFun', @lossfun`.

For more details on loss functions, see “Classification Loss” on page 32-6037.

Data Types: `char` | `string` | `function_handle`

Output Arguments

L — Classification loss

scalar

Classification loss, returned as a scalar. L is a generalization or resubstitution quality measure. Its interpretation depends on the loss function and weighting scheme, but, in general, better classifiers yield smaller loss values.

Examples

Determine the Resubstitution Loss of Naive Bayes Classifiers

Load Fisher's iris data set.

```
load fisheriris
X = meas;    % Predictors
Y = species; % Response
```

Train a naive Bayes classifier. It is good practice to specify the class order. Assume that each predictor is conditionally, normally distributed given its label.

```
Mdl = fitcnb(X,Y,'ClassNames',{'setosa','versicolor','virginica'});
```

Mdl is a trained `ClassificationNaiveBayes` classifier.

Estimate the default resubstitution loss, which is the in-sample minimum misclassification cost.

```
L = resubLoss(Mdl)
```

```
L = 0.0400
```

The average, in-sample cost of classification is 0.04.

Determine Resubstitution Classification Error of Naive Bayes Classifiers

Load Fisher's iris data set.

```
load fisheriris  
X = meas; % Predictors  
Y = species; % Response
```

Train a naive Bayes classifier. It is good practice to specify the class order. Assume that each predictor is conditionally, normally distributed given its label.

```
Mdl = fitcnb(X,Y,'ClassNames',{'setosa','versicolor','virginica'});
```

Mdl is a trained `ClassificationNaiveBayes` classifier.

Estimate the in-sample proportion of misclassified observations.

```
L = resubLoss(Mdl,'LossFun','classferror')
```

```
L = 0.0400
```

The naive Bayes classifier misclassifies 4% of the training observations.

Definitions

Classification Loss

Classification loss functions measure the predictive inaccuracy of classification models. When you compare the same type of loss among many models, a lower loss indicates a better predictive model.

Consider the following scenario.

- L is the weighted average classification loss.
- n is the sample size.
- For binary classification:
 - y_j is the observed class label. The software codes it as -1 or 1 , indicating the negative or positive class, respectively.
 - $f(X_j)$ is the raw classification score for observation (row) j of the predictor data X .
 - $m_j = y_j f(X_j)$ is the classification score for classifying observation j into the class corresponding to y_j . Positive values of m_j indicate correct classification and do not contribute much to the average loss. Negative values of m_j indicate incorrect classification and contribute significantly to the average loss.
- For algorithms that support multiclass classification (that is, $K \geq 3$):
 - y_j^* is a vector of $K - 1$ zeros, with 1 in the position corresponding to the true, observed class y_j . For example, if the true class of the second observation is the third class and $K = 4$, then $y_2^* = [0 \ 0 \ 1 \ 0]$. The order of the classes corresponds to the order in the `ClassNames` property of the input model.
 - $f(X_j)$ is the length K vector of class scores for observation j of the predictor data X . The order of the scores corresponds to the order of the classes in the `ClassNames` property of the input model.
 - $m_j = y_j^* f(X_j)$. Therefore, m_j is the scalar classification score that the model predicts for the true, observed class.
- The weight for observation j is w_j . The software normalizes the observation weights so that they sum to the corresponding prior class probability. The software also normalizes the prior probabilities so they sum to 1 . Therefore,

$$\sum_{j=1}^n w_j = 1.$$

Given this scenario, the following table describes the supported loss functions that you can specify by using the 'LossFun' name-value pair argument.

Loss Function	Value of LossFun	Equation
Binomial deviance	'binodeviance'	$L = \sum_{j=1}^n w_j \log\{1 + \exp[-2m_j]\}.$
Exponential loss	'exponential'	$L = \sum_{j=1}^n w_j \exp(-m_j).$
Classification error	'classiferror'	$L = \sum_{j=1}^n w_j I\{\hat{y}_j \neq y_j\}.$ <p>It is the weighted fraction of misclassified observations where \hat{y}_j is the class label corresponding to the class with the maximal posterior probability. $I\{x\}$ is the indicator function.</p>
Hinge loss	'hinge'	$L = \sum_{j=1}^n w_j \max\{0, 1 - m_j\}.$
Logit loss	'logit'	$L = \sum_{j=1}^n w_j \log(1 + \exp(-m_j)).$

Loss Function	Value of LossFun	Equation
Minimal cost	'mincost'	<p>Minimal cost. The software computes the weighted minimal cost using this procedure for observations $j = 1, \dots, n$.</p> <ol style="list-style-type: none"> 1 Estimate the 1-by-K vector of expected classification costs for observation j: $v_j = f(X_j)'C.$ <p>$f(X_j)$ is the column vector of class posterior probabilities for binary and multiclass classification. C is the cost matrix that the input model stores in the <code>Cost</code> property.</p> 2 For observation j, predict the class label corresponding to the minimum expected classification cost: $\hat{y}_j = \min_{j=1, \dots, K} (v_j).$ 3 Using C, identify the cost incurred (c_j) for making the prediction. <p>The weighted, average, minimum cost loss is</p> $L = \sum_{j=1}^n w_j c_j.$
Quadratic loss	'quadratic'	$L = \sum_{j=1}^n w_j (1 - m_j)^2.$

This figure compares the loss functions (except 'mincost') for one observation over m . Some functions are normalized to pass through [0,1].

Posterior Probability

The posterior probability is the probability that an observation belongs in a particular class, given the data.

For naive Bayes, the posterior probability that a classification is k for a given observation (x_1, \dots, x_P) is

$$\hat{P}(Y = k | x_1, \dots, x_P) = \frac{P(X_1, \dots, X_P | y = k) \Pi(Y = k)}{P(X_1, \dots, X_P)},$$

where:

- $P(X_1, \dots, X_P | y = k)$ is the conditional joint density of the predictors given they are in class k . `Mdl.DistributionNames` stores the distribution names of the predictors.
- $\pi(Y = k)$ is the class prior probability distribution. `Mdl.Prior` stores the prior distribution.
- $P(X_1, \dots, X_P)$ is the joint density of the predictors. The classes are discrete, so

$$P(X_1, \dots, X_P) = \sum_{k=1}^K P(X_1, \dots, X_P | y = k) \pi(Y = k).$$

Prior Probability

The prior probability of a class is the believed relative frequency with which observations from that class occur in a population.

resubLoss

Find classification loss for support vector machine (SVM) classifier by resubstitution

Syntax

```
L = resubLoss(SVMModel)
L = resubLoss(SVMModel, 'LossFun', lossFun)
```

Description

`L = resubLoss(SVMModel)` returns the classification loss on page 32-6045 by resubstitution (`L`), the in-sample classification loss, for the support vector machine (SVM) classifier `SVMModel` using the training data stored in `SVMModel.X` and the corresponding class labels stored in `SVMModel.Y`.

The classification loss (`L`) is a generalization or resubstitution quality measure. Its interpretation depends on the loss function and weighting scheme, but, in general, better classifiers yield smaller classification loss values.

`L = resubLoss(SVMModel, 'LossFun', lossFun)` returns the classification loss by resubstitution using the loss function supplied in `LossFun`.

Examples

Determine Resubstitution Loss of SVM Classifiers

Load the ionosphere data set.

```
load ionosphere
```

Train an SVM classifier. Standardize the data and specify that 'g' is the positive class.

```
SVMModel = fitcsvm(X,Y, 'ClassNames', {'b', 'g'}, 'Standardize', true);
```

`SVMModel` is a trained `ClassificationSVM` classifier.

Estimate the resubstitution loss (that is, the in-sample classification error).

```
L = resubLoss(SVMModel)
```

```
L = 0.0570
```

The SVM classifier misclassifies 5.7% of the training sample radar returns.

Determine Resubstitution Hinge Loss of SVM Classifiers

Load the ionosphere data set.

```
load ionosphere
```

Train an SVM classifier. Standardize the data and specify that 'g' is the positive class.

```
SVMModel = fitcsvm(X,Y,'ClassNames',{'b','g'},'Standardize',true);
```

SVMModel is a trained ClassificationSVM classifier.

Estimate the in-sample hinge loss.

```
L = resubLoss(SVMModel,'LossFun','hinge')
```

```
L = 0.1603
```

The hinge loss is 0.1603. Classifiers with hinge losses close to 0 are preferred.

Input Arguments

SVMModel — Full, trained SVM classifier

ClassificationSVM classifier

Full, trained SVM classifier, specified as a ClassificationSVM model trained with fitcsvm.

LossFun — Loss function

'classiferror' (default) | 'binodeviance' | 'exponential' | 'hinge' | 'logit' | 'mincost' | 'quadratic' | function handle

Loss function, specified as a built-in loss function name or a function handle.

- This table lists the available loss functions. Specify one using its corresponding character vector or string scalar.

Value	Description
'binodeviance'	Binomial deviance
'classiferror'	Classification error
'exponential'	Exponential
'hinge'	Hinge
'logit'	Logistic
'mincost'	Minimal expected misclassification cost (for classification scores that are posterior probabilities)
'quadratic'	Quadratic

'mincost' is appropriate for classification scores that are posterior probabilities. You can specify to use posterior probabilities as classification scores for SVM models by setting 'FitPosterior', true when you cross-validate the model using `fitcsvm`.

- Specify your own function by using function handle notation.

Suppose that n is the number of observations in X , and K is the number of distinct classes (`numel(SVMModel.ClassNames)`) used to create the input model (`SVMModel`). Your function must have this signature

```
lossvalue = lossfun(C,S,W,Cost)
```

where:

- The output argument `lossvalue` is a scalar.
- You choose the function name (`lossfun`).
- C is an n -by- K logical matrix with rows indicating the class to which the corresponding observation belongs. The column order corresponds to the class order in `SVMModel.ClassNames`.

Construct C by setting $C(p, q) = 1$ if observation p is in class q , for each row. Set all other elements of row p to 0.

- S is an n -by- K numeric matrix of classification scores, similar to the output of `predict`. The column order corresponds to the class order in `SVMModel.ClassNames`.
- W is an n -by-1 numeric vector of observation weights. If you pass W , the software normalizes the weights to sum to 1.
- $Cost$ is a K -by- K numeric matrix of misclassification costs. For example, $Cost = ones(K) - eye(K)$ specifies a cost of 0 for correct classification and 1 for misclassification.

Specify your function using `'LossFun', @lossfun`.

For more details on loss functions, see “Classification Loss” on page 32-6045.

Example: `'LossFun', 'binodeviance'`

Data Types: `char | string | function_handle`

Definitions

Classification Loss

Classification loss functions measure the predictive inaccuracy of classification models. When you compare the same type of loss among many models, a lower loss indicates a better predictive model.

Consider the following scenario.

- L is the weighted average classification loss.
- n is the sample size.
- For binary classification:
 - y_j is the observed class label. The software codes it as -1 or 1, indicating the negative or positive class, respectively.
 - $f(X_j)$ is the raw classification score for observation (row) j of the predictor data X .
 - $m_j = y_j f(X_j)$ is the classification score for classifying observation j into the class corresponding to y_j . Positive values of m_j indicate correct classification and do not contribute much to the average loss. Negative values of m_j indicate incorrect classification and contribute significantly to the average loss.

- For algorithms that support multiclass classification (that is, $K \geq 3$):
 - y_j^* is a vector of $K - 1$ zeros, with 1 in the position corresponding to the true, observed class y_j . For example, if the true class of the second observation is the third class and $K = 4$, then $y_2^* = [0 \ 0 \ 1 \ 0]$. The order of the classes corresponds to the order in the `ClassNames` property of the input model.
 - $f(X_j)$ is the length K vector of class scores for observation j of the predictor data X . The order of the scores corresponds to the order of the classes in the `ClassNames` property of the input model.
 - $m_j = y_j^* f(X_j)$. Therefore, m_j is the scalar classification score that the model predicts for the true, observed class.
- The weight for observation j is w_j . The software normalizes the observation weights so that they sum to the corresponding prior class probability. The software also normalizes the prior probabilities so they sum to 1. Therefore,

$$\sum_{j=1}^n w_j = 1.$$

Given this scenario, the following table describes the supported loss functions that you can specify by using the 'LossFun' name-value pair argument.

Loss Function	Value of LossFun	Equation
Binomial deviance	'binodeviance'	$L = \sum_{j=1}^n w_j \log\{1 + \exp[-2m_j]\}.$
Exponential loss	'exponential'	$L = \sum_{j=1}^n w_j \exp(-m_j).$
Classification error	'classiferror'	$L = \sum_{j=1}^n w_j I\{\hat{y}_j \neq y_j\}.$ It is the weighted fraction of misclassified observations where \hat{y}_j is the class label corresponding to the class with the maximal posterior probability. $I\{x\}$ is the indicator function.

Loss Function	Value of LossFun	Equation
Hinge loss	'hinge'	$L = \sum_{j=1}^n w_j \max\{0, 1 - m_j\}.$
Logit loss	'logit'	$L = \sum_{j=1}^n w_j \log(1 + \exp(-m_j)).$
Minimal cost	'mincost'	<p>Minimal cost. The software computes the weighted minimal cost using this procedure for observations $j = 1, \dots, n$.</p> <ol style="list-style-type: none"> Estimate the 1-by-K vector of expected classification costs for observation j: $\nu_j = f(X_j)'C.$ <p>$f(X_j)$ is the column vector of class posterior probabilities for binary and multiclass classification. C is the cost matrix that the input model stores in the <code>Cost</code> property.</p> For observation j, predict the class label corresponding to the minimum expected classification cost: $\hat{y}_j = \min_{j=1, \dots, K} (\nu_j).$ Using C, identify the cost incurred (c_j) for making the prediction. <p>The weighted, average, minimum cost loss is</p> $L = \sum_{j=1}^n w_j c_j.$
Quadratic loss	'quadratic'	$L = \sum_{j=1}^n w_j (1 - m_j)^2.$

This figure compares the loss functions (except 'mincost') for one observation over m . Some functions are normalized to pass through $[0,1]$.

Classification Score

The SVM classification score for classifying observation x is the signed distance from x to the decision boundary ranging from $-\infty$ to $+\infty$. A positive score for a class indicates that x is predicted to be in that class. A negative score indicates otherwise.

The positive class classification score $f(x)$ is the trained SVM classification function. $f(x)$ is also the numerical, predicted response for x , or the score for predicting x into the positive class.

$$f(x) = \sum_{j=1}^n \alpha_j y_j G(x_j, x) + b,$$

where $(\alpha_1, \dots, \alpha_n, b)$ are the estimated SVM parameters, $G(x_j, x)$ is the dot product in the predictor space between x and the support vectors, and the sum includes the training set observations. The negative class classification score for x , or the score for predicting x into the negative class, is $-f(x)$.

If $G(x_j, x) = x_j'x$ (the linear kernel), then the score function reduces to

$$f(x) = (x/s)'\beta + b.$$

s is the kernel scale and β is the vector of fitted linear coefficients.

For more details, see “Understanding Support Vector Machines” on page 18-189.

`ClassificationSVM` | `fitcsvm` | `loss` | `resubPredict`

Introduced in R2014a

resubLoss

Class: ClassificationTree

Classification error by resubstitution

Syntax

```
L = resubLoss(tree)
L = resubLoss(tree,Name,Value)
L = resubLoss(tree,'Subtrees',subtreevector)
[L,se] = resubLoss(tree,'Subtrees',subtreevector)
[L,se,NLeaf] = resubLoss(tree,'Subtrees',subtreevector)
[L,se,NLeaf,bestlevel] = resubLoss(tree,'Subtrees',subtreevector)
[L,...] = resubLoss(tree,'Subtrees',subtreevector,Name,Value)
```

Description

`L = resubLoss(tree)` returns the resubstitution loss, meaning the loss computed for the data that `fitctree` used to create `tree`.

`L = resubLoss(tree,Name,Value)` returns the loss with additional options specified by one or more `Name,Value` pair arguments. You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`L = resubLoss(tree,'Subtrees',subtreevector)` returns a vector of classification errors for the trees in the pruning sequence `subtreevector`.

`[L,se] = resubLoss(tree,'Subtrees',subtreevector)` returns the vector of standard errors of the classification errors.

`[L,se,NLeaf] = resubLoss(tree,'Subtrees',subtreevector)` returns the vector of numbers of leaf nodes in the trees of the pruning sequence.

`[L,se,NLeaf,bestlevel] = resubLoss(tree,'Subtrees',subtreevector)` returns the best pruning level as defined in the `TreeSize` name-value pair. By default,

`bestlevel` is the pruning level that gives loss within one standard deviation of minimal loss.

`[L, ...] = resubLoss(tree, 'Subtrees', subtreevector, Name, Value)` returns loss statistics with additional options specified by one or more `Name, Value` pair arguments. You can specify several name-value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Input Arguments

tree

A classification tree constructed by `fitctree`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

LossFun — Loss function

'classiferror' (default) | 'binodeviance' | 'exponential' | 'hinge' | 'logit' | 'mincost' | 'quadratic' | function handle

Loss function, specified as the comma-separated pair consisting of 'LossFun' and a built-in, loss-function name or function handle.

- The following table lists the available loss functions. Specify one using its corresponding character vector or string scalar.

Value	Description
'binodeviance'	Binomial deviance
'classiferror'	Classification error
'exponential'	Exponential
'hinge'	Hinge
'logit'	Logistic

Value	Description
'mincost'	Minimal expected misclassification cost (for classification scores that are posterior probabilities)
'quadratic'	Quadratic

'mincost' is appropriate for classification scores that are posterior probabilities. Classification trees return posterior probabilities as classification scores by default (see `predict`).

- Specify your own function using function handle notation.

Suppose that n be the number of observations in X and K be the number of distinct classes (`numel(tree.ClassNames)`). Your function must have this signature

```
lossvalue = lossfun(C,S,W,Cost)
```

where:

- The output argument `lossvalue` is a scalar.
- You choose the function name (`lossfun`).
- C is an n -by- K logical matrix with rows indicating which class the corresponding observation belongs. The column order corresponds to the class order in `tree.ClassNames`.

Construct C by setting $C(p, q) = 1$ if observation p is in class q , for each row. Set all other elements of row p to 0 .

- S is an n -by- K numeric matrix of classification scores. The column order corresponds to the class order in `tree.ClassNames`. S is a matrix of classification scores, similar to the output of `predict`.
- W is an n -by-1 numeric vector of observation weights. If you pass W , the software normalizes them to sum to 1.
- $Cost$ is a K -by- K numeric matrix of misclassification costs. For example, `Cost = ones(K) - eye(K)` specifies a cost of 0 for correct classification, and 1 for misclassification.

Specify your function using `'LossFun', @lossfun`.

For more details on loss functions, see “Classification Loss” on page 32-6058.

Data Types: `char` | `string` | `function_handle`

Name, Value arguments associated with pruning subtrees:

Subtrees — Pruning level

0 (default) | vector of nonnegative integers | 'all'

Pruning level, specified as the comma-separated pair consisting of 'Subtrees' and a vector of nonnegative integers in ascending order or 'all'.

If you specify a vector, then all elements must be at least 0 and at most `max(tree.PruneList)`. 0 indicates the full, unpruned tree and `max(tree.PruneList)` indicates the completely pruned tree (i.e., just the root node).

If you specify 'all', then `resubLoss` operates on all subtrees (i.e., the entire pruning sequence). This specification is equivalent to using `0:max(tree.PruneList)`.

`resubLoss` prunes `tree` to each level indicated in `Subtrees`, and then estimates the corresponding output arguments. The size of `Subtrees` determines the size of some output arguments.

To invoke `Subtrees`, the properties `PruneList` and `PruneAlpha` of `tree` must be nonempty. In other words, grow `tree` by setting 'Prune', 'on', or by pruning `tree` using `prune`.

Example: 'Subtrees', 'all'

Data Types: single | double | char | string

TreeSize — Tree size

'se' (default) | 'min'

Tree size, specified as the comma-separated pair consisting of 'TreeSize' and one of the following values:

- 'se' — `loss` returns the highest pruning level with loss within one standard deviation of the minimum ($L + se$, where L and se relate to the smallest value in `Subtrees`).
- 'min' — `loss` returns the element of `Subtrees` with smallest loss, usually the smallest element of `Subtrees`.

Output Arguments

L

Classification loss on page 32-6058, a vector the length of `Subtrees`. The meaning of the error depends on the values in `Weights` and `LossFun`.

se

Standard error of loss, a vector the length of `Subtrees`.

NLeaf

Number of leaves (terminal nodes) in the pruned subtrees, a vector the length of `Subtrees`.

bestlevel

A scalar whose value depends on `TreeSize`:

- `TreeSize = 'se'` — `loss` returns the highest pruning level with loss within one standard deviation of the minimum ($L + se$, where L and se relate to the smallest value in `Subtrees`).
- `TreeSize = 'min'` — `loss` returns the element of `Subtrees` with smallest loss, usually the smallest element of `Subtrees`.

Examples

Compute the In-Sample Classification Error

Compute the resubstitution classification error for the `ionosphere` data.

```
load ionosphere
tree = fitctree(X,Y);
L = resubLoss(tree)

L = 0.0114
```

Examine the Classification Error for Each Subtree

Unpruned decision trees tend to overfit. One way to balance model complexity and out-of-sample performance is to prune a tree (or restrict its growth) so that in-sample and out-of-sample performance are satisfactory.

Load Fisher's iris data set. Partition the data into training (50%) and validation (50%) sets.

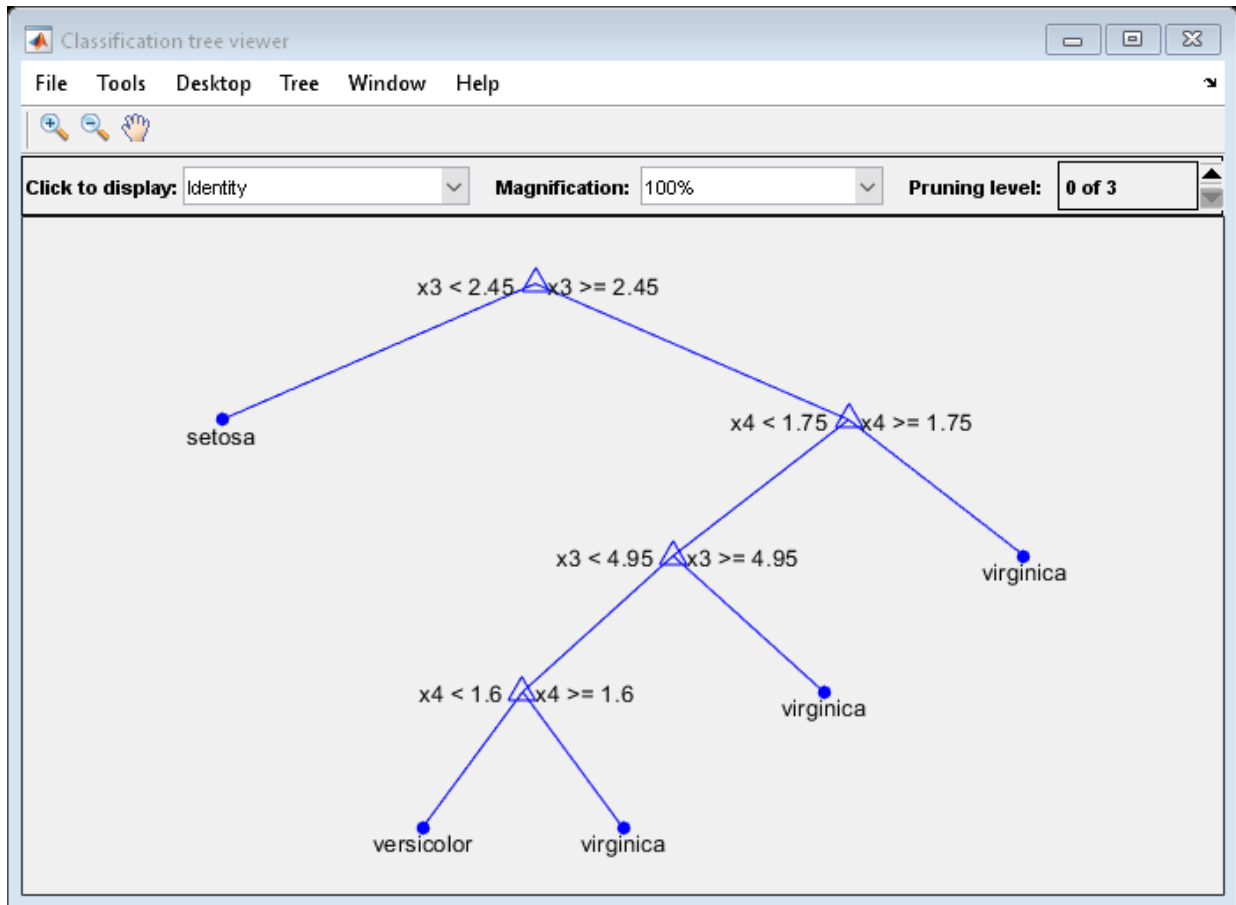

```
load fisheriris
n = size(meas,1);
rng(1) % For reproducibility
idxTrn = false(n,1);
idxTrn(randsample(n,round(0.5*n))) = true; % Training set logical indices
idxVal = idxTrn == false; % Validation set logical indices
```

Grow a classification tree using the training set.

```
Mdl = fitctree(meas(idxTrn,:),species(idxTrn));
```

View the classification tree.

```
view(Mdl, 'Mode', 'graph');
```

The classification tree has four pruning levels. Level 0 is the full, unpruned tree (as displayed). Level 3 is just the root node (i.e., no splits).

Examine the training sample classification error for each subtree (or pruning level) excluding the highest level.

```
m = max(Mdl.PruneList) - 1;
trnLoss = resubLoss(Mdl, 'SubTrees', 0:m)
```

```
trnLoss = 3x1
```

```
0.0267
```

```
0.0533
0.3067
```

- The full, unpruned tree misclassifies about 2.7% of the training observations.
- The tree pruned to level 1 misclassifies about 5.3% of the training observations.
- The tree pruned to level 2 (i.e., a stump) misclassifies about 30.6% of the training observations.

Examine the validation sample classification error at each level excluding the highest level.

```
valLoss = loss(Mdl, meas(idxVal, :), species(idxVal), 'SubTrees', 0:m)
```

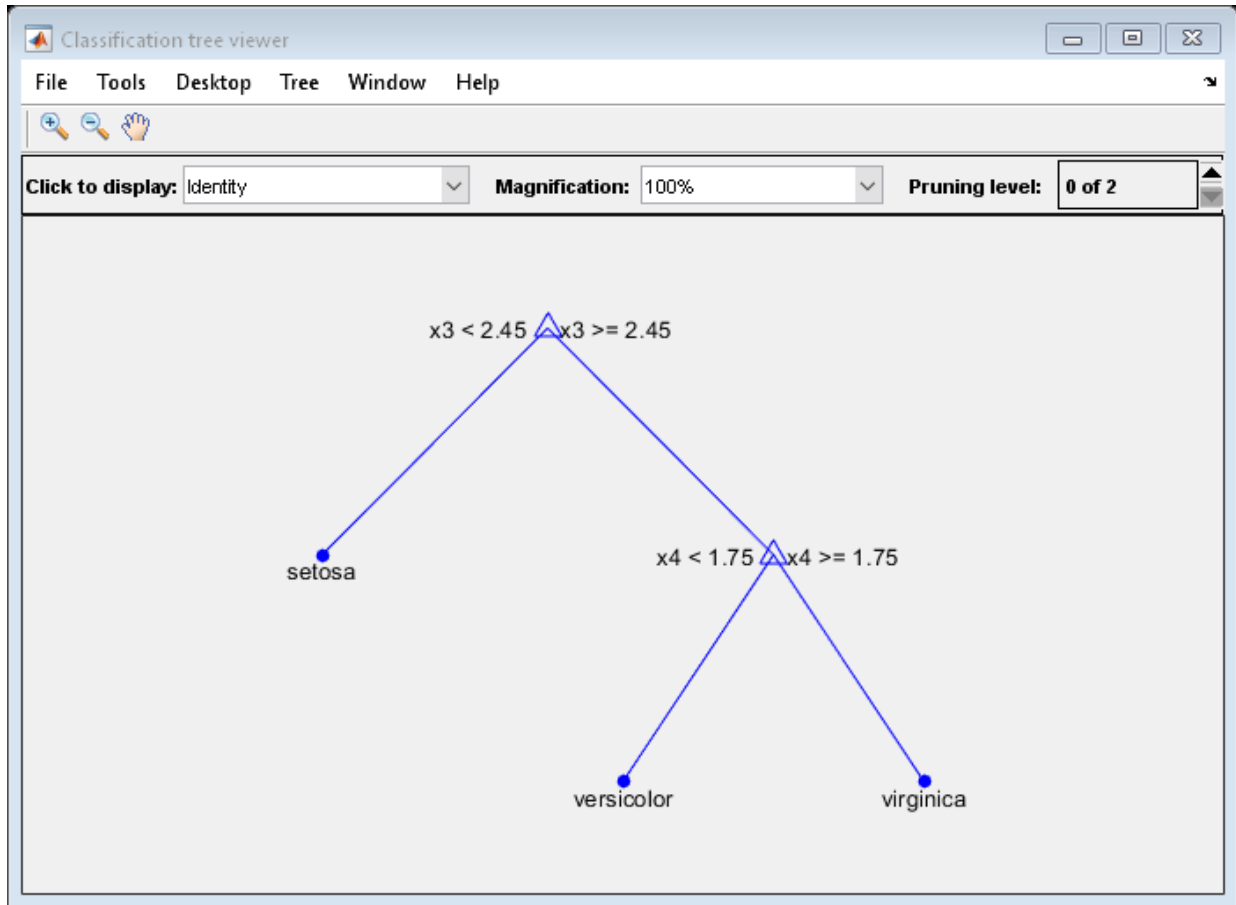

```
valLoss = 3x1
```

```
0.0369
0.0237
0.3067
```

- The full, unpruned tree misclassifies about 3.7% of the validation observations.
- The tree pruned to level 1 misclassifies about 2.4% of the validation observations.
- The tree pruned to level 2 (i.e., a stump) misclassifies about 30.7% of the validation observations.

To balance model complexity and out-of-sample performance, consider pruning Mdl to level 1.

```
pruneMdl = prune(Mdl, 'Level', 1);
view(pruneMdl, 'Mode', 'graph')
```

Definitions

Classification Loss

Classification loss functions measure the predictive inaccuracy of classification models. When you compare the same type of loss among many models, a lower loss indicates a better predictive model.

Consider the following scenario.

- L is the weighted average classification loss.
- n is the sample size.
- For binary classification:
 - y_j is the observed class label. The software codes it as -1 or 1, indicating the negative or positive class, respectively.
 - $f(X_j)$ is the raw classification score for observation (row) j of the predictor data X .
 - $m_j = y_j f(X_j)$ is the classification score for classifying observation j into the class corresponding to y_j . Positive values of m_j indicate correct classification and do not contribute much to the average loss. Negative values of m_j indicate incorrect classification and contribute significantly to the average loss.
- For algorithms that support multiclass classification (that is, $K \geq 3$):
 - y_j^* is a vector of $K - 1$ zeros, with 1 in the position corresponding to the true, observed class y_j . For example, if the true class of the second observation is the third class and $K = 4$, then $y_2^* = [0 \ 0 \ 1 \ 0]$. The order of the classes corresponds to the order in the `ClassNames` property of the input model.
 - $f(X_j)$ is the length K vector of class scores for observation j of the predictor data X . The order of the scores corresponds to the order of the classes in the `ClassNames` property of the input model.
 - $m_j = y_j^* f(X_j)$. Therefore, m_j is the scalar classification score that the model predicts for the true, observed class.
- The weight for observation j is w_j . The software normalizes the observation weights so that they sum to the corresponding prior class probability. The software also normalizes the prior probabilities so they sum to 1. Therefore,

$$\sum_{j=1}^n w_j = 1.$$

Given this scenario, the following table describes the supported loss functions that you can specify by using the 'LossFun' name-value pair argument.

Loss Function	Value of LossFun	Equation
Binomial deviance	'binodeviance'	$L = \sum_{j=1}^n w_j \log\{1 + \exp[-2m_j]\}.$

Loss Function	Value of LossFun	Equation
Exponential loss	'exponential'	$L = \sum_{j=1}^n w_j \exp(-m_j).$
Classification error	'classiferror'	$L = \sum_{j=1}^n w_j I\{\hat{y}_j \neq y_j\}.$ <p>It is the weighted fraction of misclassified observations where \hat{y}_j is the class label corresponding to the class with the maximal posterior probability. $I\{x\}$ is the indicator function.</p>
Hinge loss	'hinge'	$L = \sum_{j=1}^n w_j \max\{0, 1 - m_j\}.$
Logit loss	'logit'	$L = \sum_{j=1}^n w_j \log(1 + \exp(-m_j)).$

Loss Function	Value of LossFun	Equation
Minimal cost	'mincost'	<p>Minimal cost. The software computes the weighted minimal cost using this procedure for observations $j = 1, \dots, n$.</p> <ol style="list-style-type: none"> 1 Estimate the 1-by-K vector of expected classification costs for observation j: $v_j = f(X_j)'C.$ <p>$f(X_j)$ is the column vector of class posterior probabilities for binary and multiclass classification. C is the cost matrix that the input model stores in the <code>Cost</code> property.</p> 2 For observation j, predict the class label corresponding to the minimum expected classification cost: $\hat{y}_j = \min_{j=1, \dots, K} (v_j).$ 3 Using C, identify the cost incurred (c_j) for making the prediction. <p>The weighted, average, minimum cost loss is</p> $L = \sum_{j=1}^n w_j c_j.$
Quadratic loss	'quadratic'	$L = \sum_{j=1}^n w_j (1 - m_j)^2.$

This figure compares the loss functions (except 'mincost') for one observation over m . Some functions are normalized to pass through [0,1].

True Misclassification Cost

There are two costs associated with classification: the true misclassification cost per class, and the expected misclassification cost per observation.

You can set the true misclassification cost per class in the `Cost` name-value pair when you create the classifier using the `fitctree` method. `Cost(i, j)` is the cost of classifying an observation into class `j` if its true class is `i`. By default, `Cost(i, j) = 1` if $i \neq j$, and `Cost(i, j) = 0` if $i = j$. In other words, the cost is 0 for correct classification, and 1 for incorrect classification.

Expected Misclassification Cost

There are two costs associated with classification: the true misclassification cost per class, and the expected misclassification cost per observation.

Suppose you have `Nobs` observations that you want to classify with a trained classifier. Suppose you have `K` classes. You place the observations into a matrix `Xnew` with one observation per row.

The expected cost matrix `CE` has size `Nobs`-by-`K`. Each row of `CE` contains the expected (average) cost of classifying the observation into each of the `K` classes. `CE(n, k)` is

$$\sum_{i=1}^K \widehat{P}(i|Xnew(n))C(k|i),$$

where

- `K` is the number of classes.
- $\widehat{P}(i|Xnew(n))$ is the posterior probability of class `i` for observation `Xnew(n)`.
- `C(k|i)` is the true misclassification cost of classifying an observation as `k` when its true class is `i`.

`fitctree` | `loss` | `resubEdge` | `resubMargin` | `resubPredict`

resubLoss

Regression error by resubstitution

Syntax

```
L = resubLoss(ens)
L = resubLoss(ens,Name,Value)
```

Description

`L = resubLoss(ens)` returns the resubstitution loss, meaning the mean squared error computed for the data that `fitrensemble` used to create `ens`.

`L = resubLoss(ens,Name,Value)` calculates loss with additional options specified by one or more `Name,Value` pair arguments. You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Input Arguments

ens

A regression ensemble created with `fitrensemble`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Learners

Indices of weak learners in the ensemble ranging from 1 to `NumTrained`. `resubLoss` uses only these learners for calculating loss.

Default: 1:NumTrained

lossfun

Function handle for loss function, or 'mse', meaning mean squared error. If you pass a function handle fun, resubLoss calls it as

```
FUN(Y,Yfit,W)
```

where Y, Yfit, and W are numeric vectors of the same length. Y is the observed response, Yfit is the predicted response, and W is the observation weights.

Default: 'mse'

mode

Character vector or string scalar representing the meaning of the output L:

- 'ensemble' — L is a scalar value, the loss for the entire ensemble.
- 'individual' — L is a vector with one element per trained learner.
- 'cumulative' — L is a vector in which element J is obtained by using learners 1:J from the input list of learners.

Default: 'ensemble'

Output Arguments

L

Loss, by default the mean squared error. L can be a vector, and can mean different things, depending on the name-value pair settings.

Examples

Estimate Resubstitution Loss

Find the mean-squared difference between resubstitution predictions and training data.

Load the carsmall data set and select horsepower and vehicle weight as predictors.

```
load carsmall  
X = [Horsepower Weight];
```

Train an ensemble of regression trees, and find the mean-squared difference of predictions from the training data.

```
ens = fitrensemble(X,MPG);  
MSE = resubLoss(ens)
```

```
MSE = 0.5836
```

See Also

[loss](#) | [resubLoss](#) | [resubPredict](#)

resubLoss

Class: RegressionGP

Resubstitution loss for a trained Gaussian process regression model

Syntax

```
L = resubLoss(gprMdl)
L = resubLoss(gprMdl, Name, Value)
```

Description

`L = resubLoss(gprMdl)` returns the resubstitution mean squared error for the Gaussian process regression (GPR) model, `gprMdl`.

`L = resubLoss(gprMdl, Name, Value)` returns the resubstitution loss for the GPR model, `gprMdl`, with additional options specified by one or more `Name, Value` pair arguments. For example, you can specify a custom loss function or the observation weights.

Input Arguments

gprMdl — Gaussian process regression model

RegressionGP object

Gaussian process regression model, specified as a RegressionGP object.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

lossfun — Loss function

'mse' (default) | function handle

Loss function for the trained GPR model, specified as 'mse' or a function handle. 'mse' stands for the mean squared error.

If you pass a function handle, say `fun`, `resubLoss` calls it as `: fun(Y, Ypred, W)`, where `Y`, `Ypred`, and `W` are numeric vectors of length n , and n is the number of observations in the training data. `Y` is the observed response, `Ypred` is the predicted response, and `W` is the observation weights.

Example: `'lossfun', Fct` calls the loss function `Fct`.

Data Types: `char` | `string` | `function_handle`

weights — Observation weights

vector of 1s (default) | n -by-1 vector

Observation weights, specified as an n -by-1 vector, where n is the number of observations in the training data. By default, weight of each observation is 1.

Data Types: `double` | `single`

Output Arguments

L — Resubstitution error

scalar value

Resubstitution error for the GPR model, returned as a scalar value.

Examples

Compute the Resubstitution Loss

This example uses "Housing" data set [1] from the UCI machine learning archive [2] described in <http://archive.ics.uci.edu/ml/datasets/Housing>. Download the data and save it in your current directory as a data file named `housing.data`.

The dataset has 506 observations. The first 13 columns contain the predictor values and the last column contains the response values. The goal is to predict the median value of owner-occupied homes in the Boston suburb area as a function of 13 predictors.

Load the data and define the response vector and predictor matrix.

```
load('housing.data');  
X = housing(:,1:13);  
y = housing(:,end);
```

Fit a GPR model using subset of regressors ('sr') approximation method with Matern 3/2 ('Matern32') kernel function. Predict using the fully independent conditional ('fic') method.

```
gprMdl = fitrgp(X,y,'KernelFunction','Matern32',...  
'FitMethod','sr','PredictMethod','fic');
```

Compute the resubstitution predictions.

```
ypred = resubPredict(gprMdl);
```

Plot the predicted response values along with the actual response values.

```
plot(y,'r'); % Plot original response values  
hold on;  
plot(ypred,'b--'); % Plot predicted response values  
ylabel('y');  
legend('Actual response','Predicted response','Location','SouthWest');  
axis([0 510 -10 55]);  
hold off
```

Compute the resubstitution loss.

```
L = resubLoss(gprMdl)
```

```
L =
```

```
4.8478
```

Manually compute the regression loss.

```
n = length(y);
```

```
L = (y-ypred)'*(y-ypred)/n
```

```
L =
```

```
4.8478
```

Compute Custom Resubstitution Loss

Load the sample data and store in a table.

```
load fisheriris
tbl = table(meas(:,1),meas(:,2),meas(:,3),meas(:,4),species,...
'VariableNames',{'meas1','meas2','meas3','meas4','species'});
```

Fit a GPR model using the first measurement as the response and the other variables as the predictors.

```
mdl = fitrgp(tbl,'meas1');
```

Predict the responses using the trained model.

```
ypred = predict(mdl,tbl);
```

Compute the mean absolute error.

```
n = height(tbl);
y = tbl.meas1;
fun = @(y,ypred,w) sum(abs(y-ypred))/n;
L = resubLoss(mdl,'lossfun',fun)
```

```
L = 0.2345
```

Alternatives

To compute the regression error for new data, use `loss`.

RegressionGP | fitrgp | loss | resubPredict

Introduced in R2015b

resubLoss

Class: RegressionSVM

Resubstitution loss for support vector machine regression model

Syntax

```
L = resubLoss mdl
L = resubLoss mdl, Name, Value
```

Description

`L = resubLoss(mdl)` returns the resubstitution loss for the support vector machine (SVM) regression model `mdl`, using the training data stored in `mdl.X` and corresponding response values stored in `mdl.Y`.

`L = resubLoss(mdl, Name, Value)` returns the resubstitution loss with additional options specified by one or more `Name, Value` pair arguments. For example, you can specify the loss function or observation weights.

Input Arguments

mdl — Full, trained SVM regression model

RegressionSVM model

Full, trained SVM regression model, specified as a RegressionSVM model returned by `fitrsvm`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

LossFun — Loss function

'mse' (default) | 'epsiloninsensitive' | function handle

Loss function, specified as the comma-separated pair consisting of 'LossFun' and 'mse', 'epsiloninsensitive', or a function handle.

- The following table lists the available loss functions. Specify one using its corresponding value.

Value	Loss Function
'mse'	"Mean Squared Error" on page 32-6076
'epsiloninsensitive'	"Epsilon-Insensitive Loss Function" on page 32-6077

- Specify your own function using function handle notation.

Suppose that $n = \text{size}(X,1)$ is the sample size. Your function must have the signature `lossvalue = lossfun(Y,Yfit,W)`, where:

- The output argument `lossvalue` is a numeric value.
- You choose the function name (*lossfun*).
- `Y` is an n -by-1 numeric vector of observed response values.
- `Yfit` is an n -by-1 numeric vector of predicted response values, calculated using the corresponding predictor values in `X` (similar to the output of `predict`).
- `W` is an n -by-1 numeric vector of observation weights.

Specify your function using 'LossFun',`@lossfun`.

Example: 'LossFun','epsiloninsensitive'

Data Types: char | string | function_handle

Weights — Observation weights

ones(size(X,1),1) (default) | numeric vector

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a numeric vector. `Weights` must be the same length as the number of rows in `X`. The software weighs the observations in each row of `X` using the corresponding weight value in `Weights`.

Data Types: single | double

Output Arguments

L — Resubstitution loss

scalar value

Resubstitution loss, returned as a scalar value.

The resubstitution loss is the loss calculated between the response training data and the model's predicted response values based on the input training data.

Resubstitution loss can be an overly optimistic estimate of the predictive error on new data. If the resubstitution loss is high, the model's predictions are not likely to be very good. However, having a low resubstitution loss does not guarantee good predictions for new data.

To better assess the predictive accuracy of your model, cross validate the model using `crossval`.

Examples

Resubstitution Loss for SVM Regression Model

This example shows how to train an SVM regression model, then calculate the resubstitution loss using mean square error (MSE) and epsilon-insensitive loss.

This example uses the abalone data from the UCI Machine Learning Repository. Download the data and save it in your current directory with the name `'abalone.data'`.

Read the data into a `table`.

```
tbl = readtable('abalone.data','Filetype','text','ReadVariableNames',false);  
rng default % for reproducibility
```

The sample data contains 4177 observations. All of the predictor variables are continuous except for `sex`, which is a categorical variable with possible values `'M'` (for males), `'F'` (for females), and `'I'` (for infants). The goal is to predict the number of rings on the abalone, and thereby determine its age, using physical measurements.

Train an SVM regression model to the data, using a Gaussian kernel function with an automatic kernel scale. Standardize the data.

```
mdl = fitrsvm(tbl, 'Var9', 'KernelFunction', 'gaussian', 'KernelScale', 'auto', 'Standardize
```

Calculate the resubstitution loss using mean square error (MSE).

```
mse_loss = resubLoss(mdl)
```

```
mse_loss =
```

```
4.0603
```

Calculate the epsilon-insensitive loss.

```
eps_loss = resubLoss(mdl, 'LossFun', 'epsiloninsensitive')
```

```
eps_loss =
```

```
1.1027
```

Definitions

Mean Squared Error

The weighted mean squared error is calculated as follows:

$$\text{mse} = \frac{\sum_{j=1}^n w_j (f(x_j) - y_j)^2}{\sum_{j=1}^n w_j},$$

where:

- n is the number of rows of data
- x_j is the j th row of data
- y_j is the true response to x_j
- $f(x_j)$ is the response prediction of the SVM regression model `mdl` to x_j
- w is the vector of weights.

The weights in w are all equal to one by default. You can specify different values for weights using the 'Weights' name-value pair argument. If you specify weights, each value is divided by the sum of all weights, such that the normalized weights add to one.

Epsilon-Insensitive Loss Function

The epsilon-insensitive loss function ignores errors that are within the distance epsilon (ϵ) of the function value. It is formally described as:

$$Loss_{\epsilon} = \begin{cases} 0, & \text{if } |y - f(x)| \leq \epsilon \\ |y - f(x)| - \epsilon, & \text{otherwise.} \end{cases}$$

The mean epsilon-insensitive loss is calculated as follows:

$$Loss = \frac{\sum_{j=1}^n w_j \max(0, |y_j - f(x_j)| - \epsilon)}{\sum_{j=1}^n w_j},$$

`RegressionSVM` | `fitrsvm` | `loss` | `resubPredict`

Introduced in R2015b

resubLoss

Class: RegressionTree

Regression error by resubstitution

Syntax

```
L = resubLoss(tree)
L = resubLoss(tree,Name,Value)
L = resubLoss(tree,'Subtrees',subtreevector)
[L,se] = resubLoss(tree,'Subtrees',subtreevector)
[L,se,NLeaf] = resubLoss(tree,'Subtrees',subtreevector)
[L,se,NLeaf,bestlevel] = resubLoss(tree,'Subtrees',subtreevector)
[L,...] = resubLoss(tree,'Subtrees',subtreevector,Name,Value)
```

Description

`L = resubLoss(tree)` returns the resubstitution loss, meaning the loss computed for the data that `fitrtree` used to create `tree`.

`L = resubLoss(tree,Name,Value)` returns the loss with additional options specified by one or more `Name,Value` pair arguments. You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`L = resubLoss(tree,'Subtrees',subtreevector)` returns a vector of mean squared errors for the trees in the pruning sequence `subtreevector`.

`[L,se] = resubLoss(tree,'Subtrees',subtreevector)` returns the vector of standard errors of the classification errors.

`[L,se,NLeaf] = resubLoss(tree,'Subtrees',subtreevector)` returns the vector of numbers of leaf nodes in the trees of the pruning sequence.

`[L,se,NLeaf,bestlevel] = resubLoss(tree,'Subtrees',subtreevector)` returns the best pruning level as defined in the `TreeSize` name-value pair. By default,

`bestlevel` is the pruning level that gives loss within one standard deviation of minimal loss.

`[L, ...] = resubLoss(tree, 'Subtrees', subtreevector, Name, Value)` returns loss statistics with additional options specified by one or more `Name, Value` pair arguments. You can specify several name-value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Input Arguments

tree — Regression tree

RegressionTree model object

A regression tree (RegressionTree model object) constructed using `fitrtree`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

LossFun — Loss function

'mse' (default) | function handle

Loss function, specified as a function handle or 'mse' meaning mean squared error.

You can write your own loss function in the syntax described in “Loss Functions” on page 32-6086.

Data Types: char | string | function_handle

`Name, Value` arguments associated with pruning subtrees:

Subtrees — Pruning level

0 (default) | vector of nonnegative integers | 'all'

Pruning level, specified as the comma-separated pair consisting of 'Subtrees' and a vector of nonnegative integers in ascending order or 'all'.

If you specify a vector, then all elements must be at least 0 and at most `max(tree.PruneList)`. 0 indicates the full, unpruned tree and `max(tree.PruneList)` indicates the completely pruned tree (i.e., just the root node).

If you specify 'all', then `resubLoss` operates on all subtrees (i.e., the entire pruning sequence). This specification is equivalent to using `0:max(tree.PruneList)`.

`resubLoss` prunes `tree` to each level indicated in `Subtrees`, and then estimates the corresponding output arguments. The size of `Subtrees` determines the size of some output arguments.

To invoke `Subtrees`, the properties `PruneList` and `PruneAlpha` of `tree` must be nonempty. In other words, grow `tree` by setting 'Prune', 'on', or by pruning `tree` using `prune`.

Example: 'Subtrees', 'all'

Data Types: single | double | char | string

TreeSize — Tree size

'se' (default) | 'min'

Tree size, specified as one of the following:

- 'se' — `loss` returns the highest pruning level with loss within one standard deviation of the minimum ($L + se$, where L and se relate to the smallest value in `Subtrees`).
- 'min' — `loss` returns the element of `Subtrees` with smallest loss, usually the smallest element of `Subtrees`.

Output Arguments

L — Regression loss

numeric vector of positive values

Regression loss (mean squared error), a vector the length of `Subtrees`. The meaning of the error depends on the values in `Weights` and `LossFun`.

se — Standard error of loss

numeric vector of positive values

Standard error of loss, a vector the length of `Subtrees`.

NLeaf — Number of leaves

numeric vector of nonnegative integers

Number of leaves (terminal nodes) in the pruned subtrees, a vector the length of `Subtrees`.

bestlevel — Optimal pruning level

nonnegative numeric scalar

A scalar whose value depends on `TreeSize`:

- `TreeSize = 'se'` — `loss` returns the highest pruning level with loss within one standard deviation of the minimum ($L + se$, where L and se relate to the smallest value in `Subtrees`).
- `TreeSize = 'min'` — `loss` returns the element of `Subtrees` with smallest loss, usually the smallest element of `Subtrees`.

Examples

Compute the In-Sample MSE

Load the `carsmall` data set. Consider `Displacement`, `Horsepower`, and `Weight` as predictors of the response `MPG`.

```
load carsmall
X = [Displacement Horsepower Weight];
```

Grow a regression tree using all observations.

```
Mdl = fitrtree(X,MPG);
```

Compute the resubstitution MSE.

```
resubLoss(Mdl)
```

```
ans = 4.8952
```

Examine the MSE for Each Subtree

Unpruned decision trees tend to overfit. One way to balance model complexity and out-of-sample performance is to prune a tree (or restrict its growth) so that in-sample and out-of-sample performance are satisfactory.

Load the `carsmall` data set. Consider Displacement, Horsepower, and Weight as predictors of the response MPG.

```
load carsmall
X = [Displacement Horsepower Weight];
Y = MPG;
```

Partition the data into training (50%) and validation (50%) sets.

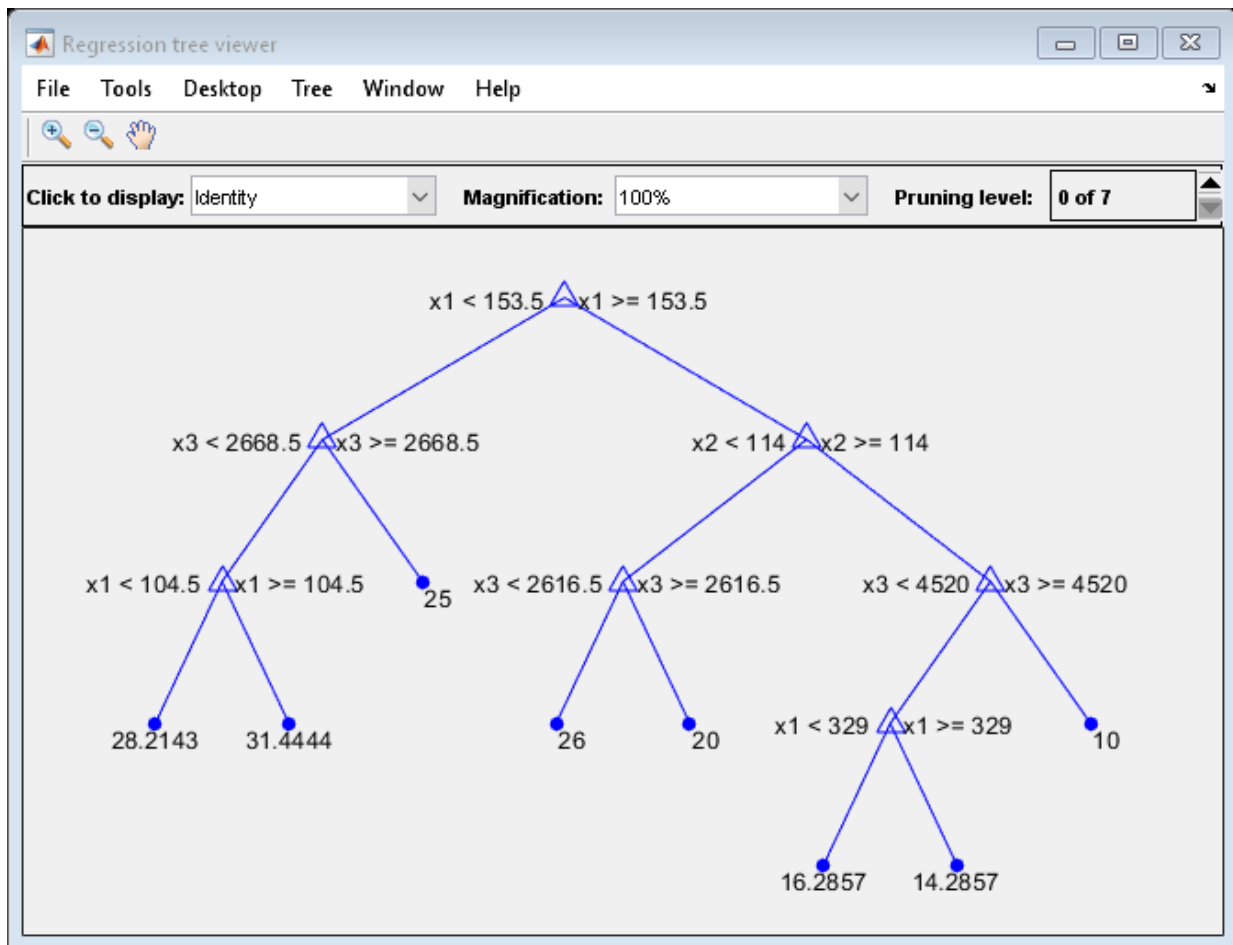

```
n = size(X,1);
rng(1) % For reproducibility
idxTrn = false(n,1);
idxTrn(randsample(n,round(0.5*n))) = true; % Training set logical indices
idxVal = idxTrn == false; % Validation set logical indices
```

Grow a regression tree using the training set.

```
Mdl = fitrtree(X(idxTrn,:),Y(idxTrn));
```

View the regression tree.

```
view(Mdl, 'Mode', 'graph');
```

The regression tree has seven pruning levels. Level 0 is the full, unpruned tree (as displayed). Level 7 is just the root node (i.e., no splits).

Examine the training sample MSE for each subtree (or pruning level) excluding the highest level.

```
m = max(Mdl.PruneList) - 1;
trnLoss = resubLoss(Mdl, 'SubTrees', 0:m)
```

```
trnLoss = 7x1
```

```
5.9789
6.2768
6.8316
7.5209
8.3951
10.7452
14.8445
```

- The MSE for the full, unpruned tree is about 6 units.
- The MSE for the tree pruned to level 1 is about 6.3 units.
- The MSE for the tree pruned to level 6 (i.e., a stump) is about 14.8 units.

Examine the validation sample MSE at each level excluding the highest level.

```
valLoss = loss(Mdl,X(idxVal,:),Y(idxVal),'SubTrees',0:m)
```

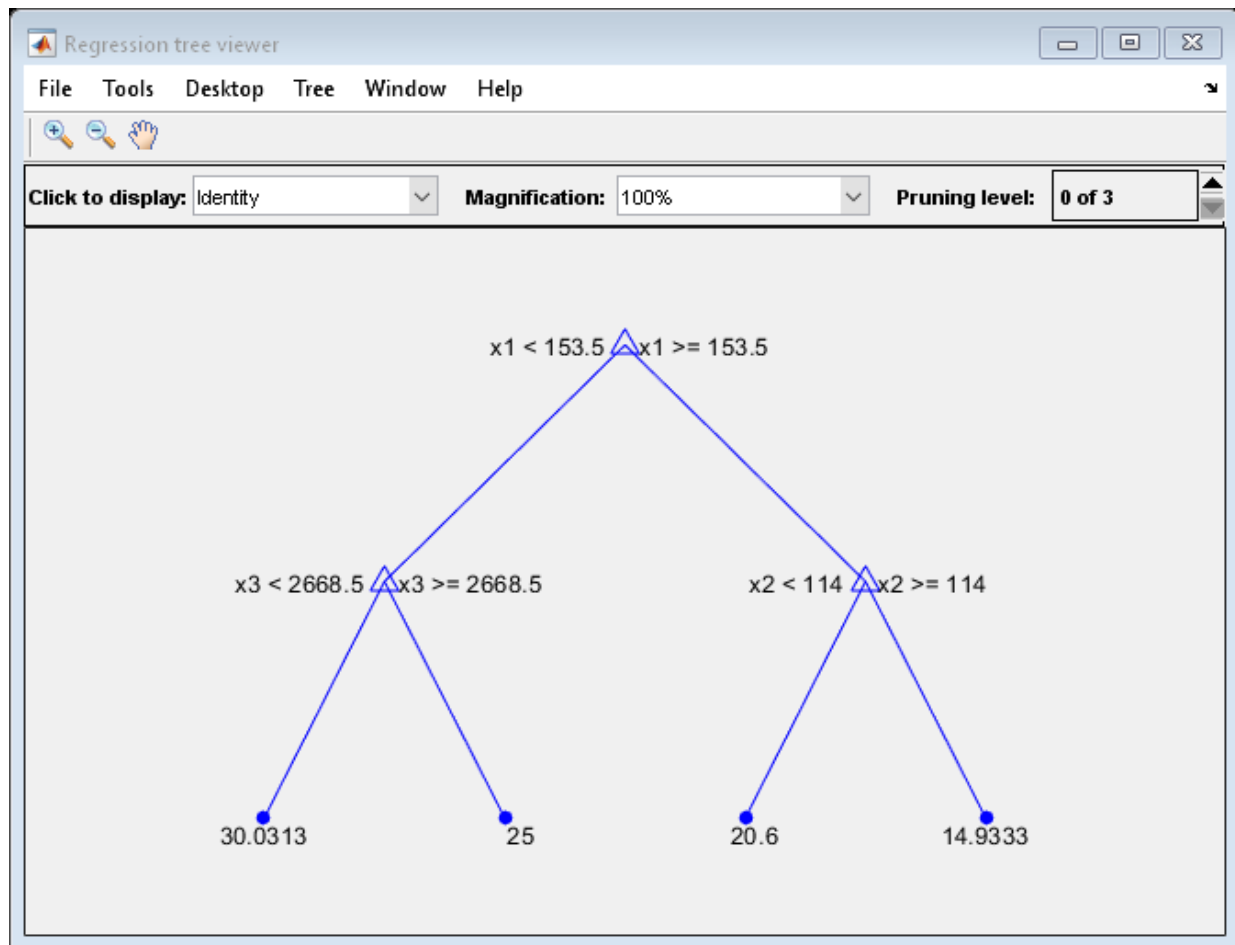

```
valLoss = 7×1
```

```
32.1205
31.5035
32.0541
30.8183
26.3535
30.0137
38.4695
```

- The MSE for the full, unpruned tree (level 0) is about 32.1 units.
- The MSE for the tree pruned to level 4 is about 26.4 units.
- The MSE for the tree pruned to level 5 is about 30.0 units.
- The MSE for the tree pruned to level 6 (i.e., a stump) is about 38.5 units.

To balance model complexity and out-of-sample performance, consider pruning Mdl to level 4.

```
pruneMdl = prune(Mdl,'Level',4);
view(pruneMdl,'Mode','graph')
```

Definitions

Loss Functions

The built-in loss function is 'mse', meaning mean squared error.

To write your own loss function, create a function file of the form

```
function loss = lossfun(Y,Yfit,W)
```

- `N` is the number of rows of `tree.X`.
- `Y` is an `N`-element vector representing the observed response.
- `Yfit` is an `N`-element vector representing the predicted responses.
- `W` is an `N`-element vector representing the observation weights.
- The output `loss` should be a scalar.

Pass the function handle `@lossfun` as the value of the `LossFun` name-value pair.

See Also

`fitrtree` | `loss` | `resubPredict`

resubMargin

Class: ClassificationDiscriminant

Classification margins by resubstitution

Syntax

`M = resubMargin(obj)`

Description

`M = resubMargin(obj)` returns resubstitution classification margins for `obj`.

Input Arguments

obj

Discriminant analysis classifier, produced using `fitcdiscr`.

Output Arguments

M

Numeric column-vector of length `size(obj.X,1)` containing the classification margins.

Examples

Estimate Resubstitution Margins for Discriminant Analysis Classifiers

Find the margins for a discriminant analysis classifier for Fisher's iris data by resubstitution. Examine several entries.

Load Fisher's iris data set.

```
load fisheriris
```

Train a discriminant analysis classifier.

```
Mdl = fitcdiscr(meas,species);
```

Compute the resubstitution margins, and display several of them.

```
m = resubMargin(Mdl);  
m(1:25:end)
```

```
ans = 6×1
```

```
1.0000  
1.0000  
0.9998  
0.9998  
1.0000  
0.9946
```

Definitions

Margin

The classification margin is the difference between the classification score for the true class and maximal classification score for the false classes.

The classification margin is a column vector with the same number of rows as in the matrix X . A high value of margin indicates a more reliable prediction than a low value.

Score

For discriminant analysis, the score of a classification is the posterior probability of the classification. For the definition of posterior probability in discriminant analysis, see "Posterior Probability" on page 20-6.

resubMargin

Resubstitution classification margins for multiclass error-correcting output codes (ECOC) model

Syntax

```
m = resubMargin(Mdl)
m = resubMargin(Mdl,Name,Value)
```

Description

`m = resubMargin(Mdl)` returns the resubstitution classification margins on page 32-6098 (`m`) for the multiclass error-correcting output codes (ECOC) model `Mdl` using the training data stored in `Mdl.X` and the corresponding class labels stored in `Mdl.Y`.

`m` is returned as a numeric column vector with the same length as `Mdl.Y`. The software estimates each entry of `m` using the trained ECOC model `Mdl`, the corresponding row of `Mdl.X`, and the true class label `Mdl.Y`.

`m = resubMargin(Mdl,Name,Value)` returns the classification margins with additional options specified by one or more name-value pair arguments. For example, you can specify a decoding scheme, binary learner loss function, and verbosity level.

Examples

Resubstitution Classification Margins of ECOC Model

Calculate the resubstitution classification margins for an ECOC model with SVM binary learners.

Load Fisher's iris data set. Specify the predictor data `X` and the response data `Y`.

```
load fisheriris
X = meas;
Y = species;
```

Train an ECOC model using SVM binary classifiers. Standardize the predictors using an SVM template, and specify the class order.

```
t = templateSVM('Standardize',true);
classOrder = unique(Y)
```

```
classOrder = 3x1 cell array
    {'setosa'   }
    {'versicolor'}
    {'virginica' }
```

```
Mdl = fitcecoc(X,Y,'Learners',t,'ClassNames',classOrder);
```

`t` is an SVM template object. During training, the software uses default values for empty properties in `t`. `Mdl` is a `ClassificationECOC` model.

Calculate the classification margins for the observations used to train `Mdl`. Display the distribution of the margins using a boxplot.

```
m = resubMargin(Mdl);

boxplot(m)
title('In-Sample Margins')
```

The classification margin of an observation is the positive-class negated loss minus the maximum negative-class negated loss. Choose classifiers that yield relatively large margins.

Select ECOC Model Features by Examining Training-Sample Margins

Perform feature selection by comparing training-sample margins from multiple models. Based solely on this comparison, the model with the greatest margins is the best model.

Load Fisher's iris data set. Define two data sets:

- `fullX` contains all four predictors.
- `partX` contains the sepal measurements only.

```
load fisheriris
X = meas;
fullX = X;
partX = X(:,1:2);
Y = species;
```

Train an ECOC model using SVM binary learners for each predictor set. Standardize the predictors using an SVM template, specify the class order, and compute posterior probabilities.

```
t = templateSVM('Standardize',true);
classOrder = unique(Y)
```

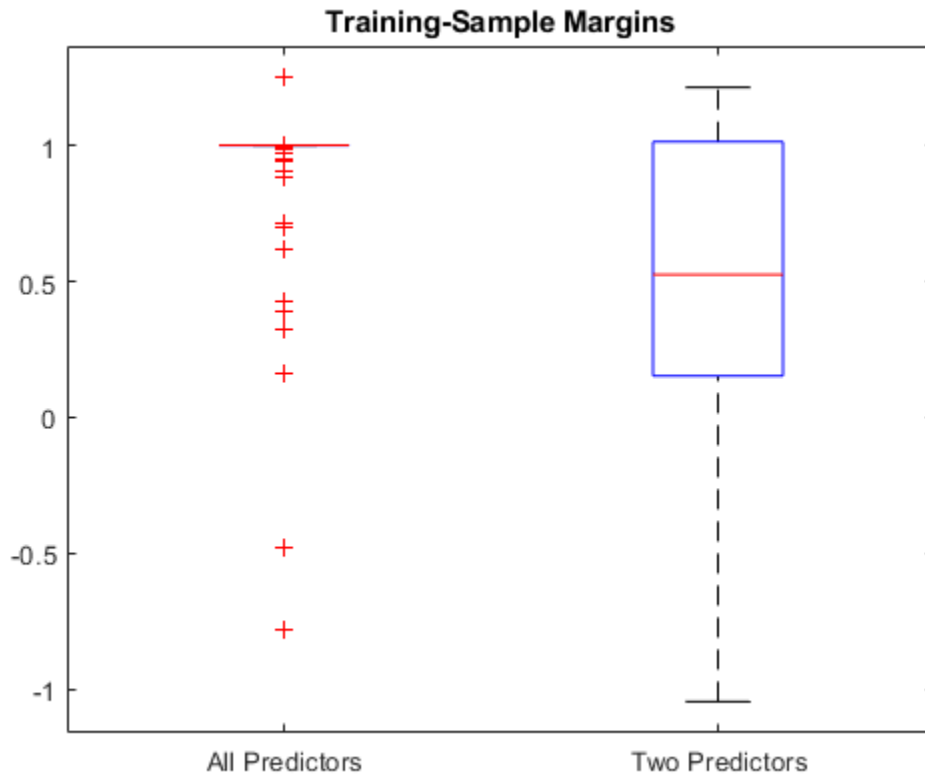

```
classOrder = 3x1 cell array
    {'setosa'   }
    {'versicolor'}
    {'virginica' }
```

```
FullMdl = fitcecoc(fullX,Y,'Learners',t,'ClassNames',classOrder,...
    'FitPosterior',true);
PartMdl = fitcecoc(partX,Y,'Learners',t,'ClassNames',classOrder,...
    'FitPosterior',true);
```

Compute the resubstitution margins for each classifier. For each model, display the distribution of the margins using a boxplot.

```
fullMargins = resubMargin(FullMdl);
partMargins = resubMargin(PartMdl);
```

```
boxplot([fullMargins partMargins],'Labels',{'All Predictors','Two Predictors'})
title('Training-Sample Margins')
```

The margin distribution of FullMdl is situated higher and has less variability than the margin distribution of PartMdl. This result suggests that the model trained with all the predictors fits the training data better.

Input Arguments

Mdl — Full, trained multiclass ECOC model

ClassificationECOC model

Full, trained multiclass ECOC model, specified as a ClassificationECOC model trained with fitcecoc.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example: `resubMargin(Mdl, 'Verbose', 1)` specifies to display diagnostic messages in the Command Window.

BinaryLoss — Binary learner loss function

'hamming' | 'linear' | 'logit' | 'exponential' | 'binodeviance' | 'hinge' | 'quadratic' | function handle

Binary learner loss function, specified as the comma-separated pair consisting of 'BinaryLoss' and a built-in loss function name or function handle.

- This table describes the built-in functions, where y_j is a class label for a particular binary learner (in the set $\{-1, 1, 0\}$), s_j is the score for observation j , and $g(y_j, s_j)$ is the binary loss formula.

Value	Description	Score Domain	$g(y_j, s_j)$
'binodeviance'	Binomial deviance	$(-\infty, \infty)$	$\log[1 + \exp(-2y_j s_j)] / [2\log(2)]$
'exponential'	Exponential	$(-\infty, \infty)$	$\exp(-y_j s_j) / 2$
'hamming'	Hamming	$[0, 1]$ or $(-\infty, \infty)$	$[1 - \text{sign}(y_j s_j)] / 2$
'hinge'	Hinge	$(-\infty, \infty)$	$\max(0, 1 - y_j s_j) / 2$
'linear'	Linear	$(-\infty, \infty)$	$(1 - y_j s_j) / 2$
'logit'	Logistic	$(-\infty, \infty)$	$\log[1 + \exp(-y_j s_j)] / [2\log(2)]$
'quadratic'	Quadratic	$[0, 1]$	$[1 - y_j(2s_j - 1)]^2 / 2$

The software normalizes binary losses so that the loss is 0.5 when $y_j = 0$. Also, the software calculates the mean binary loss for each class.

- For a custom binary loss function, for example `customFunction`, specify its function handle 'BinaryLoss', @customFunction.

`customFunction` has this form:

```
bLoss = customFunction(M,s)
```

where:

- M is the K -by- L coding matrix stored in `Mdl.CodingMatrix`.
- s is the 1-by- L row vector of classification scores.
- `bLoss` is the classification loss. This scalar aggregates the binary losses for every learner in a particular class. For example, you can use the mean binary loss to aggregate the loss over the learners for each class.
- K is the number of classes.
- L is the number of binary learners.

For an example of passing a custom binary loss function, see “Predict Test-Sample Labels of ECOC Model Using Custom Binary Loss Function” on page 32-5219.

The default `BinaryLoss` value depends on the score ranges returned by the binary learners. This table describes some default `BinaryLoss` values based on the given assumptions.

Assumption	Default Value
All binary learners are SVMs or either linear or kernel classification models of SVM learners.	'hinge'
All binary learners are ensembles trained by <code>AdaboostM1</code> or <code>GentleBoost</code> .	'exponential'
All binary learners are ensembles trained by <code>LogitBoost</code> .	'binodeviance'
All binary learners are linear or kernel classification models of logistic regression learners. Or, you specify to predict class posterior probabilities by setting ' <code>FitPosterior</code> ', <code>true</code> in <code>fitcecoc</code> .	'quadratic'

To check the default value, use dot notation to display the `BinaryLoss` property of the trained model at the command line.

```
Example: 'BinaryLoss', 'binodeviance'
```

```
Data Types: char | string | function_handle
```

Decoding — Decoding scheme

```
'lossweighted' (default) | 'lossbased'
```

Decoding scheme that aggregates the binary losses, specified as the comma-separated pair consisting of 'Decoding' and 'lossweighted' or 'lossbased'. For more information, see “Binary Loss” on page 32-6099.

Example: 'Decoding', 'lossbased'

Options — Estimation options

[] (default) | structure array returned by `statset`

Estimation options, specified as the comma-separated pair consisting of 'Options' and a structure array returned by `statset`.

To invoke parallel computing:

- You need a Parallel Computing Toolbox license.
- Specify 'Options', `statset('UseParallel', true)`.

Verbose — Verbosity level

0 (default) | 1

Verbosity level, specified as the comma-separated pair consisting of 'Verbose' and 0 or 1. Verbose controls the number of diagnostic messages that the software displays in the Command Window.

If Verbose is 0, then the software does not display diagnostic messages. Otherwise, the software displays diagnostic messages.

Example: 'Verbose', 1

Data Types: `single` | `double`

Definitions

Classification Margin

The classification margin is, for each observation, the difference between the negative loss for the true class and the maximal negative loss among the false classes. If the margins are on the same scale, then they serve as a classification confidence measure. Among multiple classifiers, those that yield greater margins are better.

Binary Loss

A binary loss is a function of the class and classification score that determines how well a binary learner classifies an observation into the class.

Suppose the following:

- m_{kj} is element (k,j) of the coding design matrix M (that is, the code corresponding to class k of binary learner j).
- s_j is the score of binary learner j for an observation.
- g is the binary loss function.
- \hat{k} is the predicted class for the observation.

In loss-based decoding [Escalera et al.] on page 18-228, the class producing the minimum sum of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \operatorname{argmin}_k \sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j).$$

In loss-weighted decoding [Escalera et al.] on page 18-228, the class producing the minimum average of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \operatorname{argmin}_k \frac{\sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j)}{\sum_{j=1}^L |m_{kj}|}.$$

Allwein et al. on page 18-227 suggest that loss-weighted decoding improves classification accuracy by keeping loss values for all classes in the same dynamic range.

This table summarizes the supported loss functions, where y_j is a class label for a particular binary learner (in the set $\{-1,1,0\}$), s_j is the score for observation j , and $g(y_j, s_j)$.

Value	Description	Score Domain	$g(y_j, s_j)$
'binodeviance'	Binomial deviance	$(-\infty, \infty)$	$\log[1 + \exp(-2y_j s_j)] / [2\log(2)]$

Value	Description	Score Domain	$g(y_j, s_j)$
'exponential'	Exponential	$(-\infty, \infty)$	$\exp(-y_j s_j)/2$
'hamming'	Hamming	$[0, 1]$ or $(-\infty, \infty)$	$[1 - \text{sign}(y_j s_j)]/2$
'hinge'	Hinge	$(-\infty, \infty)$	$\max(0, 1 - y_j s_j)/2$
'linear'	Linear	$(-\infty, \infty)$	$(1 - y_j s_j)/2$
'logit'	Logistic	$(-\infty, \infty)$	$\log[1 + \exp(-y_j s_j)]/[2\log(2)]$
'quadratic'	Quadratic	$[0, 1]$	$[1 - y_j(2s_j - 1)]^2/2$

The software normalizes binary losses such that the loss is 0.5 when $y_j = 0$, and aggregates using the average of the binary learners [Allwein et al.] on page 18-227.

Do not confuse the binary loss with the overall classification loss (specified by the 'LossFun' name-value pair argument of the `loss` and `predict` object functions), which measures how well an ECOC classifier performs as a whole.

Tips

- To compare the margins or edges of several ECOC classifiers, use template objects to specify a common score transform function among the classifiers during training.

Extended Capabilities

Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the 'UseParallel' option to true.

Set the 'UseParallel' field of the options structure to true using `statset` and specify the 'Options' name-value pair argument in the call to this function.

For example: `'Options',statset('UseParallel',true)`

For more information, see the 'Options' name-value pair argument.

For more general information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

resubMargin

Classification margins by resubstitution

Syntax

```
margin = resubMargin(ens)
margin = resubMargin(ens,Name,Value)
```

Description

`margin = resubMargin(ens)` returns the classification margin obtained by `ens` on its training data.

`margin = resubMargin(ens,Name,Value)` calculates margins with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

ens

A classification ensemble created with `fitcensemble`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

learners

Indices of weak learners in the ensemble ranging from 1 to `NumTrained`. `resubMargin` uses only these learners for calculating margin.

Default: `1:NumTrained`

Output Arguments

margin

A numeric column-vector of length `size(ens.X,1)` containing the classification margins.

Examples

Compute Resubstitution Margins for Classification Ensemble

Find the resubstitution margins for an ensemble that classifies the Fisher iris data.

Load the Fisher iris data set.

```
load fisheriris
```

Train an ensemble of 100 boosted classification trees using AdaBoostM2.

```
t = templateTree('MaxNumSplits',1); % Weak learner template tree object
ens = fitcensemble(meas,species,'Method','AdaBoostM2','Learners',t);
```

Find the resubstitution margins.

```
margin = resubMargin(ens);
[min(margin) mean(margin) max(margin)]
```

```
ans = 1×3
```

```
    -0.5674    3.2486    4.6245
```

Definitions

Margin

The classification margin is the difference between the classification score for the true class and maximal classification score for the false classes. Margin is a column vector with the same number of rows as in the matrix `ens.X`.

Score (ensemble)

For ensembles, a classification score represents the confidence of a classification into a class. The higher the score, the higher the confidence.

Different ensemble algorithms have different definitions for their scores. Furthermore, the range of scores depends on ensemble type. For example:

- AdaBoostM1 scores range from $-\infty$ to ∞ .
- Bag scores range from 0 to 1.

[resubEdge](#) | [resubLoss](#) | [resubMargin](#) | [resubPredict](#)

resubMargin

Margin of k -nearest neighbor classifier by resubstitution

Syntax

```
m = resubMargin mdl
```

Description

`m = resubMargin(mdl)` returns the classification margins on page 32-6106 (`m`) of the data used to train `mdl`.

`m` is returned as a numeric vector of length `size(mdl.X,1)`, where `mdl.X` is the training data for `mdl`. Each entry in `m` represents the margin for the corresponding row of `mdl.X` and the corresponding true class label in `mdl.Y`.

Examples

Resubstitution Margin Calculation

Create a k -nearest neighbor classifier for the Fisher iris data, where $k = 5$.

Load the Fisher iris data set.

```
load fisheriris  
X = meas;  
Y = species;
```

Create a classifier for five nearest neighbors.

```
mdl = fitcknn(X,Y,'NumNeighbors',5);
```

Examine some statistics of the resubstitution margin of the classifier.

```
m = resubMargin mdl;  
[max(m) min(m) mean(m)]  
  
ans = 1×3  
  
    1.0000    -0.6000    0.9253
```

The mean margin is over 0.9, indicating fairly high classification accuracy for resubstitution. For a more reliable assessment of model accuracy, consider cross-validation, such as `kfoldLoss`.

Input Arguments

mdl — *k*-nearest neighbor classifier model

ClassificationKNN object

k-nearest neighbor classifier model, specified as a `ClassificationKNN` object.

Definitions

Margin

The classification margin for each observation is the difference between the classification score for the true class and the maximal classification score for the false classes.

Score

The score of a classification is the posterior probability of the classification. The posterior probability is the number of neighbors with that classification divided by the number of neighbors. For a more detailed definition that includes weights and prior probabilities, see “Posterior Probability” on page 32-5188.

resubMargin

Class: ClassificationNaiveBayes

Classification margins for naive Bayes classifiers by resubstitution

Syntax

```
m = resubMargin(Mdl)
```

Description

`m = resubMargin(Mdl)` returns the resubstitution classification margins on page 32-6112 (`m`) for the naive Bayes classifier `Mdl` using the training data stored in `Mdl.X` and corresponding class labels stored in `Mdl.Y`.

