statarray = grpstats(dsa, 'Smoker', 'mean', 'DataVars', {'Age', 'Weight'})
```

```
statarray =
```

	Smoker	GroupCount	mean_Age	mean_Weight
0	false	66	37.97	149.91

```
1 true 34 38.882 161.94
```

In this case, not all variables in `dsa` (excluding the grouping variable, `Smoker`) are numeric or logical arrays; the variable `Sex` is a nominal array. When not all variables in the input dataset array are numeric or logical arrays, you must specify the variables for which you want to calculate summary statistics using `DataVars`.

Compute the minimum and maximum weight, grouped by the combinations of values in `Sex` and `Smoker`.

```
statarray = grpstats(dsa,{'Sex','Smoker'},{'min','max'},...  
                    'DataVars','Weight')
```

```
statarray =
```

	Sex	Smoker	GroupCount	min_Weight	max_Weight
Female_0	Female	false	40	111	147
Female_1	Female	true	13	115	146
Male_0	Male	false	26	158	194
Male_1	Male	true	21	164	202

There are two unique values in `Smoker` and two levels in `Sex`, for a total of four possible combinations of values: Female Nonsmoker (`Female_0`), Female Smoker (`Female_1`), Male Nonsmoker (`Male_0`), and Male Smoker (`Male_1`).

Specify the names for the columns in the output.

```
statarray = grpstats(dsa,{'Sex','Smoker'},{'min','max'},...  
                    'DataVars','Weight','VarNames',{'Gender','Smoker'},...  
                    'GroupCount','LowestWeight','HighestWeight'})
```

```
statarray =
```

	Gender	Smoker	GroupCount	LowestWeight	HighestWeight
Female_0	Female	false	40	111	147
Female_1	Female	true	13	115	146
Male_0	Male	false	26	158	194
Male_1	Male	true	21	164	202

Summary Statistics for a Dataset Array Without Grouping

Load the sample data.

```
load('hospital')
```

The dataset array `hospital` has 100 observations and 7 variables.

Create a dataset array with only the variables `Age`, `Weight`, and `Smoker`.

```
dsa = hospital(:, {'Age', 'Weight', 'Smoker'});
```

The variables `Age` and `Weight` have numeric values, and `Smoker` has logical values.

Compute the mean, minimum, and maximum for the numeric and logical arrays, `Age`, `Weight`, and `Smoker`, with no grouping.

```
statarray = grpstats(dsa, [], {'mean', 'min', 'max'})
```

```
statarray =
    All      GroupCount      mean_Age      min_Age      max_Age      mean_Weight
    All      min_Weight      max_Weight      mean_Smoker      min_Smoker      max_Smoker
    All      111            202            0.34           false           true
```

The observation name `All` indicates that all observations in `dsa` were used to compute the summary statistics.

Group Means for a Matrix Using One or More Grouping Variables

Load the sample data.

```
load('carsmall')
```

All variables are measured for 100 cars. `Origin` is the country of origin for each car (France, Germany, Italy, Japan, Sweden, or USA). `Cylinders` has three unique values, 4, 6, and 8, indicating the number of cylinders in each car.

Calculate the mean acceleration, grouped by country of origin.

```
means = grpstats(Acceleration,Origin)
```

```
means = 6×1
```

```
14.4377  
18.0500  
15.8867  
16.3778  
16.6000  
15.5000
```

`means` is a 6-by-1 vector of mean accelerations, where each value corresponds to a country of origin.

Calculate the mean acceleration, grouped by both country of origin and number of cylinders.

```
means = grpstats(Acceleration,{Origin,Cylinders})
```

```
means = 10×1
```

```
17.0818  
16.5267  
11.6406  
18.0500  
15.9143  
15.5000  
16.3375  
16.7000  
16.6000  
15.5000
```

There are 18 possible combinations of grouping variable values because `Origin` has 6 unique values and `Cylinders` has 3 unique values. Only 10 of the possible combinations appear in the data, so `means` is a 10-by-1 vector of group means corresponding to the observed combinations of values.

Return the group names along with the mean acceleration for each group.

```
[means,grps] = grpstats(Acceleration,{Origin,Cylinders},{'mean','gname'})
```

```
means = 10×1
```

```

17.0818
16.5267
11.6406
18.0500
15.9143
15.5000
16.3375
16.7000
16.6000
15.5000

```

```

grps = 10x2 cell array
    {'USA'  }    {'4' }
    {'USA'  }    {'6' }
    {'USA'  }    {'8' }
    {'France'}    {'4' }
    {'Japan' }    {'4' }
    {'Japan' }    {'6' }
    {'Germany'}    {'4' }
    {'Germany'}    {'6' }
    {'Sweden' }    {'4' }
    {'Italy'  }    {'4' }

```

The output `grps` shows the 10 observed combinations of grouping variable values. For example, the mean acceleration of 4-cylinder cars made in France is 18.05.

Multiple Summary Statistics for a Matrix Organized by Group

Load the sample data.

```
load carsmall
```

The variable `Acceleration` was measured for 100 cars. The variable `Origin` is the country of origin for each car (France, Germany, Italy, Japan, Sweden, or USA).

Return the minimum and maximum acceleration grouped by country of origin.

```
[grpMin,grpMax,grp] = grpstats(Acceleration,Origin,{'min','max','gname'})
```

```
grpMin = 6x1
```

```
8.0000
15.3000
13.9000
12.2000
15.7000
15.5000
```

```
grpMax = 6×1
```

```
22.2000
21.9000
18.2000
24.6000
17.5000
15.5000
```

```
grp = 6×1 cell array
```

```
{'USA' }
{'France' }
{'Japan' }
{'Germany' }
{'Sweden' }
{'Italy' }
```

The sample car with the lowest acceleration is made in the USA, and the sample car with the highest acceleration is made in Germany.

Plot Prediction Intervals for a New Observation in Each Group

Load the sample data.

```
load('carsmall')
```

The variable `Weight` was measured for 100 cars. The variable `Model_Year` has three unique values, 70, 76, and 82, which correspond to model years 1970, 1976, and 1982.

Calculate the mean weight and 90% prediction intervals for each model year.

```
[means,pred,grp] = grpstats(Weight,Model_Year,...
    {'mean','predci','gname'},'Alpha',0.1);
```

Plot error bars showing the mean weight and 90% prediction intervals, grouped by model year. Label the horizontal axis with the group names.

```
ngrps = length(grp); % Number of groups
errorbar((1:ngrps)', means, pred(:,2) - means)
xlim([0.5 3.5])
set(gca, 'xtick', 1:ngrps, 'xticklabel', grp)
title('90% Prediction Intervals for Weight by Year')
```

Plot Group Means and Confidence Intervals

Load the sample data.

```
load('carsmall')
```

The variables `Acceleration` and `Weight` are the acceleration and weight values measured for 100 cars. The variable `Cylinders` is the number of cylinders in each car. The variable `Model_Year` has three unique values, 70, 76, and 82, which correspond to model years 1970, 1976, and 1982.

Plot mean acceleration, grouped by `Cylinders`, with 95% confidence intervals.

```
grpstats(Acceleration,Cylinders,0.05)
```

```
ans = 3×1
```

```
16.6706
```

16.4765
11.6406

The mean acceleration for cars with 8 cylinders is significantly lower than for cars with 4 or 6 cylinders.

Plot mean acceleration and weight, grouped by Cylinders, and 95% confidence intervals. Scale the Weight values by 1000 so the means of Weight and Acceleration are the same order of magnitude.

```
grpstats([Acceleration,Weight/1000],Cylinders,0.05)
```

```
ans = 3x2
```

```
16.6706    2.3726  
16.4765    3.1255  
11.6406    3.9703
```

The average weight of cars increases with the number of cylinders, and the average acceleration decreases with the number of cylinders.

Plot mean acceleration, grouped by both Cylinders and Model_Year. Specify 95% confidence intervals.

```
grpstats(Acceleration, {Cylinders, Model_Year}, 0.05)
```

```
ans = 8×1

    16.1875
    16.8667
    16.7036
    15.5000
    17.0000
    16.0333
    11.0217
    13.2222
```

There are nine possible combinations of grouping variable values because there are three unique values in `Cylinders` and three unique values in `Model_Year`. The plot does not show 8-cylinder cars with model year 1982 because the data did not include this combination.

The mean acceleration of 8-cylinder cars made in 1976 is significantly larger than the mean acceleration of 8-cylinder cars made in 1970.

Input Arguments

tbl — Input data

table | dataset array

Input data, specified as a table or dataset array. `tbl` must include at least one variable that is a grouping variable.

Summary statistics can only be calculated for variables that have a numeric or logical data type. If any variables in `tbl` (other than the grouping variables) are not numeric or logical arrays, then use the name-value pair argument `DataVars` to specify the names or column numbers of the numeric and logical variables for which to calculate summary statistics.

groupvar — Identifiers for the grouping variables

character vector | string array | cell array of character vectors | vector of positive integers | logical vector | []

Identifiers for the grouping variables in the input data, `tbl`, specified as one of the following:

Character vector, string array, or cell array of character vectors	Names of the grouping variables
Positive integer or vector of positive integers	Variable numbers of the grouping variables
Vector of logical values with number of elements equal to the number of variables in <code>tbl</code>	Logical indicator with value <code>true</code> for grouping variables and <code>false</code> otherwise
<code>[]</code>	No groups (returns summary statistics for all data)

Any variable that is identified by `groupvar` as a grouping variable must have a valid grouping variable data type: categorical array, logical or numeric vector, datetime or duration vector, string array, or cell array of character vectors.

For example, consider an input table, `tbl`, with six variables. The fourth variable is named `Gender`. To be a valid grouping variable, the data type of `Gender` might be a string array, a cell array of character vectors, or a nominal array, with the unique values `Male` and `Female`. To specify the variable `Gender` as the grouping variable, you can use any of these syntaxes:

- `statarray = grpstats(tbl, 'Gender')`
- `statarray = grpstats(tbl, 4)`
- `statarray = grpstats(tbl, logical([0 0 0 1 0 0]))`

Data Types: `double` | `logical` | `char` | `string` | `cell`

whichstats — Types of summary statistics

character vector | string scalar | function handle | string array | cell array of character vectors and function handles

Types of summary statistics to compute, specified as a character vector, a string scalar, a function handle, a string array, or a cell array of character vectors and function handles. Use a cell array to specify multiple types of summary statistics.

Values include:

'mean'	Mean
'sem'	Standard error of the mean

'numel'	Count, or number, of non-NaN elements
'gname'	Group name
'std'	Standard deviation
'var'	Variance
'min'	Minimum
'max'	Maximum
'range'	Range
'meanci'	95% confidence interval for the mean
'predci'	95% prediction interval for a new observation

Example: `[stat1,stat2] = grpstats(X,group,{'mean','sem'})`

You can specify different significance levels for the 'meanci' and 'predci' options using the name-value pair argument, `Alpha`.

To specify other types of summary statistics, you can use function handles. You can use the handle to any function that accepts a column or matrix of data, and returns the same size output each time `grpstats` calls it (even if the output for some groups is empty).

If the function accepts a column of data, then the function can return either a scalar value, or an *nvals*-by-1 column vector for descriptive statistics of length *nvals* (for example, confidence intervals have length two). If the function accepts a matrix, it must either return a 1-by-*ncols* row vector, or an *nvals*-by-*ncols* matrix, where *ncols* is the number of columns in the input data matrix.

Example: `[stat1,stat2,stat3] = grpstats(X,group,{'mean','std',@skewness})`

For functions that do not compute column-wise statistics, specify the computation direction while specifying the function.

Example: `stat1 = grpstats(X,group,@(x)sum(x,1))`

alpha — Significance level

scalar value in the range (0,1)

Significance level, specified as a scalar value in the range (0,1).

- When you specify 'meanci' or 'predci' in `whichstats`, you can use `alpha` to specify the significance level for the confidence or prediction intervals. If you specify

`alpha`, then `grpstats` returns $100 \times (1 - \text{alpha})\%$ confidence or prediction intervals. If you do not specify `alpha`, then `grpstats` returns 95% intervals (`alpha = 0.05`).

- Use `alpha` with the syntax on page 32-3019 to plot group means and corresponding $100 \times (1 - \text{alpha})\%$ confidence intervals.

Data Types: `double`

X — Input data

`vector` | `matrix`

Input data, specified as a vector or a matrix. If `X` is a matrix, then `grpstats` returns summary statistics for each column of `X`.

Data Types: `double` | `single`

group — Grouping variable

`categorical array` | `logical or numeric vector` | `datetime or duration vector` | `string array` | `cell array of character vectors` | `[]`

Grouping variable, specified as a categorical array, logical or numeric vector, datetime or duration vector, string array, or cell array of character vectors. Each unique value in a grouping variable defines a group. `grpstats` groups data for summary statistics using the grouping variable values.

There must be a grouping variable value for each row of the input data `X`. Observations (rows) with the same value of the grouping variable are in the same group. Use `[]` to compute summary statistics for all data, without using groups.

For example, if `Gender` is a string array or cell array of character vectors with values 'Male' and 'Female', you can use `Gender` as a grouping variable to summarize your data by gender.

You can also use more than one grouping variable to group data for summary statistics. In this case, specify a cell array of grouping variables.

For example, if `Smoker` is a logical vector with values 0 for nonsmokers and 1 for smokers, then specifying the cell array `{Gender, Smoker}` divides observations into four groups: Male Smoker, Male Nonsmoker, Female Smoker, and Female Nonsmoker. `grpstats` returns summary statistics only for the combinations of values that exist in the input grouping variables (not all possible combinations).

Data Types: `single` | `double` | `logical` | `char` | `string` | `cell` | `categorical` | `datetime` | `duration`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'DataVars', [1,3,4], 'Alpha', 0.01` specifies that summary statistics be calculated for the 1st, 3rd, and 4th variables in a dataset array, with 99% confidence intervals.

Alpha — Significance level

0.05 (default) | scalar value in the range (0,1)

Significance level for confidence and prediction intervals, specified as the comma-separated pair consisting of `'Alpha'` and a scalar value in the range (0,1).

When you include `'meanci'` or `'predci'` in `whichstats`, you can use `Alpha` to specify the significance level for confidence or prediction intervals. If you specify the value α , then `grpstats` returns $100 \times (1 - \alpha)\%$ confidence or prediction intervals.

If you do not specify a value for `Alpha`, then `grpstats` returns 95% intervals ($\alpha = 0.05$).

Example: `'Alpha', 0.1`

Data Types: `double`

DataVars — Variable names or columns

string array | cell array of character vectors | vector of positive integers | logical vector

Variable names or columns indicating which variables in the input data `tbl` you want to compute summary statistics for, specified as the comma-separated pair consisting of `'DataVars'` and a string array, cell array of character vectors, vector of positive integers, or logical vector. Use a character vector or string scalar to specify a variable name, a positive integer to specify a variable column number, or logical values to indicate which variables to include (`true` if you want to compute summary statistics, `false` otherwise).

You must specify `DataVars` if there are any variables in `tbl` (other than the grouping variables specified in `groupvar`) that are not numeric or logical arrays. Summary statistics can only be calculated for variables that have a numeric or logical data type.

Example: `'DataVars', {'Height', 'Weight'}`

Data Types: `double` | `string` | `cell` | `char`

VarNames — Variable names for output

string array | cell array of character vectors

Variable names for the output `stataarray`, specified as the comma-separated pair consisting of `'VarNames'` and a string array or cell array of character vectors. By default, `grpstats` constructs output variable names by appending a prefix to the variable names from the input data `tbl`. This prefix corresponds to the summary statistic name.

Example: `'VarNames', {'Gender', 'GroupCount', 'MaleMean', 'FemaleMean'}`

Data Types: `string` | `cell`

Output Arguments

stataarray — Group summary statistics

table | dataset array

Group summary statistics, returned as a table or a dataset array. If `tbl` is a table, `grpstats` returns `stataarray` as a table. If `tbl` is a dataset array, `grpstats` returns `stataarray` as a dataset array.

`stataarray` contains summary statistic values for the groups of data in `tbl` determined by the levels of the grouping variables specified by `groupvar`. There is a row in `stataarray` for each observed value or combination of values in the variables specified by `groupvar`. The output `stataarray` contains:

- All grouping variables specified by `groupvar`.
- The variable `GroupCount`, containing the number of observations in each group.
- Group summary statistic values for all variables in `tbl` (other than those specified by `groupvar`), or for only the variables specified using `DataVars`.

The total number of variables in `stataarray` is $n_{groupvars} + 1 + n_{datavars} \times n_{stats}$, where $n_{groupvars}$ is the number of variables in `groupvar`, $n_{datavars}$ is the number of variables for which summary statistics are computed, and n_{stats} is the number of summary statistic types specified in `whichstats`.

`grpstats` assigns default names to the variables in `stataarray`, unless you specify variable names using the name-value pair argument `VarNames`.

means — Group means

column vector | array

Group means for the groups of data in the vector or matrix X determined by the levels of `group`, returned as an *ngroups*-by-*ncols* array. Here, *ngroups* is the number of unique values in the grouping variable, and *ncols* is the number of columns in X . If X is a vector, then `means` is a column vector.

stats1, . . . , statsN — Group summary statistics

column vectors | arrays

Group summary statistics for the groups of data in the vector or matrix X determined by the levels of `group`, returned as *ngroups*-by-*ncols* arrays. Here, *ngroups* is the number of unique values in the grouping variable, and *ncols* is the number of columns in X . You must specify an output argument for each type of summary statistic specified in `whichstats`.

If a summary statistic type in `whichstats` returns a value of length *nvals* (for example, a confidence interval is a descriptive statistic of length two), then the corresponding output argument is an *ngroups*-by-*ncols*-by-*nvals* array.

Algorithms

- `grpstats` treats NaNs as missing values, and removes them from the input data before calculating summary statistics.
- `grpstats` ignores empty group names.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function supports tall arrays for out-of-memory data with some limitations.

- If the input data is a tall array, then all grouping variables must also be tall and have the same number of rows as the data.

- The `whichstats` option cannot be specified as a function handle. In addition to the current built-in options, `whichstats` can also be:
 - 'Count' — Number of non-NaN's.
 - 'NNZ' — Number of nonzeros and non-NaN's.
 - 'Kurtosis' — Compute kurtosis.
 - 'Skewness' — Compute skewness.
 - 'all-stats' — Compute all summary statistics.
- Group order is not guaranteed to be the same as the in-memory `grpstats` computation. Specify 'gname' as the `whichstats` option to return the order of rows of the summary statistics. For example `[means,grpname] = grpstats(x,bins,{'mean','gname'})` returns the means of groups in `x` in the same order that the groups appear in `grpname`.
- Summary statistics for *nonnumeric* variables return NaN's.
- `grpstats` always operates on the first dimension.
- If the input is a tall table, then the output is also a tall table. However, rather than including row names, the output tall table contains an extra variable `GroupLabel` that contains the same information.

For more information, see “Tall Arrays” (MATLAB).

Introduced before R2006a

grpstats

Class: RepeatedMeasuresModel

Compute descriptive statistics of repeated measures data by group

Syntax

```
statstbl = grpstats(rm,g)
statstbl = grpstats(rm,g,stats)
```

Description

`statstbl = grpstats(rm,g)` returns the count, mean, and variance for the data used to fit the repeated measures model `rm`, grouped by the factors, `g`.

`statstbl = grpstats(rm,g,stats)` returns the statistics specified by `stats` for the data used to fit the repeated measures model `rm`, grouped by the factors, `g`.

Input Arguments

rm — Repeated measures model

RepeatedMeasuresModel object

Repeated measures model, returned as a RepeatedMeasuresModel object.

For properties and methods of this object, see RepeatedMeasuresModel.

g — Name of grouping factor or factors

character vector | string array | cell array of character vectors

Name of grouping factor or factors, specified as a character vector, string array, or cell array of character vectors.

Example: 'Drug'

Example: {'Drug', 'Sex'}

Data Types: char | string | cell

stats — Statistics to compute

character vector | string scalar | function handle | string array | cell array of multiple character vectors and function handles

Statistics to compute, specified as one of the following:

- Character vector or string scalar specifying the name of the statistics to compute. Names can be one of the following.

Name	Description
'mean'	Mean
'sem'	Standard error of the mean
'numel'	Count or number of elements
'gname'	Group name
'std'	Standard deviation
'var'	Variance
'min'	Minimum
'max'	Maximum
'range'	Maximum minus minimum
'meanci'	95% confidence interval for the mean
'predci'	95% prediction interval for a new observation

- Function handle — The function you specify must accept a vector of response values for a single group, and compute descriptive statistics for it. A function should typically return a value that has one row. A function must return the same size output each time `grpstats` calls it, even if the input for some groups is empty.
- A string array or cell array of character vectors and function handles.

Example: `@median`

Example: `@skewness`

Example: `'gname'`

Example: `{'gname','range','predci'}`

Output Arguments

statstbl — Statistics values for each group

table

Statistics values for each group, returned as a table.

Examples

Compute Group Statistics

Load the sample data.

```
load fisheriris
```

The column vector, `species` consists of iris flowers of three different species: `setosa`, `versicolor`, and `virginica`. The double matrix `meas` consists of four types of measurements on the flowers: the length and width of sepals and petals in centimeters, respectively.

Store the data in a table array.

```
t = table(species,meas(:,1),meas(:,2),meas(:,3),meas(:,4),...
'VariableNames',{'species','meas1','meas2','meas3','meas4'});
Meas = dataset([1 2 3 4]','VarNames',{'Measurements'});
```

Fit a repeated measures model, where the measurements are the responses and the species is the predictor variable.

```
rm = fitrm(t,'meas1-meas4~species','WithinDesign',Meas);
```

Compute group counts, mean, and standard deviation with respect to species.

```
grpstats(rm,'species')
```

```
ans=3x4 table
```

species	GroupCount	mean	std
'setosa'	200	2.5355	1.8483
'versicolor'	200	3.573	1.7624
'virginica'	200	4.285	1.9154

Now, compute the range of data and 95% confidence intervals for the group means for the factor species. Also display the group name.

```
grpstats(rm, 'species', {'gname', 'range', 'predci'})
```

```
ans=3x5 table
      species          gname    GroupCount    range    predci
-----
'setosa'    'setosa'         200         5.7    -1.1185    6.1895
'versicolor' 'versicolor'       200         6     0.088976    7.057
'virginica'  'virginica'        200         6.5     0.4985    8.0715
```

Statistics for Data Grouped by Two Factors

Load the sample data.

```
load repeatedmeas
```

The table `between` includes the between-subject variables `age`, `IQ`, `group`, `gender`, and eight repeated measures `y1` through `y8` as responses. The table `within` includes the within-subject variables `w1` and `w2`. This is simulated data.

Fit a repeated measures model, where the repeated measures `y1` through `y8` are the responses, and `age`, `IQ`, `group`, `gender`, and the group-gender interaction are the predictor variables. Also specify the within-subject design matrix.

```
rm = fitrm(between, 'y1-y8 ~ Group*Gender + Age + IQ', 'WithinDesign', within);
```

Compute group counts, mean, standard deviation, skewness, and kurtosis of data grouped by the factors `Group` and `Gender`.

```
GS = grpstats(rm, {'Group', 'Gender'}, {'mean', 'std', @skewness, @kurtosis})
```

```
GS=6x7 table
      Group    Gender    GroupCount    mean    std    skewness    kurtosis
-----
      A    Female         40    16.554    21.498     0.35324     3.7807

```

B	Male	40	3.6078	24.646	0.55447	2.7966
C	Female	40	-11.335	27.186	1.7499	6.1429
C	Male	40	-14.028	31.984	1.7362	5.141

Tips

- `grpstats` computes results separately for each group. The results do not depend on the fitted repeated measures model. It computes the results on all available data, without omitting entire rows that contain NaNs.

See Also

`fitrm` | `plot`

gscatter

Scatter plot by group

Syntax

```
gscatter(x,y,g)
gscatter(x,y,g,clr,sym,siz)
gscatter(x,y,g,clr,sym,siz,doleg)
gscatter(x,y,g,clr,sym,siz,doleg,xnam,ynam)
```

```
h = gscatter( ___ )
```

Description

`gscatter(x,y,g)` creates a scatter plot of `x` and `y`, grouped by `g`. The inputs `x` and `y` are vectors of the same size.

`gscatter(x,y,g,clr,sym,siz)` specifies the marker color `clr`, symbol `sym`, and size `siz` for each group.

`gscatter(x,y,g,clr,sym,siz,doleg)` controls whether a legend is displayed on the graph. `gscatter` creates a legend by default.

`gscatter(x,y,g,clr,sym,siz,doleg,xnam,ynam)` specifies the names to use for the x-axis and y-axis labels. If you do not provide `xnam` and `ynam`, and the `x` and `y` inputs are variables with names, then `gscatter` labels the axes with the variable names.

`h = gscatter(___)` returns graphics handles corresponding to the groups in `g`, using any of the input arguments in the previous syntaxes.

Examples

Scatter Plot with Default Settings

Load the `carsmall` data set.

```
load carsmall
```

Plot the `Displacement` values on the x-axis and the `Horsepower` values on the y-axis. `gscatter` uses the variable names as the default labels for the axes. Group the data points by `Model_Year`.

```
gscatter(Displacement,Horsepower,Model_Year)
```

Scatter Plot with One Grouping Variable

Load the `discrim` data set.

```
load discrim
```

The data set contains ratings of cities according to nine factors such as climate, housing, education, and health. The matrix `ratings` contains the ratings information.

Plot the relationship between the ratings for climate (first column) and housing (second column) grouped by city size in the matrix `group`. Choose different colors and plotting symbols for each group.

```
gscatter(ratings(:,1),ratings(:,2),group,'br','xo')  
xlabel('climate')  
ylabel('housing')
```

Scatter Plot with Multiple Grouping Variables

Load the hospital data set.

```
load hospital
```

Plot the ages and weights of the hospital patients. Group the patients according to their gender and smoker status. Use the o symbol to represent nonsmokers and the * symbol to represent smokers.

```
x = hospital.Age;  
y = hospital.Weight;
```

```
g = {hospital.Sex,hospital.Smoker};
gscatter(x,y,g,'rkgb','o*',8,'on','Age','Weight')
legend('Location','northeastoutside')
```

Create and Modify Scatter Plot

Load the carbig data set.

```
load carbig
```

Create a scatter plot comparing Acceleration to MPG. Group data points based on Origin.

```
h = gscatter(Acceleration,MPG,Origin)
```

```
h =  
7x1 Line array:  
  
Line (USA)  
Line (France)  
Line (Japan)  
Line (Germany)  
Line (Sweden)  
Line (Italy)  
Line (England)
```

Display the Line object corresponding to the group labeled (Japan).

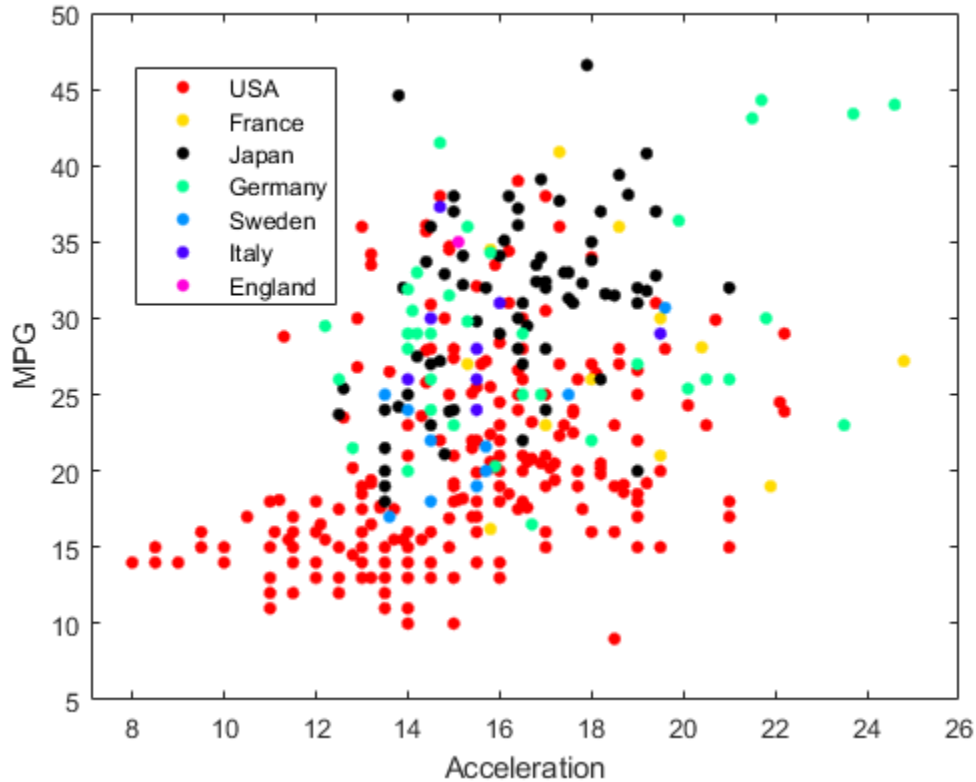

```
jgroup = h(3)
```

```
jgroup =  
Line (Japan) with properties:  
  
Color: [0.2857 1 0]  
LineStyle: 'none'  
LineWidth: 0.5000  
Marker: '.'  
MarkerSize: 15  
MarkerFaceColor: 'none'  
XData: [1x79 double]  
YData: [1x79 double]  
ZData: [1x0 double]
```

```
Show all properties
```

Change the marker color for the Japan group to black.

```
jgroup.Color = 'k';
```

Input Arguments

x — x-axis values

numeric vector

x-axis values, specified as a numeric vector. x must have the same size as y.

Data Types: single | double

y — y-axis values

numeric vector

y-axis values, specified as a numeric vector. `y` must have the same size as `x`.

Data Types: `single` | `double`

g — Grouping variable

categorical vector | logical vector | numeric vector | character array | string array | cell array of character vectors | cell array

Grouping variable, specified as a categorical vector, logical vector, numeric vector, character array, string array, or cell array of character vectors. Alternatively, `g` can be a cell array containing several grouping variables (such as `{g1 g2 g3}`), in which case observations are in the same group if they have common values of all grouping variables. Points in the same group appear on the scatter plot with the same marker color, symbol, and size.

Example: `species`

Example: `{Cylinders,Origin}`

Data Types: `categorical` | `logical` | `single` | `double` | `char` | `string` | `cell`

clr — Marker colors

character vector or string scalar of colors | matrix of RGB triplet values

Marker colors, specified as either a character vector or string scalar of colors recognized by the `plot` function or a matrix of RGB triplet values. Each RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color, respectively. Each intensity must be in the range `[0,1]`.

This table lists the available color characters and their equivalent RGB triplet values.

Long Name	Short Name	RGB Triplet
Yellow	'y'	[1 1 0]
Magenta	'm'	[1 0 1]
Cyan	'c'	[0 1 1]
Red	'r'	[1 0 0]
Green	'g'	[0 1 0]
Blue	'b'	[0 0 1]
White	'w'	[1 1 1]

Long Name	Short Name	RGB Triplet
Black	'k'	[0 0 0]

If you do not specify enough values for all groups, then `gscatter` cycles through the specified values as needed.

Example: 'rgb'

Example: [0 0 1; 0 0 0]

Data Types: char | string | single | double

sym — Marker symbols

'.' (default) | character vector or string scalar of symbols

Marker symbols, specified as a character vector or string scalar of symbols recognized by the `plot` function. This table lists the available marker symbols.

Value	Description
'o'	Circle
'+'	Plus sign
'*'	Asterisk
'.'	Point
'x'	Cross
's'	Square
'd'	Diamond
'^'	Upward-pointing triangle
'v'	Downward-pointing triangle
'>'	Right-pointing triangle
'<'	Left-pointing triangle
'p'	Five-pointed star (pentagram)
'h'	Six-pointed star (hexagram)
'none'	No markers

If you do not specify enough values for all groups, then `gscatter` cycles through the specified values as needed.

Example: 'o+*v'

Data Types: char | string

siz — Marker sizes

positive numeric vector

Marker sizes, specified as a positive numeric vector in points. The default value is determined by the number of observations. If you do not specify enough values for all groups, then `gscatter` cycles through the specified values as needed.

Example: [6 12]

Data Types: single | double

doLeg — Option to include legend

'on' (default) | 'off'

Option to include a legend, specified as either 'on' or 'off'. By default, the legend is displayed on the graph.

xnam — x-axis label

x variable name (default) | character vector | string scalar

x-axis label, specified as a character vector or string scalar.

Data Types: char | string

ynam — y-axis label

y variable name (default) | character vector | string scalar

y-axis label, specified as a character vector or string scalar.

Data Types: char | string

Output Arguments

h — Graphics handles

array of `Line` objects

Graphics handles, returned as an array of `Line` objects. Each `Line` object corresponds to one of the groups in `g`. You can use dot notation to query and set properties of the line objects. For a list of `Line` object properties, see `Chart Line`.

Topics

“Create Scatter Plots Using Grouped Data” on page 4-2

“MANOVA” on page 9-70

“Grouping Variables” on page 2-57

Introduced before R2006a

gt

Class: grandstream

Greater than relation for handles

Syntax

`h1 > h2`

Description

`h1 > h2` performs element-wise comparisons between handle arrays `h1` and `h2`. `h1` and `h2` must be of the same dimensions unless one is a scalar. The result is a logical array of the same dimensions, where each element is an element-wise `>` result.

If one of `h1` or `h2` is scalar, scalar expansion is performed and the result will match the dimensions of the array that is not scalar.

`tf = gt(h1, h2)` stores the result in a logical array of the same dimensions.

See Also

`eq` | `ge` | `le` | `lt` | `ne` | `grandstream`

haltonset

Halton quasirandom point set

Description

`haltonset` is a quasirandom point set object that produces points from the Halton sequence. The Halton sequence uses different prime bases in each dimension to fill space in a highly uniform manner.

Creation

Syntax

```
p = haltonset(d)
p = haltonset(d,Name,Value)
```

Description

`p = haltonset(d)` constructs a d -dimensional point set `p`, which is a `haltonset` object with default property settings. The input argument `d` corresponds to the `Dimensions` property of `p`.

`p = haltonset(d,Name,Value)` sets properties on page 32-3057 of `p` using one or more name-value pair arguments. Enclose each property name in quotes. For example, `haltonset(5, 'Leap', 2)` creates a five-dimensional point set from the first point, fourth point, seventh point, tenth point, and so on.

The returned object `p` encapsulates properties of a Halton quasirandom sequence. The point set is finite, with a length determined by the `Skip` and `Leap` properties and by limits on the size of the point set indices (maximum value of 2^{53}). Values of the point set are generated whenever you access `p` using `net` or parenthesis indexing. Values are not stored within `p`.

Properties

Dimensions — Number of dimensions

positive integer scalar

This property is read-only.

Number of dimensions of the points in the point set, specified as a positive integer scalar. For example, each point in the point set `p` with `p.Dimensions = 5` has five values.

Use the `d` input argument to specify the number of dimensions when you create a point set using the `haltonset` function.

Leap — Interval between points

0 (default) | positive integer scalar

Interval between points in the sequence, specified as a positive integer scalar. In other words, the `Leap` property of a point set specifies the number of points in the sequence to leap over and omit for every point taken. The default `Leap` value is 0, which corresponds to taking every point from the sequence.

Leaping is a technique used to improve the quality of a point set. However, you must choose the `Leap` values with care. Many `Leap` values create sequences that fail to touch on large sub-hyper-rectangles of the unit hypercube and, therefore, fail to be a uniform quasirandom point set. For more information, see [1].

One rule for choosing `Leap` values for Halton sets is to set the value to $(n-1)$, where n is a prime number that has not been used to generate one of the dimensions. For example, for a d -dimensional point set, specify the $(d+1)$ th or greater prime number for n .

Example: `p = haltonset(2, 'Leap', 4);` (where $d = 2$ and $n = 5$)

Example: `p.Leap = 100;`

ScrambleMethod — Settings that control scrambling

0x0 structure (default) | structure with `Type` and `Options` fields

Settings that control the scrambling of the sequence, specified as a structure with these fields:

- `Type` — A character vector containing the name of the scramble
- `Options` — A cell array of parameter values for the scramble

Use the `scramble` object function to set scrambles. For a list of valid scramble types, see the `type` input argument of `scramble`. An error occurs if you set an invalid scramble type for a given point set.

The `ScrambleMethod` property also accepts an empty matrix as a value. The software then clears all scrambling and sets the property to contain a 0×0 structure.

Skip — Number of initial points in sequence to omit

0 (default) | positive integer scalar

Number of initial points in the sequence to omit from the point set, specified as a positive integer scalar.

Initial points of a sequence sometimes exhibit undesirable properties. For example, the first point is often $(0, 0, 0, \dots)$, which can cause the sequence to be unbalanced because the counterpart of the point, $(1, 1, 1, \dots)$, never appears. Also, initial points often exhibit correlations among different dimensions, and these correlations disappear later in the sequence.

Example: `p = haltonset(__, 'Skip', 2e3);`

Example: `p.Skip = 1e3;`

Type — Sequence type

'Halton' (default)

This property is read-only.

Sequence type on which the quasirandom point set `p` is based, specified as 'Halton'.

Object Functions

`net` Generate quasirandom point set
`scramble` Scramble quasirandom point set

You can also use the following MATLAB functions with a `haltonset` object. The software treats the point set object like a matrix of multidimensional points.

`length` Length of largest array dimension
`size` Array size

Examples

Create Halton Point Set

Generate a three-dimensional Halton point set, skip the first 1000 values, and then retain every 101st point.

```
p = haltonset(3, 'Skip', 1e3, 'Leap', 1e2)

p =
Halton point set in 3 dimensions (89180190640991 points)

Properties:
      Skip : 1000
      Leap  : 100
ScrambleMethod : none
```

Apply reverse-radix scrambling by using `scramble`.

```
p = scramble(p, 'RR2')

p =
Halton point set in 3 dimensions (89180190640991 points)

Properties:
      Skip : 1000
      Leap  : 100
ScrambleMethod : RR2
```

Generate the first four points by using `net`.

```
X0 = net(p, 4)

X0 = 4x3

    0.0928    0.6950    0.0029
    0.6958    0.2958    0.8269
    0.3013    0.6497    0.4141
    0.9087    0.7883    0.2166
```

Generate every third point, up to the eleventh point, by using parenthesis indexing.

```
X = p(1:3:11,:)
X = 4x3
    0.0928    0.6950    0.0029
    0.9087    0.7883    0.2166
    0.3843    0.9840    0.9878
    0.6831    0.7357    0.7923
```

Tips

- The `Skip` and `Leap` properties are useful for parallel applications. For example, if you have a Parallel Computing Toolbox license, you can partition a sequence of points across N different workers by using the function `labindex`. On each n th worker, set the `Skip` property of the point set to $n - 1$ and the `Leap` property to $N - 1$. The following code shows how to partition a sequence across three workers.

```
Nworkers = 3;
p = haltonset(10, 'Leap', Nworkers-1);
spm(Nworkers)
    p.Skip = labindex - 1;

    % Compute something using points 1,4,7...
    % or points 2,5,8... or points 3,6,9...
end
```

Algorithms

Halton Sequence Generation

Consider a default `haltonset` object `p` that contains d -dimensional points. Each `p(i, :)` is a point in a Halton sequence. The j th coordinate of the point, `p(i, j)`, is equal to

$$\sum_k a_{i,j}(k) b_j^{-k-1}.$$

- b_j is the j th prime.

- The $a_{ij}(k)$ coefficients are nonnegative integers less than b_j such that

$$i - 1 = \sum_{k=0}^{\infty} a_{ij}(k)b_j^k.$$

In other words, the $a_{ij}(k)$ values are the base b_j digits of the integer $i - 1$.

For more information, see [1].

Topics

"Generating Quasi-Random Numbers" on page 7-16

Introduced in R2008a

harmmean

Harmonic mean

Syntax

```
m = harmmean(X)
m = harmmean(X, 'all')
m = harmmean(X, dim)
m = harmmean(X, vecdim)
m = harmmean( ____, nanflag)
```

Description

`m = harmmean(X)` calculates the harmonic mean on page 32-3067 of a sample. For vectors, `harmmean(X)` is the harmonic mean of the elements in `X`. For matrices, `harmmean(X)` is a row vector containing the harmonic means of each column. For N -dimensional arrays, `harmmean` operates along the first nonsingleton dimension of `X`.

`m = harmmean(X, 'all')` returns the harmonic mean of all elements of `X`.

`m = harmmean(X, dim)` takes the harmonic mean along the operating dimension `dim` of `X`.

`m = harmmean(X, vecdim)` returns the harmonic mean over the dimensions specified in the vector `vecdim`. Each element of `vecdim` represents a dimension of the input array `X`. The output `m` has length 1 in the specified operating dimensions. The other dimension lengths are the same for `X` and `m`. For example, if `X` is a 2-by-3-by-4 array, then `harmmean(X, [1 2])` returns a 1-by-1-by-4 array. Each element of the output array is the harmonic mean of the elements on the corresponding page of `X`.

`m = harmmean(____, nanflag)` specifies whether to exclude NaN values from the calculation, using any of the input argument combinations in previous syntaxes. By default, `harmmean` includes NaN values in the calculation (`nanflag` has the value `'includenan'`). To exclude NaN values, set the value of `nanflag` to `'omitnan'`.

Examples

Compare Harmonic and Arithmetic Mean

Set the random seed for reproducibility of the results.

```
rng('default')
```

Create a matrix of exponential random numbers with 5 rows and 4 columns.

```
X = exprnd(1,5,4)
```

```
X = 5×4
```

```
    0.2049    2.3275    1.8476    1.9527
    0.0989    1.2783    0.0298    0.8633
    2.0637    0.6035    0.0438    0.0880
    0.0906    0.0434    0.7228    0.2329
    0.4583    0.0357    0.2228    0.0414
```

Compute the harmonic and arithmetic means of the columns of X.

```
harmonic = harmmean(X)
```

```
harmonic = 1×4
```

```
    0.1743    0.0928    0.0797    0.1205
```

```
arithmetic = mean(X)
```

```
arithmetic = 1×4
```

```
    0.5833    0.8577    0.5734    0.6357
```

The arithmetic mean is greater than the harmonic mean for all the columns of X.

Harmonic Mean of All Values

Find the harmonic mean of all the values in an array.

Create a 3-by-5-by-2 array X.

```
X = reshape(1:30,[3 5 2])
```

```
X =  
X(:,:,1) =
```

1	4	7	10	13
2	5	8	11	14
3	6	9	12	15

```
X(:,:,2) =
```

16	19	22	25	28
17	20	23	26	29
18	21	24	27	30

Find the harmonic mean of the elements of X.

```
m = harmmean(X, 'all')
```

```
m = 7.5094
```

Harmonic Mean Along Specified Dimensions

Find the harmonic mean along different operating dimensions and vectors of dimensions for a multidimensional array.

Create a 3-by-5-by-2 array X.

```
X = reshape(1:30,[3 5 2])
```

```
X =  
X(:,:,1) =
```

1	4	7	10	13
2	5	8	11	14
3	6	9	12	15

```
X(:,:,2) =
```

```
16    19    22    25    28
17    20    23    26    29
18    21    24    27    30
```

Find the harmonic mean of X along the default dimension.

```
hmean1 = harmmean(X)
```

```
hmean1 =
```

```
hmean1(:,:,1) =
```

```
    1.6364    4.8649    7.9162   10.9392   13.9523
```

```
hmean1(:,:,2) =
```

```
   16.9607   19.9666   22.9710   25.9743   28.9770
```

By default, `harmmean` operates along the first dimension of X whose size does not equal 1. In this case, this dimension is the first dimension of X. Therefore, `hmean1` is a 1-by-5-by-2 array.

Find the harmonic mean of X along the second dimension.

```
hmean2 = harmmean(X,2)
```

```
hmean2 =
```

```
hmean2(:,:,1) =
```

```
    3.1852
    5.0641
    6.5693
```

```
hmean2(:,:,2) =
```

```
   21.1595
   22.1979
   23.2329
```

`hmean2` is a 3-by-1-by-2 array.

Find the harmonic mean of X along the third dimension.

```
hmean3 = harmmean(X,3)
```

```
hmean3 = 3×5
```

```
    1.8824    6.6087    10.6207    14.2857    17.7561  
    3.5789    8.0000    11.8710    15.4595    18.8837  
    5.1429    9.3333    13.0909    16.6154    20.0000
```

hmean3 is a 3-by-5 array.

Find the harmonic mean of each page of X by specifying the first and second dimensions using the `vecdim` input argument.

```
mpage = harmmean(X,[1 2])
```

```
mpage =  
mpage(:, :, 1) =
```

```
    4.5205
```

```
mpage(:, :, 2) =
```

```
    22.1645
```

For example, `mpage(1,1,2)` is the harmonic mean of the elements in `X(:, :, 2)`.

Find the harmonic mean of the elements in each `X(i, :, :)` slice by specifying the second and third dimensions.

```
mrow = harmmean(X,[2 3])
```

```
mrow = 3×1
```

```
    5.5369  
    8.2469  
   10.2425
```

For example, `mrow(3)` is the harmonic mean of the elements in `X(3, :, :)` and is equivalent to specifying `harmmean(X(3, :, :), 'all')`.

Harmonic Mean Excluding NaN

Create a vector and compute its `harmmean`, excluding NaN values.

```
x = 1:10;  
x(3) = nan; % Replace the third element of x with a NaN value  
n = harmmean(x, 'omitnan')  
  
n = 3.4674
```

If you do not specify `'omitnan'`, then `harmmean(x)` returns NaN.

Definitions

Harmonic Mean

The harmonic mean of a sample X is

$$m = \frac{n}{\sum_{i=1}^n \frac{1}{x_i}}$$

where n is the number of values in X .

Tips

- When `harmmean` computes the harmonic mean of an array containing 0 , the returned value is 0 .

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. For more information, see “Tall Arrays” (MATLAB).

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- These input arguments are not supported: 'all', `vecdim`, and `nanflag`.
- The `dim` input argument must be a compile-time constant.
- If you do not specify the `dim` input argument, the working (or operating) dimension can be different in the generated code. As a result, run-time errors can occur. For more details, see “Automatic dimension restriction” (MATLAB Coder).

For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “General Code Generation Workflow” on page 31-5.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Usage notes and limitations:

- The 'all' and `vecdim` input arguments are not supported.

For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

See Also

`geomean` | `mean` | `median` | `trimmean`

Introduced before R2006a

hist3

Bivariate histogram plot

Syntax

```
hist3(X)
hist3(X,'Nbins',nbins)
hist3(X,'Ctrs',ctrs)
hist3(X,'Edges',edges)
hist3(___,Name,Value)
hist3(ax,___)
```

```
N = hist3(___)
[N,c] = hist3(___)
```

Description

`hist3(X)` creates a bivariate histogram plot of $X(:,1)$ and $X(:,2)$ using 10-by-10 equally spaced bins. The `hist3` function displays the bins as 3-D rectangular bars, and the height of each bar indicates the number of elements in the bin.

`hist3(X,'Nbins',nbins)` specifies the number of bins in each dimension of the histogram. This syntax is equivalent to `hist3(X,nbins)`.

`hist3(X,'Ctrs',ctrs)` specifies the centers of the bins in each dimension of the histogram. This syntax is equivalent to `hist3(X,ctrs)`.

`hist3(X,'Edges',edges)` specifies the edges of the bins in each dimension.

`hist3(___,Name,Value)` specifies graphical properties using one or more name-value pair arguments in addition to the input arguments in the previous syntaxes. For example, `'FaceAlpha',0.5` creates a semitransparent histogram. For a list of properties, see [Surface Properties](#).

`hist3(ax, ___)` plots into the axes specified by `ax` instead of the current axes (`gca`). The option `ax` can precede any of the input argument combinations in the previous syntaxes.

`N = hist3(___)` returns the number of elements in `X` that fall in each bin. This syntax does not create a histogram.

`[N,c] = hist3(___)` also returns the bin centers. This syntax does not create a histogram.

Examples

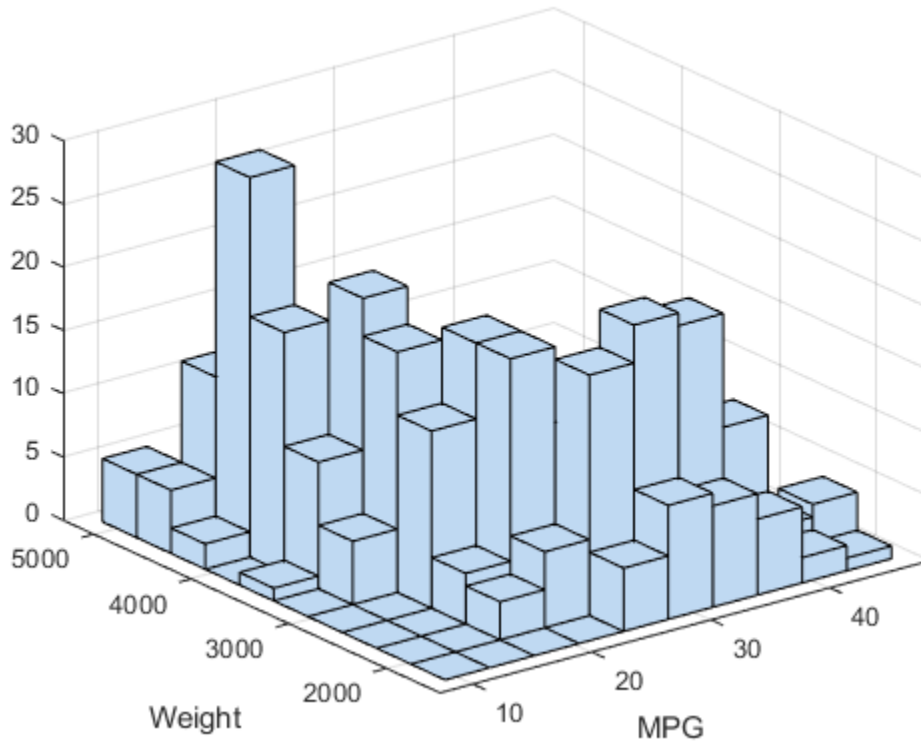

Histogram of Vectors

Load the sample data.

```
load carbig
```

Create a bivariate histogram with the default settings.

```
X = [MPG,Weight];  
hist3(X)  
xlabel('MPG')  
ylabel('Weight')
```

Specify Centers of Histogram Bins

Create a bivariate histogram on the bins specified by the bin centers, and count the number of elements in each bin.

Load the sample data.

```
load carbig
```

Create a bivariate histogram. Specify the centers of the histogram bins using a two-element cell array.

```
X = [MPG,Weight];
hist3(X,'Ctrs',{0:10:50 2000:500:5000})
xlabel('MPG')
ylabel('Weight')
```

Count the number of elements in each bin.

```
N = hist3(X,'Ctrs',{0:10:50 2000:500:5000})
```

```
N = 6x7
```

0	0	0	0	0	0	0
0	0	2	3	16	26	6
6	34	50	49	27	10	0
70	49	11	3	0	0	0

```
29    4    2    0    0    0    0
 1    0    0    0    0    0    0
```

Color Histogram Bars by Height

Load the sample data.

```
load carbig
```

Create a bivariate histogram. Specify graphical properties to color the histogram bars by height representing the frequency of the observations.

```
X = [MPG,Weight];
hist3(X, 'CDataMode', 'auto', 'FaceColor', 'interp')
xlabel('MPG')
ylabel('Weight')
```

Tiled Histogram View

Load the sample data.

```
load carbig
```

Create a bivariate tiled histogram. Specify graphical properties to color the top surface of the histogram bars by the frequency of the observations. Change the view to two-dimensional.

```
X = [MPG,Weight];
hist3(X, 'CdataMode', 'auto')
xlabel('MPG')
```

```
ylabel('Weight')
colorbar
view(2)
```

Adjust Graphical Properties

Create a bivariate histogram and adjust its graphical properties by using the handle of the histogram surface object.

Load the sample data.

```
load carbig
```

Create a bivariate histogram with 7 bins in each dimension.

```
X = [MPG,Weight];  
hist3(X,'Nbins',[7 7])  
xlabel('MPG')  
ylabel('Weight')
```

The `hist3` function creates a bivariate histogram, which is a type of surface plot. Find the handle of the surface object and adjust the face transparency.

```
s = findobj(gca,'Type','Surface');  
s.FaceAlpha = 0.65;
```

Plot Histogram with Intensity Map

Create a bivariate histogram and add the 2-D projected view of intensities to the histogram.

Load the `seamount` data set (a *seamount* is an underwater mountain). The data set consists of a set of longitude (x) and latitude (y) locations, and the corresponding seamount elevations (z) measured at those coordinates. This example uses x and y to draw a bivariate histogram.

load `seamount`

Draw a bivariate histogram.

```
hist3([x,y])
xlabel('Longitude')
ylabel('Latitude')
hold on
```

Count the number of elements in each bin.

```
N = hist3([x,y]);
```

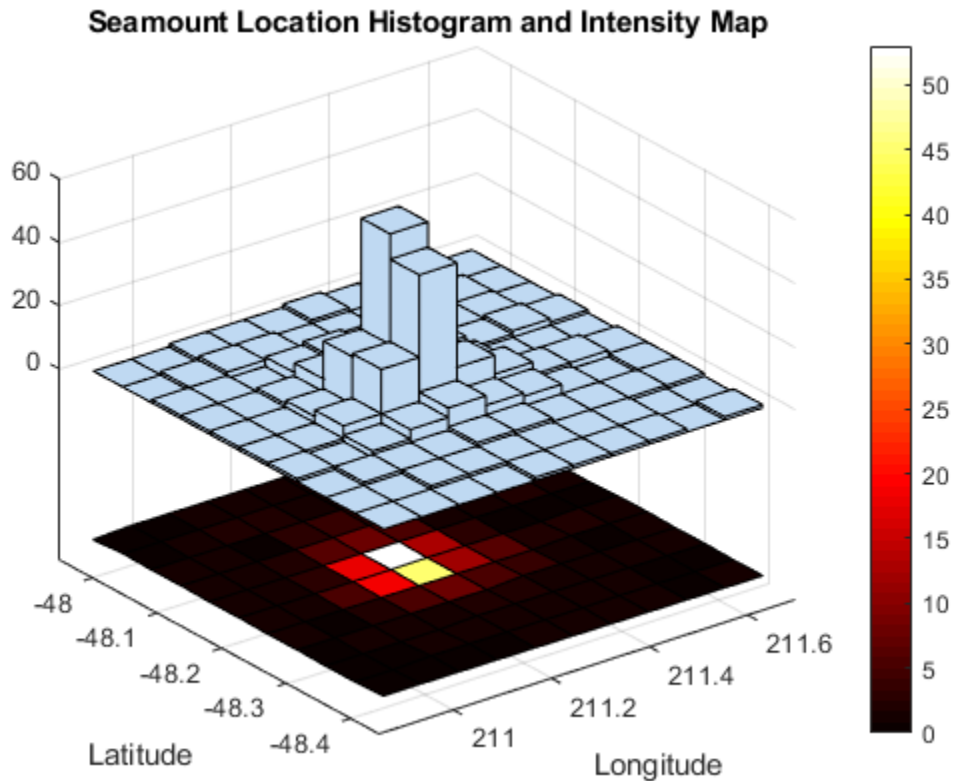

Generate a grid to draw the 2-D projected view of intensities by using `pcolor`.

```
N_pcolor = N';
N_pcolor(size(N_pcolor,1)+1,size(N_pcolor,2)+1) = 0;
```

```
xl = linspace(min(x),max(x),size(N_pcolor,2)); % Columns of N_pcolor
yl = linspace(min(y),max(y),size(N_pcolor,1)); % Rows of N_pcolor
```

Draw the intensity map by using `pcolor`. Set the z-level of the intensity map to view the histogram and the intensity map together.

```
h = pcolor(xl,yl,N_pcolor);
colormap('hot') % Change color scheme
colorbar % Display colorbar
h.ZData = -max(N_pcolor(:))*ones(size(N_pcolor));
ax = gca;
ax.ZTick(ax.ZTick < 0) = [];
title('Seamount Location Histogram and Intensity Map');
```

Input Arguments

X — Data to distribute among bins

m-by-2 numeric matrix

Data to distribute among the bins, specified as an *m*-by-2 numeric matrix, where *m* is the number of data points. Corresponding elements in `X(:,1)` and `X(:,2)` specify the *x* and *y* coordinates of 2-D data points.

`hist3` ignores all NaN values. Similarly, `hist3` ignores Inf and -Inf values unless you explicitly specify Inf or -Inf as a bin edge by using the `edges` input argument.

Data Types: `single` | `double`

nbins — Number of bins

[10 10] (default) | two-element vector of positive integers

Number of bins in each dimension, specified as a two-element vector of positive integers. `nbins(1)` specifies the number of bins in the first dimension, and `nbins(2)` specifies the number of bins in the second dimension.

Example: [10 20]

Data Types: `single` | `double`

ctrs — Bin centers

two-element cell array of numeric vectors

Bin centers in each dimension, specified as a two-element cell array of numeric vectors with monotonically nondecreasing values. `ctrs{1}` and `ctrs{2}` are the positions of the bin centers in the first and second dimensions, respectively.

`hist3` assigns rows of `X` falling outside the range of the grid to the bins along the outer edges of the grid.

Example: {0:10:100 0:50:500}

Data Types: `cell`

edges — Bin edges

two-element cell array of numeric vectors

Bin edges in each dimension, specified as a two-element cell array of numeric vectors with monotonically nondecreasing values. `edges{1}` and `edges{2}` are the positions of the bin edges in the first and second dimensions, respectively.

The value `X(k, :)` is in the (i, j) th bin if `edges{1}(i) ≤ X(k,1) < edges{1}(i+1)` and `edges{2}(j) ≤ X(k,2) < edges{2}(j+1)`.

The last bins in each dimension also include the last (outer) edge. For example, `X(k, :)` falls into the (I, j) th bin if `edges{1}(I-1) ≤ X(k,1) ≤ edges{1}(I)` and `edges{2}(j) ≤ X(k,2) < edges{2}(j+1)`, where `I` is the length of `edges{1}`. Also, `X(k, :)` falls into the (i, J) th bin if `edges{1}(i) ≤ X(k,1) < edges{1}(i+1)` and `edges{2}(J-1) ≤ X(k,2) ≤ edges{2}(J)`, where `J` is the length of `edges{2}`.

`hist3` does not count rows of `X` falling outside the range of the grid. Use `-Inf` and `Inf` in `edges` to include all non-`NaN` values.

Example: `{0:10:100 0:50:500}`

Data Types: `cell`

ax — Target axes

current axes (`gca`) (default) | Axes object

Target axes, specified as an axes object. If you do not specify an Axes object, then the `hist3` function uses the current axes (`gca`). For details, see Axes Properties.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `hist3(X, 'FaceColor', 'interp', 'CDataMode', 'auto')` colors the histogram bars according to the height of the bars.

The graphical properties listed here are only a subset. For a full list, see Surface Properties.

CDataMode — Selection mode for vertex colors

'manual' (default) | 'auto'

Selection mode for `CData` (vertex colors), specified as the comma-separated pair consisting of `'CDataMode'` and one of these values:

- `'manual'` — Use manually specified values in the `CData` property. The default color in `CData` is light steel blue corresponding to an RGB triple value of `[0.75 0.85 0.95]`.
- `'auto'` — Use the `ZData` values to set the colors. `ZData` contains the z-coordinate data for the eight corners of each bar.

Example: `'CDataMode','auto'`

EdgeColor — Edge line color

`[0 0 0]` (default) | `'none'` | `'flat'` | `'interp'` | RGB triplet | hexadecimal color code | color name | short name

Edge line color, specified as the comma-separated pair consisting of `'EdgeColor'` and one of these values:

- `'none'` — Do not draw the edges.
- `'flat'` — Use a different color for each edge based on the values in the `CData` property.
- `'interp'` — Use interpolated coloring for each edge based on the values in the `CData` property.
- RGB triplet, hexadecimal color code, color name, or short name — Use the specified color for all the edges. These values do not use the color values in the `CData` property.

The default color of `[0 0 0]` corresponds to black edges.

RGB triplets and hexadecimal color codes are useful for specifying custom colors.

- An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0,1]`; for example, `[0.4 0.6 0.7]`.
- A hexadecimal color code is a character vector or a string scalar that starts with a hash symbol (`#`) followed by three or six hexadecimal digits, which can range from `0` to `F`. The values are not case sensitive. Thus, the color codes `'#FF8800'`, `'#ff8800'`, `'#F80'`, and `'#f80'` are equivalent.

Alternatively, you can specify some common colors by name. This table lists the named color options, the equivalent RGB triplets, and hexadecimal color codes.

Color Name	Short Name	RGB Triplet	Hexadecimal Color Code	Appearance
'red'	'r'	[1 0 0]	'#FF0000'	
'green'	'g'	[0 1 0]	'#00FF00'	
'blue'	'b'	[0 0 1]	'#0000FF'	
'cyan'	'c'	[0 1 1]	'#00FFFF'	
'magenta'	'm'	[1 0 1]	'#FF00FF'	
'yellow'	'y'	[1 1 0]	'#FFFF00'	
'black'	'k'	[0 0 0]	'#000000'	
'white'	'w'	[1 1 1]	'#FFFFFF'	

Here are the RGB triplets and hexadecimal color codes for the default colors MATLAB uses in many types of plots.

RGB Triplet	Hexadecimal Color Code	Appearance
[0 0.4470 0.7410]	'#0072BD'	
[0.8500 0.3250 0.0980]	'#D95319'	
[0.9290 0.6940 0.1250]	'#EDB120'	
[0.4940 0.1840 0.5560]	'#7E2F8E'	
[0.4660 0.6740 0.1880]	'#77AC30'	
[0.3010 0.7450 0.9330]	'#4DBEEE'	
[0.6350 0.0780 0.1840]	'#A2142F'	

Example: 'EdgeColor', 'blue'

FaceAlpha — Face transparency

1 (default) | scalar in the range [0,1] | 'flat' | 'interp' | 'texturemap'

Face transparency, specified as the comma-separated pair consisting of 'FaceAlpha' and one of these values:

- Scalar in the range [0,1] — Use uniform transparency across all the faces. A value of 1 is fully opaque and 0 is completely transparent. Values between 0 and 1 are semitransparent. This option does not use the transparency values in the AlphaData property.

- `'flat'` — Use a different transparency for each face based on the values in the `AlphaData` property. The transparency value at the first vertex determines the transparency for the entire face. This value applies only when you specify the `AlphaData` property and set the `FaceColor` property to `'flat'`.
- `'interp'` — Use interpolated transparency for each face based on the values in the `AlphaData` property. The transparency varies across each face by interpolating the values at the vertices. This value applies only when you specify the `AlphaData` property and set the `FaceColor` property to `'interp'`.
- `'texturemap'` — Transform the data in `AlphaData` so that it conforms to the surface.

Example: `'FaceAlpha',0.5`

FaceColor — Face color

`'flat'` (default) | `'interp'` | `'none'` | `'texturemap'` | RGB triplet | hexadecimal color code | color name | short name

Face color, specified as the comma-separated pair consisting of `'FaceColor'` and one of these values:

- `'flat'` — Use a different color for each face based on the values in the `CData` property.
- `'interp'` — Use interpolated coloring for each face based on the values in the `CData` property.
- `'none'` — Do not draw the faces.
- `'texturemap'` — Transform the color data in `CData` so that it conforms to the surface.
- RGB triplet, hexadecimal color code, color name, or short name — Use the specified color for all the faces. These values do not use the color values in the `CData` property.

RGB triplets and hexadecimal color codes are useful for specifying custom colors.

- An RGB triplet is a three-element row vector whose elements specify the intensities of the red, green, and blue components of the color. The intensities must be in the range `[0,1]`; for example, `[0.4 0.6 0.7]`.
- A hexadecimal color code is a character vector or a string scalar that starts with a hash symbol (`#`) followed by three or six hexadecimal digits, which can range from `0` to `F`. The values are not case sensitive. Thus, the color codes `'#FF8800'`, `'#ff8800'`, `'#F80'`, and `'#f80'` are equivalent.

Alternatively, you can specify some common colors by name. This table lists the named color options, the equivalent RGB triplets, and hexadecimal color codes.

Color Name	Short Name	RGB Triplet	Hexadecimal Color Code	Appearance
'red'	'r'	[1 0 0]	'#FF0000'	
'green'	'g'	[0 1 0]	'#00FF00'	
'blue'	'b'	[0 0 1]	'#0000FF'	
'cyan'	'c'	[0 1 1]	'#00FFFF'	
'magenta'	'm'	[1 0 1]	'#FF00FF'	
'yellow'	'y'	[1 1 0]	'#FFFF00'	
'black'	'k'	[0 0 0]	'#000000'	
'white'	'w'	[1 1 1]	'#FFFFFF'	

Here are the RGB triplets and hexadecimal color codes for the default colors MATLAB uses in many types of plots.

RGB Triplet	Hexadecimal Color Code	Appearance
[0 0.4470 0.7410]	'#0072BD'	
[0.8500 0.3250 0.0980]	'#D95319'	
[0.9290 0.6940 0.1250]	'#EDB120'	
[0.4940 0.1840 0.5560]	'#7E2F8E'	
[0.4660 0.6740 0.1880]	'#77AC30'	
[0.3010 0.7450 0.9330]	'#4DBEEE'	
[0.6350 0.0780 0.1840]	'#A2142F'	

Example: 'FaceColor', 'interp'

LineStyle — Line style

'-' (default) | '--' | ':' | '-.' | 'none'

Line style, specified as the comma-separated pair consisting of 'LineStyle' and one of the options in this table.

Line Style	Description	Resulting Line
'_'	Solid line	
'--'	Dashed line	
':'	Dotted line	
'-.'	Dash-dotted line	
'none'	No line	No line

Example: 'LineStyle',':'

LineWidth — Line width

0.5 (default) | positive value

Line width, specified as the comma-separated pair consisting of 'LineWidth' and a positive value in points.

Example: 'LineWidth',0.75

Data Types: single | double

Output Arguments

N — Number of elements in each bin

numeric matrix

Number of elements in X that fall in each bin, returned as a numeric matrix.

c — Bin centers

two-element cell array of numeric vectors

Bin centers in each dimension, returned as a two-element cell array of numeric vectors. `c{1}` and `c{2}` are the positions of the bin centers in the first and second dimensions, respectively.

Tips

The `hist3` function creates a bivariate histogram, which is a type of surface plot. You can specify surface properties using one or more name-value pair arguments. Also, you can change the appearance of the histogram by changing the surface property values after you create a histogram. Get the handle of the surface object by using `s = findobj(gca, 'Type', 'Surface')`, and then use `s` to modify the surface properties. For an example, see “Adjust Graphical Properties” on page 32-3076. For a list of properties, see Surface Properties.

Alternative Functionality

The `histogram2` function enables you to create a bivariate histogram using a `Histogram2` object. You can use the name-value pair arguments of `histogram2` to use normalization (`'Normalization'`), adjust the width of the bins in each dimension (`'BinWidth'`), and display the histogram as a rectangular array of tiles instead of 3-D bars (`'DisplayStyle'`).

Introduced before R2006a

histfit

Histogram with a distribution fit

Syntax

```
histfit(data)
histfit(data,nbins)
histfit(data,nbins,dist)

h = histfit( ___ )
```

Description

`histfit(data)` plots a histogram of values in `data` using the number of bins equal to the square root of the number of elements in `data` and fits a normal density function.

`histfit(data,nbins)` plots a histogram using `nbins` bins and fits a normal density function.

`histfit(data,nbins,dist)` plots a histogram with `nbins` bins and fits a density function from the distribution specified by `dist`.

`h = histfit(___)` returns a vector of handles `h`, where `h(1)` is the handle to the histogram and `h(2)` is the handle to the density curve. It can include any of the input arguments in previous syntaxes.

Examples

Histogram with a Normal Distribution Fit

Generate a sample of size 100 from a normal distribution with mean 10 and variance 1.

```
rng default; % For reproducibility
r = normrnd(10,1,100,1);
```

Construct a histogram with a normal distribution fit.

```
histfit(r)
```

`histfit` uses `fitdist` to fit a distribution to data. Use `fitdist` to obtain parameters used in fitting.

```
pd = fitdist(r, 'Normal')
```

```
pd =  
NormalDistribution  
  
Normal distribution  
mu = 10.1231 [9.89244, 10.3537]
```

```
sigma = 1.1624 [1.02059, 1.35033]
```

The intervals next to the parameter estimates are the 95% confidence intervals for the distribution parameters.

Histogram for a Given Number of Bins

Generate a sample of size 100 from a normal distribution with mean 10 and variance 1.

```
rng default; % For reproducibility  
r = normrnd(10,1,100,1);
```

Construct a histogram using six bins with a normal distribution fit.

```
histfit(r,6)
```

Histogram with a Specified Distribution Fit

Generate a sample of size 100 from a beta distribution with parameters (3,10).

```
rng default; % For reproducibility  
b = betarnd(3,10,100,1);
```

Construct a histogram using 10 bins with a beta distribution fit.

```
histfit(b,10,'beta')
```

Histogram with a Kernel Smoothing Function Fit

Generate a sample of size 100 from a beta distribution with parameters (3,10).

```
rng default; % For reproducibility  
b = betarnd(3,10,[100,1]);
```

Construct a histogram using 10 bins with a smoothing function fit.