Input Arguments

Mdl — Fully trained naive Bayes classifier

ClassificationNaiveBayes model

A fully trained naive Bayes classifier, specified as a ClassificationNaiveBayes model trained by `fitcnb`.

Output Arguments

m — Classification margins

numeric vector

Classification margins on page 32-6112, returned as a numeric vector.

`m` has the same length equal to `size(Mdl.X,1)`. Each entry of `m` is the classification margin of the corresponding observation (row) of `Mdl.X` and element of `Mdl.Y`.

Examples

Estimate In-Sample Classification Margins of Naive Bayes Classifiers

Load Fisher's iris data set.

```
load fisheriris
X = meas;    % Predictors
Y = species; % Response
```

Train a naive Bayes classifier. It is good practice to specify the class order. Assume that each predictor is conditionally, normally distributed given its label.

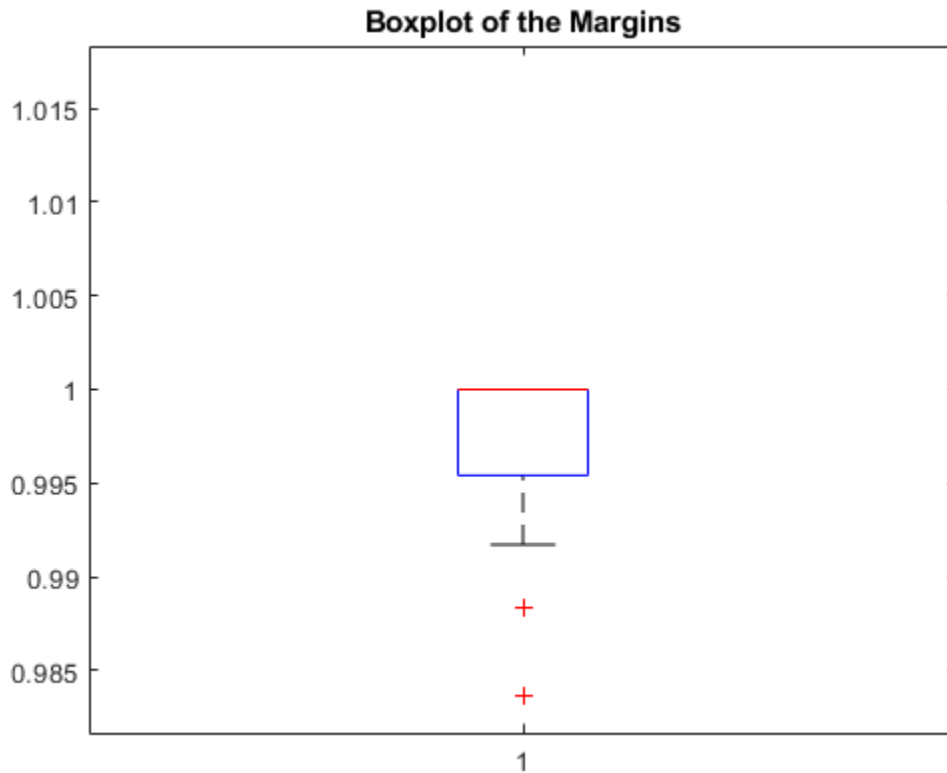

```
Mdl = fitcnb(X,Y,'ClassNames',{'setosa','versicolor','virginica'});
```

Mdl is a ClassificationNaiveBayes classifier.

Estimate the in-sample classification margins. Display the distribution of the margins using a boxplot.

```
m = resubMargin(Mdl);

figure;
boxplot(m);
h = gca;
iqr = quantile(m,0.75) - quantile(m,0.25);
h.YLim = median(m) + iqr*[-4 4];
title 'Boxplot of the Margins';
```

An observation margin is the observed (true) class score minus the maximum false class score among all scores in the respective class. Classifiers that yield relatively large margins are desirable.

Select Naive Bayes Classifier Features by Examining In-Sample Margins

The classifier margins measure, for each observation, the difference between the true class observed score and the maximal false class score for a particular class. One way to perform feature selection is to compare in-sample margins from multiple models. Based solely on this criterion, the model with the highest margins is the best model.

Load Fisher's iris data set. Define two data sets:

- `fullX` contains all predictors (except the removed column of 0s).
- `partX` contains the last 20 predictors.

```
load fisheriris
X = meas; % Predictors
Y = species; % Response
fullX = X;
partX = X(:,3:4);
```

Train naive Bayes classifiers for each predictor set.

```
FullMdl = fitcnb(fullX,Y);
PartMdl = fitcnb(partX,Y);
```

Estimate the in-sample margins for each classifier. Compute confidence intervals for each sample.

```
fullM = resubMargin(FullMdl);
partM = resubMargin(PartMdl);
n = size(X,1);
fullMCI = mean(fullM) + 2*[-std(fullM)/n std(fullM)/n]
```

```
fullMCI = 1×2
```

```
    0.8898    0.8991
```

```
partMCI = mean(partM) + 2*[-std(partM)/n std(partM)/n]
```

```
partMCI = 1×2
```

```
    0.9129    0.9209
```

The confidence intervals are tight, and mutually exclusive. The margin confidence interval of the classifier trained using just predictors 3 and 4 has higher values than that of the full model. Therefore, the model trained on two predictors has better in-sample performance.

Definitions

Classification Edge

The classification edge is the weighted mean of the classification margins.

If you supply weights, then the software normalizes them to sum to the prior probability of their respective class. The software uses the normalized weights to compute the weighted mean.

One way to choose among multiple classifiers, e.g., to perform feature selection, is to choose the classifier that yields the highest edge.

Classification Margin

The classification margins are, for each observation, the difference between the score for the true class and maximal score for the false classes. Provided that they are on the same scale, margins serve as a classification confidence measure, i.e., among multiple classifiers, those that yield larger margins are better.

Posterior Probability

The posterior probability is the probability that an observation belongs in a particular class, given the data.

For naive Bayes, the posterior probability that a classification is k for a given observation (x_1, \dots, x_p) is

$$\hat{P}(Y = k | x_1, \dots, x_p) = \frac{P(X_1, \dots, X_p | y = k)\pi(Y = k)}{P(X_1, \dots, X_p)},$$

where:

- $P(X_1, \dots, X_p | y = k)$ is the conditional joint density of the predictors given they are in class k . `Mdl.DistributionNames` stores the distribution names of the predictors.
- $\pi(Y = k)$ is the class prior probability distribution. `Mdl.Prior` stores the prior distribution.

- $P(X_1, \dots, X_P)$ is the joint density of the predictors. The classes are discrete, so

$$P(X_1, \dots, X_P) = \sum_{k=1}^K P(X_1, \dots, X_P \mid y = k) \Pi(Y = k).$$

Prior Probability

The prior probability of a class is the believed relative frequency with which observations from that class occur in a population.

Score

The naive Bayes score is the class posterior probability given the observation.

resubMargin

Find classification margins for support vector machine (SVM) classifier by resubstitution

Syntax

```
m = resubMargin(SVMModel)
```

Description

`m = resubMargin(SVMModel)` returns the resubstitution classification margins on page 32-4159 (`m`) for the support vector machine (SVM) classifier `SVMModel` using the training data stored in `SVMModel.X` and the corresponding class labels stored in `SVMModel.Y`.

`m` is returned as a numeric vector with the same length as `Y`. The software estimates each entry of `m` using the trained SVM classifier `SVMModel`, the corresponding row of `X`, and the true class label `Y`.

Examples

Estimate In-Sample Classification Margins of SVM Classifiers

Load the `ionosphere` data set.

```
load ionosphere
```

Train an SVM classifier. Standardize the data and specify that 'g' is the positive class.

```
SVMModel = fitcsvm(X,Y,'ClassNames',{'b','g'},'Standardize',true);
```

`SVMModel` is a `ClassificationSVM` classifier.

Estimate the in-sample classification margins.

```
m = resubMargin(SVMModel);  
m(10:20)
```

```
ans = 11x1
    5.5622
    4.2918
    1.9993
    4.5520
   -1.4897
    3.2816
    4.0260
    4.5419
   16.4449
    2.0006
    :
```

An observation margin is the observed (true) class score minus the maximum false class score among all scores in the respective class. Classifiers that yield relatively large margins are preferred.

Select SVM Classifier Features by Examining In-Sample Margins

Perform feature selection by comparing in-sample margins from multiple models. Based solely on this comparison, the model with the highest margins is the best model.

Load the `ionosphere` data set. Define two data sets:

- `fullX` contains all predictors (except the removed column of 0s).
- `partX` contains the last 20 predictors.

```
load ionosphere
fullX = X;
partX = X(:,end-20:end);
```

Train SVM classifiers for each predictor set.

```
FullSVMModel = fitcsvm(fullX,Y);
PartSVMModel = fitcsvm(partX,Y);
```

Estimate the in-sample margins for each classifier.

```
fullMargins = resubMargin(FullSVMModel);
partMargins = resubMargin(PartSVMModel);
```

```
n = size(X,1);  
p = sum(fullMargins < partMargins)/n  
  
p = 0.2222
```

Approximately 22% of the margins from the full model are less than those from the model with fewer predictors. This suggests that the model trained with all the predictors is better.

Input Arguments

SVMModel — Full, trained SVM classifier

ClassificationSVM classifier

Full, trained SVM classifier, specified as a ClassificationSVM model trained with `fitcsvm`.

Definitions

Classification Edge

The edge is the weighted mean of the classification margins.

The weights are the prior class probabilities. If you supply weights, then the software normalizes them to sum to the prior probabilities in the respective classes. The software uses the renormalized weights to compute the weighted mean.

One way to choose among multiple classifiers, for example, to perform feature selection, is to choose the classifier that yields the highest edge.

Classification Margin

The classification margin for binary classification is, for each observation, the difference between the classification score for the true class and the classification score for the false class.

The software defines the classification margin for binary classification as

$$m = 2yf(x).$$

x is an observation. If the true label of x is the positive class, then y is 1, and -1 otherwise. $f(x)$ is the positive-class classification score for the observation x . The classification margin is commonly defined as $m = yf(x)$.

If the margins are on the same scale, then they serve as a classification confidence measure. Among multiple classifiers, those that yield greater margins are better.

Classification Score

The SVM classification score for classifying observation x is the signed distance from x to the decision boundary ranging from $-\infty$ to $+\infty$. A positive score for a class indicates that x is predicted to be in that class. A negative score indicates otherwise.

The positive class classification score $f(x)$ is the trained SVM classification function. $f(x)$ is also the numerical, predicted response for x , or the score for predicting x into the positive class.

$$f(x) = \sum_{j=1}^n \alpha_j y_j G(x_j, x) + b,$$

where $(\alpha_1, \dots, \alpha_n, b)$ are the estimated SVM parameters, $G(x_j, x)$ is the dot product in the predictor space between x and the support vectors, and the sum includes the training set observations. The negative class classification score for x , or the score for predicting x into the negative class, is $-f(x)$.

If $G(x_j, x) = x_j'x$ (the linear kernel), then the score function reduces to

$$f(x) = (x/s)'\beta + b.$$

s is the kernel scale and β is the vector of fitted linear coefficients.

For more details, see “Understanding Support Vector Machines” on page 18-189.

Algorithms

For binary classification, the software defines the margin for observation j , m_j , as

$$m_j = 2y_j f(x_j),$$

where $y_j \in \{-1, 1\}$, and $f(x_j)$ is the predicted score of observation j for the positive class. However, $m_j = y_j f(x_j)$ is commonly used to define the margin.

Introduced in R2014a

resubMargin

Class: ClassificationTree

Classification margins by resubstitution

Syntax

```
M = resubMargin(tree)
```

Description

`M = resubMargin(tree)` returns resubstitution classification margins for `tree`.

Input Arguments

tree

A classification tree created by `fitctree`.

Output Arguments

M

A numeric column-vector of length `size(tree.X,1)` containing the classification margins.

Examples

Find the margins for a classification tree for the Fisher iris data by resubstitution. Examine several entries:

```
load fisheriris  
tree = fitctree(meas,species);
```

```
M = resubMargin(tree);  
M(1:25:end)
```

```
ans =  
    1.0000  
    1.0000  
    1.0000  
    1.0000  
    0.9565  
    0.9565
```

Definitions

Margin

Classification margin is the difference between classification score for the true class and maximal classification score for the false classes. A high value of margin indicates a more reliable prediction than a low value.

Score (tree)

For trees, the score of a classification of a leaf node is the posterior probability of the classification at that node. The posterior probability of the classification at a node is the number of training sequences that lead to that node with the classification, divided by the number of training sequences that lead to that node.

For example, consider classifying a predictor X as true when $X < 0.15$ or $X > 0.95$, and X is false otherwise.

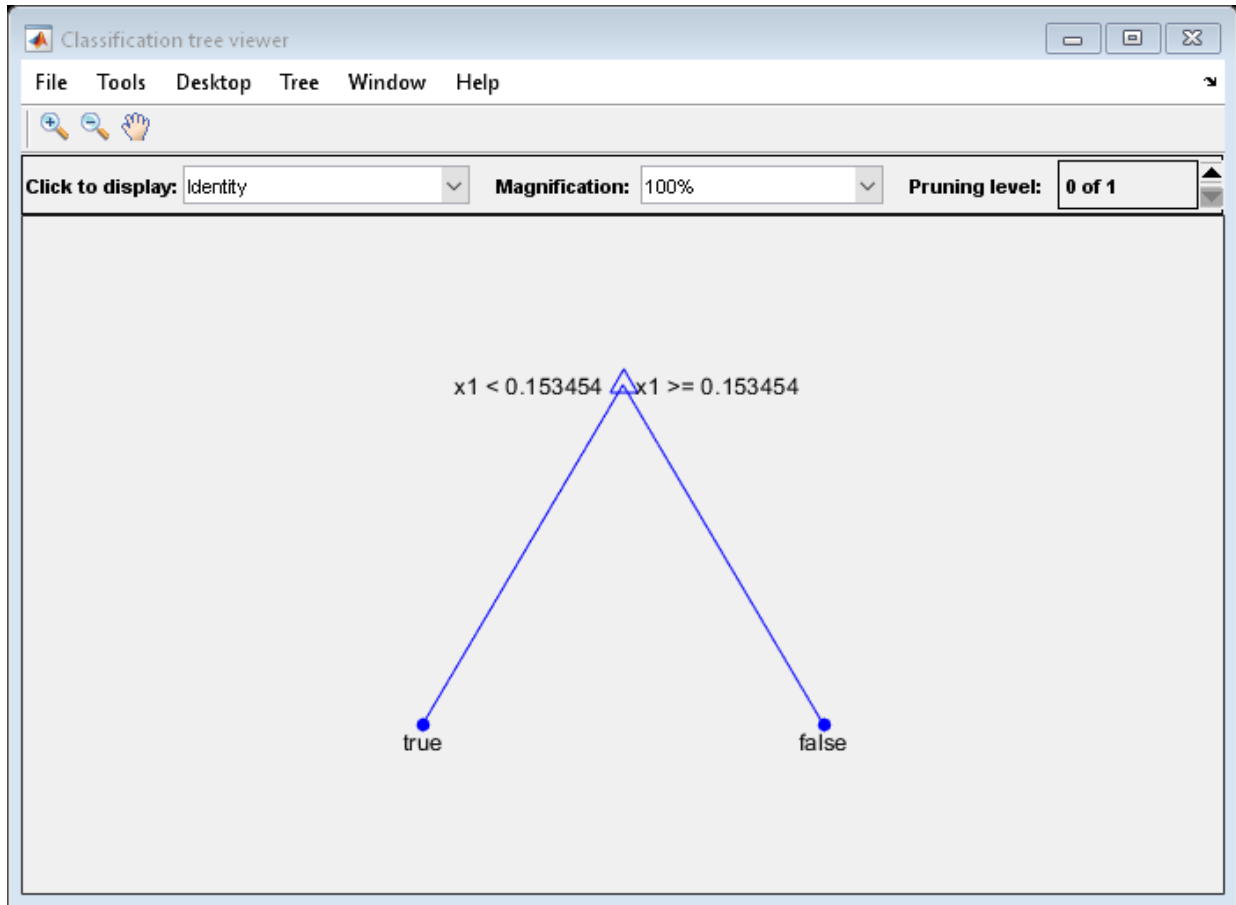

Generate 100 random points and classify them:

```
rng(0, 'twister') % for reproducibility  
X = rand(100,1);  
Y = (abs(X - .55) > .4);  
tree = fitctree(X,Y);  
view(tree, 'Mode', 'Graph')
```

Prune the tree:

```
tree1 = prune(tree, 'Level', 1);  
view(tree1, 'Mode', 'Graph')
```

The pruned tree correctly classifies observations that are less than 0.15 as `true`. It also correctly classifies observations from .15 to .94 as `false`. However, it incorrectly classifies observations that are greater than .94 as `false`. Therefore, the score for observations that are greater than .15 should be about $.05/.85=.06$ for `true`, and about $.8/.85=.94$ for `false`.

Compute the prediction scores for the first 10 rows of `X`:

```
[~,score] = predict(tree1,X(1:10));
[score X(1:10,:)]
```

```
ans = 10x3
    0.9059    0.0941    0.8147
    0.9059    0.0941    0.9058
         0     1.0000    0.1270
    0.9059    0.0941    0.9134
    0.9059    0.0941    0.6324
         0     1.0000    0.0975
    0.9059    0.0941    0.2785
    0.9059    0.0941    0.5469
    0.9059    0.0941    0.9575
    0.9059    0.0941    0.9649
```

Indeed, every value of X (the right-most column) that is less than 0.15 has associated scores (the left and center columns) of 0 and 1, while the other values of X have associated scores of 0.91 and 0.09. The difference (score 0.09 instead of the expected .06) is due to a statistical fluctuation: there are 8 observations in X in the range (.95, 1) instead of the expected 5 observations.

resubPredict

Class: ClassificationDiscriminant

Predict resubstitution labels of discriminant analysis classification model

Syntax

```
label = resubPredict(obj)
[label,posterior] = resubPredict(obj)
[label,posterior,cost] = resubPredict(obj)
```

Description

`label = resubPredict(obj)` returns the labels `obj` predicts for the data `obj.X`. `label` is the predictions of `obj` on the data that `fitcdiscr` used to create `obj`.

`[label,posterior] = resubPredict(obj)` returns the posterior class probabilities for the predictions.

`[label,posterior,cost] = resubPredict(obj)` returns the predicted misclassification costs per class for the resubstituted data.

Input Arguments

obj

Discriminant analysis classifier, produced using `fitcdiscr`.

Output Arguments

label

Response `obj` predicts for the training data. `label` is the same data type as the training response data `obj.Y`. The predicted class labels are those with minimal expected misclassification cost; see “Prediction Using Discriminant Analysis Models” on page 20-6.

posterior

N-by-K matrix of posterior probabilities for classes `obj` predicts, where N is the number of observations and K is the number of classes.

cost

N-by-K matrix of predicted misclassification costs. Each cost is the average misclassification cost with respect to the posterior probability.

Examples

Find the total number of misclassifications of the Fisher iris data for a discriminant analysis classifier:

```
load fisheriris
obj = fitcdiscr(meas,species);
Ypredict = resubPredict(obj); % the predictions
Ysame = strcmp(Ypredict,species); % true when ==
sum(~Ysame) % how many are different?

ans =
     3
```

Definitions

Posterior Probability

`posterior(i,k)` is the posterior probability of class `k` for observation `i`. For the mathematical definition, see “Posterior Probability” on page 20-6.

resubPredict

Classify observations in multiclass error-correcting output codes (ECOC) model

Syntax

```
label = resubPredict(Mdl)
label = resubPredict(Mdl,Name,Value)
[label,NegLoss,PBScore] = resubPredict( ___ )
[label,NegLoss,PBScore,Posterior] = resubPredict( ___ )
```

Description

`label = resubPredict(Mdl)` returns a vector of predicted class labels (`label`) for the trained multiclass error-correcting output codes (ECOC) model `Mdl` using the predictor data stored in `Mdl.X`.

The software predicts the classification of an observation by assigning the observation to the class yielding the largest negated average binary loss (or, equivalently, the smallest average binary loss).

`label = resubPredict(Mdl,Name,Value)` returns predicted class labels with additional options specified by one or more name-value pair arguments. For example, specify the posterior probability estimation method, decoding scheme, or verbosity level.

`[label,NegLoss,PBScore] = resubPredict(___)` uses any of the input argument combinations in the previous syntaxes and additionally returns the negated average binary loss on page 32-6141 per class (`NegLoss`) for observations, and the positive-class scores (`PBScore`) for the observations classified by each binary learner.

`[label,NegLoss,PBScore,Posterior] = resubPredict(___)` additionally returns posterior class probability estimates for observations (`Posterior`).

To obtain posterior class probabilities, you must set `'FitPosterior',true` when training the ECOC model using `fitcecoc`. Otherwise, `resubPredict` throws an error.

Examples

Predict Labels of Training Data Using ECOC Model

Load Fisher's iris data set. Specify the predictor data X, the response data Y, and the order of the classes in Y.

```
load fisheriris
X = meas;
Y = categorical(species);
classOrder = unique(Y);
```

Train an ECOC model using SVM binary classifiers. Standardize the predictors using an SVM template, and specify the class order.

```
t = templateSVM('Standardize',true);
Mdl = fitcecoc(X,Y,'Learners',t,'ClassNames',classOrder);
```

t is an SVM template object. During training, the software uses default values for empty properties in t. Mdl is a ClassificationECOC model.

Predict the labels of the training data. Print a random subset of true and predicted labels.

```
labels = resubPredict(Mdl);

rng(1); % For reproducibility
n = numel(Y); % Sample size
idx = randsample(n,10);
table(Y(idx),labels(idx),'VariableNames',{'TrueLabels','PredictedLabels'})
```

```
ans=10x2 table
  TrueLabels    PredictedLabels
  _____  _____
  setosa        setosa
  versicolor    versicolor
  virginica     virginica
  setosa        setosa
  versicolor    versicolor
  setosa        setosa
  versicolor    versicolor
  versicolor    versicolor
  setosa        setosa
```

```
setosa      setosa
```

Mdl correctly labels the observations with indices idx.

Predict Resubstitution Labels of ECOC Model Using Custom Binary Loss Function

Load Fisher's iris data set. Specify the predictor data X, the response data Y, and the order of the classes in Y.

```
load fisheriris
X = meas;
Y = categorical(species);
classOrder = unique(Y); % Class order
```

Train an ECOC model using SVM binary classifiers. Standardize the predictors using an SVM template, and specify the class order.

```
t = templateSVM('Standardize',true);
Mdl = fitcecoc(X,Y,'Learners',t,'ClassNames',classOrder);
```

t is an SVM template object. During training, the software uses default values for empty properties in t. Mdl is a ClassificationECOC model.

SVM scores are signed distances from the observation to the decision boundary. Therefore, the domain is $(-\infty, \infty)$. Create a custom binary loss function that does the following:

- Map the coding design matrix (M) and positive-class classification scores (s) for each learner to the binary loss for each observation.
- Use linear loss.
- Aggregate the binary learner loss using the median.

You can create a separate function for the binary loss function, and then save it on the MATLAB® path. Or, you can specify an anonymous binary loss function. In this case, create a function handle (customBL) to an anonymous binary loss function.

```
customBL = @(M,s)nanmedian(1 - bsxfun(@times,M,s),2)/2;
```

Predict labels for the training data and estimate the median binary loss per class. Print the median negative binary losses per class for a random set of 10 observations.

```
[label,NegLoss] = resubPredict(Mdl,'BinaryLoss',customBL);

rng(1); % For reproducibility
n = numel(Y); % Sample size
idx = randsample(n,10);
classOrder

classOrder = 3x1 categorical array
    setosa
    versicolor
    virginica

table(Y(idx),label(idx),NegLoss(idx,:), 'VariableNames',...
      {'TrueLabel', 'PredictedLabel', 'NegLoss'})

ans=10x3 table
    TrueLabel    PredictedLabel    NegLoss
    _____    _____    _____
    setosa        versicolor        0.12376    1.9575    -3.5812
    versicolor    versicolor        -1.0171    0.62948    -1.1123
    virginica     virginica         -1.9088    -0.21759    0.62641
    setosa        versicolor        0.43846    2.2448    -4.1833
    versicolor    versicolor        -1.0735    0.3965    -0.82299
    setosa        versicolor        0.26658    2.201    -3.9675
    versicolor    versicolor        -1.1237    0.69927    -1.0756
    versicolor    versicolor        -1.2716    0.51847    -0.74687
    setosa        versicolor        0.35211    2.0683    -3.9204
    setosa        versicolor        0.23342    2.1892    -3.9226
```

The order of the columns corresponds to the elements of `classOrder`. The software predicts the label based on the maximum negated loss. The results indicate that the median of the linear losses might not perform as well as other losses.

Estimate Posterior Probabilities Using ECOC Classifier

Train an ECOC classifier using SVM binary learners. First predict the training-sample labels and class posterior probabilities. Then predict the maximum class posterior probability at each point in a grid. Visualize the results.

Load Fisher's iris data set. Specify the petal dimensions as the predictors and the species names as the response.

```
load fisheriris
X = meas(:,3:4);
Y = species;
rng(1); % For reproducibility
```

Create an SVM template. Standardize the predictors, and specify the Gaussian kernel.

```
t = templateSVM('Standardize',true,'KernelFunction','gaussian');
```

`t` is an SVM template. Most of its properties are empty. When the software trains the ECOC classifier, it sets the applicable properties to their default values.

Train the ECOC classifier using the SVM template. Transform classification scores to class posterior probabilities (which are returned by `predict` or `resubPredict`) using the `'FitPosterior'` name-value pair argument. Specify the class order using the `'ClassNames'` name-value pair argument. Display diagnostic messages during training by using the `'Verbose'` name-value pair argument.

```
Mdl = fitcecoc(X,Y,'Learners',t,'FitPosterior',true,...
    'ClassNames',{'setosa','versicolor','virginica'},...
    'Verbose',2);
```

```
Training binary learner 1 (SVM) out of 3 with 50 negative and 50 positive observations
Negative class indices: 2
Positive class indices: 1
```

```
Fitting posterior probabilities for learner 1 (SVM).
Training binary learner 2 (SVM) out of 3 with 50 negative and 50 positive observations
Negative class indices: 3
Positive class indices: 1
```

```
Fitting posterior probabilities for learner 2 (SVM).
Training binary learner 3 (SVM) out of 3 with 50 negative and 50 positive observations
Negative class indices: 3
Positive class indices: 2
```

```
Fitting posterior probabilities for learner 3 (SVM).
```

`Mdl` is a `ClassificationECOC` model. The same SVM template applies to each binary learner, but you can adjust options for each binary learner by passing in a cell vector of templates.

Predict the training-sample labels and class posterior probabilities. Display diagnostic messages during the computation of labels and class posterior probabilities by using the 'Verbose' name-value pair argument.

```
[label,~,~,Posterior] = resubPredict(Mdl,'Verbose',1);
```

```
Predictions from all learners have been computed.
Loss for all observations has been computed.
Computing posterior probabilities...
```

Mdl.BinaryLoss

```
ans =
'quadratic'
```

The software assigns an observation to the class that yields the smallest average binary loss. Because all binary learners are computing posterior probabilities, the binary loss function is `quadratic`.

Display a random set of results.

```
idx = randsample(size(X,1),10,1);
Mdl.ClassNames
```

```
ans = 3x1 cell array
    {'setosa'   }
    {'versicolor'}
    {'virginica' }
```

```
table(Y(idx),label(idx),Posterior(idx,:),...
    'VariableNames',{'TrueLabel','PredLabel','Posterior'})
```

```
ans=10x3 table
    TrueLabel      PredLabel      Posterior
    _____  _____  _____
    'virginica'    'virginica'    0.0039321    0.0039869    0.99208
    'virginica'    'virginica'    0.017067    0.018263    0.96467
    'virginica'    'virginica'    0.014948    0.015856    0.9692
    'versicolor'   'versicolor'   2.2197e-14    0.87317    0.12683
    'setosa'        'setosa'        0.999    0.00025091    0.00074639
    'versicolor'   'virginica'    2.2195e-14    0.059429    0.94057
    'versicolor'   'versicolor'   2.2194e-14    0.97001    0.029986
    'setosa'        'setosa'        0.999    0.0002499    0.00074741
```

'versicolor'	'versicolor'	0.0085646	0.98259	0.008849
'setosa'	'setosa'	0.999	0.00025013	0.00074718

The columns of `Posterior` correspond to the class order of `Mdl.ClassNames`.

Define a grid of values in the observed predictor space. Predict the posterior probabilities for each instance in the grid.

```
xMax = max(X);
xMin = min(X);

x1Pts = linspace(xMin(1),xMax(1));
x2Pts = linspace(xMin(2),xMax(2));
[x1Grid,x2Grid] = meshgrid(x1Pts,x2Pts);

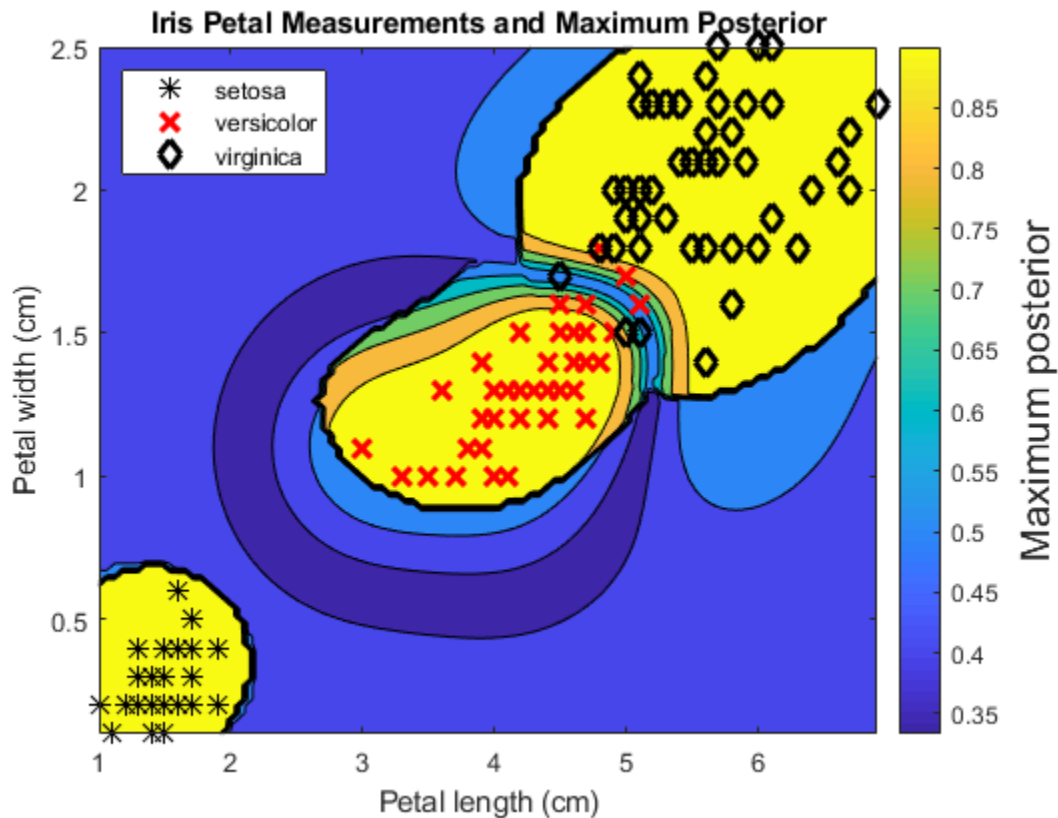

[~,~,~,PosteriorRegion] = predict(Mdl,[x1Grid(:),x2Grid(:)]);
```

For each coordinate on the grid, plot the maximum class posterior probability among all classes.

```
contourf(x1Grid,x2Grid,...
         reshape(max(PosteriorRegion,[],2),size(x1Grid,1),size(x1Grid,2)));
h = colorbar;
h.YLabel.String = 'Maximum posterior';
h.YLabel.FontSize = 15;

hold on
gh = gscatter(X(:,1),X(:,2),Y,'krk','*xd',8);
gh(2).LineWidth = 2;
gh(3).LineWidth = 2;

title('Iris Petal Measurements and Maximum Posterior')
xlabel('Petal length (cm)')
ylabel('Petal width (cm)')
axis tight
legend(gh,'Location','NorthWest')
hold off
```

Estimate Posterior Probabilities Using Parallel Computing

Train a multiclass ECOC model and estimate the posterior probabilities using parallel computing.

Load the `arrhythmia` data set. Examine the response data `Y`, and determine the number of classes.

```
load arrhythmia
Y = categorical(Y);
tabulate(Y)
```

Value	Count	Percent
1	245	54.20%
2	44	9.73%
3	15	3.32%
4	15	3.32%
5	13	2.88%
6	25	5.53%
7	3	0.66%
8	2	0.44%
9	9	1.99%
10	50	11.06%
14	4	0.88%
15	5	1.11%
16	22	4.87%

```
K = numel(unique(Y));
```

Several classes are not represented in the data, and many other classes have low relative frequencies.

Specify an ensemble learning template that uses the GentleBoost method and 50 weak classification tree learners.

```
t = templateEnsemble('GentleBoost',50,'Tree');
```

t is a template object. Most of its properties are empty ([]). The software uses default values for all empty properties during training.

Because the response variable contains many classes, specify a sparse random coding design.

```
rng(1); % For reproducibility
Coding = designecoc(K,'sparseandom');
```

Train an ECOC model using parallel computing. Specify to fit posterior probabilities.

```
pool = parpool; % Invokes workers
```

```
Starting parallel pool (parpool) using the 'local' profile ...
Connected to the parallel pool (number of workers: 6).
```

```
options = statset('UseParallel',true);
Mdl = fitcecoc(X,Y,'Learner',t,'Options',options,'Coding',Coding,...
    'FitPosterior',true);
```

Mdl is a ClassificationECOC model. You can access its properties using dot notation.

The pool invokes six workers, although the number of workers might vary among systems.

Estimate posterior probabilities, and display the posterior probability of being classified as not having arrhythmia (class 1) given a random subset of the training data.

```
[~,~,~,posterior] = resubPredict(Mdl);  
  
n = numel(Y);  
idx = randsample(n,10,1);  
table(idx,Y(idx),posterior(idx,1),...  
      'VariableNames',{'ObservationIndex','TrueLabel','PosteriorNoArrhythmia'})
```

```
ans=10x3 table  
  ObservationIndex   TrueLabel   PosteriorNoArrhythmia  
-----  
           79           1           0.93436  
          248           1           0.95574  
          398          10           0.032378  
          207           1           0.97965  
          340           1           0.93656  
          206           1           0.97795  
          345          10           0.015642  
          296           2           0.13433  
          391           1           0.9648  
          406           1           0.94861
```

Input Arguments

Mdl — Full, trained multiclass ECOC model

ClassificationECOC model

Full, trained multiclass ECOC model, specified as a `ClassificationECOC` model trained with `fitcecoc`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes.

You can specify several name and value pair arguments in any order as `Name1,Value1, . . . ,NameN,ValueN`.

Example:

`resubPredict(Mdl, 'BinaryLoss', 'linear', 'Decoding', 'lossbased')` specifies a linear binary learner loss function and a loss-based decoding scheme for aggregating the binary losses.

BinaryLoss — Binary learner loss function

'hamming' | 'linear' | 'logit' | 'exponential' | 'binodeviance' | 'hinge' | 'quadratic' | function handle

Binary learner loss function, specified as the comma-separated pair consisting of 'BinaryLoss' and a built-in loss function name or function handle.

- This table describes the built-in functions, where y_j is a class label for a particular binary learner (in the set $\{-1, 1, 0\}$), s_j is the score for observation j , and $g(y_j, s_j)$ is the binary loss formula.

Value	Description	Score Domain	$g(y_j, s_j)$
'binodeviance'	Binomial deviance	$(-\infty, \infty)$	$\log[1 + \exp(-2y_j s_j)] / [2\log(2)]$
'exponential'	Exponential	$(-\infty, \infty)$	$\exp(-y_j s_j) / 2$
'hamming'	Hamming	$[0, 1]$ or $(-\infty, \infty)$	$[1 - \text{sign}(y_j s_j)] / 2$
'hinge'	Hinge	$(-\infty, \infty)$	$\max(0, 1 - y_j s_j) / 2$
'linear'	Linear	$(-\infty, \infty)$	$(1 - y_j s_j) / 2$
'logit'	Logistic	$(-\infty, \infty)$	$\log[1 + \exp(-y_j s_j)] / [2\log(2)]$
'quadratic'	Quadratic	$[0, 1]$	$[1 - y_j(2s_j - 1)]^2 / 2$

The software normalizes binary losses so that the loss is 0.5 when $y_j = 0$. Also, the software calculates the mean binary loss for each class.

- For a custom binary loss function, for example `customFunction`, specify its function handle 'BinaryLoss', @customFunction.

`customFunction` has this form:

`bLoss = customFunction(M, s)`

where:

- `M` is the K -by- L coding matrix stored in `Mdl.CodingMatrix`.
- `s` is the 1-by- L row vector of classification scores.
- `bLoss` is the classification loss. This scalar aggregates the binary losses for every learner in a particular class. For example, you can use the mean binary loss to aggregate the loss over the learners for each class.
- K is the number of classes.
- L is the number of binary learners.

For an example of passing a custom binary loss function, see “Predict Test-Sample Labels of ECOC Model Using Custom Binary Loss Function” on page 32-5219.

The default `BinaryLoss` value depends on the score ranges returned by the binary learners. This table describes some default `BinaryLoss` values based on the given assumptions.

Assumption	Default Value
All binary learners are SVMs or either linear or kernel classification models of SVM learners.	'hinge'
All binary learners are ensembles trained by <code>AdaboostM1</code> or <code>GentleBoost</code> .	'exponential'
All binary learners are ensembles trained by <code>LogitBoost</code> .	'binodeviance'
All binary learners are linear or kernel classification models of logistic regression learners. Or, you specify to predict class posterior probabilities by setting ' <code>FitPosterior</code> ', <code>true</code> in <code>fitcecoc</code> .	'quadratic'

To check the default value, use dot notation to display the `BinaryLoss` property of the trained model at the command line.

Example: `'BinaryLoss', 'binodeviance'`

Data Types: `char` | `string` | `function_handle`

Decoding — Decoding scheme

`'lossweighted'` (default) | `'lossbased'`

Decoding scheme that aggregates the binary losses, specified as the comma-separated pair consisting of `'Decoding'` and `'lossweighted'` or `'lossbased'`. For more information, see “Binary Loss” on page 32-6141.

Example: 'Decoding', 'lossbased'

NumKLInitializations — Number of random initial values

0 (default) | nonnegative integer scalar

Number of random initial values for fitting posterior probabilities by Kullback-Leibler divergence minimization, specified as the comma-separated pair consisting of 'NumKLInitializations' and a nonnegative integer scalar.

If you do not request the fourth output argument (Posterior) and set 'PosteriorMethod', 'kl' (the default), then the software ignores the value of NumKLInitializations.

For more details, see “Posterior Estimation Using Kullback-Leibler Divergence” on page 32-6143.

Example: 'NumKLInitializations',5

Data Types: single | double

Options — Estimation options

[] (default) | structure array returned by `statset`

Estimation options, specified as the comma-separated pair consisting of 'Options' and a structure array returned by `statset`.

To invoke parallel computing:

- You need a Parallel Computing Toolbox license.
- Specify 'Options', `statset('UseParallel',true)`.

PosteriorMethod — Posterior probability estimation method

'kl' (default) | 'qp'

Posterior probability estimation method, specified as the comma-separated pair consisting of 'PosteriorMethod' and 'kl' or 'qp'.

- If `PosteriorMethod` is 'kl', then the software estimates multiclass posterior probabilities by minimizing the Kullback-Leibler divergence between the predicted and expected posterior probabilities returned by binary learners. For details, see “Posterior Estimation Using Kullback-Leibler Divergence” on page 32-6143.
- If `PosteriorMethod` is 'qp', then the software estimates multiclass posterior probabilities by solving a least-squares problem using quadratic programming. You

need an Optimization Toolbox license to use this option. For details, see “Posterior Estimation Using Quadratic Programming” on page 32-6145.

- If you do not request the fourth output argument (`Posterior`), then the software ignores the value of `PosteriorMethod`.

Example: `'PosteriorMethod','qp'`

Verbose — Verbosity level

0 (default) | 1

Verbosity level, specified as the comma-separated pair consisting of `'Verbose'` and 0 or 1. `Verbose` controls the number of diagnostic messages that the software displays in the Command Window.

If `Verbose` is 0, then the software does not display diagnostic messages. Otherwise, the software displays diagnostic messages.

Example: `'Verbose',1`

Data Types: `single` | `double`

Output Arguments

label — Predicted class labels

categorical array | character array | logical vector | numeric vector | cell array of character vectors

Predicted class labels, returned as a categorical or character array, logical or numeric vector, or cell array of character vectors.

`label` has the same data type as `Mdl.ClassNames` and has the same number of rows as `Mdl.X`.

The software predicts the classification of an observation by assigning the observation to the class yielding the largest negated average binary loss (or, equivalently, the smallest average binary loss).

NegLoss — Negated average binary losses

numeric matrix

Negated average binary losses on page 32-6141, returned as a numeric matrix. `NegLoss` is an n -by- K matrix, where n is the number of observations (`size(Mdl.X,1)`) and K is the number of unique classes (`size(Mdl.ClassNames,1)`).

PBScore — Positive-class scores

numeric matrix

Positive-class scores for each binary learner, returned as a numeric matrix. `PBScore` is an n -by- L matrix, where n is the number of observations (`size(Mdl.X,1)`) and L is the number of binary learners (`size(Mdl.CodingMatrix,2)`).

Posterior — Posterior class probabilities

numeric matrix

Posterior class probabilities, returned as a numeric matrix. `Posterior` is an n -by- K matrix, where n is the number of observations (`size(Mdl.X,1)`) and K is the number of unique classes (`size(Mdl.ClassNames,1)`).

To request `Posterior`, you must set `'FitPosterior', true` when training the ECOC model using `fitcecoc`. Otherwise, the software throws an error.

Definitions

Binary Loss

A binary loss is a function of the class and classification score that determines how well a binary learner classifies an observation into the class.

Suppose the following:

- m_{kj} is element (k,j) of the coding design matrix M (that is, the code corresponding to class k of binary learner j).
- s_j is the score of binary learner j for an observation.
- g is the binary loss function.
- \hat{k} is the predicted class for the observation.

In loss-based decoding [Escalera et al.] on page 18-228, the class producing the minimum sum of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \operatorname{argmin}_k \sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j).$$

In loss-weighted decoding [Escalera et al.] on page 18-228, the class producing the minimum average of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \operatorname{argmin}_k \frac{\sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j)}{\sum_{j=1}^L |m_{kj}|}.$$

Allwein et al. on page 18-227 suggest that loss-weighted decoding improves classification accuracy by keeping loss values for all classes in the same dynamic range.

This table summarizes the supported loss functions, where y_j is a class label for a particular binary learner (in the set $\{-1,1,0\}$), s_j is the score for observation j , and $g(y_j, s_j)$.

Value	Description	Score Domain	$g(y_j, s_j)$
'binodeviance'	Binomial deviance	$(-\infty, \infty)$	$\log[1 + \exp(-2y_j s_j)] / [2\log(2)]$
'exponential'	Exponential	$(-\infty, \infty)$	$\exp(-y_j s_j) / 2$
'hamming'	Hamming	$[0, 1]$ or $(-\infty, \infty)$	$[1 - \operatorname{sign}(y_j s_j)] / 2$
'hinge'	Hinge	$(-\infty, \infty)$	$\max(0, 1 - y_j s_j) / 2$
'linear'	Linear	$(-\infty, \infty)$	$(1 - y_j s_j) / 2$
'logit'	Logistic	$(-\infty, \infty)$	$\log[1 + \exp(-y_j s_j)] / [2\log(2)]$
'quadratic'	Quadratic	$[0, 1]$	$[1 - y_j(2s_j - 1)]^2 / 2$

The software normalizes binary losses such that the loss is 0.5 when $y_j = 0$, and aggregates using the average of the binary learners [Allwein et al.] on page 18-227.

Do not confuse the binary loss with the overall classification loss (specified by the 'LossFun' name-value pair argument of the `loss` and `predict` object functions), which measures how well an ECOC classifier performs as a whole.

Algorithms

The software can estimate class posterior probabilities by minimizing the Kullback-Leibler divergence or by using quadratic programming. For the following descriptions of the posterior estimation algorithms, assume that:

- m_{kj} is the element (k,j) of the coding design matrix M .
- I is the indicator function.
- \widehat{p}_k is the class posterior probability estimate for class k of an observation, $k = 1, \dots, K$.
- r_j is the positive-class posterior probability for binary learner j . That is, r_j is the probability that binary learner j classifies an observation into the positive class, given the training data.

Posterior Estimation Using Kullback-Leibler Divergence

By default, the software minimizes the Kullback-Leibler divergence to estimate class posterior probabilities. The Kullback-Leibler divergence between the expected and observed positive-class posterior probabilities is

$$\Delta(r, \widehat{r}) = \sum_{j=1}^L w_j \left[r_j \log \frac{r_j}{\widehat{r}_j} + (1 - r_j) \log \frac{1 - r_j}{1 - \widehat{r}_j} \right],$$

where $w_j = \sum_{S_j} w_i^*$ is the weight for binary learner j .

- S_j is the set of observation indices on which binary learner j is trained.
- w_i^* is the weight of observation i .

The software minimizes the divergence iteratively. The first step is to choose initial values $\widehat{p}_k^{(0)}$; $k = 1, \dots, K$ for the class posterior probabilities.

- If you do not specify 'NumKLIterations', then the software tries both sets of deterministic initial values described next, and selects the set that minimizes Δ .
 - $\widehat{p}_k^{(0)} = 1/K$; $k = 1, \dots, K$.
 - $\widehat{p}_k^{(0)}$; $k = 1, \dots, K$ is the solution of the system

$$M_{01}\widehat{p}^{(0)} = r,$$

where M_{01} is M with all $m_{kj} = -1$ replaced with 0, and r is a vector of positive-class posterior probabilities returned by the L binary learners [Dietterich et al.] on page 18-228. The software uses `lsqnonneg` to solve the system.

- If you specify 'NumKLIterations', c , where c is a natural number, then the software does the following to choose the set $\widehat{p}_k^{(0)}$; $k = 1, \dots, K$, and selects the set that minimizes Δ .
 - The software tries both sets of deterministic initial values as described previously.
 - The software randomly generates c vectors of length K using `rand`, and then normalizes each vector to sum to 1.

At iteration t , the software completes these steps:

- 1 Compute

$$\widehat{r}_j^{(t)} = \frac{\sum_{k=1}^K \widehat{p}_k^{(t)} I(m_{kj} = +1)}{\sum_{k=1}^K \widehat{p}_k^{(t)} I(m_{kj} = +1 \cup m_{kj} = -1)}.$$

- 2 Estimate the next class posterior probability using

$$\widehat{p}_k^{(t+1)} = \widehat{p}_k^{(t)} \frac{\sum_{j=1}^L w_j [r_j I(m_{kj} = +1) + (1 - r_j) I(m_{kj} = -1)]}{\sum_{j=1}^L w_j [\widehat{r}_j^{(t)} I(m_{kj} = +1) + (1 - \widehat{r}_j^{(t)}) I(m_{kj} = -1)]}.$$

- 3 Normalize $\widehat{p}_k^{(t+1)}$; $k = 1, \dots, K$ so that they sum to 1.
- 4 Check for convergence.

For more details, see [Hastie et al.] on page 18-228 and [Zadrozny] on page 18-230.

Posterior Estimation Using Quadratic Programming

Posterior probability estimation using quadratic programming requires an Optimization Toolbox license. To estimate posterior probabilities for an observation using this method, the software completes these steps:

- 1 Estimate the positive-class posterior probabilities, r_j , for binary learners $j = 1, \dots, L$.
- 2 Using the relationship between r_j and \hat{p}_k [Wu et al.] on page 18-230, minimize

$$\sum_{j=1}^L \left[-r_j \sum_{k=1}^K \hat{p}_k I(m_{kj} = -1) + (1 - r_j) \sum_{k=1}^K \hat{p}_k I(m_{kj} = +1) \right]^2$$

with respect to \hat{p}_k and the restrictions

$$0 \leq \hat{p}_k \leq 1$$

$$\sum_k \hat{p}_k = 1.$$

The software performs minimization using `quadprog`.

Extended Capabilities

Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the 'UseParallel' option to true.

Set the 'UseParallel' field of the options structure to true using `statset` and specify the 'Options' name-value pair argument in the call to this function.

For example: `'Options',statset('UseParallel',true)`

For more information, see the 'Options' name-value pair argument.

For more general information about parallel computing, see "Run MATLAB Functions with Automatic Parallel Support" (Parallel Computing Toolbox).

resubPredict

Classify observations in ensemble of classification models

Syntax

```
label = resubPredict(ens)
[label,score] = resubPredict(ens)
[label,score] = resubPredict(ens,Name,Value)
```

Description

`label = resubPredict(ens)` returns the labels `ens` predicts for the data `ens.X`. `label` is the predictions of `ens` on the data that `fitcensemble` used to create `ens`.

`[label,score] = resubPredict(ens)` also returns scores for all classes.

`[label,score] = resubPredict(ens,Name,Value)` finds resubstitution predictions with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

`ens`

A classification ensemble created with `fitcensemble`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Learners

Indices of weak learners in the ensemble ranging from 1 to NumTrained. oobLoss uses only these learners for calculating loss.

Default: 1:NumTrained

Output Arguments

label

The response ens predicts for the training data. label is the same data type as the training response data ens.Y, and has the same number of entries as the number of rows in ens.X.

score

An N-by-K matrix, where N is the number of rows in ens.X, and K is the number of classes in ens. High score value indicates that an observation likely comes from this class.

Examples

Find Number of Ensemble Misclassifications

Find the total number of misclassifications of the fisheriris data for a classification ensemble.

Load the Fisher iris data set.

```
load fisheriris
```

Train an ensemble of 100 boosted classification trees using AdaBoostM2.

```
t = templateTree('MaxNumSplits',1); % Weak learner template tree object
ens = fitcensemble(meas,species,'Method','AdaBoostM2','Learners',t);
```

Find the total number of misclassifications.

```
Ypredict = resubPredict(ens); % The predictions
Ysame = strcmp(Ypredict,species); % True when Ypredict and species are equal
sum(~Ysame) % Number of different predictions
```

ans = 5

Definitions

Score (ensemble)

For ensembles, a classification score represents the confidence of a classification into a class. The higher the score, the higher the confidence.

Different ensemble algorithms have different definitions for their scores. Furthermore, the range of scores depends on ensemble type. For example:

- AdaBoostM1 scores range from $-\infty$ to ∞ .
- Bag scores range from 0 to 1.

resubPredict

Predict resubstitution labels of k -nearest neighbor classifier

Syntax

```
label = resubPredict mdl
[label, score] = resubPredict mdl
[label, score, cost] = resubPredict mdl
```

Description

`label = resubPredict(mdl)` returns the labels that `mdl` predicts for the training data `mdl.X`. The output `label` contains the predictions of `mdl` on the data used by `fitcknn` to create `mdl`.

`[label, score] = resubPredict(mdl)` also returns the posterior class probabilities for the predictions.

`[label, score, cost] = resubPredict(mdl)` also returns the misclassification costs.

Examples

Predict Labels for Training Data

Examine the quality of a classifier by its resubstitution predictions.

Load the Fisher iris data set.

```
load fisheriris
X = meas;
Y = species;
```

Create a classifier for five nearest neighbors.

```
mdl = fitcknn(X,Y,'NumNeighbors',5);
```

Generate the resubstitution predictions.

```
label = resubPredict mdl;
```

Calculate the number of differences between the predictions `label` and the original data `Y`.

```
mydiff = not(strcmp(Y,label)); % mydiff(i) = 1 means they differ  
sum(mydiff) % Number of differences
```

```
ans = 5
```

A value of 1 in `mydiff` indicates that the observed label differs from the corresponding predicted label. This example has five misclassifications.

Input Arguments

mdl — *k*-nearest neighbor classifier model

`ClassificationKNN` object

k-nearest neighbor classifier model, specified as a `ClassificationKNN` object.

Output Arguments

label — Predicted class labels

categorical array | character array | logical vector | numeric vector | cell array of character vectors

Predicted class labels for the observations (rows) in the training data `X`, returned as a categorical array, character array, logical vector, numeric vector, or cell array of character vectors. `label` has length equal to the number of rows in `X`. The label is the class with minimal expected cost. See “Predicted Class Label” on page 32-6153.

score — Predicted class scores or posterior probabilities

numeric matrix

Predicted class scores or posterior probabilities, returned as a numeric matrix of size n -by- K . n is the number of observations (rows) in the training data `X`, and K is the number of classes (in `mdl.ClassNames`). `score(i,j)` is the posterior probability that observation i in `X` is of class j in `mdl.ClassNames`. See “Posterior Probability” on page 32-6153.

cost — Expected classification costs

numeric matrix

Expected classification costs, returned as a numeric matrix of size n -by- K . n is the number of observations (rows) in the training data X , and K is the number of classes (in `mdl.ClassNames`). `cost(i, j)` is the cost of classifying row i of X as class j in `mdl.ClassNames`. See “Expected Cost” on page 32-6154.

Tips

- If you standardize the predictor data, that is, `mdl.Mu` and `mdl.Sigma` are not empty (`[]`), then `resubPredict` standardizes the predictor data before predicting labels.

Algorithms**Predicted Class Label**

`resubPredict` classifies by minimizing the expected classification cost:

$$\hat{y} = \operatorname{argmin}_{y=1, \dots, K} \sum_{j=1}^K \hat{P}(j|x) C(y|j),$$

where

- \hat{y} is the predicted classification.
- K is the number of classes.
- $\hat{P}(j|x)$ is the posterior probability of class j for observation x .
- $C(y|j)$ is the cost of classifying an observation as y when its true class is j .

Posterior Probability

Consider a vector (single query point) `xnew` and a model `mdl`.

- k is the number of nearest neighbors used in prediction, `mdl.NumNeighbors`.
- `nbd(mdl, xnew)` specifies the k nearest neighbors to `xnew` in `mdl.X`.

- $Y(\text{nbid})$ specifies the classifications of the points in $\text{nbid}(\text{mdl}, \text{xnew})$, namely $\text{mdl}.Y(\text{nbid})$.
- $W(\text{nbid})$ specifies the weights of the points in $\text{nbid}(\text{mdl}, \text{xnew})$.
- `prior` specifies the priors of the classes in $\text{mdl}.Y$.

If the model contains a vector of prior probabilities, then the observation weights W are normalized by class to sum to the priors. This process might involve a calculation for the point xnew , because weights can depend on the distance from xnew to the points in $\text{mdl}.X$.

The posterior probability $p(j|\text{xnew})$ is

$$p(j|\text{xnew}) = \frac{\sum_{i \in \text{nbid}} W(i) 1_{Y(X(i)) = j}}{\sum_{i \in \text{nbid}} W(i)}.$$

Here, $1_{Y(X(i)) = j}$ is 1 when $\text{mdl}.Y(i) = j$, and 0 otherwise.

True Misclassification Cost

Two costs are associated with KNN classification: the true misclassification cost per class and the expected misclassification cost per observation.

You can set the true misclassification cost per class by using the 'Cost' name-value pair argument when you run `fitcknn`. The value `Cost(i, j)` is the cost of classifying an observation into class j if its true class is i . By default, `Cost(i, j) = 1` if $i \neq j$, and `Cost(i, j) = 0` if $i = j$. In other words, the cost is 0 for correct classification and 1 for incorrect classification.

Expected Cost

Two costs are associated with KNN classification: the true misclassification cost per class and the expected misclassification cost per observation. The third output of `resubPredict` is the expected misclassification cost per observation.

Suppose you have `Nobs` observations that you classified with a trained classifier `mdl`, and you have K classes. The command

```
[label,score,cost] = resubPredict(mdl)
```

returns a matrix `cost` of size `Nobs-by-K`, among other outputs. Each row of the `cost` matrix contains the expected (average) cost of classifying the observation into each of the `K` classes. `cost(n, j)` is

$$\sum_{i=1}^K \widehat{P}(i|X(n))C(j|i),$$

where

- K is the number of classes.
- $\widehat{P}(i|X(n))$ is the posterior probability on page 32-6153 of class i for observation $X(n)$.
- $C(j|i)$ is the true misclassification cost of classifying an observation as j when its true class is i .

Introduced in R2012a

resubPredict

Class: ClassificationNaiveBayes

Predict resubstitution labels of naive Bayes classifier

Syntax

```
label = resubPredict(Mdl)
[label,Posterior,Cost] = predict(Mdl)
```

Description

`label = resubPredict(Mdl)` returns a vector of predicted class labels (`label`) for the trained naive Bayes classifier `Mdl` using the predictor data `Mdl.X`.

`[label,Posterior,Cost] = predict(Mdl)` additionally returns posterior probabilities on page 32-6161 (`Posterior`) and predicted (expected) misclassification costs on page 32-6160 (`Cost`) corresponding to the observations (rows) in `Mdl.X`.

Input Arguments

Mdl — Fully trained naive Bayes classifier

ClassificationNaiveBayes model

A fully trained naive Bayes classifier, specified as a `ClassificationNaiveBayes` model trained by `fitcnb`.

Output Arguments

label — Predicted class labels

categorical vector | character array | logical vector | numeric vector | cell array of character vectors

Predicted class labels, returned as a categorical vector, character array, logical or numeric vector, or cell array of character vectors.

label:

- Is the same data type as the observed class labels (Y) that trained `Mdl`. (The software treats string arrays as cell arrays of character vectors.)
- Has length equal to the number of rows of `X`.
- Is the class yielding the lowest expected misclassification cost (`Cost`).

Posterior — Class posterior probabilities

numeric matrix

Class posterior probabilities on page 32-6161, returned as a numeric matrix. `Posterior` has rows equal to the number of rows of `Mdl.X` and columns equal to the number of distinct classes in the training data (`size(Mdl.ClassNames,1)`).

`Posterior(j,k)` is the predicted posterior probability of class `k` (i.e., in class `Mdl.ClassNames(k)`) given the observation in row `j` of `Mdl.X`.

Data Types: `double`

Cost — Expected misclassification costs

numeric matrix

Expected misclassification costs on page 32-6160, returned as a numeric matrix. `Cost` has rows equal to the number of rows of `Mdl.X` and columns equal to the number of distinct classes in the training data (`size(Mdl.ClassNames,1)`).

`Cost(j,k)` is the expected misclassification cost of the observation in row `j` of `Mdl.X` being predicted into class `k` (i.e., in class `Mdl.ClassNames(k)`).

Examples

Label Training Sample Observations for Naive Bayes

Load Fisher's iris data set.

```
load fisheriris
X = meas;    % Predictors
Y = species; % Response
```

Train a naive Bayes classifier. It is good practice to specify the class order. Assume that each predictor is conditionally, normally distributed given its label.

```
Mdl = fitcnb(X,Y,...
    'ClassNames',{'setosa','versicolor','virginica'});
```

Mdl is a `ClassificationNaiveBayes` classifier.

Predict the training sample labels. Display the results for the 10 observations.

```
label = resubPredict(Mdl);
rng(1); % For reproducibility
idx = randsample(size(X,1),10);
table(Y(idx),label(idx),'VariableNames',...
    {'TrueLabel','PredictedLabel'})
```

```
ans=10x2 table
    TrueLabel    PredictedLabel
    _____    _____
    'setosa'      'setosa'
    'versicolor'  'versicolor'
    'virginica'   'virginica'
    'setosa'      'setosa'
    'versicolor'  'versicolor'
    'setosa'      'setosa'
    'versicolor'  'versicolor'
    'versicolor'  'versicolor'
    'setosa'      'setosa'
    'setosa'      'setosa'
```

Estimate In-Sample Posterior Probabilities of Naive Bayes Classifiers

Load Fisher's iris data set.

```
load fisheriris
X = meas;    % Predictors
Y = species; % Response
```

Train a naive Bayes classifier. It is good practice to specify the class order. Assume that each predictor is conditionally, normally distributed given its label.

```
Mdl = fitcnb(X,Y,...
    'ClassNames',{ 'setosa','versicolor','virginica'});
```

Mdl is a ClassificationNaiveBayes classifier.

Estimate posterior probabilities and expected misclassification costs for the training data. Display the results for 10 observations.

```
[label,Posterior,MisclassCost] = resubPredict(Mdl);
rng(1); % For reproducibility
idx = randsample(size(X,1),10);
Mdl.ClassNames
```

```
ans = 3x1 cell array
    {'setosa' }
    {'versicolor'}
    {'virginica' }
```

```
table(Y(idx),label(idx),Posterior(idx,:), 'VariableNames',...
    {'TrueLabel','PredictedLabel','PosteriorProbability'})
```

```

The order of the columns of `Posterior` and `MisclassCost` corresponds to the order of the classes in `Mdl.ClassNames`.

Definitions

Misclassification Cost

A misclassification cost is the relative severity of a classifier labeling an observation into the wrong class.

There are two types of misclassification costs: true and expected. Let K be the number of classes.

- True misclassification cost — A K -by- K matrix, where element (i, j) indicates the misclassification cost of predicting an observation into class j if its true class is i . The software stores the misclassification cost in the property `Mdl.Cost`, and used in computations. By default, `Mdl.Cost(i, j) = 1` if $i \neq j$, and `Mdl.Cost(i, j) = 0` if $i = j$. In other words, the cost is 0 for correct classification, and 1 for any incorrect classification.
- Expected misclassification cost — A K -dimensional vector, where element k is the weighted average misclassification cost of classifying an observation into class k , weighted by the class posterior probabilities. In other words,

$$c_k = \sum_{j=1}^K \widehat{P}(Y = j | x_1, \dots, x_P) \text{Cost}_{jk}.$$

the software classifies observations to the class corresponding with the lowest expected misclassification cost.

Posterior Probability

The posterior probability is the probability that an observation belongs in a particular class, given the data.

For naive Bayes, the posterior probability that a classification is k for a given observation (x_1, \dots, x_p) is

$$\widehat{P}(Y = k | x_1, \dots, x_p) = \frac{P(X_1, \dots, X_p | y = k)\pi(Y = k)}{P(X_1, \dots, X_p)},$$

where:

- $P(X_1, \dots, X_p | y = k)$ is the conditional joint density of the predictors given they are in class k . `Mdl.DistributionNames` stores the distribution names of the predictors.
- $\pi(Y = k)$ is the class prior probability distribution. `Mdl.Prior` stores the prior distribution.
- $P(X_1, \dots, X_p)$ is the joint density of the predictors. The classes are discrete, so

$$P(X_1, \dots, X_p) = \sum_{k=1}^K P(X_1, \dots, X_p | y = k)\pi(Y = k).$$

Prior Probability

The prior probability of a class is the believed relative frequency with which observations from that class occur in a population.

resubPredict

Classify observations in support vector machine (SVM) classifier

Syntax

```
label = resubPredict(SVMModel)
[label,Score] = resubPredict(SVMModel)
```

Description

`label = resubPredict(SVMModel)` returns a vector of predicted class labels (`label`) for the trained support vector machine (SVM) classifier `SVMModel` using the predictor data `SVMModel.X`.

`[label,Score] = resubPredict(SVMModel)` additionally returns class likelihood measures, either scores or posterior probabilities.

Examples

Label Training Sample Observations for SVM Classifiers

Load the ionosphere data set.

```
load ionosphere
```

Train an SVM classifier. Standardize the data and specify that 'g' is the positive class.

```
SVMModel = fitcsvm(X,Y,'ClassNames',{'b','g'},'Standardize',true);
```

`SVMModel` is a `ClassificationSVM` classifier.

Predict the training sample labels and scores. Display the results for the first 10 observations.

```
[label,score] = resubPredict(SVMModel);  
table(Y(1:10),label(1:10),score(1:10,2), 'VariableNames',...  
      {'TrueLabel','PredictedLabel','Score'})
```

```
ans=10×3 table  
  TrueLabel   PredictedLabel   Score  
-----  
      'g'         'g'         1.4861  
      'b'         'b'        -1.0004  
      'g'         'g'         1.8685  
      'b'         'b'        -2.6458  
      'g'         'g'         1.2805  
      'b'         'b'        -1.4617  
      'g'         'g'         2.1672  
      'b'         'b'        -5.7085  
      'g'         'g'         2.4797  
      'b'         'b'        -2.7811
```

Estimate In-Sample Posterior Probabilities of SVM Classifiers

Load the ionosphere data set.

```
load ionosphere
```

Train an SVM classifier. Standardize the data and specify that 'g' is the positive class.

```
SVMModel = fitcsvm(X,Y,'ClassNames',{'b','g'},'Standardize',true);
```

SVMModel is a ClassificationSVM classifier.

Fit the optimal score-to-posterior-probability transformation function.

```
rng(1); % For reproducibility  
ScoreSVMModel = fitPosterior(SVMModel)  
  
ScoreSVMModel =  
  ClassificationSVM  
      ResponseName: 'Y'  
  CategoricalPredictors: []  
      ClassNames: {'b' 'g'}  
      ScoreTransform: '@(S)sigmoid(S,-9.481802e-01,-1.218745e-01)'
```

```

Input Arguments

SVMModel — Full, trained SVM classifier

ClassificationSVM classifier

Full, trained SVM classifier, specified as a ClassificationSVM model trained with `fitcsvm`.

Output Arguments

label — Predicted class labels

categorical array | character array | logical vector | numeric vector | cell array of character vectors

Predicted class labels, returned as a categorical or character array, logical or numeric vector, or cell array of character vectors.

The predicted class labels have the following:

- Same data type as the observed class labels (`SVMModel.Y`)
- Length equal to the number of rows in `SVMModel.X`

For one-class learning, `label` contains the one class represented in `SVMModel.Y`.

Score — Predicted class scores or posterior probabilities

numeric column vector | numeric matrix

Predicted class scores on page 32-6167 or posterior probabilities on page 32-6168, returned as a numeric column vector or numeric matrix.

- For one-class learning, `Score` is a column vector with the same number of rows as `SVMModel.X`. The elements are the positive class scores for the corresponding observations. You cannot obtain posterior probabilities for one-class learning.
- For two-class learning, `Score` is a two-column matrix with the same number of rows as `SVMModel.X`.
 - If you fit the optimal score-to-posterior-probability transformation function using `fitPosterior` or `fitSVMPosterior`, then `Score` contains class posterior probabilities. That is, if the value of `SVMModel.ScoreTransform` is not `none`, then the first and second columns of `Score` contain the negative class

(`SVMMoDel.ClassNames{1}`) and positive class (`SVMMoDel.ClassNames{2}`) posterior probabilities for the corresponding observations, respectively.

- Otherwise, the first column contains the negative class scores and the second column contains the positive class scores for the corresponding observations.

If `SVMMoDel.KernelParameters.Function` is 'linear', then the classification score for the observation x is

$$f(x) = (x/s)\beta + b.$$

`SVMMoDel` stores β , b , and s in the properties `Beta`, `Bias`, and `KernelParameters.Scale`, respectively.

To estimate classification scores manually, you must first apply any transformations to the predictor data that were applied during training. Specifically, if you specify 'Standardize', true when using `fitcsvm`, then you must standardize the predictor data manually by using the mean `SVMMoDel.Mu` and standard deviation `SVMMoDel.Sigma`, and then divide the result by the kernel scale in `SVMMoDel.KernelParameters.Scale`.

All SVM functions, such as `resubPredict` and `predict`, apply any required transformation before estimation.

If `SVMMoDel.KernelParameters.Function` is not 'linear', then `Beta` is empty (`[]`).

Definitions

Classification Score

The SVM classification score for classifying observation x is the signed distance from x to the decision boundary ranging from $-\infty$ to $+\infty$. A positive score for a class indicates that x is predicted to be in that class. A negative score indicates otherwise.

The positive class classification score $f(x)$ is the trained SVM classification function. $f(x)$ is also the numerical, predicted response for x , or the score for predicting x into the positive class.

$$f(x) = \sum_{j=1}^n \alpha_j y_j G(x_j, x) + b,$$

where $(\alpha_1, \dots, \alpha_n, b)$ are the estimated SVM parameters, $G(x_j, x)$ is the dot product in the predictor space between x and the support vectors, and the sum includes the training set observations. The negative class classification score for x , or the score for predicting x into the negative class, is $-f(x)$.

If $G(x_j, x) = x_j'x$ (the linear kernel), then the score function reduces to

$$f(x) = (x/s)'\beta + b.$$

s is the kernel scale and β is the vector of fitted linear coefficients.

For more details, see “Understanding Support Vector Machines” on page 18-189.

Posterior Probability

The posterior probability is the probability that an observation belongs in a particular class, given the data.

For SVM, the posterior probability is a function of the score $P(s)$ that observation j is in class $k = \{-1, 1\}$.

- For separable classes, the posterior probability is the step function

$$P(s_j) = \begin{cases} 0; & s < \max_{y_k = -1} s_k \\ \pi; & \max_{y_k = -1} s_k \leq s_j \leq \min_{y_k = +1} s_k \\ 1; & s_j > \min_{y_k = +1} s_k \end{cases},$$

where:

- s_j is the score of observation j .
- $+1$ and -1 denote the positive and negative classes, respectively.
- π is the prior probability that an observation is in the positive class.
- For inseparable classes, the posterior probability is the sigmoid function

$$P(s_j) = \frac{1}{1 + \exp(As_j + B)},$$

where the parameters A and B are the slope and intercept parameters, respectively.

Prior Probability

The prior probability of a class is the believed relative frequency with which observations from that class occur in a population.

Tips

- If you are using a linear SVM model for classification and the model has many support vectors, then using `resubPredict` for the prediction method can be slow. To efficiently classify observations based on a linear SVM model, remove the support vectors from the model object by using `discardSupportVectors`.

Algorithms

- By default and irrespective of the model kernel function, MATLAB uses the dual representation of the score function to classify observations based on trained SVM models, specifically

$$\widehat{f}(x) = \sum_{j=1}^n \widehat{\alpha}_j y_j G(x, x_j) + \widehat{b}.$$

This prediction method requires the trained support vectors and α coefficients (see the `SupportVectors` and `Alpha` properties of the SVM model).

- By default, the software computes optimal posterior probabilities using Platt's method [1]:
 - 1 Perform 10-fold cross-validation.
 - 2 Fit the sigmoid function parameters to the scores returned from the cross-validation.
 - 3 Estimate the posterior probabilities by entering the cross-validation scores into the fitted sigmoid function.
- The software incorporates prior probabilities in the SVM objective function during training.
- For SVM, `predict` and `resubPredict` classify observations into the class yielding the largest score (the largest posterior probability). The software accounts for misclassification costs by applying the average-cost correction before training the

classifier. That is, given the class prior vector P , misclassification cost matrix C , and observation weight vector w , the software defines a new vector of observation weights (W) such that

$$W_j = w_j P_j \sum_{k=1}^K C_{jk}.$$

`ClassificationSVM` | `CompactClassificationSVM` | `fitPosterior` | `fitSVMPosterior` | `fitcsvm` | `predict`

Introduced in R2014a

resubPredict

Class: ClassificationTree

Predict resubstitution labels of classification tree

Syntax

```
label = resubPredict(tree)
[label,posterior] = resubPredict(tree)
[label,posterior,node] = resubPredict(tree)
[label,posterior,node,cnum] = resubPredict(tree)
[label,...] = resubPredict(tree,Name,Value)
```

Description

`label = resubPredict(tree)` returns the labels `tree` predicts for the data `tree.X`. `label` is the predictions of `tree` on the data that `fitctree` used to create `tree`.

`[label,posterior] = resubPredict(tree)` returns the posterior class probabilities for the predictions.

`[label,posterior,node] = resubPredict(tree)` returns the node numbers of `tree` for the resubstituted data.

`[label,posterior,node,cnum] = resubPredict(tree)` returns the predicted class numbers for the predictions.

`[label,...] = resubPredict(tree,Name,Value)` returns resubstitution predictions with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

tree

A classification tree constructed by `fitctree`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Subtrees — Pruning level

0 (default) | vector of nonnegative integers | 'all'

Pruning level, specified as the comma-separated pair consisting of 'Subtrees' and a vector of nonnegative integers in ascending order or 'all'.

If you specify a vector, then all elements must be at least 0 and at most `max(tree.PruneList)`. 0 indicates the full, unpruned tree and `max(tree.PruneList)` indicates the completely pruned tree (i.e., just the root node).

If you specify 'all', then `resubPredict` operates on all subtrees (i.e., the entire pruning sequence). This specification is equivalent to using `0:max(tree.PruneList)`.

`resubPredict` prunes `tree` to each level indicated in `Subtrees`, and then estimates the corresponding output arguments. The size of `Subtrees` determines the size of some output arguments.

To invoke `Subtrees`, the properties `PruneList` and `PruneAlpha` of `tree` must be nonempty. In other words, grow `tree` by setting 'Prune', 'on', or by pruning `tree` using `prune`.

Example: 'Subtrees', 'all'

Data Types: single | double | char | string

Output Arguments

label

The response `tree` predicts for the training data. `label` is the same data type as the training response data `tree.Y`.

If the `Subtrees` name-value argument contains `m>1` entries, `label` has `m` columns, each of which represents the predictions of the corresponding subtree. Otherwise, `label` is a vector.

posterior

Matrix or array of posterior probabilities for classes `tree` predicts.

If the `Subtrees` name-value argument is a scalar or is missing, `posterior` is an n -by- k matrix, where n is the number of rows in the training data `tree.X`, and k is the number of classes.

If `Subtrees` contains $m > 1$ entries, `posterior` is an n -by- k -by- m array, where the matrix for each m gives posterior probabilities for the corresponding subtree.

node

The node numbers of `tree` where each data row resolves.

If the `Subtrees` name-value argument is a scalar or is missing, `node` is a numeric column vector with n rows, the same number of rows as `tree.X`.

If `Subtrees` contains $m > 1$ entries, `node` is a n -by- m matrix. Each column represents the node predictions of the corresponding subtree.

cnum

The class numbers that `tree` predicts for the resubstituted data.

If the `Subtrees` name-value argument is a scalar or is missing, `cnum` is a numeric column vector with n rows, the same number of rows as `tree.X`.

If `Subtrees` contains $m > 1$ entries, `cnum` is a n -by- m matrix. Each column represents the class predictions of the corresponding subtree.

Examples

Compute Number of Misclassified Observations

Find the total number of misclassifications of the Fisher iris data for a classification tree.

```
load fisheriris
tree = fitctree(meas,species);
Ypredict = resubPredict(tree);    % The predictions
```

```
Ysame = strcmp(Ypredict,species); % True when ==  
sum(~Ysame) % How many are different?
```

```
ans = 3
```

Compare In-Sample Posterior Probabilities for Each Subtree

Load Fisher's iris data set. Partition the data into training (50%)

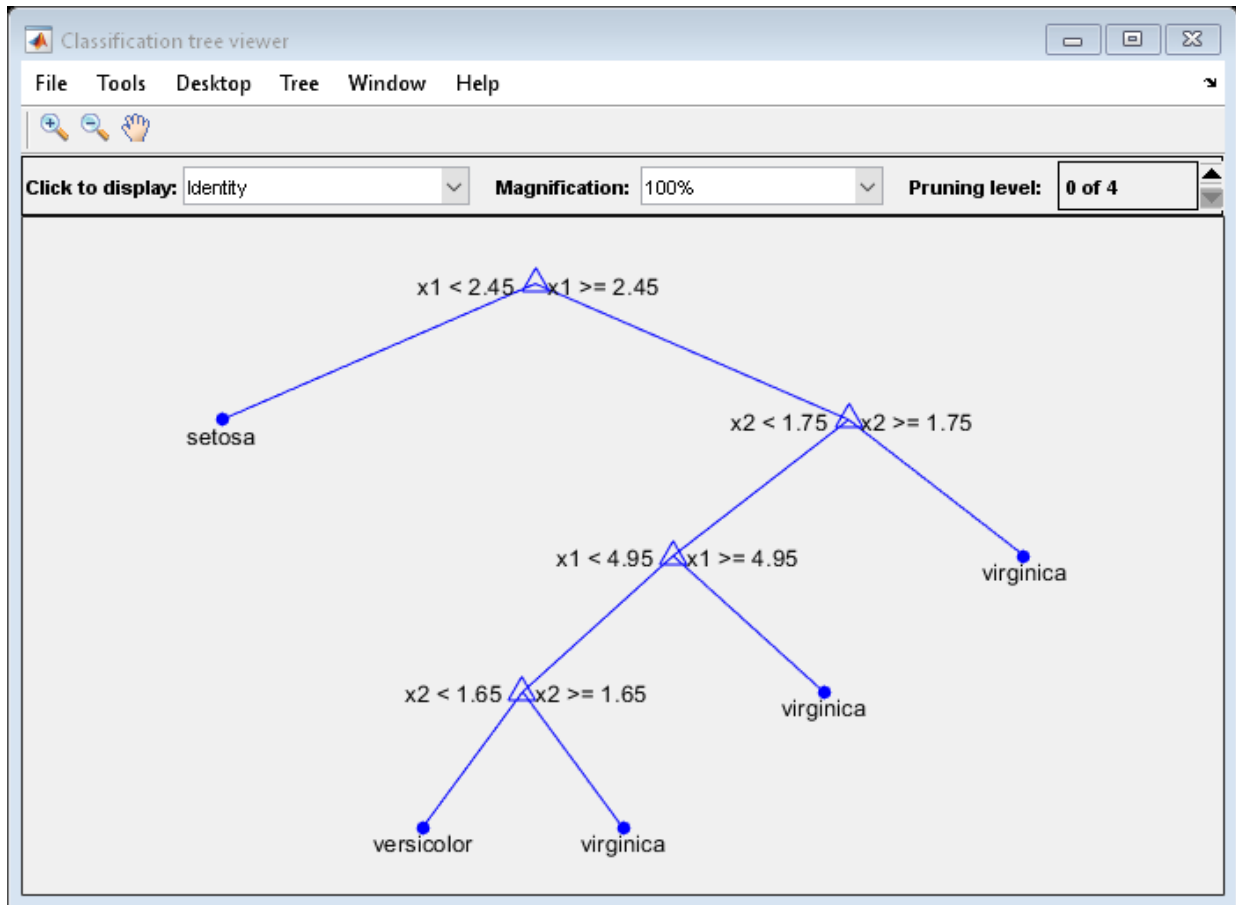

```
load fisheriris
```

Grow a classification tree using the all petal measurements.

```
Mdl = fitctree(meas(:,3:4),species);  
n = size(meas,1); % Sample size  
K = numel(Mdl.ClassNames); % Number of classes
```

View the classification tree.

```
view(Mdl, 'Mode', 'graph');
```

The classification tree has four pruning levels. Level 0 is the full, unpruned tree (as displayed). Level 4 is just the root node (i.e., no splits).

Estimate the posterior probabilities for each class using the subtrees pruned to levels 1 and 3.

```
[~,Posterior] = resubPredict(Mdl,'SubTrees',[1 3]);
```

Posterior is an n-by- K-by- 2 array of posterior probabilities. Rows of Posterior correspond to observations, columns correspond to the classes with order Mdl.ClassNames, and pages correspond to pruning level.

Display the class posterior probabilities for iris 125 using each subtree.

```
Posterior(125, :, :)  
  
ans =  
ans(:, :, 1) =  
  
    0    0.0217    0.9783  
  
ans(:, :, 2) =  
  
    0    0.5000    0.5000
```

The decision stump (page 2 of `Posterior`) has trouble predicting whether iris 125 is versicolor or virginica.

Definitions

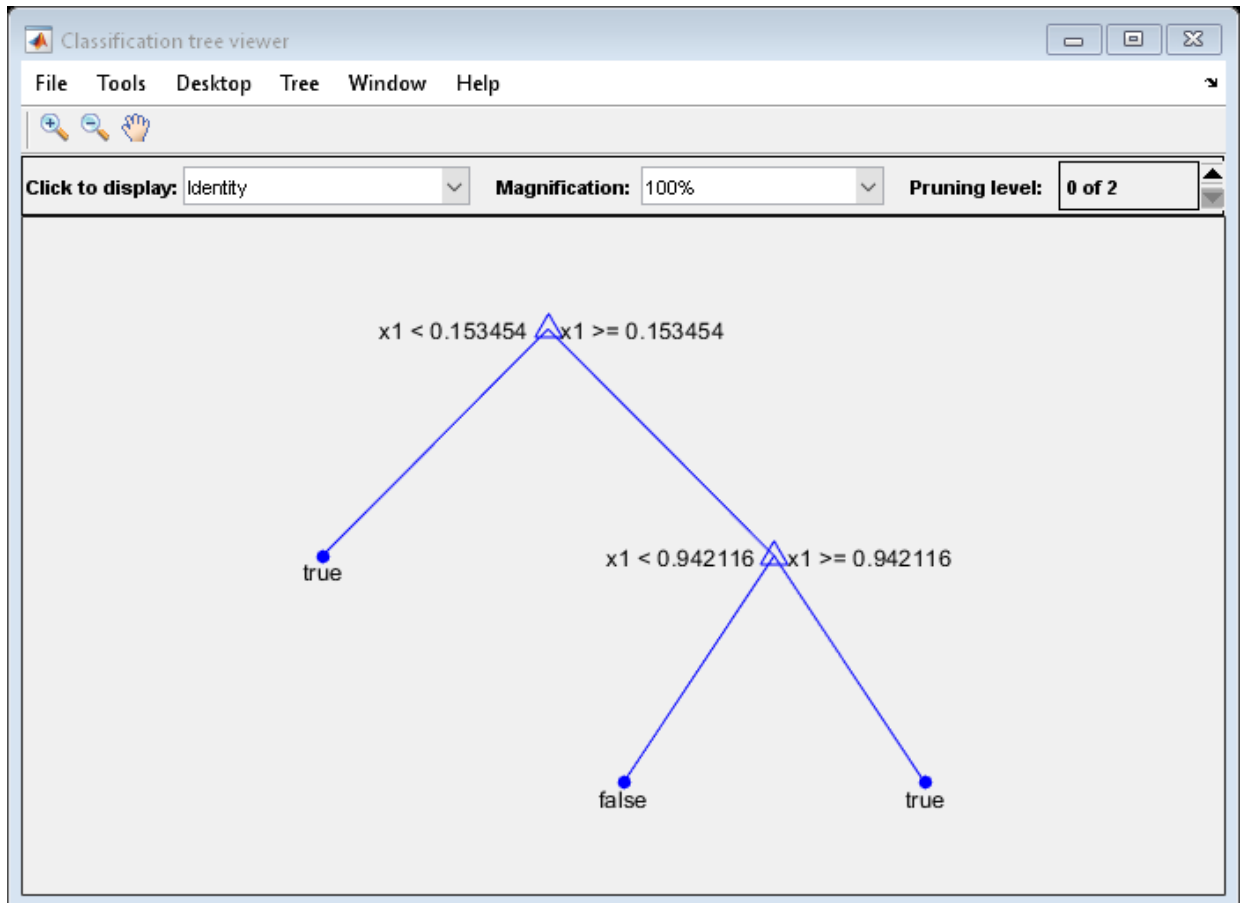

Posterior Probability

The posterior probability of the classification at a node is the number of training sequences that lead to that node with this classification, divided by the number of training sequences that lead to that node.

For example, consider classifying a predictor `X` as `true` when $X < 0.15$ or $X > 0.95$, and `X` is false otherwise.

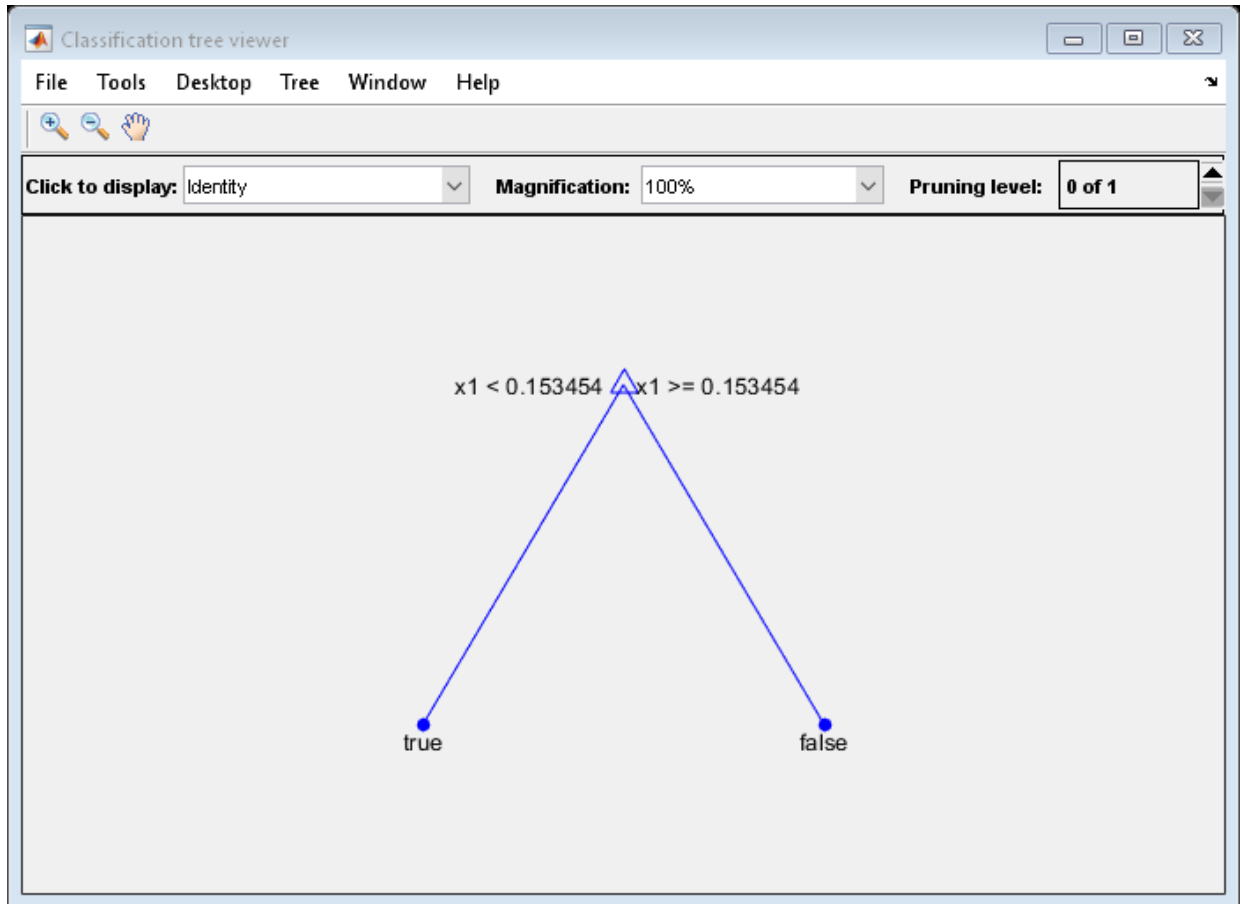

- 1 Generate 100 random points and classify them:

```
rng(0) % For reproducibility  
X = rand(100,1);  
Y = (abs(X - .55) > .4);  
tree = fitctree(X,Y);  
view(tree, 'Mode', 'graph')
```

2 Prune the tree:

```
tree1 = prune(tree, 'Level', 1);  
view(tree1, 'Mode', 'graph')
```

The pruned tree correctly classifies observations that are less than 0.15 as `true`. It also correctly classifies observations between .15 and .94 as `false`. However, it incorrectly classifies observations that are greater than .94 as `false`. Therefore the score for observations that are greater than .15 should be about $.05/.85=.06$ for `true`, and about $.8/.85=.94$ for `false`.

- 3 Compute the prediction scores for the first 10 rows of `X`:

```
[~,score] = predict(tree1,X(1:10));
[score X(1:10,:)]
```

```
ans = 10×3
```

0.9059	0.0941	0.8147
0.9059	0.0941	0.9058
0	1.0000	0.1270
0.9059	0.0941	0.9134
0.9059	0.0941	0.6324
0	1.0000	0.0975
0.9059	0.0941	0.2785
0.9059	0.0941	0.5469
0.9059	0.0941	0.9575
0.9059	0.0941	0.9649

Indeed, every value of X (the rightmost column) that is less than 0.15 has associated scores (the left and center columns) of 0 and 1, while the other values of X have associated scores of 0.94 and 0.06.

resubPredict

Predict response of ensemble by resubstitution

Syntax

```
Yfit = resubPredict(ens)
Yfit = resubPredict(ens,Name,Value)
```

Description

`Yfit = resubPredict(ens)` returns the response `ens` predicts for the data `ens.X`. `Yfit` is the predictions of `ens` on the data that `fitrensemble` used to create `ens`.

`Yfit = resubPredict(ens,Name,Value)` predicts responses with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

`ens`

A regression ensemble created with `fitrensemble`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`learners`

Indices of weak learners in the ensemble ranging from 1 to `NumTrained`. `oobLoss` uses only these learners for calculating loss.

Default: `1:NumTrained`

Output Arguments

Yfit

A vector of predicted responses to the training data, with `ens.X` elements.

Examples

Find Mean-Squared Error of Resubstitution Predictions

Find the resubstitution predictions of mileage from the `carsmall` data, and look at their mean-squared difference from the training data.

Load the `carsmall` data set and select horsepower and vehicle weight as predictors.

```
load carsmall
X = [Horsepower Weight];
```

Train an ensemble of regression trees.

```
ens = fitensemble(X,MPG,'Method','LSBoost','Learners','Tree');
```

Find the resubstitution predictions of MPG.

```
Yfit = resubPredict(ens);
```

Calculate the mean-squared difference of the resubstitution predictions from the training data.

```
MSE = mean((Yfit - ens.Y).^2)
```

```
MSE = 0.5836
```

Confirm that the result is the same as the result of `resubLoss`.

```
resubLoss(ens)
```

```
ans = 0.5836
```

See Also

`predict` | `resubLoss` | `resubPredict`

resubPredict

Class: RegressionGP

Resubstitution prediction from a trained Gaussian process regression model

Syntax

```
yPred = resubPredict(gprMdl)
[yPred, ysd] = resubPredict(gprMdl)
[yPred, ysd, yint] = predict(gprMdl)
[yPred, ysd, yint] = predict(gprMdl, Name, Value)
```

Description

`yPred = resubPredict(gprMdl)` returns the predicted responses, `yPred`, for the trained Gaussian process regression (GPR) model, `gprMdl`.

`[yPred, ysd] = resubPredict(gprMdl)` also returns the estimated standard deviations of the predicted responses corresponding to the rows of `gprMdl.X`.

`[yPred, ysd, yint] = predict(gprMdl)` also returns the 95% prediction intervals, `yint`, for the true responses corresponding to each row of training data, `gprMdl.X`.

`[yPred, ysd, yint] = predict(gprMdl, Name, Value)` returns the prediction intervals with additional options, specified by one or more `Name, Value` pair arguments. For example, you can specify the confidence level of the prediction interval.

Input Arguments

gprMdl — Gaussian process regression model

RegressionGP object

Gaussian process regression model, specified as a RegressionGP object.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Alpha — Significance level

0.05 (default) | scalar value in the range from 0 to 1

Significance level for the prediction intervals, specified as the comma-separated pair consisting of 'Alpha' and a scalar value in the range from 0 to 1.

Example: 'Alpha', 0.01 specifies 99% prediction intervals.

Data Types: single | double

Output Arguments

ypred — Predicted response values

n-by-1 vector

Predicted response values, returned as an *n*-by-1 vector, where *n* is the number of observations in the training data.

ysd — Standard deviation of the predicted response values

n-by-1 vector

Standard deviation of the predicted response values corresponding to the rows of `gprMdl.X`, returned as an *n*-by-1 vector. `ysd(i)`, $i = 1, 2, \dots, n$, contains the estimated standard deviation of the new response corresponding to the predictor values at the *i*th observation in the training data.

yint — Prediction intervals for the true response values

n-by-2 matrix

Prediction intervals for the true response values corresponding to the rows of `gprMdl.X`, returned as an *n*-by-2 matrix, where *n* is the number of observations in the training data. The first column of `yint` contains the lower limits and the second column contains the upper limits of the prediction intervals.

Examples

Plot Predicted Response and Prediction Intervals

This example uses "Housing" data set [1] from the UCI machine learning archive [2] described in <http://archive.ics.uci.edu/ml/datasets/Housing>. Download the data and save it in your current directory as a data file named housing.data.

The dataset has 506 observations. The first 13 columns contain the predictor values and the last column contains the response values. The goal is to predict the median value of owner-occupied homes in the Boston suburb area as a function of 13 predictors.

Load the data and define the response vector and predictor matrix.

```
load('housing.data');
X = housing(:,1:13);
y = housing(:,end);
```

Train a GPR model using subset of regressors ('sr') approximation method with Matern 3/2 ('Matern32') kernel function. Predict using the fully independent conditional ('fic') method.

```
gprMdl = fitrgp(X,y,'KernelFunction','Matern32',...
'FitMethod','sr','PredictMethod','fic');
```

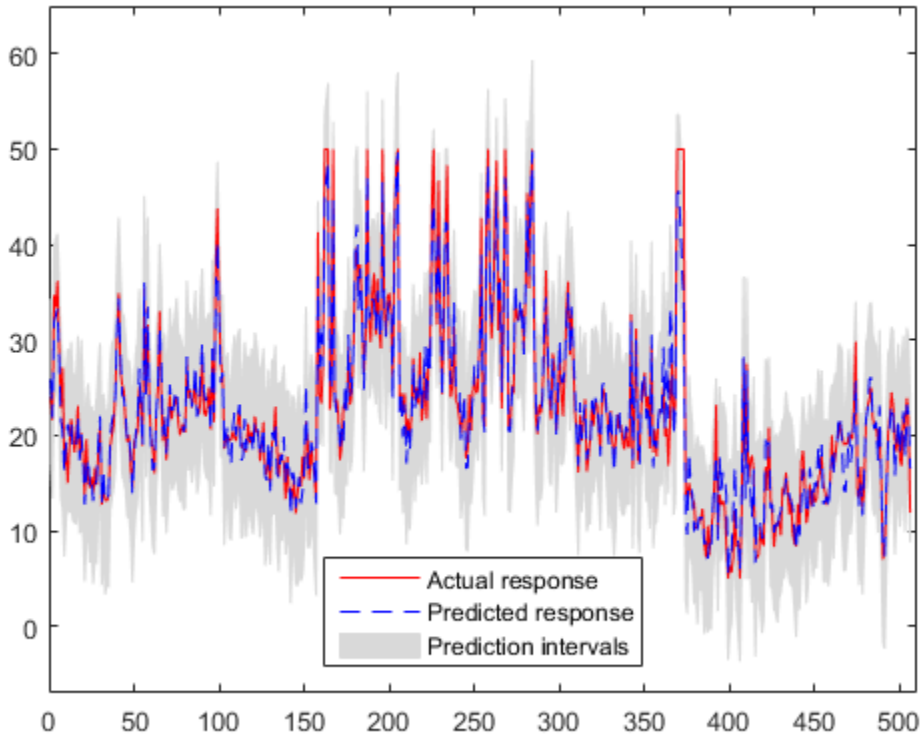

Predict the responses using the trained GPR model. Compute the 99% prediction intervals.

```
[ypred,~,yint] = resubPredict(gprMdl,'Alpha',0.01);
```

Plot the actual response values along with predictions from the GPR model.

```
figure;
h1 = area([yint(:,1) yint(:,2)-yint(:,1)],-8,...
'FaceColor',[0.85,0.85,0.85],'EdgeColor',[0.85,0.85,0.85]);
hold on;
h1(1).FaceColor = 'none'; % remove color from bottom area
h1(1).EdgeColor = 'none';
h2 = plot(y,'r'); % Plot original response values
h3 = plot(ypred,'b--'); % Plot predicted response values
legend([h2 h3 h1(2)],'Actual response','Predicted response',...
'Prediction intervals','Location','South');
```

```
axis([0 510 -7 65]);  
hold off
```

The gray area shows the 99% prediction intervals.

Tips

- You can choose the prediction method while training the GPR model using the `PredictMethod` name-value pair argument in `fitrgp`. The default prediction method is 'exact' for $n \leq 10000$, where n is the number of observations in the training data, and 'bcd' (block coordinate descent), otherwise.

- Computation of standard deviations, `ysd`, and prediction intervals, `yint`, is not supported when `PredictMethod` is `'bcd'`.

Alternatives

To compute the predicted responses for new data, use `predict`.

`RegressionGP` | `fitrgp` | `predict` | `resubLoss`

Introduced in R2015b

resubPredict

Class: RegressionSVM

Predict resubstitution response of support vector machine regression model

Syntax

```
yfit = resubPredict mdl
```

Description

`yfit = resubPredict(mdl)` returns a vector of predicted response values, `yfit`, for the trained support vector machine (SVM) regression model `mdl` using the predictor data stored in `mdl.X`.

Input Arguments

mdl — Full, trained SVM regression model

RegressionSVM model

Full, trained SVM regression model, specified as a RegressionSVM model returned by `fitrsvm`.

Output Arguments

yfit — Predicted response

vector of numeric values

Predicted responses, returned as a vector of numeric values. The length of `yfit` is equal to the number of observations in the training data, `mdl.NumObservations`.

For details about how to predict responses, see “Equation 25-1” and “Equation 25-2” in “Understanding Support Vector Machine Regression” on page 25-2.

Examples

Resubstitution Predictions for SVM Regression Model

This example shows how to train an SVM regression model, then use the model to generate predicted response values from the training data.

This example uses the abalone data from the UCI Machine Learning Repository. Download the data and save it in your current directory with the name 'abalone.data'. Read the data into a table.

```
tbl = readtable('abalone.data', 'Filetype', 'text', 'ReadVariableNames', false);
rng default % for reproducibility
```

The sample data contains 4177 observations. All of the predictor variables are continuous except for sex, which is a categorical variable with possible values 'M' (for males), 'F' (for females), and 'I' (for infants). The goal is to predict the number of rings on the abalone, and thereby determine its age, using physical measurements.

Train an SVM regression model to the data, using a Gaussian kernel function with an automatic kernel scale. Standardize the data.

```
mdl = fitrsvm(tbl, 'Var9', 'KernelFunction', 'gaussian', 'KernelScale', 'auto', 'Standardize
```

Use the trained model to predict response values based on the original data.

```
yfit = resubPredict(mdl);
```

Display the first ten predicted responses alongside the actual response values.

```
[mdl.Y(1:10), yfit(1:10)]
```

```
ans =
```

```
15.0000    8.1836
 7.0000    8.3545
 9.0000   10.9383
10.0000    9.3446
 7.0000    6.4042
 8.0000    7.7910
20.0000   13.8275
16.0000   11.7959
```

9.0000	9.5724
19.0000	13.6909

The left column shows the actual response and the right column shows the corresponding predicted response.

`RegressionSVM` | `fitrsvm` | `predict` | `resubLoss`

Introduced in R2015b

resubPredict

Class: RegressionTree

Predict resubstitution response of tree

Syntax

```
Yfit = resubPredict(tree)
[Yfit,node] = resubPredict(tree)
[Yfit,node] = resubPredict(tree,Name,Value)
```

Description

`Yfit = resubPredict(tree)` returns the responses `tree` predicts for the data `tree.X`. `Yfit` is the predictions of `tree` on the data that `fitrtree` used to create `tree`.

`[Yfit,node] = resubPredict(tree)` returns the node numbers of `tree` for the resubstituted data.

`[Yfit,node] = resubPredict(tree,Name,Value)` predicts with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

tree

A regression tree constructed using `fitrtree`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Subtrees — Pruning level

0 (default) | vector of nonnegative integers | 'all'

Pruning level, specified as the comma-separated pair consisting of 'Subtrees' and a vector of nonnegative integers in ascending order or 'all'.

If you specify a vector, then all elements must be at least 0 and at most `max(tree.PruneList)`. 0 indicates the full, unpruned tree and `max(tree.PruneList)` indicates the completely pruned tree (i.e., just the root node).

If you specify 'all', then `resubPredict` operates on all subtrees (i.e., the entire pruning sequence). This specification is equivalent to using `0:max(tree.PruneList)`.

`resubPredict` prunes `tree` to each level indicated in `Subtrees`, and then estimates the corresponding output arguments. The size of `Subtrees` determines the size of some output arguments.

To invoke `Subtrees`, the properties `PruneList` and `PruneAlpha` of `tree` must be nonempty. In other words, grow `tree` by setting 'Prune', 'on', or by pruning `tree` using `prune`.

Example: 'Subtrees', 'all'

Data Types: single | double | char | string

Output Arguments

Yfit

The response `tree` predicts for the training data.

If the `Subtrees` name-value argument is a scalar or is missing, `label` is the same data type as the training response data `tree.Y`.

If `Subtrees` contains $m > 1$ entries, `label` has m columns, each of which represents the predictions of the corresponding subtree.

node

The `tree` node numbers where `tree` sends each data row.

If the `Subtrees` name-value argument is a scalar or is missing, `node` is a numeric column vector with `n` rows, the same number of rows as `tree.X`.

If `Subtrees` contains `m > 1` entries, `node` is a `n`-by-`m` matrix. Each column represents the node predictions of the corresponding subtree.

Examples

Compute the In-Sample MSE

Load the `carsmall` data set. Consider `Displacement`, `Horsepower`, and `Weight` as predictors of the response `MPG`.

```
load carsmall
X = [Displacement Horsepower Weight];
```

Grow a regression tree using all observations.

```
Mdl = fitrtree(X,MPG);
```

Compute the resubstitution MSE.

```
Yfit = resubPredict(Mdl);
mean((Yfit - Mdl.Y).^2)
```

```
ans = 4.8952
```

You can get the same result using `resubLoss`.

```
resubLoss(Mdl)
```

```
ans = 4.8952
```

Estimate In-Sample Responses For Each Subtree

Load the `carsmall` data set. Consider `Weight` as a predictor of the response `MPG`.

```
load carsmall
idxNaN = isnan(MPG + Weight);
```

```
X = Weight(~idxNaN);
Y = MPG(~idxNaN);
n = numel(X);
```

Grow a regression tree using all observations.

```
Mdl = fitrtree(X,Y);
```

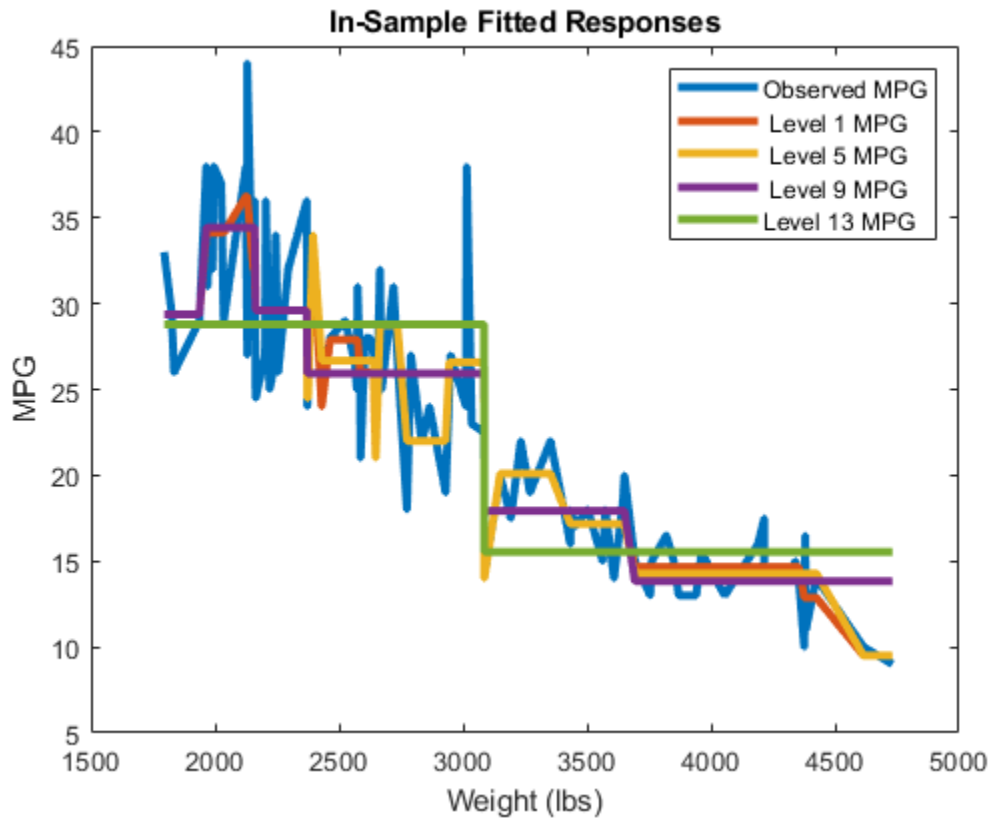

Compute resubstitution fitted values for the subtrees at several pruning levels.

```
m = max(Mdl.PruneList);
pruneLevels = 1:4:m; % Pruning levels to consider
z = numel(pruneLevels);
Yfit = resubPredict(Mdl, 'SubTrees',pruneLevels);
```

Yfit is an n-by- z matrix of fitted values in which the rows correspond to observations and the columns correspond to a subtree.

Plot several columns of Yfit and Y against X.

```
figure;
sortDat = sortrows([X Y Yfit],1); % Sort all data with respect to X
plot(repmat(sortDat(:,1),1,size(Yfit,2) + 1),sortDat(:,2:end))...
    % Vectorize for efficiency
lev = cellstr(num2str((pruneLevels)', 'Level %d MPG'));
legend(['Observed MPG'; lev])
title 'In-Sample Fitted Responses'
xlabel 'Weight (lbs)';
ylabel 'MPG';
h = findobj(gcf);
set(h(4:end), 'LineWidth',3) % Widen all lines
```

The values of Y_{fit} for lower pruning levels tend to follow the data more closely than higher levels. Higher pruning levels tend to be flat for large X intervals.

`fitrtree` | `predict` | `resubLoss`

resume

Resume a Bayesian optimization

Syntax

```
newresults = resume(results,Name,Value)
```

Description

`newresults = resume(results,Name,Value)` resumes the optimization that produced `results` with additional options specified by one or more `Name, Value` pair arguments.

Examples

Resume a Bayesian Optimization

This example shows how to resume a Bayesian optimization. The optimization is for a deterministic function known as Rosenbrock's function, which is a well-known test case for nonlinear optimization. The function has a global minimum value of 0 at the point [1,1].

Create two real variables bounded by -5 and 5.

```
x1 = optimizableVariable('x1',[-5,5]);  
x2 = optimizableVariable('x2',[-5,5]);  
vars = [x1,x2];
```

Create the objective function.

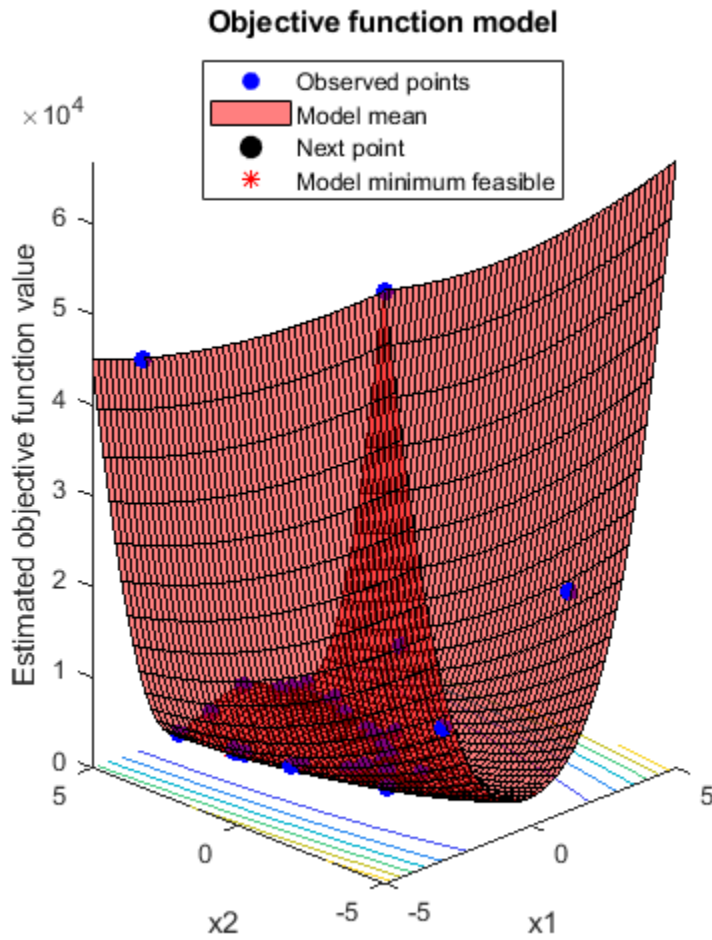

```
function f = rosenbrocks(x)  
f = 100*(x.x2 - x.x1^2)^2 + (1 - x.x1)^2;
```

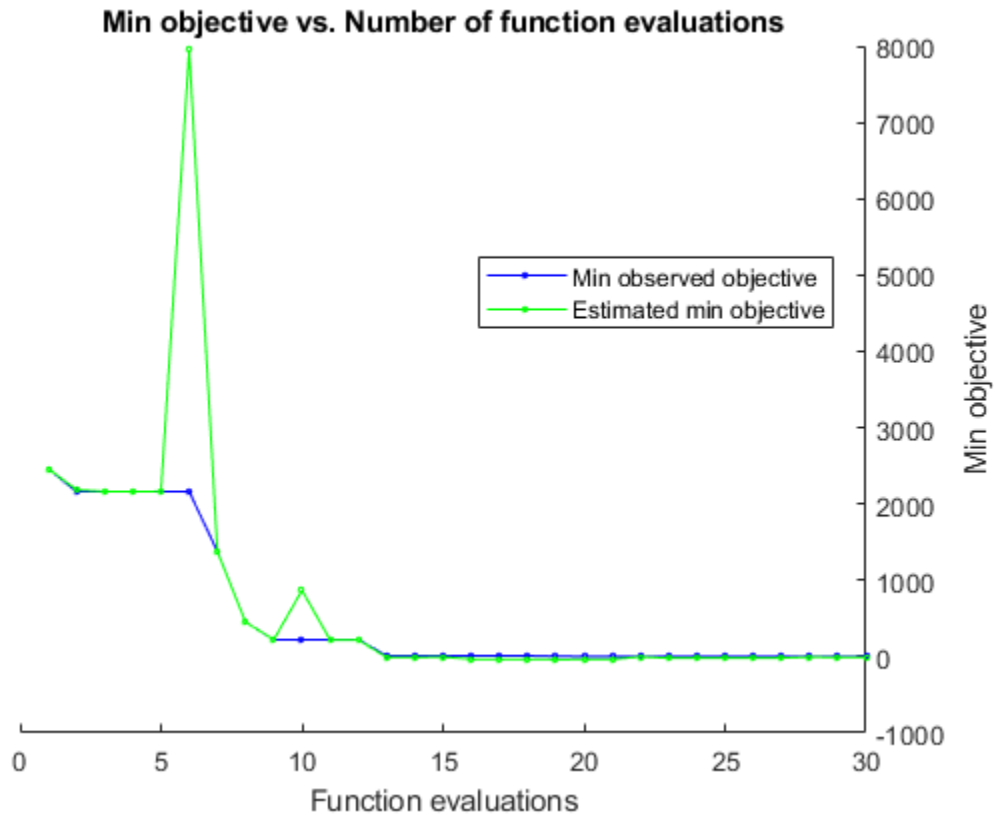

```
fun = @rosenbrocks;
```

For reproducibility, set the random seed, and set the acquisition function to 'expected-improvement-plus' in the optimization.

```
rng default  
results = bayesopt(fun,vars,'Verbose',0,...  
    'AcquisitionFunctionName','expected-improvement-plus');
```

View the best point found and the best modeled objective.

```
results.XAtMinObjective
results.MinEstimatedObjective
```

```
ans =
```

```
1x2 table
```

x1	x2
1.2421	1.5299

```
ans =  
-9.5402
```

The best point is somewhat close to the optimum, but the function model is inaccurate. Resume the optimization for 30 more points (a total of 60 points), this time telling the optimizer that the objective function is deterministic.

```
newresults = resume(results, 'IsObjectiveDeterministic', true, 'MaxObjectiveEvaluations', 30,  
newresults.XAtMinObjective  
newresults.MinEstimatedObjective
```

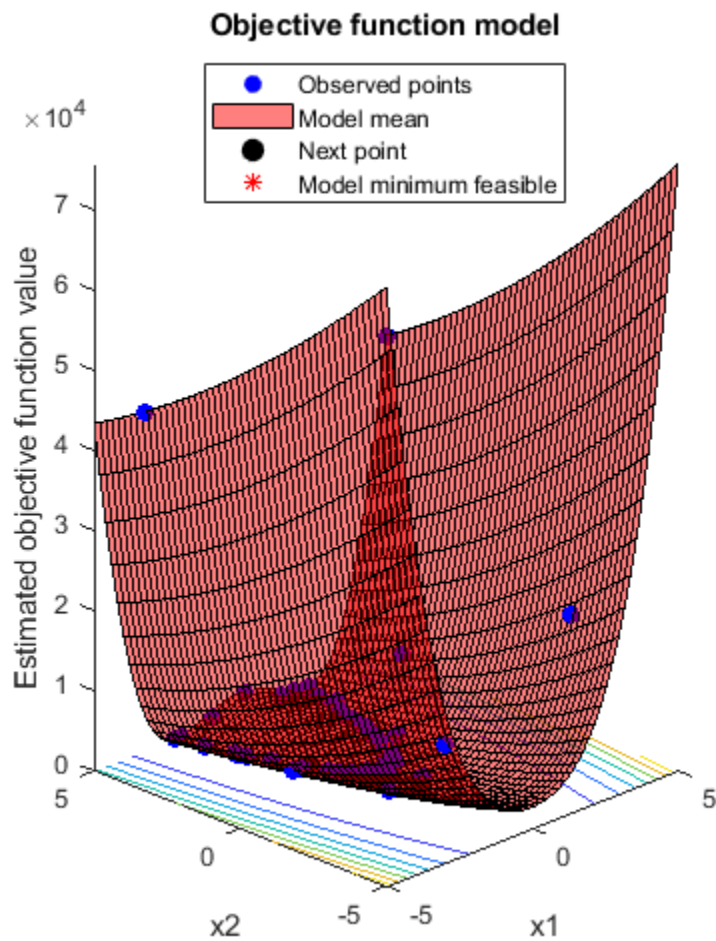

```
ans =
```

```
1x2 table
```

x1	x2
1.0516	1.1007

```
ans =
```

```
-0.0227
```

The objective function model is much closer to the true function this time. The best point is closer to the true optimum.

Input Arguments

results — Bayesian optimization results

`BayesianOptimization` object

Bayesian optimization results, specified as a `BayesianOptimization` object.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

You can use any name-value pair accepted by `bayesopt` except for those beginning with `Initial`. See the `bayesopt` “Input Arguments” on page 32-168.

Note The `MaxObjectiveEvaluations` and `MaxTime` name-value pairs mean *additional* time or evaluations, above the numbers stored in `results`. So, for example, the default number of evaluations is 30 in addition to the original specification.

Additionally, you can use the following name-value pair.

Example: `resume(results, 'MaxObjectiveEvaluations', 60)`

VariableDescriptions — Modify variable

`OptimizableVariable` object

Modify variable, specified as an `OptimizableVariable` object.

You can change only the following properties of a variable in an optimization.

- Range of real or integer variables. For example,

```
xvar = optimizableVariable('x', [-10, 10]);  
% Modify the range:  
xvar.Range = [1, 5];
```
- Type between 'integer' and 'real'. For example,

```
xvar.Type = 'integer';
```
- Transform of real or integer variables between 'log' and 'none'. For example,

```
xvar.Transform = 'log';
```

Output Arguments

newresults — Optimization results

BayesianOptimization object

Optimization results, returned as a BayesianOptimization object.

BayesianOptimization | bayesopt

Introduced in R2016b

resume

Resume training ensemble

Syntax

```
ens1 = resume(ens,nlearn)
ens1 = resume(ens,nlearn,Name,Value)
```

Description

`ens1 = resume(ens,nlearn)` trains `ens` for `nlearn` more cycles. `resume` uses the same training options `fitcensemble` used to create `ens`.

Note You cannot resume training when `ens` is a Subspace ensemble created with 'AllPredictorCombinations' number of learners.

`ens1 = resume(ens,nlearn,Name,Value)` trains `ens` with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

`ens`

A classification ensemble, created with `fitcensemble`.

`nlearn`

A positive integer, the number of cycles for additional training of `ens`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes.

You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

nprint

Printout frequency, a positive integer scalar or 'off' (no printouts). Returns to the command line the number of weak learners trained so far. Useful when you train ensembles with many learners on large data sets.

Default: 'off'

Output Arguments

ens1

The classification ensemble `ens`, augmented with additional training.

Examples

Train Classification Ensemble for Additional Cycles

Train a classification ensemble for three cycles, and compare the resubstitution error obtained after training the ensemble for more cycles.

Load the ionosphere data set.

```
load ionosphere
```

Train a classification ensemble for three cycles and examine the resubstitution error.

```
ens = fitensemble(X,Y,'Method','GentleBoost','NumLearningCycles',3);  
L = resubLoss(ens)
```

```
L = 0.0114
```

Train for three more cycles and examine the new resubstitution error.

```
ens1 = resume(ens,3);  
L = resubLoss(ens1)
```

```
L = 0
```

The resubstitution error is much lower in the new ensemble than the original.

See Also

`fitcensemble`

resume

Resume training learners on cross-validation folds

Syntax

```
ens1 = resume(ens, nlearn)
ens1 = resume(ens, nlearn, Name, Value)
```

Description

`ens1 = resume(ens, nlearn)` trains `ens` in every fold for `nlearn` more cycles. `resume` uses the same training options `fitcensemble` used to create `ens`.

`ens1 = resume(ens, nlearn, Name, Value)` trains `ens` with additional options specified by one or more `Name, Value` pair arguments.

Input Arguments

ens

A cross-validated classification ensemble. `ens` is the result of either:

- The `fitcensemble` function with a cross-validation name-value pair. The names are 'crossval', 'kfold', 'holdout', 'leaveout', or 'cvpartition'.
- The `crossval` method applied to a classification ensemble.

nlearn

A positive integer, the number of cycles for additional training of `ens`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes.

You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

nprint

Printout frequency, a positive integer scalar or 'off' (no printouts). Returns to the command line the number of weak learners trained so far. Useful when you train ensembles with many learners on large data sets.

Default: 'off'

Output Arguments

ens1

The cross-validated classification ensemble `ens`, augmented with additional training.

Examples

Train Partitioned Classification Ensemble for More Cycles

Train a partitioned classification ensemble for 10 cycles, and compare the classification loss obtained after training the ensemble for more cycles.

Load the `ionosphere` data set.

```
load ionosphere
```

Train a partitioned classification ensemble for 10 cycles and examine the error.

```
t = templateTree('MaxNumSplits',1); % Weak learner template tree object
cvens = fitcensemble(X,Y,'Method','GentleBoost','NumLearningCycles',10,'Learners',t,'c
rng(10,'twister') % For reproducibility
L = kfoldLoss(cvens)
```

```
L = 0.0940
```

Train for 10 more cycles and examine the new error.

```
cvens = resume(cvens,10);
L = kfoldLoss(cvens)
```

$L = 0.0712$

The cross-validation error is lower in the ensemble after training for 10 more cycles.

resume

Resume training support vector machine (SVM) classifier

Syntax

```
UpdatedSVMModel = resume(SVMModel, numIter)
UpdatedSVMModel = resume(SVMModel, numIter, Name, Value)
```

Description

`UpdatedSVMModel = resume(SVMModel, numIter)` returns an updated support vector machine (SVM) classifier `UpdatedSVMModel` by training the SVM classifier `SVMModel` for `numIter` more iterations. Like `SVMModel`, the updated SVM classifier is a `ClassificationSVM` classifier.

`resume` continues applying the training options set when `SVMModel` was trained with `fitcsvm`.

`UpdatedSVMModel = resume(SVMModel, numIter, Name, Value)` returns `UpdatedSVMModel` with additional options specified by one or more name-value pair arguments. For example, you can specify the verbosity level.

Examples

Resume Training SVM Classifier

Train an SVM classifier and intentionally cause the solver to fail to converge onto a solution. Then resume training the classifier without having to restart the entire learning process.

Load the ionosphere data set.

```
load ionosphere
rng(1); % For reproducibility
```

Train an SVM classifier. Specify that the optimization routine uses at most 50 iterations.

```
SVMMoDel = fitcsvm(X,Y,'IterationLimit',50);  
DidConverge = SVMMoDel.ConvergenceInfo.Converged  
  
DidConverge = logical  
    0
```

```
Reason = SVMMoDel.ConvergenceInfo.ReasonForConvergence
```

```
Reason =  
'NoConvergence'
```

`DidConverge = 0` indicates that the optimization routine did not converge onto a solution. `Reason` states the reason why the routine did not converge. Therefore, `SVMMoDel` is a partially trained SVM classifier.

Resume training the SVM classifier for another 1500 iterations.

```
UpdatedSVMMoDel = resume(SVMMoDel,1500);  
DidConverge = UpdatedSVMMoDel.ConvergenceInfo.Converged  
  
DidConverge = logical  
    1
```

```
Reason = UpdatedSVMMoDel.ConvergenceInfo.ReasonForConvergence
```

```
Reason =  
'DeltaGradient'
```

`DidConverge` indicates that the optimization routine converged onto a solution. `Reason` indicates that the gradient difference (`DeltaGradient`) reached its tolerance level (`DeltaGradientTolerance`). Therefore, `SVMMoDel` is a fully trained SVM classifier.

Monitor Training of SVM Classifier

Train an SVM classifier and intentionally cause the solver to fail to converge onto a solution. Then resume training the classifier without having to restart the entire learning process. Compare values of the resubstitution loss for the partially trained classifier and the fully trained classifier.

Load the ionosphere data set.

```
load ionosphere
```

Train an SVM classifier. Specify that the optimization routine uses at most 100 iterations. Monitor the algorithm specifying that the software prints diagnostic information every 50 iterations.

```
SVMMoDel = fitcsvm(X,Y, 'IterationLimit',100, 'Verbose',1, 'NumPrint',50);
```

Iteration	Set	Set Size	Feasibility Gap	Delta Gradient	KKT Violation
0	active	351	9.971591e-01	2.000000e+00	1.000000e+00
50	active	351	8.064425e-01	3.736929e+00	2.161317e+00

SVM optimization did not converge to the required tolerance.

The software prints an iterative display to the Command Window. The printout indicates that the optimization routine has not converged onto a solution.

Estimate the resubstitution loss of the partially trained SVM classifier.

```
partialLoss = resubLoss(SVMMoDel)
```

```
partialLoss = 0.1054
```

The training sample misclassification error is approximately 12%.

Resume training the classifier for another 1500 iterations. Specify that the software print diagnostic information every 250 iterations.

```
UpdatedSVMMoDel = resume(SVMMoDel,1500, 'NumPrint',250)
```

Iteration	Set	Set Size	Feasibility Gap	Delta Gradient	KKT Violation
250	active	351	1.441556e-01	1.701201e+00	1.015454e+00
500	active	351	3.277736e-03	9.155364e-02	4.830095e-02
750	active	351	3.928360e-04	1.367091e-02	9.155316e-03
1000	active	351	4.802547e-05	1.551900e-03	7.765843e-04
1044	active	351	3.602828e-05	9.382457e-04	5.182592e-04

Exiting Active Set upon convergence due to DeltaGradient.

```

UpdatedSVMModel =
  ClassificationSVM
    ResponseName: 'Y'
    CategoricalPredictors: []
    ClassNames: {'b' 'g'}
    ScoreTransform: 'none'
    NumObservations: 351
    Alpha: [103x1 double]
    Bias: -3.8828
    KernelParameters: [1x1 struct]
    BoxConstraints: [351x1 double]
    ConvergenceInfo: [1x1 struct]
    IsSupportVector: [351x1 logical]
    Solver: 'SMO'

```

Properties, Methods

The software resumes at iteration 1000 and uses the same verbosity level as the one set when you trained the model using `fitcsvm`. The `printout` indicates that the algorithm converged. Therefore, `UpdatedSVMModel` is a fully trained `ClassificationSVM` classifier.

```
updatedLoss = resubLoss(UpdatedSVMModel)
```

```
updatedLoss = 0.0769
```

The training sample misclassification error of the fully trained classifier is approximately 8%.

Input Arguments

SVMModel — Full, trained SVM classifier

`ClassificationSVM` classifier

Full, trained SVM classifier, specified as a `ClassificationSVM` model trained with `fitcsvm`.

numIter — Number of iterations

positive integer

Number of iterations to continue training the SVM classifier, specified as a positive integer.

Data Types: double

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example: `resume(SVMModel, 500, 'Verbose', 2)` trains `SVMModel` for 500 more iterations and specifies displaying diagnostic messages and saving convergence criteria at every iteration.

Verbose — Verbosity level

0 | 1 | 2

Verbosity level, specified as the comma-separated pair consisting of `'Verbose'` and 0, 1, or 2. `Verbose` controls the amount of optimization information displayed in the Command Window and saved as a structure to `SVMModel.ConvergenceInfo.History`.

This table summarizes the verbosity level values.

Value	Description
0	The software does not display or save convergence information.
1	The software displays diagnostic messages and saves convergence criteria every <i>numprint</i> iterations, where <i>numprint</i> is the value of the <code>'NumPrint'</code> name-value pair argument.
2	The software displays diagnostic messages and saves convergence criteria at every iteration.

By default, `Verbose` is the value that `fitcsvm` uses to train `SVMModel`.

Example: `'Verbose', 1`

Data Types: single

NumPrint — Number of iterations between diagnostic message printouts

nonnegative integer

Number of iterations between diagnostic message printouts, specified as the comma-separated pair consisting of 'NumPrint' and a nonnegative integer.

If you set 'Verbose', 1 and 'NumPrint', *numprint*, then the software displays all optimization diagnostic messages from SMO [1] and ISDA [2] every *numprint* iterations in the Command Window.

By default, NumPrint is the value that `fitcsvm` uses to train `SVMModel`.

Example: 'NumPrint', 500

Data Types: single

Tips

If optimization does not converge and the solver is 'SMO' or 'ISDA', then try to resume training the SVM classifier.

Introduced in R2014a

resume

Resume training ensemble

Syntax

```
ens1 = resume(ens, nlearn)
ens1 = resume(ens, nlearn, Name, Value)
```

Description

`ens1 = resume(ens, nlearn)` trains `ens` for `nlearn` more cycles. `resume` uses the same training options `fitrensemble` used to create `ens`.

`ens1 = resume(ens, nlearn, Name, Value)` trains `ens` with additional options specified by one or more `Name, Value` pair arguments.

Input Arguments

`ens`

A regression ensemble, created with `fitrensemble`.

`nlearn`

A positive integer, the number of cycles for additional training of `ens`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

nprint

Printout frequency, a positive integer scalar or 'off' (no printouts). Returns to the command line the number of weak learners trained so far. Useful when you train ensembles with many learners on large data sets.

Default: 'off'

Output Arguments

ens1

The regression ensemble `ens`, augmented with additional training.

Examples

Train Regression Ensemble for Additional Cycles

Train a regression ensemble for 50 cycles, and compare the resubstitution error obtained after training the ensemble for more cycles.

Load the `carsmall` data set and select displacement, horsepower, and vehicle weight as predictors.

```
load carsmall
X = [Displacement Horsepower Weight];
```

Train a regression ensemble for 50 cycles and examine the resubstitution error.

```
ens = fitensemble(X,MPG,'NumLearningCycles',50);
L = resubLoss(ens)
```

```
L = 0.5563
```

Train for 50 more cycles and examine the new resubstitution error.

```
ens = resume(ens,50);
L = resubLoss(ens)
```

```
L = 0.3463
```

The resubstitution error is lower in the new ensemble than in the original.

See Also

fitrensemble

resume

Resume training ensemble

Syntax

```
ens1 = resume(ens, nlearn)
ens1 = resume(ens, nlearn, Name, Value)
```

Description

`ens1 = resume(ens, nlearn)` trains `ens` in every fold for `nlearn` more cycles. `resume` uses the same training options `fitensemble` used to create `ens`.

`ens1 = resume(ens, nlearn, Name, Value)` trains `ens` with additional options specified by one or more `Name, Value` pair arguments.

Input Arguments

ens

A cross-validated regression ensemble. `ens` is the result of either:

- The `fitensemble` function with a cross-validation name-value pair. The names are 'crossval', 'kfold', 'holdout', 'leaveout', or 'cvpartition'.
- The `crossval` method applied to a regression ensemble.

nlearn

A positive integer, the number of cycles for additional training of `ens`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes.

You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

nprint

Printout frequency, a positive integer scalar or 'off' (no printouts). Returns to the command line the number of weak learners trained so far. Useful when you train ensembles with many learners on large data sets.

Default: 'off'

Output Arguments

ens1

The cross-validated regression ensemble `ens`, augmented with additional training.

Examples

Cross-Validate Regression Ensemble Augmented with Additional Training

Examine the cross-validation error after training a regression ensemble for more cycles.

Load the `carsmall` data set and select displacement, horsepower, and vehicle weight as predictors.

```
load carsmall
X = [Displacement Horsepower Weight];
```

Train a regression ensemble for 50 cycles.

```
ens = fitensemble(X,MPG,'NumLearningCycles',50);
```

Cross-validate the ensemble and examine the cross-validation error.

```
rng(10,'twister') % For reproducibility
cvens = crossval(ens);
L = kfoldLoss(cvens)
```

```
L = 27.9435
```

Train for 50 more cycles and examine the new cross-validation error.

```
cvens = resume(cvens,50);  
L = kfoldLoss(cvens)
```

```
L = 28.7114
```

The additional training did not improve the cross-validation error.

`fitrensemble` | `kfoldLoss`

resume

Class: RegressionSVM

Resume training support vector machine regression model

Syntax

```
updatedMdl = resume(mdl,numIter)
updatedMdl = resume(mdl,numIter,Name,Value)
```

Description

`updatedMdl = resume(mdl,numIter)` returns an updated support vector machine (SVM) regression model, `updatedMdl`, by training the model for an additional number of iterations as specified by `numIter`.

`resume` applies the same training options to `updatedMdl` that you set when using `fitrsvm` to train `mdl`.

`updatedMdl = resume(mdl,numIter,Name,Value)` returns an updated SVM regression model with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

mdl — Full, trained SVM regression model

RegressionSVM model

Full, trained SVM regression model, specified as a RegressionSVM model trained using `fitrsvm`.

numIter — Number of iterations

positive integer value

Number of iterations to continue training the SVM regression model, specified as a positive integer value.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Verbose — Verbosity level

`0` | `1` | `2`

Verbosity level, specified as the comma-separated pair consisting of `'Verbose'` and either `0`, `1`, or `2`. `Verbose` controls the amount of optimization information that the software displays to the Command Window and is saved in the model as `mdl.ModelParameters.VerbosityLevel`.

By default, `Verbose` is the value that `fitrsvm` used to train `mdl`.

Example: `'Verbose', 1`

Data Types: `single` | `double`

NumPrint — Number of iterations between diagnostic message printouts

nonnegative integer value

Number of iterations between diagnostic message printouts, specified as the comma-separated pair consisting of `'NumPrint'` and a nonnegative integer.

If you set `'Verbose', 1` and `'NumPrint', numprint`, then the software displays optimization diagnostic messages to the Command Window every `numprint` number of iterations .

By default, `NumPrint` is the value that `fitrsvm` used to train `mdl`.

Example: `'NumPrint', 500`

Data Types: `single` | `double`

Output Arguments

updatedMdl — Updated SVM regression model

RegressionSVM model

Updated SVM regression model, returned as a RegressionSVM model.

Examples

Resume Training an SVM Regression Model

This example shows how to resume training an SVM regression model that failed to converge without restarting the entire learning process.

Load the carsmall data set.

```
load carsmall
rng default % for reproducibility
```

Specify Acceleration, Cylinders, Displacement, Horsepower, and Weight as the predictor variables (X) and MPG as the response variable (Y).

```
X = [Acceleration,Cylinders,Displacement,Horsepower,Weight];
Y = MPG;
```

Train a linear SVM regression model. For illustration purposes, set the iteration limit to 50. Standardize the data.

```
mdl = fitsvm(X,Y,'IterationLimit',50,'Standardize',true);
```

Check to confirm whether the model converged.

```
mdl.ConvergenceInfo.Converged
```

```
ans =
```

```
0
```

The returned value of 0 indicates that the model did not converge.

Resume training the model for up to an additional 100 iterations.

```
updatedMdl = resume(mdl,100);
```

Check to confirm whether the updated model converged.

```
updatedMdl.ConvergenceInfo.Converged
```

```
ans =
```

```
1
```

The returned value of 1 indicates that the updated model did converge.

Check the reason for convergence and the total number of iterations required.

```
updatedMdl.ConvergenceInfo.ReasonForConvergence
```

```
updatedMdl.NumIterations
```

```
ans =
```

```
FeasibilityGap
```

```
ans =
```

```
97
```

The model converged because the feasibility gap reached its tolerance value after 97 iterations.

Tips

If optimization has not converged and 'Solver' is set to 'SMO' or 'ISDA', then try to resume training the SVM regression model.

Introduced in R2015b

rica

Feature extraction by using reconstruction ICA

Syntax

```
Mdl = rica(X,q)
Mdl = rica(X,q,Name,Value)
```

Description

`Mdl = rica(X,q)` returns a reconstruction independent component analysis (RICA) model object that contains the results from applying RICA to the table or matrix of predictor data X containing p variables. q is the number of features to extract from X , therefore `rica` learns a p -by- q matrix of transformation weights. For undercomplete or overcomplete feature representations, q can be less than or greater than the number of predictor variables, respectively.

- To access the learned transformation weights, use `Mdl.TransformWeights`.
- To transform X to the new set of features by using the learned transformation, pass `Mdl` and X to `transform`.

`Mdl = rica(X,q,Name,Value)` uses additional options specified by one or more `Name,Value` pair arguments. For example, you can standardize the predictor data or specify the value of the penalty coefficient in the reconstruction term of the objective function.

Examples

Create Reconstruction ICA Object

Create a `ReconstructionICA` object by using the `rica` function.

Load the `caltech101` image patches.

```
data = load('caltech101patches');
size(data.X)

ans = 1×2

    100000    363
```

There are 100,000 image patches, each containing 363 features.

Extract 100 features from the data.

```
rng default % For reproducibility
q = 100;
Mdl = rica(data.X,q,'IterationLimit',100)
```

Warning: Solver LBFGS was not able to converge to a solution.

```
Mdl =
  ReconstructionICA
    ModelParameters: [1x1 struct]
      NumPredictors: 363
    NumLearnedFeatures: 100
           Mu: []
          Sigma: []
       FitInfo: [1x1 struct]
    TransformWeights: [363x100 double]
InitialTransformWeights: []
NonGaussianityIndicator: [100x1 double]
```

Properties, Methods

`rica` issues a warning because it stopped due to reaching the iteration limit, instead of reaching a step-size limit or a gradient-size limit. You can still use the learned features in the returned object by calling the `transform` function.

Input Arguments

X — Predictor data

numeric matrix | table

Predictor data, specified as an n -by- p numeric matrix or table. Rows correspond to individual observations and columns correspond to individual predictor variables. If X is a table, then all of its variables must be numeric vectors.

Data Types: `single` | `double` | `table`

q — Number of features to extract

positive integer

Number of features to extract from the predictor data, specified as a positive integer.

`rica` stores a p -by- q transform weight matrix in `Mdl.TransformWeights`. Therefore, setting very large values for q can result in greater memory consumption and increased computation time.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `Mdl = rica(X,q,'IterationLimit',200,'Standardize',true)` runs `rica` with optimization iterations limited to 200 and standardized predictor data.

IterationLimit — Maximum number of iterations

1000 (default) | positive integer

Maximum number of iterations, specified as the comma-separated pair consisting of `'IterationLimit'` and a positive integer.

Example: `'IterationLimit',1e6`

Data Types: `single` | `double`

VerbosityLevel — Verbosity level

0 (default) | nonnegative integer

Verbosity level for monitoring algorithm convergence, specified as the comma-separated pair consisting of `'VerbosityLevel'` and a value in this table.

Value	Description
0	rica does not display convergence information at the command line.
Positive integer	rica displays convergence information at the command line.

Convergence Information

Heading	Meaning
FUN VALUE	Objective function value.
NORM GRAD	Norm of the gradient of the objective function.
NORM STEP	Norm of the iterative step, meaning the distance between the previous point and the current point.
CURV	OK means the weak Wolfe condition is satisfied. This condition is a combination of sufficient decrease of the objective function and a curvature condition.
GAMMA	Inner product of the step times the gradient difference, divided by the inner product of the gradient difference with itself. The gradient difference is the gradient at the current point minus the gradient at the previous point. Gives diagnostic information on the objective function curvature.
ALPHA	Step direction multiplier, which differs from 1 when the algorithm performed a line search.
ACCEPT	YES means the algorithm found an acceptable step to take.

Example: 'VerbosityLevel',1

Data Types: single | double

Lambda — Regularization coefficient value

1 (default) | positive numeric scalar

Regularization coefficient value for the transform weight matrix, specified as the comma-separated pair consisting of 'Lambda' and a positive numeric scalar. If you specify 0, then there is no regularization term in the objective function.

Example: 'Lambda',0.1

Data Types: single | double

Standardize — Flag to standardize predictor data

false (default) | true

Flag to standardize the predictor data, specified as the comma-separated pair consisting of 'Standardize' and true (1) or false (0).

If Standardize is true, then:

- `rica` centers and scales each column of the predictor data (X) by the column mean and standard deviation, respectively.
- `rica` extracts new features by using the standardized predictor matrix, and stores the predictor variable means and standard deviations in properties `Mu` and `Sigma` of `Mdl`.

Example: 'Standardize', true

Data Types: logical

ContrastFcn — Contrast function

'logcosh' (default) | 'exp' | 'sqrt'

Contrast function, specified as 'logcosh', 'exp', or 'sqrt'. The contrast function is a smooth function that is similar to an absolute value function. The `rica` objective function contains a term

$$\sum_{j=1}^q \frac{1}{n_i} \sum_{i=1}^n g(w_j^T \tilde{x}_i),$$

where g represents the contrast function, the w_j are the variables over which the optimization takes place, and the \tilde{x}_i are data.

The three available contrast functions are:

- 'logcosh' — $g = \frac{1}{2} \log(\cosh(2x))$
- 'exp' — $g = -\exp\left(-\frac{x^2}{2}\right)$
- 'sqrt' — $g = \sqrt{x^2 + 10^{-8}}$

Example: 'ContrastFcn', 'exp'

InitialTransformWeights — Transformation weights that initialize optimization`randn(p,q)` (default) | numeric matrix

Transformation weights that initialize optimization, specified as the comma-separated pair consisting of 'InitialTransformWeights' and a p -by- q numeric matrix. p must be the number of columns or variables in X and q is the value of q .

Tip You can continue optimizing a previously returned transform weight matrix by passing it as an initial value in another call to `rica`. The output model object `Mdl` stores a learned transform weight matrix in the `TransformWeights` property.

Example: 'InitialTransformWeights',`Mdl.TransformWeights`

Data Types: `single` | `double`

NonGaussianityIndicator — Non-Gaussianity of sources`ones(q,1)` (default) | length- q vector of ± 1

Non-Gaussianity of sources, specified as a length- q vector of ± 1 .

- `NonGaussianityIndicator(k) = 1` means `rica` models the k th source as super-Gaussian, with a sharp peak at 0.
- `NonGaussianityIndicator(k) = -1` means `rica` models the k th source as sub-Gaussian.

Data Types: `single` | `double`

GradientTolerance — Relative convergence tolerance on gradient norm`1e-6` (default) | positive numeric scalar

Relative convergence tolerance on gradient norm, specified as the comma-separated pair consisting of 'GradientTolerance' and a positive numeric scalar. This gradient is the gradient of the objective function.

Example: 'GradientTolerance',`1e-4`

Data Types: `single` | `double`

StepTolerance — Absolute convergence tolerance on step size`1e-6` (default) | positive numeric scalar

Absolute convergence tolerance on the step size, specified as the comma-separated pair consisting of 'StepTolerance' and a positive numeric scalar.

Example: 'StepTolerance', 1e-4

Data Types: single | double

Output Arguments

Mdl — Learned reconstruction ICA model

ReconstructionICA model object

Learned reconstruction ICA model, returned as a ReconstructionICA model object.

To access properties of Mdl, use dot notation. For example:

- To access the learned transform weights, use `Mdl.TransformWeights`.
- To access the structure of fitting information, use `Mdl.FitInfo`.

Algorithms

The `rica` function creates a linear transformation of input features to output features. The transformation is based on optimizing a nonlinear objective function that roughly balances statistical independence of the output features versus the ability to reconstruct the input data using the output features.

For details, see “Reconstruction ICA Algorithm” on page 15-159.

Introduced in R2017a

ridge

Ridge regression

Syntax

```
B = ridge(y,X,k)
B = ridge(y,X,k,scaled)
```

Description

`B = ridge(y,X,k)` returns coefficient estimates for ridge regression models on page 32-6241 of the predictor data `X` and the response `y`. Each column of `B` corresponds to a particular ridge parameter `k`. By default, the function computes `B` after centering and scaling the predictors to have mean 0 and standard deviation 1. Because the model does not include a constant term, do not add a column of 1s to `X`.

`B = ridge(y,X,k,scaled)` specifies the scaling for the coefficient estimates in `B`. When `scaled` is 1 (default), `ridge` does not restore the coefficients to the original data scale. When `scaled` is 0, `ridge` restores the coefficients to the scale of the original data. For more information, see “Coefficient Scaling” on page 32-6241.

Examples

Ridge Regression

Perform ridge regression for a range of ridge parameters and observe how the coefficient estimates change.

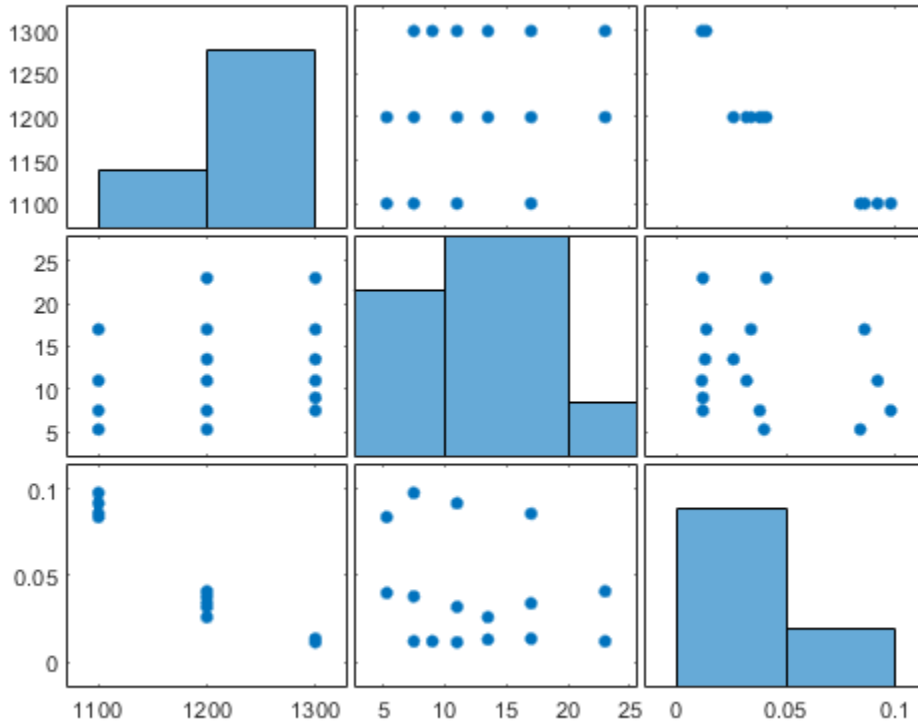

Load the acetylene data set.

```
load acetylene
```

`acetylene` contains observations for the predictor variables `x1`, `x2`, and `x3`, and the response variable `y`.

Plot the predictor variables against each other. Observe any correlation between the variables.

```
plotmatrix([x1 x2 x3])
```

For example, note the linear correlation between x1 and x3.

Compute coefficient estimates for a multilinear model with interaction terms, for a range of ridge parameters. Use `x2fx` to create interaction terms and `ridge` to perform ridge regression.

```
X = [x1 x2 x3];
D = x2fx(X, 'interaction');
D(:,1) = []; % No constant term
```

```
k = 0:1e-5:5e-3;  
B = ridge(y,D,k);
```

Plot the ridge trace.

```
figure  
plot(k,B, 'LineWidth',2)  
ylim([-100 100])  
grid on  
xlabel('Ridge Parameter')  
ylabel('Standardized Coefficient')  
title('Ridge Trace')  
legend('x1', 'x2', 'x3', 'x1x2', 'x1x3', 'x2x3')
```

The estimates stabilize to the right of the plot. Note that the coefficient of the $x_2 \times x_3$ interaction term changes sign at a value of the ridge parameter $\approx 5 * 10^{-4}$.

Predict Values Using Ridge Regression

Predict miles per gallon (MPG) values using ridge regression.

Load the `carbig` data set.

```
load carbig
X = [Acceleration Weight Displacement Horsepower];
y = MPG;
```

Split the data into training and test sets.

```
n = length(y);
rng('default') % For reproducibility
c = cvpartition(n, 'HoldOut', 0.3);
idxTrain = training(c, 1);
idxTest = ~idxTrain;
```

Find the coefficients of a ridge regression model (with $k = 5$).

```
k = 5;
b = ridge(y(idxTrain), X(idxTrain, :), k, 0);
```

Predict MPG values for the test data using the model.

```
yhat = b(1) + X(idxTest, :)*b(2:end);
```

Compare the predicted values to the actual miles per gallon (MPG) values using a reference line.

```
scatter(y(idxTest), yhat)
hold on
plot(y(idxTest), y(idxTest))
xlabel('Actual MPG')
ylabel('Predicted MPG')
hold off
```

Input Arguments

y — Response data

numeric vector

Response data, specified as an n -by-1 numeric vector, where n is the number of observations.

Data Types: `single` | `double`

X — Predictor data

numeric matrix

Predictor data, specified as an n -by- p numeric matrix. The rows of X correspond to the n observations, and the columns of X correspond to the p predictors.

Data Types: `single` | `double`

k — Ridge parameters

numeric vector

Ridge parameters, specified as a numeric vector.

Example: `[0.2 0.3 0.4 0.5]`

Data Types: `single` | `double`

scaled — Scaling flag

1 (default) | 0

Scaling flag that determines whether the coefficient estimates in B are restored to the scale of the original data, specified as either 0 or 1. If `scaled` is 0, then `ridge` performs this additional transformation. In this case, B contains $p+1$ coefficients for each value of k , with the first row of B corresponding to a constant term in the model. If `scaled` is 1, then the software omits the additional transformation, and B contains p coefficients without a constant term coefficient.

Output Arguments

B — Coefficient estimates

numeric matrix

Coefficient estimates, returned as a numeric matrix. The rows of B correspond to the predictors in X , and the columns of B correspond to the ridge parameters k .

If `scaled` is 1, then B is a p -by- m matrix, where m is the number of elements in k . If `scaled` is 0, then B is a $(p+1)$ -by- m matrix.

Definitions

Ridge Regression

Ridge regression is a method for estimating coefficients of linear models that include linearly correlated predictors.

Coefficient estimates for multiple linear regression models rely on the independence of the model terms. When terms are correlated and the columns of the design matrix X have an approximate linear dependence, the matrix $(X^T X)^{-1}$ is close to singular. Therefore, the least-squares estimate

$$\hat{\beta} = (X^T X)^{-1} X^T y$$

is highly sensitive to random errors in the observed response y , producing a large variance. This situation of multicollinearity can arise, for example, when you collect data without an experimental design.

Ridge regression addresses the problem of multicollinearity by estimating regression coefficients using

$$\hat{\beta} = (X^T X + kI)^{-1} X^T y$$

where k is the ridge parameter and I is the identity matrix. Small, positive values of k improve the conditioning of the problem and reduce the variance of the estimates. While biased, the reduced variance of ridge estimates often results in a smaller mean squared error when compared to least-squares estimates.

Coefficient Scaling

The scaling of the coefficient estimates for the ridge regression models depends on the value of the scaled input argument.

Suppose the ridge parameter k is equal to 0. The coefficients returned by `ridge`, when `scaled` is equal to `1`, are estimates of the b_i^1 in the multilinear model

$$y - \mu_y = b_1^1 z_1 + \dots + b_p^1 z_p + \varepsilon$$

where $z_i = (x_i - \mu_i)/\sigma_i$ are the centered and scaled predictors, $y - \mu_y$ is the centered response, and ε is an error term. You can rewrite the model as

$$y = b_0^0 + b_1^0 x_1 + \dots + b_p^0 x_p + \varepsilon$$

$b_0^0 = \mu_y - \sum_{i=1}^p \frac{b_i^1 \mu_i}{\sigma_i}$ and $b_i^0 = \frac{b_i^1}{\sigma_i}$. The b_i^0 terms correspond to the coefficients returned by `ridge` when `scaled` is equal to `0`.

More generally, for any value of `k`, if `B1 = ridge(y, X, k, 1)`, then

```
m = mean(X);
s = std(X,0,1)';
B1_scaled = B1./s;
B0 = [mean(y)-m*B1_scaled; B1_scaled]
```

where `B0 = ridge(y, X, k, 0)`.

Tips

- `ridge` treats NaN values in `X` or `y` as missing values. `ridge` omits observations with missing values from the ridge regression fit.
- In general, set `scaled` equal to `1` to produce plots where the coefficients are displayed on the same scale. See “Ridge Regression” on page 32-6235 for an example using a ridge trace plot, where the regression coefficients are displayed as a function of the ridge parameter. When making predictions, set `scaled` equal to `0`. For an example, see “Predict Values Using Ridge Regression” on page 32-6238.

Alternative Functionality

- Ridge, lasso, and elastic net regularization are all methods for estimating the coefficients of a linear model while penalizing large coefficients. The type of penalty depends on the method (see “Definitions” on page 32-3671 for more details). To perform lasso or elastic net regularization, use `lasso` instead.
- If you have high-dimensional full or sparse predictor data, you can use `fitrlinear` instead of `ridge`. When using `fitrlinear`, specify the 'Regularization', 'ridge' name-value pair argument. Set the value of the 'Lambda' name-value pair argument to a vector of the ridge parameters of your choice. `fitrlinear` returns a trained linear model `Mdl`. You can access the coefficient estimates stored in the `Beta` property of the model by using `Mdl.Beta`.

Introduced before R2006a

robustcov

Robust multivariate covariance and mean estimate

Syntax

```
sig = robustcov(x)
[ sig, mu ] = robustcov(x)
[ sig, mu, mah ] = robustcov(x)
[ sig, mu, mah, outliers ] = robustcov(x)
[ sig, mu, mah, outliers, s ] = robustcov(x)
[ ___ ] = robustcov(x, Name, Value)
```

Description

`sig = robustcov(x)` returns the robust covariance estimate `sig` of the multivariate data contained in `x`.

`[sig, mu] = robustcov(x)` also returns an estimate of the robust Minimum Covariance Determinant (MCD) mean, `mu`.

`[sig, mu, mah] = robustcov(x)` also returns the robust distances `mah`, computed as the Mahalanobis distances of the observations using the robust estimates of the mean and covariance.

`[sig, mu, mah, outliers] = robustcov(x)` also returns the indices of the observations retained as outliers in the sample data, `outliers`.

`[sig, mu, mah, outliers, s] = robustcov(x)` also returns a structure `s` that contains information about the estimate.

`[___] = robustcov(x, Name, Value)` returns any of the arguments shown in the previous syntaxes, using additional options specified by one or more `Name, Value` pair arguments. For example, you can specify which robust estimator to use or the start method to use for the attractors.

Examples

Detect Outliers Using Distance-Distance Plots

Use a Gaussian copula to generate random data points from a bivariate distribution.

```
rng default
rho = [1,0.05;0.05,1];
u = copularnd('Gaussian',rho,50);
```

Modify 5 randomly selected observations to be outliers.

```
noise = randperm(50,5);
u(noise,1) = u(noise,1)*5;
```

Calculate the robust covariance matrices using the three available methods: Fast-MCD, Orthogonalized Gnanadesikan-Kettenring (OGK), and Olive-Hawkins.

```
[Sfmc, Mfmc, dfmc, Outfmc] = robustcov(u);
[Sogk, Mogk, dogk, Outogk] = robustcov(u,'Method','ogk');
[Soh, Moh, doh, Outoh] = robustcov(u,'Method','olivehawkins');
```

Calculate the classical distance values for the sample data using the Mahalanobis measure.

```
d_classical = pdist2(u, mean(u),'mahal');
p = size(u,2);
chi2quantile = sqrt(chi2inv(0.975,p));
```

Create DD Plots for each robust covariance calculation method.

```
figure
subplot(2,2,1)
plot(d_classical, dfmc, 'o')
line([chi2quantile, chi2quantile], [0, 30], 'color', 'r')
line([0, 6], [chi2quantile, chi2quantile], 'color', 'r')
hold on
plot(d_classical(Outfmc), dfmc(Outfmc), 'r+')
xlabel('Mahalanobis Distance')
ylabel('Robust Distance')
title('DD Plot, FMCD method')
hold off
```

```
subplot(2,2,2)
plot(d_classical, dogk, 'o')
line([chi2quantile, chi2quantile], [0, 30], 'color', 'r')
line([0, 6], [chi2quantile, chi2quantile], 'color', 'r')
hold on
plot(d_classical(Outogk), dogk(Outogk), 'r+')
xlabel('Mahalanobis Distance')
ylabel('Robust Distance')
title('DD Plot, OGK method')
hold off

subplot(2,2,3)
plot(d_classical, doh, 'o')
line([chi2quantile, chi2quantile], [0, 30], 'color', 'r')
line([0, 6], [chi2quantile, chi2quantile], 'color', 'r')
hold on
plot(d_classical(Outoh), doh(Outoh), 'r+')
xlabel('Mahalanobis Distance')
ylabel('Robust Distance')
title('DD Plot, Olive-Hawkins method')
hold off
```

In a DD plot, the data points tend to cluster in a straight line that passes through the origin. Points that are far removed from this line are generally considered outliers. In each of the previous plots, the red '+' symbol indicates the data points that `robustcov` considers to be outliers.

Evaluate Data for Multivariate Normal Distribution

This example shows how to use `robustcov` to evaluate sample data for multivariate normal or other elliptically-contoured (EC) distributions.