```
histfit(b,10,'kernel')
```

Handle for a Histogram with a Distribution Fit

Generate a sample of size 100 from a normal distribution with mean 10 and variance 1.

```
rng default % for reproducibility  
r = normrnd(10,1,100,1);
```

Construct a histogram with a normal distribution fit.

```
h = histfit(r,10,'normal')
```

```
h =  
 2x1 graphics array:
```

```
  Bar  
  Line
```

Change the bar colors of the histogram.

```
h(1).FaceColor = [.8 .8 1];
```

Change the color of the density curve.

```
h(2).Color = [.2 .2 .2];
```

Input Arguments

data — Input data

vector

Input data, specified as a vector.

Example: `data = [1.5 2.5 4.6 1.2 3.4]`

Example: `data = [1.5 2.5 4.6 1.2 3.4]'`

Data Types: `double` | `single`

nbins — Number of bins

positive integer | []

Number of bins for the histogram, specified as a positive integer. Default value is the square root of the number of elements in `data`, rounded up. Use [] for the default number of bins when fitting a distribution.

Example: `y = histfit(x,8)`

Example: `y = histfit(x,10,'gamma')`

Example: `y = histfit(x,[],'weibull')`

Data Types: `double` | `single`

dist — Distribution to fit

'normal' (default) | character vector | string scalar

Distribution to fit to the histogram, specified as a character vector or string scalar. The following table shows the supported distributions.

dist	Description
'beta'	Beta
'birnbaumsaunders'	Birnbaum-Saunders
'burr'	Burr Type XII
'exponential'	Exponential
'extreme value' or 'ev'	Extreme value
'gamma'	Gamma
'generalized extreme value' or 'gev'	Generalized extreme value
'generalized pareto' or 'gp'	Generalized Pareto (threshold 0)
'inversegaussian'	Inverse Gaussian
'logistic'	Logistic
'loglogistic'	Loglogistic
'lognormal'	Lognormal
'nakagami'	Nakagami
'negative binomial' or 'nbin'	Negative binomial

dist	Description
'normal'	Normal
'poisson'	Poisson
'rayleigh'	Rayleigh
'rician'	Rician
'tlocation-scale'	t location-scale
'weibull' or 'wbl'	Weibull
'kernel'	Nonparametric kernel-smoothing distribution. The density is evaluated at 100 equally spaced points that cover the range of the data in <code>data</code> . It works best with continuously distributed samples.

Output Arguments

h — Handles for the plot

plot handle

Handles for the plot, returned as a vector, where `h(1)` is the handle to the histogram, and `h(2)` is the handle to the density curve. `histfit` normalizes the density to match the total area under the curve with that of the histogram.

Algorithms

`histfit` uses `fitdist` to fit a distribution to data. Use `fitdist` to obtain parameters used in fitting.

hmmdecode

Hidden Markov model posterior state probabilities

Syntax

```
PSTATES = hmmdecode(seq, TRANS, EMIS)
[PSTATES, logpseq] = hmmdecode(...)
[PSTATES, logpseq, FORWARD, BACKWARD, S] = hmmdecode(...)
hmmdecode(..., 'Symbols', SYMBOLS)
```

Description

`PSTATES = hmmdecode(seq, TRANS, EMIS)` calculates the posterior state probabilities, `PSTATES`, of the sequence `seq`, from a hidden Markov model. The posterior state probabilities are the conditional probabilities of being at state k at step i , given the observed sequence of symbols, `sym`. You specify the model by a transition probability matrix, `TRANS`, and an emissions probability matrix, `EMIS`. `TRANS(i, j)` is the probability of transition from state i to state j . `EMIS(k, seq)` is the probability that symbol `seq` is emitted from state k .

`PSTATES` is an array with the same length as `seq` and one row for each state in the model. The (i, j) th element of `PSTATES` gives the probability that the model is in state i at the j th step, given the sequence `seq`.

Note The function `hmmdecode` begins with the model in state 1 at step 0, prior to the first emission. `hmmdecode` computes the probabilities in `PSTATES` based on the fact that the model begins in state 1.

`[PSTATES, logpseq] = hmmdecode(...)` returns `logpseq`, the logarithm of the probability of sequence `seq`, given transition matrix `TRANS` and emission matrix `EMIS`.

`[PSTATES, logpseq, FORWARD, BACKWARD, S] = hmmdecode(...)` returns the forward and backward probabilities of the sequence scaled by `S`.

`hmmdecode(..., 'Symbols', SYMBOLS)` specifies the symbols that are emitted. `SYMBOLS` can be a numeric array, a string array, or a cell array of the names of the symbols. The default symbols are integers 1 through `N`, where `N` is the number of possible emissions.

Examples

```
trans = [0.95,0.05;  
         0.10,0.90];  
emis = [1/6 1/6 1/6 1/6 1/6 1/6;  
        1/10 1/10 1/10 1/10 1/10 1/2];  
  
[seq,states] = hmmgenerate(100,trans,emis);  
pStates = hmmdecode(seq,trans,emis);  
[seq,states] = hmmgenerate(100,trans,emis,...  
    'Symbols',{'one','two','three','four','five','six'})  
pStates = hmmdecode(seq,trans,emis,...  
    'Symbols',{'one','two','three','four','five','six'});
```

See Also

`hmmestimate` | `hmmgenerate` | `hmmtrain` | `hmmviterbi`

Introduced before R2006a

hmmestimate

Hidden Markov model parameter estimates from emissions and states

Syntax

```
[TRANS,EMIS] = hmmestimate(seq,states)
hmmestimate(...,'Symbols',SYMBOLS)
hmmestimate(...,'Statenames',STATENAMES)
hmmestimate(...,'Pseudoemissions',PSEUDOE)
hmmestimate(...,'Pseudotransitions',PSEUDOTR)
```

Description

`[TRANS,EMIS] = hmmestimate(seq,states)` calculates the maximum likelihood estimate of the transition, TRANS, and emission, EMIS, probabilities of a hidden Markov model for sequence, seq, with known states, states.

`hmmestimate(...,'Symbols',SYMBOLS)` specifies the symbols that are emitted. SYMBOLS can be a numeric array, a string array or a cell array of the names of the symbols. The default symbols are integers 1 through N, where N is the number of possible emissions.

`hmmestimate(...,'Statenames',STATENAMES)` specifies the names of the states. STATENAMES can be a numeric array, a string array, or a cell array of the names of the states. The default state names are 1 through M, where M is the number of states.

`hmmestimate(...,'Pseudoemissions',PSEUDOE)` specifies pseudocount emission values in the matrix PSEUDOE. Use this argument to avoid zero probability estimates for emissions with very low probability that might not be represented in the sample sequence. PSEUDOE should be a matrix of size m -by- n , where m is the number of states in the hidden Markov model and n is the number of possible emissions. If the $i \rightarrow k$ emission does not occur in seq, you can set PSEUDOE(i,k) to be a positive number representing an estimate of the expected number of such emissions in the sequence seq.

`hmmestimate(...,'Pseudotransitions',PSEUDOTR)` specifies pseudocount transition values. You can use this argument to avoid zero probability estimates for

transitions with very low probability that might not be represented in the sample sequence. PSEUDOTR should be a matrix of size m -by- m , where m is the number of states in the hidden Markov model. If the $i \rightarrow j$ transition does not occur in `states`, you can set PSEUDOTR(i, j) to be a positive number representing an estimate of the expected number of such transitions in the sequence `states`.

Pseudotransitions and Pseudoemissions

If the probability of a specific transition or emission is very low, the transition might never occur in the sequence `states`, or the emission might never occur in the sequence `seq`. In either case, the algorithm returns a probability of 0 for the given transition or emission in TRANS or EMIS. You can compensate for the absence of transition with the 'Pseudotransitions' and 'Pseudoemissions' arguments. The simplest way to do this is to set the corresponding entry of PSEUDOE or PSEUDOTR to 1. For example, if the transition $i \rightarrow j$ does not occur in `states`, set PSEUDOTR(i, j) = 1. This forces TRANS(i, j) to be positive. If you have an estimate for the expected number of transitions $i \rightarrow j$ in a sequence of the same length as `states`, and the actual number of transitions $i \rightarrow j$ that occur in `seq` is substantially less than what you expect, you can set PSEUDOTR(i, j) to the expected number. This increases the value of TRANS(i, j). For transitions that do occur in `states` with the frequency you expect, set the corresponding entry of PSEUDOTR to 0, which does not increase the corresponding entry of TRANS.

If you do not know the sequence of states, use `hmmtrain` to estimate the model parameters.

Examples

```
trans = [0.95,0.05; 0.10,0.90];
emis = [1/6 1/6 1/6 1/6 1/6 1/6;
        1/10 1/10 1/10 1/10 1/10 1/2];

[seq,states] = hmmgenerate(1000,trans,emis);
[estimateTR,estimateE] = hmmestimate(seq,states);
```

hmmgenerate

Hidden Markov model states and emissions

Syntax

```
[seq,states] = hmmgenerate(len,TRANS,EMIS)
hmmgenerate(...,'Symbols',SYMBOLS)
hmmgenerate(...,'Statenames',STATENAMES)
```

Description

[seq,states] = hmmgenerate(len,TRANS,EMIS) takes a known Markov model, specified by transition probability matrix TRANS and emission probability matrix EMIS, and uses it to generate

- A random sequence seq of emission symbols
- A random sequence states of states

The length of both seq and states is len. TRANS(i,j) is the probability of transition from state i to state j. EMIS(k,l) is the probability that symbol l is emitted from state k.

Note The function hmmgenerate begins with the model in state 1 at step 0, prior to the first emission. The model then makes a transition to state i_1 , with probability T_{1i_1} , and generates an emission a_{k_1} with probability $E_{i_1k_1}$. hmmgenerate returns i_1 as the first entry of states, and a_{k_1} as the first entry of seq.

hmmgenerate(...,'Symbols',SYMBOLS) specifies the symbols that are emitted. SYMBOLS can be specified as a numeric array, a string array, or a cell array of character vectors. The default symbols are integers 1 through N, where N is the number of possible emissions.

hmmgenerate(...,'Statenames',STATENAMES) specifies the names of the states. STATENAMES can be specified as a numeric array, a string array, or a cell array of

character vectors. The default state names are 1 through M, where M is the number of states.

Since the model always begins at state 1, whose transition probabilities are in the first row of TRANS, in the following example, the first entry of the output `states` is be 1 with probability 0.95 and 2 with probability 0.05.

Examples

```
trans = [0.95,0.05;
         0.10,0.90];
emis = [1/6 1/6 1/6 1/6 1/6 1/6;
        1/10 1/10 1/10 1/10 1/10 1/2];

[seq,states] = hmmgenerate(100,trans,emis)
[seq,states] = hmmgenerate(100,trans,emis,...
    'Symbols',{'one','two','three','four','five','six'},...
    'Statenames',{'fair';'loaded'})
```

`hmmdecode` | `hmmestimate` | `hmmtrain` | `hmmviterbi`

Introduced before R2006a

hmmtrain

Hidden Markov model parameter estimates from emissions

Syntax

```
[ESTTR,ESTEMIT] = hmmtrain(seq,TRGUESS,EMITGUESS)
hmmtrain(...,'Algorithm',algorithm)
hmmtrain(...,'Symbols',SYMBOLS)
hmmtrain(...,'Tolerance',tol)
hmmtrain(...,'Maxiterations',maxiter)
hmmtrain(...,'Verbose',true)
hmmtrain(...,'Pseudoemissions',PSEUDOE)
hmmtrain(...,'Pseudotransitions',PSEUDOTR)
```

Description

[ESTTR,ESTEMIT] = `hmmtrain(seq,TRGUESS,EMITGUESS)` estimates the transition and emission probabilities for a hidden Markov model using the Baum-Welch algorithm. `seq` can be a row vector containing a single sequence, a matrix with one row per sequence, or a cell array with each cell containing a sequence. `TRGUESS` and `EMITGUESS` are initial estimates of the transition and emission probability matrices. `TRGUESS(i,j)` is the estimated probability of transition from state `i` to state `j`. `EMITGUESS(i,k)` is the estimated probability that symbol `k` is emitted from state `i`.

`hmmtrain(...,'Algorithm',algorithm)` specifies the training algorithm. *algorithm* can be either 'BaumWelch' or 'Viterbi'. The default algorithm is 'BaumWelch'.

`hmmtrain(...,'Symbols',SYMBOLS)` specifies the symbols that are emitted. `SYMBOLS` can be a numeric array, a string array, or a cell array of the names of the symbols. The default symbols are integers 1 through `N`, where `N` is the number of possible emissions.

`hmmtrain(...,'Tolerance',tol)` specifies the tolerance used for testing convergence of the iterative estimation process. The default tolerance is `1e-4`.

`hmmtrain(..., 'Maxiterations', maxiter)` specifies the maximum number of iterations for the estimation process. The default maximum is 100.

`hmmtrain(..., 'Verbose', true)` returns the status of the algorithm at each iteration.

`hmmtrain(..., 'Pseudoemissions', PSEUDO_E)` specifies pseudocount emission values for the Viterbi training algorithm. Use this argument to avoid zero probability estimates for emissions with very low probability that might not be represented in the sample sequence. PSEUDO_E should be a matrix of size m -by- n , where m is the number of states in the hidden Markov model and n is the number of possible emissions. If the $i \rightarrow k$ emission does not occur in `seq`, you can set PSEUDO_E(i , k) to be a positive number representing an estimate of the expected number of such emissions in the sequence `seq`.

`hmmtrain(..., 'Pseudotransitions', PSEUDO_TR)` specifies pseudocount transition values for the Viterbi training algorithm. Use this argument to avoid zero probability estimates for transitions with very low probability that might not be represented in the sample sequence. PSEUDO_TR should be a matrix of size m -by- m , where m is the number of states in the hidden Markov model. If the $i \rightarrow j$ transition does not occur in `states`, you can set PSEUDO_TR(i , j) to be a positive number representing an estimate of the expected number of such transitions in the sequence `states`.

If you know the states corresponding to the sequences, use `hmmestimate` to estimate the model parameters.

Tolerance

The input argument `'tolerance'` controls how many steps the `hmmtrain` algorithm executes before the function returns an answer. The algorithm terminates when all of the following three quantities are less than the value that you specify for `tolerance`:

- The log likelihood that the input sequence `seq` is generated by the currently estimated values of the transition and emission matrices
- The change in the norm of the transition matrix, normalized by the size of the matrix
- The change in the norm of the emission matrix, normalized by the size of the matrix

The default value of `'tolerance'` is $1e-6$. Increasing the tolerance decreases the number of steps the `hmmtrain` algorithm executes before it terminates.

maxiterations

The maximum number of iterations, 'maxiterations', controls the maximum number of steps the algorithm executes before it terminates. If the algorithm executes `maxiter` iterations before reaching the specified tolerance, the algorithm terminates and the function returns a warning. If this occurs, you can increase the value of 'maxiterations' to make the algorithm reach the desired tolerance before terminating.

Examples

```
trans = [0.95,0.05;  
         0.10,0.90];  
emis = [1/6, 1/6, 1/6, 1/6, 1/6, 1/6;  
        1/10, 1/10, 1/10, 1/10, 1/10, 1/2];  
  
seq1 = hmmgenerate(100,trans,emis);  
seq2 = hmmgenerate(200,trans,emis);  
seqs = {seq1,seq2};  
[estTR,estE] = hmmtrain(seqs,trans,emis);
```

hmmviterbi

Hidden Markov model most probable state path

Syntax

```
STATES = hmmviterbi(seq,TRANS,EMIS)
hmmviterbi(...,'Symbols',SYMBOLS)
hmmviterbi(...,'Statenames',STATENAMES)
```

Description

`STATES = hmmviterbi(seq,TRANS,EMIS)` given a sequence, `seq`, calculates the most likely path through the hidden Markov model specified by transition probability matrix, `TRANS`, and emission probability matrix `EMIS`. `TRANS(i, j)` is the probability of transition from state `i` to state `j`. `EMIS(i, k)` is the probability that symbol `k` is emitted from state `i`.

Note The function `hmmviterbi` begins with the model in state 1 at step 0, prior to the first emission. `hmmviterbi` computes the most likely path based on the fact that the model begins in state 1.

`hmmviterbi(...,'Symbols',SYMBOLS)` specifies the symbols that are emitted. `SYMBOLS` can be a numeric array, a string array, or a cell array of the names of the symbols. The default symbols are integers 1 through `N`, where `N` is the number of possible emissions.

`hmmviterbi(...,'Statenames',STATENAMES)` specifies the names of the states. `STATENAMES` can be a numeric array, a string array, or a cell array of the names of the states. The default state names are 1 through `M`, where `M` is the number of states.

Examples

```
trans = [0.95,0.05;
         0.10,0.90];
```

```
emis = [1/6 1/6 1/6 1/6 1/6 1/6;  
        1/10 1/10 1/10 1/10 1/10 1/2];  
  
[seq,states] = hmmgenerate(100,trans,emis);  
estimatedStates = hmmviterbi(seq,trans,emis);  
  
[seq,states] = ...  
    hmmgenerate(100,trans,emis,...  
                'Statenames',{'fair';'loaded'});  
estimatedStates = ...  
    hmmviterbi(seq,trans,emis,...  
                'Statenames',{'fair';'loaded'});
```

horzcat

Class: dataset

Horizontal concatenation for dataset arrays

Note The dataset data type might be removed in a future release. To work with heterogeneous data, use the MATLAB® table data type instead. See MATLAB table documentation for more information.

Syntax

```
ds = horzcat(ds1, ds2, ...)
```

Description

`ds = horzcat(ds1, ds2, ...)` horizontally concatenates the dataset arrays `ds1`, `ds2`, You may concatenate dataset arrays that have duplicate variable names, however, the variables must contain identical data, and `horzcat` includes only one copy of the variable in the output dataset.

Observation names for all dataset arrays that have them must be identical except for order. `horzcat` concatenates by matching observation names when present, or by position for datasets that do not have observation names.

`cat` | `vertcat`

hougen

Hougen-Watson model

Syntax

```
yhat = hougen(beta, x)
```

Description

`yhat = hougen(beta, x)` returns the predicted values of the reaction rate, `yhat`, as a function of the vector of parameters, `beta`, and the matrix of data, `X`. `beta` must have 5 elements and `X` must have three columns.

`hougen` is a utility function for `rsmdemo`.

The model form is:

$$\hat{y} = \frac{\beta_1 x_2 - x_3 / \beta_5}{1 + \beta_2 x_1 + \beta_3 x_2 + \beta_4 x_3}$$

hygecdf

Hypergeometric cumulative distribution function

Syntax

```
hygecdf(x,M,K,N)  
hygecdf(x,M,K,N,'upper')
```

Description

`hygecdf(x,M,K,N)` computes the hypergeometric cdf at each of the values in `x` using the corresponding size of the population, `M`, number of items with the desired characteristic in the population, `K`, and number of samples drawn, `N`. Vector or matrix inputs for `x`, `M`, `K`, and `N` must all have the same size. A scalar input is expanded to a constant matrix with the same dimensions as the other inputs.

`hygecdf(x,M,K,N,'upper')` returns the complement of the hypergeometric cdf at each value in `x`, using an algorithm that more accurately computes the extreme upper tail probabilities.

The hypergeometric cdf is

$$p = F(x \mid M, K, N) = \sum_{i=0}^x \frac{\binom{K}{i} \binom{M-K}{N-i}}{\binom{M}{N}}$$

The result, p , is the probability of drawing up to x of a possible K items in N drawings without replacement from a group of M objects.

Examples

Compute Hypergeometric Distribution CDF

Suppose you have a lot of 100 floppy disks and you know that 20 of them are defective. What is the probability of drawing zero to two defective floppies if you select 10 at random?

```
p = hygecdf(2,100,20,10)
```

```
p = 0.6812
```

Extended Capabilities

Introduced before R2006a

hygeinv

Hypergeometric inverse cumulative distribution function

Syntax

```
hygeinv(P,M,K,N)
```

Description

`hygeinv(P,M,K,N)` returns the smallest integer X such that the hypergeometric cdf evaluated at X equals or exceeds P . You can think of P as the probability of observing X defective items in N drawings without replacement from a group of M items where K are defective.

Examples

Suppose you are the Quality Assurance manager for a floppy disk manufacturer. The production line turns out floppy disks in batches of 1,000. You want to sample 50 disks from each batch to see if they have defects. You want to accept 99% of the batches if there are no more than 10 defective disks in the batch. What is the maximum number of defective disks should you allow in your sample of 50?

```
x = hygeinv(0.99,1000,10,50)
x =
    3
```

What is the median number of defective floppy disks in samples of 50 disks from batches with 10 defective disks?

```
x = hygeinv(0.50,1000,10,50)
x =
    0
```

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Introduced before R2006a

hygepdf

Hypergeometric probability density function

Syntax

$Y = \text{hygepdf}(X, M, K, N)$

Description

$Y = \text{hygepdf}(X, M, K, N)$ computes the hypergeometric pdf at each of the values in X using the corresponding size of the population, M , number of items with the desired characteristic in the population, K , and number of samples drawn, N . X , M , K , and N can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other inputs.

The parameters in M , K , and N must all be positive integers, with $N \leq M$. The values in X must be less than or equal to all the parameter values.

The hypergeometric pdf is

$$y = f(x) \left| \begin{array}{l} M, K, N \end{array} \right. = \frac{\binom{K}{x} \binom{M-K}{N-x}}{\binom{M}{N}}$$

The result, y , is the probability of drawing exactly x of a possible K items in n drawings without replacement from a group of M objects.

Examples

Suppose you have a lot of 100 floppy disks and you know that 20 of them are defective. What is the probability of drawing 0 through 5 defective floppy disks if you select 10 at random?

```
p = hygepdf(0:5,100,20,10)
p =
    0.0951    0.2679    0.3182    0.2092    0.0841    0.0215
```

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

[hygecdf](#) | [hygeinv](#) | [hygernd](#) | [hygestat](#) | [pdf](#)

Introduced before R2006a

hygernd

Hypergeometric random numbers

Syntax

```
R = hygernd(M,K,N)
R = hygernd(M,K,N,m,n,...)
R = hygernd(M,K,N,[m,n,...])
```

Description

`R = hygernd(M,K,N)` generates random numbers from the hypergeometric distribution with corresponding size of the population, `M`, number of items with the desired characteristic in the population, `K`, and number of samples drawn, `N`. `M`, `K`, and `N` can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of `R`. A scalar input for `M`, `K`, or `N` is expanded to a constant array with the same dimensions as the other inputs.

`R = hygernd(M,K,N,m,n,...)` or `R = hygernd(M,K,N,[m,n,...])` generates an `m-by-n-by-...` array. The `M`, `K`, `N` parameters can each be scalars or arrays of the same size as `R`.

Examples

```
numbers = hygernd(1000,40,50)
numbers =
    1
```

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

The generated code can return a different sequence of numbers than MATLAB if either of the following is true:

- The output is nonscalar.
- An input parameter is invalid for the distribution.

For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “General Code Generation Workflow” on page 31-5.

Introduced before R2006a

hygestat

Hypergeometric mean and variance

Syntax

```
[MN,V] = hygestat(M,K,N)
```

Description

[MN,V] = hygestat(M,K,N) returns the mean of and variance for the hypergeometric distribution with corresponding size of the population, M, number of items with the desired characteristic in the population, K, and number of samples drawn, N. Vector or matrix inputs for M, K, and N must have the same size, which is also the size of MN and V. A scalar input for M, K, or N is expanded to a constant matrix with the same dimensions as the other inputs.

The mean of the hypergeometric distribution with parameters M, K, and N is NK/M , and the variance is $NK(M-K)(M-N)/[M^2(M-1)]$.

Examples

The hypergeometric distribution approaches the binomial distribution, where $p = K/M$, as M goes to infinity.

```
[m,v] = hygestat(10.^(1:4),10.^(0:3),9)
```

```
m =  
    0.9000    0.9000    0.9000    0.9000  
v =  
    0.0900    0.7445    0.8035    0.8094
```

```
[m,v] = binostat(9,0.1)
```

```
m =  
    0.9000  
v =  
    0.8100
```

Extended Capabilities

hyperparameters

Variable descriptions for optimizing a fit function

Syntax

```
VariableDescriptions = hyperparameters(FitFcnName,predictors,  
response)
```

```
VariableDescriptions = hyperparameters(FitFcnName,predictors,  
response,LearnerType)
```

Description

`VariableDescriptions = hyperparameters(FitFcnName,predictors, response)` returns the default variables for the given fit function. These are the variables that apply when you set the `OptimizeHyperparameters` name-value pair to `'auto'`.

`VariableDescriptions = hyperparameters(FitFcnName,predictors, response,LearnerType)` returns the variables for an ensemble fit with specified learner type. This syntax applies when `FitFcnName` is `'fitcecoc'`, `'fitcensemble'`, or `'fitrensemble'`.

Examples

Obtain Default Hyperparameters

Obtain the default hyperparameters for the `fitcsvm` classifier.

Load the ionosphere data.

```
load ionosphere
```

Obtain the hyperparameters.

```
VariableDescriptions = hyperparameters('fitcsvm',X,Y);
```

Examine all the hyperparameters.

```
for ii = 1:length(VariableDescriptions)
    disp(ii),disp(VariableDescriptions(ii))
end
```

1

optimizableVariable with properties:

```
    Name: 'BoxConstraint'
    Range: [1.0000e-03 1000]
    Type: 'real'
    Transform: 'log'
    Optimize: 1
```

2

optimizableVariable with properties:

```
    Name: 'KernelScale'
    Range: [1.0000e-03 1000]
    Type: 'real'
    Transform: 'log'
    Optimize: 1
```

3

optimizableVariable with properties:

```
    Name: 'KernelFunction'
    Range: {'gaussian' 'linear' 'polynomial'}
    Type: 'categorical'
    Transform: 'none'
    Optimize: 0
```

4

optimizableVariable with properties:

```
    Name: 'PolynomialOrder'
    Range: [2 4]
    Type: 'integer'
```

```
Transform: 'none'  
Optimize: 0
```

```
5
```

```
optimizableVariable with properties:
```

```
    Name: 'Standardize'  
    Range: {'true' 'false'}  
    Type: 'categorical'  
Transform: 'none'  
Optimize: 0
```

Change the `PolynomialOrder` hyperparameter to have a wider range and to be used in an optimization.

```
VariableDescriptions(4).Range = [2,5];  
VariableDescriptions(4).Optimize = true;  
disp(VariableDescriptions(4))
```

```
optimizableVariable with properties:
```

```
    Name: 'PolynomialOrder'  
    Range: [2 5]  
    Type: 'integer'  
Transform: 'none'  
Optimize: 1
```

Obtain Ensemble Hyperparameters

Obtain the default hyperparameters for the `fitrensemble` ensemble regression function.

Load the `carsmall` data.

```
load carsmall
```

Use `Horsepower` and `Weight` as predictor variables, and `MPG` as the response variable.

```
X = [Horsepower Weight];  
Y = MPG;
```

Obtain the default hyperparameters for a `Tree` learner.

```
VariableDescriptions = hyperparameters('fitrensemble',X,Y,'Tree');
```

Examine all the hyperparameters.

```
for ii = 1:length(VariableDescriptions)
    disp(ii),disp(VariableDescriptions(ii))
end
```

1

optimizableVariable with properties:

```
    Name: 'Method'
    Range: {'Bag' 'LSBoost'}
    Type: 'categorical'
    Transform: 'none'
    Optimize: 1
```

2

optimizableVariable with properties:

```
    Name: 'NumLearningCycles'
    Range: [10 500]
    Type: 'integer'
    Transform: 'log'
    Optimize: 1
```

3

optimizableVariable with properties:

```
    Name: 'LearnRate'
    Range: [1.0000e-03 1]
    Type: 'real'
    Transform: 'log'
    Optimize: 1
```

4

optimizableVariable with properties:

```
    Name: 'MinLeafSize'
    Range: [1 50]
    Type: 'integer'
```

```
Transform: 'log'  
Optimize: 1
```

5

optimizableVariable with properties:

```
    Name: 'MaxNumSplits'  
    Range: [1 99]  
    Type: 'integer'  
Transform: 'log'  
Optimize: 0
```

6

optimizableVariable with properties:

```
    Name: 'NumVariablesToSample'  
    Range: [1 2]  
    Type: 'integer'  
Transform: 'none'  
Optimize: 0
```

Change the `MaxNumSplits` hyperparameter to have a wider range and to be used in an optimization.

```
VariableDescriptions(5).Range = [1,200];  
VariableDescriptions(5).Optimize = true;  
disp(VariableDescriptions(5))
```

optimizableVariable with properties:

```
    Name: 'MaxNumSplits'  
    Range: [1 200]  
    Type: 'integer'  
Transform: 'log'  
Optimize: 1
```

Input Arguments

FitFcnName — Name of fitting function

'fitcdiscr' | 'fitcecoc' | 'fitcensemble' | 'fitckernel' | 'fitcknn' | 'fitcllinear' | 'fitcnb' | 'fitcsvm' | 'fitctree' | 'fitrensemble' | 'fitrgp' | 'fitrkernel' | 'fitrlinear' | 'fitrsvm' | 'fitrtree'

Name of fitting function, specified as one of the listed classification or regression fit function names.

If `FitFcnName` is 'fitcecoc', 'fitcensemble', or 'fitrensemble', then also specify the learner type in the `LearnerType` argument.

Example: 'fitctree'

predictors — Predictor data

matrix with D predictor columns | table with D predictor columns

Predictor data, specified as a matrix with D predictor columns or as a table with D predictor columns, where D is the number of predictors.

Example: X

Data Types: double | logical | char | string | table | cell | categorical | datetime

response — Class labels or numeric response

grouping variable | scalar

Class labels or numeric response, specified as a grouping variable (see “Grouping Variables” on page 2-57) or as a scalar.

Example: Y

Data Types: single | double | logical | char | string | cell

LearnerType — Learner type for ensemble fit

'Discriminant' | 'Kernel' | 'KNN' | 'Linear' | 'SVM' | 'Tree' | template of a listed learner

Learner type for ensemble fit, specified as 'Discriminant', 'Kernel', 'KNN', 'Linear', 'SVM', 'Tree', or a template of a listed learner. Use this argument when `FitFcnName` is 'fitcecoc', 'fitcensemble', or 'fitrensemble'.

For 'fitcensemble' you can use only 'Discriminant', 'KNN', 'Tree', or an associated template.

For 'fitrensemble', you can use only 'Tree' or templateTree.

Example: 'Tree'

Output Arguments

VariableDescriptions — Variable descriptions

vector of `optimizableVariable` objects

Variable descriptions, returned as a vector of `optimizableVariable` objects. The variables have their default parameters set, such as range and variable type. All eligible variables exist in the descriptions, but the variables unused in the 'auto' setting have their `Optimize` property set to `false`. You can update the variables by using dot notation, as shown in “Examples” on page 32-0 .

Introduced in R2016b

icdf

Package: prob

Inverse cumulative distribution function

Syntax

```
x = icdf('name', p, A)
x = icdf('name', p, A, B)
x = icdf('name', p, A, B, C)
x = icdf('name', p, A, B, C, D)

x = icdf(pd, p)
```

Description

`x = icdf('name', p, A)` returns the inverse cumulative distribution function (icdf) for the one-parameter distribution family specified by 'name' and the distribution parameter A, evaluated at the probability values in p.

`x = icdf('name', p, A, B)` returns the icdf for the two-parameter distribution family specified by 'name' and the distribution parameters A and B, evaluated at the probability values in p.

`x = icdf('name', p, A, B, C)` returns the icdf for the three-parameter distribution family specified by 'name' and the distribution parameters A, B, and C, evaluated at the probability values in p.

`x = icdf('name', p, A, B, C, D)` returns the icdf for the four-parameter distribution family specified by 'name' and the distribution parameters A, B, C, and D, evaluated at the probability values in p.

`x = icdf(pd, p)` returns the icdf function of the probability distribution object pd, evaluated at the probability values in p.

Examples

Compute the Normal Distribution icdf

Create a standard normal distribution object with the mean, μ , equal to 0 and the standard deviation, σ , equal to 1.

```
mu = 0;  
sigma = 1;  
pd = makedist('Normal','mu',mu,'sigma',sigma);
```

Define the input vector p to contain the probability values at which to calculate the icdf.

```
p = [0.1,0.25,0.5,0.75,0.9];
```

Compute the icdf values for the standard normal distribution at the values in p .

```
x = icdf(pd,p)
```

```
x = 1×5
```

```
-1.2816   -0.6745         0    0.6745    1.2816
```

Each value in x corresponds to a value in the input vector p . For example, at the value p equal to 0.9, the corresponding icdf value x is equal to 1.2816.

Alternatively, you can compute the same icdf values without creating a probability distribution object. Use the `icdf` function and specify a standard normal distribution using the same parameter values for μ and σ .

```
x2 = icdf('Normal',p,mu,sigma)
```

```
x2 = 1×5
```

```
-1.2816   -0.6745         0    0.6745    1.2816
```

The icdf values are the same as those computed using the probability distribution object.

Compute the Poisson Distribution icdf

Create a Poisson distribution object with the rate parameter, λ , equal to 2.

```
lambda = 2;
pd = makedist('Poisson', 'lambda', lambda);
```

Define the input vector p to contain the probability values at which to calculate the icdf.

```
p = [0.1, 0.25, 0.5, 0.75, 0.9];
```

Compute the icdf values for the Poisson distribution at the values in p .

```
x = icdf(pd, p)
```

```
x = 1×5
```

```
    0    1    2    3    4
```

Each value in x corresponds to a value in the input vector p . For example, at the value p equal to 0.9, the corresponding icdf value x is equal to 4.

Alternatively, you can compute the same icdf values without creating a probability distribution object. Use the `icdf` function and specify a Poisson distribution using the same value for the rate parameter λ .

```
x2 = icdf('Poisson', p, lambda)
```

```
x2 = 1×5
```

```
    0    1    2    3    4
```

The icdf values are the same as those computed using the probability distribution object.

Compute Standard Normal Critical Values

Create a standard normal distribution object.

```
pd = makedist('Normal')
```

```
pd =  
    NormalDistribution  
  
    Normal distribution  
        mu = 0  
        sigma = 1
```

Determine the critical values at the 5% significance level for a test statistic with a standard normal distribution, by computing the upper and lower 2.5% values.

```
x = icdf(pd, [.025, .975])  
  
x = 1×2  
    -1.9600    1.9600
```

Plot the cdf and shade the critical regions.

```
p = normspec(x, 0, 1, 'outside')
```

$$p = 0.0500$$

Input Arguments

'name' — Probability distribution name

character vector or string scalar of probability distribution name

Probability distribution name, specified as one of the probability distribution names in this table.

'name'	Distribution	Input Parameter A	Input Parameter B	Input Parameter C	Input Parameter D
'Beta'	"Beta Distribution" on page B-4	a first shape parameter	b second shape parameter	—	—
'Binomial'	"Binomial Distribution" on page B-9	n number of trials	p probability of success for each trial	—	—

'Weibull'	"Weibull Distribution" on page B-199	a scale parameter	b shape parameter	—	—

Example: 'Normal'

p — Probability values at which to evaluate icdf

scalar value | array of scalar values

Probability values at which to evaluate the icdf, specified as a scalar value, or an array of scalar values in the range [0,1].

If one or more of the input arguments p , A , B , C , and D are arrays, then the array sizes must be the same. In this case, `icdf` expands each scalar input into a constant array of the same size as the array inputs. See 'name' for the definitions of A , B , C , and D for each distribution.

Example: [0.1,0.25,0.5,0.75,0.9]

Data Types: single | double

A — First probability distribution parameter

scalar value | array of scalar values

First probability distribution parameter, specified as a scalar value or an array of scalar values.

If one or more of the input arguments p , A , B , C , and D are arrays, then the array sizes must be the same. In this case, `icdf` expands each scalar input into a constant array of the same size as the array inputs. See 'name' for the definitions of A , B , C , and D for each distribution.

Data Types: single | double

B — Second probability distribution parameter

scalar value | array of scalar values

Second probability distribution parameter, specified as a scalar value or an array of scalar values.

If one or more of the input arguments `p`, `A`, `B`, `C`, and `D` are arrays, then the array sizes must be the same. In this case, `icdf` expands each scalar input into a constant array of the same size as the array inputs. See 'name' for the definitions of `A`, `B`, `C`, and `D` for each distribution.

Data Types: `single` | `double`

C — Third probability distribution parameter

scalar value | array of scalar values

Third probability distribution parameter, specified as a scalar value or an array of scalar values.

If one or more of the input arguments `p`, `A`, `B`, `C`, and `D` are arrays, then the array sizes must be the same. In this case, `icdf` expands each scalar input into a constant array of the same size as the array inputs. See 'name' for the definitions of `A`, `B`, `C`, and `D` for each distribution.

Data Types: `single` | `double`

D — Fourth probability distribution parameter

scalar value | array of scalar values

Fourth probability distribution parameter, specified as a scalar value or an array of scalar values.

If one or more of the input arguments `p`, `A`, `B`, `C`, and `D` are arrays, then the array sizes must be the same. In this case, `icdf` expands each scalar input into a constant array of the same size as the array inputs. See 'name' for the definitions of `A`, `B`, `C`, and `D` for each distribution.

Data Types: `single` | `double`

pd — Probability distribution

probability distribution object

Probability distribution, specified as a probability distribution object created with a function or app in this table.

Function or App	Description
<code>makedist</code>	Create a probability distribution object using specified parameter values.
<code>fitdist</code>	Fit a probability distribution object to sample data.
Distribution Fitter	Fit a probability distribution to sample data using the interactive Distribution Fitter app and export the fitted object to the workspace.
<code>paretotails</code>	Create a piecewise distribution object that has generalized Pareto distributions in the tails.

Output Arguments

x — **icdf values**

scalar value | array of scalar values

icdf values, returned as a scalar value or an array of scalar values. **x** is the same size as **p** after any necessary scalar expansion. Each element in **x** is the icdf value of the distribution, specified by the corresponding elements in the distribution parameters (A, B, C, and D) or specified by the probability distribution object (**pd**), evaluated at the corresponding element in **p**.

Alternative Functionality

`icdf` is a generic function that accepts either a distribution by its name 'name' or a probability distribution object **pd**. It is faster to use a distribution-specific function, such as `norminv` for the normal distribution and `binoinv` for the binomial distribution. For a list of distribution-specific functions, see “Supported Distributions” on page 5-20.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The input argument 'name' must be a compile-time constant. For example, to use the normal distribution, include `coder.Constant('Normal')` in the `-args` value of `codegen`.
- Code generation does not support the probability distribution object (pd) input argument.

For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “General Code Generation Workflow” on page 31-5.

Introduced before R2006a

inconsistent

Inconsistency coefficient

Syntax

```
Y = inconsistent(Z)
Y = inconsistent(Z,d)
```

Description

`Y = inconsistent(Z)` returns the inconsistency coefficient for each link of the hierarchical cluster tree `Z` generated by the `linkage` function. `inconsistent` calculates the inconsistency coefficient for each link by comparing its height with the average height of other links at the same level of the hierarchy. The larger the coefficient, the greater the difference between the objects connected by the link. For more information, see “Algorithms” on page 32-3147.

`Y = inconsistent(Z,d)` returns the inconsistency coefficient for each link in the tree `Z` by searching to a depth `d` below each link.

Examples

Inconsistency Coefficient Calculation

Examine an inconsistency coefficient calculation for a hierarchical cluster tree.

Load the `examgrades` data set.

```
load examgrades
```

Create a hierarchical cluster tree.

```
Z = linkage(grades);
```

Create a matrix of inconsistency coefficient information using `inconsistent`. Examine the information for the 84th link.

```
Y = inconsistent(Z);
Y(84,:)
ans = 1×4
      7.2741    0.3624    3.0000    0.5774
```

The fourth column of `Y` contains the inconsistency coefficient, which is computed using the mean in the first column of `Y` and the standard deviation in the second column of `Y`.

Because the rows of `Y` correspond to the rows of `Z`, examine the 84th link in `Z`.

```
Z(84,:)
ans = 1×3
    190.0000   203.0000    7.4833
```

The 84th link connects the 190th and 203rd clusters in the tree and has a height of 7.4833. The 190th cluster corresponds to the link of index $190 - 120 = 70$, where 120 is the number of observations. The 203rd cluster corresponds to the 83rd link.

By default, `inconsistent` uses two levels of the tree to compute `Y`. Therefore, it uses only the 70th, 83rd, and 84th links to compute the inconsistency coefficient for the 84th link. Compare the values in `Y(84, :)` with the corresponding computations by using the link heights in `Z`.

```
mean84 = mean([Z(70,3) Z(83,3) Z(84,3)])
mean84 = 7.2741
std84 = std([Z(70,3) Z(83,3) Z(84,3)])
std84 = 0.3624
inconsistent84 = (Z(84,3)-mean84)/std84
inconsistent84 = 0.5774
```

Compute Inconsistency Coefficient

Create the sample data.

```
X = gallery('uniformdata',[10 2],12);
Y = pdist(X);
```

Generate the hierarchical cluster tree.

```
Z = linkage(Y,'single');
```

Generate a dendrogram plot of the hierarchical cluster tree.

```
dendrogram(Z)
```

Compute the inconsistency coefficient for each link in the cluster tree Z to depth 3.

```
W = inconsistent(Z,3)
```

W = 9×4

0.1313	0	1.0000	0
0.1386	0	1.0000	0
0.1463	0.0109	2.0000	0.7071
0.2391	0	1.0000	0
0.1951	0.0568	4.0000	0.9425
0.2308	0.0543	4.0000	0.9320
0.2395	0.0748	4.0000	0.7636
0.2654	0.0945	4.0000	0.9203
0.3769	0.0950	3.0000	1.1040

Input Arguments

Z — Agglomerative hierarchical cluster tree

numeric matrix

Agglomerative hierarchical cluster tree, specified as a numeric matrix returned by `linkage`. Z is an $(m - 1)$ -by-3 matrix, where m is the number of observations. Columns 1 and 2 of Z contain cluster indices linked in pairs to form a binary tree. $Z(I, 3)$ contains the linkage distances between the two clusters merged in row $Z(I, :)$.

Data Types: `single` | `double`

d — Depth

2 (default) | positive integer scalar

Depth, specified as a positive integer scalar. For each link k , `inconsistent` calculates the corresponding inconsistency coefficient using all the links in the tree within d levels below k .

Data Types: `single` | `double`

Output Arguments

Y — Inconsistency coefficient information

numeric matrix

Inconsistency coefficient information, returned as an $(m - 1)$ -by-4 matrix, where the $(m - 1)$ rows correspond to the rows of Z . This table describes the columns of Y .

Column	Description
1	Mean of the heights of all the links included in the calculation
2	Standard deviation of the heights of all the links included in the calculation
3	Number of links included in the calculation
4	Inconsistency coefficient

Data Types: double

Algorithms

For each link k , the inconsistency coefficient is calculated as

$$Y(k, 4) = (Z(k, 3) - Y(k, 1))/Y(k, 2),$$

where Y is the inconsistency coefficient information for links in the hierarchical cluster tree Z .

For links that have no further links below them, the inconsistency coefficient is set to 0.

Introduced before R2006a

increaseB

Class: clustering.evaluation.GapEvaluation

Package: clustering.evaluation

Increase reference data sets

Syntax

```
eva_out = increaseB(eva,nref)
```

Description

`eva_out = increaseB(eva,nref)` returns a gap criterion clustering evaluation object `eva_out` that uses the same evaluation criteria as the input object `eva` and an additional number of reference data sets as specified by `nref`.

Input Arguments

eva — Clustering evaluation data

clustering evaluation object

Clustering evaluation data, specified as a clustering evaluation object. Create a clustering evaluation object using `evalclusters`.

nref — Number of additional reference data sets

positive integer value

Number of additional reference data sets, specified as a positive integer value.

Output Arguments

eva_out — Updated clustering evaluation data

clustering evaluation object

Updated clustering evaluation data, returned as a gap criterion clustering evaluation object. `eva_out` contains evaluation data obtained using the reference data sets from the input object `eva` plus a number of additional reference data sets as specified in `nref`.

`increaseB` updates the `B` property of the input object `eva` to reflect the increase in the number of reference data sets used to compute the gap criterion values. `increaseB` also updates the `CriterionValues` property with gap criterion values computed using the total number of reference data sets. `increaseB` might also update the `OptimalK` and `OptimalY` properties to reflect the optimal number of clusters and optimal clustering solution as determined using the total number of reference data sets. Additionally, `increaseB` might also update the `LogW`, `ExpectedLogW`, `StdLogW`, and `SE` properties.

Examples

Evaluate Clustering Solutions Using Additional Reference Data

Create a gap clustering evaluation object using `evalclusters`, then use `increaseB` to increase the number of reference data sets used to compute the gap criterion values.

Load the sample data.

```
load fisheriris
```

The data contains length and width measurements from the sepals and petals of three species of iris flowers.

Cluster the flower measurement data using `kmeans`, and use the gap criterion to evaluate proposed solutions of one through five clusters. Use 50 reference data sets.

```
rng('default') % For reproducibility
eva = evalclusters(meas, 'kmeans', 'gap', 'klist', 1:5, 'B', 50)
```

```
eva =
```

```
  GapEvaluation with properties:
```

```
  NumObservations: 150
  InspectedK: [1 2 3 4 5]
  CriterionValues: [0.0870 0.5822 0.8766 1.0007 1.0465]
  OptimalK: 4
```

The clustering evaluation object `eva` contains data on each proposed clustering solution. The returned results indicate that the optimal number of clusters is four.

The value of the `B` property of `eva` shows 50 reference data sets.

```
eva.B
```

```
ans = 50
```

Increase the number of reference data sets by 100, for a total of 150 sets.

```
eva = increaseB(eva,100)
```

```
eva =
```

```
  GapEvaluation with properties:
```

```
    NumObservations: 150
```

```
      InspectedK: [1 2 3 4 5]
```

```
    CriterionValues: [0.0794 0.5850 0.8738 1.0034 1.0508]
```

```
      OptimalK: 5
```

The returned results now indicate that the optimal number of clusters is five.

The value of the `B` property of `eva` now shows 150 reference data sets.

```
eva.B
```

```
ans = 150
```

`evalclusters`

interactionplot

Interaction plot for grouped data

Syntax

```
interactionplot(Y, GROUP)
interactionplot(Y, GROUP, 'varnames', VARNAMES)
[h, AX, bigax] = interactionplot(...)
```

Description

`interactionplot(Y, GROUP)` displays the two-factor interaction plot for the group means of matrix `Y` with groups defined by entries in `GROUP`, which can be a cell array or a matrix. `Y` is a numeric matrix or vector. If `Y` is a matrix, the rows represent different observations and the columns represent replications of each observation. If `Y` is a vector, the rows give the means of each entry in `GROUP`. If `GROUP` is a cell array, then each cell of `GROUP` must contain a grouping variable that is a categorical variable, numeric vector, character matrix, string array, or single-column cell array of character vectors. If `GROUP` is a matrix, then its columns represent different grouping variables. Each grouping variable must have the same number of rows as `Y`. The number of grouping variables must be greater than 1.

The interaction plot is a matrix plot, with the number of rows and columns both equal to the number of grouping variables. The grouping variable names are printed on the diagonal of the plot matrix. The plot at off-diagonal position (i, j) is the interaction of the two variables whose names are given at row diagonal (i, i) and column diagonal (j, j) , respectively.

`interactionplot(Y, GROUP, 'varnames', VARNAMES)` displays the interaction plot with user-specified grouping variable names `VARNAMES`. `VARNAMES` is a character matrix, a string array, or a cell array of character vectors, one per grouping variable. Default names are 'X1', 'X2',

`[h, AX, bigax] = interactionplot(...)` returns a handle `h` to the figure window, a matrix `AX` of handles to the subplot axes, and a handle `bigax` to the big (invisible) axes framing the subplots.

Examples

Display Interaction Plots

Randomly generate data for a response variable y .

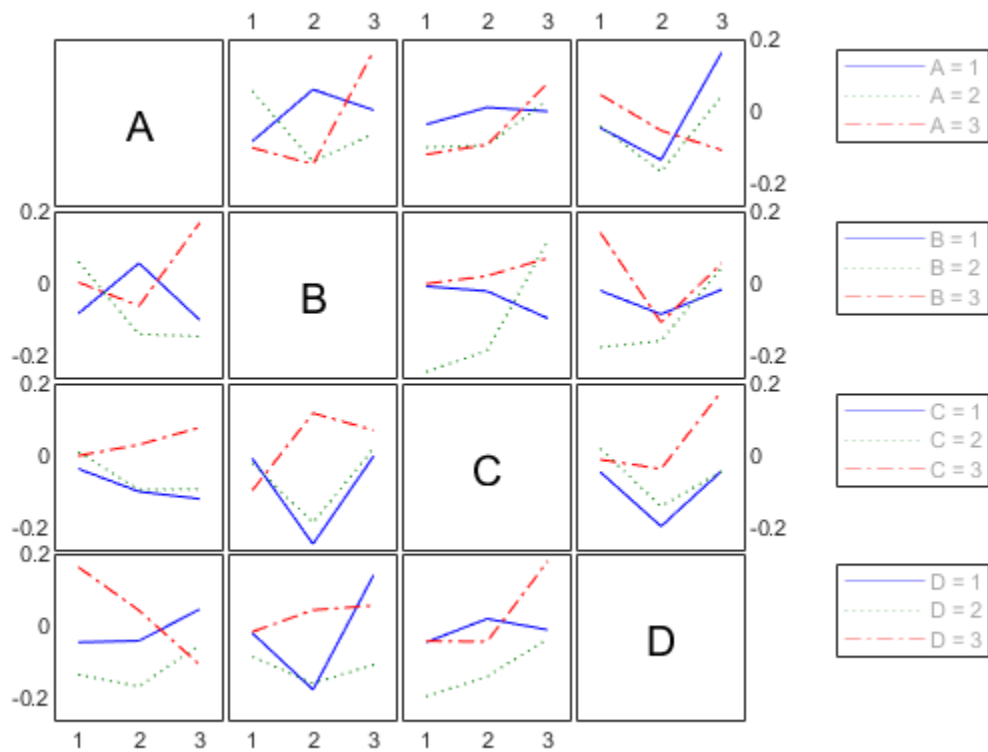

```
rng default; % For reproducibility  
y = randn(1000,1);
```

Randomly generate data for four three-level factors.

```
group = ceil(3*rand(1000,4));
```

Display the interaction plots for the factors and name the factors 'A', 'B', 'C', 'D'.

```
interactionplot(y,group,'varnames',{'A','B','C','D'})
```

`maineffectsplot` | `multivarichart`

Introduced in R2006b

intersect

Class: dataset

Set intersection for dataset array observations

Note The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB® `table` data type instead. See MATLAB `table` documentation for more information.

Syntax

```
C = intersect(A,B)
C = intersect(A,B,vars)
C = intersect(A,B,vars,setOrder)
[C,iA,iB] = intersect( ___ )
```

Description

`C = intersect(A,B)` for dataset arrays `A` and `B` returns the common set of observations from the two arrays, with repetitions removed. The observations in the dataset array `C` are in sorted order.

`C = intersect(A,B,vars)` returns the set of common observations from the two arrays, considering only the variables specified in `vars`, with repetitions removed. The observations in the dataset array `C` are sorted by those variables.

The values for variables not specified in `vars` for each observation in `C` are taken from the corresponding observations in `A`. If there are multiple observations in `A` that correspond to an observation in `C`, then those values are taken from the first occurrence.

`C = intersect(A,B,vars,setOrder)` returns the observations in `C` in the order specified by `setOrder`.

`[C,iA,iB] = intersect(___)` also returns index vectors `iA` and `iB` such that `C = A(iA,:)` and `C = B(iB,:)`. If there are repeated observations in `A` or `B`, then

`intersect` returns the index of the first occurrence. You can use any of the previous input arguments.

Input Arguments

A, B

Input dataset arrays.

vars

String array or cell array of character vectors containing variable names, or a vector of integers containing variable column numbers. `vars` indicates the variables in A and B that `intersect` considers.

Specify `vars` as `[]` to use its default value of all variables.

setOrder

Flag indicating the sorting order for the observations in C. The possible values of `setOrder` are:

'sorted'	Observations in C are in sorted order (default).
'stable'	Observations in C are in the same order that they appear in A.

Output Arguments

C

Dataset array with the common set of observations in A and B, with repetitions removed. C is in sorted order (by default), or the order specified by `setOrder`.

iA

Index vector, indicating the observations in A that are common to B. The vector `iA` contains the index to the first occurrence of any repeated observations in A.

iB

Index vector, indicating the observations in B that are common to A. The vector `iB` contains the index to the first occurrence of any repeated observations in B.

Examples

Intersection of Two Dataset Arrays

Load sample data.

```
A = dataset('XLSFile',fullfile(matlabroot,'help/toolbox/stats/examples','hospitalSmall
B = dataset('XLSFile',fullfile(matlabroot,'help/toolbox/stats/examples','hospitalSmall
```

Return the intersection and index vectors.

```
[C,iA,iB] = intersect(A,B);
```

C =

id	name	sex	age	wgt	smoke
'TRW-072'	'WHITE'	'm'	39	202	1

There is one observation in common between A and B.

Find the observation in the original dataset arrays.

```
A(iA,:)
```

ans =

id	name	sex	age	wgt	smoke
'TRW-072'	'WHITE'	'm'	39	202	1

```
B(iB,:)
```

ans =

id	name	sex	age	wgt	smoke
'TRW-072'	'WHITE'	'm'	39	202	1

invpred

Inverse prediction

Syntax

```
X0 = invpred(X,Y,Y0)
[X0,DXLO,DXUP] = invpred(X,Y,Y0)
[X0,DXLO,DXUP] = invpred(X,Y,Y0,name1,val1,name2,val2,...)
```

Description

$X0 = \text{invpred}(X, Y, Y0)$ accepts vectors X and Y of the same length, fits a simple regression, and returns the estimated value $X0$ for which the height of the line is equal to $Y0$. The output, $X0$, has the same size as $Y0$, and $Y0$ can be an array of any size.

$[X0, DXLO, DXUP] = \text{invpred}(X, Y, Y0)$ also computes 95% inverse prediction intervals. $DXLO$ and $DXUP$ define intervals with lower bound $X0 - DXLO$ and upper bound $X0 + DXUP$. Both $DXLO$ and $DXUP$ have the same size as $Y0$.

The intervals are not simultaneous and are not necessarily finite. Some intervals may extend from a finite value to $-\text{Inf}$ or $+\text{Inf}$, and some may extend over the entire real line.

$[X0, DXLO, DXUP] = \text{invpred}(X, Y, Y0, name1, val1, name2, val2, \dots)$ specifies optional argument name/value pairs chosen from the following list. Argument names are case insensitive and partial matches are allowed.

Name	Value
'alpha'	A value between 0 and 1 specifying a confidence level of $100 * (1 - \alpha) \%$. Default is $\alpha = 0.05$ for 95% confidence.

Name	Value
'predopt'	Either 'observation', the default value to compute the intervals for X_0 at which a new observation could equal Y_0 , or 'curve' to compute intervals for the X_0 value at which the curve is equal to Y_0 .

Examples

Inverse Prediction

Generate sample data.

```
x = 4*rand(25,1);  
y = 10 + 5*x + randn(size(x));
```

Make a scatterplot of the data.

```
scatter(x,y)
```

Predict the x value for a given y value of 20.

```
x0 = invpred(x,y,20)
```

```
x0 = 1.9967
```

Introduced before R2006a

iqr

Package: prob

Interquartile range

Syntax

```
r = iqr(x)
r = iqr(x, 'all')
r = iqr(x, dim)
r = iqr(x, vecdim)

r = iqr(pd)
```

Description

`r = iqr(x)` returns the interquartile range of the values in `x`.

- If `x` is a vector, then `r` is the difference between the 75th and the 25th percentiles of the data contained in `x`.
- If `x` is a matrix, then `r` is a row vector containing the difference between the 75th and the 25th percentiles of the sample data in each column of `x`.
- If `x` is a multidimensional array, then `iqr` operates along the first nonsingleton dimension of `x`. The size of this dimension becomes 1 while the sizes of all other dimensions remain the same.

`r = iqr(x, 'all')` returns the interquartile range of all the values in `x`.

`r = iqr(x, dim)` returns the interquartile range along the dimension of `x` specified by `dim`.

`r = iqr(x, vecdim)` returns the interquartile range over the dimensions specified by `vecdim`. For example, if `x` is a matrix, then `iqr(x, [1 2])` is the interquartile range of all the elements of `x` because every element of a matrix is contained in the array slice defined by dimensions 1 and 2.

`r = iqr(pd)` returns the interquartile range of the probability distribution `pd`.

Examples

Compute the Interquartile Range

Generate a 4-by-4 matrix of random data from a normal distribution with parameter values μ equal to 10 and σ equal to 1.

```
rng default % For reproducibility
x = normrnd(10,1,4)
```

```
x = 4x4
```

```
10.5377    10.3188    13.5784    10.7254
11.8339     8.6923    12.7694     9.9369
 7.7412     9.5664     8.6501    10.7147
10.8622    10.3426    13.0349     9.7950
```

Compute the interquartile range for each column of data.

```
r = iqr(x)
```

```
r = 1x4
```

```
2.2086    1.2013    2.5969    0.8541
```

Compute the interquartile range for each row of data.

```
r2 = iqr(x,2)
```

```
r2 = 4x1
```

```
1.7237
2.9870
1.9449
1.8797
```

Compute Interquartile Range of Multidimensional Array

Compute the interquartile range of a multidimensional array over multiple dimensions by specifying the 'all' and `vecdim` input arguments.

Create a 3-by-4-by-2 array X.

```
X = reshape(1:24,[3 4 2])
```

```
X =
```

```
X(:,:,1) =
```

```
     1     4     7    10
     2     5     8    11
     3     6     9    12
```

```
X(:,:,2) =
```

```
    13    16    19    22
    14    17    20    23
    15    18    21    24
```

Compute the interquartile range of all the values in X.

```
rall = iqr(X,'all')
```

```
rall = 12
```

Compute the interquartile range of each page of X. Specify the first and second dimensions as the operating dimensions along which the interquartile range is calculated.

```
rpage = iqr(X,[1 2])
```

```
rpage =
```

```
rpage(:,:,1) =
```

```
     6
```

```
rpage(:,:,2) =
```

```
     6
```

For example, `rpage(1,1,1)` is the interquartile range of all the elements in `X(:, :, 1)`.

Compute the interquartile range of the elements in each `X(i, :, :)` slice by specifying the second and third dimensions as the operating dimensions.

```
rrow = iqr(X,[2 3])
```

```
rrow = 3×1
```

```
12
12
12
```

For example, `rrow(3)` is the interquartile range of all the elements in `X(3, :, :)`.

Compute the Normal Distribution Interquartile Range

Create a standard normal distribution object with the mean, μ , equal to 0 and the standard deviation, σ , equal to 1.

```
pd = makedist('Normal','mu',0,'sigma',1);
```

Compute the interquartile range of the standard normal distribution.

```
r = iqr(pd)
```

```
r = 1.3490
```

The returned value is the difference between the 75th and the 25th percentile values for the distribution. This is equivalent to computing the difference between the inverse cumulative distribution function (`icdf`) values at the probabilities y equal to 0.75 and 0.25.

```
r2 = icdf(pd,0.75) - icdf(pd,0.25)
```

```
r2 = 1.3490
```

Interquartile Range of a Fitted Distribution

Load the sample data. Create a vector containing the first column of students' exam grade data.

```
load examgrades;  
x = grades(:,1);
```

Create a normal distribution object by fitting it to the data.

```
pd = fitdist(x, 'Normal')  
  
pd =  
NormalDistribution  
  
Normal distribution  
mu = 75.0083 [73.4321, 76.5846]  
sigma = 8.7202 [7.7391, 9.98843]
```

Compute the interquartile range of the fitted distribution.

```
r = iqr(pd)  
  
r = 11.7634
```

The returned result indicates that the difference between the 75th and 25th percentile of the students' grades is 11.7634.

Use `icdf` to determine the 75th and 25th percentiles of the students' grades.

```
y = icdf(pd, [0.25, 0.75])  
  
y = 1×2  
69.1266 80.8900
```

Calculate the difference between the 75th and 25th percentiles. This yields the same result as `iqr`.

```
y(2)-y(1)  
  
ans = 11.7634
```

Use `boxplot` to visualize the interquartile range.

```
boxplot(x)
```

The top line of the box shows the 75th percentile, and the bottom line shows the 25th percentile. The center line shows the median, which is the 50th percentile.

Input Arguments

x — Input array

vector | matrix | multidimensional array

Input array, specified as a vector, matrix, or multidimensional array.

Data Types: single | double

dim — Dimension

positive integer value

Dimension along which the interquartile range is calculated, specified as a positive integer. For example, for a matrix x , when `dim` is equal to 1, `iqr` returns the interquartile range for the columns of x . When `dim` is equal to 2, `iqr` returns the interquartile range for the rows of x . For n -dimensional arrays, `iqr` operates along the first nonsingleton dimension of x .

Data Types: `single` | `double`**vecdim — Vector of dimensions**

positive integer vector

Vector of dimensions, specified as a positive integer vector. Each element of `vecdim` represents a dimension of the input array x . The output r has length 1 in the specified operating dimensions. The other dimension lengths are the same for x and r .

For example, if x is a 2-by-3-by-3 array, then `iqr(x, [1 2])` returns a 1-by-1-by-3 array. Each element of the output array is the interquartile range of the elements on the corresponding page of x .

Data Types: `single` | `double`**pd — Probability distribution**

probability distribution object

Probability distribution, specified as a probability distribution object created using one of the following.

Function or App	Description
<code>makedist</code>	Create a probability distribution object using specified parameter values.
<code>fitdist</code>	Fit a probability distribution object to sample data.
Distribution Fitter	Fit a probability distribution to sample data using the interactive Distribution Fitter app and export the fitted object to the workspace.

Output Arguments

r – Interquartile range values

scalar | vector | matrix | multidimensional array

Interquartile range values, returned as a scalar, vector, matrix, or multidimensional array.

- If you input an array `x`, then the dimensions of `r` depend on whether the `'all'`, `dim`, or `vecdim` input arguments are specified. Each interquartile range value in `r` is the difference between the 75th and the 25th percentiles of the specified data contained in `x`.
- If you input a probability distribution `pd`, then the scalar value of `r` is the difference between the values of the 75th and 25th percentiles of the probability distribution.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- These input arguments are not supported: `'all'`, `vecdim`, and `pd`.
- The `dim` input argument must be a compile-time constant.
- If you do not specify the `dim` input argument, the working (or operating) dimension can be different in the generated code. As a result, run-time errors can occur. For more details, see “Automatic dimension restriction” (MATLAB Coder).

For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “General Code Generation Workflow” on page 31-5.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Usage notes and limitations:

- These input arguments are not supported: 'all', `vecdim`, and `pd`.

For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

Introduced before R2006a

isempty

Class: dataset

True for empty dataset array

Note The dataset data type might be removed in a future release. To work with heterogeneous data, use the MATLAB® table data type instead. See MATLAB table documentation for more information.

Syntax

```
tf = isempty(A)
```

Description

`tf = isempty(A)` returns true (1) if `A` is an empty dataset and false (0) otherwise. An empty array has no elements, that is `prod(size(A))==0`.

See Also

`size`

islevel

Determine if levels are in nominal or ordinal array

Note The `nominal` and `ordinal` array data types might be removed in a future release. To represent ordered and unordered discrete, nonnumeric data, use the “Categorical Arrays” (MATLAB) data type instead.

Syntax

```
tf = islevel(levels,A)
```

Description

`tf = islevel(levels,A)` returns a logical array indicating which of the levels in `levels` correspond to a level in the nominal or ordinal array `A`.

Input Arguments

A — Nominal or ordinal array

`nominal` array | `ordinal` array

Nominal or ordinal array, specified as a `nominal` or `ordinal` array object created with `nominal` or `ordinal`.

levels — Levels to test

character vector | string array | cell array of character vectors | 2-D character matrix

Levels to test, specified as a character vector, string array, cell array of character vectors, or 2-D character matrix.

Data Types: `char` | `string` | `cell`

Output Arguments

tf — Level indicator

logical array

Level indicator, returned as a logical array of the same size as `levels`. `tf` has the value 1 (true) when the corresponding element of `levels` is the label of a level in the nominal or ordinal array `A`, even if the level contains no elements. Otherwise, `tf` has the value 0 (false).

See Also

`isequal` | `ismember` | `nominal` | `ordinal`

Introduced in R2007a

ismember

Class: dataset

Dataset array elements that are members of set

Note The dataset data type might be removed in a future release. To work with heterogeneous data, use the MATLAB® table data type instead. See MATLAB table documentation for more information.

Syntax

```
LiA = ismember(A,B)  
LiA = ismember(A,B,vars)  
[LiA,LocB] = ismember( ___ )
```

Description

`LiA = ismember(A,B)` for dataset arrays `A` and `B` returns a vector of logical values the same length as `A`. The output vector, `LiA`, has value 1 (true) in the elements that correspond to observations in `A` that are also present in `B`, and 0 (false) otherwise.

`LiA = ismember(A,B,vars)` returns a vector of logical values the same length as `A`. The output vector, `LiA`, has value 1 (true) in the elements that correspond to observations in `A` that are also present in `B` for the variables specified in `vars` only, and 0 (false) otherwise.

`[LiA,LocB] = ismember(___)` also returns a vector the same length as `A` containing the index to the first observation in `B` that corresponds to each observation in `A`, or 0 if there is no such observation. You can use any of the previous input arguments.

Input Arguments

A

Query dataset array, containing the observations to be found in B.

B

Set dataset array. When an observation in A is found in B, for all variables or only those variables specified in `vars`, the corresponding element of `LiA` is 1.

`vars`

String array or cell array of character vectors containing variable names, or a vector of integers containing variable column numbers. `vars` indicates which variables to match observations on in A and B.

Output Arguments

`LiA`

Vector of logical values the same length as A. `LiA` has value 1 (true) when the corresponding observation in A is present in B. Otherwise, `LiA` has value 0 (false).

If you specify `vars`, `LiA` has value 1 when the corresponding observation in A is present in B for the variables in `vars` only.

`LocB`

Vector the same length as A containing the index to the first observation in B that corresponds to each observation in A, for all variables or only those variables specified in `vars`.

Examples

Find Observations That Are Members of a Dataset Array

Load sample data.

```
load('hospital')
B = hospital(1:50,1:5);
```

This set dataset array, B, has 50 observations on 5 variables.

Specify a query dataset array.

```
rng('default')
rIx = randsample(100,10);
A = hospital(rIx,1:5)
```

```
A =
```

“Dataset Arrays” on page 2-137

ismissing

Class: dataset

Find dataset array elements with missing values

Note The dataset data type might be removed in a future release. To work with heterogeneous data, use the MATLAB® table data type instead. See MATLAB table documentation for more information.

Syntax

```
I = ismissing(ds)
I = ismissing(ds,Name,Value)
```

Description

`I = ismissing(ds)` returns a logical array that indicates which elements in the dataset array, `ds`, contain a missing value. By default, `ismissing` recognizes NaN as a missing value in numeric variables, ' ' as a missing value in character variables, and <undefined> as a missing value in categorical arrays.

- `ds2 = ds(~any(I,2),:)` creates a new dataset array containing only the complete observations in `ds`.
- `ds2 = ds(:,~any(I,1))` creates a new dataset array containing only the variables from `ds` with no missing values.

`I = ismissing(ds,Name,Value)` returns missing value indices with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

ds

dataset array

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

NumericTreatAsMissing

Vector of numeric values to treat as missing value indicators in floating point `ds` variables. `ismissing` always treats a `NaN` value as a missing value.

Default:

StringTreatAsMissing

Character vector, string array, or cell array of character vectors to treat as missing value indicators in character `ds` variables. `ismissing` always treats `' '` as a missing value.

Output Arguments

I

Logical array indicating which elements in `ds` contain a missing value. `I` is the same size as `ds`, with value `1` for elements that contain a missing value.

See Also

`dataset` | `isempty` | `isnan` | `isundefined` | `replaceWithMissing`

Topics

“Clean Messy and Missing Data” on page 2-118

“Dataset Arrays” on page 2-137

isvalid

Class: grandstream

Test handle validity

Syntax

```
tf = isvalid(h)
```

Description

`tf = isvalid(h)` performs an element-wise check for validity on the handle elements of `h`. The result is a logical array of the same dimensions as `h`, where each element is the element-wise validity result.

A handle is invalid if it has been deleted or if it is an element of a handle array and has not yet been initialized.

See Also

`delete` | `grandstream`

iwishrnd

Inverse Wishart random numbers

Syntax

```
W = iwishrnd(Tau,df)
W = iwishrnd(Tau,df,DI)
[W,DI] = iwishrnd(Tau,df)
```

Description

`W = iwishrnd(Tau,df)` generates a random matrix `W` from the inverse Wishart distribution with parameters `Tau` and `df`. The inverse of `W` has the Wishart distribution with covariance matrix `Sigma = inv(Tau)` and with `df` degrees of freedom. `Tau` is a symmetric and positive definite matrix.

`W = iwishrnd(Tau,df,DI)` expects `DI` to be the transpose of the inverse of the Cholesky factor of `Tau`, so that `DI' * DI = inv(Tau)`, where `inv` is the MATLAB inverse function. `DI` is lower-triangular and the same size as `Tau`. If you call `iwishrnd` multiple times using the same value of `Tau`, it is more efficient to supply `DI` instead of computing it each time.

`[W,DI] = iwishrnd(Tau,df)` returns `DI` so you can use it as an input in future calls to `iwishrnd`.

Note that different sources use different parametrizations for the inverse Wishart distribution. This function defines the parameter `tau` so that the mean of the output matrix is `Tau / (df - d - 1)` where `d` is the dimension of `Tau`.

“Inverse Wishart Distribution” on page B-78

Introduced before R2006a

jackknife

Jackknife sampling

Syntax

```
jackstat = jackknife(jackfun,X)
jackstat = jackknife(jackfun,X,Y,...)
jackstat = jackknife(jackfun,...,'Options',option)
```

Description

`jackstat = jackknife(jackfun,X)` draws jackknife data samples from the n -by- p data array X , computes statistics on each sample using the function `jackfun`, and returns the results in the matrix `jackstat`. `jackknife` regards each row of X as one data sample, so there are n data samples. Each of the n rows of `jackstat` contains the results of applying `jackfun` to one jackknife sample. `jackfun` is a function handle specified with `@`. Row i of `jackstat` contains the results for the sample consisting of X with the i th row omitted:

```
s = x;
s(i,:) = [];
jackstat(i,:) = jackfun(s);
```

If `jackfun` returns a matrix or array, then this output is converted to a row vector for storage in `jackstat`. If X is a row vector, it is converted to a column vector.

`jackstat = jackknife(jackfun,X,Y,...)` accepts additional arguments to be supplied as inputs to `jackfun`. They may be scalars, column vectors, or matrices. `jackknife` creates each jackknife sample by sampling with replacement from the rows of the non-scalar data arguments (these must have the same number of rows). Scalar data are passed to `jackfun` unchanged. Non-scalar arguments must have the same number of rows, and each jackknife sample omits the same row from these arguments.

`jackstat = jackknife(jackfun,...,'Options',option)` provides an option to perform jackknife iterations in parallel, if the Parallel Computing Toolbox is available. Set `'Options'` as a structure you create with `statset`. `jackknife` uses the following field in the structure:

'UseParallel' If `true`, use multiple processors to compute jackknife iterations. If the Parallel Computing Toolbox is not installed, then computation occurs in serial mode. Default is `false`, meaning serial computation.

Examples

Estimate the bias of the MLE variance estimator of random samples taken from the vector `y` using `jackknife`. The bias has a known formula in this problem, so you can compare the `jackknife` value to this formula.