Generate random sample data from a multivariate normal distribution. Calculate the Mahalanobis distances for the robust covariance estimates (using the Olive-Hawkins method) and the classical covariance estimates.

```
rng('default')
x1 = mvnrnd(zeros(1,3),eye(3),200);
[~,~,d1] = robustcov(x1,'Method','olivehawkins');
d_classical1 = pdist2(x1,mean(x1),'mahalanobis');
```

Generate random sample data from an elliptically-contoured (EC) distribution. Calculate the Mahalanobis distances for the robust covariance estimates (using the Olive-Hawkins method) and the classical covariance estimates.

```
mu1 = [0 0 0];
sig1 = eye(3);
mu2 = [0 0 0];
sig2 = 25*eye(3);
x2 = [mvnrnd(mu1,sig1,120);mvnrnd(mu2,sig2,80)];
[~,~,d2] = robustcov(x2,'Method','olivehawkins');
d_classical2 = pdist2(x2,mean(x2),'mahalanobis');
```

Generate random sample data from a multivariate lognormal distribution, which is neither multivariate normal or elliptically-contoured. Calculate the Mahalanobis distances for the robust covariance estimates (using the Olive-Hawkins method) and the classical covariance estimates.

```
x3 = exp(x1);
[~,~,d3] = robustcov(x3,'Method','olivehawkins');
d_classical3 = pdist2(x3,mean(x3),'mahalanobis');
```

Create a D-D Plot for each of the three sets of sample data to compare.

```
figure
subplot(2,2,1)
plot(d_classical1,d1,'o')
line([0 4.5],[0,4.5])
xlabel('Mahalanobis Distance')
ylabel('Robust Distance')
title('DD Plot, Multivariate Normal')

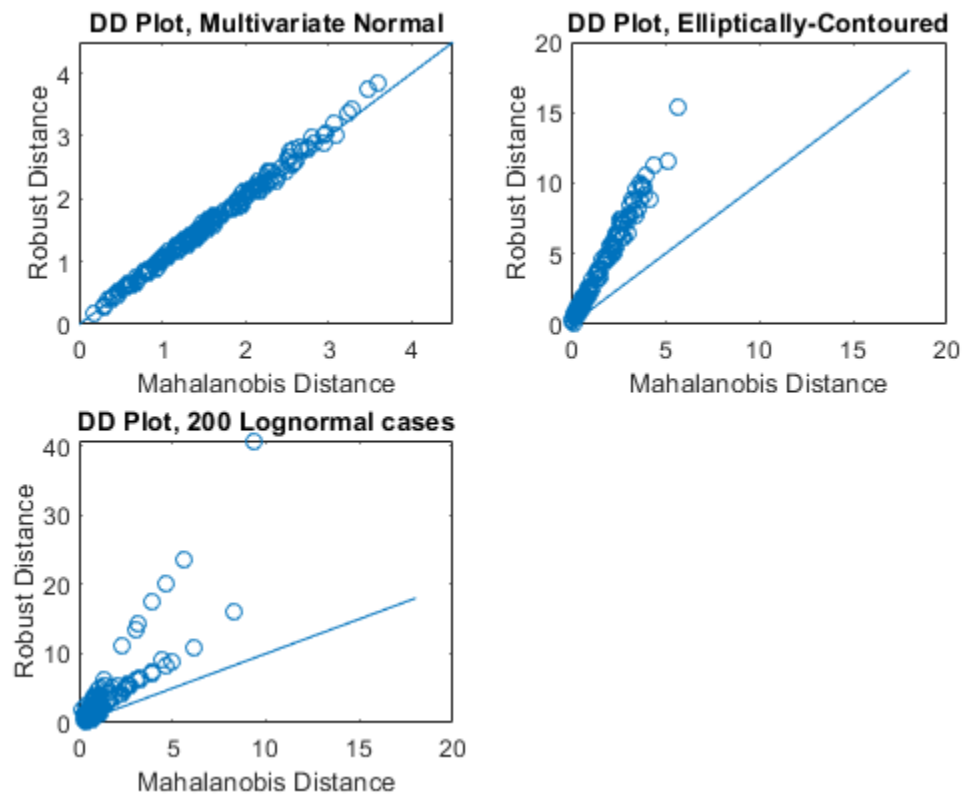

subplot(2,2,2)
plot(d_classical2,d2,'o')
line([0 18],[0,18])
xlabel('Mahalanobis Distance')
```

```

ylabel('Robust Distance')
title('DD Plot, Elliptically-Contoured')

subplot(2,2,3)
plot(d_classical3, d3, 'o')
line([0 18], [0, 18])
xlabel('Mahalanobis Distance')
ylabel('Robust Distance')
title('DD Plot, 200 Lognormal cases')

```

For data with a multivariate normal distribution (as shown in the upper left), the plotted points follow a straight, 45-degree line extending from the origin. For data with an elliptically-contoured distribution (as shown in the upper right), the plotted points follow

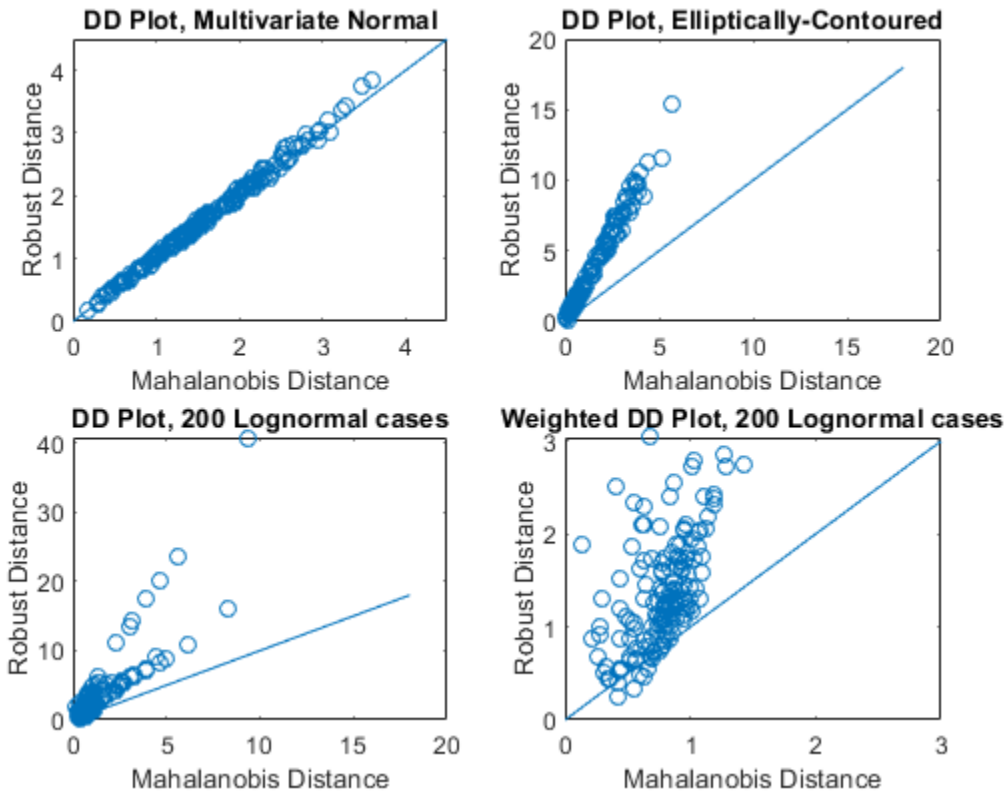

a straight line, but are not at a 45-degree angle to the origin. For the lognormal distribution (as shown in the lower left), the plotted points do not follow a straight line.

It is difficult to identify any pattern in the lognormal distribution plot because most of the points are in the lower left of the plot. Use a weighted DD plot to magnify this corner and reveal features that are obscured when large robust distances exist.

```
d3_weighted = d3(d3 < sqrt(chi2inv(0.975,3)));  
d_classical_weighted = d_classical3(d3 < sqrt(chi2inv(0.975,3)));
```

Add a fourth subplot to the figure to show the results of the weighting process on the lognormally distributed data.

```
subplot(2,2,4)  
plot(d_classical_weighted, d3_weighted, 'o')  
line([0 3], [0, 3])  
xlabel('Mahalanobis Distance')  
ylabel('Robust Distance')  
title('Weighted DD Plot, 200 Lognormal cases')
```

The scale on this plot indicates that it represents a magnified view of the original DD plot for the lognormal data. This view more clearly shows the lack of pattern to the plot, which indicates that the data is neither multivariate normal nor elliptically contoured.

Compute Robust Covariance and Plot the Outliers

Use a Gaussian copula to generate random data points from a bivariate distribution.

```
rng default
rho = [1,0.05;0.05,1];
u = copularnd('Gaussian',rho,50);
```

Modify 5 randomly selected observations to be outliers.

```
noise = randperm(50,5);  
u(noise,1) = u(noise,1)*5;
```

Visualize the bivariate data using a scatter plot.

```
figure  
scatter(u(:,1),u(:,2))
```

Most of the data points appear on the left side of the plot. However, some of the data points appear further to the right. These points are possible outliers that could affect the covariance matrix calculation.

Compare the classical and robust covariance matrices.

```
c = cov(u)
c = 2x2
    0.5523    0.0000
    0.0000    0.0913
```

```
rc = robustcov(u)
rc = 2x2
    0.1117    0.0364
    0.0364    0.1695
```

The classical and robust covariance matrices differ because the outliers present in the sample data influence the results.

Identify and plot the data points that `robustcov` considers outliers.

```
[sig,mu,mah,outliers] = robustcov(u);
figure
gscatter(u(:,1),u(:,2),outliers,'br','ox')
legend({'Not outliers','Outliers'})
```

`robustcov` identifies the data points on the right side of the plot as potential outliers, and treats them accordingly when calculating the robust covariance matrix.

Input Arguments

x — Sample data

matrix of numeric values

Sample data used to estimate the robust covariance matrix, specified as a matrix of numeric values. x is an n -by- p matrix where each row is an observation and each column is a variable.

robustcov removes any rows with missing predictor values when calculating the robust covariance matrix.

Data Types: single | double

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Example: 'Method', 'ogk', 'NumOGKIterations', 1 specifies the robust estimator as the Orthogonalized Gnanadesikan-Kettenring method and sets the number of orthogonalization iterations to 1.

For All Estimators

Method — Robust estimator

'fmcdd' (default) | 'ogk' | 'olivehawkins'

Robust estimator, specified as one of the following.

Name	Value
'fmcdd'	FAST-MCD (Minimum Covariance Determinant) on page 32-6260 method
'ogk'	Orthogonalized Gnanadesikan-Kettenring (OGK) on page 32-6261 estimate
'olivehawkins'	Concentration algorithm on page 32-6261 techniques, a family of fast, consistent and highly outlier-resistant methods

Example: 'Method', 'ogk'

For 'FMCD' and 'OliveHawkins' Estimators Only

OutlierFraction — Outlier fraction

0.5 (default) | numeric value in the range [0,0.5]

Outlier fraction, specified as the comma-separated pair consisting of 'OutlierFraction' and a numeric value in the range [0,0.5]. The value 1 -

OutlierFraction specifies the fraction of observations over which to minimize the covariance determinant.

The algorithm chooses a subsample of size $h = \text{ceiling}(n + p + 1) / 2$, where n is the number of observations and p is the number of dimensions. *OutlierFraction* is the value for which the maximum possible breakdown is achieved, and controls the size of the subsets h over which the covariance determinant is minimized. The algorithm then chooses h to approximately equal $(1 - \text{OutlierFraction}) \times n$ observations per subset.

Example: 'OutlierFraction',0.25

Data Types: single | double

NumTrials — Number of trials

positive integer value

Number of trials, specified as the comma-separated pair consisting of 'NumTrials' and a positive integer value.

If 'Method' is 'fmcD', then NumTrials is the number of random subsamples of size $(p + 1)$ drawn from the sample data as starting points in the algorithm. p is the number of dimensions in the sample data. In this case, the default value for NumTrials is 500.

If 'Method' is 'olivehawkins', then NumTrials is the number of trial fits, or attractors, to be used. In this case, the default value for NumTrials is 2. This option is only useful for non-deterministic starts.

Example: 'NumTrials',300

Data Types: single | double

For the FMCD Method Only

BiasCorrection — Flag to apply small-sample correction factor

1 (default) | 0

Flag to apply small-sample correction factor, specified as the comma-separated pair consisting of 'BiasCorrection' and either 1 or 0. A 1 value indicates that `robustcov` corrects for bias in the covariance estimate for small samples. A 0 value indicates that `robustcov` does not apply this correction.

Example: 'BiasCorrection',0

Data Types: logical

For the OGK Method Only**NumOGKIterations — Number of orthogonalization iterations**

2 (default) | positive integer value

Number of orthogonalization iterations, specified as the comma-separated pair consisting of 'NumOGKIterations' and a positive integer value. Generally, this value is set to 1 or 2, and further steps are unlikely to improve the estimation.

Example: 'NumIter',1

Data Types: single | double

UnivariateEstimator — Function for computing univariate robust estimates

'tauscale' (default) | 'qn'

Function for computing univariate robust estimates, specified as the comma-separated pair consisting of 'UnivariateEstimator' and one of the following.

Name	Value
'tauscale'	Use the “tau-scale” estimate of Yohai and Zamar, which is a truncated standard deviation and a weighted mean.
'qn'	Use the Qn scale estimate of Croux and Rousseuw.

Example: 'UnivariateEstimator','qn'

For the OliveHawkins method only**ReweightingMethod — Method for reweighting**

'rfch' (default) | 'rmvn'

Method for reweighting in the efficiency step, specified as the comma-separated pair consisting of 'ReweightingMethod' and one of the following.

Name	Value
'rfch'	Uses two reweighting steps. This is a standard method of reweighting to improve efficiency.

Name	Value
'rmvn'	Reweighted multivariate normal. Uses two reweighting steps that can be useful for estimating the true covariance matrix under a variety of outlier configurations when the clean data are multivariate normal.

Example: 'ReweightingMethod', 'rmvn'

NumConcentrationSteps — Number of concentration steps

10 (default) | positive integer value

Number of concentration steps, specified as the comma-separated pair consisting of 'NumConcentrationSteps' and a positive integer value.

Example: 'NumConcentrationSteps', 8

Data Types: single | double

StartMethod — Start method for each attractor

'classical' (default) | 'medianball' | 'elemental' | function handle | cell array

Start method for each attractor, specified as the comma-separated pair consisting of 'Start' and one of the following.

Name	Value
'classical'	Use the classical estimator as the start. This is the DGK attractor which, used on its own, is known as the DGK estimator.
'medianball'	Use the Median Ball as the start. The Median Ball is $(\text{med}(x), \text{eye}(p))$. So 50% of cases furthest in Euclidean distance from the sample median are trimmed for computing the MB start. This is the MB attractor which, used on its own, is known as the MB estimator.

Name	Value
'elemental'	The attractor is generated by concentration where the start is a randomly selected elemental start: the classical estimator applied to a randomly selected “elemental set” of $p + 1$ cases. This “elemental” attractor is computationally efficient, but suffers from theoretical drawbacks, as it is inconsistent and zero breakdown.

By default, the attractor is chosen as follows: If one of the attractors is 'medianball', then any attractor whose location estimate has greater Euclidean distance from `median(X)` than half the data (in other words, is outside the median ball) is not used. Then the final attractor is chosen based on the MCD criterion.

You can also specify a function handle for a function that returns two output arguments used for computing the initial location and scatter estimates..

You can also specify a cell array containing any combination of the options given in the previous table and function handles. The number of attractors used is equal to the length of the cell array. This option allows more control over the algorithm and the ability to specify a custom number of attractors and starts.

Example: 'StartMethod', 'medianball'

Output Arguments

sig — Robust covariance matrix estimates

numeric matrix

Robust covariance matrix estimates, returned as a p -by- p numeric matrix. p is the number of predictors contained in the sample data.

mu — Robust mean estimates

array of numeric values

Robust mean estimates, returned as a 1-by- p array of numeric values. p is the number of predictors contained in the sample data.

mah — Robust distances

array of numeric values

Robust distances, returned as a 1-by- n array of numeric values. `robustcov` removes any rows of x that contain missing data, so the number of rows of `mah` might be smaller than the number of rows in x .

outliers — Indices of outliers

array of logical values

Indices of observations retained as outliers in the sample data x , returned as a 1-by- n array of logical values. A 0 value indicates that the observation is not an outlier. A 1 value indicates that the observation is an outlier.

`robustcov` removes any rows of x that contain missing data, so the number of rows of `outliers` might be smaller than the number of rows in x .

s — Structure containing estimate information

structure

Structure containing estimate information, returned as a structure.

Algorithms

Minimum Covariance Determinant Estimate

Minimum covariance determinant (MCD) is the fastest estimator of multivariate location and scatter that is both consistent and robust. However, an exact evaluation of the MCD is impractical because it is computationally expensive to evaluate all possible subsets of the sample data. `robustcov` uses the FAST-MCD method to implement MCD [3]

The FAST-MCD method selects h observations out of n (where $n/2 < h \leq n$) whose classical covariance matrix has the lowest possible determinant. The MCD mean is the mean of the h selected observations.

The MCD covariance is the covariance matrix of the h selected points, multiplied by a consistency factor to obtain consistency at the multivariate normal distribution, and by a correction factor to correct for bias at small sample sizes.

Orthogonalized Gnanadesikan-Kettenring Estimate

Orthogonalized Gnanadesikan-Kettenring (OGK) estimate is a positive definite estimate of the scatter starting from the Gnanadesikan and Kettering (GK) estimator, a pairwise robust scatter matrix that may be non-positive definite [1]. The estimate uses a form of principal components called an orthogonalization iteration on the pairwise scatter matrix, replacing its eigenvalues, which could be negative, with robust variances. This procedure can be iterated for improved results, and convergence is usually obtained after 2 or 3 iterations.

Olive Hawkins Estimate

The Olive-Hawkins estimate uses the “concentration algorithm” techniques proposed by Olive and Hawkins. This is a family of fast, consistent, and highly outlier-resistant methods. The estimate is a robust root n -consistent estimator of covariance for elliptically contoured distributions with fourth moments. This estimate is obtained by first generating trial estimates, or starts, and then using the concentration technique from each trial fit to obtain attractors.

Suppose (T_{0j}, C_{0j}) is a start, then at the next iteration the classical mean and covariance estimators are computed from the approximately $n/2$ cases (where n is the number of observations) with the smallest Mahalanobis distances based on the estimates from the previous iteration. This iteration can be continued for a fixed number of steps k , with the estimate at the last step, k , being the attractor. The final estimate is chosen based on a given criterion.

By default, two attractors are used. The first attractor is the Devlin-Gnanadesikan-Kettering (DGK) attractor, where the start used is the classical estimator. The second attractor is the Median Ball (MB) attractor, where the start used is $(\text{median}(\mathbf{x}), \text{eye}(\mathbf{p}))$, in other words the half set of data closest to $\text{median}(\mathbf{x})$ in Euclidean distance. The MB attractor is used if the location estimator of the DGK attractor is outside of the median ball, and the attractor with the smallest determinant is used otherwise. The final mean estimate is the mean estimate of the chosen attractor, and the final covariance estimate is the covariance estimate of the chosen attractor, multiplied by a scaling factor to make the estimate consistent at the normal distribution.

COV

Introduced in R2016a

robustdemo

Interactive robust regression

Syntax

```
robustdemo  
robustdemo(x, y)
```

Description

`robustdemo` shows the difference between ordinary least squares and robust regression for data with a single predictor. With no input arguments, `robustdemo` displays a scatter plot of a sample of roughly linear data with one outlier. The bottom of the figure displays equations of lines fitted to the data using ordinary least squares and robust methods, together with estimates of the root mean squared errors.

Use the right mouse button to click on a point and view its least-squares leverage and robust weight.

Use the left mouse button to click-and-drag a point. The displays will update.

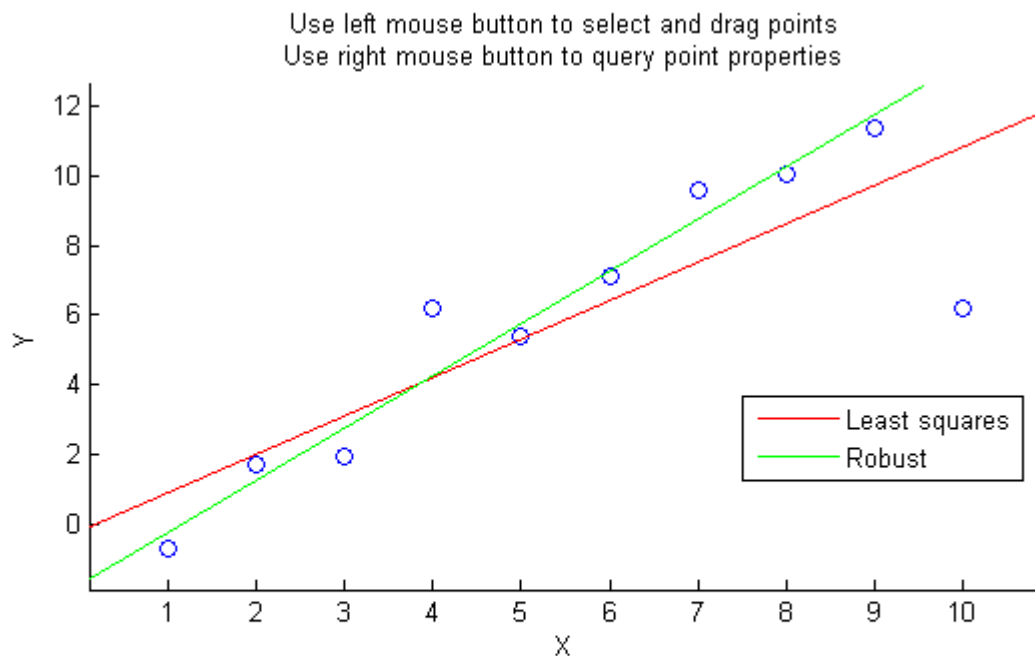

`robustdemo(x, y)` uses `x` and `y` data vectors you supply, in place of the sample data supplied with the function.

Examples

The following steps show you how to use `robustdemo`.

- 1 Start the example.** To begin using `robustdemo` with the built-in data, simply type the function name:

```
robustdemo
```

Least squares:	$Y = -0.188327 + 1.10351 * X$	RMS error = 2.21375
Robust:	$Y = -1.77278 + 1.50415 * X$	RMS error = 1.43663

The resulting figure shows a scatter plot with two fitted lines. The red line is the fit using ordinary least-squares regression. The green line is the fit using robust regression. At the bottom of the figure are the equations for the fitted lines, together with the estimated root mean squared errors for each fit.

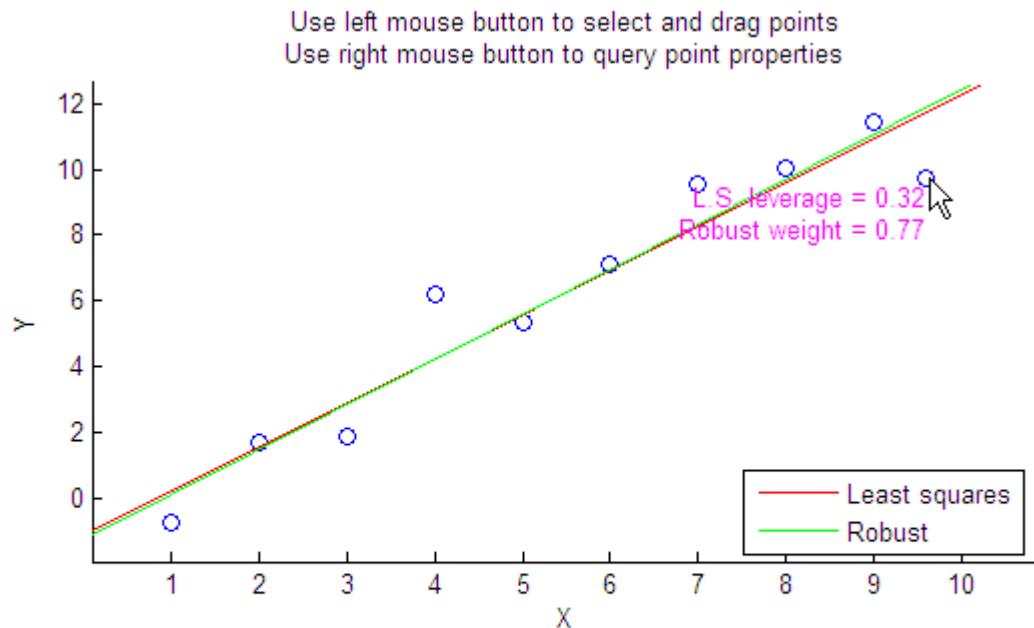

- View leverages and robust weights.** Right-click on any data point to see its least-squares leverage and robust weight:

Least squares:	$Y = -0.188327 + 1.10351 * X$	RMS error = 2.21375
Robust:	$Y = -1.77278 + 1.50415 * X$	RMS error = 1.43663

In the built-in data, the right-most point has a relatively high leverage of 0.35. The point exerts a large influence on the least-squares fit, but its small robust weight shows that it is effectively excluded from the robust fit.

- 3 See how changes in the data affect the fits.** With the left mouse button, click and hold on any data point and drag it to a new location. When you release the mouse button, the displays update:

Least squares:	$Y = -1.0661 + 1.33785 \cdot X$	RMS error = 1.21477
Robust:	$Y = -1.18916 + 1.36459 \cdot X$	RMS error = 1.27697

Bringing the right-most data point closer to the least-squares line makes the two fitted lines nearly identical. The adjusted right-most data point has significant weight in the robust fit.

leverage | robustfit

Introduced before R2006a

robustfit

Robust regression

Syntax

```
b = robustfit(X,y)
b = robustfit(X,y,wfun,tune)
b = robustfit(X,y,wfun,tune,const)
[b,stats] = robustfit(...)
```

Description

`b = robustfit(X,y)` returns a $(p + 1)$ -by-1 vector `b` of coefficient estimates for a robust multilinear regression of the responses in `y` on the predictors in `X`. `X` is an n -by- p matrix of p predictors at each of n observations. `y` is an n -by-1 vector of observed responses. By default, the algorithm uses iteratively reweighted least squares with a bisquare weighting function.

Note By default, `robustfit` adds a first column of 1s to `X`, corresponding to a constant term in the model. Do not enter a column of 1s directly into `X`. You can change the default behavior of `robustfit` using the input `const`, below.

`robustfit` treats NaNs in `X` or `y` as missing values, and removes them.

`b = robustfit(X,y,wfun,tune)` specifies a weighting function `wfun`. `tune` is a tuning constant that is divided into the residual vector before computing weights.

The weighting function `wfun` is one of the values described in this table. The default value is 'bisquare'.

Weight Function	Description	Default Tuning Constant
'andrews'	$w = (\text{abs}(r) < \pi) .* \sin(r) ./ r$	1.339

Weight Function	Description	Default Tuning Constant
'bisquare'	$w = (\text{abs}(r) < 1) .* (1 - r.^2).^2$ (also called biweight)	4.685
'cauchy'	$w = 1 ./ (1 + r.^2)$	2.385
'fair'	$w = 1 ./ (1 + \text{abs}(r))$	1.400
'huber'	$w = 1 ./ \max(1, \text{abs}(r))$	1.345
'logistic'	$w = \tanh(r) ./ r$	1.205
'ols'	Ordinary least squares (no weighting function)	None
'talwar'	$w = 1 * (\text{abs}(r) < 1)$	2.795
'welsch'	$w = \exp(-(r.^2))$	2.985
function handle	Custom weight function that accepts a vector <i>r</i> of scaled residuals, and returns a vector of weights the same size as <i>r</i>	1

If *tune* is unspecified, `robustfit` uses the default tuning value shown in the table. The default tuning constants of built-in weight functions give coefficient estimates that are approximately 95% as statistically efficient as the ordinary least-squares estimates, provided the response has a normal distribution with no outliers. Decreasing the tuning constant increases the downweight assigned to large residuals; increasing the tuning constant decreases the downweight assigned to large residuals.

The value *r* in the weight functions is

$$r = \text{resid} / (\text{tune} * s * \sqrt{1-h})$$

where *resid* is the vector of residuals from the previous iteration, *h* is the vector of leverage values from a least-squares fit, and *s* is an estimate of the standard deviation of the error term given by

$$s = \text{MAD} / 0.6745$$

Here *MAD* is the median absolute deviation of the residuals from their median. The constant 0.6745 makes the estimate unbiased for the normal distribution. If there are *p* columns in *X*, the smallest *p* absolute deviations are excluded when computing the median.

`b = robustfit(X,y,wfun,tune,const)` controls whether or not the model will include a constant term. *const* is 'on' to include the constant term (the default), or

'off' to omit it. When *const* is 'on', `robustfit` adds a first column of 1s to *X* and *b* becomes a $(p + 1)$ -by-1 vector. When *const* is 'off', `robustfit` does not alter *X*, then *b* is a p -by-1 vector.

`[b,stats] = robustfit(...)` returns the structure *stats*, whose fields contain diagnostic statistics from the regression. The fields of *stats* are:

- `ols_s` — Sigma estimate (RMSE) from ordinary least squares
- `robust_s` — Robust estimate of sigma
- `mad_s` — Estimate of sigma computed using the median absolute deviation of the residuals from their median; used for scaling residuals during iterative fitting
- `s` — Final estimate of sigma, the larger of `robust_s` and a weighted average of `ols_s` and `robust_s`
- `resid` — Residual
- `rstud` — Studentized residual (see `regress` for more information)
- `se` — Standard error of coefficient estimates
- `covb` — Estimated covariance matrix for coefficient estimates
- `coeffcorr` — Estimated correlation of coefficient estimates
- `t` — Ratio of *b* to *se*
- `p` — *p*-values for *t*
- `w` — Vector of weights for robust fit
- `R` — *R* factor in *QR* decomposition of *X*
- `dfe` — Degrees of freedom for error
- `h` — Vector of leverage values for least-squares fit

The `robustfit` function estimates the variance-covariance matrix of the coefficient estimates using $\text{inv}(X' * X) * \text{stats}.s^2$. Standard errors and correlations are derived from this estimate.

Examples

Compare Robust and Least-Squares Regression

Generate data with the trend $y = 10 - 2 * x$, then change one value to simulate an outlier.

```
x = (1:10)';  
rng default; % For reproducibility  
y = 10 - 2*x + randn(10,1);  
y(10) = 0;
```

Fit a straight line using ordinary least squares regression.

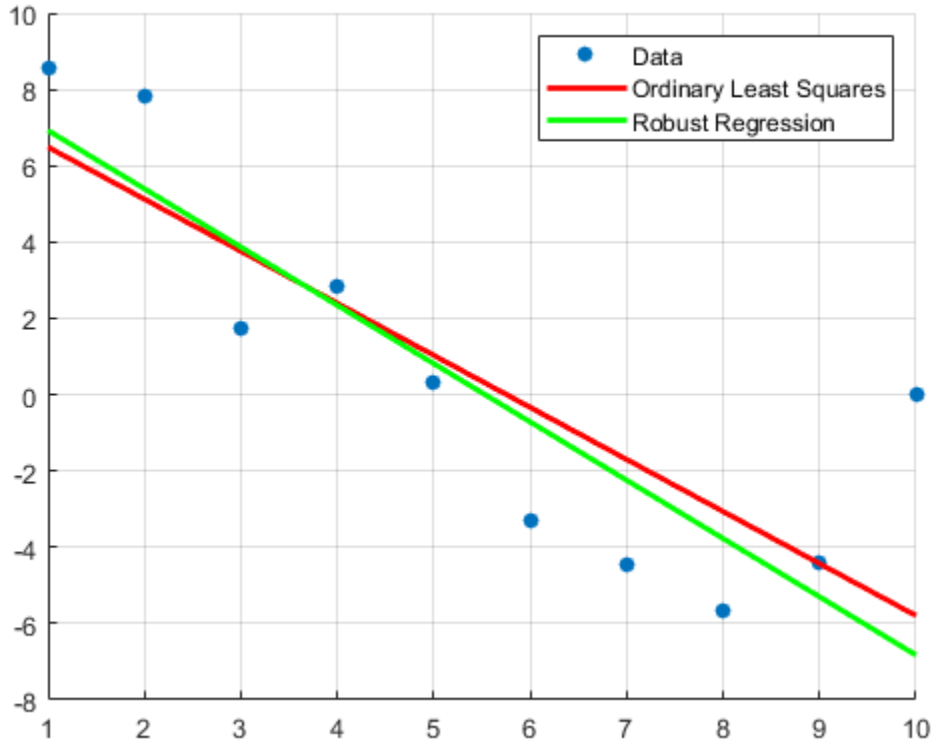

```
bls = regress(y,[ones(10,1) x])  
  
bls = 2×1  
  
    7.8518  
   -1.3644
```

Now use robust regression to estimate a straight-line fit.

```
brob = robustfit(x,y)  
  
brob = 2×1  
  
    8.4504  
   -1.5278
```

Create scatter plot of the data together with the fits.

```
scatter(x,y,'filled'); grid on; hold on  
plot(x,bls(1)+bls(2)*x,'r','LineWidth',2);  
plot(x,brob(1)+brob(2)*x,'g','LineWidth',2)  
legend('Data','Ordinary Least Squares','Robust Regression')
```

The robust fit is less influenced by the outlier than the least-squares fit.

Introduced before R2006a

rotatefactors

Rotate factor loadings

Syntax

```
B = rotatefactors(A)
B = rotatefactors(A, 'Method', 'orthomax', 'Coeff', gamma)
B = rotatefactors(A, 'Method', 'procrustes', 'Target', target)
B = rotatefactors(A, 'Method', 'pattern', 'Target', target)
B = rotatefactors(A, 'Method', 'promax')
[B,T] = rotatefactors(A, ...)
```

Description

`B = rotatefactors(A)` rotates the d -by- m loadings matrix A to maximize the varimax criterion, and returns the result in B . Rows of A and B correspond to variables and columns correspond to factors, for example, the (i, j) th element of A is the coefficient for the i th variable on the j th factor. The matrix A usually contains principal component coefficients created with `pca` or `pcacov`, or factor loadings estimated with `factoran`.

`B = rotatefactors(A, 'Method', 'orthomax', 'Coeff', gamma)` rotates A to maximize the orthomax criterion with the coefficient γ , i.e., B is the orthogonal rotation of A that maximizes

$$\text{sum}(D * \text{sum}(B.^4, 1) - \text{GAMMA} * \text{sum}(B.^2, 1).^2)$$

The default value of 1 for `gamma` corresponds to varimax rotation. Other possibilities include `gamma = 0`, `m/2`, and `d(m - 1)/(d + m - 2)`, corresponding to quartimax, equamax, and parsimax. You can also supply `'varimax'`, `'quartimax'`, `'equamax'`, or `'parsimax'` for the `'method'` parameter and omit the `'Coeff'` parameter.

If `'Method'` is `'orthomax'`, `'varimax'`, `'quartimax'`, `'equamax'`, or `'parsimax'`, then additional parameters are

- `'Normalize'` — Flag indicating whether the loadings matrix should be row-normalized for rotation. If `'on'` (the default), rows of A are normalized prior to

rotation to have unit Euclidean norm, and unnormalized after rotation. If 'off', the raw loadings are rotated and returned.

- 'Reltol' — Relative convergence tolerance in the iterative algorithm used to find T. The default is `sqrt(eps)`.
- 'Maxit' — Iteration limit in the iterative algorithm used to find T. The default is 250.

`B = rotatefactors(A, 'Method', 'procrustes', 'Target', target)` performs an oblique procrustes rotation of A to the *d*-by-*m* target loadings matrix `target`.

`B = rotatefactors(A, 'Method', 'pattern', 'Target', target)` performs an oblique rotation of the loadings matrix A to the *d*-by-*m* target pattern matrix `target`, and returns the result in B. `target` defines the "restricted" elements of B, i.e., elements of B corresponding to zero elements of `target` are constrained to have small magnitude, while elements of B corresponding to nonzero elements of `target` are allowed to take on any magnitude.

If 'Method' is 'procrustes' or 'pattern', an additional parameter is 'Type', the type of rotation. If 'Type' is 'orthogonal', the rotation is orthogonal, and the factors remain uncorrelated. If 'Type' is 'oblique' (the default), the rotation is oblique, and the rotated factors might be correlated.

When 'Method' is 'pattern', there are restrictions on `target`. If A has *m* columns, then for orthogonal rotation, the *j*th column of `target` must contain at least *m* - *j* zeros. For oblique rotation, each column of `target` must contain at least *m* - 1 zeros.

`B = rotatefactors(A, 'Method', 'promax')` rotates A to maximize the promax criterion, equivalent to an oblique Procrustes rotation with a target created by an orthomax rotation. Use the four orthomax parameters to control the orthomax rotation used internally by promax.

An additional parameter for 'promax' is 'Power', the exponent for creating promax target matrix. 'Power' must be 1 or greater. The default is 4.

`[B, T] = rotatefactors(A, ...)` returns the rotation matrix T used to create B, that is, $B = A * T$. You can find the correlation matrix of the rotated factors by using `inv(T' * T)`. For orthogonal rotation, this is the identity matrix, while for oblique rotation, it has unit diagonal elements but nonzero off-diagonal elements.

Examples

```

rng('default') % for reproducibility
X = randn(100,10);

% Default (normalized varimax) rotation:
% first three principal components.
LPC = pca(X);
[L1,T] = rotatefactors(LPC(:,1:3));

% Equamax rotation:
% first three principal components.
[L2,T] = rotatefactors(LPC(:,1:3),...
    'method','equamax');

% Promax rotation:
% first three factors.
LFA = factoran(X,3,'Rotate','none');
[L3,T] = rotatefactors(LFA(:,1:3),...
    'method','promax',...
    'power',2);

% Pattern rotation:
% first three factors.
Tgt = [1 1 1 1 1 0 1 0 1 1; ...
    0 0 0 1 1 1 0 0 0 0; ...
    1 0 0 1 0 1 1 1 1 0]';
[L4,T] = rotatefactors(LFA(:,1:3),...
    'method','pattern',...
    'target',Tgt);
inv(T'*T) % Correlation matrix of the rotated factors
ans =

    1.0000    -0.9593    -0.7098
   -0.9593     1.0000     0.5938
   -0.7098     0.5938     1.0000

Introduced before R2006a

rowexch

Row exchange

Syntax

```
dRE = rowexch(nfactors, nruns)
[dRE, X] = rowexch(nfactors, nruns)
[dRE, X] = rowexch(nfactors, nruns, model)
[dRE, X] = rowexch(..., param1, val1, param2, val2, ...)
```

Description

`dRE = rowexch(nfactors, nruns)` uses a row-exchange algorithm to generate a D -optimal design `dRE` with `nruns` runs (the rows of `dRE`) for a linear additive model with `nfactors` factors (the columns of `dRE`). The model includes a constant term.

`[dRE, X] = rowexch(nfactors, nruns)` also returns the associated design matrix X , whose columns are the model terms evaluated at each treatment (row) of `dRE`.

`[dRE, X] = rowexch(nfactors, nruns, model)` uses the linear regression model specified in `model`. `model` is one of the following:

- 'linear' — Constant and linear terms. This is the default.
- 'interaction' — Constant, linear, and interaction terms
- 'quadratic' — Constant, linear, interaction, and squared terms
- 'purequadratic' — Constant, linear, and squared terms

The order of the columns of X for a full quadratic model with n terms is:

- 1 The constant term
- 2 The linear terms in order 1, 2, ..., n
- 3 The interaction terms in order (1, 2), (1, 3), ..., (1, n), (2, 3), ..., ($n-1$, n)
- 4 The squared terms in order 1, 2, ..., n

Other models use a subset of these terms, in the same order.

Alternatively, *model* can be a matrix specifying polynomial terms of arbitrary order. In this case, *model* should have one column for each factor and one row for each term in the model. The entries in any row of *model* are powers for the factors in the columns. For example, if a model has factors X1, X2, and X3, then a row [0 1 2] in *model* specifies the term $(X1.^0) \cdot (X2.^1) \cdot (X3.^2)$. A row of all zeros in *model* specifies a constant term, which can be omitted.

[dRE,X] = rowexch(...,param1,val1,param2,val2,...) specifies additional parameter/value pairs for the design. Valid parameters and their values are listed in the following table.

Parameter	Value
'bounds'	Lower and upper bounds for each factor, specified as a 2-by-nfactors matrix. Alternatively, this value can be a cell array containing nfactors elements, each element specifying the vector of allowable values for the corresponding factor.
'categorical'	Indices of categorical predictors.
'display'	Either 'on' or 'off' to control display of the iteration counter. The default is 'on'.
'excludedefun'	Handle to a function that excludes undesirable runs. If the function is <i>f</i> , it must support the syntax $b = f(S)$, where <i>S</i> is a matrix of treatments with nfactors columns and <i>b</i> is a vector of Boolean values with the same number of rows as <i>S</i> . <i>b</i> (<i>i</i>) is true if the <i>i</i> th row <i>S</i> should be excluded.
'init'	Initial design as an nruns-by-nfactors matrix. The default is a randomly selected set of points.
'levels'	Vector of number of levels for each factor.
'maxiter'	Maximum number of iterations. The default is 10.

Parameter	Value
options	<p>A structure that specifies whether to run in parallel, and specifies the random stream or streams. Create the <code>options</code> structure with <code>statset</code>. This option requires Parallel Computing Toolbox. Option fields are:</p> <ul style="list-style-type: none"> • <code>UseParallel</code> — Set to <code>true</code> to compute in parallel. Default is <code>false</code>. • <code>UseSubstreams</code> — Set to <code>true</code> to compute in parallel in a reproducible fashion. Default is <code>false</code>. To compute reproducibly, set <code>Streams</code> to a type allowing substreams: <code>'mlfg6331_64'</code> or <code>'mrg32k3a'</code>. • <code>Streams</code> — A <code>RandStream</code> object or cell array of such objects. If you do not specify <code>Streams</code>, <code>rowexch</code> uses the default stream or streams. If you choose to specify <code>Streams</code>, use a single object except in the case <ul style="list-style-type: none"> • <code>UseParallel</code> is <code>true</code> • <code>UseSubstreams</code> is <code>false</code> <p>In that case, use a cell array the same size as the Parallel pool.</p>
'tries'	Number of times to try to generate a design from a new starting point. The algorithm uses random points for each try, except possibly the first. The default is 1.

Examples

Suppose you want a design to estimate the parameters in the following three-factor, seven-term interaction model:

$$y = \beta_0 + \beta_1x_1 + \beta_2x_2 + \beta_3x_3 + \beta_{12}x_1x_2 + \beta_{13}x_1x_3 + \beta_{23}x_2x_3 + \varepsilon$$

Use `rowexch` to generate a D -optimal design with seven runs:

```

nfactors = 3;
nruns = 7;
[dRE,X] = rowexch(nfactors,nruns,'interaction','tries',10)
dRE =
    -1    -1     1

```

$$X = \begin{matrix} & \begin{matrix} 1 & -1 & 1 \\ 1 & -1 & -1 \\ 1 & 1 & 1 \\ -1 & -1 & -1 \\ -1 & 1 & -1 \\ -1 & 1 & 1 \end{matrix} \\ \begin{matrix} 1 & -1 & -1 & 1 & 1 & -1 & -1 \\ 1 & 1 & -1 & 1 & -1 & 1 & -1 \\ 1 & 1 & -1 & -1 & -1 & -1 & 1 \\ 1 & 1 & 1 & 1 & 1 & 1 & 1 \\ 1 & -1 & -1 & -1 & 1 & 1 & 1 \\ 1 & -1 & 1 & -1 & -1 & 1 & -1 \\ 1 & -1 & 1 & 1 & -1 & -1 & 1 \end{matrix} \end{matrix}$$

Columns of the design matrix X are the model terms evaluated at each row of the design dRE. The terms appear in order from left to right: constant term, linear terms (1, 2, 3), interaction terms (12, 13, 23). Use X to fit the model, as described in “Linear Regression” on page 11-11, to response data measured at the design points in dRE.

Algorithms

Both `cordexch` and `rowexch` use iterative search algorithms. They operate by incrementally changing an initial design matrix X to increase $D = |X^T X|$ at each step. In both algorithms, there is randomness built into the selection of the initial design and into the choice of the incremental changes. As a result, both algorithms may return locally, but not globally, D -optimal designs. Run each algorithm multiple times and select the best result for your final design. Both functions have a 'tries' parameter that automates this repetition and comparison.

At each step, the row-exchange algorithm exchanges an entire row of X with a row from a design matrix C evaluated at a candidate set of feasible treatments. The `rowexch` function automatically generates a C appropriate for a specified model, operating in two steps by calling the `candgen` and `candexch` functions in sequence. Provide your own C by calling `candexch` directly. In either case, if C is large, its static presence in memory can affect computation.

Extended Capabilities

Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the 'UseParallel' option to true.

Set the 'UseParallel' field of the options structure to true using `statset` and specify the 'Options' name-value pair argument in the call to this function.

For example: `'Options',statset('UseParallel',true)`

For more information, see the 'Options' name-value pair argument.

For more general information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

Introduced before R2006a

rsmdemo

Interactive response surface demonstration

Syntax

rsmdemo

Description

rsmdemo opens a group of three graphical user interfaces for interactively investigating response surface methodology (RSM), nonlinear fitting, and the design of experiments.

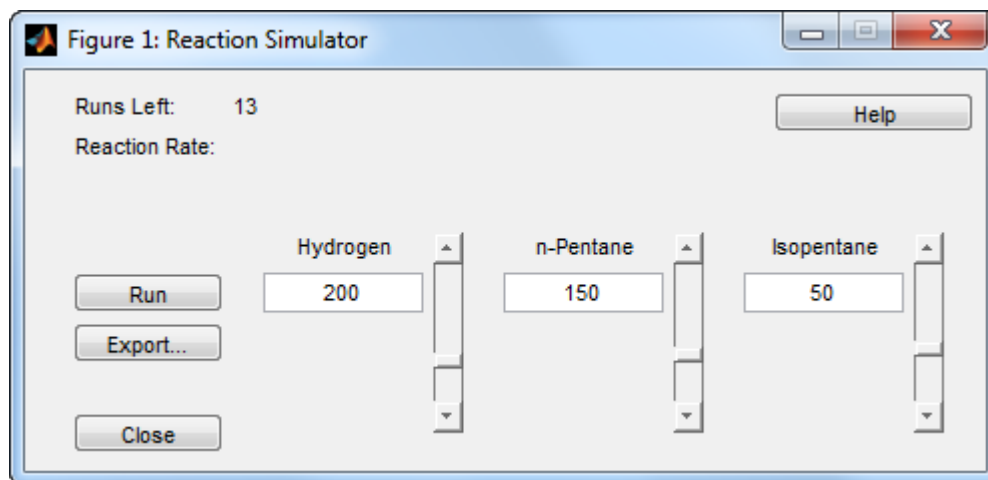

The interfaces allow you to collect and model data from a simulated chemical reaction. Experimental predictors are concentrations of three reactants (hydrogen, *n*-Pentane, and isopentane) and the response is the reaction rate. The reaction rate is simulated by a Hougen-Watson model (Bates and Watts, [2] on page C-2, pp. 271-272):

$$rate = \frac{\beta_1 x_2 - x_3 / \beta_5}{1 + \beta_2 x_1 + \beta_3 x_2 + \beta_4 x_3}$$

where *rate* is the reaction rate, x_1 , x_2 , and x_3 are the concentrations of hydrogen, *n*-pentane, and isopentane, respectively, and $\beta_1, \beta_2, \dots, \beta_5$ are fixed parameters. Random errors are used to perturb the reaction rate for each combination of reactants.

Collect data using one of two methods:

- 1 Manually set reactant concentrations in the **Reaction Simulator** interface by editing the text boxes or by adjusting the associated sliders.

When you click **Run**, the concentrations and simulated reaction rate are recorded on the **Trial and Error Data** interface.

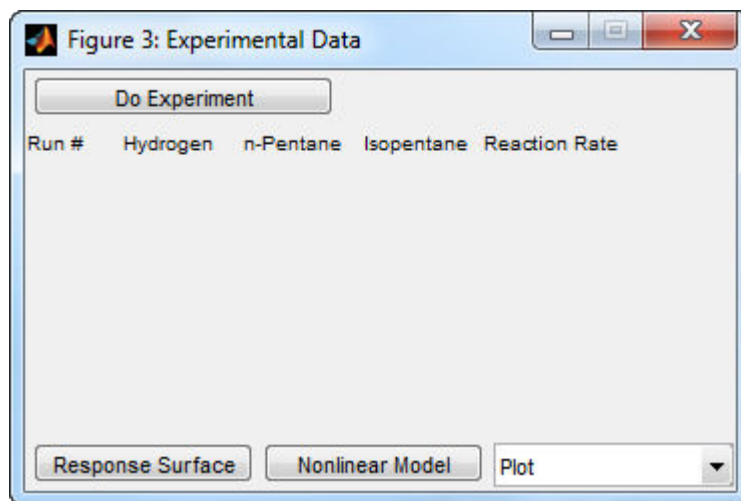

Figure 2: Trial and Error Data

Run #	Hydrogen	n-Pentane	Isopentane	Reaction Rate
1	200	150	50	5.76

Buttons: Analyze, Plot

You are allowed up to 13 independent experimental runs for data collection.

- 2 Use a designed experiment to set reactant concentrations in the **Experimental Data** interface by clicking the **Do Experiment** button.

A 13-run *D*-optimal design for a full quadratic model is generated by the `cordexch` function, and the concentrations and simulated reaction rates are recorded on the same interface.

Once data is collected, scatter plots of reaction rates vs. individual predictors are generated by selecting one of the following from the **Plot** pop-up menu below the recorded data:

- **Hydrogen vs. Rate**
- **n-Pentane vs. Rate**
- **Isopentane vs. Rate**

Fit a response surface model to the data by clicking the **Analyze** button below the trial-and-error data or the **Response Surface** button below the experimental data. Both buttons load the data into the Response Surface Tool `rstool`. By default, trial-and-error data is fit with a linear additive model and experimental data is fit with a full quadratic model, but the models can be adjusted in the Response Surface Tool.

For experimental data, you have the additional option of fitting a Hougen-Watson model. Click the **Nonlinear Model** button to load the data and the model in `hougen` into the Nonlinear Fitting Tool `nlintool`.

`cordexch` | `hougen` | `nlintool` | `rstool`

Introduced before R2006a

rstool

Interactive response surface modeling

Syntax

```
rstool  
rstool(X,Y,model)  
rstool(x,y,model,alpha)  
rstool(x,y,model,alpha,xname,yname)
```

Description

`rstool` opens a graphical user interface for interactively investigating one-dimensional contours of multidimensional response surface models.

By default, the interface opens with the data from `hald.mat` and a fitted response surface with constant, linear, and interaction terms.

A sequence of plots is displayed, each showing a contour of the response surface against a single predictor, with all other predictors held fixed. `rstool` plots a 95% simultaneous confidence band for the fitted response surface as two red curves. Predictor values are displayed in the text boxes on the horizontal axis and are marked by vertical dashed blue lines in the plots. Predictor values are changed by editing the text boxes or by dragging the dashed blue lines. When you change the value of a predictor, all plots update to show the new point in predictor space.

The pop-up menu at the lower left of the interface allows you to choose among the following models:

- Linear — Constant and linear terms (the default)
- Pure Quadratic — Constant, linear, and squared terms
- Interactions — Constant, linear, and interaction terms

- Full Quadratic — Constant, linear, interaction, and squared terms

Click **Export** to open the following dialog box:

The dialog allows you to save information about the fit to MATLAB workspace variables with valid names.

`rstool(X,Y,model)` opens the interface with the predictor data in *X*, the response data in *Y*, and the fitted model *model*. Distinct predictor variables should appear in different columns of *X*. *Y* can be a vector, corresponding to a single response, or a matrix, with columns corresponding to multiple responses. *Y* must have as many elements (or rows, if it is a matrix) as *X* has rows.

The optional input *model* can be any one of the following:

- 'linear' — Constant and linear terms (the default)
- 'purequadratic' — Constant, linear, and squared terms
- 'interaction' — Constant, linear, and interaction terms
- 'quadratic' — Constant, linear, interaction, and squared terms

To specify a polynomial model of arbitrary order, or a model without a constant term, use a matrix for *model* as described in `x2fx`.

`rstool(x,y,model,alpha)` uses $100(1-\alpha)\%$ global confidence intervals for new observations in the plots.

`rstool(x,y,model,alpha,xname,yname)` labels the axes using *xname* and *yname*. To label each subplot differently, *xname* and *yname* can be string arrays or cell arrays of character vectors.

Examples

The following uses `rstool` to visualize a quadratic response surface model of the 3-D chemical reaction data in `reaction.mat`:

```
load reaction
alpha = 0.01; % Significance level
rstool(reactants,rate,'quadratic',alpha,xn,yn)
```

The `rstool` interface is used by `rsmdemo` to visualize the results of simulated experiments with data like that in `reaction.mat`. As described in “Response Surface Designs” on page 27-9, `rsmdemo` uses a response surface model to generate simulated data at combinations of predictors specified by either the user or by a designed experiment.

Introduced before R2006a

runstest

Run test for randomness

Syntax

```
h = runstest(x)
h = runstest(x,v)
h = runstest(x,'ud')
h = runstest( ____,Name,Value)
[h,p,stats] = runstest( ____ )
```

Description

`h = runstest(x)` returns a test decision for the null hypothesis that the values in the data vector `x` come in random order, against the alternative that they do not. The test is based on the number of runs of consecutive values above or below the mean of `x`. The result `h` is 1 if the test rejects the null hypothesis at the 5% significance level, or 0 otherwise.

`h = runstest(x,v)` returns a test decision based on the number of runs of consecutive values above or below the specified reference value `v`. Values exactly equal to `v` are discarded.

`h = runstest(x,'ud')` returns a test decision based on the number of runs up or down. Too few runs indicate a trend, while too many runs indicate an oscillation. Values exactly equal to the preceding value are discarded.

`h = runstest(____,Name,Value)` returns a test decision using additional options specified by one or more name-value pair arguments. For example, you can change the significance level of the test, specify the algorithm used to calculate the *p*-value, or conduct a one-sided test.

`[h,p,stats] = runstest(____)` also returns the *p*-value of the test `p`, and a structure `stats` containing additional data about the test.

Examples

Test Data for Randomness Using Sample Median

Generate a vector of 40 random numbers from a standard normal distribution.

```
rng default; % for reproducibility
x = randn(40,1);
```

Test whether the values in `x` appear in random order, using the sample median as the reference value.

```
[h,p] = runstest(x,median(x))
```

```
h = 0
```

```
p = 0.8762
```

The returned value of `h = 0` indicates that `runstest` does not reject the null hypothesis that the values in `x` are in random order at the default 5% significance level.

Input Arguments

x — Data vector

vector of scalar values

Data vector, specified as a vector of scalar values. `runstest` treats NaN values in `x` as missing values, and ignores them.

Data Types: `single` | `double`

v — Reference value

mean of `x` (default) | scalar value

Reference value, specified as a scalar value. If you specify a value for `v`, then `runstest` performs the hypothesis test based on the number of runs of consecutive values above or below `v`. `runstest` discards values exactly equal to `v`.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Alpha',0.01,'Method','Approximate','Tail','right'` specifies a right-tailed test with 1% significance level, which returns the approximate *p*-value.

Alpha — Significance level

`0.05` (default) | scalar value in the range (0,1)

Significance level of the hypothesis test, specified as the comma-separated pair consisting of `'Alpha'` and a scalar value in the range (0,1).

Example: `'Alpha',0.01`

Data Types: `single` | `double`

Method — Method used to compute *p*-value

`'exact'` | `'approximate'`

Method used to compute *p*-value, specified as the comma-separated pair consisting of `'Method'` and either `'exact'` to use an exact algorithm, or `'approximate'` to use a normal approximation. The default is `'exact'` for runs above/below, and for runs up/down when the length of `x` is less than or equal to 50. If `runstest` tests for runs up/down and the length of `x` is greater than 50, then the default is `'approximate'`, and the `'exact'` method is not available.

Example: `'Method','approximate'`

Tail — Type of alternative hypothesis

`'both'` (default) | `'right'` | `'left'`

Type of alternative hypothesis, specified as the comma-separated pair consisting of `'Tail'` and one of the following.

<code>'both'</code>	Two-tailed test (sequence is not random)
<code>'right'</code>	Right-tailed test (like values separate for runs above/below, direction alternates for runs up/down)

'left' Left-tailed test (like values cluster for runs above/below, values trend for runs up/down)

Example: 'Tail', 'right'

Output Arguments

h — Hypothesis test result

1 | 0

Hypothesis test result, returned as 1 or 0.

- If $h = 1$, then `runstest` rejects the null hypothesis at the Alpha significance level.
- If $h = 0$, then `runstest` fails to reject the null hypothesis at the Alpha significance level.

The result in `runstest` is based on the number of runs of consecutive values above or below the mean of x . Too few runs indicate a tendency for high and low values to cluster. Too many runs indicate a tendency for high and low values to alternate.

`runstest` uses a test statistic which is the difference between the number of runs and its mean, divided by its standard deviation. The test statistic is approximately normally distributed when the null hypothesis is true.

p — *p*-value

scalar value in the range [0,1]

p-value of the test, returned as a scalar value in the range [0,1]. *p* is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. Small values of *p* cast doubt on the validity of the null hypothesis.

p is computed from either the test statistic or the exact distribution of the number of runs, depending on the value specified for the 'Method' name-value pair argument.

stats — Test data

structure

Test data, returned as a structure with the following fields.

- `nruns` — The number of runs

- n_1 — The number of values above v
- n_0 — The number of values below v
- z — The test statistic

signrank | signtest

Introduced before R2006a

sampsizepwr

Sample size and power of test

`sampsizepwr` computes the sample size, power, or alternative parameter value for a hypothesis test, given the other two values. For example, you can compute the sample size required to obtain a particular power for a hypothesis test, given the parameter value of the alternative hypothesis.

Syntax

```
nout = sampsizepwr(testtype,p0,p1)
nout = sampsizepwr(testtype,p0,p1,pwr)

pwrout = sampsizepwr(testtype,p0,p1,[],n)

plout = sampsizepwr(testtype,p0,[],pwr,n)

___ = sampsizepwr(testtype,p0,p1,pwr,n,Name,Value)
```

Description

`nout = sampsizepwr(testtype,p0,p1)` returns the sample size, `nout`, required for a two-sided test of the type specified by `testtype` to have a power (probability of rejecting the null hypothesis when the alternative hypothesis is true) of 0.90 when the significance level (probability of rejecting the null hypothesis when the null hypothesis is true) is 0.05. `p0` specifies parameter values under the null hypothesis. `p1` specifies the value, or an array of values, of the single parameter being tested under the alternative hypothesis.

`nout = sampsizepwr(testtype,p0,p1,pwr)` returns the sample size, `nout`, that corresponds to the specified power, `pwr`, and the parameter value under the alternative hypothesis, `p1`.

`pwrout = sampsizepwr(testtype,p0,p1,[],n)` returns the power achieved for a sample size of `n` when the true parameter value is `p1`.

`plout = sampsizepwr(testtype,p0,[],pwr,n)` returns the parameter value detectable with the specified sample size, `n`, and the specified power, `pwr`.

____ = sampsizewr(testtype,p0,p1,pwr,n,Name,Value) returns any of the previous arguments using one or more name-value pair arguments. For example, you can change the significance level of the test, or specify a right- or left-tailed test. The name-value pairs can appear in any order but must begin in the sixth argument position.

Examples

Compute Sample Size for Selected Power Value

A company runs a manufacturing process that fills empty bottles with 100 mL of liquid. To monitor quality, the company randomly selects several bottles and measures the volume of liquid inside.

Determine the sample size the company must use if it wants to detect a difference between 100 mL and 102 mL with a power of 0.80. Assume that prior evidence indicates a standard deviation of 5 mL.

```
nout = sampsizewr('t',[100 5],102,0.80)
```

```
nout = 52
```

The company must test 52 bottles to detect the difference between a mean volume of 100 mL and 102 mL with a power of 0.80.

Generate a power curve to visualize how the sample size affects the power of the test.

```
nn = 1:100;  
pwrout = sampsizewr('t',[100 5],102,[],nn);
```

```
figure;  
plot(nn,pwrout,'b-',nout,0.8,'ro')  
title('Power versus Sample Size')  
xlabel('Sample Size')  
ylabel('Power')
```

Compute Power and Sample Size for One-Sided Test

An employee wants to buy a house near her office. She decides to eliminate from consideration any house that has a mean morning commute time greater than 20 minutes. The null hypothesis for this right-sided test is $H_0: \mu = 20$, and the alternative hypothesis is $H_A: \mu > 20$. The selected significance level is 0.05.

To determine the mean commute time, the employee takes a test drive from the house to her office during rush hour every morning for one week, so her total sample size is 5. She assumes that the standard deviation, σ , is equal to 5.

The employee decides that a true mean commute time of 25 minutes is too different from her targeted 20-minute limit, so she wants to detect a significant departure if the true mean is 25 minutes. Find the probability of incorrectly concluding that the mean commute time is no greater than 20 minutes.

Compute the power of the test, and then subtract the power from 1 to obtain β .

```
power = sampsizewr('t',[20 5],25,[],5,'Tail','right');
beta = 1 - power

beta = 0.4203
```

The β value indicates a probability of 0.4203 that the employee concludes incorrectly that the morning commute is not greater than 20 minutes.

The employee decides that this risk is too high, and she wants no more than a 0.01 probability of reaching an incorrect conclusion. Calculate the number of test drives the employee must take to obtain a power of 0.99.

```
nout = sampsizewr('t',[20 5],25,0.99,[],'Tail','right')

nout = 18
```

The results indicate that she must take 18 test drives from a candidate house to achieve this power level.

The employee decides that she only has time to take 10 test drives. She also accepts a 0.05 probability of making an incorrect conclusion. Calculate the smallest true parameter value that produces a detectable difference in mean commute time.

```
plout = sampsizewr('t',[20 5],[],0.95,10,'Tail','right')

plout = 25.6532
```

Given the employee's target power level and sample size, her test detects a significant difference from a mean commute time of at least 25.6532 minutes.

Compute Sample Size for a Binomial Test

Compute the sample size, n , required to distinguish $p = 0.30$ from $p = 0.36$, using a binomial test with a power of 0.8.

```
napprox = sampsizepwr('p',0.30,0.36,0.8)
```

```
Warning: Values N>200 are approximate. Plotting the power as a function of N may
```

```
napprox = 485
```

The result indicates that a power of 0.8 requires a sample size of 485. However, this result is approximate.

Make a plot to see if any smaller n values provide the required power of 0.8.

```
nn = 1:500;
```

```
pwROUT = sampsizepwr('p',0.3,0.36,[],nn);
```

```
nexact = min(nn(pwROUT>=0.8))
```

```
nexact = 462
```

```
figure
```

```
plot(nn,pwROUT,'b-',[napprox nexact],pwROUT([napprox nexact]),'ro')
```

```
grid on
```

The result indicates that a sample size of 462 also provides a power of 0.8 for this test.

Compute Power for a Two-Sample t-Test

A farmer wants to test the impact of two different types of fertilizer on the yield of his bean crops. He currently uses Fertilizer A, but believes that Fertilizer B might improve crop yield. Because Fertilizer B is more expensive than Fertilizer A, the farmer wants to limit the number of plants he treats with Fertilizer B in this experiment.

The farmer uses a 2:1 ratio of plants in each treatment group. He tests 10 plants with Fertilizer A, and 5 plants with Fertilizer B. The mean yield using Fertilizer A is 1.4 kg per

plant, with a standard deviation of 0.2. The mean yield using Fertilizer B is 1.7 kg per plant. The significance level of the test is 0.05.

Compute the power of the test.

```
pwr = sampsizepwr('t2', [1.4 0.2], 1.7, [], 5, 'Ratio', 2)
pwr = 0.7165
```

The farmer wants to increase the power of the test to 0.90. Calculate how many plants he must treat with each type of fertilizer.

```
n = sampsizepwr('t2', [1.4 0.2], 1.7, 0.9, [])
n = 11
```

To increase the power of the test to 0.90, the farmer must test 11 plants with each type of fertilizer.

The farmer wants to reduce the number of plants he must treat with Fertilizer B, but keep the power of the test at 0.90. but maintain the initial 2:1 ratio of plants in each treatment group

Using a 2:1 ratio of plants in each treatment group, calculate how many plants the farmer must test to obtain a power of 0.90. Use the mean and standard deviation values obtained in the previous test.

```
[n1out, n2out] = sampsizepwr('t2', [1.4, 0.2], 1.7, 0.9, [], 'Ratio', 2)
n1out = 8
n2out = 16
```

To obtain a power of 0.90. the farmer must treat 16 plants with Fertilizer A and 8 plants with Fertilizer B.

Input Arguments

testtype — Test type

'z' | 't' | 't2' | 'var' | 'p'

Test type, specified as one of the following.

- 'z' — z-test for normally distributed data with known standard deviation.
- 't' — t-test for normally distributed data with unknown standard deviation.
- 't2' — Two-sample pooled t-test for normally distributed data with unknown standard deviation and equal variances.
- 'var' — Chi-square test of variance for normally distributed data.
- 'p' — Test of the p parameter (success probability) for a binomial distribution. The 'p' test is a discrete test for which increasing the sample size does not always increase the power. For n values larger than 200, there may exist values smaller than the returned n value that also produce the specified power.

p0 — Parameter value under null hypothesis

scalar value | two-element array of scalar values

Parameter value under the null hypothesis, specified as a scalar value or a two-element array of scalar values.

- If `testtype` is 'z' or 't', then p_0 is a two-element array $[\mu_0, \sigma_0]$ of the mean and standard deviation, respectively, under the null hypothesis.
- If `testtype` is 't2', then p_0 is a two-element array $[\mu_0, \sigma_0]$ of the mean and standard deviation, respectively, of the first sample under the null and alternative hypotheses.
- If `testtype` is 'var', then p_0 is the variance under the null hypothesis.
- If `testtype` is 'p', then p_0 is the value of p under the null hypothesis.

Data Types: single | double

p1 — Parameter value under alternative hypothesis

scalar value | array of scalar values | []

Parameter value under the alternative hypothesis, specified as a scalar value or as an array of scalar values.

- If `testtype` is 'z' or 't', then p_1 is the value of the mean under the alternative hypothesis.
- If `testtype` is 't2', then p_1 is the value of the mean of the second sample under the alternative hypothesis.
- If `testtype` is 'var', then p_1 is the variance under the alternative hypothesis.
- If `testtype` is 'p', then p_1 is the value of p under the alternative hypothesis.

If you specify `p1` as an array, then `sampsizepwr` returns an array for `nout` or `pwrout` that is the same length as `p1`.

To return the alternative parameter value, `plout`, specify `p1` using empty brackets (`[]`), as shown in the syntax description on page 32-6296.

Data Types: `single` | `double`

pwr — Power of the test

0.90 (default) | scalar value in the range (0,1) | array of scalar values in the range (0,1) | `[]`

Power of the test, specified as a scalar value in the range (0,1) or as an array of scalar values in the range (0,1). The power of a test is the probability of rejecting the null hypothesis when the alternative hypothesis is true, given a particular significance level.

If you specify `pwr` as an array, then `sampsizepwr` returns an array for `nout` or `plout` that is the same length as `pwr`.

To return a power value, `pwrout`, specify `pwr` using empty brackets (`[]`), as shown in the syntax description on page 32-6296.

Data Types: `single` | `double`

n — Sample size

positive integer value | array of positive integer values

Sample size, specified as a positive integer value or as an array of positive integer values.

If `testtype` is `'t2'`, then `sampsizepwr` assumes that the two sample sizes are equal. For unequal sample sizes, specify `n` as the smaller of the two sample sizes, and use the `'Ratio'` name-value pair argument to indicate the sample size ratio. For example, if the smaller sample size is 5 and the larger sample size is 10, specify `n` as 5, and the `'Ratio'` name-value pair as 2.

If you specify `n` as an array, then `sampsizepwr` returns an array for `pwrout` or `plout` that is the same length as `n`.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes.

You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example: `'Alpha', 0.01, 'Tail', 'right'` specifies a right-tailed test with a 0.01 significance level.

Alpha — Significance level

0.05 (default) | scalar value in the range (0,1)

Significance value of the test, specified as the comma-separated pair consisting of `'Alpha'` and a scalar value in the range (0,1).

Example: `'Alpha', 0.01`

Data Types: `single` | `double`

Ratio — Sample size ratio

1 (default) | scalar value greater than or equal to 1

Sample size ratio for a two-sample *t*-test, specified as the comma-separated pair consisting of `'Ratio'` and a scalar value greater than or equal to 1. The value of `Ratio` is equal to n_2/n_1 , where n_2 is the larger sample size, and n_1 is the smaller sample size.

To return the power, `pwrout`, or alternative parameter value, `plout`, specify the smaller of the two sample sizes for `n`, and use `'Ratio'` to indicate the sample size ratio.

Example: `'Ratio', 2`

Tail — Test type

`'both'` (default) | `'right'` | `'left'`

Test type, specified as the comma-separated pair consisting of `'Tail'` and one of the following:

- `'both'` — Two-sided test for an alternative not equal to ρ_0
- `'right'` — One-sided test for an alternative larger than ρ_0
- `'left'` — One-sided test for an alternative smaller than ρ_0

Example: `'Tail', 'right'`

Output Arguments

nout — Sample size

positive integer value | array of positive integer values

Sample size, returned as a positive integer value or as an array of positive integer values.

If `testtype` is `t2`, and you use the 'Ratio' name-value pair argument to specify the ratio of the two unequal sample sizes, then `nout` returns the smaller of the two sample sizes.

Alternatively, to return both sample sizes, specify this argument as `[n1out,n2out]`. In this case, `sampsizepwr` returns the smaller sample size as `n1out`, and the larger sample size as `n2out`.

If you specify `pwr` or `p1` as an array, then `sampsizepwr` returns an array for `nout` that is the same length as `pwr` or `p1`.

pwrout — Power

scalar value in the range (0,1) | array of scalar values in the range (0,1)

Power achieved by the test, returned as a scalar value in the range (0,1) or as an array of scalar values in the range (0,1).

If you specify `n` or `p1` as an array, then `sampsizepwr` returns an array for `pwrout` that is the same length as `n` or `p1`.

p1out — Parameter value for the alternative hypothesis

scalar value | array of scalar values

Parameter value for the alternative hypothesis, returned as a scalar value or as an array of scalar values.

When computing `p1out` for the 'p' test, if no alternative can be rejected for a given null hypothesis and significance level, the function displays a warning message and returns NaN.

Introduced in R2006b

saveCompactModel

Save model object in file for code generation

To generate C/C++ code for the object functions (`predict`, `random`, `knnsearch`, or `rangesearch`) of machine learning models, use `saveCompactModel`, `loadCompactModel`, and `codegen`. After training a machine learning model, save the model by using `saveCompactModel`. Define an entry-point function that loads the model by using `loadCompactModel` and calls an object function. Then use `codegen` or the MATLAB Coder app to generate C/C++ code. Generating C/C++ code requires MATLAB Coder.

This flow chart shows the code generation workflow for the object functions of machine learning models. Use `saveCompactModel` for the highlighted step.

Syntax

```
saveCompactModel(Mdl, filename)
```

Description

`saveCompactModel(Mdl, filename)` prepares a classification model, regression model, or nearest neighbor searcher (`Mdl`) for code generation by reducing its memory footprint and then saving it in the MATLAB formatted binary file (MAT-file) named `filename`. You can pass `filename` to `loadCompactModel` to reconstruct the model object from the `filename` file.

Examples

Generate C/C++ Code for Prediction

After training a machine learning model, save the model by using `saveCompactModel`. Define an entry-point function that loads the model by using `loadCompactModel` and calls the `predict` function of the trained model. Then use `codegen` to generate C/C++ code.

This example briefly explains the code generation workflow for the prediction of machine learning models at the command line. For more details, see “Code Generation for Prediction of Machine Learning Model at Command Line” on page 31-10. You can also generate code using the MATLAB Coder app. See “Code Generation for Prediction of Machine Learning Model Using MATLAB Coder App” on page 31-20 for details. To learn about the code generation for finding nearest neighbors using a nearest neighbor searcher model, see “Code Generation for Nearest Neighbor Searcher” on page 31-15.

Train Model

Load Fisher's iris data set. Remove all observed setosa irises data so that X and Y contain data for two classes only.

```
load fisheriris
inds = ~strcmp(species, 'setosa');
X = meas(inds,:);
Y = species(inds);
```

Train a support vector machine (SVM) classification model using the processed data set.

```
Mdl = fitcsvm(X,Y);
```

Mdl is a `ClassificationSVM` model.

Save Model

Save the SVM classification model to the file `SVMIris.mat` by using `saveCompactModel`.

```
saveCompactModel(Mdl, 'SVMIris');
```

Define Entry-Point Function

Define an entry-point function named `classifyIris` that does the following:

- Accept iris flower measurements with columns corresponding to `meas`, and return predicted labels.

- Load a trained SVM classification model.
- Predict labels using the loaded classification model for the iris flower measurements.

type `classifyIris.m` % Display contents of `classifyIris.m` file

```
function label = classifyIris(X) %#codegen
%CLASSIFYIRISES Classify iris species using SVM Model
% CLASSIFYIRISES classifies the iris flower measurements in X using the
% compact SVM model in the file SVMIris.mat, and then returns class
% labels in label.
CompactMdl = loadCompactModel('SVMIris');
label = predict(CompactMdl,X);
end
```

Add the `%#codegen` compiler directive (or pragma) to the entry-point function after the function signature to indicate that you intend to generate code for the MATLAB algorithm. Adding this directive instructs the MATLAB Code Analyzer to help you diagnose and fix violations that would result in errors during code generation.

Note: If you click the button located in the upper-right section of this example and open this example in MATLAB®, then MATLAB® opens the example folder. This folder includes the entry-point function file.

Generate Code

Generate code for the entry-point function using `codegen`. Because C and C++ are statically typed languages, you must determine the properties of all variables in the entry-point function at compile time. Pass `X` as the value of the `-args` option to specify that the generated code must accept an input that has the same data type and array size as the training data `X`. If the number of observations is unknown at compile time, you can also specify the input as variable-size by using `coder.typeof`. For details, see “Specify Variable-Size Arguments for Code Generation” on page 31-58 and “Specify Properties of Entry-Point Function Inputs” (MATLAB Coder).

```
codegen classifyIris -args {X}
```

`codegen` generates the MEX function `classifyIris_mex` with a platform-dependent extension.

Verify Generated Code

Compare the labels classified using `predict`, `classifyIris`, and `classifyIris_mex`.

```
label1 = predict(Mdl,X);  
label2 = classifyIrises(X);  
label3 = classifyIrises_mex(X);  
verify_label = isequal(label1,label2,label3)  
  
verify_label = logical  
1
```

`isequal` returns logical 1 (true), which means all the inputs are equal. The labels classified all three ways are the same.

Input Arguments

Mdl — Machine learning model

full model object | compact model object

Machine learning model, specified as a full or compact model object, as given in the following tables of supported models.

- **Classification Model Object**

Model	Full/Compact Model Objects	Training Function
Binary decision tree for classification	ClassificationTree, CompactClassificationTree	fitctree
Discriminant analysis classification	ClassificationDiscriminant, CompactClassificationDiscriminant	fitcdiscr
Ensemble classifier	ClassificationEnsemble, CompactClassificationEnsemble, ClassificationBaggedEnsemble	fitcensemble
<i>k</i> -nearest neighbor classification	ClassificationKNN	fitcknn
Linear model for binary classification of high-dimensional data	ClassificationLinear	fitclinear
Multiclass model for support vector machines (SVMs) or other classifiers	ClassificationECOC, CompactClassificationECOC	fitcecoc
Naive Bayes classifier	ClassificationNaiveBayes, CompactClassificationNaiveBayes	fitcnb
SVM for one-class and binary classification	ClassificationSVM, CompactClassificationSVM	fitsvm

- **Regression Model Object**

Model	Full/Compact Model Object	Training Function
Ensemble regression	RegressionEnsemble, CompactRegressionEnsemble, RegressionBaggedEnsemble	fitrensemble
Gaussian process regression	RegressionGP, CompactRegressionGP	fitrgp
Generalized linear model	GeneralizedLinearModel, CompactGeneralizedLinearModel	fitglm, stepwiseglm
Linear regression model	LinearModel, CompactLinearModel	fitlm, stepwiselm
Linear regression for high-dimensional data	RegressionLinear	fitrlinear
Regression tree	RegressionTree, CompactRegressionTree	fitrtree
SVM regression	RegressionSVM, CompactRegressionSVM	fitrsvm

- **Nearest Neighbor Searcher Object**

Model	Model Object	Training Function
Exhaustive nearest neighbor searcher	ExhaustiveSearcher	ExhaustiveSearcher, createns
Nearest neighbor searcher using Kd-tree	KDTreeSearcher	KDTreeSearcher, createns

filename – File name

character vector | string scalar

File name, specified as a character vector or string scalar.

If the filename file exists, then saveCompactModel overwrites the file.

The extension of the `filename` file must be `.mat`. If `filename` has no extension, then `saveCompactModel` appends `.mat`.

If `filename` does not include a full path, then `saveCompactModel` saves the file to the current folder.

Example: `'SVMmdl'`

Data Types: `char` | `string`

Algorithms

`saveCompactModel` reduces the memory footprint of classification and regression models (`Mdl`) by removing properties that are not required for prediction.

- For a model that has a corresponding compact model, the `saveCompactModel` function applies the appropriate `compact` function to the model before saving it.
- For a model that does not have a corresponding compact model, such as `ClassificationLinear`, `RegressionLinear`, `ExhaustiveSearcher`, and `KDTreeSearcher`, the `saveCompactModel` function saves the model as it is.
- A `ClassificationKNN` model object is a full object that does not have a corresponding compact object. For this model, `saveCompactModel` saves a compact version that does not include the hyperparameter optimization properties.

`loadCompactModel` loads the reduced version saved by `saveCompactModel`.

Alternative Functionality

- Use a coder configurer created by `learnerCoderConfigurer` for the models listed in this table.

Model	Coder Configurer Object
Support vector machine (SVM) regression	<code>RegressionSVMCoderConfigurer</code>
SVM for one-class and binary classification	<code>ClassificationSVMCoderConfigurer</code>

Model	Coder Configurer Object
Multiclass model for SVMs	ClassificationECOCoderConfigurer

After training a machine learning model, create a coder configurer of the model. Use the object functions and properties of the configurer to configure code generation options and to generate code for the `predict` and `update` functions of the model. If you generate code using a coder configurer, you can update model parameters in the generated code without having to regenerate the code. For details, see “Code Generation for Prediction and Update Using Coder Configurer” on page 31-96.

Introduced in R2016b

scatterhist

Scatter plot with marginal histograms

Syntax

```
scatterhist(x,y)  
scatterhist(x,y,Name,Value)
```

```
h = scatterhist( ___ )
```

Description

`scatterhist(x,y)` creates a 2-D scatter plot of the data in vectors `x` and `y`, and displays the marginal distributions of `x` and `y` as univariate histograms on the horizontal and vertical axes of the scatter plot, respectively.

`scatterhist(x,y,Name,Value)` creates the plot using additional options specified by one or more name-value pair arguments. For example, you can specify a grouping variable or change the display options.

`h = scatterhist(___)` returns a vector of three axis handles for the scatter plot, the histogram along the horizontal axis, and the histogram along the vertical axis, respectively, using any of the input arguments in the previous syntaxes.

Examples

Create a Scatterhist Plot

Load the sample data. Create data vector `x` from the first column of the data matrix, which contains sepal length measurements from iris flowers. Create data vector `y` from the second column of the data matrix, which contains sepal width measurements from the same flowers.

```
load fisheriris.mat;  
x = meas(:,1);  
y = meas(:,2);
```

Create a scatter plot and two marginal histograms to visualize the relationship between sepal length and sepal width.

```
scatterhist(x,y)
```

Display a data tip for a bin in a histogram. A data tip appears when you hover over a bin in a histogram.

The data tip displays the probability density function estimate of the selected bin and the lower and upper values for the bin edges.

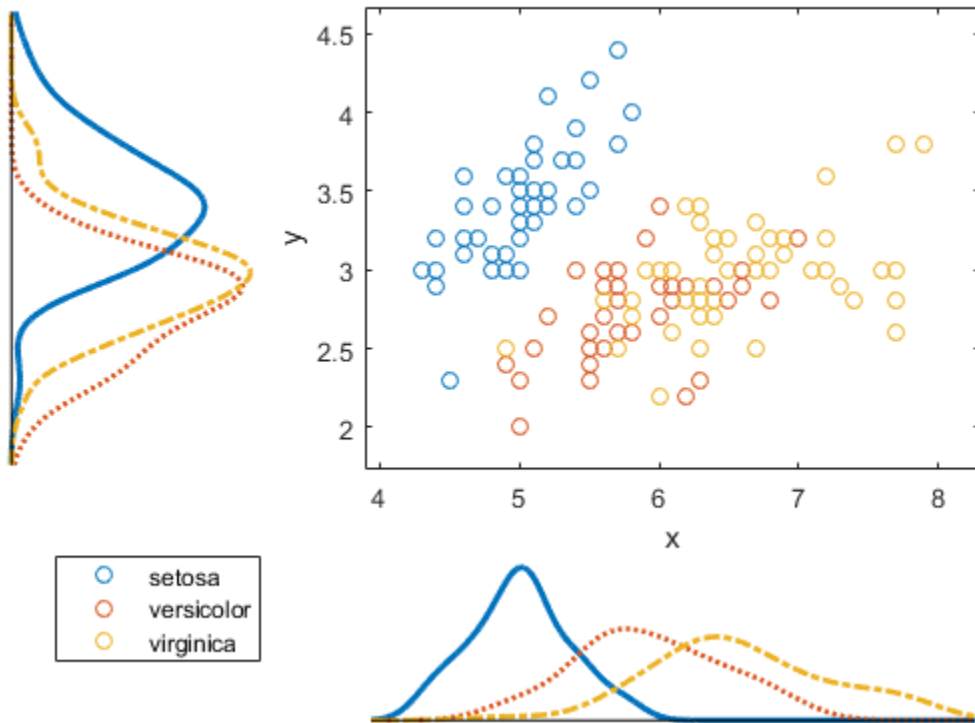

Plot Grouped Data

Load the sample data. Create data vector `x` from the first column of the data matrix, which contains sepal length measurements from three species of iris flowers. Create data vector `y` from the second column of the data matrix, which contains sepal width measurements from the same flowers.