```
sigma = 5;
y = normrnd(0,sigma,100,1);
m = jackknife(@var,y,1);
n = length(y);
bias = -sigma^2/n % known bias formula
jbias = (n-1)*(mean(m)-var(y,1)) % jackknife bias estimate

bias =
    -0.2500

jbias =
    -0.3378
```

Extended Capabilities

Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the 'UseParallel' option to `true`.

Set the 'UseParallel' field of the options structure to `true` using `statset` and specify the 'Options' name-value pair argument in the call to this function.

For example: `'Options',statset('UseParallel',true)`

For more information, see the 'Options' name-value pair argument.

For more general information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

Introduced in R2006a

jbtest

Jarque-Bera test

Syntax

```
h = jbtest(x)
h = jbtest(x,alpha)
h = jbtest(x,alpha,mctol)
[h,p] = jbtest(____)
[h,p,jbstat,critval] = jbtest(____)
```

Description

`h = jbtest(x)` returns a test decision for the null hypothesis that the data in vector `x` comes from a normal distribution with an unknown mean and variance, using the Jarque-Bera test on page 32-3190. The alternative hypothesis is that it does not come from such a distribution. The result `h` is 1 if the test rejects the null hypothesis at the 5% significance level, and 0 otherwise.

`h = jbtest(x,alpha)` returns a test decision for the null hypothesis at the significance level specified by `alpha`.

`h = jbtest(x,alpha,mctol)` returns a test decision based on a p -value computed using a Monte Carlo simulation with a maximum Monte Carlo standard error on page 32-3190 less than or equal to `mctol`.

`[h,p] = jbtest(____)` also returns the p -value `p` of the hypothesis test, using any of the input arguments from the previous syntaxes.

`[h,p,jbstat,critval] = jbtest(____)` also returns the test statistic `jbstat` and the critical value `critval` for the test.

Examples

Test for a Normal Distribution

Load the data set.

```
load carbig
```

Test the null hypothesis that car mileage, in miles per gallon (MPG), follows a normal distribution across different makes of cars.

```
h = jbtest(MPG)
```

```
h = 1
```

The returned value of $h = 1$ indicates that `jbtest` rejects the null hypothesis at the default 5% significance level.

Test the Hypothesis at a Different Significance Level

Load the data set.

```
load carbig
```

Test the null hypothesis that car mileage in miles per gallon (MPG) follows a normal distribution across different makes of cars at the 1% significance level.

```
[h,p] = jbtest(MPG,0.01)
```

```
h = 1
```

```
p = 0.0022
```

The returned value of $h = 1$, and the returned p -value less than $\alpha = 0.01$ indicate that `jbtest` rejects the null hypothesis.

Test for a Normal Distribution Using Monte Carlo Simulation

Load the data set.

```
load carbig
```

Test the null hypothesis that car mileage, in miles per gallon (MPG), follows a normal distribution across different makes of cars. Use a Monte Carlo simulation to obtain an exact p -value.

```
[h,p,jbstat,critval] = jbtest(MPG,[],0.0001)
```

```
h = 1
```

```
p = 0.0022
```

```
jbstat = 18.2275
```

```
critval = 5.8461
```

The returned value of `h = 1` indicates that `jbtest` rejects the null hypothesis at the default 5% significance level. Additionally, the test statistic, `jbstat`, is larger than the critical value, `critval`, which indicates rejection of the null hypothesis.

Input Arguments

x — Sample data

vector

Sample data for the hypothesis test, specified as a vector. `jbtest` treats NaN values in `x` as missing values and ignores them.

Data Types: `single` | `double`

alpha — Significance level

0.05 (default) | scalar value in the range (0,1)

Significance level of the hypothesis test, specified as a scalar value in the range (0,1). If `alpha` is in the range [0.001,0.50], and if the sample size is less than or equal to 2000, `jbtest` looks up the critical value for the test in a table of precomputed values. To conduct the test at a significance level outside of these specifications, use `mctol`.

Example: 0.01

Data Types: `single` | `double`

mctol — Maximum Monte Carlo standard error

nonnegative scalar value

Maximum Monte Carlo standard error on page 32-3190 for the p -value, p , specified as a nonnegative scalar value. If you specify a value for `mctol`, `jbtest` computes a Monte Carlo approximation for p directly, rather than interpolating into a table of precomputed values. `jbtest` chooses the number of Monte Carlo replications large enough to make the Monte Carlo standard error for p less than `mctol`.

If you specify a value for `mctol`, you must also specify a value for `alpha`. You can specify `alpha` as `[]` to use the default value of 0.05.

Example: 0.0001

Data Types: `single` | `double`

Output Arguments

h — Hypothesis test result

1 | 0

Hypothesis test result, returned as 1 or 0.

- If $h = 1$, this indicates the rejection of the null hypothesis at the `alpha` significance level.
- If $h = 0$, this indicates a failure to reject the null hypothesis at the `alpha` significance level.

p — p -value

scalar value in the range (0,1)

p -value of the test, returned as a scalar value in the range (0,1). p is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. Small values of p cast doubt on the validity of the null hypothesis.

`jbtest` warns when p is not found within the tabulated range of [0.001,0.50], and returns either the smallest or largest tabulated value. In this case, you can use `mctol` to compute a more accurate p -value.

jbstat — Test statistic

nonnegative scalar value

Test statistic for the Jarque-Bera test, returned as a nonnegative scalar value.

critval — Critical value

nonnegative scalar value

Critical value for the Jarque-Bera test at the `alpha` significance level, returned as a nonnegative scalar value. If `alpha` is in the range [0.001,0.50], and if the sample size is less than or equal to 2000, `jbtest` looks up the critical value for the test in a table of precomputed values. If you use `mctol`, `jbtest` determines the critical value of the test using a Monte Carlo simulation. The null hypothesis is rejected when `jbstat > critval`.

Definitions

Jarque-Bera Test

The Jarque-Bera test is a two-sided goodness-of-fit test suitable when a fully specified null distribution is unknown and its parameters must be estimated.

The test is specifically designed for alternatives in the Pearson system of distributions. The test statistic is

$$JB = \frac{n}{6} \left(s^2 + \frac{(k-3)^2}{4} \right),$$

where n is the sample size, s is the sample skewness, and k is the sample kurtosis. For large sample sizes, the test statistic has a chi-square distribution with two degrees of freedom.

Monte Carlo Standard Error

The Monte Carlo standard error is the error due to simulating the p -value.

The Monte Carlo standard error is calculated as

$$SE = \sqrt{\frac{(\hat{p})(1-\hat{p})}{\text{mcreps}}},$$

where \hat{p} is the estimated p -value of the hypothesis test, and `mcreps` is the number of Monte Carlo replications performed. `jbtest` chooses the number of Monte Carlo

replications, `mc reps`, large enough to make the Monte Carlo standard error for \hat{p} less than the value specified for `mctol`.

Algorithms

Jarque-Bera tests often use the chi-square distribution to estimate critical values for large samples, deferring to the Lilliefors test (see `lillietest`) for small samples. `jbttest`, by contrast, uses a table of critical values computed using Monte Carlo simulation for sample sizes less than 2000 and significance levels from 0.001 to 0.50. Critical values for a test are computed by interpolating into the table, using the analytic chi-square approximation only when extrapolating for larger sample sizes.

Introduced before R2006a

johnsrnd

Johnson system random numbers

Syntax

```
r = johnsrnd(quantiles,m,n)
r = johnsrnd(quantiles)
[r,type] = johnsrnd(...)
[r,type,coefs] = johnsrnd(...)
```

Description

`r = johnsrnd(quantiles,m,n)` returns an `m`-by-`n` matrix of random numbers drawn from the distribution in the Johnson system that satisfies the quantile specification given by `quantiles`. `quantiles` is a four-element vector of quantiles for the desired distribution that correspond to the standard normal quantiles [-1.5 -0.5 0.5 1.5]. In other words, you specify a distribution from which to draw random values by designating quantiles that correspond to the cumulative probabilities [0.067 0.309 0.691 0.933]. `quantiles` may also be a 2-by-4 matrix whose first row contains four standard normal quantiles, and whose second row contains the corresponding quantiles of the desired distribution. The standard normal quantiles must be spaced evenly.

Note Because `r` is a random sample, its sample quantiles typically differ somewhat from the specified distribution quantiles.

`r = johnsrnd(quantiles)` returns a scalar value.

`r = johnsrnd(quantiles,m,n,...)` or `r = johnsrnd(quantiles,[m,n,...])` returns an `m`-by-`n`-by-... array.

`[r,type] = johnsrnd(...)` returns the type of the specified distribution within the Johnson system. `type` is 'SN', 'SL', 'SB', or 'SU'. Set `m` and `n` to zero to identify the distribution type without generating any random values.

The four distribution types in the Johnson system correspond to the following transformations of a normal random variate:

- 'SN' — Identity transformation (normal distribution on page B-136)
- 'SL' — Exponential transformation (lognormal distribution on page B-94)
- 'SB' — Logistic transformation (bounded)
- 'SU' — Hyperbolic sine transformation (unbounded)

`[r,type,coefs] = johnsrnd(...)` returns coefficients `coefs` of the transformation that defines the distribution. `coefs` is `[gamma, eta, epsilon, lambda]`. If `z` is a standard normal random variable and `h` is one of the transformations defined above, $r = \lambda * h((z - \text{gamma}) / \text{eta}) + \text{epsilon}$ is a random variate from the distribution type corresponding to `h`.

Examples

Generate Random Samples Using the Johnson System

This example shows several different approaches to using the Johnson system of flexible distribution families to generate random numbers and fit a distribution to sample data.

Generate random values with longer tails than a standard normal.

```
rng default; % For reproducibility
r = johnsrnd([-1.7 -.5 .5 1.7],1000,1);
figure;
qqplot(r);
```

Generate random values skewed to the right.

```
r = johnsrnd([-1.3 -.5 .5 1.7],1000,1);  
figure;  
qqplot(r);
```

Generate random values that match some sample data well in the right-hand tail.

```
load carbig;
qnorm = [.5 1 1.5 2];
q = quantile(Acceleration, normcdf(qnorm));
r = johnsrnd([qnorm;q],1000,1);
[q;quantile(r,normcdf(qnorm))]
```

```
ans = 2×4
```

```
16.7000    18.2086    19.5376    21.7263
16.6986    18.2220    19.9078    22.0918
```

Determine the distribution type and the coefficients.

```
[r,type,coefs] = johnsrnd([qnorm;q],0)
r =
     []
type =
'SU'
coefs = 1×4
    1.0920    0.5829    18.4382    1.4494
```

Introduced in R2006a

join

Class: dataset

Merge observations

Note The dataset data type might be removed in a future release. To work with heterogeneous data, use the MATLAB® table data type instead. See MATLAB table documentation for more information.

Syntax

```
C = join(A,B)
C = join(A,B,keys)
C = join(A,B,param1,val1,param2,val2,...)
[C,IB] = join(...)
C = join(A,B,'Type',TYPE,...)
C = join(A,B,'Type',TYPE,'MergeKeys',true,...)
[C,IA,IB] = join(A,B,'Type',TYPE,...)
```

Description

`C = join(A,B)` creates a dataset array `C` by merging observations from the two dataset arrays `A` and `B`. `join` performs the merge by first finding *key variables*, that is, pairs of dataset variables, one in `A` and one in `B`, that share the same name. Each observation in `B` must contain a unique combination of values in the key variables, and must contain all combinations of values that are present in the keys from `A`. `join` then uses these key variables to define a many-to-one correspondence between observations in `A` and those in `B`. `join` uses this correspondence to replicate the observations in `B` and combine them with the observations in `A` to create `C`.

`C = join(A,B,keys)` performs the merge using the variables specified by `keys` as the key variables in both `A` and `B`. `keys` is a positive integer, a vector of positive integers, a character vector, a string array, a cell array of character vectors, or a logical vector.

`C` contains one observation for each observation in `A`. Variables in `C` include all of the variables from `A`, as well as one variable corresponding to each variable in `B` (except for

the keys from B). If A and B contain variables with identical names, `join` adds the suffix `'_left'` and `'_right'` to the corresponding variables in C.

`C = join(A,B,param1,val1,param2,val2,...)` specifies optional parameter name/value pairs to control how the dataset variables in A and B are used in the merge.

Parameters are:

- `'Keys'` — Specifies the variables to use as keys in both A and B.
- `'LeftKeys'` — Specifies the variables to use as keys in A.
- `'RightKeys'` — Specifies the variables to use as keys in B.

You may provide either the `'Keys'` parameter, or both the `'LeftKeys'` and `'RightKeys'` parameters. The value for these parameters is a positive integer, a vector of positive integers, a character vector, a string array, a cell array of character vectors, or a logical vector. `'LeftKeys'` or `'RightKeys'` must both specify the same number of key variables, and `join` pairs the left and right keys in the order specified.

- `'LeftVars'` — Specifies which variables from A to include in C. By default, `join` includes all variables from A.
- `'RightVars'` — Specifies which variables from B to include in C. By default, `join` includes all variables from B except the key variables.

You can use `'LeftVars'` or `'RightVars'` to include or exclude key variables as well as data variables. The value for these parameters is a positive integer, a vector of positive integers, a character vector, a string array, a cell array of character vectors, or a logical vector.

`[C,IB] = join(...)` returns an index vector `IB`, where `join` constructs C by horizontally concatenating `A(:,LeftVars)` and `B(IB,RightVars)`. `join` can also perform more complicated inner and outer join operations that allow a many-to-many correspondence between A and B, and allow unmatched observations in either A or B.

`C = join(A,B,'Type',TYPE,...)` performs the join operation specified by `TYPE`. `TYPE` is one of `'inner'`, `'leftouter'`, `'rightouter'`, `'fullouter'`, or `'outer'` (which is a synonym for `'fullouter'`). For an inner join, C only contains observations corresponding to a combination of key values that occurred in both A and B. For a left (or right) outer join, C also contains observations corresponding to keys in A (or B) that did not match any in B (or A). Variables in C taken from A (or B) contain null values in those observations. A full outer join is equivalent to a left and right outer join. C contains variables corresponding to the key variables from both A and B, and `join` sorts the observations in C by the key values.

For inner and outer joins, C contains variables corresponding to the key variables from both A and B by default, as well as all the remaining variables. `join` sorts the observations in the result C by the key values.

`C = join(A,B, 'Type', TYPE, 'MergeKeys', true, ...)` includes a single variable in C for each key variable pair from A and B, rather than including two separate variables. For outer joins, `join` creates the single variable by merging the key values from A and B, taking values from A where a corresponding observation exists in A, and from B otherwise. Setting the `'MergeKeys'` parameter to `true` overrides inclusion or exclusion of any key variables specified via the `'LeftVars'` or `'RightVars'` parameter. Setting the `'MergeKeys'` parameter to `false` is equivalent to not passing in the `'MergeKeys'` parameter.

`[C, IA, IB] = join(A,B, 'Type', TYPE, ...)` returns index vectors IA and IB indicating the correspondence between observations in C and those in A and B. For an inner join, `join` constructs C by horizontally concatenating `A(IA, LeftVars)` and `B(IB, RightVars)`. For an outer join, IA or IB may also contain zeros, indicating the observations in C that do not correspond to observations in A or B, respectively.

Examples

Create a dataset array from Fisher's iris data:

```
load fisheriris
NumObs = size(meas,1);
NameObs = strcat({'Obs'}, num2str((1:NumObs)', '%-d'));
iris = dataset({nominal(species), 'species'}, ...
              {meas, 'SL', 'SW', 'PL', 'PW'}, ...
              'ObsNames', NameObs);
```

Create a separate dataset array with the diploid chromosome counts for each species of iris:

```
snames = nominal({'setosa'; 'versicolor'; 'virginica'});
CC = dataset({snames, 'species'}, {[38;108;70], 'cc'});
CC =
    species      cc
    setosa       38
    versicolor   108
    virginica    70
```

Broadcast the data in `CC` to the rows of `iris` using the key variable `species` in each dataset:

```
iris2 = join(iris,CC);
iris2([1 2 51 52 101 102],:)
ans =
```

	species	SL	SW	PL	PW	cc
Obs1	setosa	5.1	3.5	1.4	0.2	38
Obs2	setosa	4.9	3	1.4	0.2	38
Obs51	versicolor	7	3.2	4.7	1.4	108
Obs52	versicolor	6.4	3.2	4.5	1.5	108
Obs101	virginica	6.3	3.3	6	2.5	70
Obs102	virginica	5.8	2.7	5.1	1.9	70

Create two datasets and join them using the `'MergeKeys'` flag:

```
% Create two data sets that both contain the key variable
% 'Key1'. The two arrays contain observations with common
% values of Key1, but each array also contains observations
% with values of Key1 not present in the other.
a = dataset({'a' 'b' 'c' 'e' 'h'},[1 2 3 11 17]',...
    'VarNames',{'Key1' 'Var1'})
b = dataset({'a' 'b' 'd' 'e'},[4 5 6 7]',...
    'VarNames',{'Key1' 'Var2'})

% Combine a and b with an outer join, which matches up
% observations with common key values, but also retains
% observations whose key values don't have a match.
% Keep the key values as separate variables in the result.
couter = join(a,b,'key','Key1','Type','outer')

% Join a and b, merging the key values as a single variable
% in the result.
coutermerge = join(a,b,'key','Key1','Type','outer',...
    'MergeKeys',true)

% Join a and b, retaining only observations whose key
% values match.
cinner = join(a,b,'key','Key1','Type','inner',...
    'MergeKeys',true)
```

```
a =
```

Key1	Var1
'a'	1

```
'b'      2
'c'      3
'e'     11
'h'     17
```

b =

```
Key1      Var2
'a'       4
'b'       5
'd'       6
'e'       7
```

couter =

```
Key1_left  Var1  Key1_right  Var2
'a'         1   'a'         4
'b'         2   'b'         5
'c'         3   ''          NaN
''          NaN  'd'         6
'e'        11   'e'         7
'h'        17   ''          NaN
```

coutermerge =

```
Key1      Var1  Var2
'a'        1    4
'b'        2    5
'c'        3   NaN
'd'       NaN    6
'e'       11    7
'h'       17   NaN
```

cinner =

```
Key1      Var1  Var2
'a'        1    4
'b'        2    5
'e'       11    7
```

KDTreeSearcher

Create Kd-tree nearest neighbor searcher

Description

KDTreeSearcher model objects store the results of a nearest neighbor search that uses the Kd-tree algorithm. Results include the training data, distance metric and its parameters, and maximum number of data points in each leaf node (that is, the bucket size). The Kd-tree algorithm partitions an n -by- K data set by recursively splitting n points in K -dimensional space into a binary tree.

Once you create a KDTreeSearcher model object, you can search the stored tree to find all neighboring points to the query data by performing a nearest neighbor search using `knnsearch` or a radius search using `rangearch`. The Kd-tree algorithm is more efficient than the exhaustive search algorithm when K is small (that is, $K \leq 10$), the training and query sets are not sparse, and the training and query sets have many observations.

Creation

Use either the `createns` function or the `KDTreeSearcher` function (described here) to create a KDTreeSearcher model object. Both functions use the same syntax except that the `createns` function has the 'NSMethod' name-value pair argument, which you use to choose the nearest neighbor search method. The `createns` function also creates an `ExhaustiveSearcher` object. Specify 'NSMethod', 'kdtree' to create a KDTreeSearcher object. The default is 'kdtree' if $K \leq 10$, the training data is not sparse, and the distance metric is Euclidean, city block, Chebychev, or Minkowski.

Syntax

```
Mdl = KDTreeSearcher(X)
Mdl = KDTreeSearcher(X,Name,Value)
```

Description

`Mdl = KDTreeSearcher(X)` grows a default Kd-tree (`Mdl`) using the n -by- K numeric matrix of training data (`X`).

`Mdl = KDTreeSearcher(X, Name, Value)` specifies additional options using one or more name-value pair arguments. You can specify the maximum number of data points in each leaf node (that is, the bucket size) and the distance metric, and set the distance metric parameter (`DistParameter`) property. For example, `KDTreeSearcher(X, 'Distance', 'minkowski', 'BucketSize', 10)` specifies to use the Minkowski distance when searching for nearest neighbors and to use 10 for the bucket size. To specify `DistParameter`, use the `P` name-value pair argument.

Input Arguments

X — Training data

numeric matrix

Training data that grows the Kd-tree, specified as a numeric matrix. `X` has n rows, each corresponding to an observation (that is, an instance or example), and K columns, each corresponding to a predictor (that is, a feature).

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'Distance', 'minkowski', 'P', 3, 'BucketSize', 10` specifies to use the following when searching for nearest neighbors: the Minkowski distance, 3 for the Minkowski distance metric exponent, and 10 for the bucket size.

Distance — Distance metric

`'euclidean'` (default) | `'chebychev'` | `'cityblock'` | `'minkowski'`

Distance metric used when you call `knnsearch` or `rangesearch` to find nearest neighbors for future query points, specified as the comma-separated pair consisting of `'Distance'` and one of these values.

Value	Description
'chebychev'	Chebychev distance (maximum coordinate difference).
'cityblock'	City block distance.
'euclidean'	Euclidean distance.
'minkowski'	Minkowski distance. The default exponent is 2. To specify a different exponent, use the 'P' name-value pair argument.

For more details, see “Distance Metrics” on page 18-16.

The software does not use the distance metric for creating a `KDTreeSearcher` model object, so you can alter the distance metric by using dot notation after creating the object.

Example: `'Distance','minkowski'`

P — Exponent for Minkowski distance metric

2 (default) | positive scalar

Exponent for the Minkowski distance metric, specified as the comma-separated pair consisting of 'P' and a positive scalar. This argument is valid only if 'Distance' is 'minkowski'.

Example: `'P',3`

Data Types: `single` | `double`

BucketSize — Maximum number of data points in each leaf node

50 (default) | positive integer

Maximum number of data points in each leaf node of the *Kd*-tree, specified as the comma-separated pair consisting of 'BucketSize' and a positive integer.

Example: `'BucketSize',10`

Data Types: `single` | `double`

Properties

X — Training data

numeric matrix

This property is read-only.

Training data that grows the Kd-tree, specified as a numeric matrix. X has n rows, each corresponding to an observation (that is, an instance or example), and K columns, each corresponding to a predictor (that is, a feature).

The input argument X of `createns` or `KDTreeSearcher` sets this property.

Data Types: `single` | `double`

Distance — Distance metric

`'chebychev'` | `'cityblock'` | `'minkowski'`

Distance metric used when you call `knnsearch` or `rangesearch` to find nearest neighbors for future query points, specified as `'chebychev'`, `'cityblock'`, `'euclidean'`, or `'minkowski'`.

The `'Distance'` name-value pair argument of `createns` or `KDTreeSearcher` sets this property.

The software does not use the distance metric for creating a `KDTreeSearcher` model object, so you can alter it by using dot notation.

DistParameter — Distance metric parameter values

`[]` | positive scalar

Distance metric parameter values, specified as empty (`[]`) or a positive scalar.

If `Distance` is `'minkowski'`, then `DistParameter` is the exponent in the Minkowski distance formula. Otherwise, `DistParameter` is `[]`, indicating that the specified distance metric formula has no parameters.

The `'P'` name-value pair argument of `createns` or `KDTreeSearcher` sets this property.

You can alter `DistParameter` by using dot notation, for example, `Mdl.DistParameter = PNew`, where `PNew` is a positive scalar.

Data Types: `single` | `double`

BucketSize — Maximum number of data points in each leaf node

positive integer

This property is read-only.

Maximum number of data points in each leaf node of the Kd-tree, specified as a positive integer.

The 'BucketSize' name-value pair argument of `createns` or `KDTreeSearcher` sets this property.

Data Types: `single` | `double`

Object Functions

`knnsearch` Find k-nearest neighbors using searcher object

`rangesearch` Find all neighbors within specified distance using searcher object

Examples

Grow Default Kd-Tree

Grow a four-dimensional Kd-tree that uses the Euclidean distance.

Load Fisher's iris data set.

```
load fisheriris
X = meas;
[n,k] = size(X)
```

```
n = 150
```

```
k = 4
```

X has 150 observations and 4 predictors.

Grow a four-dimensional Kd-tree using the entire data set as training data.

```
Mdl1 = KDTreeSearcher(X)
```

```
Mdl1 =
KDTreeSearcher with properties:
```

```
    BucketSize: 50
    Distance: 'euclidean'
    DistParameter: []
```

```
X: [150x4 double]
```

Mdl1 is a `KDTreeSearcher` model object, and its properties appear in the Command Window. The object contains information about the grown four-dimensional Kd-tree, such as the distance metric. You can alter property values using dot notation.

Alternatively, you can grow a Kd-tree by using `createns`.

```
Mdl2 = createns(X)
```

```
Mdl2 =  
  KDTreeSearcher with properties:  
    BucketSize: 50  
    Distance: 'euclidean'  
    DistParameter: []  
    X: [150x4 double]
```

Mdl2 is also a `KDTreeSearcher` model object, and it is equivalent to Mdl1. Because X has four columns and the default distance metric is Euclidean, `createns` creates a `KDTreeSearcher` model by default.

To find the nearest neighbors in X to a batch of query data, pass the `KDTreeSearcher` model object and the query data to `knnsearch` or `rangesearch`.

Specify the Minkowski Distance for Nearest Neighbor Search

Load Fisher's iris data. Focus on the petal dimensions.

```
load fisheriris  
X = meas(:, [3 4]); % Predictors
```

Grow a two-dimensional Kd-tree using `createns` and the training data. Specify the Minkowski distance metric.

```
Mdl = createns(X, 'Distance', 'Minkowski')
```

```
Mdl =  
  KDTreeSearcher with properties:
```

```

    BucketSize: 50
      Distance: 'minkowski'
    DistParameter: 2
      X: [150x2 double]

```

Because `X` has two columns and the distance metric is Minkowski, `createns` creates a `KDTreearcher` model object by default.

Access properties of `Mdl` by using dot notation. For example, use `Mdl.DistParameter` to access the Minkowski distance exponent.

```
Mdl.DistParameter
```

```
ans = 2
```

You can pass query data and `Mdl` to:

- `knnsearch` to find indices and distances of nearest neighbors
- `rangearch` to find indices of all nearest neighbors within a distance that you specify

Alter Properties of KDTreearcher Model

Create a `KDTreearcher` model object and alter the `Distance` property by using dot notation.

Load Fisher's iris data set.

```
load fisheriris
X = meas;
```

Grow a default four-dimensional `Kd`-tree using the entire data set as training data.

```
Mdl = KDTreearcher(X)
```

```
Mdl =
    KDTreearcher with properties:
```

```

    BucketSize: 50
      Distance: 'euclidean'
    DistParameter: []

```

```
X: [150x4 double]
```

Specify that the neighbor searcher use the Minkowski metric to compute the distances between the training and query data.

```
Mdl.Distance = 'minkowski'  
  
Mdl =  
  KDTreeSearcher with properties:  
    BucketSize: 50  
    Distance: 'minkowski'  
    DistParameter: 2  
    X: [150x4 double]
```

You can pass `Mdl` and the query data to either `knnsearch` or `rangesearch` to find the nearest neighbors to the points in the query data based on the Minkowski distance.

Search for Nearest Neighbors of Query Data Using Minkowski Distance

Grow a *K*d-tree nearest neighbor searcher object by using the `createns` function. Pass the object and query data to the `knnsearch` function to find *k*-nearest neighbors.

Load Fisher's iris data set.

```
load fisheriris
```

Remove five irises randomly from the predictor data to use as a query set.

```
rng(1); % For reproducibility  
n = size(meas,1); % Sample size  
qIdx = randsample(n,5); % Indices of query data  
tIdx = ~ismember(1:n,qIdx); % Indices of training data  
Q = meas(qIdx,:);  
X = meas(tIdx,:);
```

Grow a four-dimensional *K*d-tree using the training data. Specify the Minkowski distance for finding nearest neighbors.

```
Mdl = createns(X,'Distance','minkowski')
```

```
Mdl =
  KDTreeSearcher with properties:

    BucketSize: 50
    Distance: 'minkowski'
    DistParameter: 2
    X: [145x4 double]
```

Because `X` has four columns and the distance metric is Minkowski, `createns` creates a `KDTreeSearcher` model object by default. The Minkowski distance exponent is 2 by default.

Find the indices of the training data (`Mdl.X`) that are the two nearest neighbors of each point in the query data (`Q`).

```
IdxNN = knnsearch(Mdl,Q,'K',2)
```

```
IdxNN = 5x2
```

```
    17     4
     6     2
     1    12
    89    66
   124   100
```

Each row of `IdxNN` corresponds to a query data observation, and the column order corresponds to the order of the nearest neighbors, with respect to ascending distance. For example, based on the Minkowski distance, the second nearest neighbor of `Q(3, :)` is `X(12, :)`.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations: The `knnsearch` and `rangesearch` functions support code generation.

For more information, see “Introduction to Code Generation” on page 31-2 and “Code Generation for Nearest Neighbor Searcher” on page 31-15.

Introduced in R2010a

kfoldEdge

Package: classreg.learning.partition

Classification edge for cross-validated ECOC model

Syntax

```
edge = kfoldEdge(CVMdl)
edge = kfoldEdge(CVMdl,Name,Value)
```

Description

`edge = kfoldEdge(CVMdl)` returns the classification edge on page 32-3220 obtained by the cross-validated ECOC model (`ClassificationPartitionedECOC`) `CVMdl`. For every fold, `kfoldEdge` computes the classification edge for validation-fold observations using an ECOC model trained on training-fold observations. `CVMdl.X` contains both sets of observations.

`edge = kfoldEdge(CVMdl,Name,Value)` returns the classification edge with additional options specified by one or more name-value pair arguments. For example, specify the number of folds, decoding scheme, or verbosity level.

Examples

Estimate *k*-Fold Cross-Validation Edge

Load Fisher's iris data set. Specify the predictor data `X`, the response data `Y`, and the order of the classes in `Y`.

```
load fisheriris
X = meas;
Y = categorical(species);
classOrder = unique(Y);
rng(1); % For reproducibility
```

Train and cross-validate an ECOC model using support vector machine (SVM) binary classifiers. Standardize the predictor data using an SVM template, and specify the class order.

```
t = templateSVM('Standardize',1);
CVMdl = fitcecoc(X,Y,'CrossVal','on','Learners',t,'ClassNames',classOrder);
```

CVMdl is a `ClassificationPartitionedECOC` model. By default, the software implements 10-fold cross-validation. You can specify a different number of folds using the 'KFold' name-value pair argument.

Estimate the average of the edges.

```
edge = kfoldEdge(CVMdl)
```

```
edge = 0.4825
```

Alternatively, you can obtain the per-fold edges by specifying the name-value pair 'Mode','individual' in `kfoldEdge`.

Display Individual Edges for Each Cross-Validation Fold

The classification edge is a relative measure of classifier quality. To determine which folds perform poorly, display the edges for each fold.

Load Fisher's iris data set. Specify the predictor data X, the response data Y, and the order of the classes in Y.

```
load fisheriris
X = meas;
Y = categorical(species);
classOrder = unique(Y);
rng(1); % For reproducibility
```

Train an ECOC model using SVM binary classifiers. Use 8-fold cross-validation, standardize the predictors using an SVM template, and specify the class order.

```
t = templateSVM('Standardize',1);
CVMdl = fitcecoc(X,Y,'KFold',8,'Learners',t,'ClassNames',classOrder);
```

Estimate the classification edge for each fold.

```
edges = kfoldEdge(CVMdl, 'Mode', 'individual')
edges = 8×1
    0.4791
    0.4872
    0.4260
    0.5302
    0.5064
    0.4575
    0.4860
    0.4687
```

The edges have similar magnitudes across folds. Folds that perform poorly have small edges relative to the other folds.

To return the average classification edge across the folds that perform well, specify the 'Folds' name-value pair argument.

Select ECOC Model Features by Comparing Cross-Validation Edges

The classifier edge measures the average of the classifier margins. One way to perform feature selection is to compare cross-validation edges from multiple models. Based solely on this criterion, the classifier with the greatest edge is the best classifier.

Load Fisher's iris data set. Specify the predictor data X, the response data Y, and the order of the classes in Y.

```
load fisheriris
X = meas;
Y = categorical(species);
classOrder = unique(Y); % Class order
rng(1); % For reproducibility
```

Define the following two data sets.

- `fullX` contains all the predictors.
- `partX` contains the petal dimensions.

```
fullX = X;
partX = X(:,3:4);
```

For each predictor set, train and cross-validate an ECOC model using SVM binary classifiers. Standardize the predictors using an SVM template, and specify the class order.

```
t = templateSVM('Standardize',1);
CVMdl = fitcecoc(fullX,Y,'CrossVal','on','Learners',t,...
    'ClassNames',classOrder);
PCVMdl = fitcecoc(partX,Y,'CrossVal','on','Learners',t,...
    'ClassNames',classOrder);
```

CVMdl and PCVMdl are ClassificationPartitionedECOC models. By default, the software implements 10-fold cross-validation.

Estimate the edge for each classifier.

```
fullEdge = kfoldEdge(CVMdl)
fullEdge = 0.4825
partEdge = kfoldEdge(PCVMdl)
partEdge = 0.4951
```

The two models have comparable edges.

Input Arguments

CVMdl — Cross-validated ECOC model

ClassificationPartitionedECOC model

Cross-validated ECOC model, specified as a ClassificationPartitionedECOC model. You can create a ClassificationPartitionedECOC model in two ways:

- Pass a trained ECOC model (ClassificationECOC) to `crossval`.
- Train an ECOC model using `fitcecoc` and specify any one of these cross-validation name-value pair arguments: 'CrossVal', 'CVPartition', 'Holdout', 'KFold', or 'Leaveout'.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes.

You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `kfoldEdge(CVMdl,'BinaryLoss','hinge')` specifies 'hinge' as the binary learner loss function.

BinaryLoss — Binary learner loss function

'hamming' | 'linear' | 'logit' | 'exponential' | 'binodeviance' | 'hinge' | 'quadratic' | function handle

Binary learner loss function, specified as the comma-separated pair consisting of 'BinaryLoss' and a built-in loss function name or function handle.

- This table describes the built-in functions, where y_j is a class label for a particular binary learner (in the set $\{-1,1,0\}$), s_j is the score for observation j , and $g(y_j,s_j)$ is the binary loss formula.

Value	Description	Score Domain	$g(y_j,s_j)$
'binodeviance'	Binomial deviance	$(-\infty,\infty)$	$\log[1 + \exp(-2y_j s_j)]/[2\log(2)]$
'exponential'	Exponential	$(-\infty,\infty)$	$\exp(-y_j s_j)/2$
'hamming'	Hamming	$[0,1]$ or $(-\infty,\infty)$	$[1 - \text{sign}(y_j s_j)]/2$
'hinge'	Hinge	$(-\infty,\infty)$	$\max(0,1 - y_j s_j)/2$
'linear'	Linear	$(-\infty,\infty)$	$(1 - y_j s_j)/2$
'logit'	Logistic	$(-\infty,\infty)$	$\log[1 + \exp(-y_j s_j)]/[2\log(2)]$
'quadratic'	Quadratic	$[0,1]$	$[1 - y_j(2s_j - 1)]^2/2$

The software normalizes binary losses so that the loss is 0.5 when $y_j = 0$. Also, the software calculates the mean binary loss for each class.

- For a custom binary loss function, for example `customFunction`, specify its function handle 'BinaryLoss',@`customFunction`.

`customFunction` has this form:

```
bLoss = customFunction(M,s)
```

where:

- `M` is the K -by- L coding matrix stored in `Mdl.CodingMatrix`.
- `s` is the 1-by- L row vector of classification scores.
- `bLoss` is the classification loss. This scalar aggregates the binary losses for every learner in a particular class. For example, you can use the mean binary loss to aggregate the loss over the learners for each class.
- K is the number of classes.
- L is the number of binary learners.

For an example of passing a custom binary loss function, see “Predict Test-Sample Labels of ECOC Model Using Custom Binary Loss Function” on page 32-5219.

The default `BinaryLoss` value depends on the score ranges returned by the binary learners. This table describes some default `BinaryLoss` values based on the given assumptions.

Assumption	Default Value
All binary learners are SVMs or either linear or kernel classification models of SVM learners.	'hinge'
All binary learners are ensembles trained by <code>AdaboostM1</code> or <code>GentleBoost</code> .	'exponential'
All binary learners are ensembles trained by <code>LogitBoost</code> .	'binodeviance'
All binary learners are linear or kernel classification models of logistic regression learners. Or, you specify to predict class posterior probabilities by setting ' <code>FitPosterior</code> ', <code>true</code> in <code>fitcecoc</code> .	'quadratic'

To check the default value, use dot notation to display the `BinaryLoss` property of the trained model at the command line.

Example: `'BinaryLoss', 'binodeviance'`

Data Types: `char` | `string` | `function_handle`

Decoding — Decoding scheme

`'lossweighted'` (default) | `'lossbased'`

Decoding scheme that aggregates the binary losses, specified as the comma-separated pair consisting of '`Decoding`' and '`lossweighted`' or '`lossbased`'. For more information, see “Binary Loss” on page 32-3444.

Example: 'Decoding', 'lossbased'

Folds — Fold indices for prediction

1:CVMDL.KFold (default) | numeric vector of positive integers

Fold indices for prediction, specified as the comma-separated pair consisting of 'Folds' and a numeric vector of positive integers. The elements of Folds must be within the range from 1 to CVMDL.KFold.

The software uses only the folds specified in Folds for prediction.

Example: 'Folds',[1 4 10]

Data Types: single | double

Mode — Aggregation level for output

'average' (default) | 'individual'

Aggregation level for the output, specified as the comma-separated pair consisting of 'Mode' and 'average' or 'individual'.

This table describes the values.

Value	Description
'average'	The output is a scalar average over all folds.
'individual'	The output is a vector of length k containing one value per fold, where k is the number of folds.

Example: 'Mode','individual'

Options — Estimation options

[] (default) | structure array returned by `statset`

Estimation options, specified as the comma-separated pair consisting of 'Options' and a structure array returned by `statset`.

To invoke parallel computing:

- You need a Parallel Computing Toolbox license.

- Specify 'Options', `statset('UseParallel',true)`.

Verbose — Verbosity level

0 (default) | 1

Verbosity level, specified as the comma-separated pair consisting of 'Verbose' and 0 or 1. Verbose controls the number of diagnostic messages that the software displays in the Command Window.

If Verbose is 0, then the software does not display diagnostic messages. Otherwise, the software displays diagnostic messages.

Example: 'Verbose',1

Data Types: single | double

Output Arguments

edge — Classification edge

numeric scalar | numeric column vector

Classification edge on page 32-3220, returned as a numeric scalar or numeric column vector.

If Mode is 'average', then edge is the average classification edge over all folds. Otherwise, edge is a k -by-1 numeric column vector containing the classification edge for each fold, where k is the number of folds.

Definitions

Classification Edge

The classification edge is the weighted mean of the classification margins.

One way to choose among multiple classifiers, for example to perform feature selection, is to choose the classifier that yields the greatest edge.

Classification Margin

The classification margin is, for each observation, the difference between the negative loss for the true class and the maximal negative loss among the false classes. If the margins are on the same scale, then they serve as a classification confidence measure. Among multiple classifiers, those that yield greater margins are better.

Binary Loss

A binary loss is a function of the class and classification score that determines how well a binary learner classifies an observation into the class.

Suppose the following:

- m_{kj} is element (k,j) of the coding design matrix M (that is, the code corresponding to class k of binary learner j).
- s_j is the score of binary learner j for an observation.
- g is the binary loss function.
- \hat{k} is the predicted class for the observation.

In loss-based decoding [Escalera et al.] on page 18-228, the class producing the minimum sum of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \operatorname{argmin}_k \sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j).$$

In loss-weighted decoding [Escalera et al.] on page 18-228, the class producing the minimum average of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \operatorname{argmin}_k \frac{\sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j)}{\sum_{j=1}^L |m_{kj}|}.$$

Allwein et al. on page 18-227 suggest that loss-weighted decoding improves classification accuracy by keeping loss values for all classes in the same dynamic range.

This table summarizes the supported loss functions, where y_j is a class label for a particular binary learner (in the set $\{-1,1,0\}$), s_j is the score for observation j , and $g(y_j, s_j)$.

Value	Description	Score Domain	$g(y_j, s_j)$
'binodeviance'	Binomial deviance	$(-\infty, \infty)$	$\log[1 + \exp(-2y_j s_j)] / [2\log(2)]$
'exponential'	Exponential	$(-\infty, \infty)$	$\exp(-y_j s_j) / 2$
'hamming'	Hamming	$[0,1]$ or $(-\infty, \infty)$	$[1 - \text{sign}(y_j s_j)] / 2$
'hinge'	Hinge	$(-\infty, \infty)$	$\max(0, 1 - y_j s_j) / 2$
'linear'	Linear	$(-\infty, \infty)$	$(1 - y_j s_j) / 2$
'logit'	Logistic	$(-\infty, \infty)$	$\log[1 + \exp(-y_j s_j)] / [2\log(2)]$
'quadratic'	Quadratic	$[0,1]$	$[1 - y_j(2s_j - 1)]^2 / 2$

The software normalizes binary losses such that the loss is 0.5 when $y_j = 0$, and aggregates using the average of the binary learners [Allwein et al.] on page 18-227.

Do not confuse the binary loss with the overall classification loss (specified by the 'LossFun' name-value pair argument of the `loss` and `predict` object functions), which measures how well an ECOC classifier performs as a whole.

Extended Capabilities

Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the 'UseParallel' option to true.

Set the 'UseParallel' field of the options structure to true using `statset` and specify the 'Options' name-value pair argument in the call to this function.

For example: `'Options',statset('UseParallel',true)`

For more information, see the 'Options' name-value pair argument.

For more general information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

Introduced in R2014b

kfoldEdge

Classification edge for observations not used for training

Syntax

```
E = kfoldEdge(obj)
E = kfoldEdge(obj,Name,Value)
```

Description

`E = kfoldEdge(obj)` returns classification edge (average classification margin) obtained by cross-validated classification ensemble `obj`. For every fold, this method computes classification edge for in-fold observations using an ensemble trained on out-of-fold observations.

`E = kfoldEdge(obj,Name,Value)` calculates edge with additional options specified by one or more `Name,Value` pair arguments. You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Input Arguments

ens

Object of class `ClassificationPartitionedEnsemble`. Create `ens` with `fitcensemble` along with one of the cross-validation options: `'crossval'`, `'kfold'`, `'holdout'`, `'leaveout'`, or `'cvpartition'`. Alternatively, create `ens` from a classification ensemble with `crossval`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

fold

Indices of folds ranging from 1 to `ens.KFold`. Use only these folds for predictions.

Default: `1:ens.KFold`

mode

Character vector or string scalar representing the meaning of the output edge:

- `'average'` — edge is a scalar value, the average over all folds.
- `'individual'` — edge is a vector of length `ens.KFold` with one element per fold.
- `'cumulative'` — edge is a vector of length `min(ens.NTrainedPerFold)` in which element `J` is obtained by averaging values across all folds for weak learners `1:J` in each fold.

Default: `'average'`

Output Arguments

E

The average classification margin. `E` is a scalar or vector, depending on the setting of the mode name-value pair.

Examples

Compute K-Fold Edge of Held-Out Observations

Compute the k-fold edge for an ensemble trained on the Fisher iris data.

Load the sample data set.

```
load fisheriris
```

Train an ensemble of 100 boosted classification trees.

```
t = templateTree('MaxNumSplits',1); % Weak learner template tree object
ens = fitensemble(meas,species,'Learners',t);
```

Create a cross-validated ensemble from `ens` and find the classification edge.

```
rng(10, 'twister') % For reproducibility
cvens = crossval(ens);
E = kfoldEdge(cvens)
```

```
E = 3.2052
```

Definitions

Edge

The edge is the weighted mean value of the classification margin. The weights are the class probabilities in `obj.Prior`.

Margin

The classification margin is the difference between the classification score for the true class and maximal classification score for the false classes. Margin is a column vector with the same number of rows as in the matrix `obj.X`.

Score (ensemble)

For ensembles, a classification score represents the confidence of a classification into a class. The higher the score, the higher the confidence.

Different ensemble algorithms have different definitions for their scores. Furthermore, the range of scores depends on ensemble type. For example:

- AdaBoostM1 scores range from $-\infty$ to ∞ .
- Bag scores range from 0 to 1.

See Also

`crossval` | `kfoldLoss` | `kfoldMargin` | `kfoldPredict` | `kfoldfun`

kfoldEdge

Package: classreg.learning.partition

Classification edge for cross-validated kernel classification model

Syntax

```
edge = kfoldEdge(CVMdl)
edge = kfoldEdge(CVMdl, Name, Value)
```

Description

`edge = kfoldEdge(CVMdl)` returns the classification edge on page 32-3231 obtained by the cross-validated, binary kernel model (`ClassificationPartitionedKernel`) `CVMdl`. For every fold, `kfoldEdge` computes the classification edge for validation-fold observations using a model trained on training-fold observations.

`edge = kfoldEdge(CVMdl, Name, Value)` returns the classification edge with additional options specified by one or more name-value pair arguments. For example, specify the number of folds or the aggregation level.

Examples

Estimate *k*-Fold Cross-Validation Edge

Load the `ionosphere` data set. This data set has 34 predictors and 351 binary responses for radar returns, which are labeled either bad ('b') or good ('g').

```
load ionosphere
```

Cross-validate a binary kernel classification model using the data.

```
CVMdl = fitckernel(X, Y, 'Crossval', 'on')
```

```
CVMdl =  
  classreg.learning.partition.ClassificationPartitionedKernel  
    CrossValidatedModel: 'Kernel'  
      ResponseName: 'Y'  
    NumObservations: 351  
      KFold: 10  
    Partition: [1x1 cvpartition]  
    ClassNames: {'b' 'g'}  
    ScoreTransform: 'none'
```

Properties, Methods

`CVMdl` is a `ClassificationPartitionedKernel` model. By default, the software implements 10-fold cross-validation. To specify a different number of folds, use the `'KFold'` name-value pair argument instead of `'Crossval'`.

Estimate the cross-validated classification edge.

```
edge = kfoldEdge(CVMdl)
```

```
edge = 1.5585
```

Alternatively, you can obtain the per-fold edges by specifying the name-value pair `'Mode', 'individual'` in `kfoldEdge`.

Feature Selection Using *k*-Fold Edges

Perform feature selection by comparing *k*-fold edges from multiple models. Based solely on this criterion, the classifier with the greatest edge is the best classifier.

Load the `ionosphere` data set. This data set has 34 predictors and 351 binary responses for radar returns, which are labeled either bad (`'b'`) or good (`'g'`).

```
load ionosphere
```

Randomly choose half of the predictor variables.

```
rng(1); % For reproducibility  
p = size(X,2); % Number of predictors  
idxPart = randsample(p,ceil(0.5*p));
```

Cross-validate two binary kernel classification models: one that uses all of the predictors, and one that uses half of the predictors.

```
CVMdl = fitckernel(X,Y,'CrossVal','on');  
PCVMdl = fitckernel(X(:,idxPart),Y,'CrossVal','on');
```

CVMdl and PCVMdl are `ClassificationPartitionedKernel` models. By default, the software implements 10-fold cross-validation. To specify a different number of folds, use the 'KFold' name-value pair argument instead of 'Crossval'.

Estimate the k -fold edge for each classifier.

```
fullEdge = kfoldEdge(CVMdl)  
  
fullEdge = 1.5142  
  
partEdge = kfoldEdge(PCVMdl)  
  
partEdge = 1.8910
```

Based on the k -fold edges, the classifier that uses half of the predictors is the better model.

Input Arguments

CVMdl — Cross-validated, binary kernel classification model

`ClassificationPartitionedKernel` model object

Cross-validated, binary kernel classification model, specified as a `ClassificationPartitionedKernel` model object. You can create a `ClassificationPartitionedKernel` model by using `fitckernel` and specifying any one of the cross-validation name-value pair arguments.

To obtain estimates, `kfoldEdge` applies the same data used to cross-validate the kernel classification model (X and Y).

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes.

You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `kfoldEdge(CVMdl, 'Mode', 'individual')` returns the classification edge for each fold.

Folds — Fold indices for prediction

1: `CVMdl.KFold` (default) | numeric vector of positive integers

Fold indices for prediction, specified as the comma-separated pair consisting of `'Folds'` and a numeric vector of positive integers. The elements of `Folds` must be within the range from 1 to `CVMdl.KFold`.

The software uses only the folds specified in `Folds` for prediction.

Example: `'Folds', [1 4 10]`

Data Types: `single` | `double`

Mode — Aggregation level for output

`'average'` (default) | `'individual'`

Aggregation level for the output, specified as the comma-separated pair consisting of `'Mode'` and `'average'` or `'individual'`.

This table describes the values.

Value	Description
<code>'average'</code>	The output is a scalar average over all folds.
<code>'individual'</code>	The output is a vector of length k containing one value per fold, where k is the number of folds.

Example: `'Mode', 'individual'`

Output Arguments

edge — Classification edge

numeric scalar | numeric column vector

Classification edge on page 32-3231, returned as a numeric scalar or numeric column vector.

If Mode is 'average', then edge is the average classification edge over all folds. Otherwise, edge is a k -by-1 numeric column vector containing the classification edge for each fold, where k is the number of folds.

Definitions

Classification Edge

The classification edge is the weighted mean of the classification margins.

One way to choose among multiple classifiers, for example to perform feature selection, is to choose the classifier that yields the greatest edge.

Classification Margin

The classification margin for binary classification is, for each observation, the difference between the classification score for the true class and the classification score for the false class.

The software defines the classification margin for binary classification as

$$m = 2yf(x).$$

x is an observation. If the true label of x is the positive class, then y is 1, and -1 otherwise. $f(x)$ is the positive-class classification score for the observation x . The classification margin is commonly defined as $m = yf(x)$.

If the margins are on the same scale, then they serve as a classification confidence measure. Among multiple classifiers, those that yield greater margins are better.

Classification Score

For kernel classification models, the raw classification score for classifying the observation x , a row vector, into the positive class is defined by

$$f(x) = T(x)\beta + b.$$

- $T(\cdot)$ is a transformation of an observation for feature expansion.
- β is the estimated column vector of coefficients.
- b is the estimated scalar bias.

The raw classification score for classifying x into the negative class is $-f(x)$. The software classifies observations into the class that yields a positive score.

If the kernel classification model consists of logistic regression learners, then the software applies the 'logit' score transformation to the raw classification scores (see `ScoreTransform`).

Introduced in R2018b

kfoldEdge

Package: classreg.learning.partition

Classification edge for cross-validated kernel ECOC model

Syntax

```
edge = kfoldEdge(CVMdl)
edge = kfoldEdge(CVMdl, Name, Value)
```

Description

`edge = kfoldEdge(CVMdl)` returns the classification edge on page 32-3239 obtained by the cross-validated kernel ECOC model (`ClassificationPartitionedKernelECOC`) `CVMdl`. For every fold, `kfoldEdge` computes the classification edge for validation-fold observations using a model trained on training-fold observations.

`edge = kfoldEdge(CVMdl, Name, Value)` returns the classification edge with additional options specified by one or more name-value pair arguments. For example, specify the number of folds, decoding scheme, or verbosity level.

Examples

Estimate *k*-Fold Cross-Validation Edge

Load Fisher's iris data set. `X` contains flower measurements, and `Y` contains the names of flower species.

```
load fisheriris
X = meas;
Y = species;
```

Cross-validate an ECOC model composed of kernel binary learners.

```
CVMdl = fitcecoc(X,Y,'Learners','kernel','CrossVal','on')  
CVMdl =  
  classreg.learning.partition.ClassificationPartitionedKernelECOC  
    CrossValidatedModel: 'KernelECOC'  
      ResponseName: 'Y'  
    NumObservations: 150  
      KFold: 10  
    Partition: [1x1 cvpartition]  
    ClassNames: {'setosa' 'versicolor' 'virginica'}  
    ScoreTransform: 'none'
```

Properties, Methods

`CVMdl` is a `ClassificationPartitionedKernelECOC` model. By default, the software implements 10-fold cross-validation. To specify a different number of folds, use the `'KFold'` name-value pair argument instead of `'Crossval'`.

Estimate the cross-validated classification edges.

```
edge = kfoldEdge(CVMdl)
```

```
edge = 0.4145
```

Alternatively, you can obtain the per-fold edges by specifying the name-value pair `'Mode','individual'` in `kfoldEdge`.

Feature Selection Using *k*-Fold Edges

Perform feature selection by comparing *k*-fold edges from multiple models. Based solely on this criterion, the classifier with the greatest edge is the best classifier.

Load Fisher's iris data set. `X` contains flower measurements, and `Y` contains the names of flower species.

```
load fisheriris  
X = meas;  
Y = species;
```

Randomly choose half of the predictor variables.

```
rng(1); % For reproducibility
p = size(X,2); % Number of predictors
idxPart = randsample(p,ceil(0.5*p));
```

Cross-validate two ECOC models composed of kernel classification models: one that uses all of the predictors, and one that uses half of the predictors.

```
CVMDL = fitcecoc(X,Y,'Learners','kernel','CrossVal','on');
PCVMDL = fitcecoc(X(:,idxPart),Y,'Learners','kernel','CrossVal','on');
```

CVMDL and PCVMDL are ClassificationPartitionedKernelECOC models. By default, the software implements 10-fold cross-validation. To specify a different number of folds, use the 'KFold' name-value pair argument instead of 'Crossval'.

Estimate the k -fold edge for each classifier.

```
fullEdge = kfoldEdge(CVMDL)
fullEdge = 0.4092
partEdge = kfoldEdge(PCVMDL)
partEdge = 0.4161
```

Based on the k -fold edges, the two classifiers are comparable.

Input Arguments

CVMDL — Cross-validated kernel ECOC model

ClassificationPartitionedKernelECOC model

Cross-validated kernel ECOC model, specified as a ClassificationPartitionedKernelECOC model. You can create a ClassificationPartitionedKernelECOC model by training an ECOC model using fitcecoc and specifying these name-value pair arguments:

- 'Learners' - Set the value to 'kernel', a template object returned by templateKernel, or a cell array of such template objects.
- One of the arguments 'CrossVal', 'CVPartition', 'Holdout', 'KFold', or 'Leaveout'.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example: `kfoldEdge(CVMdl, 'BinaryLoss', 'hinge')` specifies 'hinge' as the binary learner loss function.

BinaryLoss — Binary learner loss function

'hamming' | 'linear' | 'logit' | 'exponential' | 'binodeviance' | 'hinge' | 'quadratic' | function handle

Binary learner loss function, specified as the comma-separated pair consisting of 'BinaryLoss' and a built-in loss function name or function handle.

- This table contains names and descriptions of the built-in functions, where y_j is a class label for a particular binary learner (in the set $\{-1, 1, 0\}$), s_j is the score for observation j , and $g(y_j, s_j)$ is the binary loss formula.

Value	Description	Score Domain	$g(y_j, s_j)$
'binodeviance'	Binomial deviance	$(-\infty, \infty)$	$\log[1 + \exp(-2y_j s_j)] / [2\log(2)]$
'exponential'	Exponential	$(-\infty, \infty)$	$\exp(-y_j s_j) / 2$
'hamming'	Hamming	$[0, 1]$ or $(-\infty, \infty)$	$[1 - \text{sign}(y_j s_j)] / 2$
'hinge'	Hinge	$(-\infty, \infty)$	$\max(0, 1 - y_j s_j) / 2$
'linear'	Linear	$(-\infty, \infty)$	$(1 - y_j s_j) / 2$
'logit'	Logistic	$(-\infty, \infty)$	$\log[1 + \exp(-y_j s_j)] / [2\log(2)]$
'quadratic'	Quadratic	$[0, 1]$	$[1 - y_j(2s_j - 1)]^2 / 2$

The software normalizes binary losses such that the loss is 0.5 when $y_j = 0$. Also, the software calculates the mean binary loss for each class.

- For a custom binary loss function, for example, `customFunction`, specify its function handle 'BinaryLoss', @customFunction.

`customFunction` has this form:

```
bLoss = customFunction(M,s)
```

where:

- M is the K -by- L coding matrix stored in `Mdl.CodingMatrix`.
- s is the 1-by- L row vector of classification scores.
- `bLoss` is the classification loss. This scalar aggregates the binary losses for every learner in a particular class. For example, you can use the mean binary loss to aggregate the loss over the learners for each class.
- K is the number of classes.
- L is the number of binary learners.

By default, if all binary learners are kernel classification models using SVM, then `BinaryLoss` is 'hinge'. If all binary learners are kernel classification models using logistic regression, then `BinaryLoss` is 'quadratic'.

Example: 'BinaryLoss', 'binodeviance'

Data Types: char | string | function_handle

Decoding — Decoding scheme

'lossweighted' (default) | 'lossbased'

Decoding scheme that aggregates the binary losses, specified as the comma-separated pair consisting of 'Decoding' and 'lossweighted' or 'lossbased'. For more information, see “Binary Loss” on page 32-3239.

Example: 'Decoding', 'lossbased'

Folds — Fold indices for prediction

1: `CVMdl.KFold` (default) | numeric vector of positive integers

Fold indices for prediction, specified as the comma-separated pair consisting of 'Folds' and a numeric vector of positive integers. The elements of `Folds` must be within the range from 1 to `CVMdl.KFold`.

The software uses only the folds specified in `Folds` for prediction.

Example: 'Folds', [1 4 10]

Data Types: single | double

Mode — Aggregation level for output

'average' (default) | 'individual'

Aggregation level for the output, specified as the comma-separated pair consisting of 'Mode' and 'average' or 'individual'.

This table describes the values.

Value	Description
'average'	The output is a scalar average over all folds.
'individual'	The output is a vector of length k containing one value per fold, where k is the number of folds.

Example: 'Mode', 'individual'

Options — Estimation options

[] (default) | structure array returned by `statset`

Estimation options, specified as the comma-separated pair consisting of 'Options' and a structure array returned by `statset`.

To invoke parallel computing:

- You need a Parallel Computing Toolbox license.
- Specify 'Options', `statset('UseParallel', true)`.

Verbose — Verbosity level

0 (default) | 1

Verbosity level, specified as the comma-separated pair consisting of 'Verbose' and 0 or 1. Verbose controls the number of diagnostic messages that the software displays in the Command Window.

If Verbose is 0, then the software does not display diagnostic messages. Otherwise, the software displays diagnostic messages.

Example: 'Verbose', 1

Data Types: single | double

Output Arguments

edge — Classification edge

numeric scalar | numeric column vector

Classification edge on page 32-3239, returned as a numeric scalar or numeric column vector.

If Mode is 'average', then edge is the average classification edge over all folds. Otherwise, edge is a k -by-1 numeric column vector containing the classification edge for each fold, where k is the number of folds.

Definitions

Classification Edge

The classification edge is the weighted mean of the classification margins.

One way to choose among multiple classifiers, for example to perform feature selection, is to choose the classifier that yields the greatest edge.

Classification Margin

The classification margin is, for each observation, the difference between the negative loss for the true class and the maximal negative loss among the false classes. If the margins are on the same scale, then they serve as a classification confidence measure. Among multiple classifiers, those that yield greater margins are better.

Binary Loss

A binary loss is a function of the class and classification score that determines how well a binary learner classifies an observation into the class.

Suppose the following:

- m_{kj} is element (k,j) of the coding design matrix M (that is, the code corresponding to class k of binary learner j).

- s_j is the score of binary learner j for an observation.
- g is the binary loss function.
- \hat{k} is the predicted class for the observation.

In loss-based decoding [Escalera et al.] on page 18-228, the class producing the minimum sum of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \operatorname{argmin}_k \sum_{j=1}^L |m_{kj}|g(m_{kj}, s_j).$$

In loss-weighted decoding [Escalera et al.] on page 18-228, the class producing the minimum average of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \operatorname{argmin}_k \frac{\sum_{j=1}^L |m_{kj}|g(m_{kj}, s_j)}{\sum_{j=1}^L |m_{kj}|}.$$

Allwein et al. on page 18-227 suggest that loss-weighted decoding improves classification accuracy by keeping loss values for all classes in the same dynamic range.

This table summarizes the supported loss functions, where y_j is a class label for a particular binary learner (in the set $\{-1,1,0\}$), s_j is the score for observation j , and $g(y_j, s_j)$.

Value	Description	Score Domain	$g(y_j, s_j)$
'binodeviance'	Binomial deviance	$(-\infty, \infty)$	$\log[1 + \exp(-2y_j s_j)] / [2\log(2)]$
'exponential'	Exponential	$(-\infty, \infty)$	$\exp(-y_j s_j) / 2$
'hamming'	Hamming	$[0,1]$ or $(-\infty, \infty)$	$[1 - \operatorname{sign}(y_j s_j)] / 2$
'hinge'	Hinge	$(-\infty, \infty)$	$\max(0, 1 - y_j s_j) / 2$
'linear'	Linear	$(-\infty, \infty)$	$(1 - y_j s_j) / 2$
'logit'	Logistic	$(-\infty, \infty)$	$\log[1 + \exp(-y_j s_j)] / [2\log(2)]$
'quadratic'	Quadratic	$[0,1]$	$[1 - y_j(2s_j - 1)]^2 / 2$

The software normalizes binary losses such that the loss is 0.5 when $y_j = 0$, and aggregates using the average of the binary learners [Allwein et al.] on page 18-227.

Do not confuse the binary loss with the overall classification loss (specified by the 'LossFun' name-value pair argument of the `loss` and `predict` object functions), which measures how well an ECOC classifier performs as a whole.

`ClassificationPartitionedKernelECOC` | `fitcecoc`

Introduced in R2018b

kfoldEdge

Classification edge for observations not used for training

Syntax

```
e = kfoldEdge(CVMdl)
e = kfoldEdge(CVMdl, Name, Value)
```

Description

`e = kfoldEdge(CVMdl)` returns the cross-validated classification edges on page 32-3249 obtained by the cross-validated, binary, linear classification model `CVMdl`. That is, for every fold, `kfoldEdge` estimates the classification edge for observations that it holds out when it trains using all other observations.

`e` contains a classification edge for each regularization strength in the linear classification models that comprise `CVMdl`.

`e = kfoldEdge(CVMdl, Name, Value)` uses additional options specified by one or more `Name, Value` pair arguments. For example, indicate which folds to use for the edge calculation.

Input Arguments

CVMdl — Cross-validated, binary, linear classification model

`ClassificationPartitionedLinear` model object

Cross-validated, binary, linear classification model, specified as a `ClassificationPartitionedLinear` model object. You can create a `ClassificationPartitionedLinear` model using `fitclinear` and specifying any one of the cross-validation, name-value pair arguments, for example, `CrossVal`.

To obtain estimates, `kfoldEdge` applies the same data used to cross-validate the linear classification model (X and Y).

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Folds — Fold indices to use for classification-score prediction

1: `CVMDL.KFold` (default) | numeric vector of positive integers

Fold indices to use for classification-score prediction, specified as the comma-separated pair consisting of `'Folds'` and a numeric vector of positive integers. The elements of `Folds` must range from 1 through `CVMDL.KFold`.

Example: `'Folds',[1 4 10]`

Data Types: `single` | `double`

Mode — Edge aggregation level

`'average'` (default) | `'individual'`

Edge aggregation level, specified as the comma-separated pair consisting of `'Mode'` and `'average'` or `'individual'`.

Value	Description
<code>'average'</code>	Returns classification edges averaged over all folds
<code>'individual'</code>	Returns classification edges for each fold

Example: `'Mode','individual'`

Output Arguments

e — Cross-validated classification edges

numeric scalar | numeric vector | numeric matrix

Cross-validated classification edges on page 32-3249, returned as a numeric scalar, vector, or matrix.

Let L be the number of regularization strengths in the cross-validated models (that is, L is `numel(CVMdl.Trained{1}.Lambda)`) and F be the number of folds (stored in `CVMdl.KFold`).

- If `Mode` is `'average'`, then e is a 1-by- L vector. $e(j)$ is the average classification edge over all folds of the cross-validated model that uses regularization strength j .
- Otherwise, e is an F -by- L matrix. $e(i, j)$ is the classification edge for fold i of the cross-validated model that uses regularization strength j .

To estimate e , `kfoldEdge` uses the data that created `CVMdl` (see X and Y).

Examples

Estimate k -Fold Cross-Validation Edge

Load the NLP data set.

```
load nlpdata
```

X is a sparse matrix of predictor data, and Y is a categorical vector of class labels. There are more than two classes in the data.

The models should identify whether the word counts in a web page are from the Statistics and Machine Learning Toolbox™ documentation. So, identify the labels that correspond to the Statistics and Machine Learning Toolbox™ documentation web pages.

```
Ystats = Y == 'stats';
```

Cross-validate a binary, linear classification model that can identify whether the word counts in a documentation web page are from the Statistics and Machine Learning Toolbox™ documentation.

```
rng(1); % For reproducibility  
CVMdl = fitlinear(X, Ystats, 'CrossVal', 'on');
```

`CVMdl` is a `ClassificationPartitionedLinear` model. By default, the software implements 10-fold cross validation. You can alter the number of folds using the `'KFold'` name-value pair argument.

Estimate the average of the out-of-fold edges.

```
e = kfoldEdge(CVMdl)
```

```
e = 8.1243
```

Alternatively, you can obtain the per-fold edges by specifying the name-value pair 'Mode', 'individual' in kfoldEdge.

Feature Selection Using *k*-fold Edges

One way to perform feature selection is to compare *k*-fold edges from multiple models. Based solely on this criterion, the classifier with the highest edge is the best classifier.

Load the NLP data set. Preprocess the data as in “Estimate *k*-Fold Cross-Validation Edge” on page 32-3244.

```
load nlpdata
Ystats = Y == 'stats';
X = X';
```

Create these two data sets:

- fullX contains all predictors.
- partX contains 1/2 of the predictors chosen at random.

```
rng(1); % For reproducibility
p = size(X,1); % Number of predictors
halfPredIdx = randsample(p,ceil(0.5*p));
fullX = X;
partX = X(halfPredIdx,:);
```

Cross-validate two binary, linear classification models: one that uses the all of the predictors and one that uses half of the predictors. Optimize the objective function using SpARSA, and indicate that observations correspond to columns.

```
CVMdl = fitlinear(fullX,Ystats,'CrossVal','on','Solver','sparsa',...
    'ObservationsIn','columns');
PCVMdl = fitlinear(partX,Ystats,'CrossVal','on','Solver','sparsa',...
    'ObservationsIn','columns');
```

CVMdl and PCVMdl are ClassificationPartitionedLinear models.

Estimate the *k*-fold edge for each classifier.

```
fullEdge = kfoldEdge(CVMdl)
fullEdge = 16.5629
partEdge = kfoldEdge(PCVMdl)
partEdge = 13.9030
```

Based on the k -fold edges, the classifier that uses all of the predictors is the better model.

Find Good Lasso Penalty Using k -fold Edge

To determine a good lasso-penalty strength for a linear classification model that uses a logistic regression learner, compare k -fold edges.

Load the NLP data set. Preprocess the data as in “Estimate k -Fold Cross-Validation Edge” on page 32-3244.

```
load nlpdata
Ystats = Y == 'stats';
X = X';
```

Create a set of 11 logarithmically-spaced regularization strengths from 10^{-8} through 10^1 .

```
Lambda = logspace(-8,1,11);
```

Cross-validate a binary, linear classification model using 5-fold cross-validation and that uses each of the regularization strengths. Optimize the objective function using SpARSA. Lower the tolerance on the gradient of the objective function to $1e-8$.

```
rng(10); % For reproducibility
CVMdl = fitlinear(X,Ystats,'ObservationsIn','columns','KFold',5,...
    'Learner','logistic','Solver','sparsa','Regularization','lasso',...
    'Lambda',Lambda,'GradientTolerance',1e-8)
```

```
CVMdl =
  classreg.learning.partition.ClassificationPartitionedLinear
  CrossValidatedModel: 'Linear'
  ResponseName: 'Y'
  NumObservations: 31572
  KFold: 5
  Partition: [1x1 cvpartition]
```

```

ClassNames: [0 1]
ScoreTransform: 'none'

```

Properties, Methods

`CVMDL` is a `ClassificationPartitionedLinear` model. Because `fitlinear` implements 5-fold cross-validation, `CVMDL` contains 5 `ClassificationLinear` models that the software trains on each fold.

Estimate the edges for each fold and regularization strength.

```
eFolds = kfoldEdge(CVMDL, 'Mode', 'individual')
```

```
eFolds = 5×11
```

0.9958	0.9958	0.9958	0.9958	0.9958	0.9925	0.9766	0.9131	0.8
0.9991	0.9991	0.9991	0.9991	0.9991	0.9939	0.9780	0.9141	0.8
0.9992	0.9992	0.9992	0.9992	0.9992	0.9942	0.9782	0.9149	0.8
0.9974	0.9974	0.9974	0.9974	0.9974	0.9931	0.9773	0.9171	0.8
0.9977	0.9977	0.9977	0.9977	0.9977	0.9942	0.9782	0.9110	0.8

`eFolds` is a 5-by-11 matrix of edges. Rows correspond to folds and columns correspond to regularization strengths in `Lambda`. You can use `eFolds` to identify ill-performing folds, that is, unusually low edges.

Estimate the average edge over all folds for each regularization strength.

```
e = kfoldEdge(CVMDL)
```

```
e = 1×11
```

0.9978	0.9978	0.9978	0.9978	0.9978	0.9936	0.9777	0.9140	0.8
--------	--------	--------	--------	--------	--------	--------	--------	-----

Determine how well the models generalize by plotting the averages of the 5-fold edge for each regularization strength. Identify the regularization strength that maximizes the 5-fold edge over the grid.

```

figure;
plot(log10(Lambda), log10(e), '-o')
[~, maxEIdx] = max(e);
maxLambda = Lambda(maxEIdx);

```

```

hold on
plot(log10(maxLambda), log10(e(maxEIdx)), 'ro');
ylabel('log_{10} 5-fold edge')
xlabel('log_{10} Lambda')
legend('Edge', 'Max edge')
hold off

```

Several values of Lambda yield similarly high edges. Higher values of lambda lead to predictor variable sparsity, which is a good quality of a classifier.

Choose the regularization strength that occurs just before the edge starts decreasing.

```
LambdaFinal = Lambda(5);
```

Train a linear classification model using the entire data set and specify the regularization strength `LambdaFinal`.

```
MdlFinal = fitclinear(X,Ystats,'ObservationsIn','columns',...  
    'Learner','logistic','Solver','sparsa','Regularization','lasso',...  
    'Lambda',LambdaFinal);
```

To estimate labels for new observations, pass `MdlFinal` and the new data to `predict`.

Definitions

Classification Edge

The classification edge is the weighted mean of the classification margins.

One way to choose among multiple classifiers, for example to perform feature selection, is to choose the classifier that yields the greatest edge.

Classification Margin

The classification margin for binary classification is, for each observation, the difference between the classification score for the true class and the classification score for the false class.

The software defines the classification margin for binary classification as

$$m = 2yf(x).$$

x is an observation. If the true label of x is the positive class, then y is 1, and -1 otherwise. $f(x)$ is the positive-class classification score for the observation x . The classification margin is commonly defined as $m = yf(x)$.

If the margins are on the same scale, then they serve as a classification confidence measure. Among multiple classifiers, those that yield greater margins are better.

Classification Score

For linear classification models, the raw classification score for classifying the observation x , a row vector, into the positive class is defined by

$$f_j(x) = x\beta_j + b_j.$$

For the model with regularization strength j , β_j is the estimated column vector of coefficients (the model property `Beta (: , j)`) and b_j is the estimated, scalar bias (the model property `Bias (j)`).

The raw classification score for classifying x into the negative class is $-f(x)$. The software classifies observations into the class that yields the positive score.

If the linear classification model consists of logistic regression learners, then the software applies the 'logit' score transformation to the raw classification scores (see `ScoreTransform`).

Introduced in R2016a

kfoldEdge

Classification edge for observations not used for training

Syntax

```
e = kfoldEdge(CVMdl)
e = kfoldEdge(CVMdl,Name,Value)
```

Description

`e = kfoldEdge(CVMdl)` returns the cross-validated classification edges on page 32-3262 obtained by the cross-validated, error-correcting output codes (ECOC) model composed of linear classification models `CVMdl`. That is, for every fold, `kfoldEdge` estimates the classification edge for observations that it holds out when it trains using all other observations.

`e` contains a classification edge for each regularization strength in the linear classification models that comprise `CVMdl`.

`e = kfoldEdge(CVMdl,Name,Value)` uses additional options specified by one or more `Name,Value` pair arguments. For example, specify a decoding scheme, which folds to use for the edge calculation, or verbosity level.

Input Arguments

CVMdl — Cross-validated, ECOC model composed of linear classification models

`ClassificationPartitionedLinearECOC` model object

Cross-validated, ECOC model composed of linear classification models, specified as a `ClassificationPartitionedLinearECOC` model object. You can create a `ClassificationPartitionedLinearECOC` model using `fitcecoc` and by:

- 1 Specifying any one of the cross-validation, name-value pair arguments, for example, `CrossVal`

- Setting the name-value pair argument `Learners` to `'linear'` or a linear classification model template returned by `templateLinear`

To obtain estimates, `kfoldEdge` applies the same data used to cross-validate the ECOC model (X and Y).

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

BinaryLoss — Binary learner loss function

`'hamming'` | `'linear'` | `'logit'` | `'exponential'` | `'binodeviance'` | `'hinge'` | `'quadratic'` | function handle

Binary learner loss function, specified as the comma-separated pair consisting of `'BinaryLoss'` and a built-in, loss-function name or function handle.

- This table contains names and descriptions of the built-in functions, where y_j is a class label for a particular binary learner (in the set $\{-1, 1, 0\}$), s_j is the score for observation j , and $g(y_j, s_j)$ is the binary loss formula.

Value	Description	Score Domain	$g(y_j, s_j)$
<code>'binodeviance'</code>	Binomial deviance	$(-\infty, \infty)$	$\log[1 + \exp(-2y_j s_j)] / [2\log(2)]$
<code>'exponential'</code>	Exponential	$(-\infty, \infty)$	$\exp(-y_j s_j) / 2$
<code>'hamming'</code>	Hamming	$[0, 1]$ or $(-\infty, \infty)$	$[1 - \text{sign}(y_j s_j)] / 2$
<code>'hinge'</code>	Hinge	$(-\infty, \infty)$	$\max(0, 1 - y_j s_j) / 2$
<code>'linear'</code>	Linear	$(-\infty, \infty)$	$(1 - y_j s_j) / 2$
<code>'logit'</code>	Logistic	$(-\infty, \infty)$	$\log[1 + \exp(-y_j s_j)] / [2\log(2)]$
<code>'quadratic'</code>	Quadratic	$[0, 1]$	$[1 - y_j(2s_j - 1)]^2 / 2$

The software normalizes the binary losses such that the loss is 0.5 when $y_j = 0$. Also, the software calculates the mean binary loss for each class.

- For a custom binary loss function, e.g., `customFunction`, specify its function handle `'BinaryLoss',@customFunction`.

`customFunction` should have this form

```
bLoss = customFunction(M,s)
```

where:

- `M` is the K -by- L coding matrix stored in `Mdl.CodingMatrix`.
- `s` is the 1-by- L row vector of classification scores.
- `bLoss` is the classification loss. This scalar aggregates the binary losses for every learner in a particular class. For example, you can use the mean binary loss to aggregate the loss over the learners for each class.
- K is the number of classes.
- L is the number of binary learners.

For an example of passing a custom binary loss function, see “Predict Test-Sample Labels of ECOC Model Using Custom Binary Loss Function” on page 32-5219.

By default, if all binary learners are linear classification models using:

- SVM, then `BinaryLoss` is `'hinge'`
- Logistic regression, then `BinaryLoss` is `'quadratic'`

Example: `'BinaryLoss','binodeviance'`

Data Types: `char` | `string` | `function_handle`

Decoding — Decoding scheme

`'lossweighted'` (default) | `'lossbased'`

Decoding scheme that aggregates the binary losses, specified as the comma-separated pair consisting of `'Decoding'` and `'lossweighted'` or `'lossbased'`. For more information, see “Binary Loss” on page 32-3444.

Example: `'Decoding','lossbased'`

Folds — Fold indices to use for classification-score prediction

1: `CVMdl.KFold` (default) | numeric vector of positive integers

Fold indices to use for classification-score prediction, specified as the comma-separated pair consisting of 'Folds' and a numeric vector of positive integers. The elements of Folds must range from 1 through `CVMdl.KFold`.

Example: `'Folds',[1 4 10]`

Data Types: `single` | `double`

Mode — Edge aggregation level

`'average'` (default) | `'individual'`

Edge aggregation level, specified as the comma-separated pair consisting of 'Mode' and 'average' or 'individual'.

Value	Description
<code>'average'</code>	Returns classification edges averaged over all folds
<code>'individual'</code>	Returns classification edges for each fold

Example: `'Mode','individual'`

Options — Estimation options

`[]` (default) | structure array returned by `statset`

Estimation options, specified as the comma-separated pair consisting of 'Options' and a structure array returned by `statset`.

To invoke parallel computing:

- You need a Parallel Computing Toolbox license.
- Specify `'Options',statset('UseParallel',true)`.

Verbose — Verbosity level

`0` (default) | `1`

Verbosity level, specified as the comma-separated pair consisting of 'Verbose' and `0` or `1`. `Verbose` controls the number of diagnostic messages that the software displays in the Command Window.

If `Verbose` is `0`, then the software does not display diagnostic messages. Otherwise, the software displays diagnostic messages.

Example: 'Verbose',1

Data Types: single | double

Output Arguments

e — Cross-validated classification edges

numeric scalar | numeric vector | numeric matrix

Cross-validated classification edges on page 32-3262, returned as a numeric scalar, vector, or matrix.

Let L be the number of regularization strengths in the cross-validated models (that is, L is `numel(CVMdl.Trained{1}.BinaryLearners{1}.Lambda)`) and F be the number of folds (stored in `CVMdl.KFold`).

- If `Mode` is 'average', then e is a 1-by- L vector. $e(j)$ is the average classification edge over all folds of the cross-validated model that uses regularization strength j .
- Otherwise, e is a F -by- L matrix. $e(i, j)$ is the classification edge for fold i of the cross-validated model that uses regularization strength j .

Examples

Estimate k -Fold Cross-Validation Edge

Load the NLP data set.

```
load nlpdata
```

X is a sparse matrix of predictor data, and Y is a categorical vector of class labels.

For simplicity, use the label 'others' for all observations in Y that are not 'simulink', 'dsp', or 'comm'.

```
Y(~(ismember(Y,{'simulink','dsp','comm'}))) = 'others';
```

Cross-validate a multiclass, linear classification model.

```
rng(1); % For reproducibility
CVMdl = fitcecoc(X,Y,'Learner','linear','CrossVal','on');
```

CVMdl is a `ClassificationPartitionedLinearECOC` model. By default, the software implements 10-fold cross validation. You can alter the number of folds using the 'KFold' name-value pair argument.

Estimate the average of the out-of-fold edges.

```
e = kfoldEdge(CVMdl)
```

```
e = 0.7232
```

Alternatively, you can obtain the per-fold edges by specifying the name-value pair 'Mode', 'individual' in `kfoldEdge`.

Feature Selection Using *k*-fold Edges

One way to perform feature selection is to compare *k*-fold edges from multiple models. Based solely on this criterion, the classifier with the highest edge is the best classifier.

Load the NLP data set. Preprocess the data as in “Estimate *k*-Fold Cross-Validation Edge” on page 32-3255, and orient the predictor data so that observations correspond to columns.

```
load nlpdata
Y(~(ismember(Y,{'simulink','dsp','comm'}))) = 'others';
X = X';
```

Create these two data sets:

- `fullX` contains all predictors.
- `partX` contains a 1/2 of the predictors chosen at random.

```
rng(1); % For reproducibility
p = size(X,1); % Number of predictors
halfPredIdx = randsample(p,ceil(0.5*p));
fullX = X;
partX = X(halfPredIdx,:);
```

Create a linear classification model template that specifies to optimize the objective function using SpARSA.

```
t = templateLinear('Solver','sparsa');
```

Cross-validate two ECOC models composed of binary, linear classification models: one that uses the all of the predictors and one that uses half of the predictors. Indicate that observations correspond to columns.

```
CVMDL = fitcecoc(fullX,Y,'Learners',t,'CrossVal','on',...
    'ObservationsIn','columns');
PCVMDL = fitcecoc(partX,Y,'Learners',t,'CrossVal','on',...
    'ObservationsIn','columns');
```

CVMDL and PCVMDL are ClassificationPartitionedLinearECOC models.

Estimate the k -fold edge for each classifier.

```
fullEdge = kfoldEdge(CVMDL)
fullEdge = 0.3090
partEdge = kfoldEdge(PCVMDL)
partEdge = 0.2617
```

Based on the k -fold edges, the classifier that uses all of the predictors is the better model.

Find Good Lasso Penalty Using k -fold Edge

To determine a good lasso-penalty strength for a linear classification model that uses a logistic regression learner, compare k -fold edges.

Load the NLP data set. Preprocess the data as in “Feature Selection Using k -fold Edges” on page 32-3256.

```
load nlpdata
Y(~(ismember(Y,{'simulink','dsp','comm'}))) = 'others';
X = X';
```

Create a set of 8 logarithmically-spaced regularization strengths from 10^{-8} through 10^1 .

```
Lambda = logspace(-8,1,8);
```

Create a linear classification model template that specifies to use logistic regression with a lasso penalty, use each of the regularization strengths, optimize the objective function using SpARSA, and reduce the tolerance on the gradient of the objective function to $1e-8$.

```
t = templateLinear('Learner','logistic','Solver','sparsa',...
    'Regularization','lasso','Lambda',Lambda,'GradientTolerance',1e-8);
```

Cross-validate an ECOC model composed of binary, linear classification models using 5-fold cross-validation and that

```
rng(10); % For reproducibility
CVMdl = fitcecoc(X,Y,'Learners',t,'ObservationsIn','columns','KFold',5)
```

```
CVMdl =
  classreg.learning.partition.ClassificationPartitionedLinearECOC
    CrossValidatedModel: 'Linear'
      ResponseName: 'Y'
    NumObservations: 31572
      KFold: 5
    Partition: [1x1 cvpartition]
    ClassNames: [comm dsp simulink others]
    ScoreTransform: 'none'
```

Properties, Methods

CVMdl is a `ClassificationPartitionedLinearECOC` model.

Estimate the edges for each fold and regularization strength.

```
eFolds = kfoldEdge(CVMdl,'Mode','individual')
```

```
eFolds = 5×8
```

0.5511	0.5520	0.5525	0.5514	0.4869	0.2933	0.1025	0.0857
0.5257	0.5270	0.5270	0.5277	0.4801	0.2944	0.1049	0.0866
0.5256	0.5265	0.5272	0.5276	0.4724	0.2884	0.1034	0.0866
0.5386	0.5394	0.5405	0.5373	0.4824	0.2903	0.1009	0.0854
0.5497	0.5551	0.5582	0.5575	0.4944	0.2939	0.1030	0.0849

eFolds is a 5-by-8 matrix of edges. Rows correspond to folds and columns correspond to regularization strengths in Lambda. You can use eFolds to identify ill-performing folds, that is, unusually low edges.

Estimate the average edge over all folds for each regularization strength.

```
e = kfoldEdge(CVMdl)
```

```
e = 1×8
```

```
    0.5382    0.5400    0.5411    0.5403    0.4832    0.2921    0.1029    0.0858
```

Determine how well the models generalize by plotting the averages of the 5-fold edge for each regularization strength. Identify the regularization strength that maximizes the 5-fold edge over the grid.

```
figure;  
plot(log10(Lambda),log10(e),'-o')  
[~, maxEIdx] = max(e);  
maxLambda = Lambda(maxEIdx);  
hold on  
plot(log10(maxLambda),log10(e(maxEIdx)),'ro');  
ylabel('log_{10} 5-fold edge')  
xlabel('log_{10} Lambda')  
legend('Edge','Max edge')  
hold off
```

Several values of `Lambda` yield similarly high edges. Greater regularization strength values lead to predictor variable sparsity, which is a good quality of a classifier.

Choose the regularization strength that occurs just before the edge starts decreasing.

```
LambdaFinal = Lambda(4);
```

Train an ECOC model composed of linear classification model using the entire data set and specify the regularization strength `LambdaFinal`.

```
t = templateLinear('Learner','logistic','Solver','sparsa',...
    'Regularization','lasso','Lambda',LambdaFinal,'GradientTolerance',1e-8);
MdlFinal = fitcecoc(X,Y,'Learners',t,'ObservationsIn','columns');
```

To estimate labels for new observations, pass `MdlFinal` and the new data to `predict`.

Definitions

Binary Loss

A binary loss is a function of the class and classification score that determines how well a binary learner classifies an observation into the class.

Suppose the following:

- m_{kj} is element (k,j) of the coding design matrix M (that is, the code corresponding to class k of binary learner j).
- s_j is the score of binary learner j for an observation.
- g is the binary loss function.
- \hat{k} is the predicted class for the observation.

In loss-based decoding [Escalera et al.] on page 18-228, the class producing the minimum sum of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \operatorname{argmin}_k \sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j).$$

In loss-weighted decoding [Escalera et al.] on page 18-228, the class producing the minimum average of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \operatorname{argmin}_k \frac{\sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j)}{\sum_{j=1}^L |m_{kj}|}.$$

Allwein et al. on page 18-227 suggest that loss-weighted decoding improves classification accuracy by keeping loss values for all classes in the same dynamic range.

This table summarizes the supported loss functions, where y_j is a class label for a particular binary learner (in the set $\{-1,1,0\}$), s_j is the score for observation j , and $g(y_j, s_j)$.

Value	Description	Score Domain	$g(y_j, s_j)$
'binodeviance'	Binomial deviance	$(-\infty, \infty)$	$\log[1 + \exp(-2y_j s_j)] / [2\log(2)]$
'exponential'	Exponential	$(-\infty, \infty)$	$\exp(-y_j s_j) / 2$
'hamming'	Hamming	$[0, 1]$ or $(-\infty, \infty)$	$[1 - \text{sign}(y_j s_j)] / 2$
'hinge'	Hinge	$(-\infty, \infty)$	$\max(0, 1 - y_j s_j) / 2$
'linear'	Linear	$(-\infty, \infty)$	$(1 - y_j s_j) / 2$
'logit'	Logistic	$(-\infty, \infty)$	$\log[1 + \exp(-y_j s_j)] / [2\log(2)]$
'quadratic'	Quadratic	$[0, 1]$	$[1 - y_j(2s_j - 1)]^2 / 2$

The software normalizes binary losses such that the loss is 0.5 when $y_j = 0$, and aggregates using the average of the binary learners [Allwein et al.] on page 18-227.

Do not confuse the binary loss with the overall classification loss (specified by the 'LossFun' name-value pair argument of the `loss` and `predict` object functions), which measures how well an ECOC classifier performs as a whole.

Classification Edge

The classification edge is the weighted mean of the classification margins.

One way to choose among multiple classifiers, for example to perform feature selection, is to choose the classifier that yields the greatest edge.

Classification Margin

The classification margin is, for each observation, the difference between the negative loss for the true class and the maximal negative loss among the false classes. If the margins are on the same scale, then they serve as a classification confidence measure. Among multiple classifiers, those that yield greater margins are better.

Extended Capabilities

Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the 'UseParallel' option to true.

Set the 'UseParallel' field of the options structure to true using `statset` and specify the 'Options' name-value pair argument in the call to this function.

For example: `'Options',statset('UseParallel',true)`

For more information, see the 'Options' name-value pair argument.

For more general information about parallel computing, see "Run MATLAB Functions with Automatic Parallel Support" (Parallel Computing Toolbox).

kfoldEdge

Classification edge for observations not used for training

Syntax

```
E = kfoldEdge(obj)
E = kfoldEdge(obj,Name,Value)
```

Description

`E = kfoldEdge(obj)` returns classification edge (average classification margin) obtained by cross-validated classification model `obj`. For every fold, this method computes classification edge for in-fold observations using an ensemble trained on out-of-fold observations.

`E = kfoldEdge(obj,Name,Value)` calculates edge with additional options specified by one or more `Name,Value` pair arguments. You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Input Arguments

obj

Object of class `ClassificationPartitionedModel`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

fold

Indices of folds ranging from 1 to `obj.KFold`. Use only these folds for predictions.

Default: `1:obj.KFold`

mode

Character vector or string scalar representing the meaning of the output `edge`:

- `'average'` — `edge` is a scalar value, the average over all folds.
- `'individual'` — `edge` is a vector of length `obj.KFold` with one element per fold.

Default: `'average'`

Output Arguments

E

The average classification margin. `E` is a scalar or vector, depending on the setting of the `mode` name-value pair.

Examples

Estimate the *k*-fold Edge of a Classifier

Compute the *k*-fold edge for a model trained on Fisher's iris data.

Load Fisher's iris data set.

```
load fisheriris
```

Train a classification tree classifier.

```
tree = fitctree(meas,species);
```

Cross validate the classifier using 10-fold cross validation.

```
cvtree = crossval(tree);
```

Compute the k -fold edge.

```
edge = kfoldEdge(cvtree)
```

```
edge = 0.8578
```

Definitions

Edge

The edge is the weighted mean value of the classification margin. The weights are class prior probabilities. If you supply additional weights, those weights are normalized to sum to the prior probabilities in the respective classes, and are then used to compute the weighted average.

Margin

The classification margin is the difference between the classification score for the true class and maximal classification score for the false classes.

The classification margin is a column vector with the same number of rows as in the matrix X . A high value of margin indicates a more reliable prediction than a low value.

Score

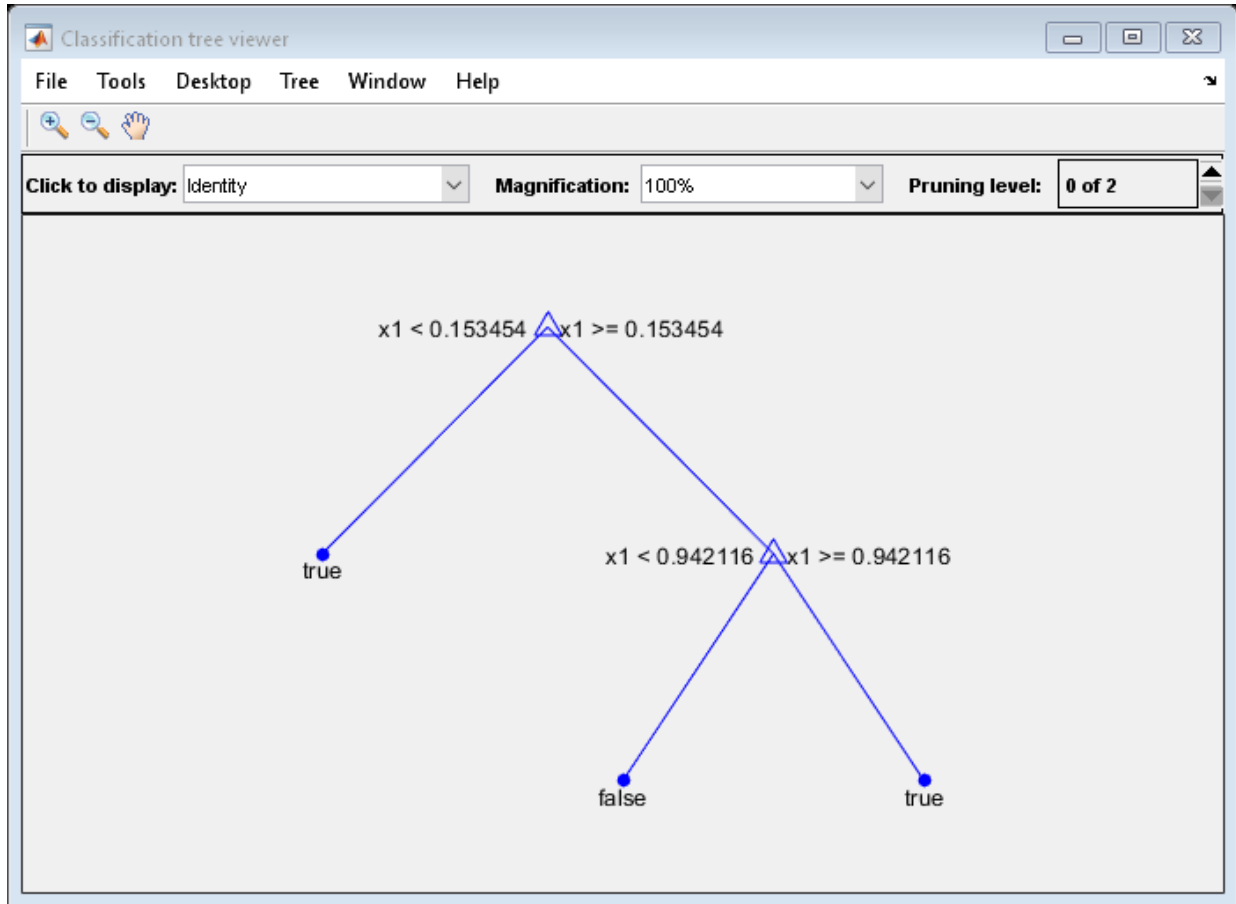

For discriminant analysis, the score of a classification is the posterior probability of the classification. For the definition of posterior probability in discriminant analysis, see "Posterior Probability" on page 20-6.

For trees, the score of a classification of a leaf node is the posterior probability of the classification at that node. The posterior probability of the classification at a node is the number of training sequences that lead to that node with the classification, divided by the number of training sequences that lead to that node.

For example, consider classifying a predictor X as `true` when $X < 0.15$ or $X > 0.95$, and X is false otherwise.

Generate 100 random points and classify them:

```
rng(0, 'twister') % for reproducibility
X = rand(100,1);
Y = (abs(X - .55) > .4);
tree = fitctree(X,Y);
view(tree, 'Mode', 'Graph')
```

Prune the tree:

```
tree1 = prune(tree, 'Level', 1);
view(tree1, 'Mode', 'Graph')
```

The pruned tree correctly classifies observations that are less than 0.15 as `true`. It also correctly classifies observations from .15 to .94 as `false`. However, it incorrectly classifies observations that are greater than .94 as `false`. Therefore, the score for observations that are greater than .15 should be about $.05/.85=.06$ for `true`, and about $.8/.85=.94$ for `false`.

Compute the prediction scores for the first 10 rows of `X`:

```
[~,score] = predict(tree1,X(1:10));
[score X(1:10,:)]
```

```
ans = 10x3
    0.9059    0.0941    0.8147
    0.9059    0.0941    0.9058
         0     1.0000    0.1270
    0.9059    0.0941    0.9134
    0.9059    0.0941    0.6324
         0     1.0000    0.0975
    0.9059    0.0941    0.2785
    0.9059    0.0941    0.5469
    0.9059    0.0941    0.9575
    0.9059    0.0941    0.9649
```

Indeed, every value of X (the right-most column) that is less than 0.15 has associated scores (the left and center columns) of 0 and 1, while the other values of X have associated scores of 0.91 and 0.09. The difference (score 0.09 instead of the expected .06) is due to a statistical fluctuation: there are 8 observations in X in the range (.95, 1) instead of the expected 5 observations.

kfoldfun

Package: classreg.learning.partition

Cross-validate function using cross-validated ECOC model

Syntax

```
vals = kfoldfun(CVMdl, fun)
```

Description

`vals = kfoldfun(CVMdl, fun)` cross-validates the function `fun` by applying `fun` to the data stored in the cross-validated ECOC model `CVMdl`. You must pass `fun` as a function handle.

Examples

Estimate Classification Error Using Custom Loss Function

Train a multiclass ECOC classifier, and then cross-validate the model using a custom k -fold loss function.

Load Fisher's iris data set. Specify the predictor data `X`, the response data `Y`, and the order of the classes in `Y`.

```
load fisheriris
X = meas;
Y = categorical(species);
classOrder = unique(Y); % Class order
rng(1); % For reproducibility
```

Train and cross-validate an ECOC model using support vector machine (SVM) binary classifiers. Standardize the predictors using an SVM template, and specify the class order.

```
t = templateSVM('Standardize',1);
CVMDL = fitcecoc(X,Y,'CrossVal','on','Learners',t,...
    'ClassNames',classOrder);
```

CVMDL is a ClassificationPartitionedECOC model. By default, the software implements 10-fold cross-validation.

Compute the classification error (proportion of misclassified observations) for the validation-fold observations.

```
L = kfoldLoss(CVMDL)
```

```
L = 0.0400
```

Examine the result when the cost of misclassifying a flower as `versicolor` is 10 and the cost of any other error is 1. Write a function named `noversicolor` that assigns a cost of 1 for general misclassification and a cost of 10 for misclassifying a flower as `versicolor`.

If you use the live script file for this example, the `noversicolor` function is already included at the end of the file. Otherwise, you need to create this function at the end of your `.m` file or add it as a file on the MATLAB path.

Compute the mean misclassification error with the `noversicolor` cost.

```
foldLoss = kfoldfun(CVMDL,@noversicolor);
mean(foldLoss)
```

```
ans = 0.0667
```

This code creates the function `noversicolor`.

```
function averageCost = noversicolor(CMP,Xtrain,Ytrain,Wtrain,Xtest,Ytest,Wtest)
% noversicolor: Example custom cross-validation function that assigns a cost of
% 10 for misclassifying versicolor irises and a cost of 1 for misclassifying
% the other irises. This example function requires the fisheriris data
% set.
Ypredict = predict(CMP,Xtest);
misclassified = not(strcmp(Ypredict,Ytest)); % Different result
classifiedAsVersicolor = strcmp(Ypredict,'versicolor'); % Index of bad decisions
cost = sum(misclassified) + ...
    9*sum(misclassified & classifiedAsVersicolor); % Total differences
averageCost = single(cost/numel(Ytest)); % Average error
end
```

Input Arguments

CVMdl — Cross-validated ECOC model

`ClassificationPartitionedECOC` model

Cross-validated ECOC model, specified as a `ClassificationPartitionedECOC` model.

fun — Cross-validated function

function handle

Cross-validated function, specified as a function handle. `fun` has this syntax:

```
testvals = fun(CMP,Xtrain,Ytrain,Wtrain,Xtest,Ytest,Wtest)
```

- `CMP` is a compact model stored in one element of the `CVMdl.Trained` property.
- `Xtrain` is the training matrix of predictor values.
- `Ytrain` is the training array of response values.
- `Wtrain` is the set of training weights for observations.
- `Xtest` and `Ytest` are the validation data, with associated weights `Wtest`.
- The returned value `testvals` must have the same size across all folds.

Data Types: `function_handle`

Output Arguments

vals — Cross-validation results

numeric matrix

Cross-validation results, returned as a numeric matrix. `vals` corresponds to the arrays of the `testvals` output, concatenated vertically over all the folds. For example, if `testvals` from every fold is a numeric vector of length n , `kfoldfun` returns a `KFold-by-n` numeric matrix with one row per fold.

Introduced in R2014b

kfoldfun

Cross validate function

Syntax

```
vals = kfoldfun(CVMdl, fun)
```

Description

`vals = kfoldfun(CVMdl, fun)` cross validates the function `fun` by applying `fun` to the data stored in the cross-validated model `CVMdl`. You must pass `fun` as a function handle.

Input Arguments

CVMdl — Cross-validated model

`ClassificationPartitionedECOC model` | `ClassificationPartitionedEnsemble model` | `ClassificationPartitionedModel model`

Cross-validated model, specified as a `ClassificationPartitionedECOC model`, `ClassificationPartitionedEnsemble model`, or a `ClassificationPartitionedModel model`.

fun — Cross-validated function

function handle

Cross-validated function, specified as a function handle. `fun` has the syntax

```
testvals = fun(CMP, Xtrain, Ytrain, Wtrain, Xtest, Ytest, Wtest)
```

- `CMP` is a compact model stored in one element of the `CVMdl`. Trained property.
- `Xtrain` is the training matrix of predictor values.
- `Ytrain` is the training array of response values.
- `Wtrain` are the training weights for observations.

- `Xtest` and `Ytest` are the test data, with associated weights `Wtest`.
- The returned value `testvals` needs the same size across all folds.

Data Types: `function_handle`

Output Arguments

`vals` — Cross-validation results

numeric matrix

Cross-validation results, returned as an numeric matrix. `vals` is the arrays of `testvals` output, concatenated vertically over all folds. For example, if `testvals` from every fold is a numeric vector of length `N`, `kfoldfun` returns a `KFold`-by-`N` numeric matrix with one row per fold.

Data Types: `double`

Examples

Estimate Classification Error Using a Custom Loss Function

Train a classification tree classifier, and then cross validate it using a custom *k*-fold loss function.

Load Fisher's iris data set.

```
load fisheriris
```

Train a classification tree classifier.

```
Mdl = fitctree(meas,species);
```

`Mdl` is a `ClassificationTree` model.

Cross validate `Mdl` using the default 10-fold cross validation. Compute the classification error (proportion of misclassified observations) for the out-of-fold observations.

```
rng(1); % For reproducibility
CVMdl = crossval(Mdl);
L = kfoldLoss(CVMdl)
```

```
L =
    0.0467
```

Examine the result when the cost of misclassifying a flower as 'versicolor' is 10, and any other error is 1. Write a function called `noversicolor.m` that attributes a cost of 1 for misclassification, but 10 for misclassifying a flower as `versicolor`, and save it on your MATLAB path.

```
function averageCost = noversicolor(CMP,Xtrain,Ytrain,Wtrain,Xtest,Ytest,Wtest)
%noversicolor Example custom cross-validation function
%   Attributes a cost of 10 for misclassifying versicolor irises, and 1 for
%   the other irises. This example function requires the |fisheriris| data
%   set.
Ypredict = predict(CMP,Xtest);
misclassified = not(strcmp(Ypredict,Ytest)); % Different result
classifiedAsVersicolor = strcmp(Ypredict,'versicolor'); % Index of bad decisions
cost = sum(misclassified) + ...
    9*sum(misclassified & classifiedAsVersicolor); % Total differences
averageCost = cost/numel(Ytest); % Average error
end
```

Compute the mean misclassification error with the `noversicolor` cost.

```
mean(kfoldfun(CVMdl,@noversicolor))

ans =

    0.2267
```

kfoldfun

Cross validate function

Syntax

```
vals = kfoldfun(obj, fun)
```

Description

`vals = kfoldfun(obj, fun)` cross validates the function `fun` by applying `fun` to the data stored in the cross-validated model `obj`. You must pass `fun` as a function handle.

Input Arguments

obj

Object of class `RegressionPartitionedModel` or `RegressionPartitionedEnsemble`. Create `obj` with `fitrtree` or `fitrensemble` along with one of the cross-validation options: `'CrossVal'`, `'KFold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'`. Alternatively, create `obj` from a regression tree or regression ensemble with `crossval`.

fun

A function handle for a cross-validation function. `fun` has the syntax

```
testvals = fun(CMP, Xtrain, Ytrain, Wtrain, Xtest, Ytest, Wtest)
```

- `CMP` is a compact model stored in one element of the `obj.Trained` property.
- `Xtrain` is the training matrix of predictor values.
- `Ytrain` is the training array of response values.
- `Wtrain` are the training weights for observations.
- `Xtest` and `Ytest` are the test data, with associated weights `Wtest`.

- The returned value `testvals` must have the same size across all folds.

Output Arguments

`vals`

The arrays of `testvals` output, concatenated vertically over all folds. For example, if `testvals` from every fold is a numeric vector of length `N`, `kfoldfun` returns a `KFold-by-N` numeric matrix with one row per fold.

Examples

Cross validate a regression tree, and obtain the mean squared error (see `kfoldLoss`):

```
load imports-85
t = fitrtree(X(:,[4 5]),X(:,16),...
    'predictorname',{'length' 'width'},...
    'responname','price');
cv = crossval(t);
L = kfoldLoss(cv)
```

```
L =
    1.5489e+007
```

Examine the result of simple averaging of responses instead of using predictions:

```
f = @(cmp,Xtrain,Ytrain,Wtrain,Xtest,Ytest,Wtest)...
    mean((Ytest-mean(Ytrain)).^2)
mean(kfoldfun(cv,f))
```

```
ans =
    6.3497e+007
```

kfoldLoss

Package: classreg.learning.partition

Classification loss for cross-validated ECOC model

Syntax

```
loss = kfoldLoss(CVMdl)
loss = kfoldLoss(CVMdl,Name,Value)
```

Description

`loss = kfoldLoss(CVMdl)` returns the classification loss obtained by the cross-validated ECOC model (`ClassificationPartitionedECOC`) `CVMdl`. For every fold, `kfoldLoss` computes the classification loss for validation-fold observations using a model trained on training-fold observations. `CVMdl.X` contains both sets of observations.

`loss = kfoldLoss(CVMdl,Name,Value)` returns the classification loss with additional options specified by one or more name-value pair arguments. For example, specify the number of folds, decoding scheme, or verbosity level.

Examples

Determine *k*-Fold Cross-Validation Loss

Load Fisher's iris data set. Specify the predictor data `X`, the response data `Y`, and the order of the classes in `Y`.

```
load fisheriris
X = meas;
Y = categorical(species);
classOrder = unique(Y); % Class order
rng(1); % For reproducibility
```

Train and cross-validate an ECOC model using support vector machine (SVM) binary classifiers. Standardize the predictors using an SVM template, and specify the class order.

```
t = templateSVM('Standardize',1);
CVMdl = fitcecoc(X,Y,'CrossVal','on','Learners',t,'ClassNames',classOrder);
```

CVMdl is a ClassificationPartitionedECOC model. By default, the software implements 10-fold cross-validation. You can specify a different number of folds using the 'KFold' name-value pair argument.

Estimate the average classification error.

```
L = kfoldLoss(CVMdl)
```

```
L = 0.0400
```

The average classification error for the folds is 4%.

Alternatively, you can obtain the per-fold losses by specifying the name-value pair 'Mode','individual' in kfoldLoss.

Display Individual Losses for Each Cross-Validation Fold

The classification loss is a measure of classifier quality. To determine which folds perform poorly, display the losses for each fold.

Load Fisher's iris data set. Specify the predictor data X, the response data Y, and the order of the classes in Y.

```
load fisheriris
X = meas;
Y = categorical(species);
classOrder = unique(Y);
rng(1); % For reproducibility
```

Train an ECOC model using SVM binary classifiers. Use 8-fold cross-validation, standardize the predictors using an SVM template, and specify the class order.

```
t = templateSVM('Standardize',1);
CVMdl = fitcecoc(X,Y,'KFold',8,'Learners',t,'ClassNames',classOrder);
```

Estimate the average classification loss across all folds and the losses for each fold.

```
loss = kfoldLoss(CVMdl)
loss = 0.0333
losses = kfoldLoss(CVMdl, 'Mode', 'individual')
losses = 8×1
    0.0556
    0.0526
    0.1579
         0
         0
         0
         0
         0
```

The third fold misclassifies a much higher percentage of observations than any other fold.

Return the average classification loss for the folds that perform well by specifying the 'Folds' name-value pair argument.

```
newloss = kfoldLoss(CVMdl, 'Folds', [1:2 4:8])
newloss = 0.0153
```

The total classification loss decreases by approximately half its original size.

Consider adjusting parameters of the binary classifiers or the coding design to see if performance for all folds improves.

Determine ECOC Model Quality Using Custom Cross-Validation Loss

In addition to knowing whether a model generally classifies observations correctly, you can determine how well the model classifies an observation into its predicted class. One way to determine this type of model quality is to pass a custom loss function to `kfoldLoss`.

Load Fisher's iris data set. Specify the predictor data *X*, the response data *Y*, and the order of the classes in *Y*.

```
load fisheriris
X = meas;
Y = categorical(species);
classOrder = unique(Y) % Class order

classOrder = 3x1 categorical array
    setosa
    versicolor
    virginica
```

```
rng(1) % For reproducibility
```

Train and cross-validate an ECOC model using SVM binary classifiers. Standardize the predictors using an SVM template, and specify the class order.

```
t = templateSVM('Standardize',1);
CVMdl = fitcecoc(X,Y,'CrossVal','on','Learners',t,'ClassNames',classOrder);
```

CVMdl is a ClassificationPartitionedECOC model. By default, the software implements 10-fold cross-validation. You can specify a different number of folds using the 'KFold' name-value pair argument.

Create a custom function that takes the minimal loss for each observation, then averages the minimal losses for all observations. S corresponds to the NegLoss output of kfoldPredict.

```
lossfun = @(~,S,~,~)mean(min(-S,[],2));
```

Compute the cross-validated custom loss.

```
kfoldLoss(CVMdl,'LossFun',lossfun)
```

```
ans = 0.0101
```

The average minimal binary loss for the validation-fold observations is 0.0101.

Input Arguments

CVMdl — Cross-validated ECOC model

ClassificationPartitionedECOC model

Cross-validated ECOC model, specified as a `ClassificationPartitionedECOC` model. You can create a `ClassificationPartitionedECOC` model in two ways:

- Pass a trained ECOC model (`ClassificationECOC`) to `crossval`.
- Train an ECOC model using `fitcecoc` and specify any one of these cross-validation name-value pair arguments: `'CrossVal'`, `'CVPartition'`, `'Holdout'`, `'Kfold'`, or `'Leaveout'`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `kfoldLoss(CVMdl, 'Folds', [1 3 5])` specifies to use only the first, third, and fifth folds to calculate the classification loss.

BinaryLoss — Binary learner loss function

`'hamming'` | `'linear'` | `'logit'` | `'exponential'` | `'binodeviance'` | `'hinge'` | `'quadratic'` | function handle

Binary learner loss function, specified as the comma-separated pair consisting of `'BinaryLoss'` and a built-in loss function name or function handle.

- This table describes the built-in functions, where y_j is a class label for a particular binary learner (in the set $\{-1, 1, 0\}$), s_j is the score for observation j , and $g(y_j, s_j)$ is the binary loss formula.

Value	Description	Score Domain	$g(y_j, s_j)$
<code>'binodeviance'</code>	Binomial deviance	$(-\infty, \infty)$	$\log[1 + \exp(-2y_j s_j)] / [2\log(2)]$
<code>'exponential'</code>	Exponential	$(-\infty, \infty)$	$\exp(-y_j s_j) / 2$
<code>'hamming'</code>	Hamming	$[0, 1]$ or $(-\infty, \infty)$	$[1 - \text{sign}(y_j s_j)] / 2$
<code>'hinge'</code>	Hinge	$(-\infty, \infty)$	$\max(0, 1 - y_j s_j) / 2$
<code>'linear'</code>	Linear	$(-\infty, \infty)$	$(1 - y_j s_j) / 2$
<code>'logit'</code>	Logistic	$(-\infty, \infty)$	$\log[1 + \exp(-y_j s_j)] / [2\log(2)]$

Value	Description	Score Domain	$g(y_j, s_j)$
'quadratic'	Quadratic	[0,1]	$[1 - y_j(2s_j - 1)]^2/2$

The software normalizes binary losses so that the loss is 0.5 when $y_j = 0$. Also, the software calculates the mean binary loss for each class.

- For a custom binary loss function, for example `customFunction`, specify its function handle `'BinaryLoss',@customFunction`.

`customFunction` has this form:

```
bLoss = customFunction(M,s)
```

where:

- M is the K -by- L coding matrix stored in `Mdl.CodingMatrix`.
- s is the 1-by- L row vector of classification scores.
- `bLoss` is the classification loss. This scalar aggregates the binary losses for every learner in a particular class. For example, you can use the mean binary loss to aggregate the loss over the learners for each class.
- K is the number of classes.
- L is the number of binary learners.

For an example of passing a custom binary loss function, see “Predict Test-Sample Labels of ECOC Model Using Custom Binary Loss Function” on page 32-5219.

The default `BinaryLoss` value depends on the score ranges returned by the binary learners. This table describes some default `BinaryLoss` values based on the given assumptions.

Assumption	Default Value
All binary learners are SVMs or either linear or kernel classification models of SVM learners.	'hinge'
All binary learners are ensembles trained by <code>AdaboostM1</code> or <code>GentleBoost</code> .	'exponential'
All binary learners are ensembles trained by <code>LogitBoost</code> .	'binodeviance'

Assumption	Default Value
All binary learners are linear or kernel classification models of logistic regression learners. Or, you specify to predict class posterior probabilities by setting 'FitPosterior', true in fitcecoc.	'quadratic'

To check the default value, use dot notation to display the BinaryLoss property of the trained model at the command line.

Example: 'BinaryLoss', 'binodeviance'

Data Types: char | string | function_handle

Decoding — Decoding scheme

'lossweighted' (default) | 'lossbased'

Decoding scheme that aggregates the binary losses, specified as the comma-separated pair consisting of 'Decoding' and 'lossweighted' or 'lossbased'. For more information, see “Binary Loss” on page 32-3444.

Example: 'Decoding', 'lossbased'

Folds — Fold indices for prediction

1: CVMdl.KFold (default) | numeric vector of positive integers

Fold indices for prediction, specified as the comma-separated pair consisting of 'Folds' and a numeric vector of positive integers. The elements of Folds must be within the range from 1 to CVMdl.KFold.

The software uses only the folds specified in Folds for prediction.

Example: 'Folds', [1 4 10]

Data Types: single | double

LossFun — Loss function

'classiferror' (default) | function handle

Loss function, specified as the comma-separated pair consisting of 'LossFun' and 'classiferror' or a function handle.

- Specify the built-in function 'classiferror'. In this case, the loss function is the classification error on page 32-3289.

- Or, specify your own function using function handle notation.

Assume that n is the number of observations in the training data (`CVMdl.NumObservations`) and K is the number of classes (`numel(CVMdl.ClassNames)`). Your function needs the signature `lossvalue = lossfun(C,S,W, Cost)`, where:

- The output argument `lossvalue` is a scalar.
- You specify the function name (`lossfun`).
- C is an n -by- K logical matrix with rows indicating the class to which the corresponding observation belongs. The column order corresponds to the class order in `CVMdl.ClassNames`.

Construct C by setting $C(p, q) = 1$ if observation p is in class q , for each row. Set every element of row p to 0.

- S is an n -by- K numeric matrix of negated loss values for the classes. Each row corresponds to an observation. The column order corresponds to the class order in `CVMdl.ClassNames`. The input S resembles the output argument `NegLoss` of `kfoldPredict`.
- W is an n -by-1 numeric vector of observation weights. If you pass W , the software normalizes its elements to sum to 1.
- $Cost$ is a K -by- K numeric matrix of misclassification costs. For example, `Cost = ones(K) - eye(K)` specifies a cost of 0 for correct classification and 1 for misclassification.

Specify your function using `'LossFun', @lossfun`.

Data Types: `char` | `string` | `function_handle`

Mode — Aggregation level for output

`'average'` (default) | `'individual'`

Aggregation level for the output, specified as the comma-separated pair consisting of `'Mode'` and `'average'` or `'individual'`.

This table describes the values.

Value	Description
'average'	The output is a scalar average over all folds.
'individual'	The output is a vector of length k containing one value per fold, where k is the number of folds.

Example: 'Mode', 'individual'

Options — Estimation options

[] (default) | structure array returned by `statset`

Estimation options, specified as the comma-separated pair consisting of 'Options' and a structure array returned by `statset`.

To invoke parallel computing:

- You need a Parallel Computing Toolbox license.
- Specify 'Options', `statset('UseParallel',true)`.

Verbose — Verbosity level

0 (default) | 1

Verbosity level, specified as the comma-separated pair consisting of 'Verbose' and 0 or 1. Verbose controls the number of diagnostic messages that the software displays in the Command Window.

If Verbose is 0, then the software does not display diagnostic messages. Otherwise, the software displays diagnostic messages.

Example: 'Verbose', 1

Data Types: `single` | `double`

Output Arguments

Loss — Classification loss

numeric scalar | numeric column vector

Classification loss, returned as a numeric scalar or numeric column vector.

If Mode is 'average', then loss is the average classification loss over all folds. Otherwise, loss is a k -by-1 numeric column vector containing the classification loss for each fold, where k is the number of folds.

Definitions

Classification Error

The classification error is a binary classification error measure that has the form

$$L = \frac{\sum_{j=1}^n w_j e_j}{\sum_{j=1}^n w_j},$$

where:

- w_j is the weight for observation j . The software renormalizes the weights to sum to 1.
- $e_j = 1$ if the predicted class of observation j differs from its true class, and 0 otherwise.

In other words, the classification error is the proportion of observations misclassified by the classifier.

Binary Loss

A binary loss is a function of the class and classification score that determines how well a binary learner classifies an observation into the class.

Suppose the following:

- m_{kj} is element (k,j) of the coding design matrix M (that is, the code corresponding to class k of binary learner j).
- s_j is the score of binary learner j for an observation.
- g is the binary loss function.
- \hat{k} is the predicted class for the observation.

In loss-based decoding [Escalera et al.] on page 18-228, the class producing the minimum sum of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \operatorname{argmin}_k \sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j).$$

In loss-weighted decoding [Escalera et al.] on page 18-228, the class producing the minimum average of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \operatorname{argmin}_k \frac{\sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j)}{\sum_{j=1}^L |m_{kj}|}.$$

Allwein et al. on page 18-227 suggest that loss-weighted decoding improves classification accuracy by keeping loss values for all classes in the same dynamic range.

This table summarizes the supported loss functions, where y_j is a class label for a particular binary learner (in the set $\{-1, 1, 0\}$), s_j is the score for observation j , and $g(y_j, s_j)$.

Value	Description	Score Domain	$g(y_j, s_j)$
'binodeviance'	Binomial deviance	$(-\infty, \infty)$	$\log[1 + \exp(-2y_j s_j)] / [2\log(2)]$
'exponential'	Exponential	$(-\infty, \infty)$	$\exp(-y_j s_j) / 2$
'hamming'	Hamming	$[0, 1]$ or $(-\infty, \infty)$	$[1 - \operatorname{sign}(y_j s_j)] / 2$
'hinge'	Hinge	$(-\infty, \infty)$	$\max(0, 1 - y_j s_j) / 2$
'linear'	Linear	$(-\infty, \infty)$	$(1 - y_j s_j) / 2$
'logit'	Logistic	$(-\infty, \infty)$	$\log[1 + \exp(-y_j s_j)] / [2\log(2)]$
'quadratic'	Quadratic	$[0, 1]$	$[1 - y_j(2s_j - 1)]^2 / 2$

The software normalizes binary losses such that the loss is 0.5 when $y_j = 0$, and aggregates using the average of the binary learners [Allwein et al.] on page 18-227.

Do not confuse the binary loss with the overall classification loss (specified by the 'LossFun' name-value pair argument of the `loss` and `predict` object functions), which measures how well an ECOC classifier performs as a whole.

Extended Capabilities

Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the 'UseParallel' option to true.

Set the 'UseParallel' field of the options structure to true using `statset` and specify the 'Options' name-value pair argument in the call to this function.

For example: `'Options',statset('UseParallel',true)`

For more information, see the 'Options' name-value pair argument.

For more general information about parallel computing, see "Run MATLAB Functions with Automatic Parallel Support" (Parallel Computing Toolbox).

Introduced in R2014b

kfoldLoss

Classification loss for observations not used for training

Syntax

```
L = kfoldLoss(ens)
L = kfoldLoss(ens,Name,Value)
```

Description

`L = kfoldLoss(ens)` returns loss obtained by cross-validated classification model `ens`. For every fold, this method computes classification loss for in-fold observations using a model trained on out-of-fold observations.

`L = kfoldLoss(ens,Name,Value)` calculates loss with additional options specified by one or more `Name,Value` pair arguments. You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Input Arguments

`ens`

Object of class `ClassificationPartitionedEnsemble`. Create `ens` with `fitcensemble` along with one of the cross-validation options: `'crossval'`, `'kfold'`, `'holdout'`, `'leaveout'`, or `'cvpartition'`. Alternatively, create `ens` from a classification ensemble with `crossval`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

folds

Indices of folds ranging from 1 to `ens.KFold`. Use only these folds for predictions.

Default: `1:ens.KFold`

 lossfun

Loss function, specified as the comma-separated pair consisting of 'LossFun' and a built-in, loss-function name or function handle.

- The following table lists the available loss functions. Specify one using its corresponding character vector or string scalar.

Value	Description
'binodeviance'	Binomial deviance
'classiferror'	Classification error
'exponential'	Exponential
'hinge'	Hinge
'logit'	Logistic
'mincost'	Minimal expected misclassification cost (for classification scores that are posterior probabilities)
'quadratic'	Quadratic

'mincost' is appropriate for classification scores that are posterior probabilities.

- Bagged and subspace ensembles return posterior probabilities by default (`ens.Method` is 'Bag' or 'Subspace').
- If the ensemble method is 'AdaBoostM1', 'AdaBoostM2', GentleBoost, or 'LogitBoost', then, to use posterior probabilities as classification scores, you must specify the double-logit score transform by entering

```
ens.ScoreTransform = 'doublelogit';
```
- For all other ensemble methods, the software does not support posterior probabilities as classification scores.
- Specify your own function using function handle notation.

Suppose that n be the number of observations in X and K be the number of distinct classes (`numel(ens.ClassNames)`, `ens` is the input model). Your function must have this signature

```
lossvalue = lossfun(C,S,W,Cost)
```

where:

- The output argument `lossvalue` is a scalar.
- You choose the function name (`lossfun`).
- C is an n -by- K logical matrix with rows indicating which class the corresponding observation belongs. The column order corresponds to the class order in `ens.ClassNames`.

Construct C by setting $C(p, q) = 1$ if observation p is in class q , for each row. Set all other elements of row p to 0 .

- S is an n -by- K numeric matrix of classification scores. The column order corresponds to the class order in `ens.ClassNames`. S is a matrix of classification scores, similar to the output of `predict`.
- W is an n -by-1 numeric vector of observation weights. If you pass W , the software normalizes them to sum to 1.
- $Cost$ is a K -by- K numeric matrix of misclassification costs. For example, $Cost = \text{ones}(K) - \text{eye}(K)$ specifies a cost of 0 for correct classification, and 1 for misclassification.

Specify your function using `'LossFun', @lossfun`.

For more details on loss functions, see “Classification Loss” on page 32-3297.

Default: `'classiferror'`

mode

A character vector or string scalar for determining the output of `kfoldLoss`:

- `'average'` — L is a scalar, the loss averaged over all folds.
- `'individual'` — L is a vector of length `ens.KFold`, where each entry is the loss for a fold.
- `'cumulative'` — L is a vector in which element J is obtained by using learners $1:J$ from the input list of learners.

Default: 'average'

Output Arguments

L

Loss, by default the fraction of misclassified data. L can be a vector, and can mean different things, depending on the name-value pair settings.

Examples

Estimate Cross-Validated Classification Error

Load the ionosphere data set.

```
load ionosphere
```

Train a classification ensemble of 100 decision trees using AdaBoostM1. Specify tree stumps as the weak learners.

```
t = templateTree('MaxNumSplits',1);  
ens = fitcensemble(X,Y,'Method','AdaBoostM1','Learners',t);
```

Cross-validate the ensemble using 10-fold cross-validation.

```
cvens = crossval(ens);
```

Estimate the cross-validated classification error.

```
L = kfoldLoss(cvens)
```

```
L = 0.0655
```

Definitions

Classification Loss

Classification loss functions measure the predictive inaccuracy of classification models. When you compare the same type of loss among many models, a lower loss indicates a better predictive model.

Consider the following scenario.

- L is the weighted average classification loss.
- n is the sample size.
- For binary classification:
 - y_j is the observed class label. The software codes it as -1 or 1, indicating the negative or positive class, respectively.
 - $f(X_j)$ is the raw classification score for observation (row) j of the predictor data X .
 - $m_j = y_j f(X_j)$ is the classification score for classifying observation j into the class corresponding to y_j . Positive values of m_j indicate correct classification and do not contribute much to the average loss. Negative values of m_j indicate incorrect classification and contribute significantly to the average loss.
- For algorithms that support multiclass classification (that is, $K \geq 3$):
 - y_j^* is a vector of $K - 1$ zeros, with 1 in the position corresponding to the true, observed class y_j . For example, if the true class of the second observation is the third class and $K = 4$, then $y_2^* = [0 \ 0 \ 1 \ 0]$. The order of the classes corresponds to the order in the `ClassNames` property of the input model.
 - $f(X_j)$ is the length K vector of class scores for observation j of the predictor data X . The order of the scores corresponds to the order of the classes in the `ClassNames` property of the input model.
 - $m_j = y_j^* f(X_j)$. Therefore, m_j is the scalar classification score that the model predicts for the true, observed class.
- The weight for observation j is w_j . The software normalizes the observation weights so that they sum to the corresponding prior class probability. The software also normalizes the prior probabilities so they sum to 1. Therefore,

$$\sum_{j=1}^n w_j = 1.$$

Given this scenario, the following table describes the supported loss functions that you can specify by using the 'LossFun' name-value pair argument.

Loss Function	Value of LossFun	Equation
Binomial deviance	'binodeviance'	$L = \sum_{j=1}^n w_j \log\{1 + \exp[-2m_j]\}.$
Exponential loss	'exponential'	$L = \sum_{j=1}^n w_j \exp(-m_j).$
Classification error	'classiferror'	$L = \sum_{j=1}^n w_j I\{\hat{y}_j \neq y_j\}.$ <p>It is the weighted fraction of misclassified observations where \hat{y}_j is the class label corresponding to the class with the maximal posterior probability. $I\{x\}$ is the indicator function.</p>
Hinge loss	'hinge'	$L = \sum_{j=1}^n w_j \max\{0, 1 - m_j\}.$
Logit loss	'logit'	$L = \sum_{j=1}^n w_j \log(1 + \exp(-m_j)).$

Loss Function	Value of LossFun	Equation
Minimal cost	'mincost'	<p>Minimal cost. The software computes the weighted minimal cost using this procedure for observations $j = 1, \dots, n$.</p> <ol style="list-style-type: none"> 1 Estimate the 1-by-K vector of expected classification costs for observation j: $\nu_j = f(X_j)'C.$ <p>$f(X_j)$ is the column vector of class posterior probabilities for binary and multiclass classification. C is the cost matrix that the input model stores in the <code>Cost</code> property.</p> 2 For observation j, predict the class label corresponding to the minimum expected classification cost: $\hat{y}_j = \min_{j=1, \dots, K} (\nu_j).$ 3 Using C, identify the cost incurred (c_j) for making the prediction. <p>The weighted, average, minimum cost loss is</p> $L = \sum_{j=1}^n w_j c_j.$
Quadratic loss	'quadratic'	$L = \sum_{j=1}^n w_j (1 - m_j)^2.$

This figure compares the loss functions (except 'mincost') for one observation over m . Some functions are normalized to pass through [0,1].

kfoldLoss

Package: classreg.learning.partition

Classification loss for cross-validated kernel classification model

Syntax

```
loss = kfoldLoss(CVMdl)
loss = kfoldLoss(CVMdl,Name,Value)
```

Description

`loss = kfoldLoss(CVMdl)` returns the classification loss on page 32-3306 obtained by the cross-validated, binary kernel model (`ClassificationPartitionedKernel`) `CVMdl`. For every fold, `kfoldLoss` computes the classification loss for validation-fold observations using a model trained on training-fold observations.

By default, `kfoldLoss` returns the classification error.

`loss = kfoldLoss(CVMdl,Name,Value)` returns the classification loss with additional options specified by one or more name-value pair arguments. For example, specify the classification loss function, number of folds, or aggregation level.

Examples

Estimate *k*-Fold Cross-Validation Classification Error

Load the `ionosphere` data set. This data set has 34 predictors and 351 binary responses for radar returns, which are labeled either bad ('b') or good ('g').

```
load ionosphere
```

Cross-validate a binary kernel classification model using the data.

```
CVMdl = fitckernel(X,Y,'Crossval','on')
```

```
CVMdl =  
  classreg.learning.partition.ClassificationPartitionedKernel  
    CrossValidatedModel: 'Kernel'  
      ResponseName: 'Y'  
        NumObservations: 351  
          KFold: 10  
            Partition: [1x1 cvpartition]  
              ClassNames: {'b' 'g'}  
                ScoreTransform: 'none'
```

Properties, Methods

`CVMdl` is a `ClassificationPartitionedKernel` model. By default, the software implements 10-fold cross-validation. To specify a different number of folds, use the `'KFold'` name-value pair argument instead of `'Crossval'`.

Estimate the cross-validated classification loss. By default, the software computes the classification error.

```
loss = kfoldLoss(CVMdl)
```

```
loss = 0.0940
```

Alternatively, you can obtain the per-fold classification errors by specifying the name-value pair `'Mode','individual'` in `kfoldLoss`.

Specify Custom Classification Loss

Load the ionosphere data set. This data set has 34 predictors and 351 binary responses for radar returns, which are labeled either bad ('b') or good ('g').

```
load ionosphere
```

Cross-validate a binary kernel classification model using the data.

```
CVMdl = fitckernel(X,Y,'Crossval','on')
```

```
CVMdl =  
  classreg.learning.partition.ClassificationPartitionedKernel  
    CrossValidatedModel: 'Kernel'
```

```

    ResponseName: 'Y'
  NumObservations: 351
    KFold: 10
    Partition: [1x1 cvpartition]
    ClassNames: {'b' 'g'}
  ScoreTransform: 'none'

```

Properties, Methods

`CVMdl` is a `ClassificationPartitionedKernel` model. By default, the software implements 10-fold cross-validation. To specify a different number of folds, use the `'KFold'` name-value pair argument instead of `'Crossval'`.

Create an anonymous function that measures linear loss, that is,

$$L = \frac{\sum_j -w_j y_j f_j}{\sum_j w_j}.$$

w_j is the weight for observation j , y_j is the response j (-1 for the negative class and 1 otherwise), and f_j is the raw classification score of observation j .

```
linearloss = @(C,S,W,Cost)sum(-W.*sum(S.*C,2))/sum(W);
```

Custom loss functions must be written in a particular form. For rules on writing a custom loss function, see the `'LossFun'` name-value pair argument.

Estimate the cross-validated classification loss using the linear loss function.

```
loss = kfoldLoss(CVMdl,'LossFun',linearloss)
```

```
loss = -0.7792
```

Input Arguments

CVMdl — Cross-validated, binary kernel classification model

`ClassificationPartitionedKernel` model object

Cross-validated, binary kernel classification model, specified as a `ClassificationPartitionedKernel` model object. You can create a

ClassificationPartitionedKernel model by using `fitckernel` and specifying any one of the cross-validation name-value pair arguments.

To obtain estimates, `kfoldLoss` applies the same data used to cross-validate the kernel classification model (X and Y).

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `kfoldLoss(CVMdl,'Folds',[1 3 5])` specifies to use only the first, third, and fifth folds to calculate the classification loss.

Folds — Fold indices for prediction

1: `CVMdl.KFold` (default) | numeric vector of positive integers

Fold indices for prediction, specified as the comma-separated pair consisting of `'Folds'` and a numeric vector of positive integers. The elements of `Folds` must be within the range from 1 to `CVMdl.KFold`.

The software uses only the folds specified in `Folds` for prediction.

Example: `'Folds',[1 4 10]`

Data Types: `single` | `double`

LossFun — Loss function

`'classiferror'` (default) | `'binodeviance'` | `'exponential'` | `'hinge'` | `'logit'` | `'mincost'` | `'quadratic'` | function handle

Loss function, specified as the comma-separated pair consisting of `'LossFun'` and a built-in loss function name or a function handle.

- This table lists the available loss functions. Specify one using its corresponding value.

Value	Description
<code>'binodeviance'</code>	Binomial deviance
<code>'classiferror'</code>	Classification error

Value	Description
'exponential'	Exponential
'hinge'	Hinge
'logit'	Logistic
'mincost'	Minimal expected misclassification cost (for classification scores that are posterior probabilities)
'quadratic'	Quadratic

'mincost' is appropriate for classification scores that are posterior probabilities. For kernel classification models, logistic regression learners return posterior probabilities as classification scores by default, but SVM learners do not (see `kfoldPredict`).

- Specify your own function by using function handle notation.

Assume that n is the number of observations in X , and K is the number of distinct classes (`numel(CVMdl.ClassNames)`, where `CVMdl` is the input model). Your function must have this signature:

```
lossvalue = lossfun(C,S,W,Cost)
```

- The output argument `lossvalue` is a scalar.
- You specify the function name (`lossfun`).
- C is an n -by- K logical matrix with rows indicating the class to which the corresponding observation belongs. The column order corresponds to the class order in `CVMdl.ClassNames`.

Construct C by setting $C(p, q) = 1$, if observation p is in class q , for each row. Set all other elements of row p to 0 .

- S is an n -by- K numeric matrix of classification scores. The column order corresponds to the class order in `CVMdl.ClassNames`. S is a matrix of classification scores, similar to the output of `kfoldPredict`.
- W is an n -by-1 numeric vector of observation weights. If you pass W , the software normalizes the weights to sum to 1.
- $Cost$ is a K -by- K numeric matrix of misclassification costs. For example, `Cost = ones(K) - eye(K)` specifies a cost of 0 for correct classification, and 1 for misclassification.

Example: `'LossFun', @lossfun`

Data Types: char | string | function_handle

Mode — Aggregation level for output

'average' (default) | 'individual'

Aggregation level for the output, specified as the comma-separated pair consisting of 'Mode' and 'average' or 'individual'.

This table describes the values.

Value	Description
'average'	The output is a scalar average over all folds.
'individual'	The output is a vector of length k containing one value per fold, where k is the number of folds.

Example: 'Mode', 'individual'

Output Arguments

Loss — Classification loss

numeric scalar | numeric column vector

Classification loss on page 32-3306, returned as a numeric scalar or numeric column vector.

If Mode is 'average', then loss is the average classification loss over all folds. Otherwise, loss is a k -by-1 numeric column vector containing the classification loss for each fold, where k is the number of folds.

Definitions

Classification Loss

Classification loss functions measure the predictive inaccuracy of classification models. When you compare the same type of loss among many models, a lower loss indicates a better predictive model.

Suppose the following:

- L is the weighted average classification loss.
- n is the sample size.
- y_j is the observed class label. The software codes it as -1 or 1, indicating the negative or positive class, respectively.
- $f(X_j)$ is the raw classification score for the transformed observation (row) j of the predictor data X using feature expansion.
- $m_j = y_j f(X_j)$ is the classification score for classifying observation j into the class corresponding to y_j . Positive values of m_j indicate correct classification and do not contribute much to the average loss. Negative values of m_j indicate incorrect classification and contribute to the average loss.
- The weight for observation j is w_j . The software normalizes the observation weights so that they sum to the corresponding prior class probability. The software also normalizes the prior probabilities so that they sum to 1. Therefore,

$$\sum_{j=1}^n w_j = 1.$$

This table describes the supported loss functions that you can specify by using the 'LossFun' name-value pair argument.

Loss Function	Value of LossFun	Equation
Binomial deviance	'binodeviance'	$L = \sum_{j=1}^n w_j \log\{1 + \exp[-2m_j]\}.$
Exponential loss	'exponential'	$L = \sum_{j=1}^n w_j \exp(-m_j).$
Classification error	'classiferror'	$L = \sum_{j=1}^n w_j I\{\hat{y}_j \neq y_j\}.$ <p>The classification error is the weighted fraction of misclassified observations where \hat{y}_j is the class label corresponding to the class with the maximal posterior probability. $I\{x\}$ is the indicator function.</p>

Loss Function	Value of LossFun	Equation
Hinge loss	'hinge'	$L = \sum_{j=1}^n w_j \max\{0, 1 - m_j\}.$
Logit loss	'logit'	$L = \sum_{j=1}^n w_j \log(1 + \exp(-m_j)).$
Minimal cost	'mincost'	<p>The software computes the weighted minimal cost using this procedure for observations $j = 1, \dots, n$.</p> <ol style="list-style-type: none"> Estimate the 1-by-K vector of expected classification costs for observation j: $\nu_j = f(X_j)'C.$ <p>$f(X_j)$ is the column vector of class posterior probabilities. C is the cost matrix that the input model stores in the <code>Cost</code> property.</p> For observation j, predict the class label corresponding to the minimum expected classification cost: $\hat{y}_j = \min_{j=1, \dots, K} (\nu_j).$ Using C, identify the cost incurred (c_j) for making the prediction. <p>The weighted, average, minimum cost loss is</p> $L = \sum_{j=1}^n w_j c_j.$
Quadratic loss	'quadratic'	$L = \sum_{j=1}^n w_j (1 - m_j)^2.$

This figure compares the loss functions (except minimal cost) for one observation over m . Some functions are normalized to pass through $[0,1]$.

kfoldLoss

Package: `classreg.learning.partition`

Classification loss for cross-validated kernel ECOC model

Syntax

```
loss = kfoldLoss(CVMdl)
loss = kfoldLoss(CVMdl,Name,Value)
```

Description

`loss = kfoldLoss(CVMdl)` returns the classification loss obtained by the cross-validated kernel ECOC model (`ClassificationPartitionedKernelECOC`) `CVMdl`. For every fold, `kfoldLoss` computes the classification loss for validation-fold observations using a model trained on training-fold observations. `kfoldLoss` applies the same data used to create `CVMdl` (see `fitcecoc`).

By default, `kfoldLoss` returns the classification error on page 32-3317.

`loss = kfoldLoss(CVMdl,Name,Value)` returns the classification loss with additional options specified by one or more name-value pair arguments. For example, specify the classification loss function, number of folds, decoding scheme, or verbosity level.

Examples

Estimate *k*-Fold Cross-Validation Classification Error

Load Fisher's iris data set. `X` contains flower measurements, and `Y` contains the names of flower species.