```
load fisheriris.mat;
x = meas(:,1);
y = meas(:,2);
```

Create a scatter plot and six kernel density plots to visualize the relationship between sepal length and sepal width, grouped by species.

```
scatterhist(x,y,'Group',species,'Kernel','on')
```

The plot shows that the relationship between sepal length and width varies depending on the flower species.

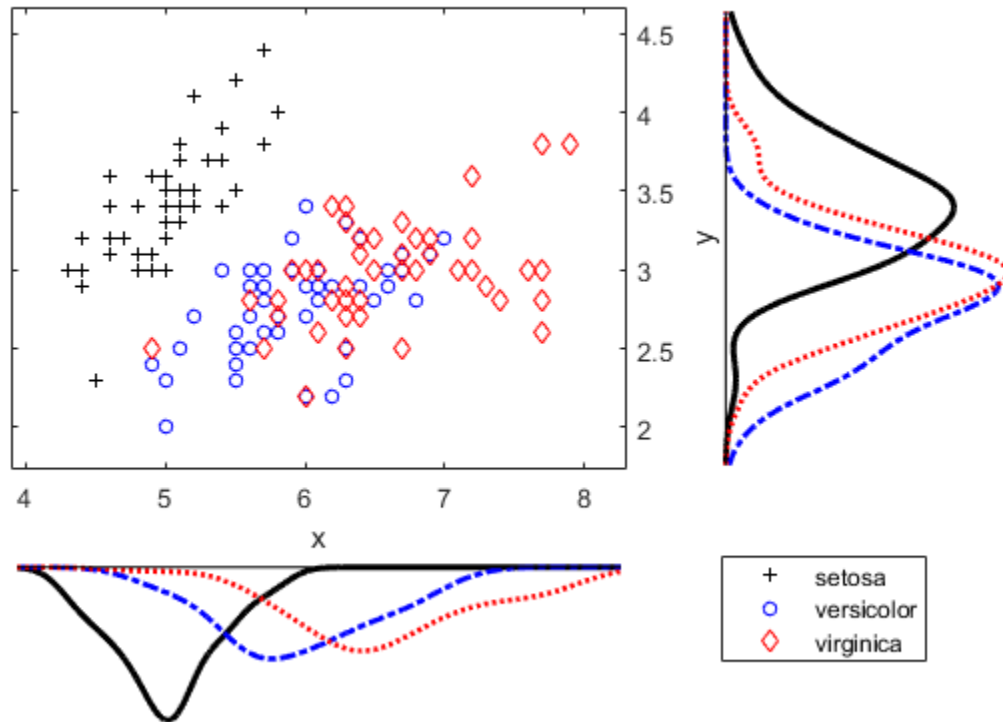

Customize the Plot Display

Load the sample data. Create data vector `x` from the first column of the data matrix, which contains sepal length measurements from three different species of iris flowers. Create data vector `y` from the second column of the data matrix, which contains sepal width measurements from the same flowers.

```
load fisheriris.mat;  
x = meas(:,1);  
y = meas(:,2);
```

Create a scatter plot and six kernel density plots to visualize the relationship between sepal length and sepal width as measured on three species of iris flowers, grouped by species. Customize the appearance of the plots.

```
scatterhist(x,y,'Group',species,'Kernel','on','Location','SouthEast',...  
            'Direction','out','Color','kbr','LineStyle',{'-','-.'},...  
            'LineWidth',[2,2,2],'Marker','+od','MarkerSize',[4,5,6]);
```

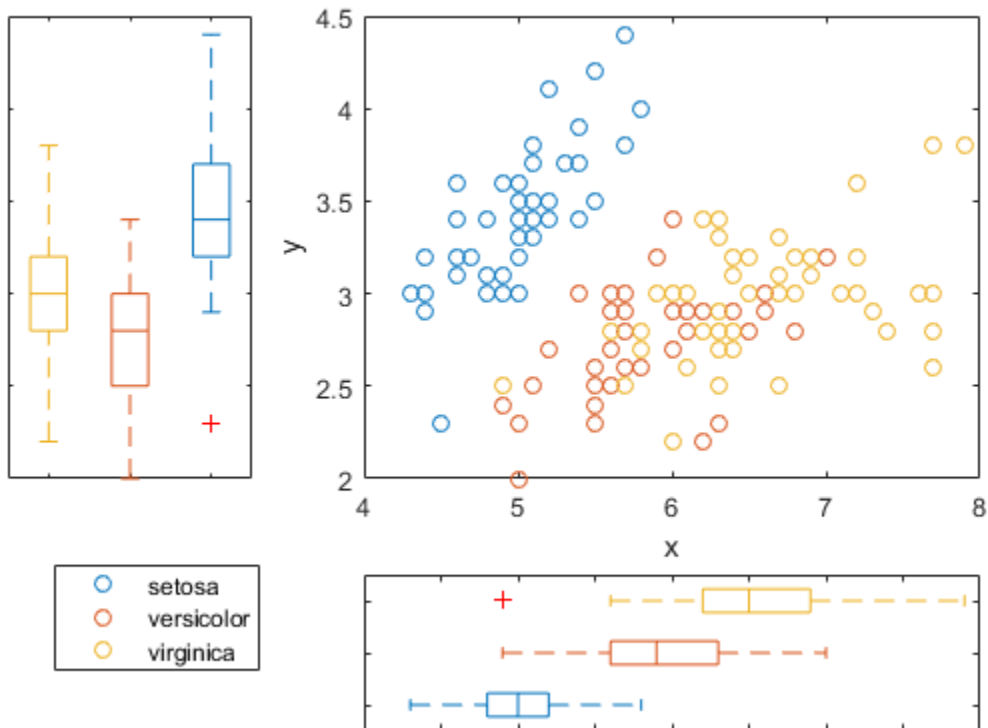

Customize Plots Using Axes Handles

Load the sample data. Create data vector `x` from the first column of the data matrix, which contains sepal length measurements from three species of iris flowers. Create data vector `y` from the second column of the data matrix, which contains sepal width measurements from the same flowers.

```
load fisheriris.mat;
x = meas(:,1);
y = meas(:,2);
```

Use axis handles to replace the marginal histograms with box plots.

```
h = scatterhist(x,y,'Group',species);
hold on;
clr = get(h(1),'colororder');
boxplot(h(2),x,species,'orientation','horizontal',...
        'label',{' ',' ',' '},'color',clr);
boxplot(h(3),y,species,'orientation','horizontal',...
        'label',{',' ',' ',' '},'color',clr);
set(h(2:3),'XTickLabel','');
view(h(3),[270,90]); % Rotate the Y plot
axis(h(1),'auto'); % Sync axes
hold off;
```

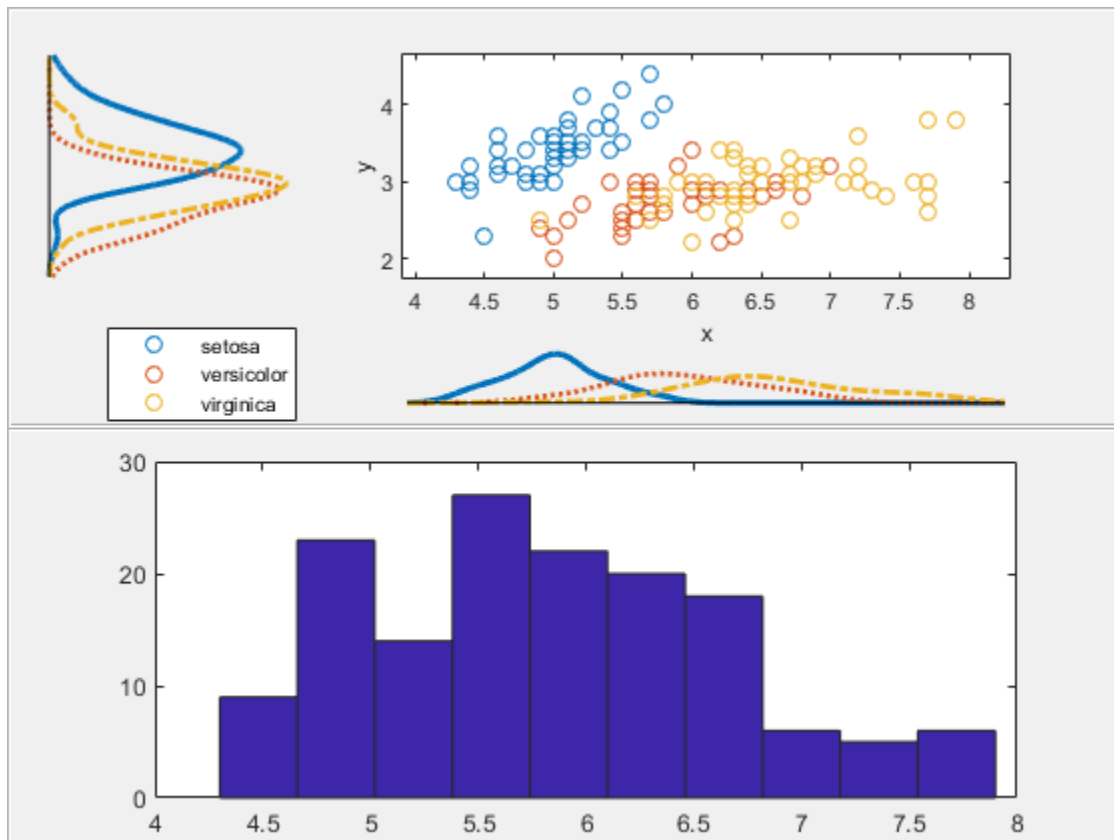

Create a scatterhist Plot in a Specified Parent Container

Load the sample data. Create data vector `x` from the first column of the data matrix, which contains sepal length measurements from iris flowers. Create data vector `y` from the second column of the data matrix, which contains sepal width measurements from the same flowers.

```
load fisheriris
x = meas(:,1);
y = meas(:,2);
```

Create a new figure and define two uipanel objects to divide the figure into two parts. In the upper half of the figure, plot the sample data using `scatterhist`. Include marginal kernel density plots grouped by species. In the lower half of the figure, plot a histogram of the sepal length measurements contained in `x`.

```
figure
hp1 = uipanel('position',[0 .5 1 .5]);
hp2 = uipanel('position',[0 0 1 .5]);
scatterhist(x,y,'Group',species,'Kernel','on','Parent',hp1);
axes('Parent',hp2);
hist(x);
```

Input Arguments

x — Sample data

vector

Sample data, specified as a vector. The data vectors `x` and `y` must be the same length.

If `x` or `y` contain NaN values, then `scatterhist`:

- Removes rows with NaN values in either `x` or `y` from both data vectors when generating the scatter plot
- Removes rows with NaN values only from the corresponding `x` or `y` data vector when generating the marginal histograms

Data Types: `single` | `double`

y — Sample data

vector

Sample data, specified as a vector. The data vectors `x` and `y` must be the same length.

If `x` or `y` contain NaN values, then `scatterhist`:

- Removes rows with NaN values in either `x` or `y` from both data vectors when generating the scatter plot
- Removes rows with NaN values only from the corresponding `x` or `y` data vector when generating the marginal histograms

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'Location', 'SouthEast', 'Direction', 'out'` specifies a plot with histograms located below and to the right of the scatter plot, with the bars directed away from the scatter plot.

NBins — Number of bins for histograms

positive integer value | vector

Number of bins for histograms, specified as the comma-separated pair consisting of 'NBins' and a positive integer value greater than or equal to 2, or vector of two such values. If the number of bins is specified as a positive integer value, that value is the number of bins for both the x and y histograms. If the number of bins is specified by a vector, the first value is the number of bins for the x data, and the second value is the number of bins for the y data. By default, the number of bins is computed based on the sample standard deviation using Scott's rule.

Example: 'NBins', [5,7]

Data Types: single | double

Location — Location of marginal histograms

'SouthWest' (default) | 'SouthEast' | 'NorthEast' | 'NorthWest'

Location of the marginal histograms in the figure, specified as the comma-separated pair consisting of 'Location' and one of the following.

'SouthWest' Plot the histograms below and to the left of the scatter plot.
t'

'SouthEast' Plot the histograms below and to the right of the scatter plot.
t'

'NorthEast' Plot the histograms above and to the right of the scatter plot.
t'

'NorthWest' Plot the histograms above and to the left of the scatter plot.
t'

Example: 'Location', 'SouthEast'

Direction — Direction of marginal histograms

'in' (default) | 'out'

Direction of the marginal histograms, specified as the comma-separated pair consisting of 'Direction' and one of the following.

'in' Plot the histograms with the bars directed toward the scatter plot.

'out' Plot the histograms with the bars directed away from the scatter plot.

Example: 'Direction', 'out'

Group — Grouping variable

categorical array | logical or numeric vector | character array | string array | cell array of character vectors

Grouping variable, specified as the comma-separated pair consisting of 'Group' and a categorical array, logical or numeric vector, character array, string array, or cell array of character vectors. Each unique value in a grouping variable defines a group.

For example, if Gender is a cell array of character vectors with values 'Male' and 'Female', you can use Gender as a grouping variable to plot your data by gender.

Example: 'Group', Gender

Data Types: categorical | single | double | logical | char | string | cell

PlotGroup — Grouped plot indicator

'on' | 'off'

Grouped plot indicator, specified as the comma-separated pair consisting of 'PlotGroup' and one of the following.

- 'on' Display grouped histograms or grouped kernel density plots. This is the default if a Group parameter is specified.
- 'off' Display histograms or kernel density plots of the whole data set. This is the default if a Group parameter is not specified.

Example: 'PlotGroup', 'off'

Style — Histogram display style

'stairs' | 'bar'

Histogram display style, specified as the comma-separated pair consisting of 'PlotGroup' and one of the following.

- 'stairs' Display a staircase plot that shows the outline of the histogram without filling the bars. This is the default if you specify a grouping variable that contains more than one group.

'bar' Display a histogram bar plot. This is the default if you specify a grouping variable that contains only one group or if `PlotGroup` is specified as 'off'.

Example: 'Style', 'bar'

Kernel — Kernel density plot indicator

'off' (default) | 'on' | 'overlay'

Kernel density plot indicator, specified as the comma-separated pair consisting of 'Kernel' and one of the following.

'off' Display the marginal distributions as histograms.
'on' Display the marginal distributions as kernel density plots.
'overlay' Display the marginal distributions as kernel density plots overlaid onto histograms, similar to `histfit`.

Example: 'Kernel', 'overlay'

Bandwidth — Bandwidth of kernel smoothing window

matrix

Bandwidth of kernel smoothing window, specified as the comma-separated pair consisting of 'Bandwidth' and a matrix of size 2-by- K , where K is the number of unique groups. The first row of the matrix gives the bandwidth of each group in x , and the second row gives the bandwidth of each group in y . By default, `scatterhist` finds the optimal bandwidth for estimating normal densities. Specifying a different bandwidth value changes the smoothing characteristics of the resulting kernel density plot. The value specified is a scaling factor for the normal distribution used to generate the kernel density plot.

Example: 'Bandwidth', [.5, .2, .1; .15, .25, .35]

Data Types: single | double

Legend — Legend visibility indicator

'on' | 'off'

Legend visibility indicator, specified as the comma-separated pair consisting of 'Legend' and one of the following.

'on' Set legend visible. This is the default if a Group parameter is specified.
 'off' Set legend invisible. This is the default if a Group parameter is not specified.

Example: 'Legend', 'on'

Parent — Parent container of the plot

uipanel container object | figure container object

Parent container for the plot, specified as a uipanel container object or figure container object. You can create panel container objects using uipanel or figure, respectively.

For example, if h1 is a panel container object, specify the parent container of the plot as follows.

Example: 'Parent', h1

LineStyle — Style of kernel density plot line

valid line style | string array or cell array of line styles

Style of kernel density plot line, specified as the comma-separated pair consisting of 'LineStyle' and a valid line style or a string array or cell array of valid line styles. See plot for valid line styles. The default is a solid line. Use a string array or cell array to specify different line styles for each group. When the total number of groups exceeds the number of specified values, scatterhist cycles through the specified values.

Example: 'LineStyle', {'-', ':', '-.'}

Data Types: char | string | cell

LineWidth — Width of kernel density plot line

0.5 (default) | nonnegative scalar value | vector

Width of kernel density plot line, specified as the comma-separated pair consisting of 'LineWidth' and a nonnegative scalar value or vector of nonnegative scalar values. The specified value is the size of the kernel density plot line measured in points. The default size is 0.5 points. Use a vector to specify different line widths for each group. When the total number of groups is greater than the number of specified values, scatterhist cycles through the specified values.

Example: 'LineWidth', [0.5, 1, 2]

Data Types: single | double

Color — Marker color for each scatter plot group

character vector or string scalar of color names | matrix of RGB values

Marker color for each scatter plot group, specified as the comma-separated pair consisting of 'Color' and a character vector or string scalar of color names, or a three-column matrix of RGB values in the range [0,1]. If you specify colors using a matrix, then each row of the matrix is an RGB triplet that represents a group. The three columns of the matrix represent the R value, G value, and B value, respectively. When the total number of groups exceeds the number of specified colors, `scatterhist` cycles through the specified colors.

This table lists the predefined colors and their equivalent RGB triplet values.

Option	Description	Equivalent RGB Triplet
'red' or 'r'	Red	[1 0 0]
'green' or 'g'	Green	[0 1 0]
'blue' or 'b'	Blue	[0 0 1]
'yellow' or 'y'	Yellow	[1 1 0]
'magenta' or 'm'	Magenta	[1 0 1]
'cyan' or 'c'	Cyan	[0 1 1]
'white' or 'w'	White	[1 1 1]
'black' or 'k'	Black	[0 0 0]

Example: 'Color', 'kcm'

Example: 'Color', [.5,0,1;0,.5,.5]

Data Types: single | double | char | string

Marker — Marker symbol for each scatterplot group

'o' (default) | character vector | string scalar

Marker symbol for each scatter plot group, specified as the comma-separated pair consisting of 'Marker' and a character vector or string scalar of one or more valid marker symbols. See `plot` for valid symbols. The default is 'o', a circle. When the total number of groups exceeds the number of specified symbols, `scatterhist` cycles through the specified symbols.

Example: 'Marker', '+do'

Data Types: `char` | `string`

MarkerSize — Marker size for each scatter plot group

6 (default) | nonnegative scalar value | vector

Marker size for each scatter plot group, specified as the comma-separated pair consisting of `'MarkerSize'` and a nonnegative scalar value or a vector of nonnegative scalar values, measured in points. When the total number of groups exceeds the number of specified values, `scatterhist` cycles through the specified values.

Example: `'MarkerSize',10`

Data Types: `single` | `double`

Output Arguments

h — Axes handles

vector

Axes handles for the three plots, returned as a vector. The vector contains the handles for the scatter plot, the histogram along the horizontal axis, and the histogram along the vertical axis, respectively.

Alternative Functionality

Alternatively, you can create a `ScatterHistogramChart` object by using the `scatterhistogram` function.

- Explore the data interactively in the object by panning, zooming, and using data tips. Unlike the `scatterhist` function, `scatterhistogram` updates the marginal histograms based on the data within the current scatter plot limits.
- Control the appearance and behavior of the scatter histogram chart by changing the `ScatterHistogramChart` Properties.

Introduced in R2007a

scramble

Scramble quasirandom point set

Syntax

```
ps = scramble(p,type)
ps = scramble(p,'clear')
ps = scramble(p)
```

Description

`ps = scramble(p,type)` returns a scrambled copy `ps` of the point set `p`, created using the scramble type specified by `type`. The point set `p` is either a `haltonset` or `sobolset` object, and each type of point set supports a different scramble type.

The scrambled point set `ps` is the same kind of object as `p`.

`ps = scramble(p,'clear')` removes the scramble setting from `p` and returns the result in `ps`.

`ps = scramble(p)` reapplies the existing scramble setting to `p`, which typically results in a different point set because of the randomness of the scrambling algorithms.

Examples

Create Halton Point Set

Generate a three-dimensional Halton point set, skip the first 1000 values, and then retain every 101st point.

```
p = haltonset(3,'Skip',1e3,'Leap',1e2)
```

```
p =
Halton point set in 3 dimensions (89180190640991 points)
```

Properties:

```
Skip : 1000
Leap : 100
ScrambleMethod : none
```

Apply reverse-radix scrambling by using `scramble`.

```
p = scramble(p, 'RR2')
```

```
p =
Halton point set in 3 dimensions (89180190640991 points)
```

Properties:

```
Skip : 1000
Leap : 100
ScrambleMethod : RR2
```

Generate the first four points by using `net`.

```
X0 = net(p,4)
```

```
X0 = 4×3
```

```
0.0928    0.6950    0.0029
0.6958    0.2958    0.8269
0.3013    0.6497    0.4141
0.9087    0.7883    0.2166
```

Generate every third point, up to the eleventh point, by using parenthesis indexing.

```
X = p(1:3:11,:)
```

```
X = 4×3
```

```
0.0928    0.6950    0.0029
0.9087    0.7883    0.2166
0.3843    0.9840    0.9878
0.6831    0.7357    0.7923
```

Scramble and Unscramble Sobol Point Set

Create and scramble a five-dimensional Sobol point set. Specify the 'MatousekAffineOwen' scramble type.

```
p = sobolset(5);
ps = scramble(p, 'MatousekAffineOwen');
```

Compare the first four points in the two point sets.

```
X = net(p,4)
```

```
X = 4×5
```

0	0	0	0	0
0.5000	0.5000	0.5000	0.5000	0.5000
0.2500	0.7500	0.2500	0.7500	0.2500
0.7500	0.2500	0.7500	0.2500	0.7500

```
X2 = net(ps,4)
```

```
X2 = 4×5
```

0.6681	0.2784	0.2476	0.5688	0.0513
0.4485	0.6735	0.5417	0.3285	0.9719
0.9940	0.9606	0.3515	0.1586	0.4742
0.1550	0.1202	0.9226	0.9262	0.5491

Remove the scramble setting from `ps` by using the 'clear' option. The point set `clearps` matches the original point set `p`.

```
clearps = scramble(ps, 'clear');
clearX = net(clearps,4)
```

```
clearX = 4×5
```

0	0	0	0	0
0.5000	0.5000	0.5000	0.5000	0.5000
0.2500	0.7500	0.2500	0.7500	0.2500
0.7500	0.2500	0.7500	0.2500	0.7500

Pass `ps` to the `scramble` function without additional input arguments. The software removes the scramble setting from `ps` and then reapplies it. Because of the randomness

of the scrambling algorithm, the new scrambled point set `newps` differs from the original scrambled point set `ps`.

```
newps = scramble(ps);  
newX = net(newps,4)
```

```
newX = 4×5
```

```
    0.6882    0.6261    0.9298    0.3314    0.4169  
    0.2442    0.1978    0.4307    0.6286    0.8666  
    0.7827    0.2868    0.5172    0.8430    0.1261  
    0.2772    0.8576    0.0164    0.1404    0.5905
```

Input Arguments

p — Point set

`haltonset` object | `sobolset` object

Point set, specified as either a `haltonset` or `sobolset` object.

Example: `sobolset(5)`

type — Scramble type

'RR2' | 'MatousekAffineOwen'

Scramble type, specified as 'RR2' or 'MatousekAffineOwen'. Different point sets support different scramble types, as indicated in this table.

Object	Scramble Type
<code>haltonset</code>	'RR2' — A permutation of the radical inverse coefficients derived by applying a reverse-radix operation to all of the possible coefficient values. The scramble is described in [1].
<code>sobolset</code>	'MatousekAffineOwen' — A random linear scramble combined with a random digital shift. The scramble is described in [2].

Introduced in R2008a

segment

Piecewise distribution segments containing input values

Syntax

```
s = segment(pd,x)
s = segment(pd,[],p)
```

Description

`s = segment(pd,x)` returns a vector `s` of positive integers indicating which segment in the piecewise distribution `pd` contains each quantile value in `x`.

The values 1, 2, and 3 in `s` indicate the lower tail, center, and upper tail segments in `pd`, respectively. If `pd` does not include a lower tail segment, then 1 and 2 indicate the center and upper tail segments, respectively.

`s = segment(pd,[],p)` returns a vector `s` of positive integers indicating which segment in the piecewise distribution `pd` contains each cumulative probability value in `p`.

Examples

Find Segment in `paretotails` Object

Generate a sample data set and create a `paretotails` object by fitting a piecewise distribution with Pareto tails to the generated data. Find the segment containing the specified quantile values by using the object function `segment`.

Generate a sample data set containing 20% outliers.

```
rng('default'); % For reproducibility
left_tail = -exprnd(1,100,1);
right_tail = exprnd(5,100,1);
```

```
center = randn(800,1);
x = [left_tail;center;right_tail];
```

Create a `paretotails` object by fitting a piecewise distribution to `x`. Specify the boundaries of the tails using the lower and upper tail cumulative probabilities so that a fitted object consists of the empirical distribution for the middle 80% of the data set and generalized Pareto distributions (GPDs) for the lower and upper 10% of the data set.

```
pd = paretotails(x,0.1,0.9)

pd =
Piecewise distribution with 3 segments
  -Inf < x < -1.33251    (0 < p < 0.1): lower tail, GPD(-0.0063504,0.567017)
 -1.33251 < x < 1.80149 (0.1 < p < 0.9): interpolated empirical cdf
  1.80149 < x < Inf     (0.9 < p < 1): upper tail, GPD(0.24874,3.00974)
```

Find the segment containing the specified points by using the `segment` function.

```
xpts = -3:3;
s = segment(pd,xpts)
```

```
s = 1×7
     1     1     2     2     2     3     3
```

1, 2, and 3 indicate the lower tail, center, and upper tail segments in `pd`, respectively.

Draw the scatter plot of the points (`xpts`) grouped by their segments over the cumulative distribution function (`cdf`) plot. Plot the `cdf` of `pd`.

```
xgrid = linspace(icdf(pd,.01), icdf(pd,.99));
ygrid = cdf(pd,xgrid);
plot(xgrid,ygrid)
```

Superimpose the scatter plot of `xpts` by using `gscatter`.

```
hold on
gscatter(xpts,cdf(pd,xpts),s)
legend('cdf','Lower tail','Center','Upper tail')
hold off
```

Find Segment Containing Boundary Points

Generate a sample data set and create a `paretotails` object by fitting a piecewise distribution with Pareto tails to the generated data. Find the segment containing the boundary points by using the object function `segment`.

Generate a sample data set containing 20% outliers.

```
rng('default'); % For reproducibility
left_tail = -exprnd(1,100,1);
right_tail = exprnd(5,100,1);
```

```
center = randn(800,1);
x = [left_tail;center;right_tail];
```

Create a `paretotails` object by fitting a piecewise distribution to `x`. Specify the boundaries of the tails using the lower and upper tail cumulative probabilities so that a fitted object consists of the empirical distribution for the middle 80% of the data set and generalized Pareto distributions (GPDs) for the lower and upper 10% of the data set.

```
pd = paretotails(x,0.1,0.9)
```

```
pd =
Piecewise distribution with 3 segments
  -Inf < x < -1.33251    (0 < p < 0.1): lower tail, GPD(-0.0063504,0.567017)
 -1.33251 < x < 1.80149 (0.1 < p < 0.9): interpolated empirical cdf
  1.80149 < x < Inf    (0.9 < p < 1): upper tail, GPD(0.24874,3.00974)
```

Return the boundary values between the piecewise segments by using the `boundary` function.

```
[p,q] = boundary(pd)
```

```
p = 2×1

    0.1000
    0.9000
```

```
q = 2×1

   -1.3325
    1.8015
```

The values in `p` are the cumulative probabilities at the boundaries, and the values in `q` are the corresponding quantiles.

Find the segment containing the boundary points by using the quantile values.

```
s1 = segment(pd,q)
```

```
s1 = 2×1

     2
     3
```

1, 2, and 3 indicate the lower tail, center, and upper tail segments in `pd`, respectively. The output `s1` implies that the first boundary between the lower tail segment and the center segment belongs to the center segment, and the second boundary between the center segment and the upper tail segment belongs to the upper tail segment.

You can also use the cumulative probability values to find the corresponding segments.

```
s2 = segment(pd, [], [0;p;1])
```

```
s2 = 4×1
```

```
1  
2  
3  
3
```

Input Arguments

pd — Piecewise distribution with Pareto tails

`paretotails` object

Piecewise distribution with Pareto tails, specified as a `paretotails` object.

x — Quantile

numeric vector

Quantile values, specified as a numeric vector.

Data Types: `single` | `double`

p — Cumulative probability

numeric vector of range `[0, 1]` values

Cumulative probability values, specified as a numeric vector of range `[0, 1]` values.

Data Types: `single` | `double`

See Also

selectModels

Class: ClassificationLinear

Choose subset of regularized, binary linear classification models

Syntax

```
SubMdl = selectModels(Mdl,idx)
```

Description

`SubMdl = selectModels(Mdl,idx)` returns a subset of trained, binary linear classification models from a set of binary linear classification models (`Mdl`) trained using various regularization strengths. The indices (`idx`) correspond to the regularization strengths in `Mdl.Lambda`, and specify which models to return.

Input Arguments

Mdl — Binary linear classification models trained using various regularization strengths

ClassificationLinear model object

Binary linear classification models trained using various regularization strengths, specified as a ClassificationLinear model object. You can create a ClassificationLinear model object using `fitclinear`.

Although `Mdl` is one model object, if `numel(Mdl.Lambda) = L ≥ 2`, then you can think of `Mdl` as L trained models.

idx — Indices corresponding to regularization strengths

numeric vector of positive integers

Indices corresponding to regularization strengths, specified as a numeric vector of positive integers. Values of `idx` must be in the interval $[1,L]$, where $L = \text{numel}(Mdl.Lambda)$.

Data Types: double | single

Output Arguments

SubMdl — Subset of binary linear classification models trained using various regularization strengths

ClassificationLinear model object

Subset of binary linear classification models trained using various regularization strengths, returned as a ClassificationLinear model object.

Examples

Find Good Lasso Penalty Using Classification Loss

To determine a good lasso-penalty strength for a linear classification model that uses a logistic regression learner, compare test-sample classification error rates.

Load the NLP data set. Preprocess the data as in “Specify Custom Classification Loss” on page 32-3879.

```
load nlpdata
Ystats = Y == 'stats';
X = X';

rng(10); % For reproducibility
Partition = cvpartition(Ystats, 'Holdout', 0.30);
testIdx = test(Partition);
XTest = X(:, testIdx);
YTest = Ystats(testIdx);
```

Create a set of 11 logarithmically-spaced regularization strengths from 10^{-6} through $10^{-0.5}$.

```
Lambda = logspace(-6, -0.5, 11);
```

Train binary, linear classification models that use each of the regularization strengths. Optimize the objective function using SpaRSA. Lower the tolerance on the gradient of the objective function to $1e-8$.

```
CVMdl = fitclinear(X,Ystats,'ObservationsIn','columns',...  
    'CVPartition',Partition,'Learner','logistic','Solver','sparsa',...  
    'Regularization','lasso','Lambda',Lambda,'GradientTolerance',1e-8)
```

```
CVMdl =  
classreg.learning.partition.ClassificationPartitionedLinear  
    CrossValidatedModel: 'Linear'  
    ResponseName: 'Y'  
    NumObservations: 31572  
    KFold: 1  
    Partition: [1x1 cvpartition]  
    ClassNames: [0 1]  
    ScoreTransform: 'none'
```

Properties, Methods

Extract the trained linear classification model.

```
Mdl = CVMdl.Trained{1}
```

```
Mdl =  
ClassificationLinear  
    ResponseName: 'Y'  
    ClassNames: [0 1]  
    ScoreTransform: 'logit'  
        Beta: [34023x11 double]  
        Bias: [1x11 double]  
        Lambda: [1x11 double]  
    Learner: 'logistic'
```

Properties, Methods

Mdl is a `ClassificationLinear` model object. Because `Lambda` is a sequence of regularization strengths, you can think of Mdl as 11 models, one for each regularization strength in `Lambda`.

Estimate the test-sample classification error.

```
ce = loss(Mdl,X(:,testIdx),Ystats(testIdx),'ObservationsIn','columns');
```

Because there are 11 regularization strengths, `ce` is a 1-by-11 vector of classification error rates.

Higher values of `Lambda` lead to predictor variable sparsity, which is a good quality of a classifier. For each regularization strength, train a linear classification model using the entire data set and the same options as when you cross-validated the models. Determine the number of nonzero coefficients per model.

```
Mdl = fitclinear(X,Ystats,'ObservationsIn','columns',...  
    'Learner','logistic','Solver','sparsa','Regularization','lasso',...  
    'Lambda',Lambda,'GradientTolerance',1e-8);  
numNZCoeff = sum(Mdl.Beta~=0);
```

In the same figure, plot the test-sample error rates and frequency of nonzero coefficients for each regularization strength. Plot all variables on the log scale.

```
figure;  
[h,hL1,hL2] = plotyy(log10(Lambda),log10(ce),...  
    log10(Lambda),log10(numNZCoeff + 1));  
hL1.Marker = 'o';  
hL2.Marker = 'o';  
ylabel(h(1),'log_{10} classification error')  
ylabel(h(2),'log_{10} nonzero-coefficient frequency')  
xlabel('log_{10} Lambda')  
title('Test-Sample Statistics')  
hold off
```

Choose the index of the regularization strength that balances predictor variable sparsity and low classification error. In this case, a value between 10^{-4} to 10^{-1} should suffice.

```
idxFinal = 7;
```

Select the model from `Mdl` with the chosen regularization strength.

```
MdlFinal = selectModels(Mdl,idxFinal);
```

`MdlFinal` is a `ClassificationLinear` model containing one regularization strength. To estimate labels for new observations, pass `MdlFinal` and the new data to `predict`.

Tip

One way to build several predictive, binary linear classification models is:

- 1 Hold out a portion of the data for testing.
- 2 Train a binary, linear classification model using `fitclinear`. Specify a grid of regularization strengths using the 'Lambda' name-value pair argument and supply the training data. `fitclinear` returns one `ClassificationLinear` model object, but it contains a model for each regularization strength.
- 3 To determine the quality of each regularized model, pass the returned model object and the held-out data to, for example, `loss`.
- 4 Identify the indices (`idx`) of a satisfactory subset of regularized models, and then pass the returned model and the indices to `selectModels`. `selectModels` returns one `ClassificationLinear` model object, but it contains `numel(idx)` regularized models.
- 5 To predict class labels for new data, pass the data and the subset of regularized models to `predict`.

See Also

`ClassificationLinear` | `fitclinear` | `loss` | `predict`

Introduced in R2016a

selectModels

Package: `classreg.learning.classif`

Choose subset of multiclass ECOC models composed of binary `ClassificationLinear` learners

Syntax

```
SubMdl = selectModels(Mdl, idx)
```

Description

`SubMdl = selectModels(Mdl, idx)` returns a subset of trained error-correcting output codes (ECOC) models composed of `ClassificationLinear` binary models from a set of multiclass ECOC models (`Mdl`) trained using various regularization strengths. The indices (`idx`) correspond to the regularization strengths in `Mdl.BinaryLearners{1}.Lambda` and specify which models to return.

`SubMdl` is returned as a `CompactClassificationECOC` model object.

Examples

Select Best Regularized Models

Choose a subset of trained ECOC models composed of linear binary learners with various regularization strengths.

Load the NLP data set.

```
load nlpdata
```

`X` is a sparse matrix of predictor data, and `Y` is a categorical vector of class labels.

Create a set of 11 logarithmically spaced regularization strengths from 10^{-8} through 10^{-1} .

```
Lambda = logspace(-8,-1,11);
```

Create a linear classification model template that specifies optimizing the objective function using SpARSA. Use lasso penalties with the strengths specified in Lambda.

```
t = templateLinear('Solver','sparsa','Regularization','lasso',...
    'Lambda',Lambda);
```

Hold out 30% of the data for testing. Identify the test-sample indices.

```
rng(1); % For reproducibility
cvp = cvpartition(Y,'Holdout',0.30);
idxTest = test(cvp);
```

Train an ECOC model composed of linear classification models. For quicker execution time, orient the predictor data so that individual observations correspond to columns.

```
X = X';
PMdl = fitcecoc(X,Y,'Learners',t,'ObservationsIn','columns','CVPartition',cvp);
Mdl = PMdl.Trained{1};
numel(Mdl.BinaryLearners{1}.Lambda)
```

```
ans = 11
```

Mdl is a CompactClassificationECOC model object. Because Lambda is an 11-dimensional vector of regularization strengths, you can think of Mdl as eleven trained models, each corresponding to a regularization strength.

Estimate the test-sample misclassification rates for each regularized model.

```
ce = loss(Mdl,X(:,idxTest),Y(idxTest),'ObservationsIn','columns');
```

Plot the misclassification rates with respect to regularization strength on the log scale.

```
figure
plot(log10(Lambda),log10(ce),'-o')
ylabel('log_{10} misclassification rates')
xlabel('log_{10} Lambda')
[~,minCEIdx] = min(ce);
minLambda = Lambda(minCEIdx);
hold on
```

```
plot(log10(minLambda), log10(ce(minCEIdx)), 'ro');  
hold off
```

Several values of Lambda yield similarly small classification error values. Consider choosing greater values of Lambda (that still yield good classification rates) because they lead to predictor variable sparsity.

Select the four models with regularization strengths that occur around the point at which the classification error starts increasing.

```
idx = 7:10;  
MdlFinal = selectModels(Mdl, idx)
```

```
MdlFinal =
  classreg.learning.classif.CompactClassificationECOC
    ResponseName: 'Y'
    ClassNames: [comm dsp encoder fixedpoint hdlcoder phased physr
    ScoreTransform: 'none'
    BinaryLearners: {78x1 cell}
    CodingMatrix: [13x78 double]
```

Properties, Methods

```
LambdaFinal = MdlFinal.BinaryLearners{1}.Lambda
```

```
LambdaFinal = 1x4
```

```
    0.0002    0.0008    0.0040    0.0200
```

`MdlFinal` is a `CompactClassificationECOC` model object. You can think of it as four models trained using the four regularization strengths in `LambdaFinal`.

Input Arguments

Mdl — Multiclass ECOC model composed of binary linear classifiers

`CompactClassificationECOC` model object

Multiclass ECOC model composed of binary linear classifiers, trained using various regularization strengths, specified as a `CompactClassificationECOC` model object.

When creating `Mdl`, you must:

- Use `fitcecoc`.
- Specify `ClassificationLinear` binary learners (see `Learners`).
- Specify the same regularization strengths for each linear binary learner.

Although `Mdl` is one model object, if `numel(Mdl.BinaryLearners{1}.Lambda) = L ≥ 2`, then you can think of `Mdl` as L trained models.

idx — Indices corresponding to regularization strengths

positive integer vector

Indices corresponding to regularization strengths, specified as a positive integer vector. Values of `idx` must be in the interval $[1,L]$, where $L = \text{numel}(\text{Mdl.BinaryLearners}\{1\}.\text{Lambda})$.

Data Types: `double` | `single`

Tips

- One way to build several predictive ECOC models composed of binary linear classification models is:
 - 1 Create a linear classification model template using `templateLinear` and specify a grid of regularization strengths using the 'Lambda' name-value pair argument.
 - 2 Hold out a portion of the data for testing.
 - 3 Train an ECOC model using `fitcecoc`. Specify the template using the 'Learners' name-value pair argument and supply the training data. `fitcecoc` returns one `CompactClassificationECOC` model object containing `ClassificationLinear` binary learners, but all binary learners contain a model for each regularization strength.
 - 4 To determine the quality of each regularized model, pass the returned model object and the held-out data to, for example, `loss`.
 - 5 Identify the indices (`idx`) of a satisfactory subset of regularized models, and then pass the returned model and the indices to `selectModels`. The function `selectModels` returns one `CompactClassificationECOC` model object, but it contains `numel(idx)` regularized models.
 - 6 To predict class labels for new data, pass the data and the subset of regularized models to `predict`.

Introduced in R2016a

selectModels

Class: RegressionLinear

Select fitted regularized linear regression models

Syntax

```
SubMdl = selectModels(Mdl,idx)
```

Description

`SubMdl = selectModels(Mdl,idx)` returns a subset of trained linear regression models from a set of linear regression models (`Mdl`) trained using various regularization strengths. The indices `idx` correspond to the regularization strengths in `Mdl.Lambda`, and specify which models to return.

Input Arguments

Mdl — Linear regression models trained using various regularization strengths

RegressionLinear model object

Linear regression models trained using various regularization strengths, specified as a RegressionLinear model object. You can create a RegressionLinear model object using `fitrlinear`.

Although `Mdl` is one model object, if $\text{numel}(\text{Mdl.Lambda}) = L \geq 2$, then you can think of `Mdl` as L trained models.

idx — Indices corresponding to regularization strengths

numeric vector of positive integers

Indices corresponding to regularization strengths, specified as a numeric vector of positive integers. Values of `idx` must be in the interval $[1,L]$, where $L = \text{numel}(\text{Mdl.Lambda})$.

Data Types: double | single

Output Arguments

SubMdl — Subset of linear regression models trained using various regularization strengths

RegressionLinear model object

Subset of linear regression models trained using various regularization strengths, returned as a RegressionLinear model object.

Examples

Find Good Lasso Penalty Using Regression Loss

Simulate 10000 observations from this model

$$y = x_{100} + 2x_{200} + e.$$

- $X = \{x_1, \dots, x_{1000}\}$ is a 10000-by-1000 sparse matrix with 10% nonzero standard normal elements.
- e is random normal error with mean 0 and standard deviation 0.3.

```
rng(1) % For reproducibility
n = 1e4;
d = 1e3;
nz = 0.1;
X = sprandn(n,d,nz);
Y = X(:,100) + 2*X(:,200) + 0.3*randn(n,1);
```

Create a set of 15 logarithmically-spaced regularization strengths from 10^{-4} through 10^{-1} .

```
Lambda = logspace(-4, -1, 15);
```

Hold out 30% of the data for testing. Identify the test-sample indices.

```
cvp = cvpartition(numel(Y), 'Holdout', 0.30);
idxTest = test(cvp);
```

Train a linear regression model using lasso penalties with the strengths in `Lambda`. Specify the regularization strengths, optimizing the objective function using SpaRSA, and the data partition. To increase execution speed, transpose the predictor data and specify that the observations are in columns.

```
X = X';
CVMdl = fitrlinear(X,Y,'ObservationsIn','columns','Lambda',Lambda,...
    'Solver','sparsa','Regularization','lasso','CVPartition',cvp);
Mdl1 = CVMdl.Trained{1};
numel(Mdl1.Lambda)
```

```
ans = 15
```

`Mdl1` is a `RegressionLinear` model. Because `Lambda` is a 15-dimensional vector of regularization strengths, you can think of `Mdl1` as 15 trained models, one for each regularization strength.

Estimate the test-sample mean squared error for each regularized model.

```
mse = loss(Mdl1,X(:,idxTest),Y(idxTest),'ObservationsIn','columns');
```

Higher values of `Lambda` lead to predictor variable sparsity, which is a good quality of a regression model. Retrain the model using the entire data set and all options used previously, except the data-partition specification. Determine the number of nonzero coefficients per model.

```
Mdl = fitrlinear(X,Y,'ObservationsIn','columns','Lambda',Lambda,...
    'Solver','sparsa','Regularization','lasso');
numNZCoeff = sum(Mdl.Beta~=0);
```

In the same figure, plot the MSE and frequency of nonzero coefficients for each regularization strength. Plot all variables on the log scale.

```
figure;
[h,hL1,hL2] = plotyy(log10(Lambda),log10(mse),...
    log10(Lambda),log10(numNZCoeff));
hL1.Marker = 'o';
hL2.Marker = 'o';
ylabel(h(1),'log_{10} MSE')
ylabel(h(2),'log_{10} nonzero-coefficient frequency')
xlabel('log_{10} Lambda')
hold off
```

Select the index or indices of `Lambda` that balance minimal classification error and predictor-variable sparsity (for example, `Lambda(11)`).

```
idx = 11;
MdlFinal = selectModels(Mdl,idx);
```

`MdlFinal` is a trained `RegressionLinear` model object that uses `Lambda(11)` as a regularization strength.

Tip

One way to build several predictive linear regression models is:

- 1 Hold out a portion of the data for testing.
- 2 Train a linear regression model using `fitrlinear`. Specify a grid of regularization strengths using the 'Lambda' name-value pair argument and supply the training data. `fitrlinear` returns one `RegressionLinear` model object, but it contains a model for each regularization strength.
- 3 To determine the quality of each regularized model, pass the returned model object and the held-out data to, for example, `loss`.
- 4 Identify the indices (`idx`) of a satisfactory subset of regularized models, and then pass the returned model and the indices to `selectModels`. `selectModels` returns one `RegressionLinear` model object, but it contains `numel(idx)` regularized models.
- 5 To predict class labels for new data, pass the data and the subset of regularized models to `predict`.

Introduced in R2016a

sequentialfs

Sequential feature selection

Syntax

```
inmodel = sequentialfs(fun,X,y)
inmodel = sequentialfs(fun,X,Y,Z,...)
[inmodel,history] = sequentialfs(fun,X,...)
[] = sequentialfs(...,param1,val1,param2,val2,...)
```

Description

`inmodel = sequentialfs(fun,X,y)` selects a subset of features from the data matrix `X` that best predict the data in `y` by sequentially selecting features until there is no improvement in prediction. Rows of `X` correspond to observations; columns correspond to variables or features. `y` is a column vector of response values or class labels for each observation in `X`. `X` and `y` must have the same number of rows. `fun` is a function handle to a function that defines the criterion used to select features and to determine when to stop. The output `inmodel` is a logical vector indicating which features are finally chosen.

Starting from an empty feature set, `sequentialfs` creates candidate feature subsets by sequentially adding each of the features not yet selected. For each candidate feature subset, `sequentialfs` performs 10-fold cross-validation by repeatedly calling `fun` with different training subsets of `X` and `y`, `XTRAIN` and `ytrain`, and test subsets of `X` and `y`, `XTEST` and `ytest`, as follows:

```
criterion = fun(XTRAIN,ytrain,XTEST,ytest)
```

`XTRAIN` and `ytrain` contain the same subset of rows of `X` and `Y`, while `XTEST` and `ytest` contain the complementary subset of rows. `XTRAIN` and `XTEST` contain the data taken from the columns of `X` that correspond to the current candidate feature set.

Each time it is called, `fun` must return a scalar value `criterion`. Typically, `fun` uses `XTRAIN` and `ytrain` to train or fit a model, then predicts values for `XTEST` using that model, and finally returns some measure of distance, or loss, of those predicted values from `ytest`. In the cross-validation calculation for a given candidate feature set,

`sequentialfs` sums the values returned by `fun` and divides that sum by the total number of test observations. It then uses that mean value to evaluate each candidate feature subset.

Typical loss measures include sum of squared errors for regression models (`sequentialfs` computes the mean-squared error in this case), and the number of misclassified observations for classification models (`sequentialfs` computes the misclassification rate in this case).

Note `sequentialfs` divides the sum of the values returned by `fun` across all test sets by the total number of test observations. Accordingly, `fun` should not divide its output value by the number of test observations.

After computing the mean `criterion` values for each candidate feature subset, `sequentialfs` chooses the candidate feature subset that minimizes the mean criterion value. This process continues until adding more features does not decrease the criterion.

`inmodel = sequentialfs(fun,X,Y,Z,...)` allows any number of input variables `X`, `Y`, `Z`, `sequentialfs` chooses features (columns) only from `X`, but otherwise imposes no interpretation on `X`, `Y`, `Z`, All data inputs, whether column vectors or matrices, must have the same number of rows. `sequentialfs` calls `fun` with training and test subsets of `X`, `Y`, `Z`, ... as follows:

```
criterion = fun(XTRAIN,YTRAIN,ZTRAIN,...,  
               XTEST,YTEST,ZTEST,...)
```

`sequentialfs` creates `XTRAIN`, `YTRAIN`, `ZTRAIN`, ... , `XTEST`, `YTEST`, `ZTEST`, ... by selecting subsets of the rows of `X`, `Y`, `Z`, `fun` must return a scalar value `criterion`, but may compute that value in any way. Elements of the logical vector `inmodel` correspond to columns of `X` and indicate which features are finally chosen.

`[inmodel,history] = sequentialfs(fun,X,...)` returns information on which feature is chosen at each step. `history` is a scalar structure with the following fields:

- `Crit` — A vector containing the criterion values computed at each step.
- `In` — A logical matrix in which row `i` indicates the features selected at step `i`.

`[] = sequentialfs(...,param1,val1,param2,val2,...)` specifies optional parameter name/value pairs from the following table.

Parameter	Value
'cv'	<p>The validation method used to compute the criterion for each candidate feature subset.</p> <ul style="list-style-type: none"> • When the value is a positive integer k, <code>sequentialfs</code> uses k-fold cross-validation without stratification. • When the value is an object of the <code>cvpartition</code> on page 32-1237 class, other forms of cross-validation can be specified. • When the value is <code>'resubstitution'</code>, the original data are passed to <code>fun</code> as both the training and test data to compute the criterion. • When the value is <code>'none'</code>, <code>sequentialfs</code> calls <code>fun</code> as <code>criterion = fun(X,Y,Z,...)</code>, without separating test and training sets. <p>The default value is <code>10</code>, that is, 10-fold cross-validation without stratification.</p> <p>So-called wrapper methods use a function <code>fun</code> that implements a learning algorithm. These methods usually apply cross-validation to select features. So-called filter methods use a function <code>fun</code> that measures characteristics of the data (such as correlation) to select features.</p>
'mcreps'	<p>A positive integer indicating the number of Monte-Carlo repetitions for cross-validation. The default value is <code>1</code>. The value must be <code>1</code> if the value of <code>'cv'</code> is <code>'resubstitution'</code> or <code>'none'</code>.</p>
'direction'	<p>The direction of the sequential search. The default is <code>'forward'</code>. A value of <code>'backward'</code> specifies an initial candidate set including all features and an algorithm that removes features sequentially until the criterion increases.</p>
'keepin'	<p>A logical vector or a vector of column numbers specifying features that must be included. The default is empty.</p>
'keepout'	<p>A logical vector or a vector of column numbers specifying features that must be excluded. The default is empty.</p>

Parameter	Value
'nfeatures'	The number of features at which <code>sequentialfs</code> should stop. <code>inmodel</code> includes exactly this many features. The default value is empty, indicating that <code>sequentialfs</code> should stop when a local minimum of the criterion is found. A nonempty value overrides values of 'MaxIter' and 'TolFun' in 'options'.
'nullmodel'	A logical value, indicating whether or not the null model (containing no features from X) should be included in feature selection and in the history output. The default is <code>false</code> .
'options'	Options structure for the iterative sequential search algorithm, as created by <code>statset</code> . <code>sequentialfs</code> uses the following <code>statset</code> parameters: <ul style="list-style-type: none"> • <code>Display</code> — Amount of information displayed by the algorithm. The default is 'off'. • <code>MaxIter</code> — Maximum number of iterations allowed. The default is <code>Inf</code>. • <code>TolFun</code> — Termination tolerance for the objective function value. The default is <code>1e-6</code> if 'direction' is 'forward'; <code>0</code> if 'direction' is 'backward'. • <code>TolTypeFun</code> — Use absolute or relative objective function tolerances. The default is 'rel'. • <code>UseParallel</code> — Set to <code>true</code> to compute in parallel. Default is <code>false</code>. • <code>UseSubstreams</code> — Set to <code>true</code> to compute in parallel in a reproducible fashion. Default is <code>false</code>. To compute reproducibly, set <code>Streams</code> to a type allowing substreams: 'mlfg6331_64' or 'mrg32k3a'. • <code>Streams</code> — A <code>RandStream</code> object or cell array consisting of one such object. If you do not specify <code>Streams</code>, <code>sequentialfs</code> uses the default stream. <p>To compute in parallel, you need Parallel Computing Toolbox.</p>

Examples

Perform sequential feature selection for classification of noisy features:

```
load fisheriris;
X = randn(150,10);
X(:,[1 3 5 7])= meas;
y = species;

c = cvpartition(y,'k',10);
opts = statset('display','iter');
fun = @(XT,yT,Xt,yt)...
      (sum(~strcmp(yt,classify(Xt,XT,yT,'quadratic'))));

[fs,history] = sequentialfs(fun,X,y,'cv',c,'options',opts)
```

Start forward sequential feature selection:

```
Initial columns included: none
Columns that cannot be included: none
Step 1, added column 7, criterion value 0.04
Step 2, added column 5, criterion value 0.0266667
Final columns included: 5 7
```

```
fs =
    0  0  0  0  1  0  1  0  0  0
history =
    In: [2x10 logical]
    Crit: [0.0400 0.0267]
```

```
history.In
ans =
    0  0  0  0  0  0  1  0  0  0
    0  0  0  0  1  0  1  0  0  0
```

Extended Capabilities

Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the 'UseParallel' option to true.

Set the 'UseParallel' field of the options structure to true using `statset` and specify the 'Options' name-value pair argument in the call to this function.

For example: `'Options',statset('UseParallel',true)`

For more information, see the 'Options' name-value pair argument.

For more general information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

Topics

“Feature Selection” on page 15-69

Introduced in R2008a

set

Class: dataset

Set and display properties

Note The dataset data type might be removed in a future release. To work with heterogeneous data, use the MATLAB[®] table data type instead. See MATLAB table documentation for more information.

Syntax

```
set(A)
set(A,PropertyName)
A = set(A,PropertyName,PropertyValue,...)
B = set(A,PropertyName,value)
```

Description

`set(A)` displays all properties of the dataset array `A` and their possible values.

`set(A,PropertyName)` displays possible values for the property specified by `PropertyName`.

`A = set(A,PropertyName,PropertyValue,...)` sets property name/value pairs.

`B = set(A,PropertyName,value)` returns a dataset array `B` that is a copy of `A`, but with the property 'PropertyName' set to the value `value`.

Note Using `set(A,'PropertyName',value)` without assigning to a variable does not modify `A`'s properties. Use `A = set(A,'PropertyName',value)` to modify `A`.

Examples

Create a dataset array from Fisher's iris data and add a description:

```
load fisheriris
NumObs = size(meas,1);
NameObs = strcat({'Obs'},num2str((1:NumObs)','%-d'));
iris = dataset({nominal(species),'species'},...
              {meas,'SL','SW','PL','PW'},...
              'ObsNames',NameObs);
iris = set(iris,'Description','Fisher''s Iris Data');
get(iris)
  Description: 'Fisher's Iris Data'
  Units: {}
  DimNames: {'Observations' 'Variables'}
  UserData: []
  ObsNames: {150x1 cell}
  VarNames: {'species' 'SL' 'SW' 'PL' 'PW'}
```

setDefaultYfit

Class: CompactTreeBagger

Set default value for predict

Syntax

`B = setDefaultYfit(B,Yfit)`

Description

`B = setDefaultYfit(B,Yfit)` sets the default prediction for ensemble `B` to `Yfit`. The default prediction must be specified as a character vector or string scalar for classification or as a numeric scalar for regression. This setting controls what predicted value `CompactTreeBagger` returns when no prediction is possible, for example when the `predict` method needs to predict for an observation which has only false values in the matrix supplied through `'UseInstanceForTree'` argument.

See Also

`predict`

setdiff

Class: dataset

Set difference for dataset array observations

Note The dataset data type might be removed in a future release. To work with heterogeneous data, use the MATLAB® table data type instead. See MATLAB table documentation for more information.

Syntax

```
C = setdiff(A,B)
C = setdiff(A,B,vars)
C = setxor(A,B,vars,setOrder)
[C,iA] = setxor( ___ )
```

Description

`C = setdiff(A,B)` for dataset arrays `A` and `B` returns the set of observations that are in `A` but not `B`, with repetitions removed. The observations in the dataset array `C` are sorted.

`C = setdiff(A,B,vars)` returns the set of observations that are in `A` but not `B`, considering only the variables specified in `vars`, with repetitions removed. The observations in the dataset array `C` are sorted by these variables. The values for variables not specified in `vars` for each observation in `C` are taken from the corresponding observation in `A`. If there are multiple observations in `A` that correspond to an observation in `C`, those values are taken from the first occurrence.

`C = setxor(A,B,vars,setOrder)` returns the observations in `C` in the order specified by `setOrder`.

`[C,iA] = setxor(___)` also returns the index vector `iA` such that `C = A(iA,:)`. If there are repeated observations in `A`, then `setxor` returns the index of the first occurrence. You can use any of the previous input arguments.

Input Arguments

A,B

Input dataset arrays.

vars

String array or cell array of character vectors containing variable names, or a vector of integers containing variable column numbers. `vars` indicates the variables that `setdiff` considers.

Specify `vars` as `[]` to use its default value of all variables.

setOrder

Flag indicating the sorting order for the observations in C. The possible values of `setOrder` are:

'sorted'	Observations in C are in sorted order (default).
'stable'	Observations in C are in the same order that they appear in A.

Output Arguments

C

Dataset array with the observations that are in A but not B, with repetitions removed. C is in sorted order (by default), or the order specified by `setOrder`.

iA

Index vector, indicating the observations from A that are in C. The vector `iA` contains the index to the first occurrence of any repeated observations in A.

Examples

Set Difference of Two Dataset Arrays

Create a scalar structure array, and then convert it into two dataset arrays.

```
S(1,1).Name = 'CLARK';
S(1,1).Gender = 'M';
S(1,1).SystolicBP = 124;
S(1,1).DiastolicBP = 93;
```

```
S(2,1).Name = 'BROWN';
S(2,1).Gender = 'F';
S(2,1).SystolicBP = 122;
S(2,1).DiastolicBP = 80;
```

```
S(3,1).Name = 'MARTIN';
S(3,1).Gender = 'M';
S(3,1).SystolicBP = 130;
S(3,1).DiastolicBP = 92;
```

```
A = struct2dataset(S(1:2));
B = struct2dataset(S(2:3));
```

The intersection of A and B is the second observation, with last name BROWN.

Return the set difference of A and B.

```
[C,iA] = setdiff(A,B)
```

```
C =
      Name      Gender  SystolicBP  DiastolicBP
      'CLARK'      'M'         124         93
```

```
iA = 1
```

The first observation in A is not present in B.

setlabels

Assign labels to levels of nominal or ordinal arrays

Note The `nominal` and `ordinal` array data types might be removed in a future release. To represent ordered and unordered discrete, nonnumeric data, use the “Categorical Arrays” (MATLAB) data type instead.

Syntax

```
B = setlabels(A, labels)
B = setlabels(A, labels, levels)
```

Description

`B = setlabels(A, labels)` returns a `nominal` or `ordinal` array object of the same type as `A`, but with levels labeled in the order specified by `labels`.

`B = setlabels(A, labels, levels)` labels only the levels specified in `levels`.

Input Arguments

A — Nominal or ordinal array

`nominal` array | `ordinal` array

Nominal or ordinal array, specified as a `nominal` or `ordinal` array object created with `nominal` or `ordinal`.

labels — Labels to assign

string array | cell array of character vectors | 2-D character matrix

Labels to assign to levels, specified as a string array, cell array of character vectors, or 2-D character matrix.

Data Types: `char` | `string` | `cell`

Levels — Levels to assign labels

string array | cell array of character vectors | 2-D character matrix

Level to assign labels to, specified as a string array, cell array of character vectors, or 2-D character matrix.

Data Types: char | string | cell

Output Arguments

B — Nominal or ordinal array

nominal array | ordinal array

Nominal or ordinal array, returned as a nominal or ordinal array object.

See Also

getlabels | nominal | ordinal

“Change Category Labels” on page 2-9

Introduced in R2007a

setxor

Class: dataset

Set exclusive or for dataset array observations

Note The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB® `table` data type instead. See MATLAB `table` documentation for more information.

Syntax

```
C = setxor(A,B)
C = setxor(A,B,vars)
C = setxor(A,B,vars,setOrder)
[C,iA,iB] = setxor( ___ )
```

Description

`C = setxor(A,B)` for dataset arrays `A` and `B` returns the set of observations that are not in the intersection of the two arrays, with repetitions removed. The observations in the dataset array `C` are sorted.

`C = setxor(A,B,vars)` returns the set of observations that are not in the intersection of the two arrays, considering only the variables specified in `vars`, with repetitions removed. The observations in the dataset array `C` are sorted by these variables. The values for variables not specified in `vars` for each observation in `C` are taken from the corresponding observation in `A` or `B`. If there are multiple observations in `A` or `B` that correspond to an observation in `C`, those values are taken from the first occurrence.

`C = setxor(A,B,vars,setOrder)` returns the observations in `C` in the order specified by `setOrder`.

`[C,iA,iB] = setxor(___)` also returns index vectors `iA` and `iB` such that `C` is a sorted combination of the values `A(iA,:)` and `B(iB,:)`. If there are repeated

observations in A or B, then `setxor` returns the index of the first occurrence. You can use any of the previous input arguments.

Input Arguments

A,B

Input dataset arrays.

vars

String array or cell array of character vectors containing variable names, or a vector of integers containing variable column numbers. `vars` indicates the variables in A and B that `setxor` considers.

Specify `vars` as `[]` to use its default value of all variables.

setOrder

Flag indicating the sorting order for the observations in C. The possible values of `setOrder` are:

'sorted'	Observations in C are in sorted order (default).
'stable'	Observations in C are in the same order that they appear in A, then B.

Output Arguments

C

Dataset array with the observations not in the intersection of A and B, with repetitions removed. C is in sorted order (by default), or the order specified by `setOrder`.

iA

Index vector, indicating the observations from A that are in C. The vector `iA` contains the index to the first occurrence of any repeated observations in A.

iB

Index vector, indicating the observations from B that are in C. The vector `iB` contains the index to the first occurrence of any repeated observations in B.

Examples

Symmetric Difference of Two Dataset Arrays

Create a scalar structure array, and then convert it into two dataset arrays.

```

```

```
S(2,1).Name = 'BROWN';
S(2,1).Gender = 'F';
S(2,1).SystolicBP = 122;
S(2,1).DiastolicBP = 80;
```

```
S(3,1).Name = 'MARTIN';
S(3,1).Gender = 'M';
S(3,1).SystolicBP = 130;
S(3,1).DiastolicBP = 92;
```

```
A = struct2dataset(S(1:2));
B = struct2dataset(S(2:3));
```

The intersection of A and B is the second observation, with last name BROWN.

Return the symmetric difference of A and B.

```
[C,iA,iB] = setxor(A,B);
C
```

```
C =
      Name      Gender  SystolicBP  DiastolicBP
      'CLARK'      'M'         124         93
      'MARTIN'     'M'         130         92
```

```
[iA iB]
```

```
ans = 1×2
```

```
    1    2
```

The symmetric difference contains the first observation from A, and the second observation from B.

“Dataset Arrays” on page 2-137

shrink

Prune ensemble

Syntax

```
cmp = shrink(ens)
cmp = shrink(ens,Name,Value)
```

Description

`cmp = shrink(ens)` returns a compact shrunken version of `ens`, a regularized ensemble. `cmp` retains only learners with weights above a threshold.

`cmp = shrink(ens,Name,Value)` returns an ensemble with additional options specified by one or more `Name,Value` pair arguments. You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Input Arguments

`ens`

A regression ensemble created with `fitrensemble`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

`Lambda`

Vector of nonnegative regularization parameter values for lasso. If `ens.Regularization` is nonempty (populate it with `regularize`), `shrink` regularizes

ens using lambda. If ens contains a `Regularization` structure, you cannot pass lambda.

Default: []

threshold

Lower cutoff on weights for weak learners, a numeric nonnegative scalar. `shrink` creates `cmp` from those learners with weights above `threshold`.

Default: 0

weightcolumn

Column index of `ens.Regularization.TrainedWeights`, a positive integer. `shrink` creates `cmp` with learner weights from this column.

Default: 1

Output Arguments

cmp

A regression ensemble of class `CompactRegressionEnsemble`. Use `cmp` for making predictions exactly as you use `ens`, with the `predict` method.

`shrink` orders the members of `cmp` from largest to smallest.

Examples

Shrink Bagged Regression Ensemble

Shrink a 300-member bagged regression ensemble, and view the number of members of the resulting ensemble.

Generate sample data.

```
X = rand(2000,20);  
Y = repmat(-1,2000,1);  
Y(sum(X(:,1:5),2)>2.5) = 1;
```

Shrink a 300-member bagged regression ensemble using 0.1 for the parameter lambda.

```
bag = fitensemble(X,Y,'Method','Bag','NumLearningCycles',300);  
cmp = shrink(bag,'lambda',0.1);
```

View the number of members of the resulting ensemble.

```
cmp.NumTrained
```

```
ans = 75
```

“Ensemble Regularization” on page 18-93

signrank

Wilcoxon signed rank test

Syntax

```
p = signrank(x)
p = signrank(x,y)
p = signrank(x,y,Name,Value)
[p,h] = signrank(____)
[p,h,stats] = signrank(____)

[____] = signrank(x,m)
[____] = signrank(x,m,Name,Value)
```

Description

`p = signrank(x)` returns the p -value of a two-sided Wilcoxon signed rank test on page 32-6390.

`signrank` tests the null hypothesis that data in the vector `x` come from a distribution whose median is zero at the 5% significance level. The test assumes that the data in `x` come from a continuous distribution symmetric about its median.

`p = signrank(x,y)` returns the p -value of a paired, two-sided test for the null hypothesis that `x - y` comes from a distribution with zero median.

`p = signrank(x,y,Name,Value)` returns the p -value for the sign test with additional options specified by one or more `Name,Value` pair arguments.

`[p,h] = signrank(____)` also returns a logical value indicating the test decision. `h = 1` indicates a rejection of the null hypothesis, and `h = 0` indicates a failure to reject the null hypothesis at the 5% significance level. You can use any of the input arguments in the previous syntaxes.

`[p,h,stats] = signrank(____)` also returns the structure `stats` with information about the test statistic.

[___] = `signrank(x,m)` returns any of the output arguments in the previous syntaxes for the null hypothesis that the data in `x` are observations from a distribution with median `m`.

[___] = `signrank(x,m,Name,Value)` returns any of the output arguments in the previous syntaxes for the signed rank test with additional options specified by one or more `Name,Value` pair arguments.

Examples

Test for Zero Median of a Single Population

Test the hypothesis of zero median.

Generate the sample data.

```
rng('default') % for reproducibility
x = randn(1,25) + 1.30;
```

Test the hypothesis that the data in `x` has zero median.

```
[p,h] = signrank(x)
```

```
p = 3.2229e-05
```

```
h = logical
    1
```

At the default 5% significance level, the value `h = 1` indicates that the test rejects the null hypothesis of zero median.

Test the Median of Differences of Paired Samples

Test the hypothesis of zero median for the difference between paired samples.

Generate the sample data.

```
rng('default') % for reproducibility
x = lognrnd(2,.25,10,1);
y = x + trnd(2,10,1);
```

Test the hypothesis that $x - y$ has zero median.

```
[p,h] = signrank(x,y)
p = 0.3223
h = logical
    0
```

The results indicate that the test fails to reject the null hypothesis of zero median in the difference at the default 5% significance level.

Signed Rank Test for Large Samples

Conduct a $-$ -sided test on a large sample using approximation.

Load the sample data.

```
load(fullfile(matlabroot,'examples','stats','gradespaired.mat'));
```

Test the null hypothesis that the median of the grade differences of students before and after participating in a tutoring program is 0 against the alternate that it is less than 0.

```
[p,h,stats] = signrank(gradespaired(:,1),...
    gradespaired(:,2),'tail','left')
p = 0.0047
h = logical
    1
stats = struct with fields:
    zval: -2.5982
    signedrank: 2.0175e+03
```

Because the sample size is greater than 15, `signrank` uses an approximate method to calculate the p -value and also returns the value of the z -statistic. The value $h = 1$

indicates that the test rejects the null hypothesis that there is no difference between the grade medians at the 5% significance level. There is enough statistical evidence to conclude that the median grade before the tutoring program is less than the median grade after the tutoring program.

Repeat the test using the exact method.

```
[p,h,stats] = signrank(gradespaired(:,1),gradespaired(:,2),...  
    'tail','left','method','exact')
```

```
p = 0.0045
```

```
h = logical  
    1
```

```
stats = struct with fields:  
    signedrank: 2.0175e+03
```

The results obtained using the approximate method are consistent with the exact method.

Two-Sided Test for the Median of a Single Population

Load the sample data.

```
load mileage
```

The data contains the mileages per gallon for three different types of cars in columns 1 to 3.

Test the hypothesis that the median mileage for the type of cars in the second column differs from 33.

```
[p,h,stats] = signrank(mileage(:,2),33)
```

```
p = 0.0313
```

```
h = logical  
    1
```

```
stats = struct with fields:  
    signedrank: 21
```

At the 5% significance level, the results indicate that the median mileage for the second type of cars differs from 33. Note that `signrank` uses an exact method to calculate the p -value for small samples and does not return the z -statistic.

Right-Sided Test for the Median of a Single Population

Use the name-value pair arguments in `signrank`.

Load the sample data.

```
load mileage
```

The data contains the mileage per gallon for three different types of cars in columns 1 to 3.

Test the hypothesis that the median mileage for the type of cars in the second row are larger than 33.

```
[p,h,stats] = signrank(mileage(:,2),33,'tail','right')
```

```
p = 0.0156
```

```
h = logical  
    1
```

```
stats = struct with fields:  
    signedrank: 21
```

Repeat the same test at the 1% significance level using the approximate method.

```
[p,h,stats] = signrank(mileage(:,2),33,'tail','right',...  
    'alpha',0.01,'method','approximate')
```

```
p = 0.0180
```

```
h = logical
    0
```

```
stats = struct with fields:
    zval: 2.0966
    signedrank: 21
```

This result, $h = 0$, indicates that the null hypothesis cannot be rejected at the 1% significance level.

Input Arguments

x — Sample data

vector

Sample data, specified as a vector.

Data Types: `single` | `double`

y — Sample data

vector

Sample data, specified as a vector. y must be the same length as x .

Data Types: `single` | `double`

m — Hypothesized value of the median

scalar

Hypothesized value of the median, specified as a scalar.

Example: `signrank(x,10)`

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes.

You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example: `'alpha', 0.01, 'method', 'approximate', 'tail', 'right'` specifies a right-tailed signed rank test with 1% significance level, which returns the approximate p -value.

alpha — Significance level

0.05 (default) | scalar value in the range 0 to 1

Significance level of the decision of a hypothesis test, specified as the comma-separated pair consisting of `'alpha'` and a scalar value in the range 0 to 1. Significance level of h is $100 * \text{alpha}\%$.

Example: `'alpha', 0.01`

Data Types: `double` | `single`

method — Computation method of p

`'exact'` | `'approximate'`

Computation method of p , specified as the comma-separated pair consisting of `'method'` and one of the following.

<code>'exact'</code>	Exact computation of the p -value, p . Default value for 15 or fewer observations in x , $x - m$, or $x - y$ when <code>method</code> is unspecified.
<code>'approximate'</code>	Normal approximation while computing the p -value, p . Default value for more than 15 observations in x , $x - m$, or $x - y$ when <code>'method'</code> is unspecified because the exact method can be slow on large samples.

Example: `'method', 'exact'`

tail — Type of test

`'both'` (default) | `'right'` | `'left'`

Type of test, specified as the comma-separated pair consisting of `'tail'` and one of the following:

'both'	Two-sided hypothesis test, which is the default test type. <ul style="list-style-type: none"> For a one-sample test, the alternate hypothesis states that the data in x come from a continuous distribution with median different than 0 or m. For a two-sample test, the alternate hypothesis states that the data in $x - y$ come from a distribution with median different than 0.
'right'	Right-tailed hypothesis test. <ul style="list-style-type: none"> For a one-sample test, the alternate hypothesis states that the data in x come from a continuous distribution with median greater than 0 or m. For a two-sample test, the alternate hypothesis states the data in $x - y$ come from a distribution with median greater than 0.
'left'	Left-tailed hypothesis test. <ul style="list-style-type: none"> For a one-sample test, the alternate hypothesis states that the data in x come from a continuous distribution with median less than 0 or m. For a two-sample test, the alternate hypothesis states the data in $x - y$ come from a distribution with median less than 0.

Example: 'tail','left'

Output Arguments

p — *p*-value of the test

nonnegative scalar

p-value of the test, returned as a nonnegative scalar from 0 to 1. *p* is the probability of observing a test statistic as or more extreme than the observed value under the null hypothesis. `signrank` computes the two-sided *p*-value by doubling the most significant one-sided value.

h — Result of the hypothesis test

1 | 0

Result of the hypothesis test, returned as a logical value.

- If $h = 1$, this indicates the rejection of the null hypothesis at the $100 * \alpha\%$ significance level.

- If $h = 0$, this indicates a failure to reject the null hypothesis at the $100 * \alpha\%$ significance level.

stats — Test statistics

structure

Test statistics, returned as a structure. The test statistics stored in `stats` are:

- `signrank`: Value of the sign rank test statistic.
- `zval`: Value of the z -statistic on page 32-6390 (computed when 'method' is 'approximate').

Definitions

Wilcoxon Signed Rank Test

The Wilcoxon signed rank test is a nonparametric test for two populations when the observations are paired. In this case, the test statistic, W , is the sum of the ranks of positive differences between the observations in the two samples (that is, $x - y$). When you use the test for one sample, then W is the sum of the ranks of positive differences between the observations and the hypothesized median value M_0 (which is 0 when you use `signrank(x)` and m when you use `signrank(x,m)`).

z-Statistic

For large samples, or when `method` is `approximate`, the `signrank` function calculates the p -value using the z -statistic, given by

$$z = \frac{(W - n(n + 1)/4)}{\sqrt{\frac{n(n + 1)(2n + 1) - \text{tieadj}}{24}}}$$

where n is the sample size of the difference $x - y$ or $x - m$. For the two-sample case, `signrank` uses `[tie_rank,tieadj] = tiedrank(abs(diffxy),0,0,epsdiff)` to obtain the tie adjustment value `tieadj`.

Algorithms

signrank treats NaNs in x and y as missing values and ignores them.

For the two-sample case, signrank uses a tolerance based on the values $\text{epsdiff} = \text{eps}(x) + \text{eps}(y)$. The signrank function treats any pair of values with difference $d(i) = x(i) - y(i)$ that differ by no more than the sum of their two eps values ($\text{abs}(d(i)) < \text{epsdiff}(i)$) as ties.

Introduced before R2006a

signtest

Sign test

Syntax

```
p = signtest(x)
p = signtest(x,y)
p = signtest(x,y,Name,Value)
[p,h] = signtest(____)
[p,h,stats] = signtest(____)

[____] = signtest(x,m)
[____] = signtest(x,m,Name,Value)
```

Description

`p = signtest(x)` returns the p -value for a two-sided sign test on page 32-6400.

`signtest` tests the hypothesis that data in `x` has a continuous distribution with zero median against the alternative that the distribution does not have zero median at the 5% significance level.

`p = signtest(x,y)` returns the p -value of a two-sided sign test on page 32-6400. Here, `signtest` tests for the hypothesis that the data in `x - y` has a distribution with zero median against the alternative that the distribution does not have zero median. Note that a hypothesis of zero median for `x - y` is not equivalent to a hypothesis of equal median for `x` and `y`.

`p = signtest(x,y,Name,Value)` returns the p -value for the sign test with additional options specified by one or more `Name,Value` pair arguments.

`[p,h] = signtest(____)` also returns a logical value indicating the test decision. The value `h = 1` indicates a rejection of the null hypothesis, and `h = 0` indicates a failure to reject the null hypothesis at the 5% significance level. You can use any of the input arguments in the previous syntaxes.

`[p,h,stats] = signtest(___)` also returns the structure `stats` containing information about the test statistic.

`[___] = signtest(x,m)` returns any of the output arguments in the previous syntaxes for the test whether the data in `x` are observations from a distribution with median `m` against the alternative that the median is different from `m`.

`[___] = signtest(x,m,Name,Value)` returns any of the output arguments in the previous syntaxes for the sign test with additional options specified by one or more `Name,Value` pair arguments.

Examples

Test for Zero Median of a Single Population

Test the hypothesis of zero median.

Generate the sample data.

```
rng('default') % for reproducibility
x = randn(1,25);
```

The sampling distribution of `x` is symmetric with zero median.

Test the null hypothesis that `x` comes from a distribution with a median different from zero median.

```
[p,h,stats] = signtest(x,0)
```

```
p = 0.1078
```

```
h = logical
    0
```

```
stats = struct with fields:
    zval: NaN
    sign: 17
```

At the default 5% significance level, the result `h = 0` indicates that `signtest` fails to reject to the null hypothesis of zero median. `signtest` calculates the *p*-value using the exact method, hence it does not calculate `zval` and returns it as a NaN.

Test for Zero Median for the Difference of Paired Samples

Test the hypothesis of zero median for the difference between paired samples.

Generate the sample data.

```
rng('default') % for reproducibility
before = lognrnd(2, .25, 10, 1);
after = before + (lognrnd(0, .5, 10, 1) - 1);
```

The sampling distribution of the difference between `before` and `after` is symmetric with zero median.

Test the null hypothesis that the difference of `before` and `after` has zero median.

```
[p,h] = signtest(before,after)
```

```
p = 0.7539
```

```
h = logical
    0
```

At the default 5% significance level, the value `h = 0` indicates that `signtest` fails to reject to the null hypothesis of zero median in the difference.

Medians of Paired Samples

Test the hypothesis of zero median for the difference between two paired samples using the exact and approximate methods.

Generate the sample data.

```
rng('default') % for reproducibility
x = lognrnd(2, .25, 15, 1);
```

```
y = x + trnd(2,15,1);  
display([x y])
```

```
8.4521    7.8047  
11.6869   11.4094  
4.2009    5.1133  
9.1664   12.1655  
8.0020   10.0300  
5.3285    6.0153  
6.6300    5.1235  
8.0499    8.6737  
18.0763   19.2164  
14.7665   15.3380  
5.2726    8.4187  
15.7798   16.2093  
8.8583    8.5575  
7.2735    7.4783  
8.8347    7.8894
```

Test the hypothesis that $x - y$ has zero median.

```
[p,h,stats] = signtest(x,y)
```

```
p = 0.3018
```

```
h = logical  
    0
```

```
stats = struct with fields:
```

```
zval: NaN  
sign: 5
```

At the default 5% significance level, the value $h = 0$ indicates that the test fails to reject the null hypothesis of zero median in the difference.

Repeat the test using the approximate method.

```
[p,h,stats] = signtest(x,y,'Method','approximate')
```

```
p = 0.3017
```

```
h = logical  
    0
```

```
stats = struct with fields:
  zval: -1.0328
  sign: 5
```

The approximate p -value, which `signtest` obtains using the z -statistic, is really close to the exact p -value.

Test for Large Samples

Perform a left-sided sign test for large samples.

Load the sample data.

```
load gradespaired
```

Test the null hypothesis that the median of the grade differences before and after the tutoring program is 0 against the alternate that it is less than 0.

```
[p,h,stats] = signtest(gradespaired(:,1),gradespaired(:,2),'Tail','left')
p = 0.0013
h = logical
    1
```

```
stats = struct with fields:
  zval: -3.0110
  sign: 37
```

Because the sample size is large (greater than 100), `signtest` uses an approximate method to calculate the p -value and also returns the value of the z -statistic. The test rejects the null hypothesis that there is no difference between the grade medians at the 5% significance level.

Test for Median of a Single Population

Test the hypothesis that the population median is different from a specified value.

Load the sample data.