```
load fisheriris
X = meas;
Y = species;
```

Cross-validate an ECOC model composed of kernel binary learners.

```
CVMdl = fitcecoc(X,Y,'Learners','kernel','CrossVal','on')

CVMdl =
  classreg.learning.partition.ClassificationPartitionedKernelECOC
    CrossValidatedModel: 'KernelECOC'
      ResponseName: 'Y'
    NumObservations: 150
      KFold: 10
    Partition: [1x1 cvpartition]
    ClassNames: {'setosa' 'versicolor' 'virginica'}
    ScoreTransform: 'none'
```

Properties, Methods

CVMdl is a `ClassificationPartitionedKernelECOC` model. By default, the software implements 10-fold cross-validation. To specify a different number of folds, use the 'KFold' name-value pair argument instead of 'Crossval'.

Estimate the cross-validated classification loss. By default, the software computes the classification error.

```
loss = kfoldLoss(CVMdl)
```

```
loss = 0.0333
```

Alternatively, you can obtain the per-fold classification errors by specifying the name-value pair 'Mode', 'individual' in `kfoldLoss`.

Determine Model Quality Using Custom Cross-Validation Loss

In addition to knowing whether a model generally classifies observations correctly, you can determine how well the model classifies an observation into its predicted class. One way to determine this type of model quality is to pass a custom loss function to `kfoldLoss`.

Load Fisher's iris data set. X contains flower measurements, and Y contains the names of flower species.

```
load fisheriris
X = meas;
Y = species;
```

Cross-validate an ECOC model composed of kernel binary learners.

```
rng(1) % For reproducibility
CVMdl = fitcecoc(X,Y,'Learners','kernel','CrossVal','on')

CVMdl =
  classreg.learning.partition.ClassificationPartitionedKernelECOC
    CrossValidatedModel: 'KernelECOC'
      ResponseName: 'Y'
    NumObservations: 150
      KFold: 10
    Partition: [1x1 cvpartition]
    ClassNames: {'setosa' 'versicolor' 'virginica'}
    ScoreTransform: 'none'
```

Properties, Methods

CVMdl is a `ClassificationPartitionedKernelECOC` model. By default, the software implements 10-fold cross-validation. To specify a different number of folds, use the 'KFold' name-value pair argument instead of 'Crossval'.

Create a custom function that takes the minimal loss for each observation, then averages the minimal losses for all observations. `S` corresponds to the `NegLoss` output of `kfoldPredict`.

```
lossfun = @(~,S,~,~)mean(min(-S,[],2));
```

Compute the cross-validated custom loss.

```
kfoldLoss(CVMdl,'LossFun',lossfun)
```

```
ans = 0.0199
```

The average minimal binary loss for the validation-fold observations is about 0.02.

Input Arguments

CVMdl — Cross-validated kernel ECOC model

ClassificationPartitionedKernelECOC model

Cross-validated kernel ECOC model, specified as a ClassificationPartitionedKernelECOC model. You can create a ClassificationPartitionedKernelECOC model by training an ECOC model using fitcecoc and specifying these name-value pair arguments:

- 'Learners' - Set the value to 'kernel', a template object returned by templateKernel, or a cell array of such template objects.
- One of the arguments 'CrossVal', 'CVPartition', 'Holdout', 'Kfold', or 'Leaveout'.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Example: kfoldLoss(CVMdl, 'Folds', [1 3 5]) specifies to use only the first, third, and fifth folds to calculate the classification loss.

BinaryLoss — Binary learner loss function

'hamming' | 'linear' | 'logit' | 'exponential' | 'binodeviance' | 'hinge' | 'quadratic' | function handle

Binary learner loss function, specified as the comma-separated pair consisting of 'BinaryLoss' and a built-in loss function name or function handle.

- This table contains names and descriptions of the built-in functions, where y_j is a class label for a particular binary learner (in the set $\{-1, 1, 0\}$), s_j is the score for observation j , and $g(y_j, s_j)$ is the binary loss formula.

Value	Description	Score Domain	$g(y_j, s_j)$
'binodeviance'	Binomial deviance	$(-\infty, \infty)$	$\log[1 + \exp(-2y_j s_j)] / [2\log(2)]$

Value	Description	Score Domain	$g(y_j, s_j)$
'exponential'	Exponential	$(-\infty, \infty)$	$\exp(-y_j s_j)/2$
'hamming'	Hamming	$[0, 1]$ or $(-\infty, \infty)$	$[1 - \text{sign}(y_j s_j)]/2$
'hinge'	Hinge	$(-\infty, \infty)$	$\max(0, 1 - y_j s_j)/2$
'linear'	Linear	$(-\infty, \infty)$	$(1 - y_j s_j)/2$
'logit'	Logistic	$(-\infty, \infty)$	$\log[1 + \exp(-y_j s_j)]/[2\log(2)]$
'quadratic'	Quadratic	$[0, 1]$	$[1 - y_j(2s_j - 1)]^2/2$

The software normalizes binary losses such that the loss is 0.5 when $y_j = 0$. Also, the software calculates the mean binary loss for each class.

- For a custom binary loss function, for example, `customFunction`, specify its function handle `'BinaryLoss', @customFunction`.

`customFunction` has this form:

```
bLoss = customFunction(M,s)
```

where:

- M is the K -by- L coding matrix stored in `Mdl.CodingMatrix`.
- s is the 1-by- L row vector of classification scores.
- `bLoss` is the classification loss. This scalar aggregates the binary losses for every learner in a particular class. For example, you can use the mean binary loss to aggregate the loss over the learners for each class.
- K is the number of classes.
- L is the number of binary learners.

By default, if all binary learners are kernel classification models using SVM, then `BinaryLoss` is `'hinge'`. If all binary learners are kernel classification models using logistic regression, then `BinaryLoss` is `'quadratic'`.

Example: `'BinaryLoss', 'binodeviance'`

Data Types: `char` | `string` | `function_handle`

Decoding — Decoding scheme

`'lossweighted'` (default) | `'lossbased'`

Decoding scheme that aggregates the binary losses, specified as the comma-separated pair consisting of 'Decoding' and 'lossweighted' or 'lossbased'. For more information, see “Binary Loss” on page 32-3318.

Example: 'Decoding', 'lossbased'

Folds — Fold indices for prediction

1: CVMdl.KFold (default) | numeric vector of positive integers

Fold indices for prediction, specified as the comma-separated pair consisting of 'Folds' and a numeric vector of positive integers. The elements of Folds must be within the range from 1 to CVMdl.KFold.

The software uses only the folds specified in Folds for prediction.

Example: 'Folds', [1 4 10]

Data Types: single | double

LossFun — Loss function

'classiferror' (default) | function handle

Loss function, specified as the comma-separated pair consisting of 'LossFun' and 'classiferror' or a function handle.

- Specify the built-in function 'classiferror'. In this case, the loss function is the classification error on page 32-3317.
- Or, specify your own function using function handle notation.

Assume that n is the number of observations in the training data (CVMdl.NumObservations) and K is the number of classes (numel(CVMdl.ClassNames)). Your function needs the signature `lossvalue = lossfun(C,S,W,Cost)`, where:

- The output argument `lossvalue` is a scalar.
- You specify the function name (`lossfun`).
- C is an n -by- K logical matrix with rows indicating the class to which the corresponding observation belongs. The column order corresponds to the class order in CVMdl.ClassNames.

Construct C by setting $C(p, q) = 1$ if observation p is in class q , for each row. Set every element of row p to θ .

- S is an n -by- K numeric matrix of negated loss values for the classes. Each row corresponds to an observation. The column order corresponds to the class order in `CVMdl.ClassNames`. The input S resembles the output argument `NegLoss` of `kfoldPredict`.
- W is an n -by-1 numeric vector of observation weights. If you pass W , the software normalizes its elements to sum to 1.
- $Cost$ is a K -by- K numeric matrix of misclassification costs. For example, $Cost = ones(K) - eye(K)$ specifies a cost of 0 for correct classification and 1 for misclassification.

Specify your function using `'LossFun', @lossfun`.

Data Types: `char` | `string` | `function_handle`

Mode — Aggregation level for output

`'average'` (default) | `'individual'`

Aggregation level for the output, specified as the comma-separated pair consisting of `'Mode'` and `'average'` or `'individual'`.

This table describes the values.

Value	Description
<code>'average'</code>	The output is a scalar average over all folds.
<code>'individual'</code>	The output is a vector of length k containing one value per fold, where k is the number of folds.

Example: `'Mode', 'individual'`

Options — Estimation options

`[]` (default) | structure array returned by `statset`

Estimation options, specified as the comma-separated pair consisting of `'Options'` and a structure array returned by `statset`.

To invoke parallel computing:

- You need a Parallel Computing Toolbox license.

- Specify 'Options', `statset('UseParallel',true)`.

Verbose — Verbosity level

0 (default) | 1

Verbosity level, specified as the comma-separated pair consisting of 'Verbose' and 0 or 1. Verbose controls the number of diagnostic messages that the software displays in the Command Window.

If Verbose is 0, then the software does not display diagnostic messages. Otherwise, the software displays diagnostic messages.

Example: 'Verbose',1

Data Types: single | double

Output Arguments

Loss — Classification loss

numeric scalar | numeric column vector

Classification loss, returned as a numeric scalar or numeric column vector.

If Mode is 'average', then loss is the average classification loss over all folds. Otherwise, loss is a k -by-1 numeric column vector containing the classification loss for each fold, where k is the number of folds.

Definitions

Classification Error

The classification error is a binary classification error measure that has the form

$$L = \frac{\sum_{j=1}^n w_j e_j}{\sum_{j=1}^n w_j},$$

where:

- w_j is the weight for observation j . The software renormalizes the weights to sum to 1.
- $e_j = 1$ if the predicted class of observation j differs from its true class, and 0 otherwise.

In other words, the classification error is the proportion of observations misclassified by the classifier.

Binary Loss

A binary loss is a function of the class and classification score that determines how well a binary learner classifies an observation into the class.

Suppose the following:

- m_{kj} is element (k,j) of the coding design matrix M (that is, the code corresponding to class k of binary learner j).
- s_j is the score of binary learner j for an observation.
- g is the binary loss function.
- \hat{k} is the predicted class for the observation.

In loss-based decoding [Escalera et al.] on page 18-228, the class producing the minimum sum of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \operatorname{argmin}_k \sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j).$$

In loss-weighted decoding [Escalera et al.] on page 18-228, the class producing the minimum average of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \operatorname{argmin}_k \frac{\sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j)}{\sum_{j=1}^L |m_{kj}|}.$$

Allwein et al. on page 18-227 suggest that loss-weighted decoding improves classification accuracy by keeping loss values for all classes in the same dynamic range.

This table summarizes the supported loss functions, where y_j is a class label for a particular binary learner (in the set $\{-1,1,0\}$), s_j is the score for observation j , and $g(y_j, s_j)$.

Value	Description	Score Domain	$g(y_j, s_j)$
'binodeviance'	Binomial deviance	$(-\infty, \infty)$	$\log[1 + \exp(-2y_j s_j)] / [2\log(2)]$
'exponential'	Exponential	$(-\infty, \infty)$	$\exp(-y_j s_j) / 2$
'hamming'	Hamming	$[0,1]$ or $(-\infty, \infty)$	$[1 - \text{sign}(y_j s_j)] / 2$
'hinge'	Hinge	$(-\infty, \infty)$	$\max(0, 1 - y_j s_j) / 2$
'linear'	Linear	$(-\infty, \infty)$	$(1 - y_j s_j) / 2$
'logit'	Logistic	$(-\infty, \infty)$	$\log[1 + \exp(-y_j s_j)] / [2\log(2)]$
'quadratic'	Quadratic	$[0,1]$	$[1 - y_j(2s_j - 1)]^2 / 2$

The software normalizes binary losses such that the loss is 0.5 when $y_j = 0$, and aggregates using the average of the binary learners [Allwein et al.] on page 18-227.

Do not confuse the binary loss with the overall classification loss (specified by the 'LossFun' name-value pair argument of the `loss` and `predict` object functions), which measures how well an ECOC classifier performs as a whole.

Introduced in R2018b

kfoldLoss

Classification loss for observations not used in training

Syntax

```
L = kfoldLoss(CVMdl)
L = kfoldLoss(CVMdl,Name,Value)
```

Description

`L = kfoldLoss(CVMdl)` returns the cross-validated classification losses on page 32-3330 obtained by the cross-validated, binary, linear classification model `CVMdl`. That is, for every fold, `kfoldLoss` estimates the classification loss for observations that it holds out when it trains using all other observations.

`L` contains a classification loss for each regularization strength in the linear classification models that compose `CVMdl`.

`L = kfoldLoss(CVMdl,Name,Value)` uses additional options specified by one or more `Name,Value` pair arguments. For example, indicate which folds to use for the loss calculation or specify the classification-loss function.

Input Arguments

CVMdl — Cross-validated, binary, linear classification model

`ClassificationPartitionedLinear` model object

Cross-validated, binary, linear classification model, specified as a `ClassificationPartitionedLinear` model object. You can create a `ClassificationPartitionedLinear` model using `fitclinear` and specifying any one of the cross-validation, name-value pair arguments, for example, `CrossVal`.

To obtain estimates, `kfoldLoss` applies the same data used to cross-validate the linear classification model (`X` and `Y`).

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Folds — Fold indices to use for classification-score prediction

1: `CVMDL.KFold` (default) | numeric vector of positive integers

Fold indices to use for classification-score prediction, specified as the comma-separated pair consisting of `'Folds'` and a numeric vector of positive integers. The elements of `Folds` must range from 1 through `CVMDL.KFold`.

Example: `'Folds',[1 4 10]`

Data Types: `single` | `double`

LossFun — Loss function

`'classiferror'` (default) | `'binodeviance'` | `'exponential'` | `'hinge'` | `'logit'` | `'mincost'` | `'quadratic'` | function handle

Loss function, specified as the comma-separated pair consisting of `'LossFun'` and a built-in, loss-function name or function handle.

- The following table lists the available loss functions. Specify one using its corresponding character vector or string scalar.

Value	Description
<code>'binodeviance'</code>	Binomial deviance
<code>'classiferror'</code>	Classification error
<code>'exponential'</code>	Exponential
<code>'hinge'</code>	Hinge
<code>'logit'</code>	Logistic
<code>'mincost'</code>	Minimal expected misclassification cost (for classification scores that are posterior probabilities)
<code>'quadratic'</code>	Quadratic

'mincost' is appropriate for classification scores that are posterior probabilities. For linear classification models, logistic regression learners return posterior probabilities as classification scores by default, but SVM learners do not (see `predict`).

- Specify your own function using function handle notation.

Let n be the number of observations in X and K be the number of distinct classes (`numel(Mdl.ClassNames)`, Mdl is the input model). Your function must have this signature

```
lossvalue = lossfun(C,S,W,Cost)
```

where:

- The output argument `lossvalue` is a scalar.
- You choose the function name (`lossfun`).
- C is an n -by- K logical matrix with rows indicating which class the corresponding observation belongs. The column order corresponds to the class order in `Mdl.ClassNames`.

Construct C by setting $C(p, q) = 1$ if observation p is in class q , for each row. Set all other elements of row p to 0 .

- S is an n -by- K numeric matrix of classification scores. The column order corresponds to the class order in `Mdl.ClassNames`. S is a matrix of classification scores, similar to the output of `predict`.
- W is an n -by-1 numeric vector of observation weights. If you pass W , the software normalizes them to sum to 1.
- $Cost$ is a K -by- K numeric matrix of misclassification costs. For example, $Cost = \text{ones}(K) - \text{eye}(K)$ specifies a cost of 0 for correct classification, and 1 for misclassification.

Specify your function using `'LossFun', @lossfun`.

Data Types: `char` | `string` | `function_handle`

Mode — Loss aggregation level

`'average'` (default) | `'individual'`

Loss aggregation level, specified as the comma-separated pair consisting of `'Mode'` and `'average'` or `'individual'`.

Value	Description
'average'	Returns losses averaged over all folds
'individual'	Returns losses for each fold

Example: 'Mode', 'individual'

Output Arguments

L — Cross-validated classification losses

numeric scalar | numeric vector | numeric matrix

Cross-validated classification losses on page 32-3330, returned as a numeric scalar, vector, or matrix. The interpretation of L depends on `LossFun`.

Let R be the number of regularizations strengths is the cross-validated models (stored in `numel(CVMdl.Trained{1}.Lambda)`) and F be the number of folds (stored in `CVMdl.KFold`).

- If `Mode` is 'average', then L is a 1-by- R vector. $L(j)$ is the average classification loss over all folds of the cross-validated model that uses regularization strength j .
- Otherwise, L is an F -by- R matrix. $L(i, j)$ is the classification loss for fold i of the cross-validated model that uses regularization strength j .

To estimate L, `kfoldLoss` uses the data that created `CVMdl` (see X and Y).

Examples

Estimate k -Fold Cross-Validation Classification Error

Load the NLP data set.

```
load nlpdata
```

X is a sparse matrix of predictor data, and Y is a categorical vector of class labels. There are more than two classes in the data.

The models should identify whether the word counts in a web page are from the Statistics and Machine Learning Toolbox™ documentation. So, identify the labels that correspond to the Statistics and Machine Learning Toolbox™ documentation web pages.

```
Ystats = Y == 'stats';
```

Cross-validate a binary, linear classification model that can identify whether the word counts in a documentation web page are from the Statistics and Machine Learning Toolbox™ documentation.

```
rng(1); % For reproducibility
CVMdl = fitlinear(X,Ystats,'CrossVal','on');
```

CVMdl is a `ClassificationPartitionedLinear` model. By default, the software implements 10-fold cross validation. You can alter the number of folds using the `'KFold'` name-value pair argument.

Estimate the average of the out-of-fold, classification error rates.

```
ce = kfoldLoss(CVMdl)
ce = 7.6017e-04
```

Alternatively, you can obtain the per-fold classification error rates by specifying the name-value pair `'Mode','individual'` in `kfoldLoss`.

Specify Custom Classification Loss

Load the NLP data set. Preprocess the data as in “Estimate k-Fold Cross-Validation Classification Error” on page 32-3324, and transpose the predictor data.

```
load nlpdata
Ystats = Y == 'stats';
X = X';
```

Cross-validate a binary, linear classification model using 5-fold cross-validation. Optimize the objective function using `SpARSA`. Specify that the predictor observations correspond to columns.

```
rng(1); % For reproducibility
CVMdl = fitlinear(X,Ystats,'Solver','sparsa','KFold',5,...
```

```
'ObservationsIn', 'columns');
CMdl = CVMdl.Trained{1};
```

CVMdl is a `ClassificationPartitionedLinear` model. It contains the property `Trained`, which is a 5-by-1 cell array holding a `ClassificationLinear` models that the software trained using the training set of each fold.

Create an anonymous function that measures linear loss, that is,

$$L = \frac{\sum_j -w_j y_j f_j}{\sum_j w_j}.$$

w_j is the weight for observation j , y_j is response j (-1 for the negative class, and 1 otherwise), and f_j is the raw classification score of observation j . Custom loss functions must be written in a particular form. For rules on writing a custom loss function, see the `LossFun` name-value pair argument. Because the function does not use classification cost, use `~` to have `kfoldLoss` ignore its position.

```
linearloss = @(C,S,W,~)sum(-W.*sum(S.*C,2))/sum(W);
```

Estimate the average cross-validated classification loss using the linear loss function. Also, obtain the loss for each fold.

```
ce = kfoldLoss(CVMdl, 'LossFun', linearloss)
```

```
ce = -8.0982
```

```
ceFold = kfoldLoss(CVMdl, 'LossFun', linearloss, 'Mode', 'individual')
```

```
ceFold = 5×1
```

```
-8.3165
-8.7633
-7.4342
-8.0423
-7.9347
```

Find Good Lasso Penalty Using k -fold Classification Loss

To determine a good lasso-penalty strength for a linear classification model that uses a logistic regression learner, compare test-sample classification error rates.

Load the NLP data set. Preprocess the data as in “Specify Custom Classification Loss” on page 32-3325.

```
load nlpdata
Ystats = Y == 'stats';
X = X';
```

Create a set of 11 logarithmically-spaced regularization strengths from 10^{-6} through $10^{0.5}$.

```
Lambda = logspace(-6, -0.5, 11);
```

Cross-validate binary, linear classification models using 5-fold cross-validation, and that use each of the regularization strengths. Optimize the objective function using SpaRSA. Lower the tolerance on the gradient of the objective function to $1e-8$.

```
rng(10); % For reproducibility
CVMdl = fitlinear(X, Ystats, 'ObservationsIn', 'columns', ...
    'KFold', 5, 'Learner', 'logistic', 'Solver', 'sparsa', ...
    'Regularization', 'lasso', 'Lambda', Lambda, 'GradientTolerance', 1e-8)
```

```
CVMdl =
    classreg.learning.partition.ClassificationPartitionedLinear
        CrossValidatedModel: 'Linear'
           ResponseName: 'Y'
      NumObservations: 31572
                KFold: 5
           Partition: [1x1 cvpartition]
           ClassNames: [0 1]
       ScoreTransform: 'none'
```

Properties, Methods

Extract a trained linear classification model.

```
Mdl1 = CVMdl.Trained{1}
```

```
Mdl1 =
    ClassificationLinear
           ResponseName: 'Y'
           ClassNames: [0 1]
       ScoreTransform: 'logit'
```

```
Beta: [34023×11 double]
Bias: [-13.2904 -13.2904 -13.2904 -13.2904 -9.9357 -7.0782 -5.4335 -4.54
Lambda: [1.0000e-06 3.5481e-06 1.2589e-05 4.4668e-05 1.5849e-04 5.6234e-04
Learner: 'logistic'
```

Properties, Methods

`Mdl1` is a `ClassificationLinear` model object. Because `Lambda` is a sequence of regularization strengths, you can think of `Mdl` as 11 models, one for each regularization strength in `Lambda`.

Estimate the cross-validated classification error.

```
ce = kfoldLoss(CVMdl);
```

Because there are 11 regularization strengths, `ce` is a 1-by-11 vector of classification error rates.

Higher values of `Lambda` lead to predictor variable sparsity, which is a good quality of a classifier. For each regularization strength, train a linear classification model using the entire data set and the same options as when you cross-validated the models. Determine the number of nonzero coefficients per model.

```
Mdl = fitlinear(X,Ystats,'ObservationsIn','columns',...
    'Learner','logistic','Solver','sparsa','Regularization','lasso',...
    'Lambda',Lambda,'GradientTolerance',1e-8);
numNZCoeff = sum(Mdl.Beta~=0);
```

In the same figure, plot the cross-validated, classification error rates and frequency of nonzero coefficients for each regularization strength. Plot all variables on the log scale.

```
figure;
[h,hL1,hL2] = plotyy(log10(Lambda),log10(ce),...
    log10(Lambda),log10(numNZCoeff));
hL1.Marker = 'o';
hL2.Marker = 'o';
ylabel(h(1),'log_{10} classification error')
ylabel(h(2),'log_{10} nonzero-coefficient frequency')
xlabel('log_{10} Lambda')
title('Test-Sample Statistics')
hold off
```

Choose the indexes of the regularization strength that balances predictor variable sparsity and low classification error. In this case, a value between 10^{-4} to 10^{-1} should suffice.

```
idxFinal = 7;
```

Select the model from `Mdl` with the chosen regularization strength.

```
MdlFinal = selectModels(Mdl,idxFinal);
```

`MdlFinal` is a `ClassificationLinear` model containing one regularization strength. To estimate labels for new observations, pass `MdlFinal` and the new data to `predict`.

Definitions

Classification Loss

Classification loss functions measure the predictive inaccuracy of classification models. When you compare the same type of loss among many models, a lower loss indicates a better predictive model.

Consider the following scenario.

- L is the weighted average classification loss.
- n is the sample size.
- For binary classification:
 - y_j is the observed class label. The software codes it as -1 or 1 , indicating the negative or positive class, respectively.
 - $f(X_j)$ is the raw classification score for observation (row) j of the predictor data X .
 - $m_j = y_j f(X_j)$ is the classification score for classifying observation j into the class corresponding to y_j . Positive values of m_j indicate correct classification and do not contribute much to the average loss. Negative values of m_j indicate incorrect classification and contribute significantly to the average loss.
- For algorithms that support multiclass classification (that is, $K \geq 3$):
 - y_j^* is a vector of $K - 1$ zeros, with 1 in the position corresponding to the true, observed class y_j . For example, if the true class of the second observation is the third class and $K = 4$, then $y_2^* = [0 \ 0 \ 1 \ 0]$. The order of the classes corresponds to the order in the `ClassNames` property of the input model.
 - $f(X_j)$ is the length K vector of class scores for observation j of the predictor data X . The order of the scores corresponds to the order of the classes in the `ClassNames` property of the input model.
 - $m_j = y_j^* f(X_j)$. Therefore, m_j is the scalar classification score that the model predicts for the true, observed class.
- The weight for observation j is w_j . The software normalizes the observation weights so that they sum to the corresponding prior class probability. The software also normalizes the prior probabilities so they sum to 1 . Therefore,

$$\sum_{j=1}^n w_j = 1.$$

Given this scenario, the following table describes the supported loss functions that you can specify by using the 'LossFun' name-value pair argument.

Loss Function	Value of LossFun	Equation
Binomial deviance	'binodeviance'	$L = \sum_{j=1}^n w_j \log\{1 + \exp[-2m_j]\}.$
Exponential loss	'exponential'	$L = \sum_{j=1}^n w_j \exp(-m_j).$
Classification error	'classiferror'	$L = \sum_{j=1}^n w_j I\{\hat{y}_j \neq y_j\}.$ <p>It is the weighted fraction of misclassified observations where \hat{y}_j is the class label corresponding to the class with the maximal posterior probability. $I\{x\}$ is the indicator function.</p>
Hinge loss	'hinge'	$L = \sum_{j=1}^n w_j \max\{0, 1 - m_j\}.$
Logit loss	'logit'	$L = \sum_{j=1}^n w_j \log(1 + \exp(-m_j)).$

Loss Function	Value of LossFun	Equation
Minimal cost	'mincost'	<p>Minimal cost. The software computes the weighted minimal cost using this procedure for observations $j = 1, \dots, n$.</p> <ol style="list-style-type: none"> 1 Estimate the 1-by-K vector of expected classification costs for observation j: $v_j = f(X_j)'C.$ <p>$f(X_j)$ is the column vector of class posterior probabilities for binary and multiclass classification. C is the cost matrix that the input model stores in the <code>Cost</code> property.</p> 2 For observation j, predict the class label corresponding to the minimum expected classification cost: $\hat{y}_j = \min_{j = 1, \dots, K} (v_j).$ 3 Using C, identify the cost incurred (c_j) for making the prediction. <p>The weighted, average, minimum cost loss is</p> $L = \sum_{j=1}^n w_j c_j.$
Quadratic loss	'quadratic'	$L = \sum_{j=1}^n w_j (1 - m_j)^2.$

This figure compares the loss functions (except 'mincost') for one observation over m . Some functions are normalized to pass through [0,1].

Introduced in R2016a

kfoldLoss

Classification loss for observations not used in training

Syntax

```
L = kfoldLoss(CVMdl)
L = kfoldLoss(CVMdl,Name,Value)
```

Description

`L = kfoldLoss(CVMdl)` returns the cross-validated classification error on page 32-3346 rates estimated by the cross-validated, error-correcting output codes (ECOC) model composed of linear classification models `CVMdl`. That is, for every fold, `kfoldLoss` estimates the classification error rate for observations that it holds out when it trains using all other observations. `kfoldLoss` applies the same data used create `CVMdl` (see `fitcecoc`).

`L` contains a classification loss for each regularization strength in the linear classification models that compose `CVMdl`.

`L = kfoldLoss(CVMdl,Name,Value)` uses additional options specified by one or more `Name,Value` pair arguments. For example, specify a decoding scheme, which folds to use for the loss calculation, or verbosity level.

Input Arguments

CVMdl — Cross-validated, ECOC model composed of linear classification models

`ClassificationPartitionedLinearECOC` model object

Cross-validated, ECOC model composed of linear classification models, specified as a `ClassificationPartitionedLinearECOC` model object. You can create a `ClassificationPartitionedLinearECOC` model using `fitcecoc` and by:

- 1 Specifying any one of the cross-validation, name-value pair arguments, for example, `CrossVal`

- Setting the name-value pair argument `Learners` to `'linear'` or a linear classification model template returned by `templateLinear`

To obtain estimates, `kfoldLoss` applies the same data used to cross-validate the ECOC model (X and Y).

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

BinaryLoss — Binary learner loss function

`'hamming'` | `'linear'` | `'logit'` | `'exponential'` | `'binodeviance'` | `'hinge'` | `'quadratic'` | function handle

Binary learner loss function, specified as the comma-separated pair consisting of `'BinaryLoss'` and a built-in, loss-function name or function handle.

- This table contains names and descriptions of the built-in functions, where y_j is a class label for a particular binary learner (in the set $\{-1, 1, 0\}$), s_j is the score for observation j , and $g(y_j, s_j)$ is the binary loss formula.

Value	Description	Score Domain	$g(y_j, s_j)$
<code>'binodeviance'</code>	Binomial deviance	$(-\infty, \infty)$	$\log[1 + \exp(-2y_j s_j)] / [2\log(2)]$
<code>'exponential'</code>	Exponential	$(-\infty, \infty)$	$\exp(-y_j s_j) / 2$
<code>'hamming'</code>	Hamming	$[0, 1]$ or $(-\infty, \infty)$	$[1 - \text{sign}(y_j s_j)] / 2$
<code>'hinge'</code>	Hinge	$(-\infty, \infty)$	$\max(0, 1 - y_j s_j) / 2$
<code>'linear'</code>	Linear	$(-\infty, \infty)$	$(1 - y_j s_j) / 2$
<code>'logit'</code>	Logistic	$(-\infty, \infty)$	$\log[1 + \exp(-y_j s_j)] / [2\log(2)]$
<code>'quadratic'</code>	Quadratic	$[0, 1]$	$[1 - y_j(2s_j - 1)]^2 / 2$

The software normalizes the binary losses such that the loss is 0.5 when $y_j = 0$. Also, the software calculates the mean binary loss for each class.

- For a custom binary loss function, e.g., `customFunction`, specify its function handle `'BinaryLoss',@customFunction`.

`customFunction` should have this form

```
bLoss = customFunction(M,s)
```

where:

- `M` is the K -by- L coding matrix stored in `Mdl.CodingMatrix`.
- `s` is the 1-by- L row vector of classification scores.
- `bLoss` is the classification loss. This scalar aggregates the binary losses for every learner in a particular class. For example, you can use the mean binary loss to aggregate the loss over the learners for each class.
- K is the number of classes.
- L is the number of binary learners.

For an example of passing a custom binary loss function, see “Predict Test-Sample Labels of ECOC Model Using Custom Binary Loss Function” on page 32-5219.

By default, if all binary learners are linear classification models using:

- SVM, then `BinaryLoss` is `'hinge'`
- Logistic regression, then `BinaryLoss` is `'quadratic'`

Example: `'BinaryLoss','binodeviance'`

Data Types: `char` | `string` | `function_handle`

Decoding — Decoding scheme

`'lossweighted'` (default) | `'lossbased'`

Decoding scheme that aggregates the binary losses, specified as the comma-separated pair consisting of `'Decoding'` and `'lossweighted'` or `'lossbased'`. For more information, see “Binary Loss” on page 32-3444.

Example: `'Decoding','lossbased'`

Folds — Fold indices to use for classification-score prediction

1: `CVMdl.KFold` (default) | numeric vector of positive integers

Fold indices to use for classification-score prediction, specified as the comma-separated pair consisting of 'Folds' and a numeric vector of positive integers. The elements of Folds must range from 1 through `CVMdl.KFold`.

Example: 'Folds',[1 4 10]

Data Types: single | double

LossFun — Loss function

'classiferror' (default) | function handle

Loss function, specified as the comma-separated pair consisting of 'LossFun' and a function handle or 'classiferror'.

You can:

- Specify the built-in function 'classiferror', then the loss function is the classification error on page 32-3346.
- Specify your own function using function handle notation.

For what follows, n is the number of observations in the training data (`CVMdl.NumObservations`) and K is the number of classes (`numel(CVMdl.ClassNames)`). Your function needs the signature `lossvalue = lossfun(C,S,W,Cost)`, where:

- The output argument `lossvalue` is a scalar.
- You choose the function name (*lossfun*).
- C is an n -by- K logical matrix with rows indicating which class the corresponding observation belongs. The column order corresponds to the class order in `CVMdl.ClassNames`.

Construct C by setting $C(p,q) = 1$ if observation p is in class q , for each row. Set every element of row p to θ .

- S is an n -by- K numeric matrix of negated loss values for classes. Each row corresponds to an observation. The column order corresponds to the class order in `CVMdl.ClassNames`. S resembles the output argument `NegLoss` of `kfoldPredict`.
- W is an n -by-1 numeric vector of observation weights. If you pass W , the software normalizes its elements to sum to 1.

- `Cost` is a K-by-K numeric matrix of misclassification costs. For example, `Cost = ones(K) - eye(K)` specifies a cost of 0 for correct classification, and 1 for misclassification.

Specify your function using `'LossFun', @lossfun`.

Data Types: `function_handle` | `char` | `string`

Mode — Loss aggregation level

`'average'` (default) | `'individual'`

Loss aggregation level, specified as the comma-separated pair consisting of `'Mode'` and `'average'` or `'individual'`.

Value	Description
<code>'average'</code>	Returns losses averaged over all folds
<code>'individual'</code>	Returns losses for each fold

Example: `'Mode', 'individual'`

Options — Estimation options

`[]` (default) | structure array returned by `statset`

Estimation options, specified as the comma-separated pair consisting of `'Options'` and a structure array returned by `statset`.

To invoke parallel computing:

- You need a Parallel Computing Toolbox license.
- Specify `'Options', statset('UseParallel', true)`.

Verbose — Verbosity level

`0` (default) | `1`

Verbosity level, specified as the comma-separated pair consisting of `'Verbose'` and `0` or `1`. `Verbose` controls the number of diagnostic messages that the software displays in the Command Window.

If `Verbose` is `0`, then the software does not display diagnostic messages. Otherwise, the software displays diagnostic messages.

Example: `'Verbose', 1`

Data Types: `single` | `double`

Output Arguments

L — Cross-validated classification losses

numeric scalar | numeric vector | numeric matrix

Cross-validated classification losses on page 32-3346, returned as a numeric scalar, vector, or matrix. The interpretation of **L** depends on `LossFun`.

Let R be the number of regularizations strengths is the cross-validated models (`CVMdl.Trained{1}.BinaryLearners{1}.Lambda`) and F be the number of folds (stored in `CVMdl.KFold`).

- If `Mode` is `'average'`, then **L** is a 1-by- R vector. $L(j)$ is the average classification loss over all folds of the cross-validated model that uses regularization strength j .
- Otherwise, **L** is a F -by- R matrix. $L(i, j)$ is the classification loss for fold i of the cross-validated model that uses regularization strength j .

Examples

Estimate k -Fold Cross-Validation Classification Error

Load the NLP data set.

```
load nlpdata
```

X is a sparse matrix of predictor data, and Y is a categorical vector of class labels.

Cross-validate an ECOC model of linear classification models.

```
rng(1); % For reproducibility
CVMdl = fitcecoc(X,Y,'Learner','linear','CrossVal','on');
```

`CVMdl` is a `ClassificationPartitionedLinearECOC` model. By default, the software implements 10-fold cross validation.

Estimate the average of the out-of-fold classification error rates.

```
ce = kfoldLoss(CVMdl)
ce = 0.0958
```

Alternatively, you can obtain the per-fold classification error rates by specifying the name-value pair `'Mode','individual'` in `kfoldLoss`.

Specify Custom Classification Loss

Load the NLP data set. Transpose the predictor data.

```
load nlpdata
X = X';
```

For simplicity, use the label `'others'` for all observations in `Y` that are not `'simulink'`, `'dsp'`, or `'comm'`.

```
Y(~(ismember(Y,{'simulink','dsp','comm'}))) = 'others';
```

Create a linear classification model template that specifies optimizing the objective function using `SpaRSA`.

```
t = templateLinear('Solver','sparsa');
```

Cross-validate an ECOC model of linear classification models using 5-fold cross-validation. Optimize the objective function using `SpaRSA`. Specify that the predictor observations correspond to columns.

```
rng(1); % For reproducibility
CVMdl = fitcecoc(X,Y,'Learners',t,'KFold',5,'ObservationsIn','columns');
CMdl1 = CVMdl.Trained{1}
```

```
CMdl1 =
  classreg.learning.classif.CompactClassificationECOC
    ResponseName: 'Y'
    ClassNames: [comm dsp simulink others]
    ScoreTransform: 'none'
    BinaryLearners: {6x1 cell}
    CodingMatrix: [4x6 double]
```

Properties, Methods

CVMdl is a `ClassificationPartitionedLinearECOC` model. It contains the property `Trained`, which is a 5-by-1 cell array holding a `CompactClassificationECOC` models that the software trained using the training set of each fold.

Create a function that takes the minimal loss for each observation, and then averages the minimal losses across all observations. Because the function does not use the class-identifier matrix (C), observation weights (W), and classification cost (Cost), use `~` to have `kfoldLoss` ignore its their positions.

```
lossfun = @(~,S,~,~)mean(min(-S,[],2));
```

Estimate the average cross-validated classification loss using the minimal loss per observation function. Also, obtain the loss for each fold.

```
ce = kfoldLoss(CVMdl, 'LossFun', lossfun)
```

```
ce = 0.0243
```

```
ceFold = kfoldLoss(CVMdl, 'LossFun', lossfun, 'Mode', 'individual')
```

```
ceFold = 5×1
```

```
0.0244
0.0255
0.0248
0.0240
0.0226
```

Find Good Lasso Penalty Using Cross-Validation

To determine a good lasso-penalty strength for an ECOC model composed of linear classification models that use logistic regression learners, implement 5-fold cross-validation.

Load the NLP data set.

```
load nlpdata
```

X is a sparse matrix of predictor data, and Y is a categorical vector of class labels.

For simplicity, use the label 'others' for all observations in Y that are not 'simulink', 'dsp', or 'comm'.

```
Y(~(ismember(Y,{'simulink','dsp','comm'}))) = 'others';
```

Create a set of 11 logarithmically-spaced regularization strengths from 10^{-7} through 10^{-2} .

```
Lambda = logspace(-7,-2,11);
```

Create a linear classification model template that specifies to use logistic regression learners, use lasso penalties with strengths in Lambda, train using SpaRSA, and lower the tolerance on the gradient of the objective function to $1e-8$.

```
t = templateLinear('Learner','logistic','Solver','sparsa',...  
    'Regularization','lasso','Lambda',Lambda,'GradientTolerance',1e-8);
```

Cross-validate the models. To increase execution speed, transpose the predictor data and specify that the observations are in columns.

```
X = X';  
rng(10); % For reproducibility  
CVMdl = fitcecoc(X,Y,'Learners',t,'ObservationsIn','columns','KFold',5);
```

CVMdl is a ClassificationPartitionedLinearECOC model.

Dissect CVMdl, and each model within it.

```
numECOCModels = numel(CVMdl.Trained)
```

```
numECOCModels = 5
```

```
ECOCmdl1 = CVMdl.Trained{1}
```

```
ECOCmdl1 =  
    classreg.learning.classif.CompactClassificationECOC  
        ResponseName: 'Y'  
        ClassNames: [comm    dsp    simulink    others]  
        ScoreTransform: 'none'  
        BinaryLearners: {6x1 cell}  
        CodingMatrix: [4x6 double]
```

Properties, Methods

```

numCLModels = numel(ECOCmdl.BinaryLearners)

numCLModels = 6

CLMdl = ECOCmdl.BinaryLearners{1}

CLMdl =
  ClassificationLinear
    ResponseName: 'Y'
    ClassNames: [-1 1]
    ScoreTransform: 'logit'
        Beta: [34023x11 double]
        Bias: [-0.3125 -0.3596 -0.3596 -0.3596 -0.3596 -0.3596 -0.1593 -0.0737 -0.0737 -0.0737 -0.0737]
        Lambda: [1.0000e-07 3.1623e-07 1.0000e-06 3.1623e-06 1.0000e-05 3.1623e-05 1.0000e-04 3.1623e-04 1.0000e-03 3.1623e-03 1.0000e-02]
        Learner: 'logistic'

```

Properties, Methods

Because `fitcecoc` implements 5-fold cross-validation, `CVMDL` contains a 5-by-1 cell array of `CompactClassificationECOC` models that the software trains on each fold. The `BinaryLearners` property of each `CompactClassificationECOC` model contains the `ClassificationLinear` models. The number of `ClassificationLinear` models within each compact ECOC model depends on the number of distinct labels and coding design. Because `Lambda` is a sequence of regularization strengths, you can think of `CLMdl` as 11 models, one for each regularization strength in `Lambda`.

Determine how well the models generalize by plotting the averages of the 5-fold classification error for each regularization strength. Identify the regularization strength that minimizes the generalization error over the grid.

```

ce = kfoldLoss(CVMDL);
figure;
plot(log10(Lambda), log10(ce))
[~, minCEIdx] = min(ce);
minLambda = Lambda(minCEIdx);
hold on
plot(log10(minLambda), log10(ce(minCEIdx)), 'ro');
ylabel('log_{10} 5-fold classification error')
xlabel('log_{10} Lambda')
legend('MSE', 'Min classification error')
hold off

```

Train an ECOC model composed of linear classification model using the entire data set, and specify the minimal regularization strength.

```
t = templateLinear('Learner','logistic','Solver','sparsa',...
    'Regularization','lasso','Lambda',minLambda,'GradientTolerance',1e-8);
MdlFinal = fitcecoc(X,Y,'Learners',t,'ObservationsIn','columns');
```

To estimate labels for new observations, pass MdlFinal and the new data to predict.

Definitions

Binary Loss

A binary loss is a function of the class and classification score that determines how well a binary learner classifies an observation into the class.

Suppose the following:

- m_{kj} is element (k,j) of the coding design matrix M (that is, the code corresponding to class k of binary learner j).
- s_j is the score of binary learner j for an observation.
- g is the binary loss function.
- \hat{k} is the predicted class for the observation.

In loss-based decoding [Escalera et al.] on page 18-228, the class producing the minimum sum of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \operatorname{argmin}_k \sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j).$$

In loss-weighted decoding [Escalera et al.] on page 18-228, the class producing the minimum average of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \operatorname{argmin}_k \frac{\sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j)}{\sum_{j=1}^L |m_{kj}|}.$$

Allwein et al. on page 18-227 suggest that loss-weighted decoding improves classification accuracy by keeping loss values for all classes in the same dynamic range.

This table summarizes the supported loss functions, where y_j is a class label for a particular binary learner (in the set $\{-1,1,0\}$), s_j is the score for observation j , and $g(y_j, s_j)$.

Value	Description	Score Domain	$g(y_j, s_j)$
'binodeviance'	Binomial deviance	$(-\infty, \infty)$	$\log[1 + \exp(-2y_j s_j)] / [2\log(2)]$
'exponential'	Exponential	$(-\infty, \infty)$	$\exp(-y_j s_j) / 2$
'hamming'	Hamming	$[0, 1]$ or $(-\infty, \infty)$	$[1 - \text{sign}(y_j s_j)] / 2$
'hinge'	Hinge	$(-\infty, \infty)$	$\max(0, 1 - y_j s_j) / 2$
'linear'	Linear	$(-\infty, \infty)$	$(1 - y_j s_j) / 2$
'logit'	Logistic	$(-\infty, \infty)$	$\log[1 + \exp(-y_j s_j)] / [2\log(2)]$
'quadratic'	Quadratic	$[0, 1]$	$[1 - y_j(2s_j - 1)]^2 / 2$

The software normalizes binary losses such that the loss is 0.5 when $y_j = 0$, and aggregates using the average of the binary learners [Allwein et al.] on page 18-227.

Do not confuse the binary loss with the overall classification loss (specified by the 'LossFun' name-value pair argument of the `loss` and `predict` object functions), which measures how well an ECOC classifier performs as a whole.

Classification Error

The classification error is a binary classification error measure that has the form

$$L = \frac{\sum_{j=1}^n w_j e_j}{\sum_{j=1}^n w_j},$$

where:

- w_j is the weight for observation j . The software renormalizes the weights to sum to 1.
- $e_j = 1$ if the predicted class of observation j differs from its true class, and 0 otherwise.

In other words, the classification error is the proportion of observations misclassified by the classifier.

Extended Capabilities

Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the 'UseParallel' option to true.

Set the 'UseParallel' field of the options structure to true using `statset` and specify the 'Options' name-value pair argument in the call to this function.

For example: `'Options',statset('UseParallel',true)`

For more information, see the 'Options' name-value pair argument.

For more general information about parallel computing, see "Run MATLAB Functions with Automatic Parallel Support" (Parallel Computing Toolbox).

kfoldLoss

Classification loss for observations not used for training

Syntax

```
L = kfoldLoss(obj)
L = kfoldLoss(obj,Name,Value)
```

Description

`L = kfoldLoss(obj)` returns loss obtained by cross-validated classification model `obj`. For every fold, this method computes classification loss for in-fold observations using a model trained on out-of-fold observations.

`L = kfoldLoss(obj,Name,Value)` calculates loss with additional options specified by one or more `Name,Value` pair arguments. You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Input Arguments

obj

Object of class `ClassificationPartitionedModel`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

foldds

Indices of folds ranging from 1 to `obj.KFold`. Use only these folds for predictions.

Default: 1:obj.KFold

lossfun

Loss function, specified as the comma-separated pair consisting of 'LossFun' and a built-in, loss-function name or function handle.

- The following table lists the available loss functions. Specify one using its corresponding character vector or string scalar.

Value	Description
'binodeviance'	Binomial deviance
'classiferror'	Classification error
'exponential'	Exponential
'hinge'	Hinge
'logit'	Logistic
'mincost'	Minimal expected misclassification cost (for classification scores that are posterior probabilities)
'quadratic'	Quadratic

'mincost' is appropriate for classification scores that are posterior probabilities. All models use posterior probabilities as classification scores by default except SVM models. You can specify to use posterior probabilities as classification scores for SVM models by setting 'FitPosterior', true when you cross-validate the model using `fitcsvm`.

- Specify your own function using function handle notation.

Suppose that n be the number of observations in X and K be the number of distinct classes (`numel(obj.ClassNames)`, `obj` is the input model). Your function must have this signature

```
lossvalue = lossfun(C,S,W,Cost)
```

where:

- The output argument `lossvalue` is a scalar.
- You choose the function name (*lossfun*).

- C is an n -by- K logical matrix with rows indicating which class the corresponding observation belongs. The column order corresponds to the class order in `obj.ClassNames`.

Construct C by setting $C(p, q) = 1$ if observation p is in class q , for each row. Set all other elements of row p to 0 .

- S is an n -by- K numeric matrix of classification scores. The column order corresponds to the class order in `obj.ClassNames`. S is a matrix of classification scores, similar to the output of `predict`.
- W is an n -by-1 numeric vector of observation weights. If you pass W , the software normalizes them to sum to 1.
- $Cost$ is a K -by- K numeric matrix of misclassification costs. For example, $Cost = ones(K) - eye(K)$ specifies a cost of 0 for correct classification, and 1 for misclassification.

Specify your function using `'LossFun', @lossfun`.

For more details on loss functions, see “Classification Loss” on page 32-3352.

Default: `'classiferror'`

mode

A character vector or string scalar for determining the output of `kfoldLoss`:

- `'average'` — L is a scalar, the loss averaged over all folds.
- `'individual'` — L is a vector of length `obj.KFold`, where each entry is the loss for a fold.

Default: `'average'`

Output Arguments

L

Loss, by default the fraction of misclassified data. L can be a vector, and can mean different things, depending on the name-value pair settings.

Examples

Estimate Cross-Validated Classification Error

Load the ionosphere data set.

```
load ionosphere
```

Grow a classification tree.

```
tree = fitctree(X,Y);
```

Cross-validate the classification tree using 10-fold cross-validation.

```
cvtree = crossval(tree);
```

Estimate the cross-validated classification error.

```
L = kfoldLoss(cvtree)
```

```
L = 0.1111
```

Definitions

Classification Loss

Classification loss functions measure the predictive inaccuracy of classification models. When you compare the same type of loss among many models, a lower loss indicates a better predictive model.

Consider the following scenario.

- L is the weighted average classification loss.
- n is the sample size.
- For binary classification:
 - y_j is the observed class label. The software codes it as -1 or 1 , indicating the negative or positive class, respectively.

- $f(X_j)$ is the raw classification score for observation (row) j of the predictor data X .
- $m_j = y_j f(X_j)$ is the classification score for classifying observation j into the class corresponding to y_j . Positive values of m_j indicate correct classification and do not contribute much to the average loss. Negative values of m_j indicate incorrect classification and contribute significantly to the average loss.
- For algorithms that support multiclass classification (that is, $K \geq 3$):
 - y_j^* is a vector of $K - 1$ zeros, with 1 in the position corresponding to the true, observed class y_j . For example, if the true class of the second observation is the third class and $K = 4$, then $y_2^* = [0 \ 0 \ 1 \ 0]$. The order of the classes corresponds to the order in the `ClassNames` property of the input model.
 - $f(X_j)$ is the length K vector of class scores for observation j of the predictor data X . The order of the scores corresponds to the order of the classes in the `ClassNames` property of the input model.
 - $m_j = y_j^* f(X_j)$. Therefore, m_j is the scalar classification score that the model predicts for the true, observed class.
- The weight for observation j is w_j . The software normalizes the observation weights so that they sum to the corresponding prior class probability. The software also normalizes the prior probabilities so they sum to 1. Therefore,

$$\sum_{j=1}^n w_j = 1.$$

Given this scenario, the following table describes the supported loss functions that you can specify by using the 'LossFun' name-value pair argument.

Loss Function	Value of LossFun	Equation
Binomial deviance	'binodeviance'	$L = \sum_{j=1}^n w_j \log\{1 + \exp[-2m_j]\}$.
Exponential loss	'exponential'	$L = \sum_{j=1}^n w_j \exp(-m_j)$.

Loss Function	Value of LossFun	Equation
Classification error	'classiferror'	$L = \sum_{j=1}^n w_j I\{\hat{y}_j \neq y_j\}.$ <p>It is the weighted fraction of misclassified observations where \hat{y}_j is the class label corresponding to the class with the maximal posterior probability. $I\{x\}$ is the indicator function.</p>
Hinge loss	'hinge'	$L = \sum_{j=1}^n w_j \max\{0, 1 - m_j\}.$
Logit loss	'logit'	$L = \sum_{j=1}^n w_j \log(1 + \exp(-m_j)).$

Loss Function	Value of LossFun	Equation
Minimal cost	'mincost'	<p>Minimal cost. The software computes the weighted minimal cost using this procedure for observations $j = 1, \dots, n$.</p> <ol style="list-style-type: none"> 1 Estimate the 1-by-K vector of expected classification costs for observation j: $v_j = f(X_j)'C.$ <p>$f(X_j)$ is the column vector of class posterior probabilities for binary and multiclass classification. C is the cost matrix that the input model stores in the <code>Cost</code> property.</p> 2 For observation j, predict the class label corresponding to the minimum expected classification cost: $\hat{y}_j = \min_{j = 1, \dots, K} (v_j).$ 3 Using C, identify the cost incurred (c_j) for making the prediction. <p>The weighted, average, minimum cost loss is</p> $L = \sum_{j=1}^n w_j c_j.$
Quadratic loss	'quadratic'	$L = \sum_{j=1}^n w_j (1 - m_j)^2.$

This figure compares the loss functions (except 'mincost') for one observation over m . Some functions are normalized to pass through [0,1].

kfoldLoss

Cross-validation loss of partitioned regression ensemble

Syntax

```
L = kfoldLoss(cvens)
L = kfoldLoss(cvens,Name,Value)
```

Description

`L = kfoldLoss(cvens)` returns the cross-validation loss of `cvens`.

`L = kfoldLoss(cvens,Name,Value)` returns cross-validation loss with additional options specified by one or more `Name,Value` pair arguments. You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Input Arguments

`cvens`

Object of class `RegressionPartitionedEnsemble`. Create `obj` with `fitrensemble` along with one of the cross-validation options: `'crossval'`, `'kfold'`, `'holdout'`, `'leaveout'`, or `'cvpartition'`. Alternatively, create `obj` from a regression ensemble with `crossval`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

fold

Indices of folds ranging from 1 to `cvens.KFold`. Use only these folds for predictions.

Default: `1:cvens.KFold`

lossfun

Function handle for loss function, or 'mse', meaning mean squared error. If you pass a function handle `fun`, `loss` calls it as

```
fun(Y,Yfit,W)
```

where `Y`, `Yfit`, and `W` are numeric vectors of the same length.

- `Y` is the observed response.
- `Yfit` is the predicted response.
- `W` is the observation weights.

The returned value `fun(Y,Yfit,W)` should be a scalar.

Default: 'mse'

mode

Method for computing cross-validation loss.

- 'average' — `L` is a scalar value, the average loss over all folds.
- 'individual' — `L` is a vector with one element per fold.
- 'cumulative' — `L` is a vector with a length of minimum number of observations used for training in each fold. Each element in the vector `L` is obtained by taking the average of loss across all folds.

Default: 'average'

Output Arguments

L

The loss (mean squared error) between the observations in a fold when compared against predictions made with an ensemble trained on the out-of-fold data. L can be a vector, and can mean different things, depending on the name-value pair settings.

Examples

Find Cross-Validation Loss for Regression Ensemble

Find the cross-validation loss for a regression ensemble of the `carsmall` data.

Load the `carsmall` data set and select displacement, horsepower, and vehicle weight as predictors.

```
load carsmall
X = [Displacement Horsepower Weight];
```

Train an ensemble of regression trees.

```
rens = fitensemble(X,MPG);
```

Create a cross-validated ensemble from `rens` and find the k-fold cross-validation loss.

```
rng(10,'twister') % For reproducibility
cvrens = crossval(rens);
L = kfoldLoss(cvrens)
```

```
L = 28.7114
```

See Also

`RegressionPartitionedEnsemble` | `kfoldPredict` | `loss`

kfoldLoss

Regression loss for observations not used in training

Syntax

```
L = kfoldLoss(CVMdl)
L = kfoldLoss(CVMdl,Name,Value)
```

Description

Description

`L = kfoldLoss(CVMdl)` returns the cross-validated mean squared error (MSE) obtained by the cross-validated, linear regression model `CVMdl`. That is, for every fold, `kfoldLoss` estimates the regression loss for observations that it holds out when it trains using all other observations.

`L` contains a regression loss for each regularization strength in the linear regression models that compose `CVMdl`.

`L = kfoldLoss(CVMdl,Name,Value)` uses additional options specified by one or more `Name,Value` pair arguments. For example, indicate which folds to use for the loss calculation or specify the regression-loss function.

Input Arguments

CVMdl — Cross-validated, linear regression model

`RegressionPartitionedLinear` model object

Cross-validated, linear regression model, specified as a `RegressionPartitionedLinear` model object. You can create a `RegressionPartitionedLinear` model using `fitrlinear` and specifying any of the one of the cross-validation, name-value pair arguments, for example, `CrossVal`.

To obtain estimates, `kfoldLoss` applies the same data used to cross-validate the linear regression model (X and Y).

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Folds — Fold indices to use for response prediction

1: `CVMdl.KFold` (default) | numeric vector of positive integers

Fold indices to use for response prediction, specified as the comma-separated pair consisting of `'Folds'` and a numeric vector of positive integers. The elements of `Folds` must range from 1 through `CVMdl.KFold`.

Example: `'Folds', [1 4 10]`

Data Types: `single` | `double`

LossFun — Loss function

`'mse'` (default) | `'epsiloninsensitive'` | function handle

Loss function, specified as the comma-separated pair consisting of `'LossFun'` and a built-in, loss-function name or function handle.

- The following table lists the available loss functions. Specify one using its corresponding character vector or string scalar. Also, in the table, $f(x) = x\beta + b$.
 - β is a vector of p coefficients.
 - x is an observation from p predictor variables.
 - b is the scalar bias.

Value	Description
<code>'epsiloninsensitive'</code>	Epsilon-insensitive loss: $\ell[y, f(x)] = \max[0, y - f(x) - \varepsilon]$
<code>'mse'</code>	MSE: $\ell[y, f(x)] = [y - f(x)]^2$

`'epsiloninsensitive'` is appropriate for SVM learners only.

- Specify your own function using function handle notation.

Let n be the number of observations in X . Your function must have this signature

`lossvalue = lossfun(Y,Yhat,W)`

where:

- The output argument `lossvalue` is a scalar.
- You choose the function name (`lossfun`).
- Y is an n -dimensional vector of observed responses. `kfoldLoss` passes the input argument Y in for Y .
- $Yhat$ is an n -dimensional vector of predicted responses, which is similar to the output of `predict`.
- W is an n -by-1 numeric vector of observation weights.

Specify your function using `'LossFun',@lossfun`.

Data Types: `char` | `string` | `function_handle`

Mode — Loss aggregation level

`'average'` (default) | `'individual'`

Loss aggregation level, specified as the comma-separated pair consisting of `'Mode'` and `'average'` or `'individual'`.

Value	Description
<code>'average'</code>	Returns losses averaged over all folds
<code>'individual'</code>	Returns losses for each fold

Example: `'Mode','individual'`

Output Arguments

L — Cross-validated regression losses

numeric scalar | numeric vector | numeric matrix

Cross-validated regression losses, returned as a numeric scalar, vector, or matrix. The interpretation of L depends on `LossFun`.

Let R be the number of regularization strengths in the cross-validated models (stored in `numel(CVMdl.Trained{1}.Lambda)`) and F be the number of folds (stored in `CVMdl.KFold`).

- If `Mode` is `'average'`, then L is a 1-by- R vector. $L(j)$ is the average regression loss over all folds of the cross-validated model that uses regularization strength j .
- Otherwise, L is an F -by- R matrix. $L(i, j)$ is the regression loss for fold i of the cross-validated model that uses regularization strength j .

To estimate L , `kfoldLoss` uses the data that created `CVMdl` (see X and Y).

Examples

Estimate k -Fold Mean Squared Error

Simulate 10000 observations from this model

$$y = x_{100} + 2x_{200} + e.$$

- $X = \{x_1, \dots, x_{1000}\}$ is a 10000-by-1000 sparse matrix with 10% nonzero standard normal elements.
- e is random normal error with mean 0 and standard deviation 0.3.

```
rng(1) % For reproducibility
n = 1e4;
d = 1e3;
nz = 0.1;
X = sprandn(n,d,nz);
Y = X(:,100) + 2*X(:,200) + 0.3*randn(n,1);
```

Cross-validate a linear regression model using SVM learners.

```
rng(1); % For reproducibility
CVMdl = fitrlinear(X,Y,'CrossVal','on');
```

`CVMdl` is a `RegressionPartitionedLinear` model. By default, the software implements 10-fold cross validation. You can alter the number of folds using the `'KFold'` name-value pair argument.

Estimate the average of the test-sample MSEs.

```
mse = kfoldLoss(CVMdl)
mse = 0.1735
```

Alternatively, you can obtain the per-fold MSEs by specifying the name-value pair 'Mode', 'individual' in `kfoldLoss`.

Specify Custom Regression Loss

Simulate data as in “Estimate k-Fold Mean Squared Error” on page 32-3363.

```
rng(1) % For reproducibility
n = 1e4;
d = 1e3;
nz = 0.1;
X = sprandn(n,d,nz);
Y = X(:,100) + 2*X(:,200) + 0.3*randn(n,1);
X = X'; % Put observations in columns for faster training
```

Cross-validate a linear regression model using 10-fold cross-validation. Optimize the objective function using `Sparse`.

```
CVMdl = fitrlinear(X,Y,'CrossVal','on','ObservationsIn','columns',...
    'Solver','sparsa');
```

`CVMdl` is a `RegressionPartitionedLinear` model. It contains the property `Trained`, which is a 10-by-1 cell array holding `RegressionLinear` models that the software trained using the training set.

Create an anonymous function that measures Huber loss ($\delta = 1$), that is,

$$L = \frac{1}{\sum w_j} \sum_{j=1}^n w_j \ell_j,$$

where

$$\ell_j = \begin{cases} 0.5\widehat{e}_j^2; & |\widehat{e}_j| \leq 1 \\ |\widehat{e}_j| - 0.5; & |\widehat{e}_j| > 1 \end{cases}$$

\hat{e}_j is the residual for observation j . Custom loss functions must be written in a particular form. For rules on writing a custom loss function, see the 'LossFun' name-value pair argument.

```
huberloss = @(Y,Yhat,W)sum(W.*((0.5*(abs(Y-Yhat)<=1).*(Y-Yhat).^2) + ...
    ((abs(Y-Yhat)>1).*abs(Y-Yhat)-0.5)))/sum(W);
```

Estimate the average Huber loss over the folds. Also, obtain the Huber loss for each fold.

```
mseAve = kfoldLoss(CVMdl,'LossFun',huberloss)
```

```
mseAve = -0.4447
```

```
mseFold = kfoldLoss(CVMdl,'LossFun',huberloss,'Mode','individual')
```

```
mseFold = 10×1
```

```
-0.4454
-0.4473
-0.4452
-0.4469
-0.4434
-0.4427
-0.4471
-0.4430

-0.4426
```

Find Good Lasso Penalty Using Cross-Validation

To determine a good lasso-penalty strength for a linear regression model that uses least squares, implement 5-fold cross-validation.

Simulate 10000 observations from this model

$$y = x_{100} + 2x_{200} + e.$$

- $X = \{x_1, \dots, x_{1000}\}$ is a 10000-by-1000 sparse matrix with 10% nonzero standard normal elements.
- e is random normal error with mean 0 and standard deviation 0.3.

```
rng(1) % For reproducibility
n = 1e4;
d = 1e3;
nz = 0.1;
X = sprandn(n,d,nz);
Y = X(:,100) + 2*X(:,200) + 0.3*randn(n,1);
```

Create a set of 15 logarithmically-spaced regularization strengths from 10^{-5} through 10^{-1} .

```
Lambda = logspace(-5,-1,15);
```

Cross-validate the models. To increase execution speed, transpose the predictor data and specify that the observations are in columns. Optimize the objective function using SpARSA.

```
X = X';
CVMdl = fitrlinear(X,Y,'ObservationsIn','columns','KFold',5,'Lambda',Lambda,...
    'Learner','leastsquares','Solver','sparsa','Regularization','lasso');
```

```
numCLModels = numel(CVMdl.Trained)
```

```
numCLModels = 5
```

CVMdl is a `RegressionPartitionedLinear` model. Because `fitrlinear` implements 5-fold cross-validation, CVMdl contains 5 `RegressionLinear` models that the software trains on each fold.

Display the first trained linear regression model.

```
Mdl1 = CVMdl.Trained{1}
```

```
Mdl1 =
  RegressionLinear
    ResponseName: 'Y'
  ResponseTransform: 'none'
           Beta: [1000x15 double]
           Bias: [1x15 double]
           Lambda: [1x15 double]
           Learner: 'leastsquares'
```

Properties, Methods

Mdl1 is a RegressionLinear model object. fitrlinear constructed Mdl1 by training on the first four folds. Because Lambda is a sequence of regularization strengths, you can think of Mdl1 as 15 models, one for each regularization strength in Lambda.

Estimate the cross-validated MSE.

```
mse = kfoldLoss(CVMdl);
```

Higher values of Lambda lead to predictor variable sparsity, which is a good quality of a regression model. For each regularization strength, train a linear regression model using the entire data set and the same options as when you cross-validated the models. Determine the number of nonzero coefficients per model.

```
Mdl = fitrlinear(X,Y,'ObservationsIn','columns','Lambda',Lambda,...
    'Learner','leastsquares','Solver','sparsa','Regularization','lasso');
numNZCoeff = sum(Mdl.Beta~=0);
```

In the same figure, plot the cross-validated MSE and frequency of nonzero coefficients for each regularization strength. Plot all variables on the log scale.

```
figure
[h,hL1,hL2] = plotyy(log10(Lambda),log10(mse),...
    log10(Lambda),log10(numNZCoeff));
hL1.Marker = 'o';
hL2.Marker = 'o';
ylabel(h(1),'log_{10} MSE')
ylabel(h(2),'log_{10} nonzero-coefficient frequency')
xlabel('log_{10} Lambda')
hold off
```

Choose the index of the regularization strength that balances predictor variable sparsity and low MSE (for example, $\text{Lambda}(10)$).

```
idxFinal = 10;
```

Extract the model with corresponding to the minimal MSE.

```
MdlFinal = selectModels(Mdl,idxFinal)
```

```
MdlFinal =
  RegressionLinear
    ResponseName: 'Y'
    ResponseTransform: 'none'
    Beta: [1000x1 double]
```

```
Bias: -0.0050  
Lambda: 0.0037  
Learner: 'leastsquares'
```

Properties, Methods

```
idxNZCoeff = find(MdlFinal.Beta~=0)
```

```
idxNZCoeff = 2×1
```

```
100  
200
```

```
EstCoeff = Mdl.Beta(idxNZCoeff)
```

```
EstCoeff = 2×1
```

```
1.0051  
1.9965
```

`MdlFinal` is a `RegressionLinear` model with one regularization strength. The nonzero coefficients `EstCoeff` are close to the coefficients that simulated the data.

`RegressionLinear` | `RegressionPartitionedLinear` | `kfoldPredict` | `loss`

Introduced in R2016a

kfoldLoss

Cross-validation loss of partitioned regression model

Syntax

```
L = kfoldLoss(cvmodel)
L = kfoldLoss(cvmodel, Name, Value)
```

Description

`L = kfoldLoss(cvmodel)` returns the cross-validation loss of `cvmodel`.

`L = kfoldLoss(cvmodel, Name, Value)` returns cross-validation loss with additional options specified by one or more `Name, Value` pair arguments. You can specify several name-value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Input Arguments

`cvmodel`

Object of class `RegressionPartitionedModel`. Create `obj` with `fitrtree` along with one of the cross-validation options: `'CrossVal'`, `'KFold'`, `'Holdout'`, `'Leaveout'`, or `'CVPartition'`. Alternatively, create `obj` from a regression tree with `crossval`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

`folds`

Indices of folds ranging from 1 to `obj.KFold`. Use only these folds for predictions.

Default: 1:obj.KFold

lossfun

Function handle for loss function or 'mse', meaning mean squared error. If you pass a function handle fun, kfoldLoss calls it as

```
fun(Y,Yfit,W)
```

where Y, Yfit, and W are numeric vectors of the same length.

- Y is the observed response.
- Yfit is the predicted response.
- W is the observation weights.

The returned value fun(Y,Yfit,W) should be a scalar.

Default: 'mse'

mode

One of the following:

- 'average' — L is the average loss over all folds.
- 'individual' — L is a vector of the individual losses of in-fold observations trained on out-of-fold data.

Default: 'average'

Output Arguments

L

The loss (mean squared error) between the observations in a fold when compared against predictions made with a tree trained on the out-of-fold data. If mode is 'individual', L is a vector of the losses. If mode is 'average', L is the average loss.

Examples

Construct a partitioned regression model, and examine the cross-validation losses for the folds:

```
load carsmall
XX = [Cylinders Displacement Horsepower Weight];
YY = MPG;
cvmodel = fitrtree(XX,YY,'crossval','on');
L = kfoldLoss(cvmodel,'mode','individual')
```

```
L =
    44.9635
    11.8525
    18.2046
     9.2965
    29.4329
    54.8659
    24.6446
     8.2085
    19.7593
    16.7394
```

Alternatives

You can avoid constructing a cross-validated tree model by calling `cvloss` instead of `kfoldLoss`. The cross-validated tree can save time if you are going to examine it more than once.

`fitrtree` | `kfoldPredict` | `loss`

kfoldMargin

Package: classreg.learning.partition

Classification margins for cross-validated ECOC model

Syntax

```
margin = kfoldMargin(CVMdl)
margin = kfoldMargin(CVMdl,Name,Value)
```

Description

`margin = kfoldMargin(CVMdl)` returns classification margins on page 32-3381 obtained by the cross-validated ECOC model (`ClassificationPartitionedECOC`) `CVMdl`. For every fold, `kfoldMargin` computes classification margins for validation-fold observations using an ECOC model trained on training-fold observations. `CVMdl.X` contains both sets of observations.

`margin = kfoldMargin(CVMdl,Name,Value)` returns classification margins with additional options specified by one or more name-value pair arguments. For example, specify the binary learner loss function, decoding scheme, or verbosity level.

Examples

Estimate *k*-Fold Cross-Validation Margins

Load Fisher's iris data set. Specify the predictor data `X`, the response data `Y`, and the order of the classes in `Y`.

```
load fisheriris
X = meas;
Y = categorical(species);
classOrder = unique(Y);
rng(1); % For reproducibility
```

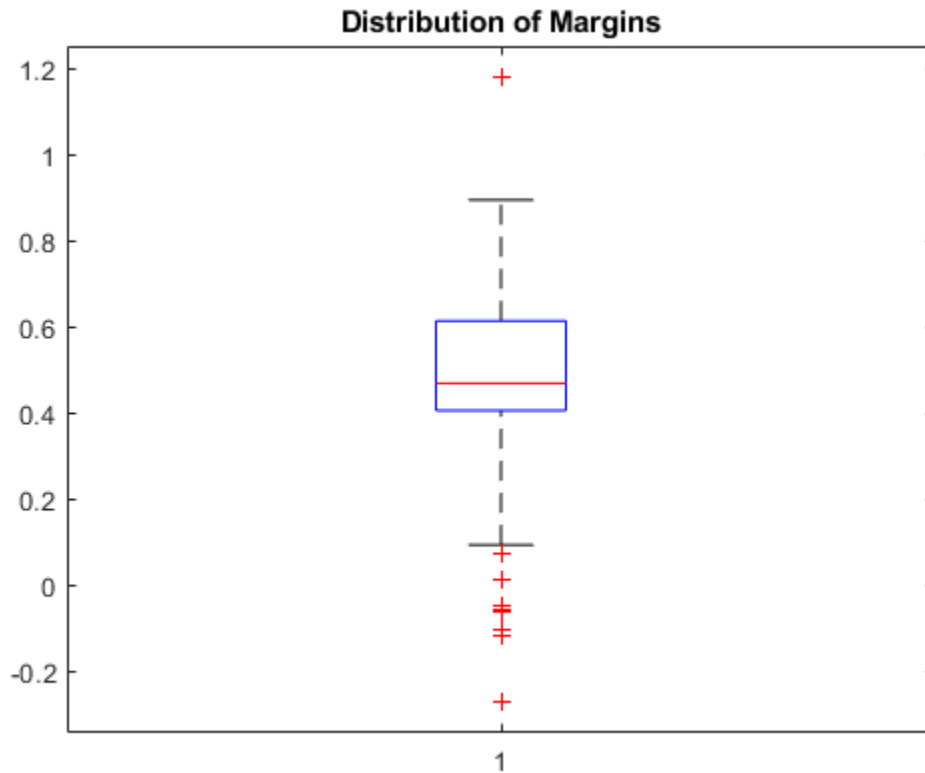

Train and cross-validate an ECOC model using support vector machine (SVM) binary classifiers. Standardize the predictor data using an SVM template, and specify the class order.

```
t = templateSVM('Standardize',1);  
CVMdl = fitcecoc(X,Y,'CrossVal','on','Learners',t,'ClassNames',classOrder);
```

CVMdl is a `ClassificationPartitionedECOC` model. By default, the software implements 10-fold cross-validation. You can specify a different number of folds using the `'KFold'` name-value pair argument.

Estimate the margins for validation-fold observations. Display the distribution of the margins using a boxplot.

```
margin = kfoldMargin(CVMdl);  
  
boxplot(margin)  
title('Distribution of Margins')
```

Select ECOC Model Features by Comparing Cross-Validation Margins

One way to perform feature selection is to compare cross-validation margins from multiple models. Based solely on this criterion, the classifier with the greatest margins is the best classifier.

Load Fisher's iris data set. Specify the predictor data X , the response data Y , and the order of the classes in Y .

```
load fisheriris  
X = meas;
```

```
Y = categorical(species);  
classOrder = unique(Y); % Class order  
rng(1); % For reproducibility
```

Define the following two data sets.

- `fullX` contains all the predictors.
- `partX` contains the petal dimensions.

```
fullX = X;  
partX = X(:,3:4);
```

For each predictor set, train and cross-validate an ECOC model using SVM binary classifiers. Standardize the predictors using an SVM template, and specify the class order.

```
t = templateSVM('Standardize',1);  
CVMdl = fitcecoc(fullX,Y,'CrossVal','on','Learners',t,...  
    'ClassNames',classOrder);  
PCVMdl = fitcecoc(partX,Y,'CrossVal','on','Learners',t,...  
    'ClassNames',classOrder);
```

`CVMdl` and `PCVMdl` are `ClassificationPartitionedECOC` models. By default, the software implements 10-fold cross-validation.

Estimate the margins for each classifier. Use loss-based decoding for aggregating the binary learner results. For each model, display the distribution of the margins using a boxplot.

```
fullMargins = kfoldMargin(CVMdl,'Decoding','lossbased');  
partMargins = kfoldMargin(PCVMdl,'Decoding','lossbased');  
  
boxplot([fullMargins partMargins],'Labels',{'All Predictors','Two Predictors'})  
title('Distributions of Margins')
```

The margin distributions are approximately the same.

Input Arguments

CVMdL — Cross-validated ECOC model

`ClassificationPartitionedECOC model`

Cross-validated ECOC model, specified as a `ClassificationPartitionedECOC` model. You can create a `ClassificationPartitionedECOC` model in two ways:

- Pass a trained ECOC model (`ClassificationECOC`) to `crossval`.

- Train an ECOC model using `fitcecoc` and specify any one of these cross-validation name-value pair arguments: 'CrossVal', 'CVPartition', 'Holdout', 'KFold', or 'Leaveout'.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `kfoldMargin(CVMdl, 'Verbose', 1)` specifies to display diagnostic messages in the Command Window.

BinaryLoss — Binary learner loss function

'hamming' | 'linear' | 'logit' | 'exponential' | 'binodeviance' | 'hinge' | 'quadratic' | function handle

Binary learner loss function, specified as the comma-separated pair consisting of 'BinaryLoss' and a built-in loss function name or function handle.

- This table describes the built-in functions, where y_j is a class label for a particular binary learner (in the set $\{-1, 1, 0\}$), s_j is the score for observation j , and $g(y_j, s_j)$ is the binary loss formula.

Value	Description	Score Domain	$g(y_j, s_j)$
'binodeviance'	Binomial deviance	$(-\infty, \infty)$	$\log[1 + \exp(-2y_j s_j)] / [2\log(2)]$
'exponential'	Exponential	$(-\infty, \infty)$	$\exp(-y_j s_j) / 2$
'hamming'	Hamming	$[0, 1]$ or $(-\infty, \infty)$	$[1 - \text{sign}(y_j s_j)] / 2$
'hinge'	Hinge	$(-\infty, \infty)$	$\max(0, 1 - y_j s_j) / 2$
'linear'	Linear	$(-\infty, \infty)$	$(1 - y_j s_j) / 2$
'logit'	Logistic	$(-\infty, \infty)$	$\log[1 + \exp(-y_j s_j)] / [2\log(2)]$
'quadratic'	Quadratic	$[0, 1]$	$[1 - y_j(2s_j - 1)]^2 / 2$

The software normalizes binary losses so that the loss is 0.5 when $y_j = 0$. Also, the software calculates the mean binary loss for each class.

- For a custom binary loss function, for example `customFunction`, specify its function handle `'BinaryLoss',@customFunction`.

`customFunction` has this form:

```
bLoss = customFunction(M,s)
```

where:

- M is the K -by- L coding matrix stored in `Mdl.CodingMatrix`.
- s is the 1-by- L row vector of classification scores.
- `bLoss` is the classification loss. This scalar aggregates the binary losses for every learner in a particular class. For example, you can use the mean binary loss to aggregate the loss over the learners for each class.
- K is the number of classes.
- L is the number of binary learners.

For an example of passing a custom binary loss function, see “Predict Test-Sample Labels of ECOC Model Using Custom Binary Loss Function” on page 32-5219.

The default `BinaryLoss` value depends on the score ranges returned by the binary learners. This table describes some default `BinaryLoss` values based on the given assumptions.

Assumption	Default Value
All binary learners are SVMs or either linear or kernel classification models of SVM learners.	'hinge'
All binary learners are ensembles trained by <code>AdaboostM1</code> or <code>GentleBoost</code> .	'exponential'
All binary learners are ensembles trained by <code>LogitBoost</code> .	'binodeviance'
All binary learners are linear or kernel classification models of logistic regression learners. Or, you specify to predict class posterior probabilities by setting <code>'FitPosterior',true</code> in <code>fitcecoc</code> .	'quadratic'

To check the default value, use dot notation to display the `BinaryLoss` property of the trained model at the command line.

Example: `'BinaryLoss','binodeviance'`

Data Types: `char` | `string` | `function_handle`

Decoding — Decoding scheme

`'lossweighted'` (default) | `'lossbased'`

Decoding scheme that aggregates the binary losses, specified as the comma-separated pair consisting of `'Decoding'` and `'lossweighted'` or `'lossbased'`. For more information, see “Binary Loss” on page 32-3444.

Example: `'Decoding', 'lossbased'`

Options — Estimation options

`[]` (default) | structure array returned by `statset`

Estimation options, specified as the comma-separated pair consisting of `'Options'` and a structure array returned by `statset`.

To invoke parallel computing:

- You need a Parallel Computing Toolbox license.
- Specify `'Options', statset('UseParallel', true)`.

Verbose — Verbosity level

`0` (default) | `1`

Verbosity level, specified as the comma-separated pair consisting of `'Verbose'` and `0` or `1`. `Verbose` controls the number of diagnostic messages that the software displays in the Command Window.

If `Verbose` is `0`, then the software does not display diagnostic messages. Otherwise, the software displays diagnostic messages.

Example: `'Verbose', 1`

Data Types: `single` | `double`

Output Arguments

margin — Classification margins

numeric vector

Classification margins on page 32-3381, returned as a numeric vector. `margin` is an n -by-1 vector, where each row is the margin of the corresponding observation and n is the number of observations (`size(CVMdl.X,1)`).

Definitions

Classification Margin

The classification margin is, for each observation, the difference between the negative loss for the true class and the maximal negative loss among the false classes. If the margins are on the same scale, then they serve as a classification confidence measure. Among multiple classifiers, those that yield greater margins are better.

Binary Loss

A binary loss is a function of the class and classification score that determines how well a binary learner classifies an observation into the class.

Suppose the following:

- m_{kj} is element (k,j) of the coding design matrix M (that is, the code corresponding to class k of binary learner j).
- s_j is the score of binary learner j for an observation.
- g is the binary loss function.
- \hat{k} is the predicted class for the observation.

In loss-based decoding [Escalera et al.] on page 18-228, the class producing the minimum sum of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \operatorname{argmin}_k \sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j).$$

In loss-weighted decoding [Escalera et al.] on page 18-228, the class producing the minimum average of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \operatorname{argmin}_k \frac{\sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j)}{\sum_{j=1}^L |m_{kj}|}.$$

Allwein et al. on page 18-227 suggest that loss-weighted decoding improves classification accuracy by keeping loss values for all classes in the same dynamic range.

This table summarizes the supported loss functions, where y_j is a class label for a particular binary learner (in the set $\{-1, 1, 0\}$), s_j is the score for observation j , and $g(y_j, s_j)$.

Value	Description	Score Domain	$g(y_j, s_j)$
'binodeviance'	Binomial deviance	$(-\infty, \infty)$	$\log[1 + \exp(-2y_j s_j)] / [2\log(2)]$
'exponential'	Exponential	$(-\infty, \infty)$	$\exp(-y_j s_j) / 2$
'hamming'	Hamming	$[0, 1]$ or $(-\infty, \infty)$	$[1 - \operatorname{sign}(y_j s_j)] / 2$
'hinge'	Hinge	$(-\infty, \infty)$	$\max(0, 1 - y_j s_j) / 2$
'linear'	Linear	$(-\infty, \infty)$	$(1 - y_j s_j) / 2$
'logit'	Logistic	$(-\infty, \infty)$	$\log[1 + \exp(-y_j s_j)] / [2\log(2)]$
'quadratic'	Quadratic	$[0, 1]$	$[1 - y_j(2s_j - 1)]^2 / 2$

The software normalizes binary losses such that the loss is 0.5 when $y_j = 0$, and aggregates using the average of the binary learners [Allwein et al.] on page 18-227.

Do not confuse the binary loss with the overall classification loss (specified by the 'LossFun' name-value pair argument of the `loss` and `predict` object functions), which measures how well an ECOC classifier performs as a whole.

Extended Capabilities

Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the 'UseParallel' option to true.

Set the 'UseParallel' field of the options structure to true using `statset` and specify the 'Options' name-value pair argument in the call to this function.

For example: `'Options',statset('UseParallel',true)`

For more information, see the 'Options' name-value pair argument.

For more general information about parallel computing, see "Run MATLAB Functions with Automatic Parallel Support" (Parallel Computing Toolbox).

kfoldMargin

Package: classreg.learning.partition

Classification margins for cross-validated kernel classification model

Syntax

```
margin = kfoldMargin(CVMdl)
```

Description

`margin = kfoldMargin(CVMdl)` returns the classification margins on page 32-3390 obtained by the cross-validated, binary kernel model (`ClassificationPartitionedKernel`) `CVMdl`. For every fold, `kfoldMargin` computes the classification margins for validation-fold observations using a model trained on training-fold observations.

Examples

Estimate *k*-Fold Cross-Validation Margins

Load the ionosphere data set. This data set has 34 predictors and 351 binary responses for radar returns, which are labeled as either bad ('b') or good ('g').

```
load ionosphere
```

Cross-validate a binary kernel classification model using the data.

```
CVMdl = fitkernel(X,Y,'Crossval','on')
```

```
CVMdl =  
  classreg.learning.partition.ClassificationPartitionedKernel  
    CrossValidatedModel: 'Kernel'  
      ResponseName: 'Y'  
    NumObservations: 351
```

```
      KFold: 10
      Partition: [1x1 cvpartition]
      ClassNames: {'b' 'g'}
      ScoreTransform: 'none'
```

Properties, Methods

`CVMDL` is a `ClassificationPartitionedKernel` model. By default, the software implements 10-fold cross-validation. To specify a different number of folds, use the `'KFold'` name-value pair argument instead of `'Crossval'`.

Estimate the classification margins for validation-fold observations.

```
m = kfoldMargin(CVMDL);
size(m)
```

```
ans = 1×2
```

```
    351     1
```

`m` is a 351-by-1 vector. `m(j)` is the classification margin for observation `j`.

Plot the `k`-fold margins using a boxplot.

```
boxplot(m, 'Labels', 'All Observations')
title('Distribution of Margins')
```

Feature Selection Using k -Fold Margins

Perform feature selection by comparing k -fold margins from multiple models. Based solely on this criterion, the classifier with the greatest margins is the best classifier.

Load the `ionosphere` data set. This data set has 34 predictors and 351 binary responses for radar returns, which are labeled either bad ('b') or good ('g').

```
load ionosphere
```

Randomly choose 10% of the predictor variables.

```
rng(1); % For reproducibility
p = size(X,2); % Number of predictors
idxPart = randsample(p,ceil(0.1*p));
```

Cross-validate two binary kernel classification models: one that uses all of the predictors, and one that uses 10% of the predictors.

```
CVMdl = fitckernel(X,Y,'CrossVal','on');
PCVMdl = fitckernel(X(:,idxPart),Y,'CrossVal','on');
```

CVMdl and PCVMdl are ClassificationPartitionedKernel models. By default, the software implements 10-fold cross-validation. To specify a different number of folds, use the 'KFold' name-value pair argument instead of 'Crossval'.

Estimate the k -fold margins for each classifier.

```
fullMargins = kfoldMargin(CVMdl);
partMargins = kfoldMargin(PCVMdl);
```

Plot the distribution of the margin sets using box plots.

```
boxplot([fullMargins partMargins], ...
        'Labels',{'All Predictors','10% of the Predictors'});
title('Distribution of Margins')
```

The quartiles of the PCVMdL margin distribution are situated higher than the quartiles of the CVMdL margin distribution, indicating that the PCVMdL model is the better classifier.

Input Arguments

CVMdL — Cross-validated, binary kernel classification model

`ClassificationPartitionedKernel` model object

Cross-validated, binary kernel classification model, specified as a `ClassificationPartitionedKernel` model object. You can create a

ClassificationPartitionedKernel model by using `fitckernel` and specifying any one of the cross-validation name-value pair arguments.

To obtain estimates, `kfoldMargin` applies the same data used to cross-validate the kernel classification model (X and Y).

Output Arguments

margin — Classification margins

numeric vector

Classification margins on page 32-3390, returned as a numeric vector. `margin` is an n -by-1 vector, where each row is the margin of the corresponding observation and n is the number of observations (`size(CVMdl.Y,1)`).

Definitions

Classification Margin

The classification margin for binary classification is, for each observation, the difference between the classification score for the true class and the classification score for the false class.

The software defines the classification margin for binary classification as

$$m = 2yf(x).$$

x is an observation. If the true label of x is the positive class, then y is 1, and -1 otherwise. $f(x)$ is the positive-class classification score for the observation x . The classification margin is commonly defined as $m = yf(x)$.

If the margins are on the same scale, then they serve as a classification confidence measure. Among multiple classifiers, those that yield greater margins are better.

Classification Score

For kernel classification models, the raw classification score for classifying the observation x , a row vector, into the positive class is defined by

$$f(x) = T(x)\beta + b.$$

- $T(\cdot)$ is a transformation of an observation for feature expansion.
- β is the estimated column vector of coefficients.
- b is the estimated scalar bias.

The raw classification score for classifying x into the negative class is $-f(x)$. The software classifies observations into the class that yields a positive score.

If the kernel classification model consists of logistic regression learners, then the software applies the 'logit' score transformation to the raw classification scores (see `ScoreTransform`).

`ClassificationPartitionedKernel` | `fitckernel`

Introduced in R2018b

kfoldMargin

Package: classreg.learning.partition

Classification margins for cross-validated kernel ECOC model

Syntax

```
margin = kfoldMargin(CVMdl)
margin = kfoldMargin(CVMdl, Name, Value)
```

Description

`margin = kfoldMargin(CVMdl)` returns the classification margins on page 32-3399 obtained by the cross-validated kernel ECOC model (`ClassificationPartitionedKernelECOC`) `CVMdl`. For every fold, `kfoldMargin` computes the classification margins for validation-fold observations using a model trained on training-fold observations.

`margin = kfoldMargin(CVMdl, Name, Value)` returns classification margins with additional options specified by one or more name-value pair arguments. For example, specify the binary learner loss function, decoding scheme, or verbosity level.

Examples

Estimate *k*-Fold Cross-Validation Margins

Load Fisher's iris data set. `X` contains flower measurements, and `Y` contains the names of flower species.

```
load fisheriris
X = meas;
Y = species;
```

Cross-validate an ECOC model composed of kernel binary learners.

```

CVMdl = fitcecoc(X,Y,'Learners','kernel','CrossVal','on')
CVMdl =
  classreg.learning.partition.ClassificationPartitionedKernelECOC
    CrossValidatedModel: 'KernelECOC'
      ResponseName: 'Y'
    NumObservations: 150
      KFold: 10
    Partition: [1x1 cvpartition]
    ClassNames: {'setosa' 'versicolor' 'virginica'}
    ScoreTransform: 'none'

```

Properties, Methods

CVMdl is a `ClassificationPartitionedKernelECOC` model. By default, the software implements 10-fold cross-validation. To specify a different number of folds, use the 'KFold' name-value pair argument instead of 'Crossval'.

Estimate the classification margins for validation-fold observations.

```

m = kfoldMargin(CVMdl);
size(m)

ans = 1x2

```

```

    150     1

```

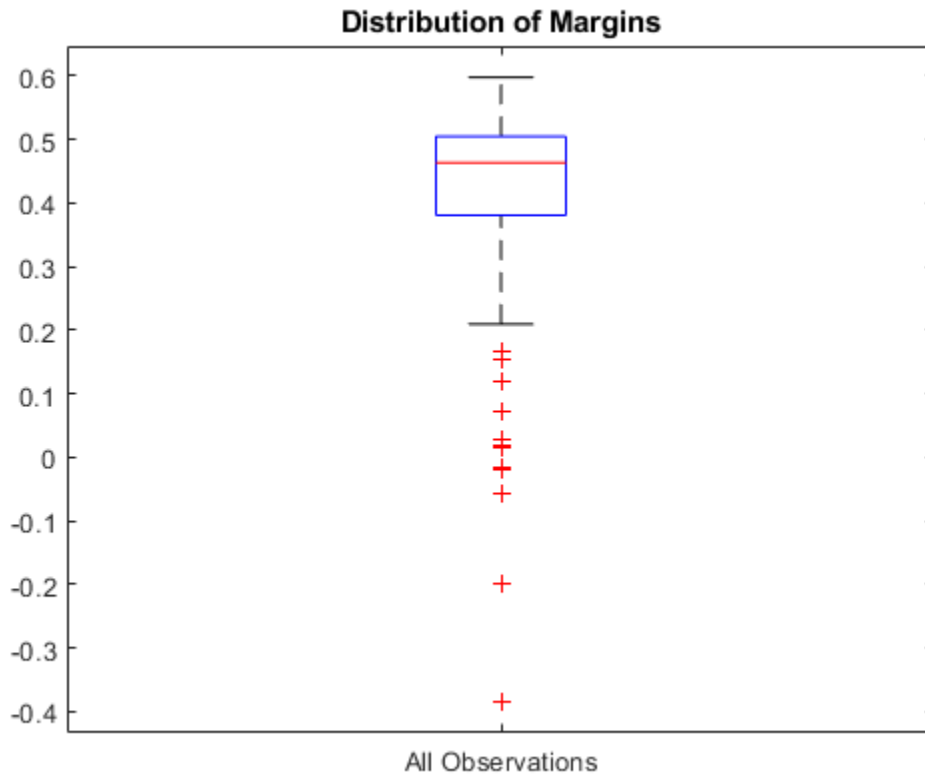

`m` is a 150-by-1 vector. `m(j)` is the classification margin for observation `j`.

Plot the k-fold margins using a boxplot.

```

boxplot(m,'Labels','All Observations')
title('Distribution of Margins')

```

Feature Selection Using k -Fold Margins

Perform feature selection by comparing k -fold margins from multiple models. Based solely on this criterion, the classifier with the greatest margins is the best classifier.

Load Fisher's iris data set. X contains flower measurements, and Y contains the names of flower species.

```
load fisheriris
X = meas;
Y = species;
```

Randomly choose half of the predictor variables.

```
rng(1); % For reproducibility
p = size(X,2); % Number of predictors
idxPart = randsample(p,ceil(0.5*p));
```

Cross-validate two ECOC models composed of kernel classification models: one that uses all of the predictors, and one that uses half of the predictors.

```
CVMDL = fitcecoc(X,Y,'Learners','kernel','CrossVal','on');
PCVMDL = fitcecoc(X(:,idxPart),Y,'Learners','kernel','CrossVal','on');
```

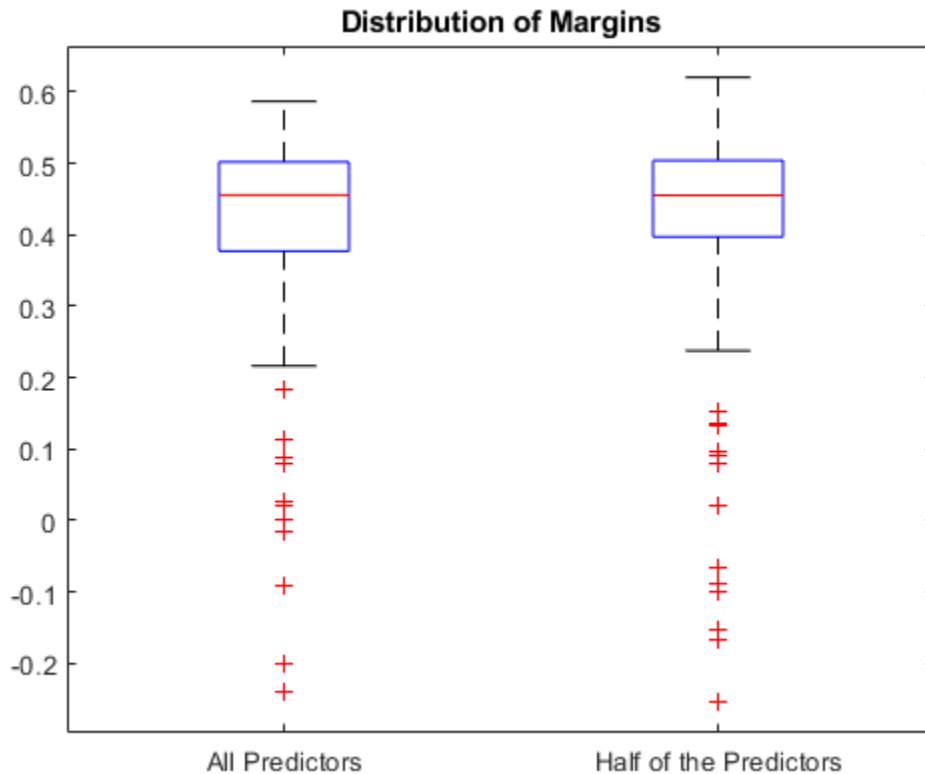

CVMDL and PCVMDL are ClassificationPartitionedKernelECOC models. By default, the software implements 10-fold cross-validation. To specify a different number of folds, use the 'KFold' name-value pair argument instead of 'Crossval'.

Estimate the k -fold margins for each classifier.

```
fullMargins = kfoldMargin(CVMDL);
partMargins = kfoldMargin(PCVMDL);
```

Plot the distribution of the margin sets using box plots.

```
boxplot([fullMargins partMargins], ...
        'Labels',{'All Predictors','Half of the Predictors'});
title('Distribution of Margins')
```

The PCVMdL margin distribution is similar to the CVMdL margin distribution.

Input Arguments

CVMdL — Cross-validated kernel ECOC model

`ClassificationPartitionedKernelECOC` model

Cross-validated kernel ECOC model, specified as a `ClassificationPartitionedKernelECOC` model. You can create a `ClassificationPartitionedKernelECOC` model by training an ECOC model using `fitcecoc` and specifying these name-value pair arguments:

- 'Learners' - Set the value to 'kernel', a template object returned by `templateKernel`, or a cell array of such template objects.
- One of the arguments 'CrossVal', 'CVPartition', 'Holdout', 'KFold', or 'Leaveout'.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `kfoldMargin(CVMdl, 'Verbose', 1)` specifies to display diagnostic messages in the Command Window.

BinaryLoss — Binary learner loss function

'hamming' | 'linear' | 'logit' | 'exponential' | 'binodeviance' | 'hinge' | 'quadratic' | function handle

Binary learner loss function, specified as the comma-separated pair consisting of 'BinaryLoss' and a built-in loss function name or function handle.

- This table contains names and descriptions of the built-in functions, where y_j is a class label for a particular binary learner (in the set $\{-1, 1, 0\}$), s_j is the score for observation j , and $g(y_j, s_j)$ is the binary loss formula.

Value	Description	Score Domain	$g(y_j, s_j)$
'binodeviance'	Binomial deviance	$(-\infty, \infty)$	$\log[1 + \exp(-2y_j s_j)] / [2\log(2)]$
'exponential'	Exponential	$(-\infty, \infty)$	$\exp(-y_j s_j) / 2$
'hamming'	Hamming	$[0, 1]$ or $(-\infty, \infty)$	$[1 - \text{sign}(y_j s_j)] / 2$
'hinge'	Hinge	$(-\infty, \infty)$	$\max(0, 1 - y_j s_j) / 2$
'linear'	Linear	$(-\infty, \infty)$	$(1 - y_j s_j) / 2$
'logit'	Logistic	$(-\infty, \infty)$	$\log[1 + \exp(-y_j s_j)] / [2\log(2)]$
'quadratic'	Quadratic	$[0, 1]$	$[1 - y_j(2s_j - 1)]^2 / 2$

The software normalizes binary losses such that the loss is 0.5 when $y_j = 0$. Also, the software calculates the mean binary loss for each class.

- For a custom binary loss function, for example, `customFunction`, specify its function handle `'BinaryLoss',@customFunction`.

`customFunction` has this form:

```
bLoss = customFunction(M,s)
```

where:

- `M` is the K -by- L coding matrix stored in `Mdl.CodingMatrix`.
- `s` is the 1-by- L row vector of classification scores.
- `bLoss` is the classification loss. This scalar aggregates the binary losses for every learner in a particular class. For example, you can use the mean binary loss to aggregate the loss over the learners for each class.
- K is the number of classes.
- L is the number of binary learners.

By default, if all binary learners are kernel classification models using SVM, then `BinaryLoss` is `'hinge'`. If all binary learners are kernel classification models using logistic regression, then `BinaryLoss` is `'quadratic'`.

Example: `'BinaryLoss','binodeviance'`

Data Types: `char | string | function_handle`

Decoding — Decoding scheme

`'lossweighted'` (default) | `'lossbased'`

Decoding scheme that aggregates the binary losses, specified as the comma-separated pair consisting of `'Decoding'` and `'lossweighted'` or `'lossbased'`. For more information, see “Binary Loss” on page 32-3400.

Example: `'Decoding','lossbased'`

Options — Estimation options

`[]` (default) | structure array returned by `statset`

Estimation options, specified as the comma-separated pair consisting of `'Options'` and a structure array returned by `statset`.

To invoke parallel computing:

- You need a Parallel Computing Toolbox license.
- Specify 'Options', `statset('UseParallel',true)`.

Verbose — Verbosity level

0 (default) | 1

Verbosity level, specified as the comma-separated pair consisting of 'Verbose' and 0 or 1. Verbose controls the number of diagnostic messages that the software displays in the Command Window.

If Verbose is 0, then the software does not display diagnostic messages. Otherwise, the software displays diagnostic messages.

Example: 'Verbose',1

Data Types: single | double

Output Arguments

margin — Classification margins

numeric vector

Classification margins on page 32-3399, returned as a numeric vector. `margin` is an n -by-1 vector, where each row is the margin of the corresponding observation and n is the number of observations (`size(CVMdl.Y,1)`).

Definitions

Classification Margin

The classification margin is, for each observation, the difference between the negative loss for the true class and the maximal negative loss among the false classes. If the margins are on the same scale, then they serve as a classification confidence measure. Among multiple classifiers, those that yield greater margins are better.

Binary Loss

A binary loss is a function of the class and classification score that determines how well a binary learner classifies an observation into the class.

Suppose the following:

- m_{kj} is element (k,j) of the coding design matrix M (that is, the code corresponding to class k of binary learner j).
- s_j is the score of binary learner j for an observation.
- g is the binary loss function.
- \hat{k} is the predicted class for the observation.

In loss-based decoding [Escalera et al.] on page 18-228, the class producing the minimum sum of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \operatorname{argmin}_k \sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j).$$

In loss-weighted decoding [Escalera et al.] on page 18-228, the class producing the minimum average of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \operatorname{argmin}_k \frac{\sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j)}{\sum_{j=1}^L |m_{kj}|}.$$

Allwein et al. on page 18-227 suggest that loss-weighted decoding improves classification accuracy by keeping loss values for all classes in the same dynamic range.

This table summarizes the supported loss functions, where y_j is a class label for a particular binary learner (in the set $\{-1,1,0\}$), s_j is the score for observation j , and $g(y_j, s_j)$.

Value	Description	Score Domain	$g(y_j, s_j)$
'binodeviance'	Binomial deviance	$(-\infty, \infty)$	$\log[1 + \exp(-2y_j s_j)] / [2\log(2)]$

Value	Description	Score Domain	$g(y_j, s_j)$
'exponential'	Exponential	$(-\infty, \infty)$	$\exp(-y_j s_j)/2$
'hamming'	Hamming	$[0,1]$ or $(-\infty, \infty)$	$[1 - \text{sign}(y_j s_j)]/2$
'hinge'	Hinge	$(-\infty, \infty)$	$\max(0, 1 - y_j s_j)/2$
'linear'	Linear	$(-\infty, \infty)$	$(1 - y_j s_j)/2$
'logit'	Logistic	$(-\infty, \infty)$	$\log[1 + \exp(-y_j s_j)]/[2\log(2)]$
'quadratic'	Quadratic	$[0,1]$	$[1 - y_j(2s_j - 1)]^2/2$

The software normalizes binary losses such that the loss is 0.5 when $y_j = 0$, and aggregates using the average of the binary learners [Allwein et al.] on page 18-227.

Do not confuse the binary loss with the overall classification loss (specified by the 'LossFun' name-value pair argument of the `loss` and `predict` object functions), which measures how well an ECOC classifier performs as a whole.

Introduced in R2018b

kfoldMargin

Classification margins for observations not used in training

Syntax

```
m = kfoldMargin(CVMdl)
```

Description

`m = kfoldMargin(CVMdl)` returns the cross-validated classification margins on page 32-3410 obtained by the cross-validated, binary, linear classification model `CVMdl`. That is, for every fold, `kfoldMargin` estimates the classification margins for observations that it holds out when it trains using all other observations.

`m` contains classification margins for each regularization strength in the linear classification models that comprise `CVMdl`.

Input Arguments

CVMdl — Cross-validated, binary, linear classification model

`ClassificationPartitionedLinear` model object

Cross-validated, binary, linear classification model, specified as a `ClassificationPartitionedLinear` model object. You can create a `ClassificationPartitionedLinear` model using `fitclinear` and specifying any one of the cross-validation, name-value pair arguments, for example, `CrossVal`.

To obtain estimates, `kfoldMargin` applies the same data used to cross-validate the linear classification model (X and Y).

Output Arguments

m — Cross-validated classification margins

numeric vector | numeric matrix

Cross-validated classification margins on page 32-3410, returned as a numeric vector or matrix.

m is n -by- L , where n is the number of observations in the data that created `CVMDL` (see X and Y) and L is the number of regularization strengths in `CVMDL` (that is, `numel(CVMDL.Trained{1}.Lambda)`).

$m(i, j)$ is the cross-validated classification margin of observation i using the linear classification model that has regularization strength `CVMDL.Trained{1}.Lambda(j)`.

Data Types: `single` | `double`

Examples

Estimate k -Fold Cross-Validation Margins

Load the NLP data set.

```
load nlpdata
```

X is a sparse matrix of predictor data, and Y is a categorical vector of class labels. There are more than two classes in the data.

The models should identify whether the word counts in a web page are from the Statistics and Machine Learning Toolbox™ documentation. So, identify the labels that correspond to the Statistics and Machine Learning Toolbox™ documentation web pages.

```
Ystats = Y == 'stats';
```

Cross-validate a binary, linear classification model that can identify whether the word counts in a documentation web page are from the Statistics and Machine Learning Toolbox™ documentation.

```
rng(1); % For reproducibility
CVMDL = fitlinear(X, Ystats, 'CrossVal', 'on');
```

CVMDL is a `ClassificationPartitionedLinear` model. By default, the software implements 10-fold cross validation. You can alter the number of folds using the 'KFold' name-value pair argument.

Estimate the cross-validated margins.

```
m = kfoldMargin(CVMdl);  
size(m)
```

```
ans = 1×2
```

```
    31572         1
```

`m` is a 31572-by-1 vector. `m(j)` is the average of the out-of-fold margins for observation `j`.

Plot the k -fold margins using box plots.

```
figure;  
boxplot(m);  
h = gca;  
h.YLim = [-5 30];  
title('Distribution of Cross-Validated Margins')
```

Feature Selection Using *k*-fold Margins

One way to perform feature selection is to compare *k*-fold margins from multiple models. Based solely on this criterion, the classifier with the larger margins is the better classifier.

Load the NLP data set. Preprocess the data as in “Estimate *k*-Fold Cross-Validation Margins” on page 32-3403.

```
load nlpdata
Ystats = Y == 'stats';
X = X';
```

Create these two data sets:

- `fullX` contains all predictors.
- `partX` contains 1/2 of the predictors chosen at random.

```
rng(1); % For reproducibility
p = size(X,1); % Number of predictors
halfPredIdx = randsample(p,ceil(0.5*p));
fullX = X;
partX = X(halfPredIdx,:);
```

Cross-validate two binary, linear classification models: one that uses the all of the predictors and one that uses half of the predictors. Optimize the objective function using `SparSA`, and indicate that observations correspond to columns.

```
CVMdl = fitlinear(fullX,Ystats,'CrossVal','on','Solver','sparsa',...
'ObservationsIn','columns');
PCVMdl = fitlinear(partX,Ystats,'CrossVal','on','Solver','sparsa',...
'ObservationsIn','columns');
```

`CVMdl` and `PCVMdl` are `ClassificationPartitionedLinear` models.

Estimate the k -fold margins for each classifier. Plot the distribution of the k -fold margins sets using box plots.

```
fullMargins = kfoldMargin(CVMdl);
partMargins = kfoldMargin(PCVMdl);

figure;
boxplot([fullMargins partMargins],'Labels',...
{'All Predictors','Half of the Predictors'});
h = gca;
h.YLim = [-30 60];
title('Distribution of Cross-Validated Margins')
```

The distributions of the margins of the two classifiers are similar.

Find Good Lasso Penalty Using k -fold Margins

To determine a good lasso-penalty strength for a linear classification model that uses a logistic regression learner, compare distributions of k -fold margins.

Load the NLP data set. Preprocess the data as in “Estimate k -Fold Cross-Validation Margins” on page 32-3403.

```
load nlpdata
Ystats = Y == 'stats';
X = X';
```

Create a set of 11 logarithmically-spaced regularization strengths from 10^{-8} through 10^1 .

```
Lambda = logspace(-8,1,11);
```

Cross-validate a binary, linear classification model using 5-fold cross-validation and that uses each of the regularization strengths. Optimize the objective function using SpaRSA. Lower the tolerance on the gradient of the objective function to $1e-8$.

```
rng(10); % For reproducibility
CVMdl = fitlinear(X,Ystats,'ObservationsIn','columns','KFold',5, ...
    'Learner','logistic','Solver','sparsa','Regularization','lasso', ...
    'Lambda',Lambda,'GradientTolerance',1e-8)
```

```
CVMdl =
  classreg.learning.partition.ClassificationPartitionedLinear
  CrossValidatedModel: 'Linear'
  ResponseName: 'Y'
  NumObservations: 31572
  KFold: 5
  Partition: [1x1 cvpartition]
  ClassNames: [0 1]
  ScoreTransform: 'none'
```

Properties, Methods

CVMdl is a `ClassificationPartitionedLinear` model. Because `fitlinear` implements 5-fold cross-validation, CVMdl contains 5 `ClassificationLinear` models that the software trains on each fold.

Estimate the k -fold margins for each regularization strength.

```
m = kfoldMargin(CVMdl);
size(m)
```

```
ans = 1x2
```

```
    31572     11
```

m is a 31572-by-11 matrix of cross-validated margins for each observation. The columns correspond to the regularization strengths.

Plot the k -fold margins for each regularization strength. Because logistic regression scores are in $[0,1]$, margins are in $[-1,1]$. Rescale the margins to help identify the regularization strength that maximizes the margins over the grid.

```
figure
boxplot(10000.^m)
ylabel('Exponentiated test-sample margins')
xlabel('Lambda indices')
```

Several values of `Lambda` yield k -fold margin distributions that are compacted near 10000. Higher values of `lambda` lead to predictor variable sparsity, which is a good quality of a classifier.

Choose the regularization strength that occurs just before the centers of the k -fold margin distributions start decreasing.

```
LambdaFinal = Lambda(5);
```

Train a linear classification model using the entire data set and specify the desired regularization strength.

```
MdlFinal = fitclinear(X,Ystats,'ObservationsIn','columns', ...  
    'Learner','logistic','Solver','sparsa','Regularization','lasso', ...  
    'Lambda',LambdaFinal);
```

To estimate labels for new observations, pass `MdlFinal` and the new data to `predict`.

Definitions

Classification Margin

The classification margin for binary classification is, for each observation, the difference between the classification score for the true class and the classification score for the false class.

The software defines the classification margin for binary classification as

$$m = 2yf(x).$$

x is an observation. If the true label of x is the positive class, then y is 1, and -1 otherwise. $f(x)$ is the positive-class classification score for the observation x . The classification margin is commonly defined as $m = yf(x)$.

If the margins are on the same scale, then they serve as a classification confidence measure. Among multiple classifiers, those that yield greater margins are better.

Classification Score

For linear classification models, the raw classification score for classifying the observation x , a row vector, into the positive class is defined by

$$f_j(x) = x\beta_j + b_j.$$

For the model with regularization strength j , β_j is the estimated column vector of coefficients (the model property `Beta (: , j)`) and b_j is the estimated, scalar bias (the model property `Bias (j)`).

The raw classification score for classifying x into the negative class is $-f(x)$. The software classifies observations into the class that yields the positive score.

If the linear classification model consists of logistic regression learners, then the software applies the 'logit' score transformation to the raw classification scores (see `ScoreTransform`).

Introduced in R2016a

kfoldMargin

Classification margins for observations not used in training

Syntax

```
m = kfoldMargin(CVMdl)
m = kfoldMargin(CVMdl, Name, Value)
```

Description

`m = kfoldMargin(CVMdl)` returns the cross-validated classification margins on page 32-3423 obtained by `CVMdl`, which is a cross-validated, error-correcting output codes (ECOC) model composed of linear classification models. That is, for every fold, `kfoldMargin` estimates the classification margins for observations that it holds out when it trains using all other observations.

`m` contains classification margins for each regularization strength in the linear classification models that comprise `CVMdl`.

`m = kfoldMargin(CVMdl, Name, Value)` uses additional options specified by one or more `Name, Value` pair arguments. For example, specify a decoding scheme or verbosity level.

Input Arguments

CVMdl — **Cross-validated, ECOC model composed of linear classification models**
`ClassificationPartitionedLinearECOC` model object

Cross-validated, ECOC model composed of linear classification models, specified as a `ClassificationPartitionedLinearECOC` model object. You can create a `ClassificationPartitionedLinearECOC` model using `fitcecoc` and by:

- 1 Specifying any one of the cross-validation, name-value pair arguments, for example, `CrossVal`

- Setting the name-value pair argument `Learners` to `'linear'` or a linear classification model template returned by `templateLinear`

To obtain estimates, `kfoldMargin` applies the same data used to cross-validate the ECOC model (X and Y).

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

BinaryLoss — Binary learner loss function

`'hamming'` | `'linear'` | `'logit'` | `'exponential'` | `'binodeviance'` | `'hinge'` | `'quadratic'` | function handle

Binary learner loss function, specified as the comma-separated pair consisting of `'BinaryLoss'` and a built-in, loss-function name or function handle.

- This table contains names and descriptions of the built-in functions, where y_j is a class label for a particular binary learner (in the set $\{-1, 1, 0\}$), s_j is the score for observation j , and $g(y_j, s_j)$ is the binary loss formula.

Value	Description	Score Domain	$g(y_j, s_j)$
<code>'binodeviance'</code>	Binomial deviance	$(-\infty, \infty)$	$\log[1 + \exp(-2y_j s_j)] / [2\log(2)]$
<code>'exponential'</code>	Exponential	$(-\infty, \infty)$	$\exp(-y_j s_j) / 2$
<code>'hamming'</code>	Hamming	$[0, 1]$ or $(-\infty, \infty)$	$[1 - \text{sign}(y_j s_j)] / 2$
<code>'hinge'</code>	Hinge	$(-\infty, \infty)$	$\max(0, 1 - y_j s_j) / 2$
<code>'linear'</code>	Linear	$(-\infty, \infty)$	$(1 - y_j s_j) / 2$
<code>'logit'</code>	Logistic	$(-\infty, \infty)$	$\log[1 + \exp(-y_j s_j)] / [2\log(2)]$
<code>'quadratic'</code>	Quadratic	$[0, 1]$	$[1 - y_j(2s_j - 1)]^2 / 2$

The software normalizes the binary losses such that the loss is 0.5 when $y_j = 0$. Also, the software calculates the mean binary loss for each class.

- For a custom binary loss function, e.g., `customFunction`, specify its function handle `'BinaryLoss',@customFunction`.

`customFunction` should have this form

```
bLoss = customFunction(M,s)
```

where:

- `M` is the K -by- L coding matrix stored in `Mdl.CodingMatrix`.
- `s` is the 1-by- L row vector of classification scores.
- `bLoss` is the classification loss. This scalar aggregates the binary losses for every learner in a particular class. For example, you can use the mean binary loss to aggregate the loss over the learners for each class.
- K is the number of classes.
- L is the number of binary learners.

For an example of passing a custom binary loss function, see “Predict Test-Sample Labels of ECOC Model Using Custom Binary Loss Function” on page 32-5219.

By default, if all binary learners are linear classification models using:

- SVM, then `BinaryLoss` is `'hinge'`
- Logistic regression, then `BinaryLoss` is `'quadratic'`

Example: `'BinaryLoss','binodeviance'`

Data Types: `char` | `string` | `function_handle`

Decoding — Decoding scheme

`'lossweighted'` (default) | `'lossbased'`

Decoding scheme that aggregates the binary losses, specified as the comma-separated pair consisting of `'Decoding'` and `'lossweighted'` or `'lossbased'`. For more information, see “Binary Loss” on page 32-3444.

Example: `'Decoding','lossbased'`

Options — Estimation options

`[]` (default) | structure array returned by `statset`

Estimation options, specified as the comma-separated pair consisting of `'Options'` and a structure array returned by `statset`.

To invoke parallel computing:

- You need a Parallel Computing Toolbox license.
- Specify 'Options', `statset('UseParallel',true)`.

Verbose — Verbosity level

0 (default) | 1

Verbosity level, specified as the comma-separated pair consisting of 'Verbose' and 0 or 1. Verbose controls the number of diagnostic messages that the software displays in the Command Window.

If Verbose is 0, then the software does not display diagnostic messages. Otherwise, the software displays diagnostic messages.

Example: 'Verbose',1

Data Types: single | double

Output Arguments

m — Cross-validated classification margins

numeric vector | numeric matrix

Cross-validated classification margins on page 32-3423, returned as a numeric vector or matrix.

m is n -by- L , where n is the number of observations in X and L is the number of regularization strengths in `Mdl` (that is, `numel(Mdl.Lambda)`).

$m(i,j)$ is the cross-validated classification margin of observation i using the ECOC model, composed of linear classification models, that has regularization strength `Mdl.Lambda(j)`.

Examples

Estimate k -Fold Cross-Validation Margins

Load the NLP data set.

```
load nlpdata
```

X is a sparse matrix of predictor data, and Y is a categorical vector of class labels.

For simplicity, use the label 'others' for all observations in Y that are not 'simulink', 'dsp', or 'comm'.

```
Y(~(ismember(Y,{'simulink','dsp','comm'}))) = 'others';
```

Cross-validate a multiclass, linear classification model.

```
rng(1); % For reproducibility
CVMdl = fitcecoc(X,Y,'Learner','linear','CrossVal','on');
```

CVMdl is a ClassificationPartitionedLinearECOC model. By default, the software implements 10-fold cross validation. You can alter the number of folds using the 'KFold' name-value pair argument.

Estimate the k -fold margins.

```
m = kfoldMargin(CVMdl);
size(m)
```

```
ans = 1×2
```

```
    31572         1
```

m is a 31572-by-1 vector. $m(j)$ is the average of the out-of-fold margins for observation j .

Plot the k -fold margins using box plots.

```
figure;
boxplot(m);
h = gca;
h.YLim = [-5 5];
title('Distribution of Cross-Validated Margins')
```

Feature Selection Using k -fold Margins

One way to perform feature selection is to compare k -fold margins from multiple models. Based solely on this criterion, the classifier with the larger margins is the better classifier.

Load the NLP data set. Preprocess the data as in “Estimate k -Fold Cross-Validation Margins” on page 32-3415, and orient the predictor data so that observations correspond to columns.

```
load nlpdata
Y(~(ismember(Y,{'simulink','dsp','comm'}))) = 'others';
X = X';
```

Create these two data sets:

- fullX contains all predictors.
- partX contains 1/2 of the predictors chosen at random.

```
rng(1); % For reproducibility
p = size(X,1); % Number of predictors
halfPredIdx = randsample(p,ceil(0.5*p));
fullX = X;
partX = X(halfPredIdx,:);
```

Create a linear classification model template that specifies optimizing the objective function using SpARSA.

```
t = templateLinear('Solver','sparsa');
```

Cross-validate two ECOC models composed of binary, linear classification models: one that uses the all of the predictors and one that uses half of the predictors. Indicate that observations correspond to columns.

```
CVMDL = fitcecoc(fullX,Y,'Learners',t,'CrossVal','on',...
    'ObservationsIn','columns');
PCVMDL = fitcecoc(partX,Y,'Learners',t,'CrossVal','on',...
    'ObservationsIn','columns');
```

CVMDL and PCVMDL are ClassificationPartitionedLinearECOC models.

Estimate the k -fold margins for each classifier. Plot the distribution of the k -fold margins sets using box plots.

```
fullMargins = kfoldMargin(CVMDL);
partMargins = kfoldMargin(PCVMDL);

figure;
boxplot([fullMargins partMargins],'Labels',...
    {'All Predictors','Half of the Predictors'});
h = gca;
h.YLim = [-1 1];
title('Distribution of Cross-Validated Margins')
```

The distributions of the k -fold margins of the two classifiers are similar.

Find Good Lasso Penalty Using k -fold Margins

To determine a good lasso-penalty strength for a linear classification model that uses a logistic regression learner, compare distributions of k -fold margins.

Load the NLP data set. Preprocess the data as in "Feature Selection Using k -fold Margins" on page 32-3417.

```
load nlpdata
Y(~(ismember(Y,{'simulink','dsp','comm'}))) = 'others';
X = X';
```

Create a set of 11 logarithmically-spaced regularization strengths from 10^{-8} through 10^1 .

```
Lambda = logspace(-8,1,11);
```

Create a linear classification model template that specifies using logistic regression with a lasso penalty, using each of the regularization strengths, optimizing the objective function using SpaRSA, and reducing the tolerance on the gradient of the objective function to $1e-8$.

```
t = templateLinear('Learner','logistic','Solver','sparsa',...
    'Regularization','lasso','Lambda',Lambda,'GradientTolerance',1e-8);
```

Cross-validate an ECOC model composed of binary, linear classification models using 5-fold cross-validation and that

```
rng(10); % For reproducibility
CVMdl = fitcecoc(X,Y,'Learners',t,'ObservationsIn','columns','KFold',5)
```

```
CVMdl =
  classreg.learning.partition.ClassificationPartitionedLinearECOC
  CrossValidatedModel: 'Linear'
  ResponseName: 'Y'
  NumObservations: 31572
  KFold: 5
  Partition: [1x1 cvpartition]
  ClassNames: [comm dsp simulink others]
  ScoreTransform: 'none'
```

Properties, Methods

CVMdl is a `ClassificationPartitionedLinearECOC` model.

Estimate the k -fold margins for each regularization strength. The scores for logistic regression are in $[0,1]$. Apply the quadratic binary loss.

```
m = kfoldMargin(CVMdl,'BinaryLoss','quadratic');
size(m)
```

```
ans = 1x2
```

31572

11

m is a 31572-by-11 matrix of cross-validated margins for each observation. The columns correspond to the regularization strengths.

Plot the k -fold margins for each regularization strength.

```
figure;  
boxplot(m)  
ylabel('Cross-validated margins')  
xlabel('Lambda indices')
```

Several values of `Lambda` yield similarly high margin distribution centers with low spreads. Higher values of `Lambda` lead to predictor variable sparsity, which is a good quality of a classifier.

Choose the regularization strength that occurs just before the margin distribution center starts decreasing and spread starts increasing.

```
LambdaFinal = Lambda(5);
```

Train an ECOC model composed of linear classification model using the entire data set and specify the regularization strength `LambdaFinal`.

```
t = templateLinear('Learner','logistic','Solver','sparsa',...  
    'Regularization','lasso','Lambda',Lambda(5),'GradientTolerance',1e-8);  
MdlFinal = fitcecoc(X,Y,'Learners',t,'ObservationsIn','columns');
```

To estimate labels for new observations, pass `MdlFinal` and the new data to `predict`.

Definitions

Binary Loss

A binary loss is a function of the class and classification score that determines how well a binary learner classifies an observation into the class.

Suppose the following:

- m_{kj} is element (k,j) of the coding design matrix M (that is, the code corresponding to class k of binary learner j).
- s_j is the score of binary learner j for an observation.
- g is the binary loss function.
- \hat{k} is the predicted class for the observation.

In loss-based decoding [Escalera et al.] on page 18-228, the class producing the minimum sum of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \operatorname{argmin}_k \sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j).$$

In loss-weighted decoding [Escalera et al.] on page 18-228, the class producing the minimum average of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \operatorname{argmin}_k \frac{\sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j)}{\sum_{j=1}^L |m_{kj}|}.$$

Allwein et al. on page 18-227 suggest that loss-weighted decoding improves classification accuracy by keeping loss values for all classes in the same dynamic range.

This table summarizes the supported loss functions, where y_j is a class label for a particular binary learner (in the set $\{-1, 1, 0\}$), s_j is the score for observation j , and $g(y_j, s_j)$.

Value	Description	Score Domain	$g(y_j, s_j)$
'binodeviance'	Binomial deviance	$(-\infty, \infty)$	$\log[1 + \exp(-2y_j s_j)] / [2\log(2)]$
'exponential'	Exponential	$(-\infty, \infty)$	$\exp(-y_j s_j) / 2$
'hamming'	Hamming	$[0, 1]$ or $(-\infty, \infty)$	$[1 - \operatorname{sign}(y_j s_j)] / 2$
'hinge'	Hinge	$(-\infty, \infty)$	$\max(0, 1 - y_j s_j) / 2$
'linear'	Linear	$(-\infty, \infty)$	$(1 - y_j s_j) / 2$
'logit'	Logistic	$(-\infty, \infty)$	$\log[1 + \exp(-y_j s_j)] / [2\log(2)]$
'quadratic'	Quadratic	$[0, 1]$	$[1 - y_j(2s_j - 1)]^2 / 2$

The software normalizes binary losses such that the loss is 0.5 when $y_j = 0$, and aggregates using the average of the binary learners [Allwein et al.] on page 18-227.

Do not confuse the binary loss with the overall classification loss (specified by the 'LossFun' name-value pair argument of the `loss` and `predict` object functions), which measures how well an ECOC classifier performs as a whole.

Classification Margin

The classification margin is, for each observation, the difference between the negative loss for the true class and the maximal negative loss among the false classes. If the

margins are on the same scale, then they serve as a classification confidence measure. Among multiple classifiers, those that yield greater margins are better.

Extended Capabilities

Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the `'UseParallel'` option to `true`.

Set the `'UseParallel'` field of the options structure to `true` using `statset` and specify the `'Options'` name-value pair argument in the call to this function.

For example: `'Options',statset('UseParallel',true)`

For more information, see the `'Options'` name-value pair argument.

For more general information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

kfoldMargin

Classification margins for observations not used for training

Syntax

```
M = kfoldMargin(obj)
```

Description

`M = kfoldMargin(obj)` returns classification margins obtained by cross-validated classification model `obj`. For every fold, this method computes classification margins for in-fold observations using a model trained on out-of-fold observations.

Input Arguments

obj

A partitioned classification model of type `ClassificationPartitionedModel` or `ClassificationPartitionedEnsemble`.

Output Arguments

M

The classification margin.

Examples

Estimate the *k*-fold Margins of a Classifier

Find the *k*-fold margins for an ensemble that classifies the `ionosphere` data.

Load the ionosphere data set.

```
load ionosphere
```

Create a template tree stump.

```
t = templateTree('MaxNumSplits',1);
```

Train a classification ensemble of decision trees. Specify `t` as the weak learner.

```
Mdl = fitcensemble(X,Y,'Method','AdaBoostM1','Learners',t);
```

Cross validate the classifier using 10-fold cross validation.

```
cvens = crossval(Mdl);
```

Compute the k-fold margins. Display summary statistics for the margins.

```
m = kfoldMargin(cvens);
marginStats = table(min(m),mean(m),max(m),...
    'VariableNames',{'Min','Mean','Max'})
```

```
marginStats=1x3 table
    Min      Mean      Max
-----
-11.312    7.3236    23.517
```

Definitions

Margin

The classification margin is the difference between the classification score for the true class and maximal classification score for the false classes.

The classification margin is a column vector with the same number of rows as in the matrix `X`. A high value of margin indicates a more reliable prediction than a low value.

Score

For discriminant analysis, the score of a classification is the posterior probability of the classification. For the definition of posterior probability in discriminant analysis, see “Posterior Probability” on page 20-6.

For ensembles, a classification score represents the confidence of a classification into a class. The higher the score, the higher the confidence.

Different ensemble algorithms have different definitions for their scores. Furthermore, the range of scores depends on ensemble type. For example:

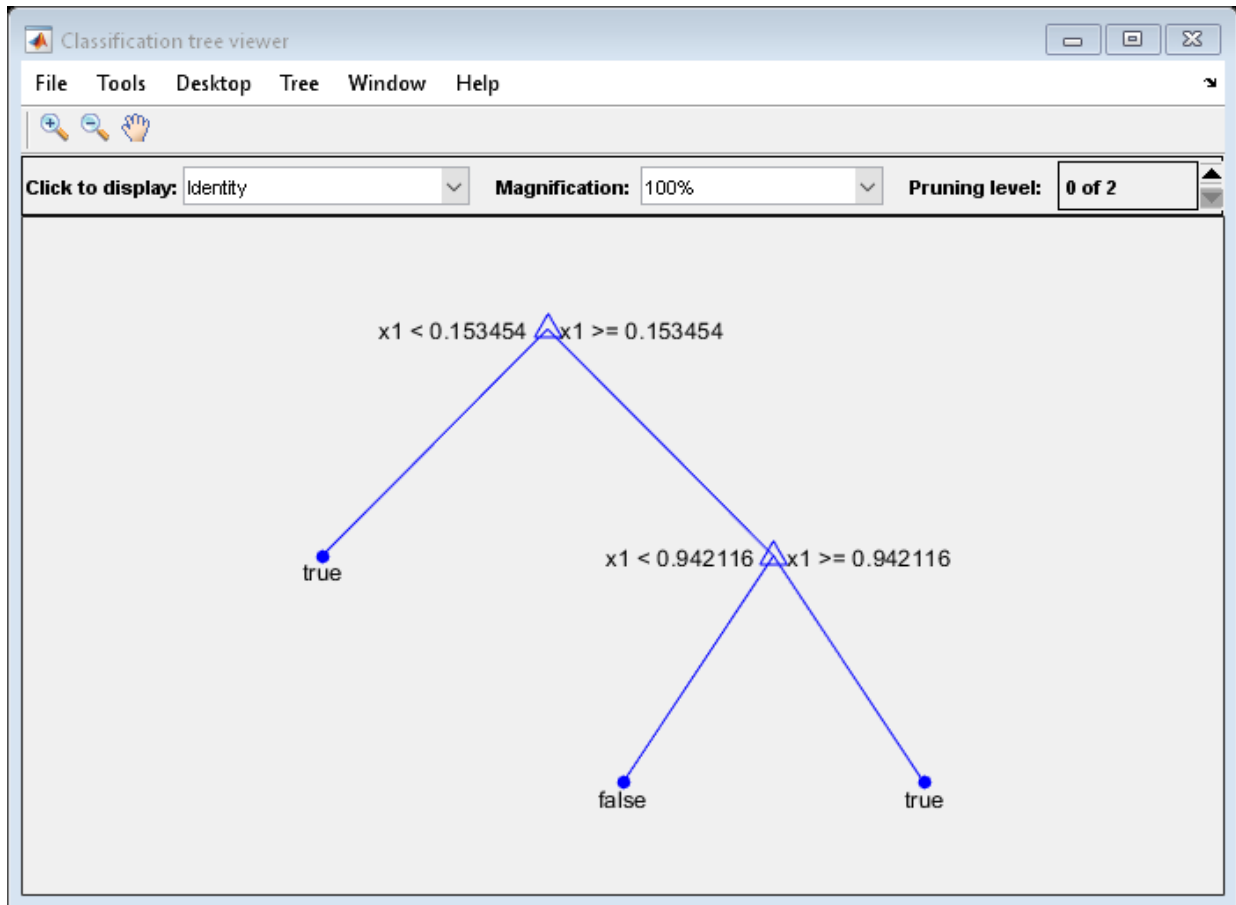

- AdaBoostM1 scores range from $-\infty$ to ∞ .
- Bag scores range from 0 to 1.

For trees, the score of a classification of a leaf node is the posterior probability of the classification at that node. The posterior probability of the classification at a node is the number of training sequences that lead to that node with the classification, divided by the number of training sequences that lead to that node.

For example, consider classifying a predictor X as true when $X < 0.15$ or $X > 0.95$, and X is false otherwise.

Generate 100 random points and classify them:

```
rng(0,'twister') % for reproducibility
X = rand(100,1);
Y = (abs(X - .55) > .4);
tree = fitctree(X,Y);
view(tree,'Mode','Graph')
```

Prune the tree:

```
tree1 = prune(tree, 'Level', 1);  
view(tree1, 'Mode', 'Graph')
```

The pruned tree correctly classifies observations that are less than 0.15 as `true`. It also correctly classifies observations from .15 to .94 as `false`. However, it incorrectly classifies observations that are greater than .94 as `false`. Therefore, the score for observations that are greater than .15 should be about $.05/.85=.06$ for `true`, and about $.8/.85=.94$ for `false`.

Compute the prediction scores for the first 10 rows of `X`:

```
[~,score] = predict(tree1,X(1:10));
[score X(1:10,:)]
```

```
ans = 10x3
    0.9059    0.0941    0.8147
    0.9059    0.0941    0.9058
         0     1.0000    0.1270
    0.9059    0.0941    0.9134
    0.9059    0.0941    0.6324
         0     1.0000    0.0975
    0.9059    0.0941    0.2785
    0.9059    0.0941    0.5469
    0.9059    0.0941    0.9575
    0.9059    0.0941    0.9649
```

Indeed, every value of X (the right-most column) that is less than 0.15 has associated scores (the left and center columns) of 0 and 1, while the other values of X have associated scores of 0.91 and 0.09. The difference (score 0.09 instead of the expected .06) is due to a statistical fluctuation: there are 8 observations in X in the range (.95, 1) instead of the expected 5 observations.

kfoldPredict

Package: `classreg.learning.partition`

Classify observations in cross-validated ECOC model

Syntax

```
label = kfoldPredict(CVMdl)
label = kfoldPredict(CVMdl,Name,Value)
[label,NegLoss,PBScore] = kfoldPredict(____)
[label,NegLoss,PBScore,Posterior] = kfoldPredict(____)
```

Description

`label = kfoldPredict(CVMdl)` returns class labels predicted by the cross-validated ECOC model (`ClassificationPartitionedECOC`) `CVMdl`. For every fold, `kfoldPredict` predicts class labels for observations that it holds out during training. `CVMdl.X` contains both sets of observations.

The software predicts the classification of an observation by assigning the observation to the class yielding the largest negated average binary loss (or, equivalently, the smallest average binary loss).

`label = kfoldPredict(CVMdl,Name,Value)` returns predicted class labels with additional options specified by one or more name-value pair arguments. For example, specify the posterior probability estimation method, decoding scheme, or verbosity level.

`[label,NegLoss,PBScore] = kfoldPredict(____)` additionally returns negated values of the average binary loss per class (`NegLoss`) for validation-fold observations and positive-class scores (`PBScore`) for validation-fold observations classified by each binary learner, using any of the input argument combinations in the previous syntaxes.

If the coding matrix varies across folds (that is, the coding scheme is `sparseandom` or `denserandom`), then `PBScore` is empty (`[]`).

[label, NegLoss, PBScore, Posterior] = kfoldPredict(___) additionally returns posterior class probability estimates for validation-fold observations (Posterior).

To obtain posterior class probabilities, you must set 'FitPosterior', 1 when training the cross-validated ECOC model using fitcecoc. Otherwise, kfoldPredict throws an error.

Examples

Predict *k*-Fold Cross-Validation Labels

Load Fisher's iris data set. Specify the predictor data X, the response data Y, and the order of the classes in Y.

```
load fisheriris
X = meas;
Y = categorical(species);
classOrder = unique(Y);
rng(1); % For reproducibility
```

Train and cross-validate an ECOC model using support vector machine (SVM) binary classifiers. Standardize the predictor data using an SVM template, and specify the class order.

```
t = templateSVM('Standardize',1);
CVMdl = fitcecoc(X,Y,'CrossVal','on','Learners',t,'ClassNames',classOrder);
```

CVMdl is a ClassificationPartitionedECOC model. By default, the software implements 10-fold cross-validation. You can specify a different number of folds using the 'KFold' name-value pair argument.

Predict the validation-fold labels. Print a random subset of true and predicted labels.

```
labels = kfoldPredict(CVMdl);
idx = randsample(numel(labels),10);
table(Y(idx),labels(idx),...
      'VariableNames',{'TrueLabels','PredictedLabels'})
```

```
ans=10x2 table
   TrueLabels   PredictedLabels
```

```
setosa      setosa
versicolor versicolor
setosa      setosa
virginica   virginica
versicolor versicolor
setosa      setosa
virginica   virginica
virginica   virginica
setosa      setosa
setosa      setosa
```

CVMDL correctly labels the validation-fold observations with indices `idx`.

Predict Cross-Validation Labels Using Custom Binary Loss Function

Load Fisher's iris data set. Specify the predictor data `X`, the response data `Y`, and the order of the classes in `Y`.

```
load fisheriris
X = meas;
Y = categorical(species);
classOrder = unique(Y); % Class order
K = numel(classOrder); % Number of classes
rng(1); % For reproducibility
```

Train and cross-validate an ECOC model using SVM binary classifiers. Standardize the predictor data using an SVM template, and specify the class order.

```
t = templateSVM('Standardize',1);
CVMDL = fitcecoc(X,Y,'CrossVal','on','Learners',t,'ClassNames',classOrder);
```

CVMDL is a `ClassificationPartitionedECOC` model. By default, the software implements 10-fold cross-validation. You can specify a different number of folds using the `'KFold'` name-value pair argument.

SVM scores are signed distances from the observation to the decision boundary. Therefore, the domain is $(-\infty, \infty)$. Create a custom binary loss function that:

- Maps the coding design matrix (M) and positive-class classification scores (s) for each learner to the binary loss for each observation
- Uses linear loss
- Aggregates the binary learner loss using the median

You can create a separate function for the binary loss function, and then save it on the MATLAB® path. Alternatively, you can specify an anonymous binary loss function. In this case, create a function handle (`customBL`) to an anonymous binary loss function.

```
customBL = @(M,s)nanmedian(1 - bsxfun(@times,M,s),2)/2;
```

Predict cross-validation labels and estimate the median binary loss per class. Print the median negative binary losses per class for a random set of 10 validation-fold observations.

```
[label,NegLoss] = kfoldPredict(CVMdl,'BinaryLoss',customBL);
```

```
idx = randsample(numel(label),10);
classOrder
```

```
classOrder = 3x1 categorical array
    setosa
    versicolor
    virginica
```

```
table(Y(idx),label(idx),NegLoss(idx,:),'VariableNames',...
    {'TrueLabel','PredictedLabel','NegLoss'})
```

```
ans=10x3 table
    TrueLabel    PredictedLabel    NegLoss
```

TrueLabel	PredictedLabel	NegLoss
setosa	versicolor	0.37141
versicolor	versicolor	-1.2167
setosa	versicolor	0.23927
virginica	virginica	-1.9154
versicolor	versicolor	-1.3746
setosa	versicolor	0.20061
virginica	versicolor	-1.4928
virginica	virginica	-1.7669
setosa	versicolor	0.19999
setosa	versicolor	0.16108

The order of the columns corresponds to the elements of `classOrder`. The software predicts the label based on the maximum negated loss. The results indicate that the median of the linear losses might not perform as well as other losses.

Estimate Cross-Validation Posterior Probabilities

Load Fisher's iris data set. Use the petal dimensions as the predictor data `X`. Specify the response data `Y` and the order of the classes in `Y`.

```
load fisheriris
X = meas(:,3:4);
Y = categorical(species);
classOrder = unique(Y);
rng(1); % For reproducibility
```

Create an SVM template. Standardize the predictors, and specify the Gaussian kernel.

```
t = templateSVM('Standardize',1,'KernelFunction','gaussian');
```

`t` is an SVM template. Most of its properties are empty. When training the ECOC classifier, the software sets the applicable properties to their default values.

Train and cross-validate an ECOC classifier using the SVM template. Transform classification scores to class posterior probabilities (returned by `kfoldPredict`) using the 'FitPosterior' name-value pair argument. Specify the class order.