```
load lawdata
```

The data set has 15 observations for variables `gpa` and `lsat`.

Test the hypothesis that the median `lsat` score is higher than 570.

```
[p,h,stats] = signtest(lsat,570,'Tail','right')
```

```
p = 0.0176
```

```
h = logical  
    1
```

```
stats = struct with fields:  
    zval: NaN  
    sign: 12
```

Both the p -value, 0.0176, and $h = 1$ indicate that at the 5% significance level the test concludes in favor of the alternate hypothesis.

Input Arguments

x — Sample data

vector

Sample data, specified as a vector.

Data Types: `single` | `double`

y — Sample data

vector

Sample data, specified as a vector. y must be the same length as x .

Data Types: `single` | `double`

m — Hypothesized value of the median

scalar

Hypothesized value of the median, specified as a scalar.

Example: `signtest(x,35)`

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Alpha',0.01,'Method','approximate','Tail','right'` specifies a right-tailed sign test with 1% significance level, which returns the approximate *p*-value.

Alpha — Significance level

0.05 (default) | scalar value in the range 0 to 1

Significance level of the hypothesis test, specified as the comma-separated pair consisting of `'Alpha'` and a scalar value in the range 0 to 1. The default value of `Alpha` is 0.05. Significance level of *h* is $100 * \text{Alpha}\%$.

Example: `'Alpha',0.01`

Data Types: `double` | `single`

Method — *p*-value computation method

`'exact'` | `'approximate'`

p-value computation method, specified as the comma-separated pair consisting of `'Method'` and one of the following:

<code>'exact'</code>	Exact computation of the <i>p</i> -value, <i>p</i> .
<code>'approximate'</code>	Normal approximation for computing the <i>p</i> -value, <i>p</i> .

The default computation method is `'exact'`, if there are fewer than 100 observations and `'approximate'` if there are 100 observations or more.

Example: `'Method','exact'`

Tail — Type of test

`'both'` (default) | `'right'` | `'left'`

Type of test, specified as the comma-separated pair consisting of 'Tail' and one of the following:

'both'	Two-sided hypothesis test, which is the default test type. <ul style="list-style-type: none"> For a one-sample test, the alternate hypothesis states that the data in x come from a continuous distribution with median different than zero (or m). For a two-sample test, the alternate hypothesis states that the data in $x - y$ come from a distribution with median different than zero.
'right'	Right-tailed hypothesis test. <ul style="list-style-type: none"> For a one-sample test, the alternate hypothesis states that the data in x come from a continuous distribution with median greater than zero (or m). For a two-sample test, the alternate hypothesis states the data in $x - y$ come from a distribution with median greater than zero.
'left'	Left-tailed hypothesis test. <ul style="list-style-type: none"> For a one-sample test, the alternate hypothesis states that the data in x come from a continuous distribution with median less than zero (or m). For a two-sample test, the alternative hypothesis states the data in $x - y$ come from a distribution with median less than zero.

Example: 'Tail','left'

Output Arguments

p — *p*-value of the test

nonnegative scalar

p-value of the test, returned as a nonnegative scalar from 0 to 1. *p* is the probability of observing a test statistic as or more extreme than the observed value under the null hypothesis. `signtest` computes the two-sided *p*-value by doubling the most significant one-sided value.

h — Result of the hypothesis test

1 | 0

Result of the hypothesis test, returned as a logical value.

- If $h = 1$, this indicates rejection of the null hypothesis at the $100 * \text{Alpha}\%$ significance level.
- If $h = 0$, this indicates a failure to reject the null hypothesis at the $100 * \text{Alpha}\%$ significance level.

stats — Test statistics

structure

Test statistics, returned as a structure. The test statistics stored in `stats` are:

- `sign`: Value of the sign test statistic.
- `zval`: Value of the z-statistic on page 32-6400 (computed only for large samples).

Definitions

Sign Test

The sign test is a nonparametric test for the median of a population or median of the difference of two populations.

For example, for tests on a single population median:

- If the test is two-sided, then the test statistic, S , is the minimum of the number of observations that are smaller or larger than the hypothesized median value, M_0 .
- If the test is right-sided, then S is the number of observations that are larger than the hypothesized median value M_0 .
- If the test is left-sided, then S is the number of observations that are smaller than the hypothesized median value M_0 .

z-Statistic

For a large sample, `signtest` uses the z-statistic to approximate the p -value.

The `signtest` test statistic is the number of elements that are greater than θ (for `signtest(x)` or `signtest(x-y)`), or m (for `signtest(x,m)`). Hence, the z-statistic of the sign test, with the continuity correction, is:

$$z = \frac{(S - E(S))}{\sqrt{V(S)}} = \frac{(S - (0.5)n - 0.5\text{sign}(n\text{pos} - n\text{neg}))}{\sqrt{(0.5)(0.5)n}}$$

where *npos* and *nneg* are the number of positive and negative differences from the hypothesized median value, respectively.

Algorithms

For a one-sample test, `signtest` omits values in `x` that are zero or `NaN`.

For a two-sample test, `signtest` omits values in `x - y` that are zero or `NaN`.

silhouette

Silhouette plot

Syntax

```
silhouette(X, clust)
silhouette(X, clust, Distance)
silhouette(X, clust, Distance, DistParameter)
```

```
s = silhouette( ___ )
[s, h] = silhouette( ___ )
```

Description

`silhouette(X, clust)` plots cluster silhouettes for the n -by- p input data matrix X , given the cluster assignment `clust` of each point (observation) in X .

`silhouette(X, clust, Distance)` plots the silhouettes using the inter-point distance metric specified in `Distance`.

`silhouette(X, clust, Distance, DistParameter)` accepts one or more additional distance metric parameter values when you specify `Distance` as a custom distance function handle `@distfun` that accepts the additional parameter values.

`s = silhouette(___)` returns the silhouette values in `s` for any of the input argument combinations in the previous syntaxes without plotting the cluster silhouettes.

`[s, h] = silhouette(___)` plots the silhouettes and returns the figure handle `h` in addition to the silhouette values in `s`.

Examples

Create Silhouette Plot

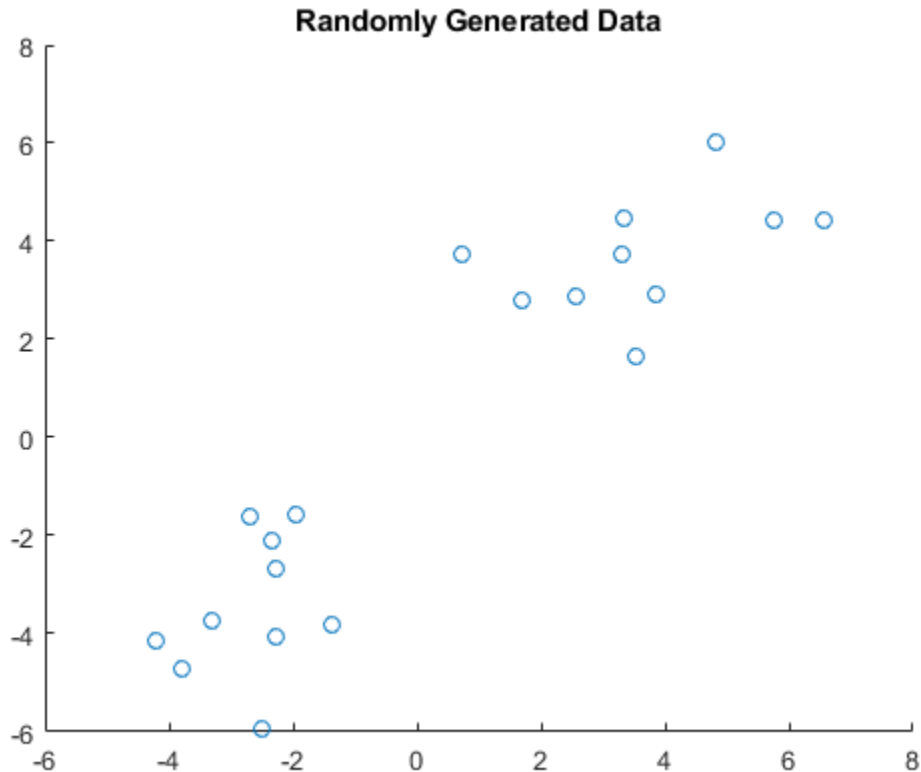

Create silhouette plots from clustered data using different distance metrics.

Generate random sample data.

```
rng('default') % For reproducibility  
X = [randn(10,2)+3;randn(10,2)-3];
```

Create a scatter plot of the data.

```
scatter(X(:,1),X(:,2));  
title('Randomly Generated Data');
```

The scatter plot shows that the data appears to be split into two clusters of equal size.

Partition the data into two clusters using `kmeans` with the default squared Euclidean distance metric.

```
clust = kmeans(X,2);
```

`clust` contains the cluster indices of the data.

Create a silhouette plot from the clustered data using the default squared Euclidean distance metric.

```
silhouette(X,clust)
```

The silhouette plot shows that the data is split into two clusters of equal size. All the points in the two clusters have large silhouette values (0.8 or greater), indicating that the clusters are well separated.

Create a silhouette plot from the clustered data using the Euclidean distance metric.

```
silhouette(X,clust,'Euclidean')
```

The silhouette plot shows that the data is split into two clusters of equal size. All the points in the two clusters have large silhouette values (0.6 or greater), indicating that the clusters are well separated.

Compute Silhouette Values

Compute the silhouette values from clustered data.

Generate random sample data.

```
rng('default') % For reproducibility
X = [randn(10,2)+1;randn(10,2)-1];
```

Cluster the data in X based on the sum of absolute differences in distance by using `kmeans`.

```
clust = kmeans(X,2,'distance','cityblock');
```

`clust` contains the cluster indices of the data.

Compute the silhouette values from the clustered data. Specify the distance metric as `'cityblock'` to indicate that the `kmeans` clustering is based on the sum of absolute differences.

```
s = silhouette(X,clust,'cityblock')
```

```
s = 20×1
```

```

Find Silhouette Values Using Custom Distance Metric

Find silhouette values from clustered data using a custom chi-square distance metric. Verify that the chi-square distance metric is equivalent to the Euclidean distance metric, but with an optional scaling parameter.

Generate random sample data.

```
rng('default'); % For reproducibility  
X = [randn(10,2)+3;randn(10,2)-3];
```

Cluster the data in X using kmeans with the default squared Euclidean distance metric.

```
clust = kmeans(X,2);
```

Find silhouette values and create a silhouette plot from the clustered data using the Euclidean distance metric.

```
[s,h] = silhouette(X,clust,'Euclidean')
```

```
s = 20×1
```

```

Units: 'pixels'
```

```
Show all properties
```

The chi-square distance between J -dimensional points x and z is

$$\chi(x, z) = \sqrt{\sum_{j=1}^J w_j (x_j - z_j)^2},$$

where w_j is the weight associated with dimension j .

Set weights for each dimension and specify the chi-square distance function. The distance function must:

- Take as input arguments the n -by- p input data matrix X , one row of X (for example, x), and a scaling (or weight) parameter w .
- Calculate the distance from x to each row of X .
- Return a vector of length n . Each element of the vector is the distance between the observation corresponding to x and the observations corresponding to each row of X .

```
w = [0.4; 0.6]; % Set arbitrary weights for illustration
chiSqrDist = @(x,Z,w) sqrt((bsxfun(@minus,x,Z).^2)*w);
```

Find silhouette values from the clustered data using the custom distance metric `chiSqrDist`.

```
s1 = silhouette(X,clust,chiSqrDist,w)
```

```
s1 = 20×1
```

```
    0.6288
    0.7239
    0.6244
    0.7696
    0.7957
    0.6688
    0.7386
    0.7865
    0.7223
    0.7572
    :
```

Set the weight for both dimensions to 1 to use `chiSqrDist` as the Euclidean distance metric. Find silhouette values and verify that they are the same as the values in `s`.

```
w2 = [1; 1];
s2 = silhouette(X,clust,chiSqrDist,w2);
AreValuesEqual = isequal(s2,s)
```

```
AreValuesEqual = logical
    1
```

The silhouette values are the same in `s` and `s2`.

Input Arguments

X — Input data

numeric matrix

Input data, specified as a numeric matrix of size n -by- p . Rows correspond to points, and columns correspond to coordinates.

Data Types: `single` | `double`

c`l`ust — Cluster assignment

categorical variable | numeric vector | character matrix | string array | cell array of character vectors

Cluster assignment, specified as a categorical variable, numeric vector, character matrix, string array, or cell array of character vectors containing a cluster name for each point in `X`.

`silhouette` treats NaNs and empty values in `clust` as missing values and ignores the corresponding rows of `X`.

Data Types: `single` | `double` | `char` | `string` | `cell` | `categorical`

D`i`stance — Distance metric

'`sqEuclidean`' (default) | '`Euclidean`' | '`cityblock`' | function handle | vector of pairwise distances | ...

Distance metric, specified as a character vector, string scalar, or function handle, as described in this table.

Metric	Description
' <code>Euclidean</code> '	Euclidean distance
' <code>sqEuclidean</code> '	Squared Euclidean distance (default)
' <code>cityblock</code> '	Sum of absolute differences
' <code>cosine</code> '	One minus the cosine of the included angle between points (treated as vectors)
' <code>correlation</code> '	One minus the sample correlation between points (treated as sequences of values)
' <code>Hamming</code> '	Percentage of coordinates that differ
' <code>Jaccard</code> '	Percentage of nonzero coordinates that differ
Vector	A numeric row vector of pairwise distances, in the form created by the <code>pdist</code> function. <code>X</code> is not used in this case, and can safely be set to <code>[]</code> .

Metric	Description
@ <i>distfun</i>	<p>Custom distance function handle. A distance function has the form</p> <pre>function D = distfun(X0,X,DistParameter) % calculation of distance ...</pre> <p>where</p> <ul style="list-style-type: none"> • X0 is a 1-by-<i>p</i> vector containing a single point (observation) of the input data matrix X. • X is an <i>n</i>-by-<i>p</i> matrix of points. • DistParameter represents one or more additional parameter values specific to @<i>distfun</i>. • D is an <i>n</i>-by-1 vector of distances, and D(k) is the distance between observations X0 and X(k, :).

For more information, see “Distance Metrics” on page 18-16.

Example: 'cosine'

Data Types: char | string | function_handle | single | double

DistParameter — Distance metric parameter value

positive scalar | numeric vector | numeric matrix

Distance metric parameter value, specified as a positive scalar, numeric vector, or numeric matrix. This argument is valid only when you specify a custom distance function handle @*distfun* that accepts one or more parameter values in addition to the input parameters X0 and X.

Example: silhouette(X,clust,distfun,p1,p2) where p1 and p2 are additional distance metric parameter values for @*distfun*

Data Types: single | double

Output Arguments

s — Silhouette values

n-by-1 vector of values ranging from -1 to 1

Silhouette values, returned as an n -by-1 vector of values ranging from -1 to 1 . A silhouette value measures how similar a point is to points in its own cluster, when compared to points in other clusters. Values range from -1 to 1 . A high silhouette value indicates that a point is well matched to its own cluster, and poorly matched to other clusters.

Data Types: `single` | `double`

h — Figure handle

scalar

Figure handle, returned as a scalar. You can use the figure handle to query and modify figure properties. For more information, see `Figure`.

Definitions

Silhouette Value

The silhouette value for each point is a measure of how similar that point is to points in its own cluster, when compared to points in other clusters. The silhouette value S_i for the i th point is defined as

$$S_i = (b_i - a_i) / \max(a_i, b_i)$$

where a_i is the average distance from the i th point to the other points in the same cluster as i , and b_i is the minimum average distance from the i th point to points in a different cluster, minimized over clusters.

The silhouette value ranges from -1 to 1 . A high silhouette value indicates that i is well matched to its own cluster, and poorly matched to other clusters. If most points have a high silhouette value, then the clustering solution is appropriate. If many points have a low or negative silhouette value, then the clustering solution might have too many or too few clusters. You can use silhouette values as a clustering evaluation criterion with any distance metric.

SilhouetteEvaluation

Package: clustering.evaluation

Superclasses:

Silhouette criterion clustering evaluation object

Description

`SilhouetteEvaluation` is an object consisting of sample data, clustering data, and silhouette criterion values used to evaluate the optimal number of data clusters. Create a silhouette criterion clustering evaluation object using `evalclusters`.

Construction

`eva = evalclusters(x, clust, 'Silhouette')` creates a silhouette criterion clustering evaluation object.

`eva = evalclusters(x, clust, 'Silhouette', Name, Value)` creates a silhouette criterion clustering evaluation object using additional options specified by one or more name-value pair arguments.

Input Arguments

x — Input data

matrix

Input data, specified as an N -by- P matrix. N is the number of observations, and P is the number of variables.

Data Types: `single` | `double`

clust — Clustering algorithm

'kmeans' | 'linkage' | 'gmdistribution' | matrix of clustering solutions | function handle

Clustering algorithm, specified as one of the following.

'kmeans'	Cluster the data in <code>x</code> using the kmeans clustering algorithm, with 'EmptyAction' set to 'singleton' and 'Replicates' set to 5.
'linkage'	Cluster the data in <code>x</code> using the clusterdata agglomerative clustering algorithm, with 'Linkage' set to 'ward'.
'gmdistribution'	Cluster the data in <code>x</code> using the gmdistribution Gaussian mixture distribution algorithm, with 'SharedCov' set to true and 'Replicates' set to 5.

If `criterion` is 'CalinskiHarabasz', 'DaviesBouldin', or 'silhouette', you can specify a clustering algorithm using a function handle (MATLAB). The function must be of the form `C = clustfun(DATA,K)`, where `DATA` is the data to be clustered, and `K` is the number of clusters. The output of `clustfun` must be one of the following:

- A vector of integers representing the cluster index for each observation in `DATA`. There must be `K` unique values in this vector.
- A numeric n -by- K matrix of score for n observations and K classes. In this case, the cluster index for each observation is determined by taking the largest score value in each row.

If `criterion` is 'CalinskiHarabasz', 'DaviesBouldin', or 'silhouette', you can also specify `clust` as a n -by- K matrix containing the proposed clustering solutions. n is the number of observations in the sample data, and K is the number of proposed clustering solutions. Column j contains the cluster indices for each of the N points in the j th clustering solution.

Data Types: `single` | `double` | `char` | `string` | `function_handle`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'KList',[1:5],'Distance','cityblock'` specifies to test 1, 2, 3, 4, and 5 clusters using the city block distance metric.

ClusterPriors — Prior probabilities for each cluster

'empirical' (default) | 'equal'

Prior probabilities for each cluster, specified as the comma-separated pair consisting of 'ClusterPriors' and one of the following.

'empirical'	Compute the overall silhouette value for the clustering solution by averaging the silhouette values for all points. Each cluster contributes to the overall silhouette value proportionally to its size.
'equal'	Compute the overall silhouette value for the clustering solution by averaging the silhouette values for all points within each cluster, and then averaging those values across all clusters. Each cluster contributes equally to the overall silhouette value, regardless of its size.

Example: 'ClusterPriors','empirical'

Distance — Distance metric

'sqEuclidean' (default) | 'Euclidean' | 'cityblock' | vector | function | ...

Distance metric used for computing the criterion values, specified as the comma-separated pair consisting of 'Distance' and one of the following.

'sqEuclidean'	Squared Euclidean distance
'Euclidean'	Euclidean distance. This option is not valid for the kmeans clustering algorithm.
'cityblock'	Sum of absolute differences
'cosine'	One minus the cosine of the included angle between points (treated as vectors)
'correlation'	One minus the sample correlation between points (treated as sequences of values)
'Hamming'	Percentage of coordinates that differ. This option is only valid for the Silhouette criterion.
'Jaccard'	Percentage of nonzero coordinates that differ. This option is only valid for the Silhouette criterion.

For detailed information about each distance metric, see `pdist`.

You can also specify a function for the distance metric using a function handle (MATLAB). The distance function must be of the form `d2 = distfun(XI,XJ)`, where `XI` is a 1-by- n vector corresponding to a single row of the input matrix X , and `XJ` is an m_2 -by- n matrix

corresponding to multiple rows of X . `distfun` must return an m_2 -by-1 vector of distances d_2 , whose k th element is the distance between X_I and $X_J(k, :)$.

`Distance` only accepts a function handle if the clustering algorithm `clust` accepts a function handle as the distance metric. For example, the `kmeans` clustering algorithm does not accept a function handle as the distance metric. Therefore, if you use the `kmeans` algorithm and then specify a function handle for `Distance`, the software errors.

- If `criterion` is 'silhouette', you can also specify `Distance` as the output vector created by the function `pdist`.
- When `clust` is 'kmeans' or 'gmdistribution', `evalclusters` uses the distance metric specified for `Distance` to cluster the data.
- If `clust` is 'linkage', and `Distance` is either 'sqEuclidean' or 'Euclidean', then the clustering algorithm uses the Euclidean distance and Ward linkage.
- If `clust` is 'linkage' and `Distance` is any other metric, then the clustering algorithm uses the specified distance metric and average linkage.
- In all other cases, the distance metric specified for `Distance` must match the distance metric used in the clustering algorithm to obtain meaningful results.

Example: 'Distance', 'Euclidean'

Data Types: single | double | char | string | function_handle

KList — List of number of clusters to evaluate

vector

List of number of clusters to evaluate, specified as the comma-separated pair consisting of 'KList' and a vector of positive integer values. You must specify `KList` when `clust` is a clustering algorithm name or a function handle. When `criterion` is 'gap', `clust` must be a character vector, a string scalar, or a function handle, and you must specify `KList`.

Example: 'KList', [1:6]

Data Types: single | double

Properties

ClusteringFunction

Clustering algorithm used to cluster the input data, stored as a valid clustering algorithm name or function handle. If the clustering solutions are provided in the input, `ClusteringFunction` is empty.

ClusterPriors

Prior probabilities for each cluster, stored as valid prior probability name.

ClusterSilhouettes

Silhouette values corresponding to each proposed number of clusters in `InspectedK`, stored as a cell array of vectors.

CriterionName

Name of the criterion used for clustering evaluation, stored as a valid criterion name.

CriterionValues

Criterion values corresponding to each proposed number of clusters in `InspectedK`, stored as a vector of numerical values.

Distance

Distance metric used for clustering data, stored as a valid distance metric name.

InspectedK

List of the number of proposed clusters for which to compute criterion values, stored as a vector of positive integer values.

Missing

Logical flag for excluded data, stored as a column vector of logical values. If `Missing` equals `true`, then the corresponding value in the data matrix `x` is not used in the clustering solution.

NumObservations

Number of observations in the data matrix X , minus the number of missing (NaN) values in X , stored as a positive integer value.

OptimalK

Optimal number of clusters, stored as a positive integer value.

OptimalY

Optimal clustering solution corresponding to **OptimalK**, stored as a column vector of positive integer values. If the clustering solutions are provided in the input, **OptimalY** is empty.

X

Data used for clustering, stored as a matrix of numerical values.

Methods

Inherited Methods

addK	Evaluate additional numbers of clusters
plot	Plot clustering evaluation object criterion values
compact	Compact clustering evaluation object

Examples

Evaluate the Clustering Solution Using Silhouette Criterion

Evaluate the optimal number of clusters using the silhouette clustering evaluation criterion.

Generate sample data containing random numbers from three multivariate distributions with different parameter values.

```
rng('default'); % For reproducibility
mu1 = [2 2];
sigma1 = [0.9 -0.0255; -0.0255 0.9];

mu2 = [5 5];
sigma2 = [0.5 0 ; 0 0.3];

mu3 = [-2, -2];
sigma3 = [1 0 ; 0 0.9];

N = 200;

X = [mvnrnd(mu1,sigma1,N);...
     mvnrnd(mu2,sigma2,N);...
     mvnrnd(mu3,sigma3,N)];
```

Evaluate the optimal number of clusters using the silhouette criterion. Cluster the data using `kmeans`.

```
E = evalclusters(X,'kmeans','silhouette','klist',[1:6])
```

```
E =
SilhouetteEvaluation with properties:
    NumObservations: 600
    InspectedK: [1 2 3 4 5 6]
    CriterionValues: [NaN 0.8055 0.8551 0.7155 0.6071 0.6232]
    OptimalK: 3
```

The `OptimalK` value indicates that, based on the silhouette criterion, the optimal number of clusters is three.

Plot the silhouette criterion values for each number of clusters tested.

```
figure;
plot(E)
```

The plot shows that the highest silhouette value occurs at three clusters, suggesting that the optimal number of clusters is three.

Create a grouped scatter plot to visually examine the suggested clusters.

```
figure;  
gscatter(X(:,1),X(:,2),E.OptimalY,'rbg','xod')
```

The plot shows three distinct clusters within the data: Cluster 1 is in the lower-left corner, cluster 2 is in the upper-right corner, and cluster 3 is near the center of the plot.

Definitions

Silhouette Value

The silhouette value for each point is a measure of how similar that point is to points in its own cluster, when compared to points in other clusters. The silhouette value S_i for the i th point is defined as

$$S_i = (b_i - a_i) / \max(a_i, b_i)$$

where a_i is the average distance from the i th point to the other points in the same cluster as i , and b_i is the minimum average distance from the i th point to points in a different cluster, minimized over clusters.

The silhouette value ranges from -1 to 1 . A high silhouette value indicates that i is well matched to its own cluster, and poorly matched to other clusters. If most points have a high silhouette value, then the clustering solution is appropriate. If many points have a low or negative silhouette value, then the clustering solution might have too many or too few clusters. You can use silhouette values as a clustering evaluation criterion with any distance metric.

Topics

[Class Attributes \(MATLAB\)](#)

[Property Attributes \(MATLAB\)](#)

single

Class: dataset

Convert dataset variables to single array

Note The dataset data type might be removed in a future release. To work with heterogeneous data, use the MATLAB® table data type instead. See MATLAB table documentation for more information.

Syntax

```
B = single(A)
B = single(A,vars)
```

Description

`B = single(A)` returns the contents of the dataset `A`, converted to one single array. The classes of the variables in the dataset must support the conversion.

`B = single(A,vars)` returns the contents of the dataset variables specified by `vars`. `vars` is a positive integer, a vector of positive integers, a character vector, a string array, a cell array of character vectors, or a logical vector.

See Also

dataset | double | replacedata

size

Class: dataset

Size of dataset array

Note The dataset data type might be removed in a future release. To work with heterogeneous data, use the MATLAB® table data type instead. See MATLAB table documentation for more information.

Syntax

```
D = SIZE(A)
[NOBS,NVARS] = SIZE(A)
[M1,M2,M3,...,MN] = SIZE(A)
M = size(A,dim)
```

Description

`D = SIZE(A)` returns the two-element row vector `D = [NOBS,NVARS]` containing the number of observations and number of variables in the dataset `A`. A dataset array always has two dimensions.

`[NOBS,NVARS] = SIZE(A)` returns the numbers of observations and variables in the dataset `A` as separate output variables.

`[M1,M2,M3,...,MN] = SIZE(A)`, for `N > 2`, returns `M1 = NOBS`, `M2 = NVARS`, and `M3,..,MN = 1`.

`M = size(A,dim)` returns the length of the dimension specified by the scalar `dim`:

- `M = size(A,1)` returns `NOBS`
- `M = size(A,2)` returns `NVARS`
- `M = size(A,k)` returns 1 for `k > 2`

See Also

`length` | `ndims` | `numel`

slicesample

Slice sampler

Syntax

```
rnd = slicesample(initial,nsamples,'pdf',pdf)
rnd = slicesample(initial,nsamples,'logpdf',logpdf)
[rnd,neval] = slicesample(initial,...)
[rnd,neval] = slicesample(initial,...,Name,Value)
```

Description

`rnd = slicesample(initial,nsamples,'pdf',pdf)` generates `nsamples` random samples using the slice sampling method (see “Algorithms” on page 32-6432). `pdf` gives the target probability density function (pdf). `initial` is a row vector or scalar containing the initial value of the random sample sequences.

`rnd = slicesample(initial,nsamples,'logpdf',logpdf)` generates samples using the logarithm of the pdf.

`[rnd,neval] = slicesample(initial,...)` returns the average number of function evaluations that occurred in the slice sampling.

`[rnd,neval] = slicesample(initial,...,Name,Value)` generates random samples with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

initial

Initial point, a scalar or row vector. Set `initial` so `pdf(initial)` is a strictly positive scalar. `length(initial)` is the number of dimensions of each sample.

nsamples

Positive integer, the number of samples that `slice_sample` generates.

pdf

Handle to a function that generates the probability density function, specified with `@. pdf` can be unnormalized, meaning it need not integrate to 1.

logpdf

Handle to a function that generates the logarithm of the probability density function, specified with `@. logpdf` can be the logarithm of an unnormalized pdf.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

burnin

Nonnegative integer, the number of samples to generate and discard before generating the samples to return. The slice sampling algorithm is a Markov chain whose stationary distribution is proportional to that of the `pdf` argument. Set `burnin` to a high enough value that you believe the Markov chain approximately reaches stationarity after `burnin` samples.

Default: 0

thin

Positive integer, where `slice_sample` discards every `thin - 1` samples and returns the next. The slice sampling algorithm is a Markov chain, so the samples are serially correlated. To reduce the serial correlation, choose a larger value of `thin`.

Default: 1

width

Width of the interval around the current sample, a scalar or vector of positive values. `slicesample` begins with this interval and searches for an appropriate region containing the points of pdf that evaluate to a large enough value.

- If `width` is a scalar and the samples have multiple dimensions, `slicesample` uses `width` for each dimension.
- If `width` is a vector, it should have the same length as `initial`.

Default: 10

Output Arguments

rnd

`nsamples-by-length(initial)` matrix, where each row is one sample.

neval

Scalar, the mean number of function evaluations per sample. `neval` includes the `burnin` and `thin` evaluations, not just the evaluations of samples returned in `rnd`. Therefore the total number of function evaluations is

`neval*(nsamples*thin + burnin)`.

Examples

Generate Random Samples From a Multimodal Density

This example shows how to generate random samples from a multimodal density using `slicesample`.

Define a function proportional to a multimodal density.

```
rng default % For reproducibility
f = @(x) exp(-x.^2/2).*(1 + (sin(3*x)).^2).*...
    (1 + (cos(5*x)).^2));
area = integral(f,-5,5);
```

Generate 2000 samples from the density, using a burn-in period of 1000, and keeping one in five samples.

```
N = 2000;  
x = slicesample(1,N, 'pdf', f, 'thin', 5, 'burnin', 1000);
```

Plot a histogram of the sample.

```
[binheight,bincenter] = hist(x,50);  
h = bar(bincenter,binheight, 'hist');  
h.FaceColor = [.8 .8 1];
```

Scale the density to have the same area as the histogram, and superimpose it on the histogram.

```
hold on
h = gca;
xd = h.XLim;
xgrid = linspace(xd(1),xd(2),1000);
binwidth = (bincenter(2)-bincenter(1));
y = (N*binwidth/area) * f(xgrid);
plot(xgrid,y,'r','LineWidth',2)
hold off
```

The samples seem to fit the theoretical distribution well, so the burnin value seems adequate.

Tips

- There are no definitive suggestions for choosing appropriate values for `burnin`, `thin`, or `width`. Choose starting values of `burnin` and `thin`, and increase them, if necessary, to give the requisite independence and marginal distributions. See Neal [1] for details of the effect of adjusting `width`.

Algorithms

At each point in the sequence of random samples, `slicesample` selects the next point by “slicing” the density to form a neighborhood around the previous point where the density is above some value. Consequently, the sample points are not independent. Nearby points in the sequence tend to be closer together than they would be from a sample of independent values. For many purposes, the entire set of points can be used as a sample from the target distribution. However, when this type of serial correlation is a problem, the `burnin` and `thin` parameters can help reduce that correlation.

`slicesample` uses the slice sampling algorithm of Neal [1]. For numerical stability, it converts a `pdf` function into a `logpdf` function. The algorithm to resize the support region for each level, called “stepping-out” and “stepping-in,” was suggested by Neal.

Introduced in R2006a

skewness

Skewness

Syntax

```
y = skewness(X)
y = skewness(X, flag)
y = skewness(X, flag, 'all')
y = skewness(X, flag, dim)
y = skewness(X, flag, vecdim)
```

Description

`y = skewness(X)` returns the sample skewness of `X`.

- If `X` is a vector, then `skewness(X)` returns a scalar value that is the skewness of the elements in `X`.
- If `X` is a matrix, then `skewness(X)` returns a row vector containing the sample skewness of each column in `X`.
- If `X` is a multidimensional array, then `skewness(X)` operates along the first nonsingleton dimension of `X`.

`y = skewness(X, flag)` specifies whether to correct for bias (`flag = 0`) or not (`flag = 1`, the default). When `X` represents a sample from a population, the skewness of `X` is biased, meaning it tends to differ from the population skewness by a systematic amount based on the sample size. You can set `flag` to `0` to correct for this systematic bias.

`y = skewness(X, flag, 'all')` returns the skewness of all elements of `X`.

`y = skewness(X, flag, dim)` returns the skewness along the operating dimension `dim` of `X`.

`y = skewness(X, flag, vecdim)` returns the skewness over the dimensions specified in the vector `vecdim`. For example, if `X` is a 2-by-3-by-4 array, then `skewness(X, 1, [1 2])`

returns a 1-by-1-by-4 array. Each element of the output array is the biased skewness of the elements on the corresponding page of X .

Examples

Find Skewness of Matrix

Set the random seed for reproducibility of the results.

```
rng('default')
```

Generate a matrix with 5 rows and 4 columns.

```
X = randn(5,4)
```

```
X = 5×4
```

```
    0.5377   -1.3077   -1.3499   -0.2050  
    1.8339   -0.4336    3.0349   -0.1241  
   -2.2588    0.3426    0.7254    1.4897  
    0.8622    3.5784   -0.0631    1.4090  
    0.3188    2.7694    0.7147    1.4172
```

Find the sample skewness of X .

```
y = skewness(X)
```

```
y = 1×4
```

```
   -0.9362    0.2333    0.4363   -0.4075
```

y is a row vector containing the sample skewness of each column in X .

Correct for Bias in Sample Skewness

For an input vector, correct for bias in the calculation of skewness by specifying the `flag` input argument.

Set the random seed for reproducibility of the results.

```
rng('default')
```

Generate a vector of length 10.

```
x = randn(10,1)
```

```
x = 10×1
```

```
    0.5377  
    1.8339  
   -2.2588  
    0.8622  
    0.3188  
   -1.3077  
   -0.4336  
    0.3426  
    3.5784  
    2.7694
```

Find the biased skewness of x . By default, `skewness` sets the value of `flag` to 1 for computing the biased skewness.

```
y1 = skewness(x) % flag is 1 by default
```

```
y1 = 0.1061
```

Find the bias-corrected skewness of x by setting the value of `flag` to 0.

```
y2 = skewness(x,0)
```

```
y2 = 0.1258
```

Find Skewness Along Given Dimension

Find the skewness along different dimensions for a multidimensional array.

Set the random seed for reproducibility of the results.

```
rng('default')
```

Create a 4-by-3-by-2 array of random numbers.

```
X = randn([4,3,2])
```

```
X =
```

```
X(:,:,1) =
```

```
    0.5377    0.3188    3.5784  
    1.8339   -1.3077    2.7694  
   -2.2588   -0.4336   -1.3499  
    0.8622    0.3426    3.0349
```

```
X(:,:,2) =
```

```
    0.7254   -0.1241    0.6715  
   -0.0631    1.4897   -1.2075  
    0.7147    1.4090    0.7172  
   -0.2050    1.4172    1.6302
```

Find the skewness of X along the default dimension.

```
Y1 = skewness(X)
```

```
Y1 =
```

```
Y1(:,:,1) =
```

```
   -0.8084   -0.5578   -1.0772
```

```
Y1(:,:,2) =
```

```
   -0.0403   -1.1472   -0.6632
```

By default, skewness operates along the first dimension of X whose size does not equal 1. In this case, this dimension is the first dimension of X. Therefore, Y1 is a 1-by-3-by-2 array.

Find the biased skewness of X along the second dimension.

```
Y2 = skewness(X,1,2)
```

```
Y2 =
```

```
Y2(:,:,1) =
```

```

0.6956
-0.5575
0.0049
0.6033

```

```
Y2(:, :, 2) =
```

```

-0.6969
0.1828
0.7071
-0.6714

```

Y2 is a 4-by-1-by-2 array.

Find the biased skewness of X along the third dimension.

```
Y3 = skewness(X, 1, 3)
```

```
Y3 = 4x3
10-15 ×
```

```

      0      0.1597      0.5062
0.1952      0      0
      0     -0.2130      0
0.3654      0      0.4807

```

Y3 is a 4-by-3 matrix.

Find Skewness Along Vector of Dimensions

Find the skewness over multiple dimensions by using the 'all' and vecdim input arguments.

Set the random seed for reproducibility of the results.

```
rng('default')
```

Create a 4-by-3-by-2 array of random numbers.

```
X = randn([4 3 2])  
X =  
X(:,:,1) =  
  
    0.5377    0.3188    3.5784  
    1.8339   -1.3077    2.7694  
   -2.2588   -0.4336   -1.3499  
    0.8622    0.3426    3.0349  
  
X(:,:,2) =  
  
    0.7254   -0.1241    0.6715  
   -0.0631    1.4897   -1.2075  
    0.7147    1.4090    0.7172  
   -0.2050    1.4172    1.6302
```

Find the biased skewness of X.

```
yall = skewness(X,1,'all')  
yall = 0.0916
```

yall is the biased skewness of the entire input data set X.

Find the biased skewness of each page of X by specifying the first and second dimensions.

```
ypage = skewness(X,1,[1 2])  
ypage =  
ypage(:,:,1) =  
  
    0.1070  
  
ypage(:,:,2) =  
  
   -0.6263
```

For example, ypage(1,1,2) is the biased skewness of the elements in X(:,:,2).

Find the biased skewness of the elements in each X(:,i,:) slice by specifying the first and third dimensions.

```
ycol = skewness(X,1,[1 3])  
ycol = 1×3  
    -1.0755    -0.3108    -0.2209
```

For example, `ycol(3)` is the biased skewness of the elements in `X(:,3,:)`.

Input Arguments

X — Input data

vector | matrix | multidimensional array

Input data that represents a sample from a population, specified as a vector, matrix, or multidimensional array.

- If `X` is a vector, then `skewness(X)` returns a scalar value that is the skewness of the elements in `X`.
- If `X` is a matrix, then `skewness(X)` returns a row vector containing the sample skewness of each column in `X`.
- If `X` is a multidimensional array, then `skewness(X)` operates along the first nonsingleton dimension of `X`.

To specify the operating dimension when `X` is a matrix or an array, use the `dim` input argument.

`skewness` treats NaN values in `X` as missing values and removes them.

Data Types: `single` | `double`

flag — Indicator for bias

1 (default) | 0

Indicator for the bias, specified as 0 or 1.

- If `flag` is 1 (default), then the skewness of `X` is biased, meaning it tends to differ from the population skewness by a systematic amount based on the sample size.
- If `flag` is 0, then `skewness` corrects for the systematic bias.

Data Types: `single` | `double` | `logical`

dim — Dimension

positive integer

Dimension along which to operate, specified as a positive integer. If you do not specify a value for `dim`, then the default is the first dimension of `X` whose size does not equal 1.

Consider the skewness of a matrix `X`:

- If `dim` is equal to 1, then `skewness` returns a row vector that contains the sample skewness of each column in `X`.
- If `dim` is equal to 2, then `skewness` returns a column vector that contains the sample skewness of each row in `X`.

If `dim` is greater than `ndims(X)` or if `size(X, dim)` is 1, then `skewness` returns an array of NaNs the same size as `X`.

Data Types: `single` | `double`

vecdim — Vector of dimensions

positive integer vector

Vector of dimensions, specified as a positive integer vector. Each element of `vecdim` represents a dimension of the input array `X`. The output `y` has length 1 in the specified operating dimensions. The other dimension lengths are the same for `X` and `y`.

For example, if `X` is a 2-by-3-by-3 array, then `skewness(X, 1, [1 2])` returns a 1-by-1-by-3 array. Each element of the output array is the biased skewness of the elements on the corresponding page of `X`.

Data Types: `single` | `double`

Output Arguments

y — Skewness

scalar | vector | matrix | multidimensional array

Skewness, returned as a scalar, vector, matrix, or multidimensional array.

Algorithms

Skewness is a measure of the asymmetry of the data around the sample mean. If skewness is negative, the data spreads out more to the left of the mean than to the right. If skewness is positive, the data spreads out more to the right. The skewness of the normal distribution on page B-136 (or any perfectly symmetric distribution) is zero.

The skewness of a distribution is defined as

$$s = \frac{E(x - \mu)^3}{\sigma^3},$$

where μ is the mean of x , σ is the standard deviation of x , and $E(t)$ represents the expected value of the quantity t . The skewness function computes a sample version of this population value.

When you set `flag` to 1, the skewness is biased, and the following equation applies:

$$s_1 = \frac{\frac{1}{n} \sum_{i=1}^n (x_i - \bar{x})^3}{\left(\sqrt{\frac{1}{n} \sum_{i=1}^n (x_i - \bar{x})^2} \right)^3}.$$

When you set `flag` to 0, skewness corrects for the systematic bias, and the following equation applies:

$$s_0 = \frac{\sqrt{n(n-1)}}{n-2} s_1.$$

This bias-corrected equation requires that X contain at least three elements.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. For more information, see “Tall Arrays” (MATLAB).

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The 'all' and `vecdim` input arguments are not supported.
- The `dim` input argument must be a compile-time constant.
- If you do not specify the `dim` input argument, the working (or operating) dimension can be different in the generated code. As a result, run-time errors can occur. For more details, see “Automatic dimension restriction” (MATLAB Coder).

For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “General Code Generation Workflow” on page 31-5.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Usage notes and limitations:

- The 'all' and `vecdim` input arguments are not supported.

For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

sobolset

Sobol quasirandom point set

Description

`sobolset` is a quasirandom point set object that produces points from the Sobol sequence. The Sobol sequence is a base-2 digital sequence that fills space in a highly uniform manner.

Creation

Syntax

```
p = sobolset(d)
p = sobolset(d,Name,Value)
```

Description

`p = sobolset(d)` constructs a d -dimensional point set `p`, which is a `sobolset` object with default property settings. The input argument `d` corresponds to the `Dimensions` property of `p`.

`p = sobolset(d,Name,Value)` sets properties on page 32-6445 of `p` using one or more name-value pair arguments. Enclose each property name in quotes. For example, `sobolset(5, 'Leap', 2)` creates a five-dimensional point set from the first point, fourth point, seventh point, tenth point, and so on.

The returned object `p` encapsulates properties of a Sobol quasirandom sequence. The point set is finite, with a length determined by the `Skip` and `Leap` properties and by limits on the size of the point set indices (maximum value of 2^{53}). Values of the point set are generated whenever you access `p` using `net` or parenthesis indexing. Values are not stored within `p`.

Properties

Dimensions — Number of dimensions

positive integer scalar in interval [1,1111]

This property is read-only.

Number of dimensions of the points in the point set, specified as a positive integer scalar in the interval [1,1111]. For example, each point in the point set `p` with `p.Dimensions = 5` has five values.

Use the `d` input argument to specify the number of dimensions when you create a point set using the `sobolset` function.

Use the `reduceDimensions` object function to reduce the number of dimensions after you create a point set.

Leap — Interval between points

0 (default) | positive integer scalar

Interval between points in the sequence, specified as a positive integer scalar. In other words, the `Leap` property of a point set specifies the number of points in the sequence to leap over and omit for every point taken. The default `Leap` value is 0, which corresponds to taking every point from the sequence.

Leaping is a technique used to improve the quality of a point set. However, you must choose the `Leap` values with care. Many `Leap` values create sequences that fail to touch on large sub-hyper-rectangles of the unit hypercube and, therefore, fail to be a uniform quasirandom point set. For more information, see [4].

Example: `p = sobolset(__, 'Leap', 50);`

Example: `p.Leap = 100;`

PointOrder — Point generation method

'standard' (default) | 'graycode'

Point generation method, specified as 'standard' or 'graycode'. The `PointOrder` property specifies the order in which the Sobol sequence points are produced. When `PointOrder` is set to 'standard', the points produced match the original Sobol sequence implementation. When `PointOrder` is set to 'graycode', the sequence is generated by an implementation that uses the Gray code of the index instead of the index itself.

You can use the 'graycode' option for faster sequence generation, but the software then changes the order of the generated points. For more information on the Gray code implementation, see [1].

```
Example: p = sobolset(__, 'PointOrder', 'graycode');
```

```
Example: p.PointOrder = 'standard';
```

ScrambleMethod — Settings that control scrambling

0×0 structure (default) | structure with Type and Options fields

Settings that control the scrambling of the sequence, specified as a structure with these fields:

- **Type** — A character vector containing the name of the scramble
- **Options** — A cell array of parameter values for the scramble

Use the `scramble` object function to set scrambles. For a list of valid scramble types, see the `type` input argument of `scramble`. An error occurs if you set an invalid scramble type for a given point set.

The `ScrambleMethod` property also accepts an empty matrix as a value. The software then clears all scrambling and sets the property to contain a 0×0 structure.

Skip — Number of initial points in sequence to omit

0 (default) | positive integer scalar

Number of initial points in the sequence to omit from the point set, specified as a positive integer scalar.

Initial points of a sequence sometimes exhibit undesirable properties. For example, the first point is often (0, 0, 0, . . .), which can cause the sequence to be unbalanced because the counterpart of the point, (1, 1, 1, . . .), never appears. Also, initial points often exhibit correlations among different dimensions, and these correlations disappear later in the sequence.

```
Example: p = sobolset(__, 'Skip', 2e3);
```

```
Example: p.Skip = 1e3;
```

Type — Sequence type

'Sobol' (default)

This property is read-only.

Sequence type on which the quasirandom point set `p` is based, specified as `'Sobol'`.

Object Functions

<code>net</code>	Generate quasirandom point set
<code>reduceDimensions</code>	Reduce dimensions of Sobol point set
<code>scramble</code>	Scramble quasirandom point set

You can also use the following MATLAB functions with a `sobolset` object. The software treats the point set object like a matrix of multidimensional points.

<code>length</code>	Length of largest array dimension
<code>size</code>	Array size

Examples

Create Sobol Point Set

Generate a three-dimensional Sobol point set, skip the first 1000 values, and then retain every 101st point.

```
p = sobolset(3, 'Skip', 1e3, 'Leap', 1e2)
```

```
p =
Sobol point set in 3 dimensions (89180190640991 points)
```

Properties:

```
    Skip : 1000
    Leap : 100
ScrambleMethod : none
    PointOrder : standard
```

Apply a random linear scramble combined with a random digital shift by using `scramble`.

```
p = scramble(p, 'MatousekAffineOwen')
```

```
p =
Sobol point set in 3 dimensions (89180190640991 points)
```

Properties:

```
Skip : 1000
Leap : 100
ScrambleMethod : MatousekAffineOwen
PointOrder : standard
```

Generate the first four points by using `net`.

```
X0 = net(p,4)
```

```
X0 = 4×3
```

```
0.7601    0.5919    0.9529
0.1795    0.0856    0.0491
0.5488    0.0785    0.8483
0.3882    0.8771    0.8755
```

Generate every third point, up to the eleventh point, by using parenthesis indexing.

```
X = p(1:3:11,:)
```

```
X = 4×3
```

```
0.7601    0.5919    0.9529
0.3882    0.8771    0.8755
0.6905    0.4951    0.8464
0.1955    0.5679    0.3192
```

Tips

- The `Skip` and `Leap` properties are useful for parallel applications. For example, if you have a Parallel Computing Toolbox license, you can partition a sequence of points across N different workers by using the function `labindex`. On each n th worker, set the `Skip` property of the point set to $n - 1$ and the `Leap` property to $N - 1$. The following code shows how to partition a sequence across three workers.

```
Nworkers = 3;
p = sobolset(10, 'Leap', Nworkers-1);
spmd(Nworkers)
    p.Skip = labindex - 1;
```

```

    % Compute something using points 1,4,7...
    % or points 2,5,8... or points 3,6,9...
end

```

Algorithms

Sobol Sequence Generation

Consider a default `sobolset` object `p` that contains d -dimensional points. Each $p(i, :)$ is a point in a Sobol sequence. The j th coordinate of the i th point, $p(i, j)$, is equal to

$$\begin{cases} 0, & i = 1 \\ \gamma_i(1)v_j(1) \oplus \gamma_i(2)v_j(2) \oplus \dots, & i > 1. \end{cases}$$

- The $\gamma_i(n)$ values are 0s or 1s such that

$$i - 1 = \sum_{n=1} \gamma_i(n)2^{n-1}.$$

In other words, the $\gamma_i(n)$ values are the binary digits of the integer $i - 1$.

- The $v_j(n)$ values are called direction numbers. They are uniquely defined for each coordinate j . For more details on these values, see “Direction Numbers Generation” on page 32-6450.
- The \oplus operator is the bitwise exclusive-or operator. For two numbers expressed in binary, the \oplus operator compares the digits in each position. For a given digit position, the \oplus operator returns a 1 if the digits in that position differ and returns a 0 if the digits in that position are the same.
 - For example, $19 \oplus 24 = (10011)_2 \oplus (11000)_2 = (01011)_2 = 11$.
 - Similarly, $\frac{1}{2} \oplus \frac{3}{4} = (0.1)_2 \oplus (0.11)_2 = (0.01)_2 = \frac{1}{4}$.

For more information, see [3].

Direction Numbers Generation

The set of direction numbers $v_j(n)$ depends on the coordinate j . Define the direction numbers in terms of $m_j(n)$ values:

$$v_j(n) = \frac{m_j(n)}{2^n}.$$

For each j , you can generate the direction numbers by selecting the following:

- A primitive polynomial in \mathbb{Z}_2 of some degree s_j

$$x^{s_j} + a_j(1)x^{s_j-1} + a_j(2)x^{s_j-2} + \dots + a_j(s_j-1)x + 1.$$

Each coefficient in the polynomial is either 0 or 1.

- s_j initial direction numbers. For each initial direction number, the corresponding $m_j(n)$ value must be either 1 or an odd number less than 2^n .

The remaining direction numbers are determined by the following recurrence relation, which uses the coefficients of the primitive polynomial, the previous direction numbers, and the \oplus bitwise exclusive-or operator.

$$m_j(n) = 2a_j(1)m_j(n-1) \oplus 2^2a_j(2)m_j(n-2) \oplus \dots \oplus 2^{s_j-1}a_j(s_j-1)m_j(n-s_j+1) \oplus 2^{s_j}m_j(n-s_j) \oplus m_j(n-s_j).$$

`sobolset` uses the same primitive polynomials and initial direction numbers described in [3]. These parameters are provided for the first 1111 dimensions.

Introduced in R2008a

sortClasses

Package: mlearnlib.graphics.chart

Sort classes of confusion matrix chart

Syntax

```
sortClasses(cm,order)
```

Description

`sortClasses(cm,order)` sorts the classes of the confusion matrix chart `cm` in the order specified by `order`. You can sort the classes in their natural order, by the values along the diagonal of the confusion matrix, or in fixed order that you specify.

Examples

Sort Classes by Precision or Recall

Create a confusion matrix chart and sort the classes of the chart according to the class-wise true positive rate (recall) or the class-wise positive predictive value (precision).

Load and inspect the `arrhythmia` data set.

```
load arrhythmia
isLabels = unique(Y);
nLabels = numel(isLabels)

nLabels = 13

tabulate(categorical(Y))
```

Value	Count	Percent
1	245	54.20%
2	44	9.73%

3	15	3.32%
4	15	3.32%
5	13	2.88%
6	25	5.53%
7	3	0.66%
8	2	0.44%
9	9	1.99%
10	50	11.06%
14	4	0.88%
15	5	1.11%
16	22	4.87%

The data contains 16 distinct labels that describe various degrees of arrhythmia, but the response (Y) includes only 13 distinct labels.

Train a classification tree and predict the resubstitution response of the tree.

```
Mdl = fitctree(X,Y);
predictedY = resubPredict(Mdl);
```

Create a confusion matrix chart from the true labels Y and the predicted labels predictedY. Specify 'RowSummary' as 'row-normalized' to display the true positive rates and false positive rates in the row summary. Also, specify 'ColumnSummary' as 'column-normalized' to display the positive predictive values and false discovery rates in the column summary.

```
fig = figure;
cm = confusionchart(Y,predictedY,'RowSummary','row-normalized','ColumnSummary','column-normalized');
```

Resize the container of the confusion chart so percentages appear in the row summary.

```
fig_Position = fig.Position;
fig_Position(3) = fig_Position(3)*1.5;
fig.Position = fig_Position;
```

True Class	1	240				4				1						98.0%	2.0%

		Predicted Class															

To sort the confusion matrix according to the true positive rate, normalize the cell values across each row by setting the `Normalization` property to `'row-normalized'` and then use `sortClasses`. After sorting, reset the `Normalization` property back to `'absolute'` to display the total number of observations in each cell.

```
cm.Normalization = 'row-normalized';
sortClasses(cm, 'descending-diagonal')
cm.Normalization = 'absolute';
```

3	15															100.0%		
1		240	4	1												98.0%	2.0%

		Predicted Class																

To sort the confusion matrix according to the positive predictive value, normalize the cell values across each column by setting the `Normalization` property to `'column-normalized'` and then use `sortClasses`. After sorting, reset the `Normalization` property back to `'absolute'` to display the total number of observations in each cell.

```
cm.Normalization = 'column-normalized';
sortClasses(cm, 'descending-diagonal')
cm.Normalization = 'absolute';
```

Sort Classes to Cluster Similar Classes

Create a confusion matrix chart by using the `confusionchart` function, and sort the classes to cluster similar classes by using the `'cluster'` option of the `sortClasses` function. This example also shows how to cluster by using the `pdist`, `linkage`, and `optimalleaforder` functions.

Generate a sample data set that contains eight distinct classes.

```
rng('default') % For reproducibility
trueLabels = randi(8,1000,1);
predictedLabels = trueLabels;
```

Insert confusion among classes {1,4,7}, {2,8}, and {5,6} for the first 200 samples.

```
rename = [4 8 3 7 6 5 1 2];
predictedLabels(1:100) = rename(predictedLabels(1:100));
rename = [7 8 3 1 6 5 4 2];
predictedLabels(101:200) = rename(predictedLabels(101:200));
```

Create a confusion matrix chart from the true labels `trueLabels` and the predicted labels `predictedLabels`.

```
figure
cm1 = confusionchart(trueLabels,predictedLabels);
```

Cluster Using 'cluster'

Sort the classes to cluster similar classes by using the 'cluster' option.

```
sortClasses(cm1, 'cluster')
```

3	116							
4		107	11	14				
7		14	89	16				
1		10	14	106				
2					105	29		
8					26	81		
5							99	21
6							21	121
	3	4	7	1	2	8	5	6

Predicted Class

Cluster Using `pdist`, `linkage`, and `optimalleaforder`

Instead of using the `'cluster'` option, you can use the `pdist`, `linkage`, and `optimalleaforder` functions to cluster confusion matrix values. You can customize clustering by using the options of these functions. For details, see the corresponding function reference pages.

Suppose you have a confusion matrix and class labels.

```
m = confusionmat(trueLabels,predictedLabels);
labels = [1 2 3 4 5 6 7 8];
```

Compute the clustered matrix and find the corresponding class labels by using `pdist`, `linkage`, and `optimalleaforder`. The `pdist` function computes the Euclidean

distance D between pairs of the confusion matrix values. The `optimalleaforder` function returns an optimal leaf ordering for the hierarchical binary cluster tree `linkage(D)` using the distance D .

```
D = pdist(m);
idx = optimalleaforder(linkage(D),D);
clusteredM = m(idx,idx);
clusteredLabels = labels(idx);
```

Create a confusion matrix chart using the clustered matrix and the corresponding class labels. Then, sort the classes using the class labels.

```
cm2 = confusionchart(clusteredM,clusteredLabels);
sortClasses(cm2,clusteredLabels)
```

The sorted confusion matrix chart `cm2`, which you created by using `pdist`, `linkage`, and `optimalleaforder`, is identical to the sorted confusion matrix chart `cm1`, which you created by using the `'cluster'` option.

Sort Classes in Fixed Order

Create a confusion matrix chart and sort the classes of the chart in a fixed order.

Load Fisher's iris data set.

```
load fisheriris
X = meas([51:150,1:50],:);
Y = species([51:150,1:50],:);
```

`X` is a numeric matrix that contains four petal measurements for 150 irises. `Y` is a cell array of character vectors that contains the corresponding iris species.

Train a k -nearest neighbor (KNN) classifier, where the number of nearest neighbors in the predictors (k) is 5. A good practice is to standardize numeric predictor data.

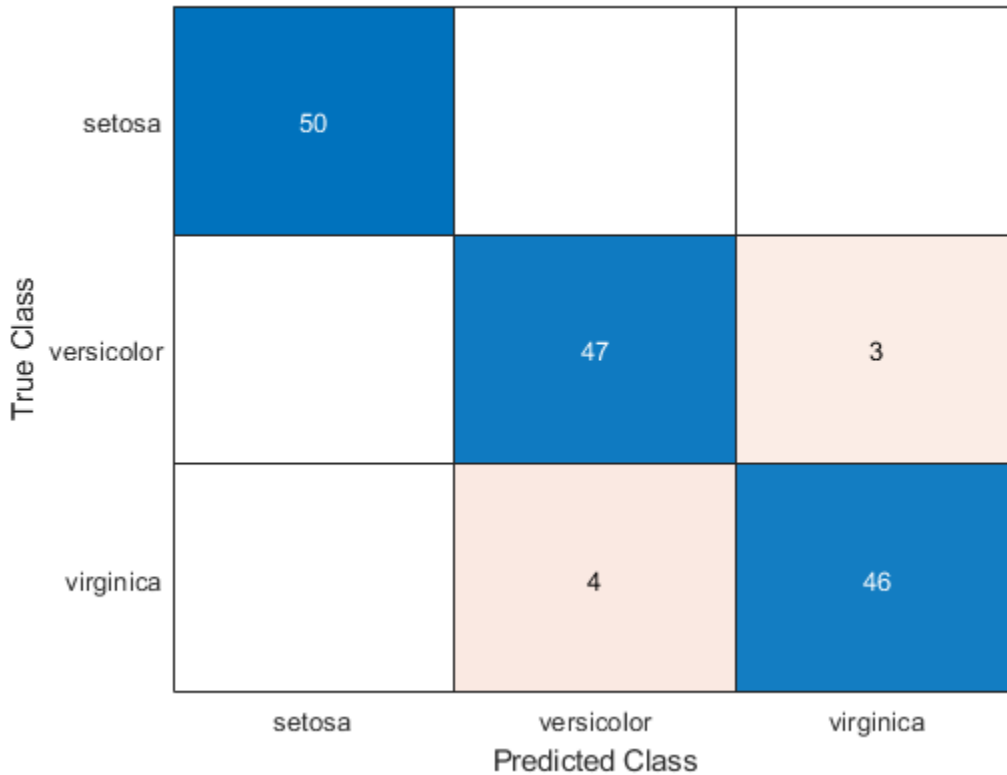

```
Mdl = fitcknn(X,Y,'NumNeighbors',5,'Standardize',1);
```

Predict the labels of the training data.

```
predictedY = resubPredict(Mdl);
```

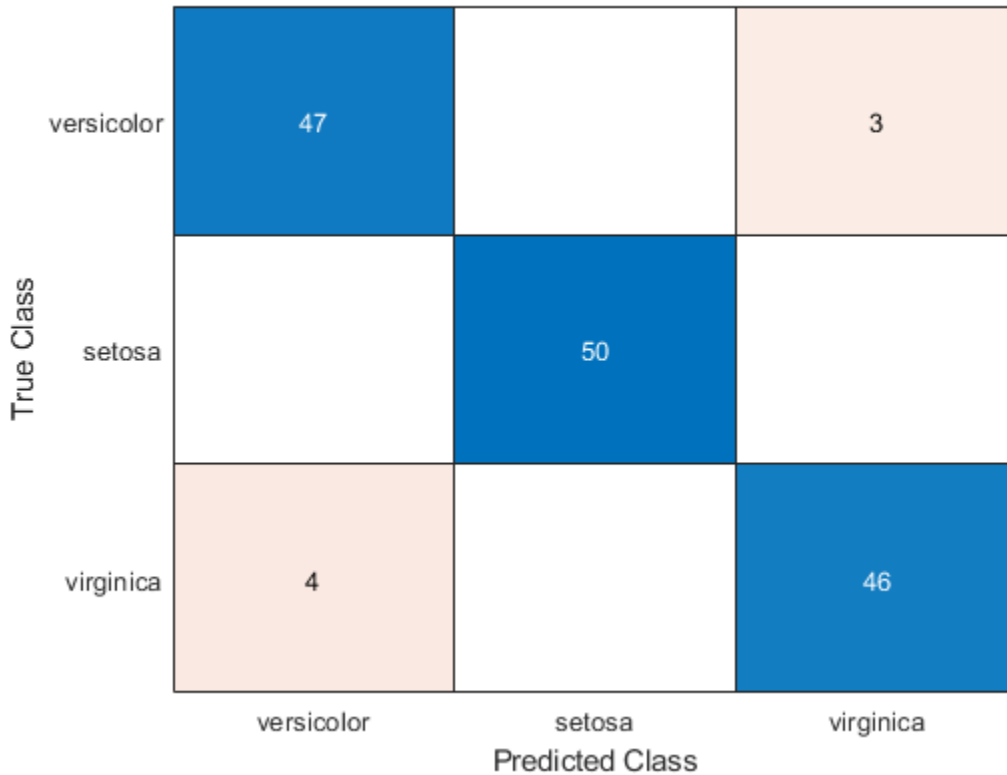

Create a confusion matrix chart from the true labels `Y` and the predicted labels `predictedY`.

```
cm = confusionchart(Y,predictedY);
```

By default, `confusionchart` sorts the classes into their natural order as defined by `sort`. In this example, the class labels are character vectors, so `confusionchart` sorts the classes alphabetically. Reorder the classes of the confusion matrix chart in a fixed order.

```
sortClasses(cm, ["versicolor", "setosa", "virginica"])
```

Input Arguments

cm — Confusion matrix chart

ConfusionMatrixChart object

Confusion matrix chart, specified as a ConfusionMatrixChart object. To create a confusion matrix chart, use `confusionchart`,

order — Order in which to sort classes

'auto' | 'ascending-diagonal' | 'descending-diagonal' | 'cluster' | array

Order in which to sort the classes of the confusion matrix chart, specified as one of these values:

- `'auto'` — Sorts the classes into their natural order as defined by the `sort` function. For example, if the class labels of the confusion matrix chart are a string vector, then sort alphabetically. If the class labels are an ordinal categorical vector, then use the order of the class labels.
- `'ascending-diagonal'` — Sort the classes so that the values along the diagonal of the confusion matrix increase from top left to bottom right.
- `'descending-diagonal'` — Sort the classes so that the values along the diagonal of the confusion matrix decrease from top left to bottom right.
- `'cluster'` — Sort the classes to cluster similar classes. You can customize clustering by using the `pdist`, `linkage`, and `optimalleaforder` functions. For details, see “Sort Classes to Cluster Similar Classes” on page 32-6456.
- `Array` — Sort the classes in a unique order specified by a categorical vector, numeric vector, string vector, character array, cell array of character vectors, or logical vector. The array must be a permutation of the `ClassLabels` property of the confusion matrix chart.

Example: `sortClasses(cm, 'ascending-diagonal')`

Example: `sortClasses(cm, ["owl", "cat", "toad"])`

Properties

`ConfusionMatrixChart` Properties

Introduced in R2018b

sortrows

Class: dataset

Sort rows of dataset array

Note The dataset data type might be removed in a future release. To work with heterogeneous data, use the MATLAB® table data type instead. See MATLAB table documentation for more information.

Syntax

```
B = sortrows(A)
B = sortrows(A,vars)
B = sortrows(A,'obsnames')
B = sortrows(A,vars,mode)
[B,idx] = sortrows(A)
```

Description

`B = sortrows(A)` returns a copy of the dataset array `A`, with the observations sorted in ascending order by all of the variables in `A`. The observations in `B` are sorted first by the first variable, next by the second variable, and so on. Each variable in `A` must be a valid input to `sort`, or, if a variable has multiple columns, to the MATLAB `sortrows` function or to its `ownsorrows` method.

`B = sortrows(A,vars)` sorts the observations in `A` by the variables specified by `vars`. `vars` is a positive integer, a vector of positive integers, a character vector, a string array, a cell array of character vectors, or a logical vector.

`B = sortrows(A,'obsnames')` sorts the observations in `A` by observation name.

`B = sortrows(A,vars,mode)` sorts in the direction specified by `mode`. When `mode` is 'ascend' (the default) or 'descend', `sortrows` sorts `A` by the variables specified by `vars` in ascending or descending order, respectively. `mode` can also be a string array or

cell array containing 'ascend' or 'descend', to specify a different sorting direction for each variable in vars. Specify [] for vars to sort using all variables.

[B,idx] = sortrows(A) also returns an index vector idx such that B = A(idx,:).

Examples

Sort the data in hospital.mat by age and then by last name:

```
load hospital
hospital(1:5,1:3)
ans =
```

	LastName	Sex	Age
YPL-320	'SMITH'	Male	38
GLI-532	'JOHNSON'	Male	43
PNI-258	'WILLIAMS'	Female	38
MIJ-579	'JONES'	Female	40
XLK-030	'BROWN'	Female	49

```
hospital = sortrows(hospital,{'Age','LastName'});
hospital(1:5,1:3)
ans =
```

	LastName	Sex	Age
REV-997	'ALEXANDER'	Male	25
FZR-250	'HALL'	Male	25
LIM-480	'HILL'	Female	25
XUE-826	'JACKSON'	Male	25
SCQ-914	'JAMES'	Male	25

Sort the data in hospital by gender in ascending order, and age in descending order.

```
hospital = sortrows(hospital,{'Sex','Age'},{'ascend','descend'});
hospital(1:5,1:3)
ans =
```

	LastName	Sex	Age
XLK-030	'BROWN'	Female	49
GGU-691	'HUGHES'	Female	49
KKL-155	'ADAMS'	Female	48
HQQ-561	'BRYANT'	Female	48
BKD-785	'CLARK'	Female	48

```
hospital(end-4:end,1:3)
```

ans =

	LastName	Sex	Age
VNL-702	'MOORE '	Male	28
REV-997	'ALEXANDER '	Male	25
FZR-250	'HALL '	Male	25
XUE-826	'JACKSON '	Male	25
SCQ-914	'JAMES '	Male	25

sparsefilt

Feature extraction by using sparse filtering

Syntax

```
Mdl = sparsefilt(X,q)
Mdl = sparsefilt(X,q,Name,Value)
```

Description

`Mdl = sparsefilt(X,q)` returns a sparse filtering model object that contains the results from applying sparse filtering to the table or matrix of predictor data X containing p variables. q is the number of features to extract from X , therefore `sparsefilt` learns a p -by- q matrix of transformation weights. For undercomplete or overcomplete feature representations, q can be less than or greater than the number of predictor variables, respectively.

- To access the learned transformation weights, use `Mdl.TransformWeights`.
- To transform X to the new set of features by using the learned transformation, pass `Mdl` and X to `transform`.

`Mdl = sparsefilt(X,q,Name,Value)` uses additional options specified by one or more `Name,Value` pair arguments. For example, you can standardize the predictor data or apply L^2 regularization.

Examples

Create Sparse Filter

Create a `SparseFiltering` object by using the `sparsefilt` function.

Load the `caltech101` image patches.

```
data = load('caltech101patches');
size(data.X)

ans = 1×2

    100000    363
```

There are 100,000 image patches, each containing 363 features.

Extract 100 features from the data.

```
rng default % For reproducibility
Q = 100;
obj = sparsefilt(data.X,Q,'IterationLimit',100)
```

Warning: Solver LBFGS was not able to converge to a solution.

```
obj =
  SparseFiltering
      ModelParameters: [1x1 struct]
      NumPredictors: 363
      NumLearnedFeatures: 100
      Mu: []
      Sigma: []
      FitInfo: [1x1 struct]
      TransformWeights: [363x100 double]
      InitialTransformWeights: []
```

Properties, Methods

`sparsefilt` issues a warning because it stopped due to reaching the iteration limit, instead of reaching a step-size limit or a gradient-size limit. You can still use the learned features in the returned object by calling the `transform` function.

Restart `sparsefilt`

Continue optimizing a sparse filter.

Load the `caltech101` image patches.

```

data = load('caltech101patches');
size(data.X)

ans = 1x2

    100000     363

```

There are 100,000 image patches, each containing 363 features.

Extract 100 features from the data and use an iteration limit of 20.

```

rng default % For reproducibility
q = 100;
Mdl = sparsefilt(data.X,q,'IterationLimit',20);

```

Warning: Solver LBFGS was not able to converge to a solution.

View the resulting transformation matrix as image patches.

```

wts = Mdl.TransformWeights;
W = reshape(wts,[11,11,3,q]);
[dx,dy,~,~] = size(W);
for f = 1:q
    Wvec = W(:,:,,f);
    Wvec = Wvec(:);
    Wvec = (Wvec - min(Wvec))/(max(Wvec) - min(Wvec));
    W(:,:,,f) = reshape(Wvec,dx,dy,3);
end
m = ceil(sqrt(q));
n = m;
img = zeros(m*dx,n*dy,3);
f = 1;
for i = 1:m
    for j = 1:n
        if (f <= q)
            img((i-1)*dx+1:i*dx,(j-1)*dy+1:j*dy,:) = W(:,:,,f);
            f = f+1;
        end
    end
end
end
imshow(img,'InitialMagnification',300);

```

The image patches appear noisy. To clean up the noise, try more iterations. Restart the optimization from where it stopped for another 40 iterations.

```
Mdl = sparsefilt(data.X,q, 'IterationLimit',40, 'InitialTransformWeights',wts);
```

Warning: Solver LBFGS was not able to converge to a solution.

View the updated transformation matrix as image patches.

```
wts = Mdl.TransformWeights;  
W = reshape(wts,[11,11,3,q]);  
[dx,dy,~,~] = size(W);  
for f = 1:q  
    Wvec = W(:,:,f);
```

```
Wvec = Wvec(:);
Wvec =(Wvec - min(Wvec))/(max(Wvec) - min(Wvec));
W(:,:,,f) = reshape(Wvec,dx,dy,3);
end
m = ceil(sqrt(q));
n = m;
img = zeros(m*dx,n*dy,3);
f = 1;
for i = 1:m
    for j = 1:n
        if (f <= q)
            img((i-1)*dx+1:i*dx,(j-1)*dy+1:j*dy,:) = W(:,:,,f);
            f = f+1;
        end
    end
end
end
imshow(img, 'InitialMagnification',300);
```

These images are much less noisy.

Input Arguments

X — Predictor data

numeric matrix | table

Predictor data, specified as an n -by- p numeric matrix or table. Rows correspond to individual observations and columns correspond to individual predictor variables. If X is a table, then all of its variables must be numeric vectors.

Data Types: `single` | `double` | `table`

q — Number of features to extract

positive integer

Number of features to extract from the predictor data, specified as a positive integer.

`sparsefilt` stores a p -by- q transform weight matrix in `Mdl.TransformWeights`. Therefore, setting very large values for q can result in greater memory consumption and increased computation time.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'Standardize', true, 'Lambda', 1` standardizes the predictor data and applies a penalty of 1 to the transform weight matrix.

IterationLimit — Maximum number of iterations

1000 (default) | positive integer

Maximum number of iterations, specified as the comma-separated pair consisting of `'IterationLimit'` and a positive integer.

Example: `'IterationLimit', 1e6`

Data Types: `single` | `double`

VerbosityLevel — Verbosity level

0 (default) | nonnegative integer

Verbosity level for monitoring algorithm convergence, specified as the comma-separated pair consisting of `'VerbosityLevel'` and a value in this table.

Value	Description
0	<code>sparsefilt</code> does not display convergence information at the command line.

Value	Description
Positive integer	<code>sparsefilt</code> displays convergence information at the command line.

Convergence Information

Heading	Meaning
FUN VALUE	Objective function value.
NORM GRAD	Norm of the gradient of the objective function.
NORM STEP	Norm of the iterative step, meaning the distance between the previous point and the current point.
CURV	OK means the weak Wolfe condition is satisfied. This condition is a combination of sufficient decrease of the objective function and a curvature condition.
GAMMA	Inner product of the step times the gradient difference, divided by the inner product of the gradient difference with itself. The gradient difference is the gradient at the current point minus the gradient at the previous point. Gives diagnostic information on the objective function curvature.
ALPHA	Step direction multiplier, which differs from 1 when the algorithm performed a line search.
ACCEPT	YES means the algorithm found an acceptable step to take.

Example: `'VerbosityLevel',1`

Data Types: `single` | `double`

Lambda — L^2 regularization coefficient value

0 (default) | positive numeric scalar

L^2 regularization coefficient value for the transform weight matrix, specified as the comma-separated pair consisting of `'Lambda'` and a positive numeric scalar. If you specify 0, the default, then there is no regularization term in the objective function.

Example: `'Lambda',0.1`

Data Types: `single` | `double`

Standardize — Flag to standardize predictor data

false (default) | true

Flag to standardize the predictor data, specified as the comma-separated pair consisting of 'Standardize' and true (1) or false (0).

If Standardize is true, then:

- `sparsefilt` centers and scales each column of the predictor data (X) by the column mean and standard deviation, respectively.
- `sparsefilt` extracts new features by using the standardized predictor matrix, and stores the predictor variable means and standard deviations in properties `Mu` and `Sigma` of `Mdl`.

Example: 'Standardize',true

Data Types: logical

InitialTransformWeights — Transformation weights that initialize optimization

`randn(p,q)` (default) | numeric matrix

Transformation weights that initialize optimization, specified as the comma-separated pair consisting of 'InitialTransformWeights' and a p -by- q numeric matrix. p must be the number of columns or variables in X and q is the value of q .

Tip You can continue optimizing a previously returned transform weight matrix by passing it as an initial value in another call to `sparsefilt`. The output model object `Mdl` stores a learned transform weight matrix in the `TransformWeights` property.

Example: 'InitialTransformWeights',`Mdl.TransformWeights`

Data Types: single | double

GradientTolerance — Relative convergence tolerance on gradient norm

`1e-6` (default) | positive numeric scalar

Relative convergence tolerance on gradient norm, specified as the comma-separated pair consisting of 'GradientTolerance' and a positive numeric scalar. This gradient is the gradient of the objective function.

Example: 'GradientTolerance',`1e-4`

Data Types: single | double

StepTolerance — Absolute convergence tolerance on step size

1e-6 (default) | positive numeric scalar

Absolute convergence tolerance on the step size, specified as the comma-separated pair consisting of 'StepTolerance' and a positive numeric scalar.

Example: 'StepTolerance',1e-4

Data Types: single | double

Output Arguments

Mdl — Learned sparse filtering model

SparseFiltering model object

Learned sparse filtering model, returned as a SparseFiltering model object.

To access properties of Mdl, use dot notation. For example:

- To access the learned transform weights, use `Mdl.TransformWeights`.
- To access the fitting information structure, use `Mdl.FitInfo`.

To find sparse filtering coefficients for new data, use the `transform` function.

Algorithms

The `sparsefilt` function creates a nonlinear transformation of input features to output features. The transformation is based on optimizing an objective function that encourages the representation of each example by as few output features as possible while at the same time keeping the output features equally active across examples.

For details, see “Sparse Filtering Algorithm” on page 15-157.

“Feature Extraction Workflow” on page 15-163

“Feature Extraction” on page 15-157

Introduced in R2017a

SparseFiltering

Feature extraction by sparse filtering

Description

`SparseFiltering` uses sparse filtering to learn a transformation that maps input predictors to new predictors.

Creation

Create a `SparseFiltering` object using the `sparsefilt` function.

Properties

FitInfo — Fitting history

structure

This property is read-only.

Fitting history, returned as a structure with two fields:

- **Iteration** — Iteration numbers from 0 through the final iteration.
- **Objective** — Objective function value at each corresponding iteration. Iteration 0 corresponds to the initial values, before any fitting.

Data Types: `struct`

InitialTransformWeights — Initial feature transformation weights

p-by-q matrix

This property is read-only.

Initial feature transformation weights, returned as a p-by-q matrix, where p is the number of predictors passed in X and q is the number of features that you want. These weights

are the initial weights passed to the creation function. The data type is single when the training data X is single.

Data Types: `single` | `double`

ModelParameters — Parameters used for training model

structure

This property is read-only.

Parameters used for training the model, returned as a structure. The structure contains a subset of the fields that corresponds to the `sparsefilt` name-value pairs that were in effect during model creation:

- `IterationLimit`
- `VerbosityLevel`
- `Lambda`
- `Standardize`
- `GradientTolerance`
- `StepTolerance`

For details, see the `sparsefilt` name-value pairs in the documentation.

Data Types: `struct`

Mu — Predictor means when standardizing

p -by-1 vector

This property is read-only.

Predictor means when standardizing, returned as a p -by-1 vector. This property is nonempty when the `Standardize` name-value pair is `true` at model creation. The value is the vector of predictor means in the training data. The data type is single when the training data X is single.

Data Types: `single` | `double`

NumLearnedFeatures — Number of output features

positive integer

This property is read-only.

Number of output features, returned as a positive integer. This value is the `q` argument passed to the creation function, which is the requested number of features to learn.

Data Types: `double`

NumPredictors — Number of input predictors

positive integer

This property is read-only.

Number of input predictors, returned as a positive integer. This value is the number of predictors passed in `X` to the creation function.

Data Types: `double`

Sigma — Predictor standard deviations when standardizing

`p`-by-1 vector

This property is read-only.

Predictor standard deviations when standardizing, returned as a `p`-by-1 vector. This property is nonempty when the `Standardize` name-value pair is `true` at model creation. The value is the vector of predictor standard deviations in the training data. The data type is `single` when the training data `X` is `single`.

Data Types: `single` | `double`

TransformWeights — Feature transformation weights

`p`-by-`q` matrix

This property is read-only.

Feature transformation weights, returned as a `p`-by-`q` matrix, where `p` is the number of predictors passed in `X` and `q` is the number of features that you want. The data type is `single` when the training data `X` is `single`.

Data Types: `single` | `double`

Object Functions

`transform` Transform predictors into extracted features

Examples

Create Sparse Filter

Create a SparseFiltering object by using the `sparsefilt` function.

Load the caltech101 image patches.

```
data = load('caltech101patches');
size(data.X)
```

```
ans = 1x2
```

```
    100000    363
```

There are 100,000 image patches, each containing 363 features.