```
CVMdl = fitcecoc(X,Y,'Learners',t,'CrossVal','on','FitPosterior',true,...
    'ClassNames',classOrder);
```

`CVMdl` is a `ClassificationPartitionedECOC` model. By default, the software uses 10-fold cross-validation.

Predict the validation-fold class posterior probabilities. Use 10 random initial values for the Kullback-Leibler algorithm.

```
[label,~,~,Posterior] = kfoldPredict(CVMdl,'NumKLInitializations',10);
```

The software assigns an observation to the class that yields the smallest average binary loss. Because all the binary learners compute posterior probabilities, the binary loss function is quadratic.

Display a random set of results.

```

idx = randsample(size(X,1),10);
CVMdl.ClassNames

ans = 3x1 categorical array
    setosa
    versicolor
    virginica

table(Y(idx),label(idx),Posterior(idx,:),...
      'VariableNames',{'TrueLabel','PredLabel','Posterior'})

ans=10x3 table
    TrueLabel      PredLabel      Posterior
    _____      _____      _____
    versicolor    versicolor    0.0086394    0.98243    0.0089291
    versicolor    virginica     2.2197e-14    0.12447    0.87553
    setosa        setosa        0.999        0.00022837 0.00076884
    versicolor    versicolor    2.2194e-14    0.98916    0.010839
    virginica     virginica     0.012318     0.012925    0.97476
    virginica     virginica     0.0015571    0.0015638    0.99688
    virginica     virginica     0.0042895    0.0043556    0.99135
    setosa        setosa        0.999        0.00028329 0.00071382
    virginica     virginica     0.0094721    0.0098231    0.9807
    setosa        setosa        0.999        0.00013562 0.00086192

```

The columns of Posterior correspond to the class order of CVMdl.ClassNames.

Estimate Cross-Validation Posterior Probabilities Using Parallel Computing

Train a multiclass ECOC model and estimate the posterior probabilities using parallel computing.

Load the arrhythmia data set. Examine the response data Y.

```

load arrhythmia
Y = categorical(Y);
tabulate(Y)

    Value      Count      Percent
    _____      _____      _____
    1           245         54.20%

```

2	44	9.73%
3	15	3.32%
4	15	3.32%
5	13	2.88%
6	25	5.53%
7	3	0.66%
8	2	0.44%
9	9	1.99%
10	50	11.06%
14	4	0.88%
15	5	1.11%
16	22	4.87%

```
n = numel(Y);  
K = numel(unique(Y));
```

Several classes are not represented in the data, and many of the other classes have low relative frequencies.

Specify an ensemble learning template that uses the GentleBoost method and 50 weak classification tree learners.

```
t = templateEnsemble('GentleBoost',50,'Tree');
```

`t` is a template object. Most of the options are empty (`[]`). The software uses default values for all empty options during training.

Because the response variable contains many classes, specify a sparse random coding design.

```
rng(1); % For reproducibility  
Coding = designecoc(K,'sparserandom');
```

Train and cross-validate an ECOC model using parallel computing. Fit posterior probabilities (returned by `kfoldPredict`).

```
pool = parpool; % Invokes workers
```

Starting parallel pool (`parpool`) using the 'local' profile ...
connected to 6 workers.

```
options = statset('UseParallel',1);  
CVMdl = fitcecoc(X,Y,'Learner',t,'Options',options,'Coding',Coding,...  
    'FitPosterior',1,'CrossVal','on');
```

Warning: One or more folds do not contain points from all the groups.

CVMdl is a `ClassificationPartitionedECOC` model. By default, the software implements 10-fold cross-validation. You can specify a different number of folds using the 'KFold' name-value pair argument.

The pool invokes six workers, although the number of workers might vary among systems. Because some classes have low relative frequency, one or more folds most likely do not contain observations from all classes.

Estimate posterior probabilities, and display the posterior probability of being classified as not having arrhythmia (class 1) given the data for a random set of validation-fold observations.

```
[~,~,~,posterior] = kfoldPredict(CVMdl,'Options',options);
idx = randsample(n,10);
table(idx,Y(idx),posterior(idx,1),...
      'VariableNames',{'00FSampleIndex','TrueLabel','PosteriorNoArrhythmia'})
```

```
ans=10x3 table
      00FSampleIndex      TrueLabel      PosteriorNoArrhythmia
      _____      _____      _____
           171              1              0.33654
           221              1              0.85135
            72             16              0.9174
            3             10             0.025649
          202              1              0.8438
          243              1              0.9435
            18              1              0.81198
            49              6             0.090154
          234              1              0.61625
          315              1              0.97187
```

Input Arguments

CVMdl — Cross-validated ECOC model

`ClassificationPartitionedECOC` model

Cross-validated ECOC model, specified as a `ClassificationPartitionedECOC` model. You can create a `ClassificationPartitionedECOC` model in two ways:

- Pass a trained ECOC model (`ClassificationECOC`) to `crossval`.
- Train an ECOC model using `fitcecoc` and specify any one of these cross-validation name-value pair arguments: `'CrossVal'`, `'CVPartition'`, `'Holdout'`, `'KFold'`, or `'Leaveout'`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example: `kfoldPredict(CVMdl, 'PosteriorMethod', 'qp')` specifies to estimate multiclass posterior probabilities by solving a least-squares problem using quadratic programming.

BinaryLoss — Binary learner loss function

'hamming' | 'linear' | 'logit' | 'exponential' | 'binodeviance' | 'hinge' | 'quadratic' | function handle

Binary learner loss function, specified as the comma-separated pair consisting of `'BinaryLoss'` and a built-in loss function name or function handle.

- This table describes the built-in functions, where y_j is a class label for a particular binary learner (in the set $\{-1, 1, 0\}$), s_j is the score for observation j , and $g(y_j, s_j)$ is the binary loss formula.

Value	Description	Score Domain	$g(y_j, s_j)$
'binodeviance'	Binomial deviance	$(-\infty, \infty)$	$\log[1 + \exp(-2y_j s_j)] / [2\log(2)]$
'exponential'	Exponential	$(-\infty, \infty)$	$\exp(-y_j s_j) / 2$
'hamming'	Hamming	$[0, 1]$ or $(-\infty, \infty)$	$[1 - \text{sign}(y_j s_j)] / 2$
'hinge'	Hinge	$(-\infty, \infty)$	$\max(0, 1 - y_j s_j) / 2$
'linear'	Linear	$(-\infty, \infty)$	$(1 - y_j s_j) / 2$
'logit'	Logistic	$(-\infty, \infty)$	$\log[1 + \exp(-y_j s_j)] / [2\log(2)]$
'quadratic'	Quadratic	$[0, 1]$	$[1 - y_j(2s_j - 1)]^2 / 2$

The software normalizes binary losses so that the loss is 0.5 when $y_j = 0$. Also, the software calculates the mean binary loss for each class.

- For a custom binary loss function, for example `customFunction`, specify its function handle `'BinaryLoss',@customFunction`.

`customFunction` has this form:

```
bLoss = customFunction(M,s)
```

where:

- `M` is the K -by- L coding matrix stored in `Mdl.CodingMatrix`.
- `s` is the 1-by- L row vector of classification scores.
- `bLoss` is the classification loss. This scalar aggregates the binary losses for every learner in a particular class. For example, you can use the mean binary loss to aggregate the loss over the learners for each class.
- K is the number of classes.
- L is the number of binary learners.

For an example of passing a custom binary loss function, see “Predict Test-Sample Labels of ECOC Model Using Custom Binary Loss Function” on page 32-5219.

The default `BinaryLoss` value depends on the score ranges returned by the binary learners. This table describes some default `BinaryLoss` values based on the given assumptions.

Assumption	Default Value
All binary learners are SVMs or either linear or kernel classification models of SVM learners.	'hinge'
All binary learners are ensembles trained by <code>AdaboostM1</code> or <code>GentleBoost</code> .	'exponential'
All binary learners are ensembles trained by <code>LogitBoost</code> .	'binodeviance'
All binary learners are linear or kernel classification models of logistic regression learners. Or, you specify to predict class posterior probabilities by setting <code>'FitPosterior',true</code> in <code>fitcecoc</code> .	'quadratic'

To check the default value, use dot notation to display the `BinaryLoss` property of the trained model at the command line.

Example: 'BinaryLoss', 'binodeviance'

Data Types: char | string | function_handle

Decoding — Decoding scheme

'lossweighted' (default) | 'lossbased'

Decoding scheme that aggregates the binary losses, specified as the comma-separated pair consisting of 'Decoding' and 'lossweighted' or 'lossbased'. For more information, see “Binary Loss” on page 32-3444.

Example: 'Decoding', 'lossbased'

NumKLInitializations — Number of random initial values

0 (default) | nonnegative integer scalar

Number of random initial values for fitting posterior probabilities by Kullback-Leibler divergence minimization, specified as the comma-separated pair consisting of 'NumKLInitializations' and a nonnegative integer scalar.

If you do not request the fourth output argument (Posterior) and set 'PosteriorMethod', 'kl' (the default), then the software ignores the value of NumKLInitializations.

For more details, see “Posterior Estimation Using Kullback-Leibler Divergence” on page 32-3446.

Example: 'NumKLInitializations', 5

Data Types: single | double

Options — Estimation options

[] (default) | structure array returned by `statset`

Estimation options, specified as the comma-separated pair consisting of 'Options' and a structure array returned by `statset`.

To invoke parallel computing:

- You need a Parallel Computing Toolbox license.
- Specify 'Options', `statset('UseParallel', true)`.

PosteriorMethod — Posterior probability estimation method

'kl' (default) | 'qp'

Posterior probability estimation method, specified as the comma-separated pair consisting of 'PosteriorMethod' and 'kl' or 'qp'.

- If `PosteriorMethod` is 'kl', then the software estimates multiclass posterior probabilities by minimizing the Kullback-Leibler divergence between the predicted and expected posterior probabilities returned by binary learners. For details, see “Posterior Estimation Using Kullback-Leibler Divergence” on page 32-3446.
- If `PosteriorMethod` is 'qp', then the software estimates multiclass posterior probabilities by solving a least-squares problem using quadratic programming. You need an Optimization Toolbox license to use this option. For details, see “Posterior Estimation Using Quadratic Programming” on page 32-3448.
- If you do not request the fourth output argument (`Posterior`), then the software ignores the value of `PosteriorMethod`.

Example: 'PosteriorMethod', 'qp'

Verbose — Verbosity level

0 (default) | 1

Verbosity level, specified as the comma-separated pair consisting of 'Verbose' and 0 or 1. `Verbose` controls the number of diagnostic messages that the software displays in the Command Window.

If `Verbose` is 0, then the software does not display diagnostic messages. Otherwise, the software displays diagnostic messages.

Example: 'Verbose', 1

Data Types: single | double

Output Arguments

label — Predicted class labels

categorical array | character array | logical vector | numeric vector | cell array of character vectors

Predicted class labels, returned as a categorical or character array, logical or numeric vector, or cell array of character vectors.

`label` has the same data type and number of rows as `CVMDL.Y`.

The software predicts the classification of an observation by assigning the observation to the class yielding the largest negated average binary loss (or, equivalently, the smallest average binary loss).

NegLoss — Negated average binary losses

numeric matrix

Negated average binary losses, returned as a numeric matrix. `NegLoss` is an n -by- K matrix, where n is the number of observations (`size(CVMdl.X,1)`) and K is the number of unique classes (`size(CVMdl.ClassNames,1)`).

PBScore — Positive-class scores

numeric matrix

Positive-class scores for each binary learner, returned as a numeric matrix. `PBScore` is an n -by- L matrix, where n is the number of observations (`size(CVMdl.X,1)`) and L is the number of binary learners (`size(CVMdl.CodingMatrix,2)`).

If the coding matrix varies across folds (that is, the coding scheme is `sparserandom` or `denserandom`), then `PBScore` is empty (`[]`).

Posterior — Posterior class probabilities

numeric matrix

Posterior class probabilities, returned as a numeric matrix. `Posterior` is an n -by- K matrix, where n is the number of observations (`size(CVMdl.X,1)`) and K is the number of unique classes (`size(CVMdl.ClassNames,1)`).

You must set `'FitPosterior',1` when training the cross-validated ECOC model using `fitcecoc` in order to request `Posterior`. Otherwise, the software throws an error.

Definitions

Binary Loss

A binary loss is a function of the class and classification score that determines how well a binary learner classifies an observation into the class.

Suppose the following:

- m_{kj} is element (k,j) of the coding design matrix M (that is, the code corresponding to class k of binary learner j).
- s_j is the score of binary learner j for an observation.
- g is the binary loss function.
- \hat{k} is the predicted class for the observation.

In loss-based decoding [Escalera et al.] on page 18-228, the class producing the minimum sum of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \operatorname{argmin}_k \sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j).$$

In loss-weighted decoding [Escalera et al.] on page 18-228, the class producing the minimum average of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \operatorname{argmin}_k \frac{\sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j)}{\sum_{j=1}^L |m_{kj}|}.$$

Allwein et al. on page 18-227 suggest that loss-weighted decoding improves classification accuracy by keeping loss values for all classes in the same dynamic range.

This table summarizes the supported loss functions, where y_j is a class label for a particular binary learner (in the set $\{-1,1,0\}$), s_j is the score for observation j , and $g(y_j, s_j)$.

Value	Description	Score Domain	$g(y_j, s_j)$
'binodeviance'	Binomial deviance	$(-\infty, \infty)$	$\log[1 + \exp(-2y_j s_j)] / [2\log(2)]$
'exponential'	Exponential	$(-\infty, \infty)$	$\exp(-y_j s_j) / 2$
'hamming'	Hamming	$[0,1]$ or $(-\infty, \infty)$	$[1 - \operatorname{sign}(y_j s_j)] / 2$
'hinge'	Hinge	$(-\infty, \infty)$	$\max(0, 1 - y_j s_j) / 2$
'linear'	Linear	$(-\infty, \infty)$	$(1 - y_j s_j) / 2$

Value	Description	Score Domain	$g(y_j, s_j)$
'logit'	Logistic	$(-\infty, \infty)$	$\log[1 + \exp(-y_j s_j)] / [2\log(2)]$
'quadratic'	Quadratic	[0,1]	$[1 - y_j(2s_j - 1)]^2/2$

The software normalizes binary losses such that the loss is 0.5 when $y_j = 0$, and aggregates using the average of the binary learners [Allwein et al.] on page 18-227.

Do not confuse the binary loss with the overall classification loss (specified by the 'LossFun' name-value pair argument of the `loss` and `predict` object functions), which measures how well an ECOC classifier performs as a whole.

Algorithms

The software can estimate class posterior probabilities by minimizing the Kullback-Leibler divergence or by using quadratic programming. For the following descriptions of the posterior estimation algorithms, assume that:

- m_{kj} is the element (k,j) of the coding design matrix M .
- I is the indicator function.
- \hat{p}_k is the class posterior probability estimate for class k of an observation, $k = 1, \dots, K$.
- r_j is the positive-class posterior probability for binary learner j . That is, r_j is the probability that binary learner j classifies an observation into the positive class, given the training data.

Posterior Estimation Using Kullback-Leibler Divergence

By default, the software minimizes the Kullback-Leibler divergence to estimate class posterior probabilities. The Kullback-Leibler divergence between the expected and observed positive-class posterior probabilities is

$$\Delta(r, \hat{r}) = \sum_{j=1}^L w_j \left[r_j \log \frac{r_j}{\hat{r}_j} + (1 - r_j) \log \frac{1 - r_j}{1 - \hat{r}_j} \right],$$

where $w_j = \sum_{s_j} w_i^*$ is the weight for binary learner j .

- S_j is the set of observation indices on which binary learner j is trained.
- w_i^* is the weight of observation i .

The software minimizes the divergence iteratively. The first step is to choose initial values $\widehat{p}_k^{(0)}$; $k = 1, \dots, K$ for the class posterior probabilities.

- If you do not specify 'NumKLIterations', then the software tries both sets of deterministic initial values described next, and selects the set that minimizes Δ .

- $\widehat{p}_k^{(0)} = 1/K$; $k = 1, \dots, K$.
- $\widehat{p}_k^{(0)}$; $k = 1, \dots, K$ is the solution of the system

$$M_{01}\widehat{p}^{(0)} = r,$$

where M_{01} is M with all $m_{kj} = -1$ replaced with 0, and r is a vector of positive-class posterior probabilities returned by the L binary learners [Dietterich et al.] on page 18-228. The software uses `lsqnonneg` to solve the system.

- If you specify 'NumKLIterations', c , where c is a natural number, then the software does the following to choose the set $\widehat{p}_k^{(0)}$; $k = 1, \dots, K$, and selects the set that minimizes Δ .
 - The software tries both sets of deterministic initial values as described previously.
 - The software randomly generates c vectors of length K using `rand`, and then normalizes each vector to sum to 1.

At iteration t , the software completes these steps:

- 1 Compute

$$\widehat{r}_j^{(t)} = \frac{\sum_{k=1}^K \widehat{p}_k^{(t)} I(m_{kj} = +1)}{\sum_{k=1}^K \widehat{p}_k^{(t)} I(m_{kj} = +1 \cup m_{kj} = -1)}.$$

- 2 Estimate the next class posterior probability using

$$\widehat{p}_k^{(t+1)} = \widehat{p}_k^{(t)} \frac{\sum_{j=1}^L w_j [r_j I(m_{kj} = +1) + (1 - r_j) I(m_{kj} = -1)]}{\sum_{j=1}^L w_j [\widehat{r}_j^{(t)} I(m_{kj} = +1) + (1 - \widehat{r}_j^{(t)}) I(m_{kj} = -1)]}.$$

- 3 Normalize $\widehat{p}_k^{(t+1)}$; $k = 1, \dots, K$ so that they sum to 1.
- 4 Check for convergence.

For more details, see [Hastie et al.] on page 18-228 and [Zadrozny] on page 18-230.

Posterior Estimation Using Quadratic Programming

Posterior probability estimation using quadratic programming requires an Optimization Toolbox license. To estimate posterior probabilities for an observation using this method, the software completes these steps:

- 1 Estimate the positive-class posterior probabilities, r_j , for binary learners $j = 1, \dots, L$.
- 2 Using the relationship between r_j and \widehat{p}_k [Wu et al.] on page 18-230, minimize

$$\sum_{j=1}^L \left[-r_j \sum_{k=1}^K \widehat{p}_k I(m_{kj} = -1) + (1 - r_j) \sum_{k=1}^K \widehat{p}_k I(m_{kj} = +1) \right]^2$$

with respect to \widehat{p}_k and the restrictions

$$0 \leq \widehat{p}_k \leq 1$$

$$\sum_k \widehat{p}_k = 1.$$

The software performs minimization using `quadprog`.

Extended Capabilities

Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the 'UseParallel' option to true.

Set the 'UseParallel' field of the options structure to true using `statset` and specify the 'Options' name-value pair argument in the call to this function.

For example: `'Options',statset('UseParallel',true)`

For more information, see the 'Options' name-value pair argument.

For more general information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

kfoldPredict

Package: classreg.learning.partition

Classify observations in cross-validated kernel classification model

Syntax

```
label = kfoldPredict(CVMdl)
[label,score] = kfoldPredict(CVMdl)
```

Description

`label = kfoldPredict(CVMdl)` returns class labels predicted by the cross-validated, binary kernel model (`ClassificationPartitionedKernel`) `CVMdl`. For every fold, `kfoldPredict` predicts class labels for validation-fold observations using a model trained on training-fold observations.

`[label,score] = kfoldPredict(CVMdl)` also returns classification scores on page 32-3457 for both classes.

Examples

Classify Observations Using Cross-Validation

Classify observations using a cross-validated, binary kernel classifier, and display the confusion matrix for the resulting classification.

Load the `ionosphere` data set. This data set has 34 predictors and 351 binary responses for radar returns, which are labeled either bad ('b') or good ('g').

```
load ionosphere
```

Cross-validate a binary kernel classification model using the data.

```
rng(1); % For reproducibility
CVMdl = fitckernel(X,Y,'Crossval','on')

CVMdl =
    classreg.learning.partition.ClassificationPartitionedKernel
    CrossValidatedModel: 'Kernel'
    ResponseName: 'Y'
    NumObservations: 351
    KFold: 10
    Partition: [1x1 cvpartition]
    ClassNames: {'b' 'g'}
    ScoreTransform: 'none'
```

Properties, Methods

`CVMdl` is a `ClassificationPartitionedKernel` model. By default, the software implements 10-fold cross-validation. To specify a different number of folds, use the `'KFold'` name-value pair argument instead of `'Crossval'`.

Classify the observations that `fitckernel` does not use in training the folds.

```
label = kfoldPredict(CVMdl);
```

Construct a confusion matrix to compare the true classes of the observations to their predicted labels.

```
C = confusionchart(Y,label);
```

The `CVMdl` model misclassifies 32 good ('g') radar returns as being bad ('b') and misclassifies 7 bad radar returns as being good.

Estimate *k*-Fold Cross-Validation Posterior Class Probabilities

Estimate posterior class probabilities using a cross-validated, binary kernel classifier, and determine the quality of the model by plotting a receiver operating characteristic (ROC) curve. Cross-validated kernel classification models return posterior probabilities for logistic regression learners only.

Load the `ionosphere` data set. This data set has 34 predictors and 351 binary responses for radar returns, which are labeled either bad ('b') or good ('g').

```
load ionosphere
```

Cross-validate a binary kernel classification model using the data. Specify the class order, and fit logistic regression learners.

```
rng(1); % For reproducibility
CVMdl = fitckernel(X,Y,'Crossval','on', ...
    'ClassNames',{'b','g'},'Learner','logistic')

CVMdl =
    classreg.learning.partition.ClassificationPartitionedKernel
    CrossValidatedModel: 'Kernel'
    ResponseName: 'Y'
    NumObservations: 351
    KFold: 10
    Partition: [1x1 cvpartition]
    ClassNames: {'b' 'g'}
    ScoreTransform: 'none'
```

Properties, Methods

`CVMdl` is a `ClassificationPartitionedKernel` model. By default, the software implements 10-fold cross-validation. To specify a different number of folds, use the 'KFold' name-value pair argument instead of 'Crossval'.

Predict the posterior class probabilities for the observations that `fitckernel` does not use in training the folds.

```
[~,posterior] = kfoldPredict(CVMdl);
```

The output `posterior` is a matrix with two columns and `n` rows, where `n` is the number of observations. Column `i` contains posterior probabilities of `CVMdl.ClassNames(i)` given a particular observation.

Obtain false and true positive rates, and estimate the area under the curve (AUC). Specify that the second class is the positive class.

```
[fpr,tpr,~,auc] = perfcurve(Y,posterior(:,2),CVMdl.ClassNames(2));
auc
```

```
auc = 0.9441
```

The AUC is close to 1, which indicates that the model predicts labels well.

Plot an ROC curve.

```
plot(fpr, tpr)  
xlabel('False positive rate')  
ylabel('True positive rate')  
title('ROC Curve')
```

Input Arguments

CVMDL — Cross-validated, binary kernel classification model

`ClassificationPartitionedKernel` model object

Cross-validated, binary kernel classification model, specified as a `ClassificationPartitionedKernel` model object. You can create a `ClassificationPartitionedKernel` model by using `fitckernel` and specifying any one of the cross-validation name-value pair arguments.

To obtain estimates, `kfoldPredict` applies the same data used to cross-validate the kernel classification model (X and Y).

Output Arguments

label — Predicted class labels

categorical array | character array | logical matrix | numeric matrix | cell array of character vectors

Predicted class labels, returned as a categorical or character array, logical or numeric matrix, or cell array of character vectors.

`label` has n rows, where n is the number of observations in X , and has the same data type as the observed class labels (Y) used to train `CVMDL`. (The software treats string arrays as cell arrays of character vectors.)

`kfoldPredict` classifies observations into the class yielding the highest score.

score — Classification scores

numeric array

Classification scores on page 32-3457, returned as an n -by-2 numeric array, where n is the number of observations in X . `score(i, j)` is the score for classifying observation i into class j . The order of the classes is stored in `CVMDL.ClassNames`.

If `CVMDL.Trained{1}.Learner` is `'logistic'`, then classification scores are posterior probabilities.

Definitions

Classification Score

For kernel classification models, the raw classification score for classifying the observation x , a row vector, into the positive class is defined by

$$f(x) = T(x)\beta + b.$$

- $T(\cdot)$ is a transformation of an observation for feature expansion.
- β is the estimated column vector of coefficients.
- b is the estimated scalar bias.

The raw classification score for classifying x into the negative class is $-f(x)$. The software classifies observations into the class that yields a positive score.

If the kernel classification model consists of logistic regression learners, then the software applies the 'logit' score transformation to the raw classification scores (see `ScoreTransform`).

`ClassificationPartitionedKernel` | `fitckernel`

Introduced in R2018b

kfoldPredict

Package: `classreg.learning.partition`

Classify observations in cross-validated kernel ECOC model

Syntax

```
label = kfoldPredict(CVMdl)
label = kfoldPredict(CVMdl, Name, Value)
[label, NegLoss, PBScore] = kfoldPredict( ___ )
[label, NegLoss, PBScore, Posterior] = kfoldPredict( ___ )
```

Description

`label = kfoldPredict(CVMdl)` returns class labels predicted by the cross-validated kernel ECOC model (`ClassificationPartitionedKernelECOC`) `CVMdl`. For every fold, `kfoldPredict` predicts class labels for validation-fold observations using a model trained on training-fold observations. `kfoldPredict` applies the same data used to create `CVMdl` (see `fitcecoc`).

The software predicts the classification of an observation by assigning the observation to the class yielding the largest negated average binary loss (or, equivalently, the smallest average binary loss).

`label = kfoldPredict(CVMdl, Name, Value)` returns predicted class labels with additional options specified by one or more name-value pair arguments. For example, specify the posterior probability estimation method, decoding scheme, or verbosity level.

`[label, NegLoss, PBScore] = kfoldPredict(___)` additionally returns negated values of the average binary loss per class (`NegLoss`) for validation-fold observations and positive-class scores (`PBScore`) for validation-fold observations classified by each binary learner, using any of the input argument combinations in the previous syntaxes.

If the coding matrix varies across folds (that is, the coding scheme is `sparseandom` or `denserandom`), then `PBScore` is empty (`[]`).

[label, NegLoss, PBScore, Posterior] = kfoldPredict(___) additionally returns posterior class probability estimates for validation-fold observations (Posterior).

To obtain posterior class probabilities, the kernel classification binary learners must be logistic regression models. Otherwise, kfoldPredict throws an error.

Examples

Classify Observations Using Cross-Validation

Classify observations using a cross-validated, multiclass kernel ECOC classifier, and display the confusion matrix for the resulting classification.

Load Fisher's iris data set. X contains flower measurements, and Y contains the names of flower species.

```
load fisheriris
X = meas;
Y = species;
```

Cross-validate an ECOC model composed of kernel binary learners.

```
rng(1); % For reproducibility
CVMdl = fitcecoc(X,Y,'Learners','kernel','CrossVal','on')

CVMdl =
  classreg.learning.partition.ClassificationPartitionedKernelECOC
    CrossValidatedModel: 'KernelECOC'
      ResponseName: 'Y'
    NumObservations: 150
      KFold: 10
    Partition: [1x1 cvpartition]
    ClassNames: {'setosa' 'versicolor' 'virginica'}
    ScoreTransform: 'none'
```

Properties, Methods

CVMdl is a `ClassificationPartitionedKernelECOC` model. By default, the software implements 10-fold cross-validation. To specify a different number of folds, use the 'KFold' name-value pair argument instead of 'Crossval'.

Classify the observations that `fitcecoc` does not use in training the folds.

```
label = kfoldPredict(CVMdl);
```

Construct a confusion matrix to compare the true classes of the observations to their predicted labels.

```
C = confusionchart(Y,label);
```

The CVMdl model misclassifies four 'versicolor' irises as 'virginica' irises and misclassifies one 'virginica' iris as a 'versicolor' iris.

Predict Cross-Validation Labels Using Custom Binary Loss

Load Fisher's iris data set. X contains flower measurements, and Y contains the names of flower species.

```
load fisheriris
X = meas;
Y = species;
```

Cross-validate an ECOC model of kernel classification models using 5-fold cross-validation.

```
rng(1); % For reproducibility
CVMdl = fitcecoc(X,Y,'Learners','kernel','KFold',5)

CVMdl =
  classreg.learning.partition.ClassificationPartitionedKernelECOC
    CrossValidatedModel: 'KernelECOC'
      ResponseName: 'Y'
    NumObservations: 150
      KFold: 5
    Partition: [1x1 cvpartition]
    ClassNames: {'setosa' 'versicolor' 'virginica'}
    ScoreTransform: 'none'
```

Properties, Methods

CVMdl is a ClassificationPartitionedKernelECOC model. It contains the property Trained, which is a 5-by-1 cell array of CompactClassificationECOC models.

By default, the kernel classification models that compose the CompactClassificationECOC models use SVMs. SVM scores are signed distances from the observation to the decision boundary. Therefore, the domain is $(-\infty, \infty)$. Create a custom binary loss function that:

- Maps the coding design matrix (M) and positive-class classification scores (s) for each learner to the binary loss for each observation

- Uses linear loss
- Aggregates the binary learner loss using the median

You can create a separate function for the binary loss function, and then save it on the MATLAB® path. Or, you can specify an anonymous binary loss function. In this case, create a function handle (`customBL`) to an anonymous binary loss function.

```
customBL = @(M,s)nanmedian(1 - bsxfun(@times,M,s),2)/2;
```

Predict cross-validation labels and estimate the median binary loss per class. Print the median negative binary losses per class for a random set of 10 observations.

```
[label,NegLoss] = kfoldPredict(CVMdl,'BinaryLoss',customBL);
idx = randsample(numel(label),10);
table(Y(idx),label(idx),NegLoss(idx,1),NegLoss(idx,2),NegLoss(idx,3),...
    'VariableNames',{'True'};{'Predicted'};...
    unique(CVMdl.ClassNames))
```

```
ans=10x5 table
    True      Predicted    setosa    versicolor    virginica
    _____    _____    _____    _____    _____
    'setosa'      'setosa'      0.20926    -0.84572    -0.86354
    'setosa'      'setosa'      0.16144    -0.90572    -0.75572
    'virginica'   'versicolor'  -0.83532    -0.12157    -0.54311
    'virginica'   'virginica'   -0.97235    -0.69759    0.16994
    'virginica'   'virginica'   -0.89441    -0.69937    0.093778
    'virginica'   'virginica'   -0.86774    -0.47297    -0.15929
    'setosa'      'setosa'      -0.1026    -0.69671    -0.70069
    'setosa'      'setosa'      0.1001     -0.89163    -0.70848
    'virginica'   'virginica'   -1.0106    -0.52919    0.039829
    'versicolor' 'versicolor'  -1.0298    0.027354    -0.49757
```

The cross-validated model correctly predicts the labels for 9 of the 10 random observations.

Estimate k -Fold Cross-Validation Posterior Class Probabilities

Estimate posterior class probabilities using a cross-validated, multiclass kernel ECOC classification model. Kernel classification models return posterior probabilities for logistic regression learners only.

Load Fisher's iris data set. X contains flower measurements, and Y contains the names of flower species.

```
load fisheriris
X = meas;
Y = species;
```

Create a kernel template for the binary kernel classification models. Specify to fit logistic regression learners.

```
t = templateKernel('Learner','logistic')

t =
Fit template for classification Kernel.

    BetaTolerance: []
      BlockSize: []
    BoxConstraint: []
         Epsilon: []
NumExpansionDimensions: []
    GradientTolerance: []
    HessianHistorySize: []
    IterationLimit: []
      KernelScale: []
         Lambda: []
         Learner: 'logistic'
    LossFunction: []
         Stream: []
    VerbosityLevel: []
         Version: 1
         Method: 'Kernel'
         Type: 'classification'
```

t is a kernel template. Most of its properties are empty. When training an ECOC classifier using the template, the software sets the applicable properties to their default values.

Cross-validate an ECOC model using the kernel template.

```
rng('default'); % For reproducibility
CVMdl = fitcecoc(X,Y,'Learners',t,'CrossVal','on')

CVMdl =
  classreg.learning.partition.ClassificationPartitionedKernelECOC
  CrossValidatedModel: 'KernelECOC'
  ResponseName: 'Y'
  NumObservations: 150
  KFold: 10
  Partition: [1x1 cvpartition]
  ClassNames: {'setosa' 'versicolor' 'virginica'}
  ScoreTransform: 'none'
```

Properties, Methods

CVMdl is a `ClassificationPartitionedECOC` model. By default, the software uses 10-fold cross-validation.

Predict the validation-fold class posterior probabilities.

```
[label,~,~,Posterior] = kfoldPredict(CVMdl);
```

The software assigns an observation to the class that yields the smallest average binary loss. Because all binary learners are computing posterior probabilities, the binary loss function is **quadratic**.

Display the posterior probabilities for 10 randomly selected observations.

```
idx = randsample(size(X,1),10);
CVMdl.ClassNames

ans = 3x1 cell array
    {'setosa' }
    {'versicolor'}
    {'virginica' }
```

```
table(Y(idx),label(idx),Posterior(idx,:),...
      'VariableNames',{'TrueLabel','PredLabel','Posterior'})

ans=10x3 table
    TrueLabel    PredLabel    Posterior
```

'setosa'	'setosa'	0.68216	0.18546	0.13238

'virginica'	'virginica'	0.082705	0.1428	0.7745

The columns of Posterior correspond to the class order of `CVmdl.ClassNames`.

Input Arguments

CVmdl — Cross-validated kernel ECOC model

ClassificationPartitionedKernelECOC model

Cross-validated kernel ECOC model, specified as a `ClassificationPartitionedKernelECOC` model. You can create a `ClassificationPartitionedKernelECOC` model by training an ECOC model using `fitceoc` and specifying these name-value pair arguments:

- `'Learners'` - Set the value to `'kernel'`, a template object returned by `templateKernel`, or a cell array of such template objects.
- One of the arguments `'CrossVal'`, `'CVPartition'`, `'Holdout'`, `'Kfold'`, or `'Leaveout'`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `kfoldPredict(CVMdl, 'PosteriorMethod', 'qp')` specifies to estimate multiclass posterior probabilities by solving a least-squares problem using quadratic programming.

BinaryLoss — Binary learner loss function

'hamming' | 'linear' | 'logit' | 'exponential' | 'binodeviance' | 'hinge' | 'quadratic' | function handle

Binary learner loss function, specified as the comma-separated pair consisting of 'BinaryLoss' and a built-in loss function name or function handle.

- This table contains names and descriptions of the built-in functions, where y_j is a class label for a particular binary learner (in the set $\{-1, 1, 0\}$), s_j is the score for observation j , and $g(y_j, s_j)$ is the binary loss formula.

Value	Description	Score Domain	$g(y_j, s_j)$
'binodeviance'	Binomial deviance	$(-\infty, \infty)$	$\log[1 + \exp(-2y_j s_j)] / [2\log(2)]$
'exponential'	Exponential	$(-\infty, \infty)$	$\exp(-y_j s_j) / 2$
'hamming'	Hamming	$[0, 1]$ or $(-\infty, \infty)$	$[1 - \text{sign}(y_j s_j)] / 2$
'hinge'	Hinge	$(-\infty, \infty)$	$\max(0, 1 - y_j s_j) / 2$
'linear'	Linear	$(-\infty, \infty)$	$(1 - y_j s_j) / 2$
'logit'	Logistic	$(-\infty, \infty)$	$\log[1 + \exp(-y_j s_j)] / [2\log(2)]$
'quadratic'	Quadratic	$[0, 1]$	$[1 - y_j(2s_j - 1)]^2 / 2$

The software normalizes binary losses such that the loss is 0.5 when $y_j = 0$. Also, the software calculates the mean binary loss for each class.

- For a custom binary loss function, for example, `customFunction`, specify its function handle 'BinaryLoss', @customFunction.

`customFunction` has this form:

```
bLoss = customFunction(M,s)
```

where:

- M is the K -by- L coding matrix stored in `Mdl.CodingMatrix`.

- s is the 1-by- L row vector of classification scores.
- `bLoss` is the classification loss. This scalar aggregates the binary losses for every learner in a particular class. For example, you can use the mean binary loss to aggregate the loss over the learners for each class.
- K is the number of classes.
- L is the number of binary learners.

By default, if all binary learners are kernel classification models using SVM, then `BinaryLoss` is 'hinge'. If all binary learners are kernel classification models using logistic regression, then `BinaryLoss` is 'quadratic'.

Example: 'BinaryLoss', 'binodeviance'

Data Types: char | string | function_handle

Decoding — Decoding scheme

'lossweighted' (default) | 'lossbased'

Decoding scheme that aggregates the binary losses, specified as the comma-separated pair consisting of 'Decoding' and 'lossweighted' or 'lossbased'. For more information, see “Binary Loss” on page 32-3470.

Example: 'Decoding', 'lossbased'

NumKLInitializations — Number of random initial values

0 (default) | nonnegative integer scalar

Number of random initial values for fitting posterior probabilities by Kullback-Leibler divergence minimization, specified as the comma-separated pair consisting of 'NumKLInitializations' and a nonnegative integer scalar.

If you do not request the fourth output argument (Posterior) and set 'PosteriorMethod', 'kl' (the default), then the software ignores the value of `NumKLInitializations`.

For more details, see “Posterior Estimation Using Kullback-Leibler Divergence” on page 32-3472.

Example: 'NumKLInitializations', 5

Data Types: single | double

Options — Estimation options

[] (default) | structure array returned by `statset`

Estimation options, specified as the comma-separated pair consisting of 'Options' and a structure array returned by `statset`.

To invoke parallel computing:

- You need a Parallel Computing Toolbox license.
- Specify 'Options', `statset('UseParallel',true)`.

PosteriorMethod — Posterior probability estimation method

'kl' (default) | 'qp'

Posterior probability estimation method, specified as the comma-separated pair consisting of 'PosteriorMethod' and 'kl' or 'qp'.

- If `PosteriorMethod` is 'kl', then the software estimates multiclass posterior probabilities by minimizing the Kullback-Leibler divergence between the predicted and expected posterior probabilities returned by binary learners. For details, see “Posterior Estimation Using Kullback-Leibler Divergence” on page 32-3472.
- If `PosteriorMethod` is 'qp', then the software estimates multiclass posterior probabilities by solving a least-squares problem using quadratic programming. You need an Optimization Toolbox license to use this option. For details, see “Posterior Estimation Using Quadratic Programming” on page 32-3473.
- If you do not request the fourth output argument (`Posterior`), then the software ignores the value of `PosteriorMethod`.

Example: 'PosteriorMethod', 'qp'

Verbose — Verbosity level

0 (default) | 1

Verbosity level, specified as the comma-separated pair consisting of 'Verbose' and 0 or 1. `Verbose` controls the number of diagnostic messages that the software displays in the Command Window.

If `Verbose` is 0, then the software does not display diagnostic messages. Otherwise, the software displays diagnostic messages.

Example: 'Verbose', 1

Data Types: `single` | `double`

Output Arguments

Label — Predicted class labels

categorical array | character array | logical vector | numeric vector | cell array of character vectors

Predicted class labels, returned as a categorical or character array, logical or numeric vector, or cell array of character vectors.

Label has the same data type and number of rows as `CVMDL.Y`.

The software predicts the classification of an observation by assigning the observation to the class yielding the largest negated average binary loss (or, equivalently, the smallest average binary loss).

NegLoss — Negated average binary losses

numeric matrix

Negated average binary losses, returned as a numeric matrix. `NegLoss` is an n -by- K matrix, where n is the number of observations (`size(CVMDL.Y,1)`) and K is the number of unique classes (`size(CVMDL.ClassNames,1)`).

PBScore — Positive-class scores

numeric matrix

Positive-class scores for each binary learner, returned as a numeric matrix. `PBScore` is an n -by- L matrix, where n is the number of observations (`size(CVMDL.Y,1)`) and L is the number of binary learners (`size(CVMDL.CodingMatrix,2)`).

If the coding matrix varies across folds (that is, the coding scheme is `sparserandom` or `denserandom`), then `PBScore` is empty (`[]`).

Posterior — Posterior class probabilities

numeric matrix

Posterior class probabilities, returned as a numeric matrix. `Posterior` is an n -by- K matrix, where n is the number of observations (`size(CVMDL.Y,1)`) and K is the number of unique classes (`size(CVMDL.ClassNames,1)`).

To return posterior probabilities, each kernel classification binary learner must have its `Learner` property set to `'logistic'`. Otherwise, the software throws an error.

Definitions

Binary Loss

A binary loss is a function of the class and classification score that determines how well a binary learner classifies an observation into the class.

Suppose the following:

- m_{kj} is element (k,j) of the coding design matrix M (that is, the code corresponding to class k of binary learner j).
- s_j is the score of binary learner j for an observation.
- g is the binary loss function.
- \hat{k} is the predicted class for the observation.

In loss-based decoding [Escalera et al.] on page 18-228, the class producing the minimum sum of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \operatorname{argmin}_k \sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j).$$

In loss-weighted decoding [Escalera et al.] on page 18-228, the class producing the minimum average of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \operatorname{argmin}_k \frac{\sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j)}{\sum_{j=1}^L |m_{kj}|}.$$

Allwein et al. on page 18-227 suggest that loss-weighted decoding improves classification accuracy by keeping loss values for all classes in the same dynamic range.

This table summarizes the supported loss functions, where y_j is a class label for a particular binary learner (in the set $\{-1,1,0\}$), s_j is the score for observation j , and $g(y_j, s_j)$.

Value	Description	Score Domain	$g(y_j, s_j)$
'binodeviance'	Binomial deviance	$(-\infty, \infty)$	$\log[1 + \exp(-2y_j s_j)] / [2\log(2)]$
'exponential'	Exponential	$(-\infty, \infty)$	$\exp(-y_j s_j) / 2$
'hamming'	Hamming	$[0, 1]$ or $(-\infty, \infty)$	$[1 - \text{sign}(y_j s_j)] / 2$
'hinge'	Hinge	$(-\infty, \infty)$	$\max(0, 1 - y_j s_j) / 2$
'linear'	Linear	$(-\infty, \infty)$	$(1 - y_j s_j) / 2$
'logit'	Logistic	$(-\infty, \infty)$	$\log[1 + \exp(-y_j s_j)] / [2\log(2)]$
'quadratic'	Quadratic	$[0, 1]$	$[1 - y_j(2s_j - 1)]^2 / 2$

The software normalizes binary losses such that the loss is 0.5 when $y_j = 0$, and aggregates using the average of the binary learners [Allwein et al.] on page 18-227.

Do not confuse the binary loss with the overall classification loss (specified by the 'LossFun' name-value pair argument of the `loss` and `predict` object functions), which measures how well an ECOC classifier performs as a whole.

Algorithms

The software can estimate class posterior probabilities by minimizing the Kullback-Leibler divergence or by using quadratic programming. For the following descriptions of the posterior estimation algorithms, assume that:

- m_{kj} is the element (k, j) of the coding design matrix M .
- I is the indicator function.
- \hat{p}_k is the class posterior probability estimate for class k of an observation, $k = 1, \dots, K$.
- r_j is the positive-class posterior probability for binary learner j . That is, r_j is the probability that binary learner j classifies an observation into the positive class, given the training data.

Posterior Estimation Using Kullback-Leibler Divergence

By default, the software minimizes the Kullback-Leibler divergence to estimate class posterior probabilities. The Kullback-Leibler divergence between the expected and observed positive-class posterior probabilities is

$$\Delta(r, \hat{r}) = \sum_{j=1}^L w_j \left[r_j \log \frac{r_j}{\hat{r}_j} + (1 - r_j) \log \frac{1 - r_j}{1 - \hat{r}_j} \right],$$

where $w_j = \sum_{S_j} w_i^*$ is the weight for binary learner j .

- S_j is the set of observation indices on which binary learner j is trained.
- w_i^* is the weight of observation i .

The software minimizes the divergence iteratively. The first step is to choose initial values $\hat{p}_k^{(0)}$; $k = 1, \dots, K$ for the class posterior probabilities.

- If you do not specify 'NumKLIterations', then the software tries both sets of deterministic initial values described next, and selects the set that minimizes Δ .
 - $\hat{p}_k^{(0)} = 1/K$; $k = 1, \dots, K$.
 - $\hat{p}_k^{(0)}$; $k = 1, \dots, K$ is the solution of the system

$$M_{01} \hat{p}^{(0)} = r,$$

where M_{01} is M with all $m_{kj} = -1$ replaced with 0, and r is a vector of positive-class posterior probabilities returned by the L binary learners [Dietterich et al.] on page 18-228. The software uses `lsqnonneg` to solve the system.

- If you specify 'NumKLIterations', c , where c is a natural number, then the software does the following to choose the set $\hat{p}_k^{(0)}$; $k = 1, \dots, K$, and selects the set that minimizes Δ .
 - The software tries both sets of deterministic initial values as described previously.
 - The software randomly generates c vectors of length K using `rand`, and then normalizes each vector to sum to 1.

At iteration t , the software completes these steps:

- 1 Compute

$$\hat{r}_j^{(t)} = \frac{\sum_{k=1}^K \hat{p}_k^{(t)} I(m_{kj} = +1)}{\sum_{k=1}^K \hat{p}_k^{(t)} I(m_{kj} = +1 \cup m_{kj} = -1)}.$$

- 2 Estimate the next class posterior probability using

$$\hat{p}_k^{(t+1)} = \hat{p}_k^{(t)} \frac{\sum_{j=1}^L w_j [r_j I(m_{kj} = +1) + (1 - r_j) I(m_{kj} = -1)]}{\sum_{j=1}^L w_j [\hat{r}_j^{(t)} I(m_{kj} = +1) + (1 - \hat{r}_j^{(t)}) I(m_{kj} = -1)]}.$$

- 3 Normalize $\hat{p}_k^{(t+1)}$; $k = 1, \dots, K$ so that they sum to 1.
- 4 Check for convergence.

For more details, see [Hastie et al.] on page 18-228 and [Zadrozny] on page 18-230.

Posterior Estimation Using Quadratic Programming

Posterior probability estimation using quadratic programming requires an Optimization Toolbox license. To estimate posterior probabilities for an observation using this method, the software completes these steps:

- 1 Estimate the positive-class posterior probabilities, r_j , for binary learners $j = 1, \dots, L$.
- 2 Using the relationship between r_j and \hat{p}_k [Wu et al.] on page 18-230, minimize

$$\sum_{j=1}^L \left[-r_j \sum_{k=1}^K \hat{p}_k I(m_{kj} = -1) + (1 - r_j) \sum_{k=1}^K \hat{p}_k I(m_{kj} = +1) \right]^2$$

with respect to \hat{p}_k and the restrictions

$$0 \leq \hat{p}_k \leq 1$$

$$\sum_k \hat{p}_k = 1.$$

The software performs minimization using quadprog.

Introduced in R2018b

kfoldPredict

Predict labels for observations not used for training

Syntax

```
Label = kfoldPredict(CVMdl)
[Label,Score] = kfoldPredict(CVMdl)
```

Description

`Label = kfoldPredict(CVMdl)` returns cross-validated class labels predicted by the cross-validated, binary, linear classification model `CVMdl`. That is, for every fold, `kfoldPredict` predicts class labels for observations that it holds out when it trains using all other observations.

`Label` contains predicted class labels for each regularization strength in the linear classification models that compose `CVMdl`.

`[Label,Score] = kfoldPredict(CVMdl)` also returns cross-validated classification scores on page 32-3485 for both classes. `Score` contains classification scores for each regularization strength in `CVMdl`.

Input Arguments

CVMdl — Cross-validated, binary, linear classification model

`ClassificationPartitionedLinear` model object

Cross-validated, binary, linear classification model, specified as a `ClassificationPartitionedLinear` model object. You can create a `ClassificationPartitionedLinear` model using `fitclinear` and specifying any one of the cross-validation, name-value pair arguments, for example, `CrossVal`.

To obtain estimates, `kfoldPredict` applies the same data used to cross-validate the linear classification model (X and Y).

Output Arguments

Label — Cross-validated, predicted class labels

categorical array | character array | logical matrix | numeric matrix | cell array of character vectors

Cross-validated, predicted class labels, returned as a categorical or character array, logical or numeric matrix, or cell array of character vectors.

In most cases, `Label` is an n -by- L array of the same data type as the observed class labels (see `Y`) used to create `CVMdl`. (The software treats string arrays as cell arrays of character vectors.) n is the number of observations in the predictor data (see `X`) and L is the number of regularization strengths in `CVMdl.Trained{1}.Lambda`. That is, `Label(i, j)` is the predicted class label for observation i using the linear classification model that has regularization strength `CVMdl.Trained{1}.Lambda(j)`.

If `Y` is a character array and $L > 1$, then `Label` is a cell array of class labels.

Score — Cross-validated classification scores

numeric array

Cross-validated classification scores on page 32-3485, returned as an n -by-2-by- L numeric array. n is the number of observations in the predictor data that created `CVMdl` (see `X`) and L is the number of regularization strengths in `CVMdl.Trained{1}.Lambda`. `Score(i, k, j)` is the score for classifying observation i into class k using the linear classification model that has regularization strength `CVMdl.Trained{1}.Lambda(j)`. `CVMdl.ClassNames` stores the order of the classes.

If `CVMdl.Trained{1}.Learner` is 'logistic', then classification scores are posterior probabilities.

Examples

Predict k -fold Cross-Validation Labels

Load the NLP data set.

```
load nlpdata
```

X is a sparse matrix of predictor data, and Y is a categorical vector of class labels. There are more than two classes in the data.

The models should identify whether the word counts in a web page are from the Statistics and Machine Learning Toolbox™ documentation. So, identify the labels that correspond to the Statistics and Machine Learning Toolbox™ documentation web pages.

```
Ystats = Y == 'stats';
```

Cross-validate a binary, linear classification model using the entire data set, which can identify whether the word counts in a documentation web page are from the Statistics and Machine Learning Toolbox™ documentation.

```
rng(1); % For reproducibility
CVMdl = fitlinear(X,Ystats,'CrossVal','on');
Mdl1 = CVMdl.Trained{1}
```

```
Mdl1 =
  ClassificationLinear
    ResponseName: 'Y'
      ClassNames: [0 1]
    ScoreTransform: 'none'
              Beta: [34023x1 double]
              Bias: -1.0008
              Lambda: 3.5193e-05
              Learner: 'svm'
```

Properties, Methods

CVMdl is a `ClassificationPartitionedLinear` model. By default, the software implements 10-fold cross validation. You can alter the number of folds using the 'KFold' name-value pair argument.

Predict labels for the observations that `fitlinear` did not use in training the folds.

```
label = kfoldPredict(CVMdl);
```

Because there is one regularization strength in `Mdl1`, `label` is a column vector of predictions containing as many rows as observations in X.

Construct a confusion matrix.

```
ConfusionTrain = confusionchart(Ystats,label);
```

True Class	false	30009	9
	true	15	1539
		false	true
		Predicted Class	

The model misclassifies 15 'stats' documentation pages as being outside of the Statistics and Machine Learning Toolbox documentation, and misclassifies nine pages as 'stats' pages.

Estimate *k*-fold Cross-Validation Posterior Class Probabilities

Linear classification models return posterior probabilities for logistic regression learners only.

Load the NLP data set and preprocess it as in “Predict *k*-fold Cross-Validation Labels” on page 32-3476. Transpose the predictor data matrix.

```
load nlpdata
Ystats = Y == 'stats';
X = X';
```

Cross-validate binary, linear classification models using 5-fold cross-validation. Optimize the objective function using SpaRSA. Lower the tolerance on the gradient of the objective function to $1e-8$.

```
rng(10); % For reproducibility
CVMdl = fitlinear(X,Ystats,'ObservationsIn','columns',...
    'KFold',5,'Learner','logistic','Solver','sparsa',...
    'Regularization','lasso','GradientTolerance',1e-8);
```

Predict the posterior class probabilities for observations not used to train each fold.

```
[~,posterior] = kfoldPredict(CVMdl);
CVMdl.ClassNames
```

```
ans = 2x1 logical array
```

```
0
1
```

Because there is one regularization strength in CVMdl, `posterior` is a matrix with 2 columns and rows equal to the number of observations. Column i contains posterior probabilities of `Mdl.ClassNames(i)` given a particular observation.

Obtain false and true positive rates, and estimate the AUC. Specify that the second class is the positive class.

```
[fpr,tpr,~,auc] = perfcurve(Ystats,posterior(:,2),CVMdl.ClassNames(2));
auc
```

```
auc = 0.9990
```

The AUC is 0.9990, which indicates a model that predicts well.

Plot an ROC curve.

```
figure;
plot(fpr,tpr)
h = gca;
h.XLim(1) = -0.1;
h.YLim(2) = 1.1;
```

```
xlabel('False positive rate')  
ylabel('True positive rate')  
title('ROC Curve')
```

The ROC curve indicates that the model classifies almost perfectly.

Find Good Lasso Penalty Using Cross-Validated AUC

To determine a good lasso-penalty strength for a linear classification model that uses a logistic regression learner, compare cross-validated AUC values.

Load the NLP data set. Preprocess the data as in “Estimate k-fold Cross-Validation Posterior Class Probabilities” on page 32-3478.

```
load nlpdata
Ystats = Y == 'stats';
X = X';
```

There are 9471 observations in the test sample.

Create a set of 11 logarithmically-spaced regularization strengths from 10^{-6} through $10^{-0.5}$.

```
Lambda = logspace(-6, -0.5, 11);
```

Cross-validate a binary, linear classification models that use each of the regularization strengths and 5-fold cross-validation. Optimize the objective function using SpARSA. Lower the tolerance on the gradient of the objective function to $1e-8$.

```
rng(10); % For reproducibility
CVMdl = fitlinear(X, Ystats, 'ObservationsIn', 'columns', ...
    'KFold', 5, 'Learner', 'logistic', 'Solver', 'sparsa', ...
    'Regularization', 'lasso', 'Lambda', Lambda, 'GradientTolerance', 1e-8)
```

```
CVMdl =
  classreg.learning.partition.ClassificationPartitionedLinear
    CrossValidatedModel: 'Linear'
      ResponseName: 'Y'
    NumObservations: 31572
      KFold: 5
    Partition: [1x1 cvpartition]
    ClassNames: [0 1]
    ScoreTransform: 'none'
```

Properties, Methods

```
Mdl1 = CVMdl.Trained{1}
```

```
Mdl1 =
  ClassificationLinear
    ResponseName: 'Y'
    ClassNames: [0 1]
    ScoreTransform: 'logit'
```

```
Beta: [34023×11 double]
Bias: [-13.2904 -13.2904 -13.2904 -13.2904 -9.9357 -7.0782 -5.4335 -4.54
Lambda: [1.0000e-06 3.5481e-06 1.2589e-05 4.4668e-05 1.5849e-04 5.6234e-04
Learner: 'logistic'
```

Properties, Methods

`Mdl1` is a `ClassificationLinear` model object. Because `Lambda` is a sequence of regularization strengths, you can think of `Mdl1` as 11 models, one for each regularization strength in `Lambda`.

Predict the cross-validated labels and posterior class probabilities.

```
[label,posterior] = kfoldPredict(CVMdl);
CVMdl.ClassNames;
[n,K,L] = size(posterior)
```

```
n = 31572
```

```
K = 2
```

```
L = 11
```

```
posterior(3,1,5)
```

```
ans = 1.0000
```

`label` is a 31572-by-11 matrix of predicted labels. Each column corresponds to the predicted labels of the model trained using the corresponding regularization strength. `posterior` is a 31572-by-2-by-11 matrix of posterior class probabilities. Columns correspond to classes and pages correspond to regularization strengths. For example, `posterior(3,1,5)` indicates that the posterior probability that the first class (label 0) is assigned to observation 3 by the model that uses `Lambda(5)` as a regularization strength is 1.0000.

For each model, compute the AUC. Designate the second class as the positive class.

```
auc = 1:numel(Lambda); % Preallocation
for j = 1:numel(Lambda)
    [~,~,~,auc(j)] = perfcurve(Ystats,posterior(:,2,j),CVMdl.ClassNames(2));
end
```

Higher values of `Lambda` lead to predictor variable sparsity, which is a good quality of a classifier. For each regularization strength, train a linear classification model using the

entire data set and the same options as when you trained the model. Determine the number of nonzero coefficients per model.

```
Mdl = fitclinear(X,Ystats,'ObservationsIn','columns',...  
    'Learner','logistic','Solver','sparsa','Regularization','lasso',...  
    'Lambda',Lambda,'GradientTolerance',1e-8);  
numNZCoeff = sum(Mdl.Beta~=0);
```

In the same figure, plot the test-sample error rates and frequency of nonzero coefficients for each regularization strength. Plot all variables on the log scale.

```
figure;  
[h,hL1,hL2] = plotyy(log10(Lambda),log10(auc),...  
    log10(Lambda),log10(numNZCoeff + 1));  
hL1.Marker = 'o';  
hL2.Marker = 'o';  
ylabel(h(1),'log_{10} AUC')  
ylabel(h(2),'log_{10} nonzero-coefficient frequency')  
xlabel('log_{10} Lambda')  
title('Cross-Validated Statistics')  
hold off
```

Choose the index of the regularization strength that balances predictor variable sparsity and high AUC. In this case, a value between 10^{-3} to 10^{-1} should suffice.

```
idxFinal = 9;
```

Select the model from `Mdl` with the chosen regularization strength.

```
MdlFinal = selectModels(Mdl,idxFinal);
```

`MdlFinal` is a `ClassificationLinear` model containing one regularization strength. To estimate labels for new observations, pass `MdlFinal` and the new data to `predict`.

Definitions

Classification Score

For linear classification models, the raw classification score for classifying the observation x , a row vector, into the positive class is defined by

$$f_j(x) = x\beta_j + b_j.$$

For the model with regularization strength j , β_j is the estimated column vector of coefficients (the model property `Beta (:, j)`) and b_j is the estimated, scalar bias (the model property `Bias (j)`).

The raw classification score for classifying x into the negative class is $-f(x)$. The software classifies observations into the class that yields the positive score.

If the linear classification model consists of logistic regression learners, then the software applies the 'logit' score transformation to the raw classification scores (see `ScoreTransform`).

Introduced in R2016a

kfoldPredict

Predict labels for observations not used for training

Syntax

```
Label = kfoldPredict(CVMdl)
Label = kfoldPredict(CVMdl, Name, Value)
[Label, NegLoss, PBScore] = kfoldPredict( ___ )
[Label, NegLoss, PBScore, Posterior] = kfoldPredict( ___ )
```

Description

`Label = kfoldPredict(CVMdl)` returns class labels predicted by the cross-validated ECOC model composed of linear classification models `CVMdl`. That is, for every fold, `kfoldPredict` predicts class labels for observations that it holds out when it trains using all other observations. `kfoldPredict` applies the same data used create `CVMdl` (see `fitcecoc`).

Also, `Label` contains class labels for each regularization strength in the linear classification models that compose `CVMdl`.

`Label = kfoldPredict(CVMdl, Name, Value)` returns predicted class labels with additional options specified by one or more `Name, Value` pair arguments. For example, specify the posterior probability estimation method, decoding scheme, or verbosity level.

`[Label, NegLoss, PBScore] = kfoldPredict(___)` additionally returns, for held-out observations and each regularization strength:

- Negated values of the average binary loss per class (`NegLoss`).
- Positive-class scores (`PBScore`) for each binary learner.

`[Label, NegLoss, PBScore, Posterior] = kfoldPredict(___)` additionally returns posterior class probability estimates for held-out observations and for each regularization strength. To return posterior probabilities, the linear classification model learners must be logistic regression models.

Input Arguments

CVMdL — Cross-validated, ECOC model composed of linear classification models

`ClassificationPartitionedLinearECOC` model object

Cross-validated, ECOC model composed of linear classification models, specified as a `ClassificationPartitionedLinearECOC` model object. You can create a `ClassificationPartitionedLinearECOC` model using `fitcecoc` and by:

- 1 Specifying any one of the cross-validation, name-value pair arguments, for example, `CrossVal`
- 2 Setting the name-value pair argument `Learners` to `'linear'` or a linear classification model template returned by `templateLinear`

To obtain estimates, `kfoldPredict` applies the same data used to cross-validate the ECOC model (X and Y).

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

BinaryLoss — Binary learner loss function

`'hamming'` | `'linear'` | `'logit'` | `'exponential'` | `'binodeviance'` | `'hinge'` | `'quadratic'` | function handle

Binary learner loss function, specified as the comma-separated pair consisting of `'BinaryLoss'` and a built-in, loss-function name or function handle.

- This table contains names and descriptions of the built-in functions, where y_j is a class label for a particular binary learner (in the set $\{-1, 1, 0\}$), s_j is the score for observation j , and $g(y_j, s_j)$ is the binary loss formula.

Value	Description	Score Domain	$g(y_j, s_j)$
<code>'binodeviance'</code>	Binomial deviance	$(-\infty, \infty)$	$\log[1 + \exp(-2y_j s_j)] / [2\log(2)]$
<code>'exponential'</code>	Exponential	$(-\infty, \infty)$	$\exp(-y_j s_j) / 2$

Value	Description	Score Domain	$g(y_j, s_j)$
'hamming'	Hamming	[0,1] or $(-\infty, \infty)$	$[1 - \text{sign}(y_j s_j)]/2$
'hinge'	Hinge	$(-\infty, \infty)$	$\max(0, 1 - y_j s_j)/2$
'linear'	Linear	$(-\infty, \infty)$	$(1 - y_j s_j)/2$
'logit'	Logistic	$(-\infty, \infty)$	$\log[1 + \exp(-y_j s_j)]/[2\log(2)]$
'quadratic'	Quadratic	[0,1]	$[1 - y_j(2s_j - 1)]^2/2$

The software normalizes the binary losses such that the loss is 0.5 when $y_j = 0$. Also, the software calculates the mean binary loss for each class.

- For a custom binary loss function, e.g., `customFunction`, specify its function handle `'BinaryLoss', @customFunction`.

`customFunction` should have this form

```
bLoss = customFunction(M,s)
```

where:

- `M` is the K -by- L coding matrix stored in `Mdl.CodingMatrix`.
- `s` is the 1-by- L row vector of classification scores.
- `bLoss` is the classification loss. This scalar aggregates the binary losses for every learner in a particular class. For example, you can use the mean binary loss to aggregate the loss over the learners for each class.
- K is the number of classes.
- L is the number of binary learners.

For an example of passing a custom binary loss function, see “Predict Test-Sample Labels of ECOC Model Using Custom Binary Loss Function” on page 32-5219.

By default, if all binary learners are linear classification models using:

- SVM, then `BinaryLoss` is `'hinge'`
- Logistic regression, then `BinaryLoss` is `'quadratic'`

Example: `'BinaryLoss', 'binodeviance'`

Data Types: `char` | `string` | `function_handle`

Decoding — Decoding scheme

'lossweighted' (default) | 'lossbased'

Decoding scheme that aggregates the binary losses, specified as the comma-separated pair consisting of 'Decoding' and 'lossweighted' or 'lossbased'. For more information, see “Binary Loss” on page 32-3444.

Example: 'Decoding', 'lossbased'

NumKLInitializations — Number of random initial values

0 (default) | nonnegative integer

Number of random initial values for fitting posterior probabilities by Kullback-Leibler divergence minimization, specified as the comma-separated pair consisting of 'NumKLInitializations' and a nonnegative integer.

To use this option, you must:

- Return the fourth output argument (Posterior).
- The linear classification models that compose the ECOC models must use logistic regression learners (that is, `CVMdl.Trained{1}.BinaryLearners{1}.Learner` must be 'logistic').
- `PosteriorMethod` must be 'kl'.

For more details, see “Posterior Estimation Using Kullback-Leibler Divergence” on page 32-3500.

Example: 'NumKLInitializations',5

Data Types: single | double

Options — Estimation options

[] (default) | structure array returned by `statset`

Estimation options, specified as the comma-separated pair consisting of 'Options' and a structure array returned by `statset`.

To invoke parallel computing:

- You need a Parallel Computing Toolbox license.
- Specify 'Options', `statset('UseParallel',true)`.

PosteriorMethod — Posterior probability estimation method

'kl' (default) | 'qp'

Posterior probability estimation method, specified as the comma-separated pair consisting of 'PosteriorMethod' and 'kl' or 'qp'.

- To use this option, you must return the fourth output argument (**Posterior**) and the linear classification models that compose the ECOC models must use logistic regression learners (that is, `CVMdl.Trained{1}.BinaryLearners{1}.Learner` must be 'logistic').
- If **PosteriorMethod** is 'kl', then the software estimates multiclass posterior probabilities by minimizing the Kullback-Leibler divergence between the predicted and expected posterior probabilities returned by binary learners. For details, see “Posterior Estimation Using Kullback-Leibler Divergence” on page 32-3500.
- If **PosteriorMethod** is 'qp', then the software estimates multiclass posterior probabilities by solving a least-squares problem using quadratic programming. You need an Optimization Toolbox license to use this option. For details, see “Posterior Estimation Using Quadratic Programming” on page 32-3501.

Example: 'PosteriorMethod', 'qp'

Verbose — Verbosity level

0 (default) | 1

Verbosity level, specified as the comma-separated pair consisting of 'Verbose' and 0 or 1. **Verbose** controls the number of diagnostic messages that the software displays in the Command Window.

If **Verbose** is 0, then the software does not display diagnostic messages. Otherwise, the software displays diagnostic messages.

Example: 'Verbose', 1

Data Types: single | double

Output Arguments

Label — Cross-validated, predicted class labels

categorical array | character array | logical matrix | numeric matrix | cell array of character vectors

Cross-validated, predicted class labels, returned as a categorical or character array, logical or numeric matrix, or cell array of character vectors.

In most cases, `Label` is an n -by- L array of the same data type as the observed class labels (Y) used to create `CVMdl`. (The software treats string arrays as cell arrays of character vectors.) n is the number of observations in the predictor data (X) and L is the number of regularization strengths in the linear classification models that compose the cross-validated ECOC model. That is, `Label(i, j)` is the predicted class label for observation i using the ECOC model of linear classification models that has regularization strength `CVMdl.Trained{1}.BinaryLearners{1}.Lambda(j)`.

If Y is a character array and $L > 1$, then `Label` is a cell array of class labels.

The software assigns the predicted label corresponding to the class with the largest, negated, average binary loss (`NegLoss`), or, equivalently, the smallest average binary loss.

NegLoss — Cross-validated, negated, average binary losses

numeric array

Cross-validated, negated, average binary losses, returned as an n -by- K -by- L numeric matrix or array. K is the number of distinct classes in the training data and columns correspond to the classes in `CVMdl.ClassNames`. For n and L , see `Label`. `NegLoss(i, k, j)` is the negated, average binary loss for classifying observation i into class k using the linear classification model that has regularization strength `CVMdl.Trained{1}.BinaryLoss{1}.Lambda(j)`.

PBScore — Cross-validated, positive-class scores

numeric array

Cross-validated, positive-class scores, returned as an n -by- B -by- L numeric array. B is the number of binary learners in the cross-validated ECOC model and columns correspond to the binary learners in `CVMdl.Trained{1}.BinaryLearners`. For n and L , see `Label`. `PBScore(i, b, j)` is the positive-class score of binary learner b for classifying observation i into its positive class, using the linear classification model that has regularization strength `CVMdl.Trained{1}.BinaryLearners{1}.Lambda(j)`.

If the coding matrix varies across folds (that is, if the coding scheme is `sparsrandom` or `denserandom`), then `PBScore` is empty (`[]`).

Posterior — Cross-validated posterior class probabilities

numeric array

Cross-validated posterior class probabilities, returned as an n -by- K -by- L numeric array. For dimension definitions, see `NegLoss`. `Posterior(i,k,j)` is the posterior probability for classifying observation i into class k using the linear classification model that has regularization strength `CVMdl.Trained{1}.BinaryLearners{1}.Lambda(j)`.

To return posterior probabilities, `CVMdl.Trained{1}.BinaryLearner{1}.Learner` must be `'logistic'`.

Examples

Predict k -fold Cross-Validation Labels

Load the NLP data set.

```
load nlpdata
```

X is a sparse matrix of predictor data, and Y is a categorical vector of class labels.

Cross-validate an ECOC model of linear classification models.

```
rng(1); % For reproducibility
CVMdl = fitcecoc(X,Y,'Learner','linear','CrossVal','on');
```

`CVMdl` is a `ClassificationPartitionedLinearECOC` model. By default, the software implements 10-fold cross validation.

Predict labels for the observations that `fitcecoc` did not use in training the folds.

```
label = kfoldPredict(CVMdl);
```

Because there is one regularization strength in `CVMdl`, `label` is a column vector of predictions containing as many rows as observations in X .

Construct a confusion matrix.

```
cm = confusionchart(Y,label);
```

		Predicted Class													

Specify Custom Binary Loss

Load the NLP data set. Transpose the predictor data.

```
load nlpdata
X = X';
```

For simplicity, use the label 'others' for all observations in Y that are not 'simulink', 'dsp', or 'comm'.

```
Y(~(ismember(Y,{'simulink','dsp','comm'}))) = 'others';
```

Create a linear classification model template that specifies optimizing the objective function using SpaRSA.

```
t = templateLinear('Solver','sparsa');
```

Cross-validate an ECOC model of linear classification models using 5-fold cross-validation. Specify that the predictor observations correspond to columns.