Extract 100 features from the data.

```
rng default % For reproducibility
Q = 100;
obj = sparsefilt(data.X,Q,'IterationLimit',100)
```

Warning: Solver LBFGS was not able to converge to a solution.

```
obj =
  SparseFiltering
      ModelParameters: [1x1 struct]
      NumPredictors: 363
      NumLearnedFeatures: 100
      Mu: []
      Sigma: []
      FitInfo: [1x1 struct]
      TransformWeights: [363x100 double]
      InitialTransformWeights: []
```

Properties, Methods

`sparsefilt` issues a warning because it stopped due to reaching the iteration limit, instead of reaching a step-size limit or a gradient-size limit. You can still use the learned features in the returned object by calling the `transform` function.

“Feature Extraction Workflow” on page 15-163

“Feature Extraction” on page 15-157

Introduced in R2017a

squareform

Format distance matrix

Syntax

```
ZOut = squareform(yIn)
y0Out = squareform(ZIn)
```

```
ZOut = squareform(yIn, 'tomatrix')
y0Out = squareform(ZIn, 'tovector')
```

Description

`ZOut = squareform(yIn)` converts `yIn`, a pairwise distance vector of length $m(m-1)/2$ for m observations, into `ZOut`, an m -by- m symmetric matrix with zeros along the diagonal.

The pairwise distances in `yIn` are arranged in the order (2,1), (3,1), ..., (m,1), (3,2), ..., (m,2), ..., (m,m-1). The pairwise distance between the i th and j th observations is in `ZOut(i, j)` and `yIn((i-1)*(m-i/2)+j-i)` for $i \leq j$.

`y0Out = squareform(ZIn)` converts `ZIn`, a square, symmetric matrix with zeros along the diagonal, into `y0Out`, a vector containing the `ZIn` elements below the diagonal.

`ZOut = squareform(yIn, 'tomatrix')` forces `squareform` to treat `yIn` as a vector and converts `yIn` into a matrix.

`y0Out = squareform(ZIn, 'tovector')` forces `squareform` to treat `ZIn` as a matrix and converts `ZIn` into a vector. If `ZIn` is a scalar (1-by-1), then `ZIn` must be zero.

The previous two syntaxes are useful when the input argument is a scalar. If you do not specify either `'tomatrix'` or `'tovector'`, then the default is `'tomatrix'`.

Examples

Compute Euclidean Distance and Convert Distance Vector to Matrix

Compute the Euclidean distance between pairs of observations, and convert the distance vector to a matrix using `squareform`.

Create a matrix with three observations and two variables.

```
rng('default') % For reproducibility
X = rand(3,2);
```

Compute the Euclidean distance.

```
D = pdist(X)
```

```
D = 1×3
```

```
    0.2954    1.0670    0.9448
```

The pairwise distances are arranged in the order (2,1), (3,1), (3,2). You can easily locate the distance between observations *i* and *j* by using `squareform`.

```
Z = squareform(D)
```

```
Z = 3×3
```

```
    0    0.2954    1.0670
    0.2954    0    0.9448
    1.0670    0.9448    0
```

`squareform` returns a symmetric matrix where $Z(i, j)$ corresponds to the pairwise distance between observations *i* and *j*. For example, you can find the distance between observations 2 and 3.

```
Z(2,3)
```

```
ans = 0.9448
```

Pass *Z* to the `squareform` function to reproduce the output of the `pdist` function.

```
y = squareform(Z)
```

```
y = 1×3
```

0.2954 1.0670 0.9448

The outputs `y` from `squareform` and `D` from `pdist` are the same.

Input Arguments

yIn — Input distance vector

numeric vector | logical vector

Input distance vector, specified as a numeric or logical vector of length $m(m-1)/2$, where m is the number of observations.

The pairwise distances in `yIn` are arranged in the order (2,1), (3,1), ..., (m,1), (3,2), ..., (m,2), ..., (m,m-1), i.e., the lower-left triangle of the m -by- m distance matrix in column order. The pairwise distance between observations i and j is in `yIn((i-1)*(m-i/2)+j-i)` for $i \leq j$.

You can create `yIn` by using the `pdist` function. m is the number of observations in the input data of `pdist`.

Data Types: `single` | `double` | `logical`

ZIn — Input distance matrix

numeric matrix | logical matrix

Input distance matrix, specified as a numeric or logical matrix. `ZIn` is an m -by- m symmetric matrix with zeros along the diagonal, where m is the number of observations. `ZIn(i, j)` denotes the distance between the i th and j th observations.

Data Types: `single` | `double` | `logical`

Output Arguments

y0ut — Distance vector

numeric vector | logical vector

Distance vector, returned as a numeric or logical vector of length $m(m-1)/2$, where m is the number of observations.

The pairwise distances in `yOut` are arranged in the order (2,1), (3,1), ..., (m,1), (3,2), ..., (m,2), ..., (m,m-1), i.e., the lower-left triangle of the m -by- m distance matrix in column order. The pairwise distance between observations i and j is in `yOut((i-1)*(m-i/2)+j-i)` for $i \leq j$.

`yOut` has the same format as the output from the `pdist` function.

ZOut — Distance matrix

numeric matrix | logical matrix

Distance matrix, returned as a numeric or logical matrix. `ZOut` is an m -by- m symmetric matrix with zeros along the diagonal, where m is the number of observations. `ZOut(i,j)` denotes the distance between the i th and j th observations.

Tips

- You can use `squareform` to format a vector or matrix that is similar to a distance vector or matrix, such as the correlation coefficient matrix (`corrcoef`).

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations: The conversion direction `'tomatrix'` or `'tovector'` must be a compile-time constant. For example, to specify the conversion direction as `'tovector'`, include `coder.Constant('tovector')` in the `-args` value of `codegen`.

For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “General Code Generation Workflow” on page 31-5.

Introduced before R2006a

stack

Class: dataset

Stack data from multiple variables into single variable

Note The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB® `table` data type instead. See MATLAB `table` documentation for more information.

Syntax

```
B = stack(A,datavars)
[B,iA] = stack(A,datavars)
B = stack(A,datavars,Parameter,value)
```

Description

`B = stack(A,datavars)` stacks multiple variables in dataset array `A` into a single variable in `B`. In general, `B` contains fewer variables but more observations than `A`.

`datavars` specifies a group of `m` data variables in `A`. `stack` creates a single data variable in `B` by interleaving their values, and if `A` has `n` observations, then `B` has `m-by-n` observations. In other words, `stack` takes the `m` data values from each observation in `A` and stacks them up to create `m` observations in `B`. `datavars` is a positive integer, a vector of positive integers, a character vector, a string array, a cell array of character vectors, or a logical vector. `stack` also creates a grouping variable in `B` to indicate which of the `m` data variables in `A` each observation in `B` corresponds to.

`stack` assigns values for the "per-variable properties (e.g., `Units` and `VarDescription`)" for the new data variable in `B` from the corresponding property values for the first variable listed in `datavars`.

`stack` copies the remaining variables from `A` to `B` without stacking, by replicating each of their values `m` times. These variables are typically grouping variables. Because their

values are constant across each group of m observations in B, they identify which observation in A an observation in B came from.

`[B, iA] = stack(A, datavars)` returns an index vector `iA` indicating the correspondence between observations in B and those in A. `stack` creates `B(j, :)` using `A(iA(j), datavarss)`.

For more information on grouping variables, see “Grouping Variables” on page 2-57.

Input Arguments

`B = stack(A, datavars, Parameter, value)` uses the following parameter name/value pairs to control how `stack` converts variables in A to variables in B:

'ConstVars'	Variables in A to copy to B without stacking. <code>ConstVars</code> is a positive integer, a vector of positive integers, a character vector, a string array, a cell array of character vectors, or a logical vector. The default is all variables in A not specified in <code>datavars</code> .
'NewDataVarName'	A name for the data variable to be created in B. The default is a concatenation of the names of the m variables that are stacked up.
'IndVarName'	A name for the grouping variable to create in B to indicate the source of each value in the new data variable. The default is based on the 'NewDataVarName' parameter.

You can also specify multiple groups of data variables in A, each of which becomes a variable in B. All groups must contain the same number of variables. Use a string array or cell array of character vectors to contain multiple parameter values for `datavars` or to contain multiple values for 'NewDataVarName'.

Examples

Combine several variables for estimated influenza rates into a single variable. Then unstack the estimated influenza rates by date.

```
load flu
```

```
% FLU has a 'Date' variable, and 10 variables for estimated influenza rates
% (in 9 different regions, estimated from Google searches, plus a
% nationwide estimate from the CDC). Combine those 10 variables into an
% array that has a single data variable, 'FluRate', and an indicator
% variable, 'Region', that says which region each estimate is from.
[flu2,iflu] = stack(flu, 2:11, 'NewDataVarName','FluRate', ...
    'IndVarName','Region')
```

```
% The second observation in FLU is for 10/16/2005. Find the observations
% in FLU2 that correspond to that date.
```

```
flu(2,:)
flu2(iflu==2,:)
```

```
% Use the 'Date' variable from that array to split 'FluRate' into 52
% separate variables, each containing the estimated influenza rates for
% each unique date. The new array has one observation for each region. In
% effect, this is the original array FLU "on its side".
```

```
dateNames = cellstr(datestr(flu.Date,'mmm_DD_YYYY'));
[flu3,iflu2] = unstack(flu2, 'FluRate', 'Date', ...
    'NewDataVarNames',dateNames)
```

```
% Since observations in FLU3 represent regions, IFLU2 indicates the first
% occurrence in FLU2 of each region.
```

```
flu2(iflu2,:)
```

“Grouping Variables” on page 2-57

State property

Class: grandstream

Current state of the stream

Description

The `State` property of a quasi-random stream contains the index into the associated point set of the next point to draw in the stream. Getting and resetting the `State` property allows you to return a stream to a previous state. The initial value of `State` is 1.

Examples

```
Q = grandstream('sobol', 5);  
s = Q.State;  
u1 = grand(Q, 10)  
Q.State = s;  
u2 = grand(Q, 10) % contains exactly the same values as u1
```

See Also

grand

statget

Access values in statistics options structure

Syntax

```
val = statget(options,param)
val = statget(options,param,default)
```

Description

`val = statget(options,param)` returns the value of the parameter specified by `param` in the statistics options structure `options`. The input `param` is a character vector or a string scalar of the parameter name. If the parameter is undefined in `options`, `statget` returns `[]`. You need to type only enough leading characters to define the parameter name uniquely. `statget` ignores case for parameter names. For available options, see Inputs.

`val = statget(options,param,default)` returns `default` if the specified parameter is undefined in the optimization options structure `options`.

Input Arguments

DerivStep

Relative difference used in finite difference derivative calculations. A positive scalar, or a vector of positive scalars the same size as the vector of parameters estimated by the Statistics and Machine Learning Toolbox function using the options structure.

Display

Amount of information displayed by the algorithm.

- 'off' — Displays no information.
- 'final' — Displays the final output.

- 'iter' — Displays iterative output to the command window for some functions; otherwise displays the final output.

FunValCheck

Check for invalid values, such as NaN or Inf, from the objective function.

- 'off'
- 'on'

GradObj

Flags whether the objective function returns a gradient vector as a second output.

- 'off'
- 'on'

Jacobian

Flags whether the objective function returns a Jacobian as a second output.

- 'off'
- 'on'

MaxFunEvals

Maximum number of objective function evaluations allowed. Positive integer.

MaxIter

Maximum number of iterations allowed. Positive integer.

OutputFcn

The solver calls all output functions after each iteration.

- Function handle specified using @
- a cell array with function handles
- an empty array (default)

Robust

Invoke robust fitting option.

- 'off'
- 'on'

RobustWgtFun

A weight function for robust fitting. Valid only when **Robust** is 'on'. Can also be a function handle that accepts a normalized residual as input and returns the robust weights as output.

- 'bisquare'
- 'andrews'
- 'cauchy'
- 'fair'
- 'huber'
- 'logistic'
- 'talwar'
- 'welsch'

Streams

A single instance of the `RandStream` class, or a cell array of `RandStream` instances. The `Streams` option is accepted by some functions to govern what stream(s) to use in generating random numbers within the function. If 'UseSubstreams' is true, the `Streams` value must be a scalar, or must be empty. If 'UseParallel' is true and 'UseSubstreams' is false, then the `Streams` argument must either be empty, or its length must match the number of processors used in the computation: equal to the *parpool* size if a *parpool* is open, a scalar otherwise.

TolBnd

Parameter bound tolerance. Positive scalar.

TolFun

Termination tolerance for the objective function value. Positive scalar.

TolTypeFun

Use `TolFun` for absolute or relative objective function tolerances.

- 'abs'
- 'rel'

TolTypeX

Use `TolX` for absolute or relative parameter tolerances.

- 'abs'
- 'rel'

TolX

Termination tolerance for the parameters. Positive scalar.

Tune

The tuning constant used in robust fitting to normalize the residuals before applying the weight function. The default value depends upon the weight function. This parameter is necessary if you specify the weight function as a function handle. Positive scalar.

UseParallel

Flag indicating whether eligible functions should use capabilities of the Parallel Computing Toolbox (PCT), if the capabilities are available. That is, if the PCT is installed, and a PCT parpool is in effect. Valid values are `false` (the default), for serial computation, and `true`, for parallel computation.

UseSubstreams

Flag indicating whether the random number generator in eligible functions should use `Substream` property of the `RandStream` class. `false` (default) or `true`. When `true`, high level iterations within the function will set the `Substream` property to the value of the iteration. This behavior helps to generate reproducible random number streams in parallel and/or serial mode computation.

WgtFun

A weight function for robust fitting. Valid only when `Robust` is `'on'`. Can also be a function handle that accepts a normalized residual as input and returns the robust weights as output.

- `'bisquare'`
- `'andrews'`
- `'cauchy'`
- `'fair'`
- `'huber'`
- `'logistic'`
- `'talwar'`
- `'welsch'`

Examples

This statement returns the value of the `Display` statistics options parameter from the structure called `my_options`.

```
val = statget(my_options, 'Display')
```

Return the value of the `Display` statistics options parameter from the structure called `my_options` (as in the previous example). If the `Display` parameter is undefined, `statget` returns the value `'final'`.

```
optnew = statget(my_options, 'Display', 'final');
```

See Also

`statset`

Introduced before R2006a

statset

Create statistics options structure

Syntax

```
statset
statset(statfun)
options = statset(...)
options = statset(fieldname1,val1,fieldname2,val2,...)
options = statset(olddopts,fieldname1,val1,fieldname2,val2,...)
options = statset(olddopts,newopts)
```

Description

`statset` with no input arguments and no output arguments displays all fields of a statistics options structure and their possible values.

`statset(statfun)` displays fields and default values used by the Statistics and Machine Learning Toolbox function `statfun`. Specify `statfun` using a character vector, a string scalar, or a function handle.

`options = statset(...)` creates a statistics options structure `options`. With no input arguments, all fields of the options structure are an empty array (`[]`). With a specified `statfun`, function-specific fields are default values and the remaining fields are `[]`. Function-specific fields set to `[]` indicate that the function is to use its default value for that parameter. For available options, see Inputs.

`options = statset(fieldname1,val1,fieldname2,val2,...)` creates an options structure in which the named fields have the specified values. Any unspecified values are `[]`. Use character vectors or string scalars for field names. For named values, you must input the complete character vector or string scalar for the value. If you provide an invalid character vector or string scalar for a value, `statset` uses the default.

`options = statset(olddopts,fieldname1,val1,fieldname2,val2,...)` creates a copy of `olddopts` with the named parameters changed to the specified values.

`options = statset(oldopts,newopts)` combines an existing options structure, `oldopts`, with a new options structure, `newopts`. Any parameters in `newopts` with nonempty values overwrite corresponding parameters in `oldopts`.

Input Arguments

DerivStep

Relative difference used in finite difference derivative calculations. A positive scalar, or a vector of positive scalars the same size as the vector of parameters estimated by the Statistics and Machine Learning Toolbox function using the options structure.

Display

Amount of information displayed by the algorithm.

- 'off' — Displays no information.
- 'final' — Displays the final output.
- 'iter' — Displays iterative output to the command window for some functions; otherwise displays the final output.

FunValCheck

Check for invalid values, such as NaN or Inf, from the objective function.

- 'off'
- 'on'

GradObj

Flags whether the objective function returns a gradient vector as a second output.

- 'off'
- 'on'

Jacobian

Flags whether the objective function returns a Jacobian as a second output.

- 'off'

- 'on'

MaxFunEvals

Maximum number of objective function evaluations allowed. Positive integer.

MaxIter

Maximum number of iterations allowed. Positive integer.

OutputFcn

The solver calls all output functions after each iteration.

- Function handle specified using @
- a cell array with function handles
- an empty array (default)

Robust

Invoke robust fitting option.

- 'off'
- 'on'

Robust will be removed in a future software release. Use `RobustWgtFun` for robust fitting.

RobustWgtFun

Weight function for robust fitting. Can also be a function handle that accepts a normalized residual as input and returns the robust weights as output. If you use a function handle, give a Tune constant. See “Robust Options” on page 32-6502.

Streams

A single instance of the `RandStream` class, or a cell array of `RandStream` instances. The `Streams` option is accepted by some functions to govern what stream(s) to use in generating random numbers within the function. If `'UseSubstreams'` is true, the `Streams` value must be a scalar, or must be empty. If `'UseParallel'` is true and `'UseSubstreams'` is false, then the `Streams` argument must either be empty, or its

length must match the number of processors used in the computation: equal to the *parpool* size if a *parpool* is open, a scalar otherwise.

TolBnd

Parameter bound tolerance. Positive scalar.

TolFun

Termination tolerance for the objective function value. Positive scalar.

TolTypeFun

Use `TolFun` for absolute or relative objective function tolerances.

- 'abs'
- 'rel'

TolTypeX

Use `TolX` for absolute or relative parameter tolerances.

- 'abs'
- 'rel'

TolX

Termination tolerance for the parameters. Positive scalar.

Tune

Tuning constant used in robust fitting to normalize the residuals before applying the weight function. The default value depends upon the weight function. This parameter is necessary if you specify the weight function as a function handle. Positive scalar. See “Robust Options” on page 32-6502.

UseParallel

Flag indicating whether eligible functions should use capabilities of the Parallel Computing Toolbox (PCT), if the capabilities are available. That is, if the PCT is installed, and a PCT *parpool* is in effect. Valid values are `false` (the default), for serial computation, and `true`, for parallel computation.

UseSubstreams

Flag indicating whether the random number generator in eligible functions should use Substream property of the RandStream class. `false` (default) or `true`. When `true`, high level iterations within the function will set the Substream property to the value of the iteration. This behavior helps to generate reproducible random number streams in parallel and/or serial mode computation.

WgtFun

Weight function for robust fitting. Valid only when `Robust` is `'on'`. Can also be a function handle that accepts a normalized residual as input and returns the robust weights as output. See “Robust Options” on page 32-6502.

`WgtFun` will be removed in a future software release. Use `RobustWgtFun` instead.

Examples

Suppose you want to change the default parameter values for the function `evfit`, which fits an extreme value distribution to data. The defaults parameter values are:

```
statset('evfit')
ans =
    Display: 'off'
    MaxFunEvals: []
    MaxIter: []
    TolBnd: []
    TolFun: []
    TolTypeFun: []
    TolX: 1.0000e-06
    TolTypeX: []
    GradObj: []
    Jacobian: []
    DerivStep: []
    FunValCheck: []
    Robust: []
    RobustWgtFun: []
    WgtFun: []
    Tune: []
    UseParallel: []
    UseSubstreams: []
```

```
Streams: []
OutputFcn: []
```

The only parameters that `evfit` uses are `Display` and `TolX`. To create an options structure with the value of `TolX` set to `1e-8`, enter:

```
options = statset('TolX',1e-8)
% Pass options to evfit:
mu = 1;
sigma = 1;
data = evrnd(mu,sigma,1,100);

paramhat = evfit(data,[],[],[],options)
```

`statget`

Introduced before R2006a

std

Package: prob

Standard deviation of probability distribution

Syntax

```
s = std(pd)
```

Description

`s = std(pd)` returns the standard deviation `s` of the probability distribution `pd`.

Examples

Standard Deviation of a Fitted Distribution

Load the sample data. Create a vector containing the first column of students' exam grade data.

```
load examgrades
x = grades(:,1);
```

Fit a normal distribution object to the data.

```
pd = fitdist(x, 'Normal')

pd =
  NormalDistribution

  Normal distribution
      mu = 75.0083    [73.4321, 76.5846]
      sigma = 8.7202    [7.7391, 9.98843]
```

Compute the standard deviation of the fitted distribution.

```
s = std(pd)
```

```
s = 8.7202
```

For a normal distribution, the standard deviation is equal to the parameter σ .

Standard Deviation of a Skewed Distribution

Create a Weibull probability distribution object

```
pd = makedist('Weibull', 'a', 5, 'b', 2)
```

```
pd =  
  WeibullDistribution  
  
  Weibull distribution  
    A = 5  
    B = 2
```

Compute the standard deviation of the distribution.

```
s = std(pd)
```

```
s = 2.3163
```

Standard Deviation of a Triangular Distribution

Create a triangular distribution object.

```
pd = makedist('Triangular', 'a', -3, 'b', 1, 'c', 3)
```

```
pd =  
  TriangularDistribution
```

```
A = -3, B = 1, C = 3
```

Compute the standard deviation of the distribution.

```
s = std(pd)
```

```
s = 1.2472
```

Standard Deviation of a Kernel Distribution

Load the sample data. Create a vector containing the first column of students' exam grade data.

```
load examgrades;  
x = grades(:,1);
```

Create a probability distribution object by fitting a kernel distribution to the data.

```
pd = fitdist(x, 'Kernel')  
  
pd =  
    KernelDistribution  
  
    Kernel = normal  
    Bandwidth = 3.61677  
    Support = unbounded
```

Compute the standard deviation of the fitted distribution.

```
s = std(pd)  
  
s = 9.4069
```

Input Arguments

pd — Probability distribution

probability distribution object

Probability distribution, specified as a probability distribution object created using one of the following.

Function or App	Description
makedist	Create a probability distribution object using specified parameter values.
fitdist	Fit a probability distribution object to sample data.

Function or App	Description
Distribution Fitter	Fit a probability distribution to sample data using the interactive Distribution Fitter app and export the fitted object to the workspace.

Output Arguments

s — Standard deviation

nonnegative scalar value

Standard deviation of the probability distribution, returned as a nonnegative scalar value.

See Also

Distribution Fitter | `fitdist` | `makedist` | `mean` | `var`

Introduced in R2013a

step

Class: GeneralizedLinearModel

Improve generalized linear regression model by adding or removing terms

Syntax

```
mdl1 = step(mdl)
mdl1 = step(mdl, Name, Value)
```

Description

`mdl1 = step(mdl)` returns a generalized linear model based on `mdl` using stepwise regression to add or remove one predictor.

`mdl1 = step(mdl, Name, Value)` specifies additional options using one or more name-value pair arguments. For example, you can specify the criterion to use to add or remove terms and the maximum number of steps to take.

Input Arguments

mdl — Generalized linear model
GeneralizedLinearModel object

Generalized linear model representing a least-squares fit of the link of the response to the data, returned as a GeneralizedLinearModel object.

For properties and methods of the generalized linear model object, `mdl`, see the GeneralizedLinearModel class page.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes.

You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Criterion — Criterion to add or remove terms

`'Deviance'` (default) | `'sse'` | `'aic'` | `'bic'` | `'rsquared'` | `'adjrsquared'`

Criterion to add or remove terms, specified as the comma-separated pair consisting of `'Criterion'` and one of the following:

- `'Deviance'` — p -value for F or chi-squared test of the change in the deviance by adding or removing the term. F -test is for testing a single model. Chi-squared test is for comparing two different models.
- `'sse'` — p -value for an F -test of the change in the sum of squared error by adding or removing the term.
- `'aic'` — Change in the value of Akaike information criterion (AIC).
- `'bic'` — Change in the value of Bayesian information criterion (BIC).
- `'rsquared'` — Increase in the value of R^2 .
- `'adjrsquared'` — Increase in the value of adjusted R^2 .

Example: `'Criterion','bic'`

Lower — Model specification describing terms that cannot be removed from model

`'constant'` (default) | character vector | string scalar | terms matrix

Model specification describing terms that cannot be removed from the model, specified as the comma-separated pair consisting of `'Lower'` and one of the options for `modelspec` naming the model.

Example: `'Lower','linear'`

NSteps — Maximum number of steps to take

1 (default) | positive integer

Maximum number of steps to take, specified as the comma-separated pair consisting of `'NSteps'` and a positive integer.

Example: `'NSteps',5`

Data Types: `single` | `double`

PEnter — Threshold for criterion to add term

scalar value

Threshold for the criterion to add a term, specified as the comma-separated pair consisting of 'PEnter' and a scalar value, as described in this table.

Criterion	Default Value	Decision
'Deviance'	0.05	If the p -value of F -statistic or chi-squared statistic is less than PEnter (p -value to enter), add the term to the model.
'SSE'	0.05	If the SSE of the model is less than PEnter, add the term to the model.
'AIC'	0	If the change in the AIC of the model is less than PEnter, add the term to the model.
'BIC'	0	If the change in the BIC of the model is less than PEnter, add the term to the model.
'Rsquared'	0.1	If the increase in the R-squared value of the model is greater than PEnter, add the term to the model.
'AdjRsquared'	0	If the increase in the adjusted R-squared value of the model is greater than PEnter, add the term to the model.

For more information, see the Criterion name-value pair argument.

Example: 'PEnter', 0.075

PRemove — Threshold for criterion to remove term

scalar value

Threshold for the criterion to remove a term, specified as the comma-separated pair consisting of 'PRemove' and a scalar value, as described in this table.

Criterion	Default Value	Decision
'Deviance'	0.10	If the p -value of F -statistic or chi-squared statistic is greater than PRemove (p -value to remove), remove the term from the model.
'SSE'	0.10	If the p -value of the F statistic is greater than PRemove, remove the term from the model.
'AIC'	0.01	If the change in the AIC of the model is greater than PRemove, remove the term from the model.
'BIC'	0.01	If the change in the BIC of the model is greater than PRemove, remove the term from the model.
'Rsquared'	0.05	If the increase in the R-squared value of the model is less than PRemove, remove the term from the model.
'AdjRsquared'	-0.05	If the increase in the adjusted R-squared value of the model is less than PRemove, remove the term from the model.

At each step, the `step` function also checks whether a term is redundant (linearly dependent) with other terms in the current model. When any term is linearly dependent with other terms in the current model, the `step` function removes the redundant term, regardless of the criterion value.

For more information, see the `Criterion` name-value pair argument.

Example: 'PRemove', 0.05

Upper — Model specification describing largest set of terms in fit

'interactions' (default) | character vector | string scalar | terms matrix

Model specification describing the largest set of terms in the fit, specified as the comma-separated pair consisting of 'Upper' and one of the options for `modelspec` naming the model.

Example: 'Upper', 'quadratic'

Verbose — Control for display of information

1 (default) | 0 | 2

Control for the display of information, specified as the comma-separated pair consisting of 'Verbose' and one of these values:

- 0 — Suppress all display.
- 1 — Display the action taken at each step.
- 2 — Display the evaluation process and the action taken at each step.

Example: 'Verbose', 2

Output Arguments

mdl1 — Generalized linear model

`GeneralizedLinearModel` object

Generalized linear model, returned as a `GeneralizedLinearModel` object. To overwrite `mdl`, set `mdl1` equal to `mdl`.

Examples

Add Predictors One at a Time

Fit a Poisson regression model using random data and a single predictor, then step in other predictors.

Generate artificial data with 20 predictors, using three of the predictors for the responses.

```
rng('default') % for reproducibility
X = randn(100,20);
mu = exp(X(:,[5 10 15])*[.4;.2;.3] + 1);
y = poissrnd(mu);
```

Construct a generalized linear model using $X(:, 1)$ as the only predictor.

```
mdl = fitglm(X,y,...
    'y ~ x1','Distribution','poisson')
```

```
mdl =
Generalized linear regression model:
log(y) ~ 1 + x1
Distribution = Poisson
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	1.1278	0.057487	19.618	1.0904e-85
x1	0.061287	0.04848	1.2642	0.20617

```
100 observations, 98 error degrees of freedom
Dispersion: 1
Chi^2-statistic vs. constant model: 1.59, p-value = 0.208
```

Add a variable to the model using `step`.

```
mdl1 = step(mdl)
```

```
1. Adding x5, Deviance = 134.2976, Chi2Stat = 50.80176, PValue = 1.021821e-12
```

```
mdl1 =
Generalized linear regression model:
log(y) ~ 1 + x1 + x5
Distribution = Poisson
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
--	----------	----	-------	--------

(Intercept)	1.0418	0.062341	16.712	1.07e-62
x1	0.018803	0.049916	0.37671	0.70639
x5	0.47881	0.067875	7.0542	1.7357e-12

100 observations, 97 error degrees of freedom
 Dispersion: 1
 Chi²-statistic vs. constant model: 52.4, p-value = 4.21e-12

Add another variable to the model using `step`.

```
mdl1 = step(mdl1)
```

2. Adding x15, Deviance = 105.9973, Chi2Stat = 28.30027, PValue = 1.038814e-07

```
mdl1 =  

Generalized linear regression model:  

log(y) ~ 1 + x1 + x5 + x15  

Distribution = Poisson
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	1.0459	0.0627	16.681	1.7975e-62
x1	0.026907	0.05003	0.53782	0.5907
x5	0.3983	0.068376	5.8251	5.7073e-09
x15	0.28949	0.053992	5.3618	8.2375e-08

100 observations, 96 error degrees of freedom
 Dispersion: 1
 Chi²-statistic vs. constant model: 80.7, p-value = 2.18e-17

Tips

- Use `addTerms` or `removeTerms` to control exactly which terms enter or leave the model.

Algorithms

- Stepwise regression is a systematic method for adding and removing terms from a linear or generalized linear model based on their statistical significance in explaining the response variable. The method begins with an initial model, specified using `modelspec`, and then compares the explanatory power of incrementally larger and smaller models.

The `step` function uses forward and backward stepwise regression to determine a final model. At each step, the function searches for terms to add to the model or remove from the model based on the value of the `'Criterion'` name-value pair argument.

The default value of `'Criterion'` for a linear regression model is `'sse'`. In this case, `stepwiselm` and `step` of `LinearModel` use the p -value of an F -statistic to test models with and without a potential term at each step. If a term is not currently in the model, the null hypothesis is that the term would have a zero coefficient if added to the model. If there is sufficient evidence to reject the null hypothesis, the function adds the term to the model. Conversely, if a term is currently in the model, the null hypothesis is that the term has a zero coefficient. If there is insufficient evidence to reject the null hypothesis, the function removes the term from the model.

Stepwise regression takes these steps when `'Criterion'` is `'sse'`:

- 1 Fit the initial model.
- 2 Examine a set of available terms not in the model. If any of the terms have p -values less than an entrance tolerance (that is, if it is unlikely a term would have a zero coefficient if added to the model), add the term with the smallest p -value and repeat this step; otherwise, go to step 3.
- 3 If any of the available terms in the model have p -values greater than an exit tolerance (that is, the hypothesis of a zero coefficient cannot be rejected), remove the term with the largest p -value and return to step 2; otherwise, end the process.

At any stage, the function will not add a higher-order term if the model does not also include all lower-order terms that are subsets of the higher-order term. For example, the function will not try to add the term $X1 : X2^2$ unless both $X1$ and $X2^2$ are already in the model. Similarly, the function will not remove lower-order terms that are subsets of higher-order terms that remain in the model. For example, the function will not try to remove $X1$ or $X2^2$ if $X1 : X2^2$ remains in the model.

The default value of 'Criterion' for a generalized linear model is 'Deviance'. `stepwiseglm` and `step` of `GeneralizedLinearModel` follow a similar procedure for adding or removing terms.

You can specify other criteria by using the 'Criterion' name-value pair argument. For example, you can specify the change in the value of the Akaike information criterion, Bayesian information criterion, R-squared, or adjusted R-squared as the criterion to add or remove terms.

Depending on the terms included in the initial model, and the order in which the function adds and removes terms, the function might build different models from the same set of potential terms. The function terminates when no single step improves the model. However, a different initial model or a different sequence of steps does not guarantee a better fit. In this sense, stepwise models are locally optimal, but might not be globally optimal.

- `step` treats a categorical predictor as follows:
 - A model with a categorical predictor that has L levels (categories) includes $L - 1$ indicator variables. The model uses the first category as a reference level, so it does not include the indicator variable for the reference level. If the data type of the categorical predictor is `categorical`, then you can check the order of categories by using `categories` and reorder the categories by using `reordercats` to customize the reference level.
 - `step` treats the group of $L - 1$ indicator variables as a single variable. If you want to treat the indicator variables as distinct predictor variables, create indicator variables manually by using `dummyvar`. Then use the indicator variables, except the one corresponding to the reference level of the categorical variable, when you fit a model. For the categorical predictor X , if you specify all columns of `dummyvar(X)` and an intercept term as predictors, then the design matrix becomes rank deficient.
 - Interaction terms between a continuous predictor and a categorical predictor with L levels consist of the element-wise product of the $L - 1$ indicator variables with the continuous predictor.
 - Interaction terms between two categorical predictors with L and M levels consist of the $(L - 1)*(M - 1)$ indicator variables to include all possible combinations of the two categorical predictor levels.
 - You cannot specify higher-order terms for a categorical predictor because the square of an indicator is equal to itself.

Therefore, if `step` adds or removes a categorical predictor, the function actually adds or removes the group of indicator variables in one step. Similarly, if `step` adds or removes an interaction term with a categorical predictor, the function actually adds or removes the group of interaction terms including the categorical predictor.

- `step` considers `NaN`, `' '` (empty character vector), `" "` (empty string), `<missing>`, and `<undefined>` values in `tbl`, `X`, and `Y` to be missing values. `step` does not use observations with missing values in the fit. The `ObservationInfo` property of a fitted model indicates whether or not `step` uses each observation in the fit.

Alternatives

Use `stepwiseglm` to select a model from a starting model, continuing until no single step is beneficial.

Use `addTerms` or `removeTerms` to add or remove particular terms.

“Plots to Understand Predictor Effects and How to Modify a Model” on page 12-28

“Generalized Linear Models” on page 12-12

step

Improve linear regression model by adding or removing terms

Syntax

```
NewMdl = step mdl
NewMdl = step(mdl, Name, Value)
```

Description

`NewMdl = step(mdl)` returns a linear regression model based on `mdl` using stepwise regression to add or remove one predictor.

`NewMdl = step(mdl, Name, Value)` specifies additional options using one or more name-value pair arguments. For example, you can specify the criterion to use to add or remove terms and the maximum number of steps to take.

Examples

Modify Linear Regression Model Using `step`

Fit a linear regression model and use `step` to improve the model by adding or removing terms. This example also describes how the `step` function treats a categorical predictor.

Load the `carsmall` data set, and create a table using the `Weight`, `Model_Year`, and `MPG` variables.

```
load carsmall
tbl1 = table(MPG, Weight);
tbl1.Year = categorical(Model_Year);
```

Create a linear regression model of `MPG` as a function of `Weight`.

```
mdl1 = fitlm(tbl1, 'MPG ~ Weight')
```

```
mdl1 =
Linear regression model:
MPG ~ 1 + Weight
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	49.238	1.6411	30.002	2.7015e-49
Weight	-0.0086119	0.0005348	-16.103	1.6434e-28

```
Number of observations: 94, Error degrees of freedom: 92
Root Mean Squared Error: 4.13
R-squared: 0.738, Adjusted R-Squared: 0.735
F-statistic vs. constant model: 259, p-value = 1.64e-28
```

Adjust the model to include up to 'quadratic' terms by using `step`. Specify 'NSteps' as 5 to allow at most 5 steps of stepwise regression. Specify 'Verbose' as 2 to display the evaluation process and the decision taken at each step.

```
NewMdl1 = step(mdl1, 'Upper', 'quadratic', 'NSteps', 5, 'Verbose', 2)
```

```
pValue for adding Year is 8.2284e-15
pValue for adding Weight^2 is 0.15454
1. Adding Year, FStat = 47.5136, pValue = 8.22836e-15
pValue for adding Weight:Year is 0.0071637
pValue for adding Weight^2 is 0.0022303
2. Adding Weight^2, FStat = 9.9164, pValue = 0.0022303
pValue for adding Weight:Year is 0.19519
pValue for removing Year is 2.9042e-16
```

```
NewMdl1 =
Linear regression model:
MPG ~ 1 + Weight + Year + Weight^2
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	54.206	4.7117	11.505	2.6648e-19
Weight	-0.016404	0.0031249	-5.2493	1.0283e-06
Year_76	2.0887	0.71491	2.9215	0.0044137
Year_82	8.1864	0.81531	10.041	2.6364e-16
Weight^2	1.5573e-06	4.9454e-07	3.149	0.0022303

```
Number of observations: 94, Error degrees of freedom: 89
Root Mean Squared Error: 2.78
R-squared: 0.885, Adjusted R-Squared: 0.88
F-statistic vs. constant model: 172, p-value = 5.52e-41
```

`step` creates two indicator variables, `Year_76` and `Year_82`, because `Year` includes three distinct values. `step` does not consider the square terms of indicator variables because the square of an indicator variable is itself.

Because `'Verbose'` is 2, `step` displays the evaluation process:

- `step` computes the p -values for adding `Year` or `Weight^2`. The p -value for `Year` is less than both the p -value for `Weight^2` and the default threshold value of 0.05; therefore, `step` adds `Year` to the model.
- `step` computes the p -values for adding `Weight:Year` or `Weight^2`. Because the p -value for `Weight^2` is less than the p -value for `Weight:Year`, the `step` function adds `Weight^2` to the model.
- After adding the quadratic term, `step` computes the p -value for adding `Weight:Year` again, but the p -value is greater than the threshold value. Therefore, `step` does not add the term to the model. `step` does not examine adding `Weight^3` because of the upper bound specified by the `'Upper'` name-value pair argument.
- `step` looks for terms to remove. `step` already examined `Weight^2`, so it computes only the p -value for removing `Year`. Because the p -value is less than the default threshold value of 0.10, `step` does not remove the term.
- Although the maximum allowed number of steps is 5, `step` terminates the process after two steps because the model does not improve by adding or removing a term.

`step` treats the two indicator variables as one predictor variable and adds `Year` in one step. To treat the two indicator variables as two distinct predictor variables, use `dummyvar` to create separate categorical variables.

```
temp_Year = dummyvar(tbl1.Year);
Year_76 = temp_Year(:,2);
Year_82 = temp_Year(:,3);
```

Create a table containing `MPG`, `Weight`, `Year_76`, and `Year_82`.

```
tbl2 = table(MPG,Weight,Year_76,Year_82);
```

Create a linear regression model of MPG as a function of Weight, and use step to improve the model.

```
mdl2 = fitlm(tbl2, 'MPG ~ Weight');
NewMdl2 = step(mdl2, 'Upper', 'quadratic', 'NSteps', 5)
```

1. Adding Year_82, FStat = 83.1956, pValue = 1.76163e-14
2. Adding Weight:Year_82, FStat = 8.0641, pValue = 0.0055818
3. Adding Year_76, FStat = 8.1284, pValue = 0.0054157

```
NewMdl2 =
Linear regression model:
  MPG ~ 1 + Year_76 + Weight*Year_82
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	38.844	1.5294	25.397	1.503e-42
Weight	-0.006272	0.00042673	-14.698	1.5622e-25
Year_76	2.0395	0.71537	2.851	0.0054157
Year_82	19.607	3.8731	5.0623	2.2163e-06
Weight:Year_82	-0.0046268	0.0014979	-3.0888	0.0026806

```
Number of observations: 94, Error degrees of freedom: 89
Root Mean Squared Error: 2.79
R-squared: 0.885, Adjusted R-Squared: 0.88
F-statistic vs. constant model: 171, p-value = 6.54e-41
```

The model NewMdl2 includes the interaction term Weight:Year_82 instead of Weight^2, the term included in NewMdl1.

Input Arguments

mdl — Linear regression model

LinearModel object

Linear regression model, specified as a LinearModel object created using fitlm or stepwiselm.

You can use `step` only if you create `mdl` by using `fitlm` with the `'RobustOpts'` name-value pair argument set to the default `'off'`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'Criterion', 'aic', 'Upper', 'quadratic', 'Verbose', 2` instructs `step` to use the Akaike information criterion, include (at most) the quadratic terms in the model, and display the evaluation process and the decision taken at each step.

Criterion — Criterion to add or remove terms

`'sse'` (default) | `'aic'` | `'bic'` | `'rsquared'` | `'adjrsquared'`

Criterion to add or remove terms, specified as the comma-separated pair consisting of `'Criterion'` and one of these values:

- `'sse'` — p -value for an F -test of the change in the sum of squared error that results from adding or removing the term
- `'aic'` — Change in the value of Akaike information criterion (AIC)
- `'bic'` — Change in the value of Bayesian information criterion (BIC)
- `'rsquared'` — Increase in the value of R^2
- `'adjrsquared'` — Increase in the value of adjusted R^2

Example: `'Criterion', 'bic'`

Lower — Model specification describing terms that cannot be removed

`'constant'` (default) | `'linear'` | `'interactions'` | t -by- $(p + 1)$ terms matrix | character vector or string scalar of the form `'Y ~ terms'` | ...

Model specification describing terms that cannot be removed from the model, specified as the comma-separated pair consisting of `'Lower'` and one of these values:

- A character vector or string scalar naming the model.

Value	Model Type
'constant'	Model contains only a constant (intercept) term.
'linear'	Model contains an intercept and linear term for each predictor.
'interactions'	Model contains an intercept, linear term for each predictor, and all products of pairs of distinct predictors (no squared terms).
'purequadratic'	Model contains an intercept term and linear and squared terms for each predictor.
'quadratic'	Model contains an intercept term, linear and squared terms for each predictor, and all products of pairs of distinct predictors.
'polyijk'	Model is a polynomial with all terms up to degree i in the first predictor, degree j in the second predictor, and so on. Specify the maximum degree for each predictor by using numerals 0 through 9. The model contains interaction terms, but the degree of each interaction term does not exceed the maximum value of the specified degrees. For example, 'poly13' has an intercept and x_1 , x_2 , x_2^2 , x_2^3 , x_1*x_2 , and $x_1*x_2^2$ terms, where x_1 and x_2 are the first and second predictors, respectively.

- A t -by- $(p + 1)$ matrix, or a “Terms Matrix” on page 32-6527, specifying terms in the model, where t is the number of terms and p is the number of predictor variables, and +1 accounts for the response variable. A terms matrix is convenient when the number of predictors is large and you want to generate the terms programmatically.
- A character vector or string scalar representing a “Formula” on page 32-6528 in the form
`'Y ~ terms'`,
where the terms are in “Wilkinson Notation” on page 32-6528.

Example: 'Lower', 'linear'

Data Types: single | double | char | string

NSteps — Maximum number of steps to take

1 (default) | positive integer

Maximum number of steps to take, specified as the comma-separated pair consisting of 'NSteps' and a positive integer.

Example: 'NSteps',5

Data Types: single | double

PEnter — Threshold for criterion to add term

scalar value

Threshold for the criterion to add a term, specified as the comma-separated pair consisting of 'PEnter' and a scalar value, as described in this table.

Criterion	Default Value	Decision
'SSE'	0.05	If the p -value of the F -statistic is less than PEnter (p -value to enter), add the term to the model.
'AIC'	0	If the change in the AIC of the model is less than PEnter, add the term to the model.
'BIC'	0	If the change in the BIC of the model is less than PEnter, add the term to the model.
'Rsquared'	0.1	If the increase in the R-squared value of the model is greater than PEnter, add the term to the model.
'AdjRsquared'	0	If the increase in the adjusted R-squared value of the model is greater than PEnter, add the term to the model.

For more information, see the Criterion name-value pair argument.

Example: 'PEnter',0.075

PRemove — Threshold for criterion to remove term

scalar value

Threshold for the criterion to remove a term, specified as the comma-separated pair consisting of 'PRemove' and a scalar value, as described in this table.

Criterion	Default Value	Decision
'SSE'	0.10	If the p -value of the F -statistic is greater than PRemove (p -value to remove), remove the term from the model.
'AIC'	0.01	If the change in the AIC of the model is greater than PRemove, remove the term from the model.
'BIC'	0.01	If the change in the BIC of the model is greater than PRemove, remove the term from the model.
'Rsquared'	0.05	If the increase in the R-squared value of the model is less than PRemove, remove the term from the model.
'AdjRsquared'	-0.05	If the increase in the adjusted R-squared value of the model is less than PRemove, remove the term from the model.

At each step, the `step` function also checks whether a term is redundant (linearly dependent) with other terms in the current model. When any term is linearly dependent with other terms in the current model, the `step` function removes the redundant term, regardless of the criterion value.

For more information, see the Criterion name-value pair argument.

Example: 'PRemove', 0.05

Upper — Model specification describing largest set of terms in fit

'interactions' (default) | 'constant' | 'linear' | t -by- $(p + 1)$ terms matrix | character vector or string scalar of the form 'Y ~ terms' | ...

Model specification describing the largest set of terms in the fit, specified as the comma-separated pair consisting of 'Upper' and one of these values:

- A character vector or string scalar naming the model.

Value	Model Type
'constant'	Model contains only a constant (intercept) term.
'linear'	Model contains an intercept and linear term for each predictor.
'interactions'	Model contains an intercept, linear term for each predictor, and all products of pairs of distinct predictors (no squared terms).
'purequadratic'	Model contains an intercept term and linear and squared terms for each predictor.
'quadratic'	Model contains an intercept term, linear and squared terms for each predictor, and all products of pairs of distinct predictors.
'polyijk'	Model is a polynomial with all terms up to degree i in the first predictor, degree j in the second predictor, and so on. Specify the maximum degree for each predictor by using numerals 0 through 9. The model contains interaction terms, but the degree of each interaction term does not exceed the maximum value of the specified degrees. For example, 'poly13' has an intercept and x_1 , x_2 , x_2^2 , x_2^3 , x_1*x_2 , and $x_1*x_2^2$ terms, where x_1 and x_2 are the first and second predictors, respectively.

- A t -by- $(p + 1)$ matrix, or a “Terms Matrix” on page 32-6527, specifying terms in the model, where t is the number of terms and p is the number of predictor variables, and +1 accounts for the response variable. A terms matrix is convenient when the number of predictors is large and you want to generate the terms programmatically.
- A character vector or string scalar representing a “Formula” on page 32-6528 in the form

`'Y ~ terms'`,
 where the `terms` are in “Wilkinson Notation” on page 32-6528.

Example: `'Upper', 'quadratic'`

Data Types: `single | double | char | string`

Verbose — Control for display of information

`1 (default) | 0 | 2`

Control for the display of information, specified as the comma-separated pair consisting of `'Verbose'` and one of these values:

- `0` — Suppress all display.
- `1` — Display the action taken at each step.
- `2` — Display the evaluation process and the action taken at each step.

Example: `'Verbose', 2`

Output Arguments

NewMdl — Linear regression model

`LinearModel` object

Linear regression model, returned as a `LinearModel` object

To overwrite the input argument `mdl`, assign the new model to `mdl`.

```
mdl = step(mdl);
```

Definitions

Terms Matrix

A terms matrix T is a t -by- $(p + 1)$ matrix specifying terms in a model, where t is the number of terms, p is the number of predictor variables, and $+1$ accounts for the response variable. The value of $T(i, j)$ is the exponent of variable j in term i .

For example, suppose that an input includes three predictor variables A, B, and C and the response variable Y in the order A, B, C, and Y. Each row of T represents one term:

- $[0 \ 0 \ 0 \ 0]$ — Constant term or intercept
- $[0 \ 1 \ 0 \ 0]$ — B; equivalently, $A^0 * B^1 * C^0$
- $[1 \ 0 \ 1 \ 0]$ — $A * C$
- $[2 \ 0 \ 0 \ 0]$ — A^2
- $[0 \ 1 \ 2 \ 0]$ — $B * (C^2)$

The 0 at the end of each term represents the response variable. In general, a column vector of zeros in a terms matrix represents the position of the response variable. If you have the predictor and response variables in a matrix and column vector, then you must include 0 for the response variable in the last column of each row.

Formula

A formula for model specification is a character vector or string scalar of the form '*Y ~ terms*'.

- *Y* is the response name.
- *terms* represents the predictor terms in a model using Wilkinson notation.

For example:

- '*Y ~ A + B + C*' specifies a three-variable linear model with intercept.
- '*Y ~ A + B + C - 1*' specifies a three-variable linear model without intercept.
Note that formulas include a constant (intercept) term by default. To exclude a constant term from the model, you must include -1 in the formula.

Wilkinson Notation

Wilkinson notation describes the terms present in a model. The notation relates to the terms present in a model, not to the multipliers (coefficients) of those terms.

Wilkinson notation uses these symbols:

- $+$ means include the next variable.
- $-$ means do not include the next variable.

- `:` defines an interaction, which is a product of terms.
- `*` defines an interaction and all lower-order terms.
- `^` raises the predictor to a power, exactly as in `*` repeated, so `^` includes lower-order terms as well.
- `()` groups terms.

This table shows typical examples of Wilkinson notation.

Wilkinson Notation	Term in Standard Notation
1	Constant (intercept) term
A^k , where k is a positive integer	A, A^2, \dots, A^k
$A + B$	A, B
$A*B$	$A, B, A*B$
$A:B$	$A*B$ only
$-B$	Do not include B
$A*B + C$	$A, B, C, A*B$
$A + B + C + A:B$	$A, B, C, A*B$
$A*B*C - A:B:C$	$A, B, C, A*B, A*C, B*C$
$A*(B + C)$	$A, B, C, A*B, A*C$

Statistics and Machine Learning Toolbox notation always includes a constant term unless you explicitly remove the term using `-1`.

For more details, see “Wilkinson Notation” on page 11-117.

Algorithms

- Stepwise regression is a systematic method for adding and removing terms from a linear or generalized linear model based on their statistical significance in explaining the response variable. The method begins with an initial model, specified using `modelspec`, and then compares the explanatory power of incrementally larger and smaller models.

The `step` function uses forward and backward stepwise regression to determine a final model. At each step, the function searches for terms to add to the model or

remove from the model based on the value of the 'Criterion' name-value pair argument.

The default value of 'Criterion' for a linear regression model is 'sse'. In this case, `stepwiselm` and `step` of `LinearModel` use the p -value of an F -statistic to test models with and without a potential term at each step. If a term is not currently in the model, the null hypothesis is that the term would have a zero coefficient if added to the model. If there is sufficient evidence to reject the null hypothesis, the function adds the term to the model. Conversely, if a term is currently in the model, the null hypothesis is that the term has a zero coefficient. If there is insufficient evidence to reject the null hypothesis, the function removes the term from the model.

Stepwise regression takes these steps when 'Criterion' is 'sse':

- 1 Fit the initial model.
- 2 Examine a set of available terms not in the model. If any of the terms have p -values less than an entrance tolerance (that is, if it is unlikely a term would have a zero coefficient if added to the model), add the term with the smallest p -value and repeat this step; otherwise, go to step 3.
- 3 If any of the available terms in the model have p -values greater than an exit tolerance (that is, the hypothesis of a zero coefficient cannot be rejected), remove the term with the largest p -value and return to step 2; otherwise, end the process.

At any stage, the function will not add a higher-order term if the model does not also include all lower-order terms that are subsets of the higher-order term. For example, the function will not try to add the term $X1:X2^2$ unless both $X1$ and $X2^2$ are already in the model. Similarly, the function will not remove lower-order terms that are subsets of higher-order terms that remain in the model. For example, the function will not try to remove $X1$ or $X2^2$ if $X1:X2^2$ remains in the model.

The default value of 'Criterion' for a generalized linear model is 'Deviance'. `stepwiseglm` and `step` of `GeneralizedLinearModel` follow a similar procedure for adding or removing terms.

You can specify other criteria by using the 'Criterion' name-value pair argument. For example, you can specify the change in the value of the Akaike information criterion, Bayesian information criterion, R-squared, or adjusted R-squared as the criterion to add or remove terms.

Depending on the terms included in the initial model, and the order in which the function adds and removes terms, the function might build different models from the

same set of potential terms. The function terminates when no single step improves the model. However, a different initial model or a different sequence of steps does not guarantee a better fit. In this sense, stepwise models are locally optimal, but might not be globally optimal.

- `step` treats a categorical predictor as follows:
 - A model with a categorical predictor that has L levels (categories) includes $L - 1$ indicator variables. The model uses the first category as a reference level, so it does not include the indicator variable for the reference level. If the data type of the categorical predictor is `categorical`, then you can check the order of categories by using `categories` and reorder the categories by using `reordercats` to customize the reference level.
 - `step` treats the group of $L - 1$ indicator variables as a single variable. If you want to treat the indicator variables as distinct predictor variables, create indicator variables manually by using `dummyvar`. Then use the indicator variables, except the one corresponding to the reference level of the categorical variable, when you fit a model. For the categorical predictor X , if you specify all columns of `dummyvar(X)` and an intercept term as predictors, then the design matrix becomes rank deficient.
 - Interaction terms between a continuous predictor and a categorical predictor with L levels consist of the element-wise product of the $L - 1$ indicator variables with the continuous predictor.
 - Interaction terms between two categorical predictors with L and M levels consist of the $(L - 1)*(M - 1)$ indicator variables to include all possible combinations of the two categorical predictor levels.
 - You cannot specify higher-order terms for a categorical predictor because the square of an indicator is equal to itself.

Therefore, if `step` adds or removes a categorical predictor, the function actually adds or removes the group of indicator variables in one step. Similarly, if `step` adds or removes an interaction term with a categorical predictor, the function actually adds or removes the group of interaction terms including the categorical predictor.

Alternative Functionality

- Use `stepwiselm` to specify terms in a starting model and continue improving the model until no single step of adding or removing a term is beneficial.

- Use `addTerms` or `removeTerms` to add or remove specific terms.

Introduced in R2012a

stepwise

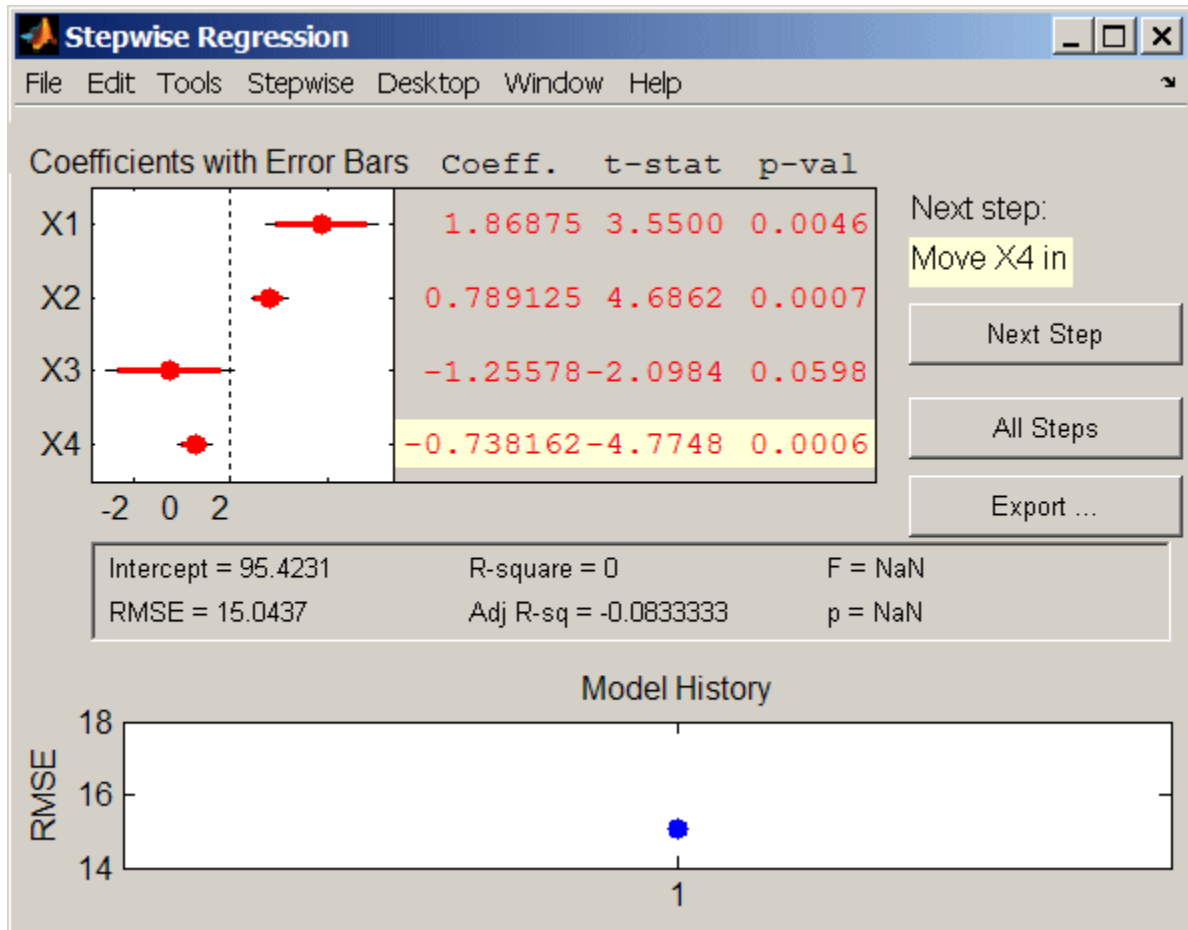

Interactive stepwise regression

Syntax

```
stepwise  
stepwise(X,y)  
stepwise(X,y,inmodel,penalty,remove)
```

Description

stepwise uses the sample data in `hald.mat` to display a graphical user interface for performing stepwise regression of the response values in `heat` on the predictive terms in `ingredients`.

The upper left of the interface displays estimates of the coefficients for all potential terms, with horizontal bars indicating 90% (colored) and 95% (grey) confidence intervals. The red color indicates that, initially, the terms are not in the model. Values displayed in the table are those that would result if the terms were added to the model.

The middle portion of the interface displays summary statistics for the entire model. These statistics are updated with each step.

The lower portion of the interface, **Model History**, displays the RMSE for the model. The plot tracks the RMSE from step to step, so you can compare the optimality of different

models. Hover over the blue dots in the history to see which terms were in the model at a particular step. Click on a blue dot in the history to open a copy of the interface initialized with the terms in the model at that step.

Initial models, as well as entrance/exit tolerances for the p -values of F -statistics, are specified using additional input arguments to `stepwise`. Defaults are an initial model with no terms, an entrance tolerance of 0.05, and an exit tolerance of 0.10.

To center and scale the input data (compute z-scores) to improve conditioning of the underlying least-squares problem, select `Scale Inputs` from the **Stepwise** menu.

You proceed through a stepwise regression in one of two ways:

- 1 Click **Next Step** to select the recommended next step. The recommended next step either adds the most significant term or removes the least significant term. When the regression reaches a local minimum of RMSE, the recommended next step is "Move no terms." You can perform all of the recommended steps at once by clicking **All Steps**.
- 2 Click a line in the plot or in the table to toggle the state of the corresponding term. Clicking a red line, corresponding to a term not currently in the model, adds the term to the model and changes the line to blue. Clicking a blue line, corresponding to a term currently in the model, removes the term from the model and changes the line to red.

To call `addedvarplot` and produce an added variable plot from the `stepwise` interface, select **Added Variable Plot** from the **Stepwise** menu. A list of terms is displayed. Select the term you want to add, and then click **OK**.

Click **Export** to display a dialog box that allows you to select information from the interface to save to the MATLAB workspace. Check the information you want to export and, optionally, change the names of the workspace variables to be created. Click **OK** to export the information.

`stepwise(X, y)` displays the interface using the p predictive terms in the n -by- p matrix X and the response values in the n -by-1 vector y . Distinct predictive terms should appear in different columns of X .

Note `stepwise` automatically includes a constant term in all models. Do not enter a column of 1s directly into X .

stepwise treats NaN values in either X or y as missing values, and ignores them.

`stepwise(X, y, inmodel, penter, premove)` additionally specifies the initial model (`inmodel`) and the entrance (`penter`) and exit (`prremove`) tolerances for the p -values of F -statistics. `inmodel` is either a logical vector with length equal to the number of columns of X , or a vector of indices, with values ranging from 1 to the number of columns in X . The value of `penter` must be less than or equal to the value of `prremove`.

Algorithms

Stepwise regression is a systematic method for adding and removing terms from a multilinear model based on their statistical significance in a regression. The method begins with an initial model and then compares the explanatory power of incrementally larger and smaller models. At each step, the p value of an F -statistic is computed to test models with and without a potential term. If a term is not currently in the model, the null hypothesis is that the term would have a zero coefficient if added to the model. If there is sufficient evidence to reject the null hypothesis, the term is added to the model. Conversely, if a term is currently in the model, the null hypothesis is that the term has a zero coefficient. If there is insufficient evidence to reject the null hypothesis, the term is removed from the model. The method proceeds as follows:

- 1 Fit the initial model.
- 2 If any terms not in the model have p -values less than an entrance tolerance (that is, if it is unlikely that they would have zero coefficient if added to the model), add the one with the smallest p value and repeat this step; otherwise, go to step 3.
- 3 If any terms in the model have p -values greater than an exit tolerance (that is, if it is unlikely that the hypothesis of a zero coefficient can be rejected), remove the one with the largest p value and go to step 2; otherwise, end.

Depending on the terms included in the initial model and the order in which terms are moved in and out, the method may build different models from the same set of potential terms. The method terminates when no single step improves the model. There is no guarantee, however, that a different initial model or a different sequence of steps will not lead to a better fit. In this sense, stepwise models are locally optimal, but may not be globally optimal.

Introduced before R2006a

GeneralizedLinearModel.stepwise

Class: GeneralizedLinearModel

(Not Recommended) Create generalized linear regression model by stepwise regression

Note GeneralizedLinearModel.stepwise is not recommended. Use stepwiseglm instead.

Syntax

```
mdl = GeneralizedLinearModel.stepwise(tbl,modelspec)
mdl = GeneralizedLinearModel.stepwise(X,y,modelspec)
mdl = GeneralizedLinearModel.stepwise(...,modelspec,Name,Value)
```

Description

mdl = GeneralizedLinearModel.stepwise(tbl,modelspec) creates a generalized linear model of a table or dataset array tbl, using stepwise regression to add or remove predictors. modelspec is the starting model for the stepwise procedure.

mdl = GeneralizedLinearModel.stepwise(X,y,modelspec) creates a generalized linear model of the responses y to a data matrix X, using stepwise regression to add or remove predictors.

mdl = GeneralizedLinearModel.stepwise(...,modelspec,Name,Value) creates a generalized linear model with additional options specified by one or more Name,Value pair arguments.

Input Arguments

tbl — Input data

table | dataset array

Input data, specified as a table or dataset array. When modelspec is a formula, the formula specifies the predictor and response variables. Otherwise, if you do not specify

the predictor and response variables, the last variable in `tbl` is the response variable and the others are the predictor variables by default.

The predictor variables and response variable can be numeric, logical, categorical, character, or string. The response variable can have a data type other than numeric only if `'Distribution'` is `'binomial'`.

To set a different column as the response variable, use the `ResponseVar` name-value pair argument. To use a subset of the columns as predictors, use the `PredictorVars` name-value pair argument.

X — Predictor variables

matrix

Predictor variables, specified as an n -by- p matrix, where n is the number of observations and p is the number of predictor variables. Each column of `X` represents one variable, and each row represents one observation.

By default, there is a constant term in the model, unless you explicitly remove it, so do not include a column of 1s in `X`.

Data Types: `single` | `double`

y — Response variable

vector

Response variable, specified as an n -by-1 vector, where n is the number of observations. Each entry in `y` is the response for the corresponding row of `X`.

Data Types: `single` | `double` | `logical` | `categorical`

modelspec — Starting model

character vector or string scalar specifying the model | t -by- $(p+1)$ terms matrix | character vector or string scalar of the form `'Y ~ terms'`

Starting model, specified as one of the following:

- Character vector or string scalar specifying the type of model.

Value	Model Type
'constant'	Model contains only a constant (intercept) term.

Value	Model Type
'linear'	Model contains an intercept and linear term for each predictor.
'interactions'	Model contains an intercept, linear term for each predictor, and all products of pairs of distinct predictors (no squared terms).
'purequadratic'	Model contains an intercept term and linear and squared terms for each predictor.
'quadratic'	Model contains an intercept term, linear and squared terms for each predictor, and all products of pairs of distinct predictors.
'polyijk'	Model is a polynomial with all terms up to degree i in the first predictor, degree j in the second predictor, and so on. Specify the maximum degree for each predictor by using numerals 0 through 9. The model contains interaction terms, but the degree of each interaction term does not exceed the maximum value of the specified degrees. For example, 'poly13' has an intercept and x_1 , x_2 , x_2^2 , x_2^3 , x_1*x_2 , and $x_1*x_2^2$ terms, where x_1 and x_2 are the first and second predictors, respectively.

- t -by- $(p+1)$ matrix, namely terms matrix on page 32-6551, specifying terms to include in model, where t is the number of terms and p is the number of predictor variables, and plus one is for the response variable.
- Character vector or string scalar representing a formula on page 32-6551 in the form

'Y ~ terms',

where the terms are in "Wilkinson Notation" on page 32-6552.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

BinomialSize — Number of trials for binomial distribution

1 (default) | scalar value | vector

Number of trials for binomial distribution, that is the sample size, specified as the comma-separated pair consisting of a scalar value or a vector of the same length as the response. This is the parameter n for the fitted binomial distribution. `BinomialSize` applies only when the `Distribution` parameter is `'binomial'`.

If `BinomialSize` is a scalar value, that means all observations have the same number of trials.

As an alternative to `BinomialSize`, you can specify the response as a two-column vector with counts in column 1 and `BinomialSize` in column 2.

Data Types: `single` | `double`

CategoricalVars — Categorical variable list

string array | cell array of character vectors | logical or numeric index vector

Categorical variable list, specified as the comma-separated pair consisting of `'CategoricalVars'` and either a string array or cell array of character vectors containing categorical variable names in the table or dataset array `tbl`, or a logical or numeric index vector indicating which columns are categorical.

- If data is in a table or dataset array `tbl`, then, by default, `GeneralizedLinearModel.stepwise` treats all categorical values, logical values, character arrays, string arrays, and cell arrays of character vectors as categorical variables.
- If data is in matrix X , then the default value of `'CategoricalVars'` is an empty matrix `[]`. That is, no variable is categorical unless you specify it as categorical.

For example, you can specify the observations 2 and 3 out of 6 as categorical using either of the following examples.

Example: `'CategoricalVars',[2,3]`

Example: `'CategoricalVars',logical([0 1 1 0 0 0])`

Data Types: `single` | `double` | `logical` | `string` | `cell`

Criterion — Criterion to add or remove terms`'Deviance'` (default) | `'sse'` | `'aic'` | `'bic'` | `'rsquared'` | `'adjrsquared'`

Criterion to add or remove terms, specified as the comma-separated pair consisting of 'Criterion' and one of the following:

- 'Deviance' — p -value for F or chi-squared test of the change in the deviance by adding or removing the term. F -test is for testing a single model. Chi-squared test is for comparing two different models.
- 'sse' — p -value for an F -test of the change in the sum of squared error by adding or removing the term.
- 'aic' — Change in the value of Akaike information criterion (AIC).
- 'bic' — Change in the value of Bayesian information criterion (BIC).
- 'rsquared' — Increase in the value of R^2 .
- 'adjrsquared' — Increase in the value of adjusted R^2 .

Example: 'Criterion', 'bic'

DispersionFlag — Indicator to compute dispersion parameter

false for 'binomial' and 'poisson' distributions (default) | true

Indicator to compute dispersion parameter for 'binomial' and 'poisson' distributions, specified as the comma-separated pair consisting of 'DispersionFlag' and one of the following.

true	Estimate a dispersion parameter when computing standard errors
false	Default. Use the theoretical value when computing standard errors

The fitting function always estimates the dispersion for other distributions.

Example: 'DispersionFlag', true

Distribution — Distribution of the response variable

'normal' (default) | 'binomial' | 'poisson' | 'gamma' | 'inverse gaussian'

Distribution of the response variable, specified as the comma-separated pair consisting of 'Distribution' and one of the following.

'normal'	Normal distribution
'binomial'	Binomial distribution

'poisson'	Poisson distribution
'gamma'	Gamma distribution
'inverse gaussian'	Inverse Gaussian distribution

Example: 'Distribution', 'gamma'

Exclude — Observations to exclude

logical or numeric index vector

Observations to exclude from the fit, specified as the comma-separated pair consisting of 'Exclude' and a logical or numeric index vector indicating which observations to exclude from the fit.

For example, you can exclude observations 2 and 3 out of 6 using either of the following examples.

Example: 'Exclude', [2,3]

Example: 'Exclude', logical([0 1 1 0 0 0])

Data Types: single | double | logical

Intercept — Indicator for constant term

true (default) | false

Indicator for the constant term (intercept) in the fit, specified as the comma-separated pair consisting of 'Intercept' and either true to include or false to remove the constant term from the model.

Use 'Intercept' only when specifying the model using a character vector or string scalar, not a formula or matrix.

Example: 'Intercept', false

Link — Link function

canonical link function (default) | scalar value | structure

Link function to use in place of the canonical link function, specified as the comma-separated pair consisting of 'Link' and one of the following.

Link Function Name	Link Function	Mean (Inverse) Function
'identity'	$f(\mu) = \mu$	$\mu = Xb$

Link Function Name	Link Function	Mean (Inverse) Function
'log'	$f(\mu) = \log(\mu)$	$\mu = \exp(Xb)$
'logit'	$f(\mu) = \log(\mu/(1-\mu))$	$\mu = \exp(Xb) / (1 + \exp(Xb))$
'probit'	$f(\mu) = \Phi^{-1}(\mu)$	$\mu = \Phi(Xb)$
'comploglog'	$f(\mu) = \log(-\log(1 - \mu))$	$\mu = 1 - \exp(-\exp(Xb))$
'reciprocal'	$f(\mu) = 1/\mu$	$\mu = 1/(Xb)$
p (a number)	$f(\mu) = \mu^p$	$\mu = Xb^{1/p}$
S (a structure) with three fields. Each field holds a function handle that accepts a vector of inputs and returns a vector of the same size: <ul style="list-style-type: none"> • S.Link — The link function • S.Inverse — The inverse link function • S.Derivative — The derivative of the link function 	$f(\mu) = S.Link(\mu)$	$\mu = S.Inverse(Xb)$

The link function defines the relationship $f(\mu) = X*b$ between the mean response μ and the linear combination of predictors $X*b$.

For more information on the canonical link functions, see “Canonical Link Function” on page 32-6553.

Example: 'Link', 'probit'

Data Types: char | string | single | double | struct

Lower — Model specification describing terms that cannot be removed from model

'constant' (default) | character vector | string scalar | terms matrix

Model specification describing terms that cannot be removed from the model, specified as the comma-separated pair consisting of 'Lower' and one of the options for `modelspec` naming the model.

Example: 'Lower', 'linear'

Offset — Offset variable

[] (default) | vector | character vector | string scalar

Offset variable in the fit, specified as the comma-separated pair consisting of 'Offset' and a vector or name of a variable with the same length as the response.

GeneralizedLinearModel.stepwise uses Offset as an additional predictor, with a coefficient value fixed at 1.0. In other words, the formula for fitting is

$$f(\mu) \sim \text{Offset} + (\text{terms involving real predictors})$$

with the Offset predictor having coefficient 1.

For example, consider a Poisson regression model. Suppose the number of counts is known for theoretical reasons to be proportional to a predictor A. By using the log link function and by specifying $\log(A)$ as an offset, you can force the model to satisfy this theoretical constraint.

Data Types: single | double | char | string

PEnter — Threshold for criterion to add term

scalar value

Threshold for the criterion to add a term, specified as the comma-separated pair consisting of 'PEnter' and a scalar value, as described in this table.

Criterion	Default Value	Decision
'Deviance'	0.05	If the p -value of F -statistic or chi-squared statistic is less than PEnter (p -value to enter), add the term to the model.
'SSE'	0.05	If the SSE of the model is less than PEnter, add the term to the model.

Criterion	Default Value	Decision
'AIC'	0	If the change in the AIC of the model is less than <code>PEnter</code> , add the term to the model.
'BIC'	0	If the change in the BIC of the model is less than <code>PEnter</code> , add the term to the model.
'Rsquared'	0.1	If the increase in the R-squared value of the model is greater than <code>PEnter</code> , add the term to the model.
'AdjRsquared'	0	If the increase in the adjusted R-squared value of the model is greater than <code>PEnter</code> , add the term to the model.

For more information, see the `Criterion` name-value pair argument.

Example: `'PEnter', 0.075`

PredictorVars — Predictor variables

string array | cell array of character vectors | logical or numeric index vector

Predictor variables to use in the fit, specified as the comma-separated pair consisting of `'PredictorVars'` and either a string array or cell array of character vectors of the variable names in the table or dataset array `tbl`, or a logical or numeric index vector indicating which columns are predictor variables.

The string values or character vectors should be among the names in `tbl`, or the names you specify using the `'VarNames'` name-value pair argument.

The default is all variables in `X`, or all variables in `tbl` except for `ResponseVar`.

For example, you can specify the second and third variables as the predictor variables using either of the following examples.

Example: `'PredictorVars', [2,3]`

Example: 'PredictorVars',logical([0 1 1 0 0 0])

Data Types: single | double | logical | string | cell

PRemove — Threshold for criterion to remove term

scalar value

Threshold for the criterion to remove a term, specified as the comma-separated pair consisting of 'PRemove' and a scalar value, as described in this table.

Criterion	Default Value	Decision
'Deviance'	0.10	If the p -value of F -statistic or chi-squared statistic is greater than PRemove (p -value to remove), remove the term from the model.
'SSE'	0.10	If the p -value of the F statistic is greater than PRemove, remove the term from the model.
'AIC'	0.01	If the change in the AIC of the model is greater than PRemove, remove the term from the model.
'BIC'	0.01	If the change in the BIC of the model is greater than PRemove, remove the term from the model.
'Rsquared'	0.05	If the increase in the R-squared value of the model is less than PRemove, remove the term from the model.
'AdjRsquared'	-0.05	If the increase in the adjusted R-squared value of the model is less than PRemove, remove the term from the model.

At each step, the `GeneralizedLinearModel.stepwise` function also checks whether a term is redundant (linearly dependent) with other terms in the current model. When any term is linearly dependent with other terms in the current model, the `GeneralizedLinearModel.stepwise` function removes the redundant term, regardless of the criterion value.

For more information, see the `Criterion` name-value pair argument.

Example: `'PRemove',0.05`

ResponseVar — Response variable

last column in `tbl` (default) | character vector or string scalar containing variable name | logical or numeric index vector

Response variable to use in the fit, specified as the comma-separated pair consisting of `'ResponseVar'` and either a character vector or string scalar containing the variable name in the table or dataset array `tbl`, or a logical or numeric index vector indicating which column is the response variable. You typically need to use `'ResponseVar'` when fitting a table or dataset array `tbl`.

For example, you can specify the fourth variable, say `yield`, as the response out of six variables, in one of the following ways.

Example: `'ResponseVar','yield'`

Example: `'ResponseVar',[4]`

Example: `'ResponseVar',logical([0 0 0 1 0 0])`

Data Types: `single` | `double` | `logical` | `char` | `string`

Upper — Model specification describing largest set of terms in fit

`'interactions'` (default) | character vector | string scalar | terms matrix

Model specification describing the largest set of terms in the fit, specified as the comma-separated pair consisting of `'Upper'` and one of the options for `modelspec` naming the model.

Example: `'Upper','quadratic'`

VarNames — Names of variables

`{'x1','x2',...,'xn','y'}` (default) | string array | cell array of character vectors

Names of variables, specified as the comma-separated pair consisting of 'VarNames' and a string array or cell array of character vectors including the names for the columns of X first, and the name for the response variable y last.

'VarNames' is not applicable to variables in a table or dataset array, because those variables already have names.

For example, if in your data, horsepower, acceleration, and model year of the cars are the predictor variables, and miles per gallon (MPG) is the response variable, then you can name the variables as follows.

Example: 'VarNames', {'Horsepower', 'Acceleration', 'Model_Year', 'MPG'}

Data Types: string | cell

Weights — Observation weights

ones(n,1) (default) | *n*-by-1 vector of nonnegative scalar values

Observation weights, specified as the comma-separated pair consisting of 'Weights' and an *n*-by-1 vector of nonnegative scalar values, where *n* is the number of observations.

Data Types: single | double

Output Arguments

mdl — Generalized linear model

GeneralizedLinearModel object

Generalized linear model representing a least-squares fit of the link of the response to the data, returned as a GeneralizedLinearModel object.

For properties and methods of the generalized linear model object, mdl, see the GeneralizedLinearModel class page.

Examples

Create a Generalized Linear Model Stepwise

Create response data using just three of 20 predictors, and create a generalized linear model stepwise to see if it uses just the correct predictors.

Create data with 20 predictors, and Poisson response using just three of the predictors, plus a constant.

```
rng default % for reproducibility
X = randn(100,20);
mu = exp(X(:,[5 10 15])*[.4;.2;.3] + 1);
y = poissrnd(mu);
```

Fit a generalized linear model using the Poisson distribution.

```
mdl = stepwiseglm(X,y,...
    'constant','upper','linear','Distribution','poisson')
```

1. Adding x5, Deviance = 134.439, Chi2Stat = 52.24814, PValue = 4.891229e-13
2. Adding x15, Deviance = 106.285, Chi2Stat = 28.15393, PValue = 1.1204e-07
3. Adding x10, Deviance = 95.0207, Chi2Stat = 11.2644, PValue = 0.000790094

```
mdl =
Generalized linear regression model:
log(y) ~ 1 + x5 + x10 + x15
Distribution = Poisson
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	1.0115	0.064275	15.737	8.4217e-56
x5	0.39508	0.066665	5.9263	3.0977e-09
x10	0.18863	0.05534	3.4085	0.0006532
x15	0.29295	0.053269	5.4995	3.8089e-08

```
100 observations, 96 error degrees of freedom
Dispersion: 1
Chi^2-statistic vs. constant model: 91.7, p-value = 9.61e-20
```

Definitions

Terms Matrix

A terms matrix T is a t -by- $(p + 1)$ matrix specifying terms in a model, where t is the number of terms, p is the number of predictor variables, and $+1$ accounts for the response variable. The value of $T(i, j)$ is the exponent of variable j in term i .

For example, suppose that an input includes three predictor variables A , B , and C and the response variable Y in the order A , B , C , and Y . Each row of T represents one term:

- $[0 \ 0 \ 0 \ 0]$ — Constant term or intercept
- $[0 \ 1 \ 0 \ 0]$ — B ; equivalently, $A^0 * B^1 * C^0$
- $[1 \ 0 \ 1 \ 0]$ — $A * C$
- $[2 \ 0 \ 0 \ 0]$ — A^2
- $[0 \ 1 \ 2 \ 0]$ — $B * (C^2)$

The 0 at the end of each term represents the response variable. In general, a column vector of zeros in a terms matrix represents the position of the response variable. If you have the predictor and response variables in a matrix and column vector, then you must include 0 for the response variable in the last column of each row.

Formula

A formula for model specification is a character vector or string scalar of the form ' $Y \sim terms$ '.

- Y is the response name.
- $terms$ represents the predictor terms in a model using Wilkinson notation.

For example:

- ' $Y \sim A + B + C$ ' specifies a three-variable linear model with intercept.
- ' $Y \sim A + B + C - 1$ ' specifies a three-variable linear model without intercept. Note that formulas include a constant (intercept) term by default. To exclude a constant term from the model, you must include -1 in the formula.

Wilkinson Notation

Wilkinson notation describes the terms present in a model. The notation relates to the terms present in a model, not to the multipliers (coefficients) of those terms.

Wilkinson notation uses these symbols:

- $+$ means include the next variable.
- $-$ means do not include the next variable.
- $:$ defines an interaction, which is a product of terms.
- $*$ defines an interaction and all lower-order terms.
- $^$ raises the predictor to a power, exactly as in $*$ repeated, so $^$ includes lower-order terms as well.
- $()$ groups terms.

This table shows typical examples of Wilkinson notation.

Wilkinson Notation	Term in Standard Notation
1	Constant (intercept) term
A^k , where k is a positive integer	A, A^2, \dots, A^k
$A + B$	A, B
$A*B$	$A, B, A*B$
$A:B$	$A*B$ only
$-B$	Do not include B
$A*B + C$	$A, B, C, A*B$
$A + B + C + A:B$	$A, B, C, A*B$
$A*B*C - A:B:C$	$A, B, C, A*B, A*C, B*C$
$A*(B + C)$	$A, B, C, A*B, A*C$

Statistics and Machine Learning Toolbox notation always includes a constant term unless you explicitly remove the term using -1 .

For more details, see “Wilkinson Notation” on page 11-117.

Canonical Link Function

The default link function for a generalized linear model is the canonical link function.

Canonical Link Functions for Generalized Linear Models

Distribution	Link Function Name	Link Function	Mean (Inverse) Function
'normal'	'identity'	$f(\mu) = \mu$	$\mu = Xb$
'binomial'	'logit'	$f(\mu) = \log(\mu/(1-\mu))$	$\mu = \exp(Xb) / (1 + \exp(Xb))$
'poisson'	'log'	$f(\mu) = \log(\mu)$	$\mu = \exp(Xb)$
'gamma'	-1	$f(\mu) = 1/\mu$	$\mu = 1/(Xb)$
'inverse gaussian'	-2	$f(\mu) = 1/\mu^2$	$\mu = (Xb)^{-1/2}$

Tips

- The generalized linear model `mdl` is a standard linear model unless you specify otherwise with the `Distribution` name-value pair.
- For other methods such as `devianceTest`, or properties of the `GeneralizedLinearModel` object, see `GeneralizedLinearModel`.

Algorithms

Stepwise regression is a systematic method for adding and removing terms from a linear or generalized linear model based on their statistical significance in explaining the response variable. The method begins with an initial model, specified using `modelspec`, and then compares the explanatory power of incrementally larger and smaller models.

The `GeneralizedLinearModel.stepwise` function uses forward and backward stepwise regression to determine a final model. At each step, the function searches for terms to add to the model or remove from the model based on the value of the `'Criterion'` name-value pair argument.

The default value of `'Criterion'` for a linear regression model is `'sse'`. In this case, `stepwiselm` and `step` of `LinearModel` use the p -value of an F -statistic to test models with and without a potential term at each step. If a term is not currently in the model, the

null hypothesis is that the term would have a zero coefficient if added to the model. If there is sufficient evidence to reject the null hypothesis, the function adds the term to the model. Conversely, if a term is currently in the model, the null hypothesis is that the term has a zero coefficient. If there is insufficient evidence to reject the null hypothesis, the function removes the term from the model.

Stepwise regression takes these steps when 'Criterion' is 'sse':

- 1 Fit the initial model.
- 2 Examine a set of available terms not in the model. If any of the terms have p -values less than an entrance tolerance (that is, if it is unlikely a term would have a zero coefficient if added to the model), add the term with the smallest p -value and repeat this step; otherwise, go to step 3.
- 3 If any of the available terms in the model have p -values greater than an exit tolerance (that is, the hypothesis of a zero coefficient cannot be rejected), remove the term with the largest p -value and return to step 2; otherwise, end the process.

At any stage, the function will not add a higher-order term if the model does not also include all lower-order terms that are subsets of the higher-order term. For example, the function will not try to add the term $X1:X2^2$ unless both $X1$ and $X2^2$ are already in the model. Similarly, the function will not remove lower-order terms that are subsets of higher-order terms that remain in the model. For example, the function will not try to remove $X1$ or $X2^2$ if $X1:X2^2$ remains in the model.

The default value of 'Criterion' for a generalized linear model is 'Deviance'. `stepwiseglm` and `step` of `GeneralizedLinearModel` follow a similar procedure for adding or removing terms.

You can specify other criteria by using the 'Criterion' name-value pair argument. For example, you can specify the change in the value of the Akaike information criterion, Bayesian information criterion, R-squared, or adjusted R-squared as the criterion to add or remove terms.

Depending on the terms included in the initial model, and the order in which the function adds and removes terms, the function might build different models from the same set of potential terms. The function terminates when no single step improves the model. However, a different initial model or a different sequence of steps does not guarantee a better fit. In this sense, stepwise models are locally optimal, but might not be globally optimal.

Alternatives

You can also create a stepwise generalized linear model using `stepwiseglm`.

Use `fitglm` to create a model with a fixed specification. Use `step`, `addTerms`, or `removeTerms` to adjust a fitted model.

LinearModel.stepwise

(Not Recommended) Create linear regression model by stepwise regression

Note `LinearModel.stepwise` is not recommended. Use `stepwiselm` instead.

Syntax

```
mdl = LinearModel.stepwise(tbl,modelspec)
mdl = LinearModel.stepwise(X,y,modelspec)
mdl = LinearModel.stepwise( ____,modelspec,Name,Value)
```

Description

`mdl = LinearModel.stepwise(tbl,modelspec)` returns a linear model of a table or dataset array `tbl`, using stepwise regression to add or remove predictors. `modelspec` is the starting model for the stepwise procedure.

`mdl = LinearModel.stepwise(X,y,modelspec)` creates a linear model of the responses `y` to a data matrix `X`, using stepwise regression to add or remove predictors. `modelspec` is the starting model for the stepwise procedure.

`mdl = LinearModel.stepwise(____,modelspec,Name,Value)` creates a linear model for any of the inputs in the previous syntaxes, with additional options specified by one or more `Name,Value` pair arguments.

For example, you can specify the categorical variables, the smallest or largest set of terms to use in the model, the maximum number of steps to take, or the criterion `LinearModel.stepwise` uses to add or remove terms.

Input Arguments

tbl — Input data

table | dataset array

Input data, specified as a table or dataset array. When `modelspec` is a formula, the formula specifies the predictor and response variables. Otherwise, if you do not specify the predictor and response variables, the last variable in `tbl` is the response variable and the others are the predictor variables by default.

The predictor variables can be numeric, logical, categorical, character, or string. The response variable must be numeric or logical.

To set a different column as the response variable, use the `ResponseVar` name-value pair argument. To use a subset of the columns as predictors, use the `PredictorVars` name-value pair argument.

X — Predictor variables

matrix

Predictor variables, specified as an n -by- p matrix, where n is the number of observations and p is the number of predictor variables. Each column of X represents one variable, and each row represents one observation.

By default, there is a constant term in the model, unless you explicitly remove it, so do not include a column of 1s in X .

Data Types: `single` | `double`

y — Response variable

vector

Response variable, specified as an n -by-1 vector, where n is the number of observations. Each entry in y is the response for the corresponding row of X .

Data Types: `single` | `double` | `logical`

modelspec — Starting model

character vector or string scalar specifying the model | t -by- $(p+1)$ terms matrix | character vector or string scalar of the form 'Y ~ terms'

Starting model for the stepwise regression, specified as one of the following:

- Character vector or string scalar specifying the type of starting model.

Value	Model Type
'constant'	Model contains only a constant (intercept) term.

Value	Model Type
'linear'	Model contains an intercept and linear term for each predictor.
'interactions'	Model contains an intercept, linear term for each predictor, and all products of pairs of distinct predictors (no squared terms).
'purequadratic'	Model contains an intercept term and linear and squared terms for each predictor.
'quadratic'	Model contains an intercept term, linear and squared terms for each predictor, and all products of pairs of distinct predictors.
'polyijk'	Model is a polynomial with all terms up to degree i in the first predictor, degree j in the second predictor, and so on. Specify the maximum degree for each predictor by using numerals 0 through 9. The model contains interaction terms, but the degree of each interaction term does not exceed the maximum value of the specified degrees. For example, 'poly13' has an intercept and x_1 , x_2 , x_2^2 , x_2^3 , x_1*x_2 , and $x_1*x_2^2$ terms, where x_1 and x_2 are the first and second predictors, respectively.

If you want to specify the smallest or largest set of terms in the model, use the **Lower** and **Upper** name-value pair arguments.

- t -by- $(p+1)$ matrix, namely a terms matrix on page 32-6567, specifying terms to include in model, where t is the number of terms and p is the number of predictor variables, and plus one is for the response variable.
- Character vector or string scalar representing a formula on page 32-6568 in the form

'Y ~ terms',

where the terms are in "Wilkinson Notation" on page 32-6568.

Name-Value Pair Arguments

Specify optional comma-separated pairs of **Name**, **Value** arguments. **Name** is the argument name and **Value** is the corresponding value. **Name** must appear inside quotes.

You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

CategoricalVars — Categorical variable list

string array | cell array of character vectors | logical or numeric index vector

Categorical variable list, specified as the comma-separated pair consisting of 'CategoricalVars' and either a string array or cell array of character vectors containing categorical variable names in the table or dataset array `tbl`, or a logical or numeric index vector indicating which columns are categorical.

- If data is in a table or dataset array `tbl`, then, by default, `LinearModel.stepwise` treats all categorical values, logical values, character arrays, string arrays, and cell arrays of character vectors as categorical variables.
- If data is in matrix `X`, then the default value of 'CategoricalVars' is an empty matrix `[]`. That is, no variable is categorical unless you specify it as categorical.

For example, you can specify the observations 2 and 3 out of 6 as categorical using either of the following examples.

Example: 'CategoricalVars', [2,3]

Example: 'CategoricalVars', logical([0 1 1 0 0 0])

Data Types: single | double | logical | string | cell

Criterion — Criterion to add or remove terms

'sse' (default) | 'aic' | 'bic' | 'rsquared' | 'adjrsquared'

Criterion to add or remove terms, specified as the comma-separated pair consisting of 'Criterion' and one of these values:

- 'sse' — p -value for an F -test of the change in the sum of squared error that results from adding or removing the term
- 'aic' — Change in the value of Akaike information criterion (AIC)
- 'bic' — Change in the value of Bayesian information criterion (BIC)
- 'rsquared' — Increase in the value of R^2
- 'adjrsquared' — Increase in the value of adjusted R^2

Example: 'Criterion', 'bic'

Exclude — Observations to exclude

logical or numeric index vector

Observations to exclude from the fit, specified as the comma-separated pair consisting of 'Exclude' and a logical or numeric index vector indicating which observations to exclude from the fit.

For example, you can exclude observations 2 and 3 out of 6 using either of the following examples.

Example: 'Exclude', [2,3]

Example: 'Exclude', logical([0 1 1 0 0 0])

Data Types: single | double | logical

Intercept — Indicator for constant term

true (default) | false

Indicator for the constant term (intercept) in the fit, specified as the comma-separated pair consisting of 'Intercept' and either true to include or false to remove the constant term from the model.

Use 'Intercept' only when specifying the model using a character vector or string scalar, not a formula or matrix.

Example: 'Intercept', false

Lower — Model specification describing terms that cannot be removed from model

'constant' (default) | character vector | string scalar | terms matrix

Model specification describing terms that cannot be removed from the model, specified as the comma-separated pair consisting of 'Lower' and one of the options for `modelspec` naming the model.

Example: 'Lower', 'linear'

NSteps — Maximum number of steps to take

no limit (default) | positive integer

Maximum number of steps to take, specified as the comma-separated pair consisting of 'NSteps' and a positive integer.

Example: 'NSteps', 5

Data Types: single | double

PEnter — Threshold for criterion to add term

scalar value

Threshold for the criterion to add a term, specified as the comma-separated pair consisting of 'PEnter' and a scalar value, as described in this table.

Criterion	Default Value	Decision
'SSE'	0.05	If the p -value of the F -statistic is less than PEnter (p -value to enter), add the term to the model.
'AIC'	0	If the change in the AIC of the model is less than PEnter, add the term to the model.
'BIC'	0	If the change in the BIC of the model is less than PEnter, add the term to the model.
'Rsquared'	0.1	If the increase in the R-squared value of the model is greater than PEnter, add the term to the model.
'AdjRsquared'	0	If the increase in the adjusted R-squared value of the model is greater than PEnter, add the term to the model.

For more information, see the Criterion name-value pair argument.

Example: 'PEnter',0.075

PredictorVars — Predictor variables

string array | cell array of character vectors | logical or numeric index vector

Predictor variables to use in the fit, specified as the comma-separated pair consisting of 'PredictorVars' and either a string array or cell array of character vectors of the

variable names in the table or dataset array `tbl`, or a logical or numeric index vector indicating which columns are predictor variables.

The string values or character vectors should be among the names in `tbl`, or the names you specify using the `'VarNames'` name-value pair argument.

The default is all variables in X , or all variables in `tbl` except for `ResponseVar`.

For example, you can specify the second and third variables as the predictor variables using either of the following examples.

Example: `'PredictorVars',[2,3]`

Example: `'PredictorVars',logical([0 1 1 0 0 0])`

Data Types: `single` | `double` | `logical` | `string` | `cell`

PRemove — Threshold for criterion to remove term

scalar value

Threshold for the criterion to remove a term, specified as the comma-separated pair consisting of `'PRemove'` and a scalar value, as described in this table.

Criterion	Default Value	Decision
'SSE'	0.10	If the p -value of the F -statistic is greater than <code>PRemove</code> (p -value to remove), remove the term from the model.
'AIC'	0.01	If the change in the AIC of the model is greater than <code>PRemove</code> , remove the term from the model.
'BIC'	0.01	If the change in the BIC of the model is greater than <code>PRemove</code> , remove the term from the model.

Criterion	Default Value	Decision
'Rsquared'	0.05	If the increase in the R-squared value of the model is less than PRemove, remove the term from the model.
'AdjRsquared'	-0.05	If the increase in the adjusted R-squared value of the model is less than PRemove, remove the term from the model.

At each step, the `LinearModel.stepwise` function also checks whether a term is redundant (linearly dependent) with other terms in the current model. When any term is linearly dependent with other terms in the current model, the `LinearModel.stepwise` function removes the redundant term, regardless of the criterion value.

For more information, see the `Criterion` name-value pair argument.

Example: `'PRemove', 0.05`

ResponseVar — Response variable

last column in `tbl` (default) | character vector or string scalar containing variable name | logical or numeric index vector

Response variable to use in the fit, specified as the comma-separated pair consisting of `'ResponseVar'` and either a character vector or string scalar containing the variable name in the table or dataset array `tbl`, or a logical or numeric index vector indicating which column is the response variable. You typically need to use `'ResponseVar'` when fitting a table or dataset array `tbl`.

For example, you can specify the fourth variable, say `yield`, as the response out of six variables, in one of the following ways.

Example: `'ResponseVar', 'yield'`

Example: `'ResponseVar', [4]`

Example: `'ResponseVar', logical([0 0 0 1 0 0])`

Data Types: `single` | `double` | `logical` | `char` | `string`

Upper — Model specification describing largest set of terms in fit`'interactions'` (default) | character vector | string scalar | terms matrix

Model specification describing the largest set of terms in the fit, specified as the comma-separated pair consisting of `'Upper'` and one of the options for `modelSpec` naming the model.

Example: `'Upper', 'quadratic'`

VarNames — Names of variables`{'x1', 'x2', ..., 'xn', 'y'}` (default) | string array | cell array of character vectors

Names of variables, specified as the comma-separated pair consisting of `'VarNames'` and a string array or cell array of character vectors including the names for the columns of X first, and the name for the response variable y last.

`'VarNames'` is not applicable to variables in a table or dataset array, because those variables already have names.

For example, if in your data, horsepower, acceleration, and model year of the cars are the predictor variables, and miles per gallon (MPG) is the response variable, then you can name the variables as follows.

Example: `'VarNames', {'Horsepower', 'Acceleration', 'Model_Year', 'MPG'}`

Data Types: `string` | `cell`

Verbose — Control for display of information`1` (default) | `0` | `2`

Control for the display of information, specified as the comma-separated pair consisting of `'Verbose'` and one of these values:

- `0` — Suppress all display.
- `1` — Display the action taken at each step.
- `2` — Display the evaluation process and the action taken at each step.

Example: `'Verbose', 2`

Weights — Observation weights`ones(n, 1)` (default) | n -by-1 vector of nonnegative scalar values

Observation weights, specified as the comma-separated pair consisting of `'Weights'` and an n -by-1 vector of nonnegative scalar values, where n is the number of observations.

Data Types: single | double

Output Arguments

mdl — Linear model

LinearModel object

Linear model representing a least-squares fit of the response to the data, returned as a LinearModel object.

For the properties and methods of the linear model object, `mdl`, see the LinearModel class page.

Examples

Fit Linear Model Using Stepwise Regression

Load the `hald` data set, which measures the effect of cement composition on its hardening heat.

```
load hald
```

This data set includes the variables `ingredients` and `heat`. The matrix `ingredients` contains the percent composition of four chemicals present in the cement. The vector `heat` contains the values for the heat hardening after 180 days for each cement sample.

Fit a stepwise linear regression model to the data. Specify 0.06 as the threshold for the criterion to add a term to the model.

```
mdl = stepwiselm(ingredients,heat,'PEnter',0.06)
```

1. Adding x4, FStat = 22.7985, pValue = 0.000576232
2. Adding x1, FStat = 108.2239, pValue = 1.105281e-06
3. Adding x2, FStat = 5.0259, pValue = 0.051687
4. Removing x4, FStat = 1.8633, pValue = 0.2054

```
mdl =  
Linear regression model:  
y ~ 1 + x1 + x2
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	52.577	2.2862	22.998	5.4566e-10
x1	1.4683	0.1213	12.105	2.6922e-07
x2	0.66225	0.045855	14.442	5.029e-08

Number of observations: 13, Error degrees of freedom: 10

Root Mean Squared Error: 2.41

R-squared: 0.979, Adjusted R-Squared: 0.974

F-statistic vs. constant model: 230, p-value = 4.41e-09

By default, the starting model is a constant model. `stepwiselm` performs forward selection and adds the `x4`, `x1`, and `x2` terms (in that order), because the corresponding p -values are less than the `PEnter` value of 0.06. `stepwiselm` then uses backward elimination and removes `x4` from the model because, once `x2` is in the model, the p -value of `x4` is greater than the default value of `PRemove`, 0.1.

Stepwise Regression Using Specified Model Formula and Variables

Perform stepwise regression using variables stored in a dataset array. Specify the starting model using Wilkinson notation, and identify the response and predictor variables using optional arguments.

Load the sample data.

```
load hospital
```

The `hospital` dataset array includes the gender, age, weight, and smoking status of patients.

Fit a linear model with a starting model of a constant term and `Smoker` as the predictor variable. Specify the response variable, `Weight`, and categorical predictor variables, `Sex`, `Age`, and `Smoker`.

```
mdl = stepwiselm(hospital, 'Weight~1+Smoker', ...
    'ResponseVar', 'Weight', 'PredictorVars', {'Sex', 'Age', 'Smoker'}, ...
    'CategoricalVar', {'Sex', 'Smoker'})
```

1. Adding Sex, FStat = 770.0158, pValue = 6.262758e-48
2. Removing Smoker, FStat = 0.21224, pValue = 0.64605

```
mdl =
Linear regression model:
  Weight ~ 1 + Sex
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	130.47	1.1995	108.77	5.2762e-104
Sex_Male	50.06	1.7496	28.612	2.2464e-49

```
Number of observations: 100, Error degrees of freedom: 98
Root Mean Squared Error: 8.73
R-squared: 0.893, Adjusted R-Squared: 0.892
F-statistic vs. constant model: 819, p-value = 2.25e-49
```

At each step, `stepwiselm` searches for terms to add and remove. At first step, stepwise algorithm adds `Sex` to the model with a p -value of 6.26e-48. Then, removes `Smoker` from the model, since given `Sex` in the model, the variable `Smoker` becomes redundant. `stepwiselm` only includes `Sex` in the final linear model. The weight of the patients do not seem to differ significantly according to age or the status of smoking.

Definitions

Terms Matrix

A terms matrix T is a t -by- $(p + 1)$ matrix specifying terms in a model, where t is the number of terms, p is the number of predictor variables, and $+1$ accounts for the response variable. The value of $T(i, j)$ is the exponent of variable j in term i .

For example, suppose that an input includes three predictor variables A , B , and C and the response variable Y in the order A , B , C , and Y . Each row of T represents one term:

- $[0 \ 0 \ 0 \ 0]$ — Constant term or intercept
- $[0 \ 1 \ 0 \ 0]$ — B ; equivalently, $A^0 * B^1 * C^0$

- $[1 \ 0 \ 1 \ 0]$ — $A * C$
- $[2 \ 0 \ 0 \ 0]$ — A^2
- $[0 \ 1 \ 2 \ 0]$ — $B * (C^2)$

The 0 at the end of each term represents the response variable. In general, a column vector of zeros in a terms matrix represents the position of the response variable. If you have the predictor and response variables in a matrix and column vector, then you must include 0 for the response variable in the last column of each row.

Formula

A formula for model specification is a character vector or string scalar of the form ' $Y \sim terms$ '.

- Y is the response name.
- $terms$ represents the predictor terms in a model using Wilkinson notation.

For example:

- ' $Y \sim A + B + C$ ' specifies a three-variable linear model with intercept.
- ' $Y \sim A + B + C - 1$ ' specifies a three-variable linear model without intercept. Note that formulas include a constant (intercept) term by default. To exclude a constant term from the model, you must include -1 in the formula.

Wilkinson Notation

Wilkinson notation describes the terms present in a model. The notation relates to the terms present in a model, not to the multipliers (coefficients) of those terms.

Wilkinson notation uses these symbols:

- $+$ means include the next variable.
- $-$ means do not include the next variable.
- $:$ defines an interaction, which is a product of terms.
- $*$ defines an interaction and all lower-order terms.
- $^$ raises the predictor to a power, exactly as in $*$ repeated, so $^$ includes lower-order terms as well.

- () groups terms.

This table shows typical examples of Wilkinson notation.

Wilkinson Notation	Term in Standard Notation
1	Constant (intercept) term
A^k , where k is a positive integer	A, A^2, \dots, A^k
$A + B$	A, B
$A*B$	$A, B, A*B$
$A:B$	$A*B$ only
$-B$	Do not include B
$A*B + C$	$A, B, C, A*B$
$A + B + C + A:B$	$A, B, C, A*B$
$A*B*C - A:B:C$	$A, B, C, A*B, A*C, B*C$
$A*(B + C)$	$A, B, C, A*B, A*C$

Statistics and Machine Learning Toolbox notation always includes a constant term unless you explicitly remove the term using `-1`.

For more details, see “Wilkinson Notation” on page 11-117.

Tips

- You cannot use robust regression with stepwise regression. Check your data for outliers before using `LinearModel.stepwise`.
- For other methods or properties of the `LinearModel` object, see `LinearModel`.

Algorithms

Stepwise regression is a systematic method for adding and removing terms from a linear or generalized linear model based on their statistical significance in explaining the response variable. The method begins with an initial model, specified using `modelspec`, and then compares the explanatory power of incrementally larger and smaller models.

The `LinearModel.stepwise` function uses forward and backward stepwise regression to determine a final model. At each step, the function searches for terms to add to the model or remove from the model based on the value of the 'Criterion' name-value pair argument.

The default value of 'Criterion' for a linear regression model is 'sse'. In this case, `stepwiselm` and `step` of `LinearModel` use the p -value of an F -statistic to test models with and without a potential term at each step. If a term is not currently in the model, the null hypothesis is that the term would have a zero coefficient if added to the model. If there is sufficient evidence to reject the null hypothesis, the function adds the term to the model. Conversely, if a term is currently in the model, the null hypothesis is that the term has a zero coefficient. If there is insufficient evidence to reject the null hypothesis, the function removes the term from the model.

Stepwise regression takes these steps when 'Criterion' is 'sse':

- 1 Fit the initial model.
- 2 Examine a set of available terms not in the model. If any of the terms have p -values less than an entrance tolerance (that is, if it is unlikely a term would have a zero coefficient if added to the model), add the term with the smallest p -value and repeat this step; otherwise, go to step 3.
- 3 If any of the available terms in the model have p -values greater than an exit tolerance (that is, the hypothesis of a zero coefficient cannot be rejected), remove the term with the largest p -value and return to step 2; otherwise, end the process.

At any stage, the function will not add a higher-order term if the model does not also include all lower-order terms that are subsets of the higher-order term. For example, the function will not try to add the term $X1:X2^2$ unless both $X1$ and $X2^2$ are already in the model. Similarly, the function will not remove lower-order terms that are subsets of higher-order terms that remain in the model. For example, the function will not try to remove $X1$ or $X2^2$ if $X1:X2^2$ remains in the model.

The default value of 'Criterion' for a generalized linear model is 'Deviance'. `stepwiseglm` and `step` of `GeneralizedLinearModel` follow a similar procedure for adding or removing terms.

You can specify other criteria by using the 'Criterion' name-value pair argument. For example, you can specify the change in the value of the Akaike information criterion, Bayesian information criterion, R-squared, or adjusted R-squared as the criterion to add or remove terms.

Depending on the terms included in the initial model, and the order in which the function adds and removes terms, the function might build different models from the same set of potential terms. The function terminates when no single step improves the model. However, a different initial model or a different sequence of steps does not guarantee a better fit. In this sense, stepwise models are locally optimal, but might not be globally optimal.

Alternatives

You can also construct a stepwise linear model using `stepwiselm`.

You can construct a model using `fitlm`, then manually adjust the model using `step`, `addTerms`, or `removeTerms`. Use `fitlm` for robust regression. You cannot use robust regression and stepwise regression together.

stepwiseglm

Create generalized linear regression model by stepwise regression

Syntax

```
mdl = stepwiseglm(tbl)
mdl = stepwiseglm(X,y)
mdl = stepwiseglm( ____,modelspec)
mdl = stepwiseglm( ____,modelspec,Name,Value)
```

Description

`mdl = stepwiseglm(tbl)` creates a generalized linear model of a table or dataset array `tbl` using stepwise regression to add or remove predictors, starting from a constant model. `stepwiseglm` uses the last variable of `tbl` as the response variable. `stepwiseglm` uses forward and backward stepwise regression to determine a final model. At each step, the function searches for terms to add the model to or remove from the model, based on the value of the 'Criterion' argument.

`mdl = stepwiseglm(X,y)` creates a generalized linear model of the responses `y` to a data matrix `X`.

`mdl = stepwiseglm(____,modelspec)` specifies the starting model `modelspec` using any of the input argument combinations in previous syntaxes.

`mdl = stepwiseglm(____,modelspec,Name,Value)` specifies additional options using one or more name-value pair arguments. For example, you can specify the categorical variables, the smallest or largest set of terms to use in the model, the maximum number of steps to take, or the criterion that `stepwiseglm` uses to add or remove terms.

Examples

Generalized Linear Model Using Stepwise Algorithm

Create response data using just three of 20 predictors, and create a generalized linear model using stepwise algorithm to see if it uses just the correct predictors.

Create data with 20 predictors, and Poisson response using just three of the predictors, plus a constant.

```
rng('default') % for reproducibility
X = randn(100,20);
mu = exp(X(:, [5 10 15])*[.4;.2;.3]+ 1);
y = poissrnd(mu);
```

Fit a generalized linear model using the Poisson distribution.

```
mdl = stepwiseglm(X,y,...
    'constant','upper','linear','Distribution','poisson')
```

1. Adding x5, Deviance = 134.439, Chi2Stat = 52.24814, PValue = 4.891229e-13
2. Adding x15, Deviance = 106.285, Chi2Stat = 28.15393, PValue = 1.1204e-07
3. Adding x10, Deviance = 95.0207, Chi2Stat = 11.2644, PValue = 0.000790094

```
mdl =
Generalized linear regression model:
log(y) ~ 1 + x5 + x10 + x15
Distribution = Poisson
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	1.0115	0.064275	15.737	8.4217e-56
x5	0.39508	0.066665	5.9263	3.0977e-09
x10	0.18863	0.05534	3.4085	0.0006532
x15	0.29295	0.053269	5.4995	3.8089e-08

```
100 observations, 96 error degrees of freedom
Dispersion: 1
Chi^2-statistic vs. constant model: 91.7, p-value = 9.61e-20
```

The starting model is the constant model. `stepwiseglm` by default uses deviance of the model as the criterion. It first adds `x5` into the model, as the p -value for the test statistic, deviance (the differences in the deviances of the two models), is less than the default threshold value 0.05. Then, it adds `x15` because given `x5` is in the model, when `x15` is

added, the p -value for chi-squared test is smaller than 0.05. It then adds `x10` because given `x5` and `x15` are in the model, when `x10` is added, the p -value for the chi-square test statistic is again less than 0.05.

Input Arguments

tbl — Input data

table | dataset array

Input data, specified as a table or dataset array. When `modelspec` is a formula, the formula specifies the predictor and response variables. Otherwise, if you do not specify the predictor and response variables, the last variable in `tbl` is the response variable and the others are the predictor variables by default.

The predictor variables and response variable can be numeric, logical, categorical, character, or string. The response variable can have a data type other than numeric only if 'Distribution' is 'binomial'.

To set a different column as the response variable, use the `ResponseVar` name-value pair argument. To use a subset of the columns as predictors, use the `PredictorVars` name-value pair argument.

X — Predictor variables

matrix

Predictor variables, specified as an n -by- p matrix, where n is the number of observations and p is the number of predictor variables. Each column of `X` represents one variable, and each row represents one observation.

By default, there is a constant term in the model, unless you explicitly remove it, so do not include a column of 1s in `X`.

Data Types: `single` | `double`

y — Response variable

vector

Response variable, specified as an n -by-1 vector, where n is the number of observations. Each entry in `y` is the response for the corresponding row of `X`.

Data Types: `single` | `double` | `logical` | `categorical`

modelspec — Starting model

'constant' (default) | character vector or string scalar specifying the model | t -by- $(p+1)$ terms matrix | character vector or string scalar of the form 'Y ~ terms'

Starting model for `stepwiseglm`, specified as one of the following:

- A character vector or string scalar naming the model.

Value	Model Type
'constant'	Model contains only a constant (intercept) term.
'linear'	Model contains an intercept and linear term for each predictor.
'interactions'	Model contains an intercept, linear term for each predictor, and all products of pairs of distinct predictors (no squared terms).
'purequadratic'	Model contains an intercept term and linear and squared terms for each predictor.
'quadratic'	Model contains an intercept term, linear and squared terms for each predictor, and all products of pairs of distinct predictors.
'polyijk'	Model is a polynomial with all terms up to degree i in the first predictor, degree j in the second predictor, and so on. Specify the maximum degree for each predictor by using numerals 0 through 9. The model contains interaction terms, but the degree of each interaction term does not exceed the maximum value of the specified degrees. For example, 'poly13' has an intercept and x_1 , x_2 , x_2^2 , x_2^3 , x_1*x_2 , and $x_1*x_2^2$ terms, where x_1 and x_2 are the first and second predictors, respectively.

- A t -by- $(p + 1)$ matrix, or a “Terms Matrix” on page 32-6585, specifying terms in the model, where t is the number of terms and p is the number of predictor variables, and +1 accounts for the response variable. A terms matrix is convenient when the number of predictors is large and you want to generate the terms programmatically.
- A character vector or string scalar representing a “Formula” on page 32-6586 in the form
'Y ~ terms',

where the terms are in “Wilkinson Notation” on page 32-6586.

If you want to specify the smallest or largest set of terms in the model that `stepwiselm` fits, use the `Lower` and `Upper` name-value pair arguments.

Data Types: `char` | `string` | `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example:

`'Criterion', 'aic', 'Distribution', 'poisson', 'Upper', 'interactions'` specifies Akaike Information Criterion as the criterion to add or remove variables to the model, Poisson distribution as the distribution of the response variable, and a model with all possible interactions as the largest model to consider as the fit.

BinomialSize — Number of trials for binomial distribution

1 (default) | scalar value | vector

Number of trials for binomial distribution, that is the sample size, specified as the comma-separated pair consisting of a scalar value or a vector of the same length as the response. This is the parameter `n` for the fitted binomial distribution. `BinomialSize` applies only when the `Distribution` parameter is `'binomial'`.

If `BinomialSize` is a scalar value, that means all observations have the same number of trials.

As an alternative to `BinomialSize`, you can specify the response as a two-column vector with counts in column 1 and `BinomialSize` in column 2.

Data Types: `single` | `double`

CategoricalVars — Categorical variable list

string array | cell array of character vectors | logical or numeric index vector

Categorical variable list, specified as the comma-separated pair consisting of `'CategoricalVars'` and either a string array or cell array of character vectors containing categorical variable names in the table or dataset array `tbl`, or a logical or numeric index vector indicating which columns are categorical.

- If data is in a table or dataset array `tbl`, then, by default, `stepwiseglm` treats all categorical values, logical values, character arrays, string arrays, and cell arrays of character vectors as categorical variables.
- If data is in matrix `X`, then the default value of `'CategoricalVars'` is an empty matrix `[]`. That is, no variable is categorical unless you specify it as categorical.

For example, you can specify the observations 2 and 3 out of 6 as categorical using either of the following examples.

Example: `'CategoricalVars',[2,3]`

Example: `'CategoricalVars',logical([0 1 1 0 0 0])`

Data Types: `single | double | logical | string | cell`

Criterion — Criterion to add or remove terms

`'Deviance'` (default) | `'sse'` | `'aic'` | `'bic'` | `'rsquared'` | `'adjrsquared'`

Criterion to add or remove terms, specified as the comma-separated pair consisting of `'Criterion'` and one of the following:

- `'Deviance'` — p -value for F or chi-squared test of the change in the deviance by adding or removing the term. F -test is for testing a single model. Chi-squared test is for comparing two different models.
- `'sse'` — p -value for an F -test of the change in the sum of squared error by adding or removing the term.
- `'aic'` — Change in the value of Akaike information criterion (AIC).
- `'bic'` — Change in the value of Bayesian information criterion (BIC).
- `'rsquared'` — Increase in the value of R^2 .
- `'adjrsquared'` — Increase in the value of adjusted R^2 .

Example: `'Criterion','bic'`

DispersionFlag — Indicator to compute dispersion parameter

`false` for `'binomial'` and `'poisson'` distributions (default) | `true`

Indicator to compute dispersion parameter for `'binomial'` and `'poisson'` distributions, specified as the comma-separated pair consisting of `'DispersionFlag'` and one of the following.

<code>true</code>	Estimate a dispersion parameter when computing standard errors
<code>false</code>	Default. Use the theoretical value when computing standard errors

The fitting function always estimates the dispersion for other distributions.

Example: `'DispersionFlag', true`

Distribution — Distribution of the response variable

`'normal' (default) | 'binomial' | 'poisson' | 'gamma' | 'inverse gaussian'`

Distribution of the response variable, specified as the comma-separated pair consisting of `'Distribution'` and one of the following.

<code>'normal'</code>	Normal distribution
<code>'binomial'</code>	Binomial distribution
<code>'poisson'</code>	Poisson distribution
<code>'gamma'</code>	Gamma distribution
<code>'inverse gaussian'</code>	Inverse Gaussian distribution

Example: `'Distribution', 'gamma'`

Exclude — Observations to exclude

logical or numeric index vector

Observations to exclude from the fit, specified as the comma-separated pair consisting of `'Exclude'` and a logical or numeric index vector indicating which observations to exclude from the fit.

For example, you can exclude observations 2 and 3 out of 6 using either of the following examples.

Example: `'Exclude', [2,3]`

Example: `'Exclude', logical([0 1 1 0 0 0])`

Data Types: `single | double | logical`

Intercept — Indicator for constant term

`true (default) | false`

Indicator for the constant term (intercept) in the fit, specified as the comma-separated pair consisting of 'Intercept' and either true to include or false to remove the constant term from the model.

Use 'Intercept' only when specifying the model using a character vector or string scalar, not a formula or matrix.

Example: 'Intercept', false

Link — Link function

canonical link function (default) | scalar value | structure

Link function to use in place of the canonical link function, specified as the comma-separated pair consisting of 'Link' and one of the following.

Link Function Name	Link Function	Mean (Inverse) Function
'identity'	$f(\mu) = \mu$	$\mu = Xb$
'log'	$f(\mu) = \log(\mu)$	$\mu = \exp(Xb)$
'logit'	$f(\mu) = \log(\mu/(1-\mu))$	$\mu = \exp(Xb) / (1 + \exp(Xb))$
'probit'	$f(\mu) = \Phi^{-1}(\mu)$	$\mu = \Phi(Xb)$
'comploglog'	$f(\mu) = \log(-\log(1 - \mu))$	$\mu = 1 - \exp(-\exp(Xb))$
'reciprocal'	$f(\mu) = 1/\mu$	$\mu = 1/(Xb)$
p (a number)	$f(\mu) = \mu^p$	$\mu = Xb^{1/p}$
S (a structure) with three fields. Each field holds a function handle that accepts a vector of inputs and returns a vector of the same size: <ul style="list-style-type: none"> • S.Link — The link function • S.Inverse — The inverse link function • S.Derivative — The derivative of the link function 	$f(\mu) = S.Link(\mu)$	$\mu = S.Inverse(Xb)$

The link function defines the relationship $f(\mu) = X*b$ between the mean response μ and the linear combination of predictors $X*b$.

For more information on the canonical link functions, see “Canonical Function” on page 32-6587.

Example: 'Link', 'probit'

Data Types: char | string | single | double | struct

Lower — Model specification describing terms that cannot be removed from model

'constant' (default) | character vector | string scalar | terms matrix

Model specification describing terms that cannot be removed from the model, specified as the comma-separated pair consisting of 'Lower' and one of the options for `modelspec` naming the model.

Example: 'Lower', 'linear'

NSteps — Maximum number of steps to take

no limit (default) | positive integer

Maximum number of steps to take, specified as the comma-separated pair consisting of 'NSteps' and a positive integer.

Example: 'NSteps', 5

Data Types: single | double

Offset — Offset variable

[] (default) | vector | character vector | string scalar

Offset variable in the fit, specified as the comma-separated pair consisting of 'Offset' and a vector or name of a variable with the same length as the response.

`stepwiseglm` uses `Offset` as an additional predictor, with a coefficient value fixed at 1.0. In other words, the formula for fitting is

$$f(\mu) \sim \text{Offset} + (\text{terms involving real predictors})$$

with the `Offset` predictor having coefficient 1.

For example, consider a Poisson regression model. Suppose the number of counts is known for theoretical reasons to be proportional to a predictor A. By using the log link

function and by specifying $\log(A)$ as an offset, you can force the model to satisfy this theoretical constraint.

Data Types: `single` | `double` | `char` | `string`

PEnter – Threshold for criterion to add term

scalar value

Threshold for the criterion to add a term, specified as the comma-separated pair consisting of 'PEnter' and a scalar value, as described in this table.

Criterion	Default Value	Decision
'Deviance'	0.05	If the p -value of F -statistic or chi-squared statistic is less than PEnter (p -value to enter), add the term to the model.
'SSE'	0.05	If the SSE of the model is less than PEnter, add the term to the model.
'AIC'	0	If the change in the AIC of the model is less than PEnter, add the term to the model.
'BIC'	0	If the change in the BIC of the model is less than PEnter, add the term to the model.
'Rsquared'	0.1	If the increase in the R-squared value of the model is greater than PEnter, add the term to the model.
'AdjRsquared'	0	If the increase in the adjusted R-squared value of the model is greater than PEnter, add the term to the model.

For more information, see the Criterion name-value pair argument.

Example: 'PEnter',0.075

PredictorVars — Predictor variables

string array | cell array of character vectors | logical or numeric index vector

Predictor variables to use in the fit, specified as the comma-separated pair consisting of 'PredictorVars' and either a string array or cell array of character vectors of the variable names in the table or dataset array `tbl`, or a logical or numeric index vector indicating which columns are predictor variables.

The string values or character vectors should be among the names in `tbl`, or the names you specify using the 'VarNames' name-value pair argument.

The default is all variables in `X`, or all variables in `tbl` except for `ResponseVar`.

For example, you can specify the second and third variables as the predictor variables using either of the following examples.

Example: 'PredictorVars',[2,3]

Example: 'PredictorVars',logical([0 1 1 0 0 0])

Data Types: single | double | logical | string | cell

PRemove — Threshold for criterion to remove term

scalar value

Threshold for the criterion to remove a term, specified as the comma-separated pair consisting of 'PRemove' and a scalar value, as described in this table.

Criterion	Default Value	Decision
'Deviance'	0.10	If the p -value of F -statistic or chi-squared statistic is greater than <code>PRemove</code> (p -value to remove), remove the term from the model.
'SSE'	0.10	If the p -value of the F statistic is greater than <code>PRemove</code> , remove the term from the model.

Criterion	Default Value	Decision
'AIC'	0.01	If the change in the AIC of the model is greater than PRemove, remove the term from the model.
'BIC'	0.01	If the change in the BIC of the model is greater than PRemove, remove the term from the model.
'Rsquared'	0.05	If the increase in the R-squared value of the model is less than PRemove, remove the term from the model.
'AdjRsquared'	-0.05	If the increase in the adjusted R-squared value of the model is less than PRemove, remove the term from the model.

At each step, the `stepwiseglm` function also checks whether a term is redundant (linearly dependent) with other terms in the current model. When any term is linearly dependent with other terms in the current model, the `stepwiseglm` function removes the redundant term, regardless of the criterion value.

For more information, see the `Criterion` name-value pair argument.

Example: `'PRemove', 0.05`

ResponseVar — Response variable

last column in `tbl` (default) | character vector or string scalar containing variable name | logical or numeric index vector

Response variable to use in the fit, specified as the comma-separated pair consisting of `'ResponseVar'` and either a character vector or string scalar containing the variable name in the table or dataset array `tbl`, or a logical or numeric index vector indicating which column is the response variable. You typically need to use `'ResponseVar'` when fitting a table or dataset array `tbl`.

For example, you can specify the fourth variable, say `yield`, as the response out of six variables, in one of the following ways.

Example: `'ResponseVar', 'yield'`

Example: `'ResponseVar', [4]`

Example: `'ResponseVar', logical([0 0 0 1 0 0])`

Data Types: `single | double | logical | char | string`

Upper — Model specification describing largest set of terms in fit

`'interactions'` (default) | character vector | string scalar | terms matrix

Model specification describing the largest set of terms in the fit, specified as the comma-separated pair consisting of `'Upper'` and one of the options for `modelspec` naming the model.

Example: `'Upper', 'quadratic'`

VarNames — Names of variables

`{'x1', 'x2', ..., 'xn', 'y'}` (default) | string array | cell array of character vectors

Names of variables, specified as the comma-separated pair consisting of `'VarNames'` and a string array or cell array of character vectors including the names for the columns of `X` first, and the name for the response variable `y` last.

`'VarNames'` is not applicable to variables in a table or dataset array, because those variables already have names.

For example, if in your data, horsepower, acceleration, and model year of the cars are the predictor variables, and miles per gallon (MPG) is the response variable, then you can name the variables as follows.

Example: `'VarNames', {'Horsepower', 'Acceleration', 'Model_Year', 'MPG'}`

Data Types: `string | cell`

Verbose — Control for display of information

`1` (default) | `0` | `2`

Control for the display of information, specified as the comma-separated pair consisting of `'Verbose'` and one of these values:

- `0` — Suppress all display.

- 1 — Display the action taken at each step.
- 2 — Display the evaluation process and the action taken at each step.

Example: 'Verbose', 2

Weights — Observation weights

`ones(n,1)` (default) | n -by-1 vector of nonnegative scalar values

Observation weights, specified as the comma-separated pair consisting of 'Weights' and an n -by-1 vector of nonnegative scalar values, where n is the number of observations.

Data Types: `single` | `double`

Output Arguments

mdl — Generalized linear model

`GeneralizedLinearModel` object

Generalized linear model representing a least-squares fit of the link of the response to the data, returned as a `GeneralizedLinearModel` object.

For properties and methods of the generalized linear model object, `mdl`, see the `GeneralizedLinearModel` class page.

Definitions

Terms Matrix

A terms matrix T is a t -by- $(p + 1)$ matrix specifying terms in a model, where t is the number of terms, p is the number of predictor variables, and $+1$ accounts for the response variable. The value of $T(i, j)$ is the exponent of variable j in term i .

For example, suppose that an input includes three predictor variables A, B, and C and the response variable Y in the order A, B, C, and Y. Each row of T represents one term:

- $[0 \ 0 \ 0 \ 0]$ — Constant term or intercept
- $[0 \ 1 \ 0 \ 0]$ — B; equivalently, $A^0 * B^1 * C^0$

- $[1 \ 0 \ 1 \ 0]$ — $A * C$
- $[2 \ 0 \ 0 \ 0]$ — A^2
- $[0 \ 1 \ 2 \ 0]$ — $B * (C^2)$

The 0 at the end of each term represents the response variable. In general, a column vector of zeros in a terms matrix represents the position of the response variable. If you have the predictor and response variables in a matrix and column vector, then you must include 0 for the response variable in the last column of each row.

Formula

A formula for model specification is a character vector or string scalar of the form ' $Y \sim terms$ '.

- Y is the response name.
- $terms$ represents the predictor terms in a model using Wilkinson notation.

For example:

- ' $Y \sim A + B + C$ ' specifies a three-variable linear model with intercept.
- ' $Y \sim A + B + C - 1$ ' specifies a three-variable linear model without intercept. Note that formulas include a constant (intercept) term by default. To exclude a constant term from the model, you must include -1 in the formula.

Wilkinson Notation

Wilkinson notation describes the terms present in a model. The notation relates to the terms present in a model, not to the multipliers (coefficients) of those terms.

Wilkinson notation uses these symbols:

- $+$ means include the next variable.
- $-$ means do not include the next variable.
- $:$ defines an interaction, which is a product of terms.
- $*$ defines an interaction and all lower-order terms.
- $^$ raises the predictor to a power, exactly as in $*$ repeated, so $^$ includes lower-order terms as well.

- () groups terms.

This table shows typical examples of Wilkinson notation.

Wilkinson Notation	Term in Standard Notation
1	Constant (intercept) term
A^k , where k is a positive integer	A, A^2, \dots, A^k
$A + B$	A, B
$A*B$	$A, B, A*B$
$A:B$	$A*B$ only
$-B$	Do not include B
$A*B + C$	$A, B, C, A*B$
$A + B + C + A:B$	$A, B, C, A*B$
$A*B*C - A:B:C$	$A, B, C, A*B, A*C, B*C$
$A*(B + C)$	$A, B, C, A*B, A*C$

Statistics and Machine Learning Toolbox notation always includes a constant term unless you explicitly remove the term using -1 .

For more details, see “Wilkinson Notation” on page 11-117.

Canonical Function

The default link function for a generalized linear model is the canonical link function.

Canonical Link Functions for Generalized Linear Models

Distribution	Link Function Name	Link Function	Mean (Inverse) Function
'normal'	'identity'	$f(\mu) = \mu$	$\mu = Xb$
'binomial'	'logit'	$f(\mu) = \log(\mu/(1-\mu))$	$\mu = \exp(Xb) / (1 + \exp(Xb))$
'poisson'	'log'	$f(\mu) = \log(\mu)$	$\mu = \exp(Xb)$
'gamma'	-1	$f(\mu) = 1/\mu$	$\mu = 1/(Xb)$
'inverse gaussian'	-2	$f(\mu) = 1/\mu^2$	$\mu = (Xb)^{-1/2}$

Tips

- The generalized linear model `mdl` is a standard linear model unless you specify otherwise with the `Distribution` name-value pair.
- For other methods such as `devianceTest`, or properties of the `GeneralizedLinearModel` object, see `GeneralizedLinearModel`.
- After training a model, you can generate C/C++ code that predicts responses for new data. Generating C/C++ code requires MATLAB Coder. For details, see “Introduction to Code Generation” on page 31-2.

Algorithms

- Stepwise regression is a systematic method for adding and removing terms from a linear or generalized linear model based on their statistical significance in explaining the response variable. The method begins with an initial model, specified using `modelspec`, and then compares the explanatory power of incrementally larger and smaller models.

The `stepwiseglm` function uses forward and backward stepwise regression to determine a final model. At each step, the function searches for terms to add to the model or remove from the model based on the value of the `'Criterion'` name-value pair argument.

The default value of `'Criterion'` for a linear regression model is `'sse'`. In this case, `stepwiselm` and `step` of `LinearModel` use the p -value of an F -statistic to test models with and without a potential term at each step. If a term is not currently in the model, the null hypothesis is that the term would have a zero coefficient if added to the model. If there is sufficient evidence to reject the null hypothesis, the function adds the term to the model. Conversely, if a term is currently in the model, the null hypothesis is that the term has a zero coefficient. If there is insufficient evidence to reject the null hypothesis, the function removes the term from the model.

Stepwise regression takes these steps when `'Criterion'` is `'sse'`:

- 1 Fit the initial model.
- 2 Examine a set of available terms not in the model. If any of the terms have p -values less than an entrance tolerance (that is, if it is unlikely a term would have a zero coefficient if added to the model), add the term with the smallest p -value and repeat this step; otherwise, go to step 3.

- 3 If any of the available terms in the model have p -values greater than an exit tolerance (that is, the hypothesis of a zero coefficient cannot be rejected), remove the term with the largest p -value and return to step 2; otherwise, end the process.

At any stage, the function will not add a higher-order term if the model does not also include all lower-order terms that are subsets of the higher-order term. For example, the function will not try to add the term $X1:X2^2$ unless both $X1$ and $X2^2$ are already in the model. Similarly, the function will not remove lower-order terms that are subsets of higher-order terms that remain in the model. For example, the function will not try to remove $X1$ or $X2^2$ if $X1:X2^2$ remains in the model.

The default value of 'Criterion' for a generalized linear model is 'Deviance'. `stepwiseglm` and `step` of `GeneralizedLinearModel` follow a similar procedure for adding or removing terms.

You can specify other criteria by using the 'Criterion' name-value pair argument. For example, you can specify the change in the value of the Akaike information criterion, Bayesian information criterion, R-squared, or adjusted R-squared as the criterion to add or remove terms.

Depending on the terms included in the initial model, and the order in which the function adds and removes terms, the function might build different models from the same set of potential terms. The function terminates when no single step improves the model. However, a different initial model or a different sequence of steps does not guarantee a better fit. In this sense, stepwise models are locally optimal, but might not be globally optimal.

- `stepwiseglm` treats a categorical predictor as follows:
 - A model with a categorical predictor that has L levels (categories) includes $L - 1$ indicator variables. The model uses the first category as a reference level, so it does not include the indicator variable for the reference level. If the data type of the categorical predictor is `categorical`, then you can check the order of categories by using `categories` and reorder the categories by using `reordercats` to customize the reference level.
 - `stepwiseglm` treats the group of $L - 1$ indicator variables as a single variable. If you want to treat the indicator variables as distinct predictor variables, create indicator variables manually by using `dummyvar`. Then use the indicator variables, except the one corresponding to the reference level of the categorical variable, when you fit a model. For the categorical predictor X , if you specify all columns of `dummyvar(X)` and an intercept term as predictors, then the design matrix becomes rank deficient.

- Interaction terms between a continuous predictor and a categorical predictor with L levels consist of the element-wise product of the $L - 1$ indicator variables with the continuous predictor.
- Interaction terms between two categorical predictors with L and M levels consist of the $(L - 1)*(M - 1)$ indicator variables to include all possible combinations of the two categorical predictor levels.
- You cannot specify higher-order terms for a categorical predictor because the square of an indicator is equal to itself.

Therefore, if `stepwiseglm` adds or removes a categorical predictor, the function actually adds or removes the group of indicator variables in one step. Similarly, if `stepwiseglm` adds or removes an interaction term with a categorical predictor, the function actually adds or removes the group of interaction terms including the categorical predictor.

- `stepwiseglm` considers `NaN`, `' '` (empty character vector), `""` (empty string), `<missing>`, and `<undefined>` values in `tbl`, `X`, and `Y` to be missing values. `stepwiseglm` does not use observations with missing values in the fit. The `ObservationInfo` property of a fitted model indicates whether or not `stepwiseglm` uses each observation in the fit.

Alternatives

- Use `fitglm` to create a model with a fixed specification. Use `step`, `addTerms`, or `removeTerms` to adjust a fitted model.

Introduced in R2013b

stepwiselm

Fit linear regression model using stepwise regression

Syntax

```
mdl = stepwiselm(tbl)
mdl = stepwiselm(X,y)
mdl = stepwiselm( ___,modelspec)
mdl = stepwiselm( ___,Name,Value)
```

Description

`mdl = stepwiselm(tbl)` creates a linear model for the variables in the table or dataset array `tbl` using stepwise regression to add or remove predictors, starting from a constant model. `stepwiselm` uses the last variable of `tbl` as the response variable. `stepwiselm` uses forward and backward stepwise regression to determine a final model. At each step, the function searches for terms to add the model to or remove from the model, based on the value of the 'Criterion' argument.

`mdl = stepwiselm(X,y)` creates a linear model of the responses `y` to the predictor variables in the data matrix `X`.

`mdl = stepwiselm(___,modelspec)` specifies the starting model `modelspec` using any of the input argument combinations in previous syntaxes.

`mdl = stepwiselm(___,Name,Value)` specifies additional options using one or more name-value pair arguments. For example, you can specify the categorical variables, the smallest or largest set of terms to use in the model, the maximum number of steps to take, or the criterion that `stepwiselm` uses to add or remove terms.

Examples

Fit Linear Model Using Stepwise Regression

Load the `hald` data set, which measures the effect of cement composition on its hardening heat.

```
load hald
```

This data set includes the variables `ingredients` and `heat`. The matrix `ingredients` contains the percent composition of four chemicals present in the cement. The vector `heat` contains the values for the heat hardening after 180 days for each cement sample.

Fit a stepwise linear regression model to the data. Specify 0.06 as the threshold for the criterion to add a term to the model.

```
mdl = stepwiselm(ingredients,heat,'PEnter',0.06)
```

1. Adding x4, FStat = 22.7985, pValue = 0.000576232
2. Adding x1, FStat = 108.2239, pValue = 1.105281e-06
3. Adding x2, FStat = 5.0259, pValue = 0.051687
4. Removing x4, FStat = 1.8633, pValue = 0.2054

```
mdl =  
Linear regression model:  
y ~ 1 + x1 + x2
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	52.577	2.2862	22.998	5.4566e-10
x1	1.4683	0.1213	12.105	2.6922e-07
x2	0.66225	0.045855	14.442	5.029e-08

Number of observations: 13, Error degrees of freedom: 10

Root Mean Squared Error: 2.41

R-squared: 0.979, Adjusted R-Squared: 0.974

F-statistic vs. constant model: 230, p-value = 4.41e-09

By default, the starting model is a constant model. `stepwiselm` performs forward selection and adds the `x4`, `x1`, and `x2` terms (in that order), because the corresponding p -values are less than the `PEnter` value of 0.06. `stepwiselm` then uses backward elimination and removes `x4` from the model because, once `x2` is in the model, the p -value of `x4` is greater than the default value of `PRemove`, 0.1.

Stepwise Regression Using Specified Model Formula and Variables

Perform stepwise regression using variables stored in a dataset array. Specify the starting model using Wilkinson notation, and identify the response and predictor variables using optional arguments.

Load the sample data.

```
load hospital
```

The hospital dataset array includes the gender, age, weight, and smoking status of patients.

Fit a linear model with a starting model of a constant term and Smoker as the predictor variable. Specify the response variable, `Weight`, and categorical predictor variables, `Sex`, `Age`, and `Smoker`.

```
mdl = stepwiselm(hospital, 'Weight~1+Smoker', ...
    'ResponseVar', 'Weight', 'PredictorVars', {'Sex', 'Age', 'Smoker'}, ...
    'CategoricalVar', {'Sex', 'Smoker'})
```

1. Adding Sex, FStat = 770.0158, pValue = 6.262758e-48
2. Removing Smoker, FStat = 0.21224, pValue = 0.64605

```
mdl =
Linear regression model:
    Weight ~ 1 + Sex
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	130.47	1.1995	108.77	5.2762e-104
Sex_Male	50.06	1.7496	28.612	2.2464e-49

```
Number of observations: 100, Error degrees of freedom: 98
Root Mean Squared Error: 8.73
R-squared: 0.893, Adjusted R-Squared: 0.892
F-statistic vs. constant model: 819, p-value = 2.25e-49
```

At each step, `stepwiselm` searches for terms to add and remove. At first step, stepwise algorithm adds `Sex` to the model with a *p*-value of 6.26e-48. Then, removes `Smoker` from

the model, since given Sex in the model, the variable Smoker becomes redundant. `stepwiselm` only includes Sex in the final linear model. The weight of the patients do not seem to differ significantly according to age or the status of smoking.

Stepwise Regression Using Terms Matrix

Load a sample data set and define the matrix of predictors.

```
load carsmall
X = [Acceleration,Weight];
```

Define the starting model and the upper model using terms matrices.

```
T_starting = [0 0 0] % a constant model
```

```
T_starting = 1x3
    0     0     0
```

```
T_upper = [0 0 0;1 0 0;0 1 0;1 1 0] % a linear model with interactions
```

```
T_upper = 4x3
    0     0     0
    1     0     0
    0     1     0
    1     1     0
```

Create a linear regression model using stepwise regression. Specify the starting model and the upper bound of the model using the terms matrices, and specify 'Verbose' as 2 to display the evaluation process and the decision taken at each step.

```
mdl = stepwiselm(X,MPG,T_starting,'upper',T_upper,'Verbose',2)
```

```
pValue for adding x1 is 4.0973e-06
pValue for adding x2 is 1.6434e-28
1. Adding x2, FStat = 259.3087, pValue = 1.643351e-28
pValue for adding x1 is 0.18493
No candidate terms to remove
```

```
mdl =  
Linear regression model:  
  y ~ 1 + x2  
  
Estimated Coefficients:  
              Estimate          SE          tStat          pValue  
-----  
(Intercept)    49.238         1.6411         30.002      2.7015e-49  
x2             -0.0086119      0.0005348      -16.103      1.6434e-28
```

```
Number of observations: 94, Error degrees of freedom: 92  
Root Mean Squared Error: 4.13  
R-squared: 0.738, Adjusted R-Squared: 0.735  
F-statistic vs. constant model: 259, p-value = 1.64e-28
```

Stepwise Regression with Categorical Predictor

Fit a linear regression model with a categorical predictor using stepwise regression. `stepwiselm` adds or removes a group of indicator variables in one step to add or removes a categorical predictor. This example also shows how to create indicator variables manually and pass them to `stepwiselm` so that `stepwiselm` treats each indicator variable as a separate predictor.

Load the `carsmall` data set, and create a table using the `Weight`, `Model_Year`, and `MPG` variables.

```
load carsmall  
Year = categorical(Model_Year);  
tbl1 = table(MPG,Weight,Year);
```

Fit a linear regression model of `MPG` using stepwise regression. Specify the starting model as a function of `Weight`. Set the upper bound of the model to `'poly21'`, meaning the model can include (at most) a constant and the terms `Weight`, `Weight^2`, `Year`, and `Weight*Year`. Specify `'Verbose'` as 2 to display the evaluation process and the decision taken at each step.

```
mdl1 = stepwiselm(tbl1, 'MPG ~ Weight', 'Upper', 'poly21', 'Verbose', 2)  
  
pValue for adding Year is 8.2284e-15  
pValue for adding Weight^2 is 0.15454
```

1. Adding Year, FStat = 47.5136, pValue = 8.22836e-15
 pValue for adding Weight^2 is 0.0022303
 pValue for adding Weight:Year is 0.0071637
2. Adding Weight^2, FStat = 9.9164, pValue = 0.0022303
 pValue for adding Weight:Year is 0.19519
 pValue for removing Year is 2.9042e-16

mdl1 =

Linear regression model:

MPG ~ 1 + Weight + Year + Weight^2

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	54.206	4.7117	11.505	2.6648e-19
Weight	-0.016404	0.0031249	-5.2493	1.0283e-06
Year_76	2.0887	0.71491	2.9215	0.0044137
Year_82	8.1864	0.81531	10.041	2.6364e-16
Weight^2	1.5573e-06	4.9454e-07	3.149	0.0022303

Number of observations: 94, Error degrees of freedom: 89

Root Mean Squared Error: 2.78

R-squared: 0.885, Adjusted R-Squared: 0.88

F-statistic vs. constant model: 172, p-value = 5.52e-41

stepwiselm creates two indicator variables, Year_76 and Year_82, because Year includes three distinct values.

Because 'Verbose' is 2, stepwiselm displays the evaluation process:

- stepwiselm creates a model as a function of Weight.
- stepwiselm computes the p -values for adding Year or Weight^2. The p -value for Year is less than both the p -value for Weight^2 and the default threshold value of 0.05; therefore, stepwiselm adds Year to the model.
- stepwiselm computes the p -values for adding Weight:Year or Weight^2. Because the p -value for Weight^2 is less than the p -value for Weight:Year, the stepwiselm function adds Weight^2 to the model.
- After adding the quadratic term, stepwiselm computes the p -value for adding Weight:Year again, but the p -value is greater than the threshold value. Therefore, stepwiselm does not add the term to the model. stepwiselm does not examine

adding Weight^3 because of the upper bound specified by the 'Upper' name-value pair argument.

- `stepwiselm` looks for terms to remove. `stepwiselm` already examined Weight^2 , so it computes only the p -value for removing `Year`. Because the p -value is less than the default threshold value of 0.10, `stepwiselm` does not remove the term.
- Although the maximum allowed number of steps is 5, `stepwiselm` terminates the process after two steps because the model does not improve by adding or removing a term.

`stepwiselm` treats the two indicator variables as one predictor variable and adds `Year` in one step. To treat the two indicator variables as two distinct predictor variables, use `dummyvar` to create separate categorical variables.

```
temp_Year = dummyvar(Year);
Year_76 = logical(temp_Year(:,2));
Year_82 = logical(temp_Year(:,3));
```

Create a table containing `MPG`, `Weight`, `Year_76`, and `Year_82`.

```
tbl2 = table(MPG,Weight,Year_76,Year_82);
```

Create a stepwise linear regression model from the same starting model used for `mdl1`.

```
mdl2 = stepwiselm(tbl2,'MPG ~ Weight','Upper','poly211')
```

1. Adding `Year_82`, $F\text{Stat} = 83.1956$, $p\text{Value} = 1.76163\text{e-}14$
2. Adding `Weight:Year_82`, $F\text{Stat} = 8.0641$, $p\text{Value} = 0.0055818$
3. Adding `Year_76`, $F\text{Stat} = 8.1284$, $p\text{Value} = 0.0054157$

```
mdl2 =
Linear regression model:
    MPG ~ 1 + Year_76 + Weight*Year_82
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	38.844	1.5294	25.397	1.503e-42
Weight	-0.006272	0.00042673	-14.698	1.5622e-25
Year_76_1	2.0395	0.71537	2.851	0.0054157
Year_82_1	19.607	3.8731	5.0623	2.2163e-06
Weight:Year_82_1	-0.0046268	0.0014979	-3.0888	0.0026806

Number of observations: 94, Error degrees of freedom: 89
Root Mean Squared Error: 2.79
R-squared: 0.885, Adjusted R-Squared: 0.88
F-statistic vs. constant model: 171, p-value = 6.54e-41

The model `mdl2` includes the interaction term `Weight:Year_82_1` instead of `Weight^2`, the term included in `mdl1`.

Input Arguments

tbl — Input data

table | dataset array

Input data, specified as a table or dataset array. When `modelspec` is a formula, the formula specifies the predictor and response variables. Otherwise, if you do not specify the predictor and response variables, the last variable in `tbl` is the response variable and the others are the predictor variables by default.

The predictor variables can be numeric, logical, categorical, character, or string. The response variable must be numeric or logical.

To set a different column as the response variable, use the `ResponseVar` name-value pair argument. To use a subset of the columns as predictors, use the `PredictorVars` name-value pair argument.

X — Predictor variables

matrix

Predictor variables, specified as an n -by- p matrix, where n is the number of observations and p is the number of predictor variables. Each column of `X` represents one variable, and each row represents one observation.

By default, there is a constant term in the model, unless you explicitly remove it, so do not include a column of 1s in `X`.

Data Types: single | double

y — Response variable

vector

Response variable, specified as an n -by-1 vector, where n is the number of observations. Each entry in y is the response for the corresponding row of X .

Data Types: single | double | logical

modelspec — Starting model

'constant' (default) | character vector or string scalar specifying the model | t -by- $(p+1)$ terms matrix | character vector or string scalar of the form 'Y ~ terms'

Starting model for the stepwise regression, specified as one of the following:

- A character vector or string scalar naming the model.

Value	Model Type
'constant'	Model contains only a constant (intercept) term.
'linear'	Model contains an intercept and linear term for each predictor.
'interactions'	Model contains an intercept, linear term for each predictor, and all products of pairs of distinct predictors (no squared terms).
'purequadratic'	Model contains an intercept term and linear and squared terms for each predictor.
'quadratic'	Model contains an intercept term, linear and squared terms for each predictor, and all products of pairs of distinct predictors.
'polyijk'	Model is a polynomial with all terms up to degree i in the first predictor, degree j in the second predictor, and so on. Specify the maximum degree for each predictor by using numerals 0 through 9. The model contains interaction terms, but the degree of each interaction term does not exceed the maximum value of the specified degrees. For example, 'poly13' has an intercept and x_1 , x_2 , x_2^2 , x_2^3 , x_1*x_2 , and $x_1*x_2^2$ terms, where x_1 and x_2 are the first and second predictors, respectively.

- A t -by- $(p + 1)$ matrix, or a “Terms Matrix” on page 32-6607, specifying terms in the model, where t is the number of terms and p is the number of predictor variables, and +1 accounts for the response variable. A terms matrix is convenient when the number of predictors is large and you want to generate the terms programmatically.

- A character vector or string scalar representing a “Formula” on page 32-6608 in the form
`'Y ~ terms'`,
 where the `terms` are in “Wilkinson Notation” on page 32-6608.

If you want to specify the smallest or largest set of terms in the model that `stepwiselm` fits, use the `Lower` and `Upper` name-value pair arguments.

Data Types: `char` | `string` | `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'Criterion', 'aic', 'Upper', 'interactions', 'Verbose', 1` instructs `stepwiselm` to use the Akaike information criterion, display the action it takes at each step, and include at most the interaction terms in the model.

CategoricalVars — Categorical variable list

string array | cell array of character vectors | logical or numeric index vector

Categorical variable list, specified as the comma-separated pair consisting of `'CategoricalVars'` and either a string array or cell array of character vectors containing categorical variable names in the table or dataset array `tbl`, or a logical or numeric index vector indicating which columns are categorical.

- If data is in a table or dataset array `tbl`, then, by default, `stepwiselm` treats all categorical values, logical values, character arrays, string arrays, and cell arrays of character vectors as categorical variables.
- If data is in matrix `X`, then the default value of `'CategoricalVars'` is an empty matrix `[]`. That is, no variable is categorical unless you specify it as categorical.

For example, you can specify the observations 2 and 3 out of 6 as categorical using either of the following examples.

Example: `'CategoricalVars', [2,3]`

Example: `'CategoricalVars', logical([0 1 1 0 0 0])`

Data Types: `single` | `double` | `logical` | `string` | `cell`

Criterion — Criterion to add or remove terms`'sse' (default) | 'aic' | 'bic' | 'rsquared' | 'adjrsquared'`

Criterion to add or remove terms, specified as the comma-separated pair consisting of 'Criterion' and one of these values:

- 'sse' — p -value for an F -test of the change in the sum of squared error that results from adding or removing the term
- 'aic' — Change in the value of Akaike information criterion (AIC)
- 'bic' — Change in the value of Bayesian information criterion (BIC)
- 'rsquared' — Increase in the value of R^2
- 'adjrsquared' — Increase in the value of adjusted R^2

Example: 'Criterion', 'bic'

Exclude — Observations to exclude`logical or numeric index vector`

Observations to exclude from the fit, specified as the comma-separated pair consisting of 'Exclude' and a logical or numeric index vector indicating which observations to exclude from the fit.

For example, you can exclude observations 2 and 3 out of 6 using either of the following examples.

Example: 'Exclude', [2,3]

Example: 'Exclude', logical([0 1 1 0 0 0])

Data Types: single | double | logical

Intercept — Indicator for constant term`true (default) | false`

Indicator for the constant term (intercept) in the fit, specified as the comma-separated pair consisting of 'Intercept' and either `true` to include or `false` to remove the constant term from the model.

Use 'Intercept' only when specifying the model using a character vector or string scalar, not a formula or matrix.

Example: 'Intercept', false

Lower — Model specification describing terms that cannot be removed from model

'constant' (default) | character vector | string scalar | terms matrix

Model specification describing terms that cannot be removed from the model, specified as the comma-separated pair consisting of 'Lower' and one of the options for `modelSpec` naming the model.

Example: 'Lower', 'linear'

NSteps — Maximum number of steps to take

no limit (default) | positive integer

Maximum number of steps to take, specified as the comma-separated pair consisting of 'NSteps' and a positive integer.

Example: 'NSteps', 5

Data Types: single | double

PEnter — Threshold for criterion to add term

scalar value

Threshold for the criterion to add a term, specified as the comma-separated pair consisting of 'PEnter' and a scalar value, as described in this table.

Criterion	Default Value	Decision
'SSE'	0.05	If the p -value of the F -statistic is less than PEnter (p -value to enter), add the term to the model.
'AIC'	0	If the change in the AIC of the model is less than PEnter, add the term to the model.
'BIC'	0	If the change in the BIC of the model is less than PEnter, add the term to the model.

Criterion	Default Value	Decision
'Rsquared'	0.1	If the increase in the R-squared value of the model is greater than PEnter, add the term to the model.
'AdjRsquared'	0	If the increase in the adjusted R-squared value of the model is greater than PEnter, add the term to the model.

For more information, see the Criterion name-value pair argument.

Example: 'PEnter', 0.075

PredictorVars — Predictor variables

string array | cell array of character vectors | logical or numeric index vector

Predictor variables to use in the fit, specified as the comma-separated pair consisting of 'PredictorVars' and either a string array or cell array of character vectors of the variable names in the table or dataset array `tbl`, or a logical or numeric index vector indicating which columns are predictor variables.

The string values or character vectors should be among the names in `tbl`, or the names you specify using the 'VarNames' name-value pair argument.

The default is all variables in `X`, or all variables in `tbl` except for `ResponseVar`.

For example, you can specify the second and third variables as the predictor variables using either of the following examples.

Example: 'PredictorVars', [2,3]

Example: 'PredictorVars', logical([0 1 1 0 0 0])

Data Types: single | double | logical | string | cell

PRemove — Threshold for criterion to remove term

scalar value

Threshold for the criterion to remove a term, specified as the comma-separated pair consisting of 'PRemove' and a scalar value, as described in this table.

Criterion	Default Value	Decision
'SSE'	0.10	If the p -value of the F -statistic is greater than <code>PRemove</code> (p -value to remove), remove the term from the model.
'AIC'	0.01	If the change in the AIC of the model is greater than <code>PRemove</code> , remove the term from the model.
'BIC'	0.01	If the change in the BIC of the model is greater than <code>PRemove</code> , remove the term from the model.
'Rsquared'	0.05	If the increase in the R-squared value of the model is less than <code>PRemove</code> , remove the term from the model.
'AdjRsquared'	-0.05	If the increase in the adjusted R-squared value of the model is less than <code>PRemove</code> , remove the term from the model.

At each step, the `stepwiselm` function also checks whether a term is redundant (linearly dependent) with other terms in the current model. When any term is linearly dependent with other terms in the current model, the `stepwiselm` function removes the redundant term, regardless of the criterion value.

For more information, see the `Criterion` name-value pair argument.

Example: `'PRemove', 0.05`

ResponseVar — Response variable

last column in `tbl` (default) | character vector or string scalar containing variable name | logical or numeric index vector

Response variable to use in the fit, specified as the comma-separated pair consisting of 'ResponseVar' and either a character vector or string scalar containing the variable name in the table or dataset array `tbl`, or a logical or numeric index vector indicating which column is the response variable. You typically need to use 'ResponseVar' when fitting a table or dataset array `tbl`.

For example, you can specify the fourth variable, say `yield`, as the response out of six variables, in one of the following ways.

Example: `'ResponseVar','yield'`

Example: `'ResponseVar',[4]`

Example: `'ResponseVar',logical([0 0 0 1 0 0])`

Data Types: `single` | `double` | `logical` | `char` | `string`

Upper — Model specification describing largest set of terms in fit

`'interactions'` (default) | character vector | string scalar | terms matrix

Model specification describing the largest set of terms in the fit, specified as the comma-separated pair consisting of 'Upper' and one of the options for `modelspec` naming the model.

Example: `'Upper','quadratic'`

VarNames — Names of variables

`{'x1','x2',..., 'xn','y'}` (default) | string array | cell array of character vectors

Names of variables, specified as the comma-separated pair consisting of 'VarNames' and a string array or cell array of character vectors including the names for the columns of `X` first, and the name for the response variable `y` last.

'VarNames' is not applicable to variables in a table or dataset array, because those variables already have names.

For example, if in your data, horsepower, acceleration, and model year of the cars are the predictor variables, and miles per gallon (MPG) is the response variable, then you can name the variables as follows.

Example: `'VarNames',{'Horsepower','Acceleration','Model_Year','MPG'}`

Data Types: `string` | `cell`

Verbose — Control for display of information

`1` (default) | `0` | `2`

Control for the display of information, specified as the comma-separated pair consisting of 'Verbose' and one of these values:

- 0 — Suppress all display.
- 1 — Display the action taken at each step.
- 2 — Display the evaluation process and the action taken at each step.

Example: 'Verbose',2

Weights — Observation weights

ones(n,1) (default) | *n*-by-1 vector of nonnegative scalar values

Observation weights, specified as the comma-separated pair consisting of 'Weights' and an *n*-by-1 vector of nonnegative scalar values, where *n* is the number of observations.

Data Types: single | double

Output Arguments

mdl — Linear model

LinearModel object

Linear model representing a least-squares fit of the response to the data, returned as a LinearModel object.

For the properties and methods of the linear model object, mdl, see the LinearModel class page.

Definitions

Terms Matrix

A terms matrix *T* is a *t*-by-(*p* + 1) matrix specifying terms in a model, where *t* is the number of terms, *p* is the number of predictor variables, and +1 accounts for the response variable. The value of *T*(*i*, *j*) is the exponent of variable *j* in term *i*.

For example, suppose that an input includes three predictor variables *A*, *B*, and *C* and the response variable *Y* in the order *A*, *B*, *C*, and *Y*. Each row of *T* represents one term:

- $[0\ 0\ 0\ 0]$ — Constant term or intercept
- $[0\ 1\ 0\ 0]$ — B; equivalently, $A^0 * B^1 * C^0$
- $[1\ 0\ 1\ 0]$ — $A*C$
- $[2\ 0\ 0\ 0]$ — A^2
- $[0\ 1\ 2\ 0]$ — $B*(C^2)$

The 0 at the end of each term represents the response variable. In general, a column vector of zeros in a terms matrix represents the position of the response variable. If you have the predictor and response variables in a matrix and column vector, then you must include 0 for the response variable in the last column of each row.

Formula

A formula for model specification is a character vector or string scalar of the form ' $Y \sim terms$ '.

- Y is the response name.
- $terms$ represents the predictor terms in a model using Wilkinson notation.

For example:

- ' $Y \sim A + B + C$ ' specifies a three-variable linear model with intercept.
- ' $Y \sim A + B + C - 1$ ' specifies a three-variable linear model without intercept. Note that formulas include a constant (intercept) term by default. To exclude a constant term from the model, you must include -1 in the formula.

Wilkinson Notation

Wilkinson notation describes the terms present in a model. The notation relates to the terms present in a model, not to the multipliers (coefficients) of those terms.

Wilkinson notation uses these symbols:

- $+$ means include the next variable.
- $-$ means do not include the next variable.
- $:$ defines an interaction, which is a product of terms.
- $*$ defines an interaction and all lower-order terms.

- \wedge raises the predictor to a power, exactly as in $*$ repeated, so \wedge includes lower-order terms as well.
- $()$ groups terms.

This table shows typical examples of Wilkinson notation.

Wilkinson Notation	Term in Standard Notation
1	Constant (intercept) term
A^k , where k is a positive integer	A, A^2, \dots, A^k
$A + B$	A, B
$A*B$	$A, B, A*B$
$A:B$	$A*B$ only
$-B$	Do not include B
$A*B + C$	$A, B, C, A*B$
$A + B + C + A:B$	$A, B, C, A*B$
$A*B*C - A:B:C$	$A, B, C, A*B, A*C, B*C$
$A*(B + C)$	$A, B, C, A*B, A*C$

Statistics and Machine Learning Toolbox notation always includes a constant term unless you explicitly remove the term using -1 .

For more details, see “Wilkinson Notation” on page 11-117.

Tips

- You cannot use robust regression with stepwise regression. Check your data for outliers before using `stepwiselm`.
- For other methods such as `anova`, or properties of the `LinearModel` object, see `LinearModel`.
- After training a model, you can generate C/C++ code that predicts responses for new data. Generating C/C++ code requires MATLAB Coder. For details, see “Introduction to Code Generation” on page 31-2.

Algorithms

- Stepwise regression is a systematic method for adding and removing terms from a linear or generalized linear model based on their statistical significance in explaining the response variable. The method begins with an initial model, specified using `modelspec`, and then compares the explanatory power of incrementally larger and smaller models.

The `stepwiselm` function uses forward and backward stepwise regression to determine a final model. At each step, the function searches for terms to add to the model or remove from the model based on the value of the 'Criterion' name-value pair argument.

The default value of 'Criterion' for a linear regression model is 'sse'. In this case, `stepwiselm` and `step` of `LinearModel` use the p -value of an F -statistic to test models with and without a potential term at each step. If a term is not currently in the model, the null hypothesis is that the term would have a zero coefficient if added to the model. If there is sufficient evidence to reject the null hypothesis, the function adds the term to the model. Conversely, if a term is currently in the model, the null hypothesis is that the term has a zero coefficient. If there is insufficient evidence to reject the null hypothesis, the function removes the term from the model.

Stepwise regression takes these steps when 'Criterion' is 'sse':

- 1 Fit the initial model.
- 2 Examine a set of available terms not in the model. If any of the terms have p -values less than an entrance tolerance (that is, if it is unlikely a term would have a zero coefficient if added to the model), add the term with the smallest p -value and repeat this step; otherwise, go to step 3.
- 3 If any of the available terms in the model have p -values greater than an exit tolerance (that is, the hypothesis of a zero coefficient cannot be rejected), remove the term with the largest p -value and return to step 2; otherwise, end the process.