```
rng(1); % For reproducibility
CVMdl = fitcecoc(X,Y,'Learners',t,'KFold',5,'ObservationsIn','columns');
CMdl1 = CVMdl.Trained{1}
```

```
CMdl1 =
  classreg.learning.classif.CompactClassificationECOC
    ResponseName: 'Y'
    ClassNames: [comm dsp simulink others]
    ScoreTransform: 'none'
    BinaryLearners: {6x1 cell}
    CodingMatrix: [4x6 double]
```

Properties, Methods

`CVMdl` is a `ClassificationPartitionedLinearECOC` model. It contains the property `Trained`, which is a 5-by-1 cell array holding a `CompactClassificationECOC` models that the software trained using the training set of each fold.

By default, the linear classification models that compose the ECOC models use SVMs. SVM scores are signed distances from the observation to the decision boundary. Therefore, the domain is $(-\infty, \infty)$. Create a custom binary loss function that:

- Maps the coding design matrix (M) and positive-class classification scores (s) for each learner to the binary loss for each observation
- Uses linear loss
- Aggregates the binary learner loss using the median.

You can create a separate function for the binary loss function, and then save it on the MATLAB® path. Or, you can specify an anonymous binary loss function.

```
customBL = @(M,s)nanmedian(1 - bsxfun(@times,M,s),2)/2;
```

Predict cross-validation labels and estimate the median binary loss per class. Print the median negative binary losses per class for a random set of 10 out-of-fold observations.

```
[label,NegLoss] = kfoldPredict(CVMdl,'BinaryLoss',customBL);

idx = randsample(numel(label),10);
table(Y(idx),label(idx),NegLoss(idx,1),NegLoss(idx,2),NegLoss(idx,3),...
      NegLoss(idx,4),'VariableNames',{ 'True';{'Predicted'};...
      categories(CVMdl.ClassNames)})

ans=10x6 table
      True      Predicted      comm      dsp      simulink      others

others      others      -1.9511     -1.3175      0.24735     0.95111
simulink     others      -7.848      -5.8203      4.8203      6.8457
```

The software predicts the label based on the maximum negated loss.

Estimate Posterior Class Probabilities

ECOC models composed of linear classification models return posterior probabilities for logistic regression learners only. This example requires the Parallel Computing Toolbox™ and the Optimization Toolbox™

Load the NLP data set and preprocess the data as in “Specify Custom Binary Loss” on page 32-3493.

```
load nlpdata
X = X';
Y(~(ismember(Y,{'simulink','dsp','comm'}))) = 'others';
```

Create a set of 5 logarithmically-spaced regularization strengths from 10^{-5} through $10^{-0.5}$.

```
Lambda = logspace(-6,-0.5,5);
```

Create a linear classification model template that specifies optimizing the objective function using SpaRSA and to use logistic regression learners.

```
t = templateLinear('Solver','sparsa','Learner','logistic','Lambda',Lambda);
```

Cross-validate an ECOC model of linear classification models using 5-fold cross-validation. Specify that the predictor observations correspond to columns, and to use parallel computing.

```
rng(1); % For reproducibility
Options = statset('UseParallel',true);
CVMdl = fitcecoc(X,Y,'Learners',t,'KFold',5,'ObservationsIn','columns',...
    'Options',Options);
```

Starting parallel pool (parpool) using the 'local' profile ...
connected to 6 workers.

Predict the cross-validated posterior class probabilities. Specify to use parallel computing and to estimate posterior probabilities using quadratic programming.

```
[label,~,~,Posterior] = kfoldPredict(CVMdl,'Options',Options,...
    'PosteriorMethod','qp');
size(label)
label(3,4)
size(Posterior)
Posterior(3,:,4)
```

```
ans =
```

```
    31572         5
```

```
ans =
```

```
    categorical
```

```
    others
```

```
ans =
```

```
    31572         4         5
```

```
ans =
    0.0293    0.0373    0.1738    0.7596
```

Because there are five regularization strengths:

- `label` is a 31572-by-5 categorical array. `label(3,4)` is the predicted, cross-validated label for observation 3 using the model trained with regularization strength `Lambda(4)`.
- `Posterior` is a 31572-by-4-by-5 matrix. `Posterior(3,:,4)` is the vector of all estimated, posterior class probabilities for observation 3 using the model trained with regularization strength `Lambda(4)`. The order of the second dimension corresponds to `CVmdl.ClassNames`. Display a random set of 10 posterior class probabilities.

Display a random sample of cross-validated labels and posterior probabilities for the model trained using `Lambda(4)`.

```
idx = randsample(size(label,1),10);
table(Y(idx),label(idx,4),Posterior(idx,1,4),Posterior(idx,2,4),...
    Posterior(idx,3,4),Posterior(idx,4,4),...
    'VariableNames',{'True'};{'Predicted'};categories(CVmdl.ClassNames))
```

```
ans =
```

```
10x6 table
```

True	Predicted	comm	dsp	simulink	others

Definitions

Binary Loss

A binary loss is a function of the class and classification score that determines how well a binary learner classifies an observation into the class.

Suppose the following:

- m_{kj} is element (k,j) of the coding design matrix M (that is, the code corresponding to class k of binary learner j).
- s_j is the score of binary learner j for an observation.
- g is the binary loss function.
- \hat{k} is the predicted class for the observation.

In loss-based decoding [Escalera et al.] on page 18-228, the class producing the minimum sum of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \operatorname{argmin}_k \sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j).$$

In loss-weighted decoding [Escalera et al.] on page 18-228, the class producing the minimum average of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \operatorname{argmin}_k \frac{\sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j)}{\sum_{j=1}^L |m_{kj}|}.$$

Allwein et al. on page 18-227 suggest that loss-weighted decoding improves classification accuracy by keeping loss values for all classes in the same dynamic range.

This table summarizes the supported loss functions, where y_j is a class label for a particular binary learner (in the set $\{-1,1,0\}$), s_j is the score for observation j , and $g(y_j, s_j)$.

Value	Description	Score Domain	$g(y_j, s_j)$
'binodeviance'	Binomial deviance	$(-\infty, \infty)$	$\log[1 + \exp(-2y_j s_j)] / [2\log(2)]$
'exponential'	Exponential	$(-\infty, \infty)$	$\exp(-y_j s_j) / 2$
'hamming'	Hamming	$[0, 1]$ or $(-\infty, \infty)$	$[1 - \text{sign}(y_j s_j)] / 2$
'hinge'	Hinge	$(-\infty, \infty)$	$\max(0, 1 - y_j s_j) / 2$
'linear'	Linear	$(-\infty, \infty)$	$(1 - y_j s_j) / 2$
'logit'	Logistic	$(-\infty, \infty)$	$\log[1 + \exp(-y_j s_j)] / [2\log(2)]$
'quadratic'	Quadratic	$[0, 1]$	$[1 - y_j(2s_j - 1)]^2 / 2$

The software normalizes binary losses such that the loss is 0.5 when $y_j = 0$, and aggregates using the average of the binary learners [Allwein et al.] on page 18-227.

Do not confuse the binary loss with the overall classification loss (specified by the 'LossFun' name-value pair argument of the `loss` and `predict` object functions), which measures how well an ECOC classifier performs as a whole.

Algorithms

The software can estimate class posterior probabilities by minimizing the Kullback-Leibler divergence or by using quadratic programming. For the following descriptions of the posterior estimation algorithms, assume that:

- m_{kj} is the element (k, j) of the coding design matrix M .
- I is the indicator function.
- \hat{p}_k is the class posterior probability estimate for class k of an observation, $k = 1, \dots, K$.
- r_j is the positive-class posterior probability for binary learner j . That is, r_j is the probability that binary learner j classifies an observation into the positive class, given the training data.

Posterior Estimation Using Kullback-Leibler Divergence

By default, the software minimizes the Kullback-Leibler divergence to estimate class posterior probabilities. The Kullback-Leibler divergence between the expected and observed positive-class posterior probabilities is

$$\Delta(r, \hat{r}) = \sum_{j=1}^L w_j \left[r_j \log \frac{r_j}{\hat{r}_j} + (1 - r_j) \log \frac{1 - r_j}{1 - \hat{r}_j} \right],$$

where $w_j = \sum_{S_j} w_i^*$ is the weight for binary learner j .

- S_j is the set of observation indices on which binary learner j is trained.
- w_i^* is the weight of observation i .

The software minimizes the divergence iteratively. The first step is to choose initial values $\hat{p}_k^{(0)}$; $k = 1, \dots, K$ for the class posterior probabilities.

- If you do not specify 'NumKLIterations', then the software tries both sets of deterministic initial values described next, and selects the set that minimizes Δ .

- $\hat{p}_k^{(0)} = 1/K$; $k = 1, \dots, K$.
- $\hat{p}_k^{(0)}$; $k = 1, \dots, K$ is the solution of the system

$$M_{01} \hat{p}^{(0)} = r,$$

where M_{01} is M with all $m_{kj} = -1$ replaced with 0, and r is a vector of positive-class posterior probabilities returned by the L binary learners [Dietterich et al.] on page 18-228. The software uses `lsqnonneg` to solve the system.

- If you specify 'NumKLIterations', c , where c is a natural number, then the software does the following to choose the set $\hat{p}_k^{(0)}$; $k = 1, \dots, K$, and selects the set that minimizes Δ .
 - The software tries both sets of deterministic initial values as described previously.
 - The software randomly generates c vectors of length K using `rand`, and then normalizes each vector to sum to 1.

At iteration t , the software completes these steps:

- 1 Compute

$$\hat{r}_j^{(t)} = \frac{\sum_{k=1}^K \hat{p}_k^{(t)} I(m_{kj} = +1)}{\sum_{k=1}^K \hat{p}_k^{(t)} I(m_{kj} = +1 \cup m_{kj} = -1)}.$$

- 2 Estimate the next class posterior probability using

$$\hat{p}_k^{(t+1)} = \hat{p}_k^{(t)} \frac{\sum_{j=1}^L w_j [r_j I(m_{kj} = +1) + (1 - r_j) I(m_{kj} = -1)]}{\sum_{j=1}^L w_j [\hat{r}_j^{(t)} I(m_{kj} = +1) + (1 - \hat{r}_j^{(t)}) I(m_{kj} = -1)]}.$$

- 3 Normalize $\hat{p}_k^{(t+1)}$; $k = 1, \dots, K$ so that they sum to 1.
- 4 Check for convergence.

For more details, see [Hastie et al.] on page 18-228 and [Zadrozny] on page 18-230.

Posterior Estimation Using Quadratic Programming

Posterior probability estimation using quadratic programming requires an Optimization Toolbox license. To estimate posterior probabilities for an observation using this method, the software completes these steps:

- 1 Estimate the positive-class posterior probabilities, r_j , for binary learners $j = 1, \dots, L$.
- 2 Using the relationship between r_j and \hat{p}_k [Wu et al.] on page 18-230, minimize

$$\sum_{j=1}^L \left[-r_j \sum_{k=1}^K \hat{p}_k I(m_{kj} = -1) + (1 - r_j) \sum_{k=1}^K \hat{p}_k I(m_{kj} = +1) \right]^2$$

with respect to \hat{p}_k and the restrictions

$$0 \leq \hat{p}_k \leq 1$$

$$\sum_k \hat{p}_k = 1.$$

The software performs minimization using quadprog.

Extended Capabilities

Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the 'UseParallel' option to true.

Set the 'UseParallel' field of the options structure to true using `statset` and specify the 'Options' name-value pair argument in the call to this function.

For example: `'Options',statset('UseParallel',true)`

For more information, see the 'Options' name-value pair argument.

For more general information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

kfoldPredict

Predict response for observations not used for training

Syntax

```
label = kfoldPredict(obj)
[label, score] = kfoldPredict(obj)
[label, score, cost] = kfoldPredict(obj)
```

Description

`label = kfoldPredict(obj)` returns class labels predicted by `obj`, a cross-validated classification. For every fold, `kfoldPredict` predicts class labels for in-fold observations using a model trained on out-of-fold observations.

`[label, score] = kfoldPredict(obj)` returns the predicted classification scores for in-fold observations using a model trained on out-of-fold observations.

`[label, score, cost] = kfoldPredict(obj)` returns misclassification costs.

Input Arguments

obj

Object of class `ClassificationPartitionedModel` or `ClassificationPartitionedEnsemble`.

Output Arguments

label

Vector of class labels of the same type as the response data used in training `obj`. (The software treats string arrays as cell arrays of character vectors.) Each entry of `label` corresponds to a predicted class label for the corresponding row of `X`.

score

Numeric matrix of size N-by-K, where N is the number of observations (rows) in `obj.X`, and K is the number of classes (in `obj.ClassNames`). `score(i,j)` represents the confidence that row `i` of `obj.X` is of class `j`. For details, see “Definitions” on page 32-3506.

cost

Numeric matrix of misclassification costs of size N-by-K. `cost(i,j)` is the average misclassification cost of predicting that row `i` of `obj.X` is of class `j`.

Examples

Estimate Cross-Validation Predictions from an Ensemble

Find the cross-validation predictions for a model based on Fisher's iris data.

Load Fisher's iris data set.

```
load fisheriris
```

Train an ensemble of classification trees using AdaBoostM2. Specify tree stumps as the weak learners.

```
rng(1); % For reproducibility
t = templateTree('MaxNumSplits',1);
Mdl = fitensemble(meas,species,'Method','AdaBoostM2','Learners',t);
```

Cross validate the trained ensemble using 10-fold cross validation.

```
CVMDL = crossval(Mdl);
```

Estimate cross-validation predicted labels and scores.

```
[elabel,escore] = kfoldPredict(CVMDL);
```

Display the maximum and minimum scores of each class.

```
max(escore)
```

```
ans = 1×3
```

```
          9.3862    8.9871    10.1866

min(escore)

ans = 1×3

          0.0017    3.8359    0.8981
```

Definitions

Cost (discriminant analysis)

The average misclassification cost is the mean misclassification cost for predictions made by the cross-validated classifiers trained on out-of-fold observations. The matrix of expected costs per observation is defined in “Cost” on page 20-7.

Score

For discriminant analysis, the score of a classification is the posterior probability of the classification. For the definition of posterior probability in discriminant analysis, see “Posterior Probability” on page 20-6.

For ensembles, a classification score represents the confidence of a classification into a class. The higher the score, the higher the confidence.

Different ensemble algorithms have different definitions for their scores. Furthermore, the range of scores depends on ensemble type. For example:

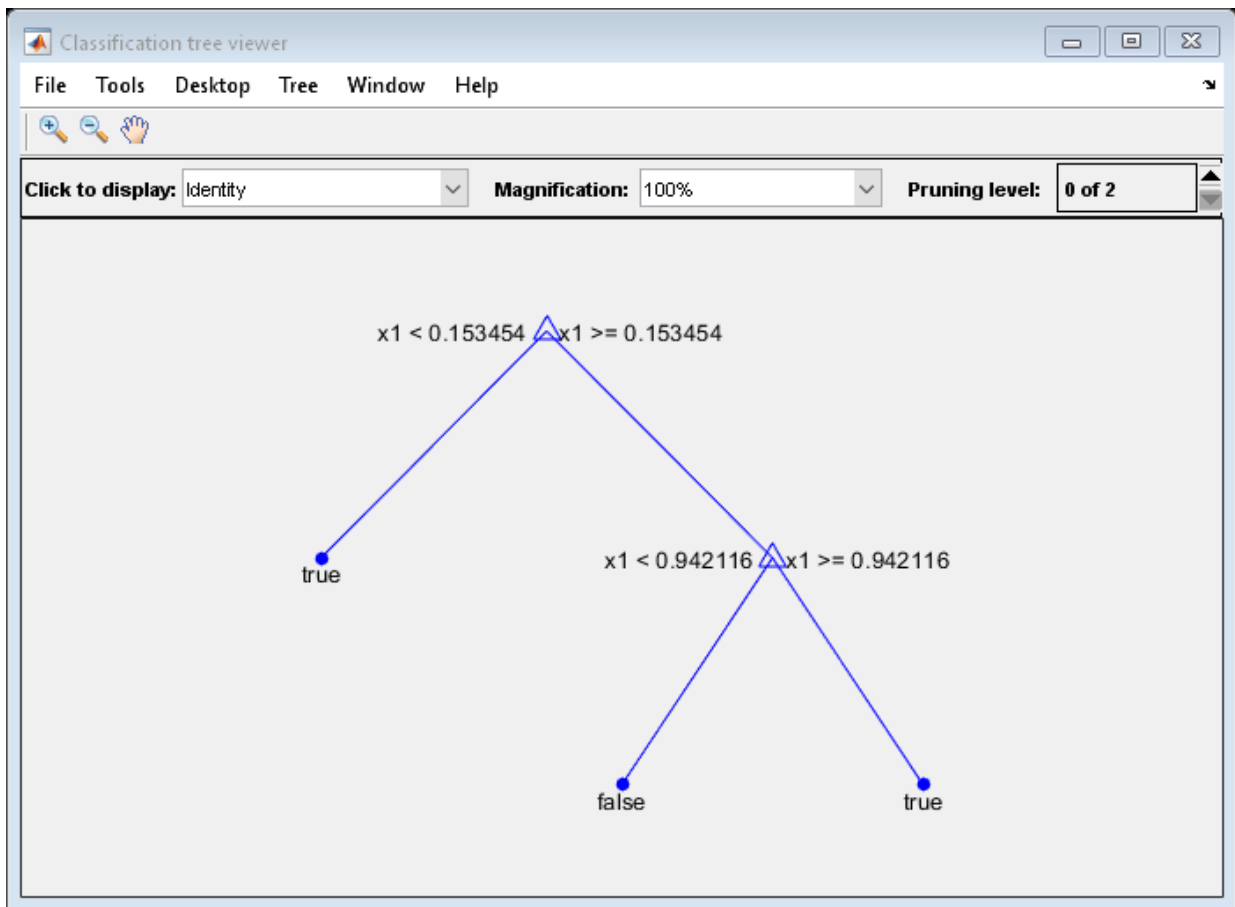

- AdaBoostM1 scores range from $-\infty$ to ∞ .
- Bag scores range from 0 to 1.

For trees, the score of a classification of a leaf node is the posterior probability of the classification at that node. The posterior probability of the classification at a node is the number of training sequences that lead to that node with the classification, divided by the number of training sequences that lead to that node.

For example, consider classifying a predictor X as true when $X < 0.15$ or $X > 0.95$, and X is false otherwise.

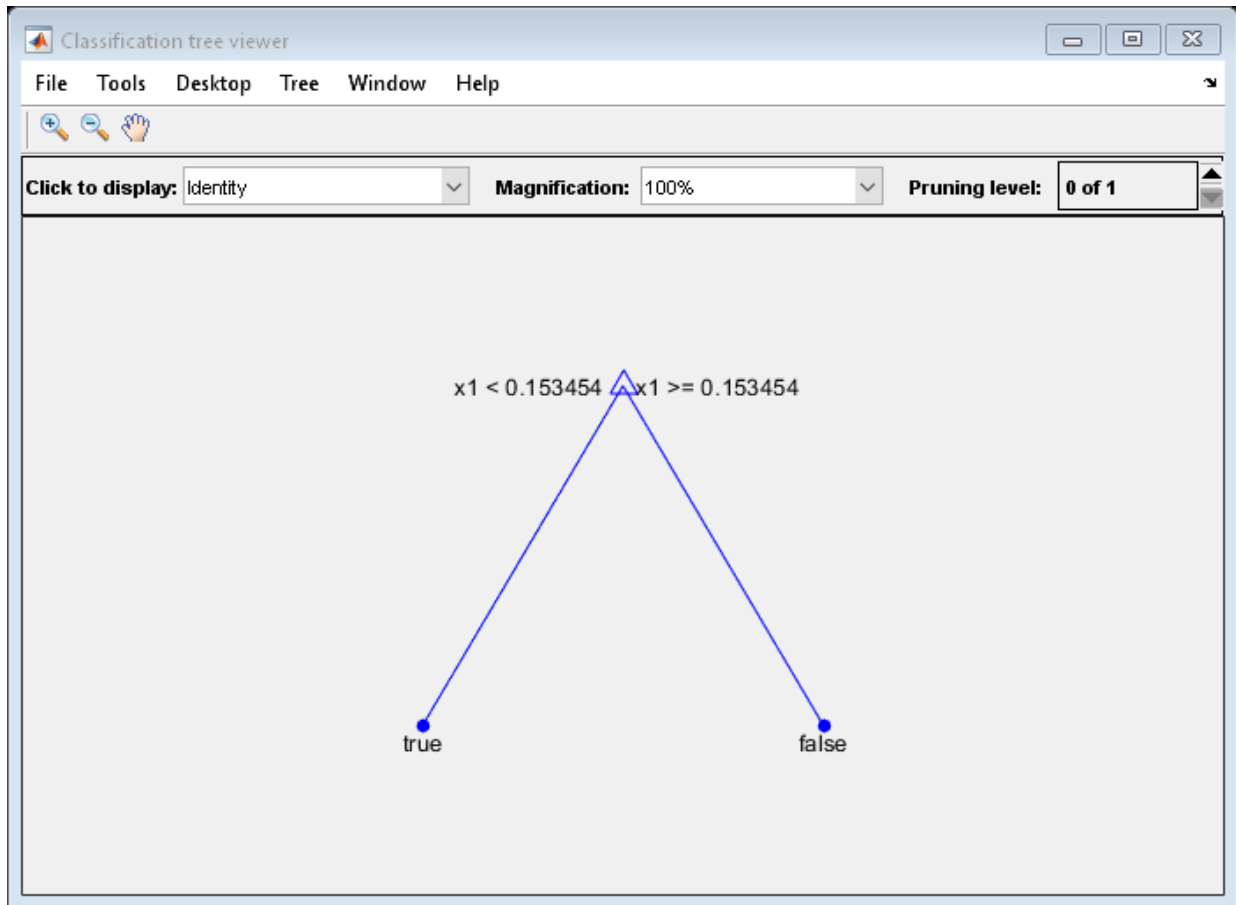

Generate 100 random points and classify them:

```
rng(0, 'twister') % for reproducibility
X = rand(100,1);
Y = (abs(X - .55) > .4);
tree = fitctree(X,Y);
view(tree, 'Mode', 'Graph')
```

Prune the tree:

```
tree1 = prune(tree, 'Level', 1);
view(tree1, 'Mode', 'Graph')
```

The pruned tree correctly classifies observations that are less than 0.15 as `true`. It also correctly classifies observations from .15 to .94 as `false`. However, it incorrectly classifies observations that are greater than .94 as `false`. Therefore, the score for observations that are greater than .15 should be about $.05/.85=.06$ for `true`, and about $.8/.85=.94$ for `false`.

Compute the prediction scores for the first 10 rows of `X`:

```
[~,score] = predict(tree1,X(1:10));  
[score X(1:10,:)]
```

```
ans = 10×3
```

```
    0.9059    0.0941    0.8147  
    0.9059    0.0941    0.9058  
         0     1.0000    0.1270  
    0.9059    0.0941    0.9134  
    0.9059    0.0941    0.6324  
         0     1.0000    0.0975  
    0.9059    0.0941    0.2785  
    0.9059    0.0941    0.5469  
    0.9059    0.0941    0.9575  
    0.9059    0.0941    0.9649
```

Indeed, every value of X (the right-most column) that is less than 0.15 has associated scores (the left and center columns) of 0 and 1, while the other values of X have associated scores of 0.91 and 0.09. The difference (score 0.09 instead of the expected .06) is due to a statistical fluctuation: there are 8 observations in X in the range (.95, 1) instead of the expected 5 observations.

kfoldPredict

Predict responses for observations not used for training

Syntax

```
YHat = kfoldPredict(CVMdl)
```

Description

`YHat = kfoldPredict(CVMdl)` returns cross-validated predicted responses by the cross-validated linear regression model `CVMdl`. That is, for every fold, `kfoldPredict` predicts responses for observations that it holds out when it trains using all other observations.

`YHat` contains predicted responses for each regularization strength in the linear regression models that compose `CVMdl`.

Input Arguments

CVMdl — Cross-validated, linear regression model

`RegressionPartitionedLinear` model object

Cross-validated, linear regression model, specified as a `RegressionPartitionedLinear` model object. You can create a `RegressionPartitionedLinear` model using `fitrlinear` and specifying any of the one of the cross-validation, name-value pair arguments, for example, `CrossVal`.

To obtain estimates, `kfoldPredict` applies the same data used to cross-validate the linear regression model (X and Y).

Output Arguments

YHat — Cross-validated predicted responses

numeric array

Cross-validated predicted responses, returned as an n -by- L numeric array. n is the number of observations in the predictor data that created `CVMDL` (see `X`) and L is the number of regularization strengths in `CVMDL.Trained{1}.Lambda`. `YHat(i,j)` is the predicted response for observation i using the linear regression model that has regularization strength `CVMDL.Trained{1}.Lambda(j)`.

The predicted response using the model with regularization strength j is $\hat{y}_j = x\beta_j + b_j$.

- x is an observation from the predictor data matrix `X`, and is row vector.
- β_j is the estimated column vector of coefficients. The software stores this vector in `Mdl.Beta(:,j)`.
- b_j is the estimated, scalar bias, which the software stores in `Mdl.Bias(j)`.

Examples

Predict Cross-Validated Responses

Simulate 10000 observations from this model

$$y = x_{100} + 2x_{200} + e.$$

- $X = x_1, \dots, x_{1000}$ is a 10000-by-1000 sparse matrix with 10% nonzero standard normal elements.
- e is random normal error with mean 0 and standard deviation 0.3.

```
rng(1) % For reproducibility
n = 1e4;
d = 1e3;
nz = 0.1;
X = sprandn(n,d,nz);
Y = X(:,100) + 2*X(:,200) + 0.3*randn(n,1);
```

Cross-validate a linear regression model.

```
CVMdl = fitrlinear(X,Y,'CrossVal','on')  
  
CVMdl =  
    classreg.learning.partition.RegressionPartitionedLinear  
    CrossValidatedModel: 'Linear'  
    ResponseName: 'Y'  
    NumObservations: 10000  
    KFold: 10  
    Partition: [1x1 cvpartition]  
    ResponseTransform: 'none'
```

Properties, Methods

```
Mdl1 = CVMdl.Trained{1}
```

```
Mdl1 =  
    RegressionLinear  
    ResponseName: 'Y'  
    ResponseTransform: 'none'  
    Beta: [1000x1 double]  
    Bias: 0.0107  
    Lambda: 1.1111e-04  
    Learner: 'svm'
```

Properties, Methods

By default, `fitrlinear` implements 10-fold cross-validation. `CVMdl` is a `RegressionPartitionedLinear` model. It contains the property `Trained`, which is a 10-by-1 cell array holding 10 `RegressionLinear` models that the software trained using the training set.

Predict responses for observations that `fitrlinear` did not use in training the folds.

```
yHat = kfoldPredict(CVMdl);
```

Because there is one regularization strength in `Mdl`, `yHat` is a numeric vector.

Predict for Models Containing Several Regularization Strengths

Simulate 10000 observations as in “Predict Cross-Validated Responses” on page 32-3511.

```
rng(1) % For reproducibility
n = 1e4;
d = 1e3;
nz = 0.1;
X = sprandn(n,d,nz);
Y = X(:,100) + 2*X(:,200) + 0.3*randn(n,1);
```

Create a set of 15 logarithmically-spaced regularization strengths from 10^{-5} through 10^{-1} .

```
Lambda = logspace(-5, -1, 15);
```

Cross-validate the models. To increase execution speed, transpose the predictor data and specify that the observations are in columns. Specify using least squares with a lasso penalty and optimizing the objective function using SpaRSA.

```
X = X';
CVMdl = fitrlinear(X,Y,'ObservationsIn','columns','KFold',5,'Lambda',Lambda,...
    'Learner','leastsquares','Solver','sparsa','Regularization','lasso');
```

CVMdl is a `RegressionPartitionedLinear` model. Its `Trained` property contains a 5-by-1 cell array of trained `RegressionLinear` models, each one holds out a different fold during training. Because `fitrlinear` trained using 15 regularization strengths, you can think of each `RegressionLinear` model as 15 models.

Predict cross-validated responses.

```
YHat = kfoldPredict(CVMdl);
size(YHat)
```

```
ans = 1×2
```

```
    10000    15
```

```
YHat(2,:)
ans = 1×15
```

```
-1.7338 -1.7332 -1.7319 -1.7299 -1.7266 -1.7239 -1.7135 -1.7210 -1.7
```

YHat is a 10000-by-15 matrix. YHat(2, :) is the cross-validated response for observation 2 using the model regularized with all 15 regularization values.

RegressionLinear | RegressionPartitionedLinear | fitrlinear | predict

Introduced in R2016a

kfoldPredict

Predict response for observations not used for training

Syntax

```
yfit = kfoldPredict(obj)
```

Description

`yfit = kfoldPredict(obj)` returns the predicted values for the responses of the training data based on `obj`, an object trained on out-of-fold observations.

Input Arguments

`obj`

Object of class `RegressionPartitionedModel`. Create `obj` with `fitrtree` or `fitrensemble` along with one of the cross-validation options: `'crossval'`, `'kfold'`, `'holdout'`, `'leaveout'`, or `'cvpartition'`. Alternatively, create `obj` from a regression tree or regression ensemble with `crossval`.

Output Arguments

`yfit`

A vector of predicted values for the response data based on a model trained on out-of-fold observations.

Examples

Construct a partitioned regression model, and examine the cross-validation loss. The cross-validation loss is the mean squared error between `yfit` and the true response data:

```
load carsmall
XX = [Cylinders Displacement Horsepower Weight];
YY = MPG;
tree = fitrtree(XX,YY);
cvmodel = crossval(tree);
L = kfoldLoss(cvmodel)
```

```
L =
    26.5271
```

```
yfit = kfoldPredict(cvmodel);
mean( (yfit - tree.Y).^2 )
```

```
ans =
    26.5271
```

See Also

[fitrtree](#) | [kfoldLoss](#)

kmeans

k-means clustering

Syntax

```
idx = kmeans(X,k)
idx = kmeans(X,k,Name,Value)
[idx,C] = kmeans(____)
[idx,C,sumd] = kmeans(____)
[idx,C,sumd,D] = kmeans(____)
```

Description

`idx = kmeans(X,k)` performs *k*-means clustering on page 32-3537 to partition the observations of the *n*-by-*p* data matrix *X* into *k* clusters, and returns an *n*-by-1 vector (`idx`) containing cluster indices of each observation. Rows of *X* correspond to points and columns correspond to variables.

By default, `kmeans` uses the squared Euclidean distance metric and the *k*-means++ algorithm on page 32-3538 for cluster center initialization.

`idx = kmeans(X,k,Name,Value)` returns the cluster indices with additional options specified by one or more `Name,Value` pair arguments.

For example, specify the cosine distance, the number of times to repeat the clustering using new initial values, or to use parallel computing.

`[idx,C] = kmeans(____)` returns the *k* cluster centroid locations in the *k*-by-*p* matrix *C*.

`[idx,C,sumd] = kmeans(____)` returns the within-cluster sums of point-to-centroid distances in the *k*-by-1 vector `sumd`.

`[idx,C,sumd,D] = kmeans(____)` returns distances from each point to every centroid in the *n*-by-*k* matrix *D*.

Examples

Train a *k*-Means Clustering Algorithm

Cluster data using *k*-means clustering, then plot the cluster regions.

Load Fisher's iris data set. Use the petal lengths and widths as predictors.

```
load fisheriris
X = meas(:,3:4);

figure;
plot(X(:,1),X(:,2),'k*','MarkerSize',5);
title 'Fisher''s Iris Data';
xlabel 'Petal Lengths (cm)';
ylabel 'Petal Widths (cm)';
```

The larger cluster seems to be split into a lower variance region and a higher variance region. This might indicate that the larger cluster is two, overlapping clusters.

Cluster the data. Specify $k = 3$ clusters.

```
rng(1); % For reproducibility
[idx,C] = kmeans(X,3);
```

`kmeans` uses the k -means++ algorithm for centroid initialization and squared Euclidean distance by default. It is good practice to search for lower, local minima by setting the 'Replicates' name-value pair argument.

`idx` is a vector of predicted cluster indices corresponding to the observations in `X`. `C` is a 3-by-2 matrix containing the final centroid locations.

Use `kmeans` to compute the distance from each centroid to points on a grid. To do this, pass the centroids (`C`) and points on a grid to `kmeans`, and implement one iteration of the algorithm.

```
x1 = min(X(:,1)):0.01:max(X(:,1));
x2 = min(X(:,2)):0.01:max(X(:,2));
[x1G,x2G] = meshgrid(x1,x2);
XGrid = [x1G(:),x2G(:)]; % Defines a fine grid on the plot

idx2Region = kmeans(XGrid,3,'MaxIter',1,'Start',C);
```

```
Warning: Failed to converge in 1 iterations.
```

```
    % Assigns each node in the grid to the closest centroid
```

`kmeans` displays a warning stating that the algorithm did not converge, which you should expect since the software only implemented one iteration.

Plot the cluster regions.

```
figure;
gscatter(XGrid(:,1),XGrid(:,2),idx2Region,...
        [0,0.75,0.75;0.75,0,0.75;0.75,0.75,0],'.');
hold on;
plot(X(:,1),X(:,2),'k*','MarkerSize',5);
title 'Fisher's Iris Data';
xlabel 'Petal Lengths (cm)';
ylabel 'Petal Widths (cm)';
legend('Region 1','Region 2','Region 3','Data','Location','SouthEast');
hold off;
```

Partition Data into Two Clusters

Randomly generate the sample data.

```
rng default; % For reproducibility
X = [randn(100,2)*0.75+ones(100,2);
     randn(100,2)*0.5-ones(100,2)];
```

```
figure;
plot(X(:,1),X(:,2),'.');
title 'Randomly Generated Data';
```

There appears to be two clusters in the data.

Partition the data into two clusters, and choose the best arrangement out of five initializations. Display the final output.

```
opts = statset('Display','final');  
[idx,C] = kmeans(X,2,'Distance','cityblock',...  
    'Replicates',5,'Options',opts);
```

```
Replicate 1, 3 iterations, total sum of distances = 201.533.  
Replicate 2, 5 iterations, total sum of distances = 201.533.  
Replicate 3, 3 iterations, total sum of distances = 201.533.  
Replicate 4, 3 iterations, total sum of distances = 201.533.
```

Replicate 5, 2 iterations, total sum of distances = 201.533.
Best total sum of distances = 201.533

By default, the software initializes the replicates separately using *k*-means++.

Plot the clusters and the cluster centroids.

```
figure;  
plot(X(idx==1,1),X(idx==1,2), 'r.', 'MarkerSize', 12)  
hold on  
plot(X(idx==2,1),X(idx==2,2), 'b.', 'MarkerSize', 12)  
plot(C(:,1),C(:,2), 'kx', ...  
      'MarkerSize', 15, 'LineWidth', 3)  
legend('Cluster 1', 'Cluster 2', 'Centroids', ...  
       'Location', 'NW')  
title 'Cluster Assignments and Centroids'  
hold off
```

You can determine how well separated the clusters are by passing `idx` to `silhouette`.

Cluster Data Using Parallel Computing

Clustering large data sets might take time, particularly if you use online updates (set by default). If you have a Parallel Computing Toolbox™ license and you set the options for parallel computing, then `kmeans` runs each clustering task (or replicate) in parallel. And, if `Replicates`>1, then parallel computing decreases time to convergence.

Randomly generate a large data set from a Gaussian mixture model.

```

Mu = bsxfun(@times,ones(20,30),(1:20)'); % Gaussian mixture mean
rn30 = randn(30,30);
Sigma = rn30'*rn30; % Symmetric and positive-definite covariance
Mdl = gmdistribution(Mu,Sigma); % Define the Gaussian mixture distribution

rng(1); % For reproducibility
X = random(Mdl,10000);

```

Mdl is a 30-dimensional gmdistribution model with 20 components. X is a 10000-by-30 matrix of data generated from Mdl.

Specify the options for parallel computing.

```

stream = RandStream('mlfg6331_64'); % Random number stream
options = statset('UseParallel',1,'UseSubstreams',1,...
    'Streams',stream);

```

The input argument 'mlfg6331_64' of RandStream specifies to use the multiplicative lagged Fibonacci generator algorithm. options is a structure array with fields that specify options for controlling estimation.

Cluster the data using k -means clustering. Specify that there are $k = 20$ clusters in the data and increase the number of iterations. Typically, the objective function contains local minima. Specify 10 replicates to help find a lower, local minimum.

```

tic; % Start stopwatch timer
[idx,C,sumd,D] = kmeans(X,20,'Options',options,'MaxIter',10000,...
    'Display','final','Replicates',10);

```

```

Starting parallel pool (parpool) using the 'local' profile ...
connected to 6 workers.
Replicate 5, 72 iterations, total sum of distances = 7.73161e+06.
Replicate 1, 64 iterations, total sum of distances = 7.72988e+06.
Replicate 3, 68 iterations, total sum of distances = 7.72576e+06.
Replicate 4, 84 iterations, total sum of distances = 7.72696e+06.
Replicate 6, 82 iterations, total sum of distances = 7.73006e+06.
Replicate 7, 40 iterations, total sum of distances = 7.73451e+06.
Replicate 2, 194 iterations, total sum of distances = 7.72953e+06.
Replicate 9, 105 iterations, total sum of distances = 7.72064e+06.
Replicate 10, 125 iterations, total sum of distances = 7.72816e+06.
Replicate 8, 70 iterations, total sum of distances = 7.73188e+06.
Best total sum of distances = 7.72064e+06

```

```

toc % Terminate stopwatch timer

```

Elapsed time is 61.915955 seconds.

The Command Window indicates that six workers are available. The number of workers might vary on your system. The Command Window displays the number of iterations and the terminal objective function value for each replicate. The output arguments contain the results of replicate 9 because it has the lowest total sum of distances.

Assign New Data to Existing Clusters and Generate C/C++ Code

`kmeans` performs k -means clustering to partition data into k clusters. When you have a new data set to cluster, you can create new clusters that include the existing data and the new data by using `kmeans`. The `kmeans` function supports C/C++ code generation, so you can generate code that accepts training data and returns clustering results, and then deploy the code to a device. In this workflow, you must pass training data, which can be of considerable size. To save memory on the device, you can separate training and prediction by using `kmeans` and `pdist2`, respectively.

Use `kmeans` to create clusters in MATLAB® and use `pdist2` in the generated code to assign new data to existing clusters. For code generation, define an entry-point function that accepts the cluster centroid positions and the new data set, and returns the index of the nearest cluster. Then, generate code for the entry-point function.

Generating C/C++ code requires MATLAB® Coder™.

Perform k -Means Clustering

Generate a training data set using three distributions.

```
rng('default') % For reproducibility
X = [randn(100,2)*0.75+ones(100,2);
     randn(100,2)*0.5-ones(100,2);
     randn(100,2)*0.75];
```

Partition the training data into three clusters by using `kmeans`.

```
[idx,C] = kmeans(X,3);
```

Plot the clusters and the cluster centroids.

```
figure
gscatter(X(:,1),X(:,2),idx,'bgm')
```

```
hold on
plot(C(:,1),C(:,2),'kx')
legend('Cluster 1','Cluster 2','Cluster 3','Cluster Centroid')
```

Assign New Data to Existing Clusters

Generate a test data set.

```
Xtest = [randn(10,2)*0.75+ones(10,2);
         randn(10,2)*0.5-ones(10,2);
         randn(10,2)*0.75];
```

Classify the test data set using the existing clusters. Find the nearest centroid from each test data point by using `pdist2`.

```
[~,idx_test] = pdist2(C,Xtest,'euclidean','Smallest',1);
```

Plot the test data and label the test data using `idx_test` by using `gscatter`.

```
gscatter(Xtest(:,1),Xtest(:,2),idx_test,'bgm','ooo')
legend('Cluster 1','Cluster 2','Cluster 3','Cluster Centroid', ...
       'Data classified to Cluster 1','Data classified to Cluster 2', ...
       'Data classified to Cluster 3')
```

Generate Code

Generate C code that assigns new data to the existing clusters. Note that generating C/C++ code requires MATLAB® Coder™.

Define an entry-point function named `findNearestCentroid` that accepts centroid positions and new data, and then find the nearest cluster by using `pdist2`.

Add the `codegen` compiler directive (or pragma) to the entry-point function after the function signature to indicate that you intend to generate code for the MATLAB algorithm. Adding this directive instructs the MATLAB Code Analyzer to help you diagnose and fix violations that would cause errors during code generation.

```
type findNearestCentroid % Display contents of findNearestCentroid.m
```

```
function idx = findNearestCentroid(C,X) %codegen
[~,idx] = pdist2(C,X,'euclidean','Smallest',1); % Find the nearest centroid
```

Note: If you click the button located in the upper-right section of this page and open this example in MATLAB®, then MATLAB® opens the example folder. This folder includes the entry-point function file.

Generate code by using `codegen`. Because C and C++ are statically typed languages, you must determine the properties of all variables in the entry-point function at compile time. To specify the data type and array size of the inputs of `findNearestCentroid`, pass a MATLAB expression that represents the set of values with a certain data type and array size by using the `-args` option. For details, see “Specify Variable-Size Arguments for Code Generation” on page 31-58.

```
codegen findNearestCentroid -args {C,Xtest}
```

Warning: C Compiler produced warnings. See the build log for further details.

Code generation successful (with warnings): To view the report, open('codegen\mex\findNearestCentroid_mex')

`codegen` generates the MEX function `findNearestCentroid_mex` with a platform-dependent extension.

Verify the generated code.

```
myIndx = findNearestCentroid(C,Xtest);
myIndex_mex = findNearestCentroid_mex(C,Xtest);
verifyMEX = isequal(idx_test,myIndx,myIndex_mex)
```

```
verifyMEX = logical
    1
```

`isequal` returns logical 1 (true), which means all the inputs are equal. The comparison confirms that the `pdist2` function, the `findNearestCentroid` function, and the MEX function return the same index.

You can also generate optimized CUDA® code using GPU Coder™.

```
cfg = coder.gpuConfig('mex');  
codegen -config cfg findNearestCentroid -args {C,Xtest}
```

For more information on code generation, see “General Code Generation Workflow” on page 31-5. For more information on GPU coder, see “Getting Started with GPU Coder” (GPU Coder) and “Supported Functions” (GPU Coder).

Input Arguments

X — Data

numeric matrix

Data, specified as a numeric matrix. The rows of *X* correspond to observations, and the columns correspond to variables.

If *X* is a numeric vector, then `kmeans` treats it as an *n*-by-1 data matrix, regardless of its orientation.

Data Types: `single` | `double`

k — Number of clusters

positive integer

Number of clusters in the data, specified as a positive integer.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example:

```
'Distance', 'cosine', 'Replicates', 10, 'Options', statset('UseParallel',
```

1) specifies the cosine distance, 10 replicate clusters at different starting values, and to use parallel computing.

Display — Level of output to display

'off' (default) | 'final' | 'iter'

Level of output to display in the Command Window, specified as the comma-separated pair consisting of 'Display' and one of the following options:

- 'final' — Displays results of the final iteration
- 'iter' — Displays results of each iteration
- 'off' — Displays nothing

Example: 'Display', 'final'

Distance — Distance metric

'sqeuclidean' (default) | 'cityblock' | 'cosine' | 'correlation' | 'hamming'

Distance metric, in p -dimensional space, used for minimization, specified as the comma-separated pair consisting of 'Distance' and 'sqeuclidean', 'cityblock', 'cosine', 'correlation', or 'hamming'.

kmeans computes centroid clusters differently for the different, supported distance metrics. This table summarizes the available distance metrics. In the formulae, x is an observation (that is, a row of X) and c is a centroid (a row vector).

Distance Metric	Description	Formula
'sqeuclidean'	Squared Euclidean distance (default). Each centroid is the mean of the points in that cluster.	$d(x, c) = (x - c)(x - c)'$
'cityblock'	Sum of absolute differences, i.e., the L_1 distance. Each centroid is the component-wise median of the points in that cluster.	$d(x, c) = \sum_{j=1}^p x_j - c_j $

Distance Metric	Description	Formula
'cosine'	One minus the cosine of the included angle between points (treated as vectors). Each centroid is the mean of the points in that cluster, after normalizing those points to unit Euclidean length.	$d(x, c) = 1 - \frac{xc'}{\sqrt{(xx')(cc')}}$
'correlation'	One minus the sample correlation between points (treated as sequences of values). Each centroid is the component-wise mean of the points in that cluster, after centering and normalizing those points to zero mean and unit standard deviation.	$d(x, c) = 1 - \frac{(x - \vec{x})(c - \vec{c})}{\sqrt{(x - \vec{x})(x - \vec{x})} \sqrt{(c - \vec{c})(c - \vec{c})}}$ <p>where</p> <ul style="list-style-type: none"> • $\vec{x} = \frac{1}{p} \left(\sum_{j=1}^p x_j \right) \vec{1}_p$ • $\vec{c} = \frac{1}{p} \left(\sum_{j=1}^p c_j \right) \vec{1}_p$ • $\vec{1}_p$ is a row vector of p ones.
'hamming'	This metric is only suitable for binary data. It is the proportion of bits that differ. Each centroid is the component-wise median of points in that cluster.	$d(x, y) = \frac{1}{p} \sum_{j=1}^p I\{x_j \neq y_j\}$ <p>},</p> <p>where I is the indicator function.</p>

Example: 'Distance', 'cityblock'

EmptyAction — Action to take if cluster loses all member observations

'singleton' (default) | 'error' | 'drop'

Action to take if a cluster loses all its member observations, specified as the comma-separated pair consisting of 'EmptyAction' and one of the following options.

Value	Description
'error'	Treat an empty cluster as an error.
'drop'	Remove any clusters that become empty. kmeans sets the corresponding return values in C and D to NaN.
'singleton'	Create a new cluster consisting of the one point furthest from its centroid (default).

Example: 'EmptyAction', 'error'

MaxIter — Maximum number of iterations

100 (default) | positive integer

Maximum number of iterations, specified as the comma-separated pair consisting of 'MaxIter' and a positive integer.

Example: 'MaxIter', 1000

Data Types: double | single

OnlinePhase — Online update flag

'off' (default) | 'on'

Online update flag, specified as the comma-separated pair consisting of 'OnlinePhase' and 'off' or 'on'.

If OnlinePhase is on, then kmeans performs an online update phase in addition to a batch update phase. The online phase can be time consuming for large data sets, but guarantees a solution that is a local minimum of the distance criterion. In other words, the software finds a partition of the data in which moving any single point to a different cluster increases the total sum of distances.

Example: 'OnlinePhase', 'on'

Options — Options for controlling iterative algorithm for minimizing fitting criteria

[] (default) | structure array returned by `statset`

Options for controlling the iterative algorithm for minimizing the fitting criteria, specified as the comma-separated pair consisting of 'Options' and a structure array returned by `statset`. Supported fields of the structure array specify options for controlling the iterative algorithm.

This table summarizes the supported fields. Note that the supported fields require Parallel Computing Toolbox.

Field	Description
'Streams'	<p>A <code>RandStream</code> object or cell array of such objects. If you do not specify <code>Streams</code>, <code>kmeans</code> uses the default stream or streams. If you specify <code>Streams</code>, use a single object except when all of the following conditions exist:</p> <ul style="list-style-type: none"> • You have an open parallel pool. • <code>UseParallel</code> is true. • <code>UseSubstreams</code> is false. <p>In this case, use a cell array the same size as the parallel pool. If a parallel pool is not open, then <code>Streams</code> must supply a single random number stream.</p>
'UseParallel'	<ul style="list-style-type: none"> • If true and <code>Replicates > 1</code>, then <code>kmeans</code> implements the <i>k</i>-means algorithm on each replicate in parallel. • If Parallel Computing Toolbox is not installed, then computation occurs in serial mode. The default is false, indicating serial computation.

Field	Description
'UseSubstreams'	Set to <code>true</code> to compute in parallel in a reproducible fashion. The default is <code>false</code> . To compute reproducibly, set <code>Streams</code> to a type allowing substreams: <code>'mlfg6331_64'</code> or <code>'mrg32k3a'</code> .

To ensure more predictable results, use `parpool` and explicitly create a parallel pool before invoking `kmeans` and setting `'Options',statset('UseParallel',1)`.

Example: `'Options',statset('UseParallel',1)`

Data Types: `struct`

Replicates — Number of times to repeat clustering using new initial cluster centroid positions

1 (default) | positive integer

Number of times to repeat clustering using new initial cluster centroid positions, specified as the comma-separated pair consisting of `'Replicates'` and an integer. `kmeans` returns the solution with the lowest `sumd`.

You can set `'Replicates'` implicitly by supplying a 3-D array as the value for the `'Start'` name-value pair argument.

Example: `'Replicates',5`

Data Types: `double` | `single`

Start — Method for choosing initial cluster centroid positions

'plus' (default) | 'cluster' | 'sample' | 'uniform' | numeric matrix | numeric array

Method for choosing initial cluster centroid positions (or seeds), specified as the comma-separated pair consisting of `'Start'` and `'cluster'`, `'plus'`, `'sample'`, `'uniform'`, a numeric matrix, or a numeric array. This table summarizes the available options for choosing seeds.

Value	Description
'cluster'	Perform a preliminary clustering phase on a random 10% subsample of <i>X</i> when the number of observations in the subsample is greater than <i>k</i> . This preliminary phase is itself initialized using 'sample'. If the number of observations in the random 10% subsample is less than <i>k</i> , then the software selects <i>k</i> observations from <i>X</i> at random.
'plus' (default)	Select <i>k</i> seeds by implementing the <i>k</i> -means++ algorithm on page 32-3538 for cluster center initialization.
'sample'	Select <i>k</i> observations from <i>X</i> at random.
'uniform'	Select <i>k</i> points uniformly at random from the range of <i>X</i> . Not valid with the Hamming distance.
numeric matrix	<i>k</i> -by- <i>p</i> matrix of centroid starting locations. The rows of <i>Start</i> correspond to seeds. The software infers <i>k</i> from the first dimension of <i>Start</i> , so you can pass in [] for <i>k</i> .
numeric array	<i>k</i> -by- <i>p</i> -by- <i>r</i> array of centroid starting locations. The rows of each page correspond to seeds. The third dimension invokes replication of the clustering routine. Page <i>j</i> contains the set of seeds for replicate <i>j</i> . The software infers the number of replicates (specified by the 'Replicates' name-value pair argument) from the size of the third dimension.

Example: 'Start', 'sample'

Data Types: char | string | double | single

Note The software treats NaNs as missing data, and removes any row of X containing at least one NaN. Removing rows of X reduces the sample size.

Output Arguments

idx — Cluster indices

numeric column vector

Cluster indices, returned as a numeric column vector. `idx` has as many rows as X , and each row indicates the cluster assignment of the corresponding observation.

C — Cluster centroid locations

numeric matrix

Cluster centroid locations, returned as a numeric matrix. C is a k -by- p matrix, where row j is the centroid of cluster j .

sumd — Within-cluster sums of point-to-centroid distances

numeric column vector

Within-cluster sums of point-to-centroid distances, returned as a numeric column vector. `sumd` is a k -by-1 vector, where element j is the sum of point-to-centroid distances within cluster j .

D — Distances from each point to every centroid

numeric matrix

Distances from each point to every centroid, returned as a numeric matrix. D is an n -by- k matrix, where element (j,m) is the distance from observation j to centroid m .

Definitions

k-Means Clustering

k -means clustering, or Lloyd's algorithm [2], is an iterative, data-partitioning algorithm that assigns n observations to exactly one of k clusters defined by centroids, where k is chosen before the algorithm starts.

The algorithm proceeds as follows:

- 1 Choose k initial cluster centers (centroid). For example, choose k observations at random (by using 'Start', 'sample') or use the k -means ++ algorithm on page 32-3538 for cluster center initialization (the default).
- 2 Compute point-to-cluster-centroid distances of all observations to each centroid.
- 3 There are two ways to proceed (specified by `OnlinePhase`):
 - Batch update — Assign each observation to the cluster with the closest centroid.
 - Online update — Individually assign observations to a different centroid if the reassignment decreases the sum of the within-cluster, sum-of-squares point-to-cluster-centroid distances.

For more details, see “Algorithms” on page 32-3539.

- 4 Compute the average of the observations in each cluster to obtain k new centroid locations.
- 5 Repeat steps 2 through 4 until cluster assignments do not change, or the maximum number of iterations is reached.

k -means++ Algorithm

The k -means++ algorithm uses an heuristic to find centroid seeds for k -means clustering. According to Arthur and Vassilvitskii [1], k -means++ improves the running time of Lloyd’s algorithm, and the quality of the final solution.

The k -means++ algorithm chooses seeds as follows, assuming the number of clusters is k .

- 1 Select an observation uniformly at random from the data set, X . The chosen observation is the first centroid, and is denoted c_1 .
- 2 Compute distances from each observation to c_1 . Denote the distance between c_j and the observation m as $d(x_m, c_j)$.
- 3 Select the next centroid, c_2 at random from X with probability

$$\frac{d^2(x_m, c_1)}{\sum_{j=1}^n d^2(x_j, c_1)}.$$

- 4 To choose center j :
 - a Compute the distances from each observation to each centroid, and assign each observation to its closest centroid.

- b** For $m = 1, \dots, n$ and $p = 1, \dots, j - 1$, select centroid j at random from X with probability

$$\frac{d^2(x_m, c_p)}{\sum_{\{h; x_h \in C_p\}} d^2(x_h, c_p)},$$

where C_p is the set of all observations closest to centroid c_p and x_m belongs to C_p .

That is, select each subsequent center with a probability proportional to the distance from itself to the closest center that you already chose.

- 5** Repeat step 4 until k centroids are chosen.

Arthur and Vassilvitskii [1] demonstrate, using a simulation study for several cluster orientations, that k -means++ achieves faster convergence to a lower sum of within-cluster, sum-of-squares point-to-cluster-centroid distances than Lloyd's algorithm.

Algorithms

- k means uses a two-phase iterative algorithm to minimize the sum of point-to-centroid distances, summed over all k clusters.
 - 1** This first phase uses batch updates, where each iteration consists of reassigning points to their nearest cluster centroid, all at once, followed by recalculation of cluster centroids. This phase occasionally does not converge to solution that is a local minimum. That is, a partition of the data where moving any single point to a different cluster increases the total sum of distances. This is more likely for small data sets. The batch phase is fast, but potentially only approximates a solution as a starting point for the second phase.
 - 2** This second phase uses online updates, where points are individually reassigned if doing so reduces the sum of distances, and cluster centroids are recomputed after each reassignment. Each iteration during this phase consists of one pass though all the points. This phase converges to a local minimum, although there might be other local minima with lower total sum of distances. In general, finding the global minimum is solved by an exhaustive choice of starting points, but using several replicates with random starting points typically results in a solution that is a global minimum.

- If `Replicates = r > 1` and `Start` is `plus` (the default), then the software selects r possibly different sets of seeds according to the `k-means++` algorithm on page 32-3538.
- If you enable the `UseParallel` option in `Options` and `Replicates > 1`, then each worker selects seeds and clusters in parallel.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

Usage notes and limitations:

- Supported syntaxes are:
 - `idx = kmeans(X,k)`
 - `[idx,C] = kmeans(X,k)`
 - `[idx,C,sumd] = kmeans(X,k)`
 - `[___] = kmeans(___,Name,Value)`
- Supported name-value pair arguments, and any differences, are:

- 'Display' — Default value is 'iter'.
- 'MaxIter'
- 'Options' — Supports only the 'TolFun' field of the structure array created by `statset`. The default value of 'TolFun' is $1e-4$. The `kmeans` function uses the value of 'TolFun' as the termination tolerance for the within-cluster sums of point-to-centroid distances. For example, you can specify `'Options', statset('TolFun', 1e-8)`.
- 'Replicates'
- 'Start' — Supports only 'plus', 'sample', and a numeric array.

For more information, see “Tall Arrays” (MATLAB).

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- If the `Start` method uses random selections, the initial centroid cluster positions might not match MATLAB.
- If the number of rows in `X` is fixed, code generation does not remove rows of `X` that contain a `NaN`.
- The cluster centroid locations in `C` can have a different order than in MATLAB. In this case, the cluster indices in `idx` have corresponding differences.
- If you provide `Display`, its value must be 'off'.
- If you provide `Streams`, it must be empty and `UseSubstreams` must be `false`.
- When you set the `UseParallel` option to `true`:
 - Some computations can execute in parallel even when `Replicates` is 1. For large data sets, when `Replicates` is 1, consider setting the `UseParallel` option to `true`.
 - `kmeans` uses `parfor` to create loops that run in parallel on supported shared-memory multicore platforms. Loops that run in parallel can be faster than loops that run on a single thread. If your compiler does not support the Open Multiprocessing (OpenMP) application interface or you disable OpenMP library, MATLAB Coder treats the `parfor`-loops as `for`-loops. To find supported compilers, see https://www.mathworks.com/support/compilers/current_release/.

- To save memory on the device to which you deploy generated code, you can separate training and prediction by using `kmeans` and `pdist2`, respectively. Use `kmeans` to create clusters in MATLAB and use `pdist2` in the generated code to assign new data to existing clusters. For code generation, define an entry-point function that accepts the cluster centroid positions and the new data set, and returns the index of the nearest cluster. Then, generate code for the entry-point function. For an example, see “Assign New Data to Existing Clusters and Generate C/C++ Code” on page 32-3526.

For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “General Code Generation Workflow” on page 31-5.

Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the `'UseParallel'` option to `true`.

Set the `'UseParallel'` field of the options structure to `true` using `statset` and specify the `'Options'` name-value pair argument in the call to this function.

For example: `'Options',statset('UseParallel',true)`

For more information, see the `'Options'` name-value pair argument.

For more general information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU arrays. For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

kmedoids

k-medoids clustering

Syntax

```
idx = kmedoids(X,k)
idx = kmedoids(X,k,Name,Value)
[idx,C] = kmedoids(____)
[idx,C,sumd] = kmedoids(____)
[idx,C,sumd,D] = kmedoids(____)
[idx,C,sumd,D,midx] = kmedoids(____)
[idx,C,sumd,D,midx,info] = kmedoids(____)
```

Description

`idx = kmedoids(X,k)` performs “*k*-medoids Clustering” on page 32-3560 to partition the observations of the *n*-by-*p* matrix *X* into *k* clusters, and returns an *n*-by-1 vector `idx` containing cluster indices of each observation. Rows of *X* correspond to points and columns correspond to variables. By default, `kmedoids` uses squared Euclidean distance metric and the *k*-means++ algorithm on page 32-3538 for choosing initial cluster medoid positions.

`idx = kmedoids(X,k,Name,Value)` uses additional options specified by one or more `Name,Value` pair arguments.

`[idx,C] = kmedoids(____)` returns the *k* cluster medoid locations in the *k*-by-*p* matrix *C*.

`[idx,C,sumd] = kmedoids(____)` returns the within-cluster sums of point-to-medoid distances in the *k*-by-1 vector `sumd`.

`[idx,C,sumd,D] = kmedoids(____)` returns distances from each point to every medoid in the *n*-by-*k* matrix *D*.

`[idx,C,sumd,D,midx] = kmedoids(____)` returns the indices `midx` such that `C = X(midx,:)`. `midx` is a *k*-by-1 vector.

`[idx,C,sumd,D,midx,info] = kmedoids(____)` returns a structure `info` with information about the options used by the algorithm when executed.

Examples

Group Data into Two Clusters

Randomly generate data.

```
rng('default'); % For reproducibility
X = [randn(100,2)*0.75+ones(100,2);
     randn(100,2)*0.55-ones(100,2)];
figure;
plot(X(:,1),X(:,2),'.');
title('Randomly Generated Data');
```

Group data into two clusters using `kmedoids`. Use the `cityblock` distance metric.

```
opts = statset('Display','iter');
[idx,C,sumd,d,midx,info] = kmedoids(X,2,'Distance','cityblock','Options',opts);
```

```
    rep      iter      sum
     1         1    209.856
     1         2    209.856
Best total sum of distances = 209.856
```

`info` is a struct that contains information about how the algorithm was executed. For example, `bestReplicate` field indicates the replicate that was used to produce the final solution. In this example, the replicate number 1 was used since the default number of replicates is 1 for the default algorithm, which is `pam` in this case.

```
info
```

```
info = struct with fields:
    algorithm: 'pam'
    start: 'plus'
    distance: 'cityblock'
    iterations: 2
    bestReplicate: 1
```

Plot the clusters and the cluster medoids.

```
figure;
plot(X(idx==1,1),X(idx==1,2), 'r.', 'MarkerSize', 7)
hold on
plot(X(idx==2,1),X(idx==2,2), 'b.', 'MarkerSize', 7)
plot(C(:,1),C(:,2), 'co', ...
     'MarkerSize', 7, 'LineWidth', 1.5)
legend('Cluster 1', 'Cluster 2', 'Medoids', ...
     'Location', 'NW');
title('Cluster Assignments and Medoids');
hold off
```

Cluster Categorical Data Using k-Medoids

This example uses "Mushroom" data set [3][4][5] [6][7] from the UCI machine learning archive [7], described in <http://archive.ics.uci.edu/ml/datasets/Mushroom>. The data set includes 22 predictors for 8,124 observations of various mushrooms. The predictors are categorical data types. For example, cap shape is categorized with features of 'b' for bell-shaped cap and 'c' for conical. Mushroom color is also categorized with features of 'n' for brown, and 'p' for pink. The data set also includes a classification for each mushroom of either edible or poisonous.

Since the features of the mushroom data set are categorical, it is not possible to define the mean of several data points, and therefore the widely-used k -means clustering algorithm cannot be meaningfully applied to this data set. k -medoids is a related algorithm that partitions data into k distinct clusters, by finding medoids that minimize the sum of dissimilarities between points in the data and their nearest medoid.

The medoid of a set is a member of that set whose average dissimilarity with the other members of the set is the smallest. Similarity can be defined for many types of data that do not allow a mean to be calculated, allowing k -medoids to be used for a broader range of problems than k -means.

Using k -medoids, this example clusters the mushrooms into two groups, based on the predictors provided. It then explores the relationship between those clusters and the classifications of the mushrooms as either edible or poisonous.

This example assumes that you have downloaded the "Mushroom" data set [3][4][5] [6][7] from the UCI database (<http://archive.ics.uci.edu/ml/machine-learning-databases/mushroom/>) and saved it in your current directory as a text file named `agaricus-lepiota.txt`. There is no column headers in the data, so `readtable` uses the default variable names.

```
clear all
data = readtable('agaricus-lepiota.txt', 'ReadVariableNames', false);
```

Display the first 5 mushrooms with their first few features.

```
data(1:5, 1:10)
```

```
ans =
```

Var1	Var2	Var3	Var4	Var5	Var6	Var7	Var8	Var9	Var10
'p'	'x'	's'	'n'	't'	'p'	'f'	'c'	'n'	'k'
'e'	'x'	's'	'y'	't'	'a'	'f'	'c'	'b'	'k'
'e'	'b'	's'	'w'	't'	'l'	'f'	'c'	'b'	'n'
'p'	'x'	'y'	'w'	't'	'p'	'f'	'c'	'n'	'n'
'e'	'x'	's'	'g'	'f'	'n'	'f'	'w'	'b'	'k'

Extract the first column, labeled data for edible and poisonous groups. Then delete the column.

```
labels = data(:,1);
labels = categorical(labels{:,:});
data(:,1) = [];
```

Store the names of predictors (features), which are described in <http://archive.ics.uci.edu/ml/machine-learning-databases/mushroom/agaricus-lepiota.names>.

```
VarNames = {'cap_shape' 'cap_surface' 'cap_color' 'bruises' 'odor' ...
            'gill_attachment' 'gill_spacing' 'gill_size' 'gill_color' ...
            'stalk_shape' 'stalk_root' 'stalk_surface_above_ring' ...
            'stalk_surface_below_ring' 'stalk_color_above_ring' ...
            'stalk_color_below_ring' 'veil_type' 'veil_color' 'ring_number' ....
            'ring_type' 'spore_print_color' 'population' 'habitat'};
```

Set the variable names.

```
data.Properties.VariableNames = VarNames;
```

There are a total of 2480 missing values denoted as '?'.
sum(char(data{:,:}) == '?')

```
ans =
```

```
2480
```

Based on the inspection of the data set and its description, the missing values belong only to the 11th variable (`stalk_root`). Remove the column from the table.

```
data(:,11) = [];
```

`kmedoids` only accepts numeric data. You need to cast the categories you have into numeric type. The distance function you will use to define the dissimilarity of the data will be based on the double representation of the categorical data.

```
cats = categorical(data{:,:});
data = double(cats);
```

`kmedoids` can use any distance metric supported by `pdist2` to cluster. For this example you will cluster the data using the Hamming distance because this is an appropriate distance metric for categorical data as illustrated below. The Hamming distance between two vectors is the percentage of the vector components that differ. For instance, consider these two vectors.

```
v1 = [1 0 2 1];
```

```
v2 = [1 1 2 1];
```

They are equal in the 1st, 3rd and 4th coordinate. Since 1 of the 4 coordinates differ, the Hamming distance between these two vectors is .25.

You can use the function `pdist2` to measure the Hamming distance between the first and second row of data, the numerical representation of the categorical mushroom data. The value .2857 means that 6 of the 21 features of the mushroom differ.

```
pdist2(data(1,:),data(2:,:), 'hamming')
```

```
ans =
```

```
0.2857
```

In this example, you're clustering the mushroom data into two clusters based on features to see if the clustering corresponds to edibility. The `kmedoids` function is guaranteed to converge to a local minima of the clustering criterion; however, this may not be a global minimum for the problem. It is a good idea to cluster the problem a few times using the 'replicates' parameter. When 'replicates' is set to a value, n , greater than 1, the k -medoids algorithm is run n times, and the best result is returned.

To run `kmedoids` to cluster data into 2 clusters, based on the Hamming distance and to return the best result of 3 replicates, you run the following.

```
rng('default'); % For reproducibility
[IDX, C, SUMD, D, MIDX, INFO] = kmedoids(data,2, 'distance', 'hamming', 'replicates',3);
```

Let's assume that mushrooms in the predicted group 1 are poisonous and group 2 are all edible. To determine the performance of clustering results, calculate how many mushrooms in group 1 are indeed poisonous and group 2 are edible based on the known labels. In other words, calculate the number of false positives, false negatives, as well as true positives and true negatives.

Construct a confusion matrix (or matching matrix), where the diagonal elements represent the number of true positives and true negatives, respectively. The off-diagonal elements represent false negatives and false positives, respectively. For convenience, use the `confusionmat` function, which calculates a confusion matrix given known labels and predicted labels. Get the predicted label information from the `IDX` variable. `IDX` contains values of 1 and 2 for each data point, representing poisonous and edible groups, respectively.

```
predLabels = labels; % Initialize a vector for predicted labels.
predLabels(IDX==1) = categorical({'p'}); % Assign group 1 to be poisonous.
```

```
predLabels(IDX==2) = categorical({'e'}); % Assign group 2 to be edible.  
confMatrix = confusionmat(labels,predLabels)
```

```
confMatrix =
```

```
      4176      32  
      816     3100
```

Out of 4208 edible mushrooms, 4176 were correctly predicted to be in group 2 (edible group), and 32 were incorrectly predicted to be in group 1 (poisonous group). Similarly, out of 3916 poisonous mushrooms, 3100 were correctly predicted to be in group 1 (poisonous group), and 816 were incorrectly predicted to be in group 2 (edible group).

Given this confusion matrix, calculate the accuracy, which is the proportion of true results (both true positives and true negatives) against the overall data, and precision, which is the proportion of the true positives against all the positive results (true positives and false positives).

```
accuracy = (confMatrix(1,1)+confMatrix(2,2))/(sum(sum(confMatrix)))
```

```
accuracy =
```

```
    0.8956
```

```
precision = confMatrix(1,1) / (confMatrix(1,1)+confMatrix(2,1))
```

```
precision =
```

```
    0.8365
```

The results indicated that applying the k-medoids algorithm to the categorical features of mushrooms resulted in clusters that were associated with edibility.

Input Arguments

X — Data

numeric matrix

Data, specified as a numeric matrix. The rows of X correspond to observations, and the columns correspond to variables.

k — Number of medoids

positive integer

Number of medoids in the data, specified as a positive integer.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example:

```
'Distance','euclidean','Replicates',3,'Options',statset('UseParallel',1)
```

 specifies Euclidean distance, three replicate medoids at different starting values, and to use parallel computing.

Algorithm — Algorithm to find medoids

```
'pam' | 'small' | 'clara' | 'large'
```

Algorithm to find medoids, specified as the comma-separated pair consisting of `'Algorithm'` and `'pam'`, `'small'`, `'clara'`, or `'large'`. The default algorithm depends on the number of rows of `X`.

- If the number of rows of `X` is less than 3000, `'pam'` is the default algorithm.
- If the number of rows is between 3000 and 10000, `'small'` is the default algorithm.
- For all other cases, `'large'` is the default algorithm.

You can override the default choice by explicitly stating the algorithm. This table summarizes the available algorithms.

Algorithm	Description
'pam'	<p>Partitioning Around Medoids (PAM) is the classical algorithm for solving the k-medoids problem described in [1]. After applying the initialization function to select initial medoid positions, the program performs the swap-step of the PAM algorithm, that is, it searches over all possible swaps between medoids and non-medoids to see if the sum of medoid to cluster member distances goes down. You can specify which initialization function to use via the 'Start' name-value pair argument.</p> <p>The algorithm proceeds as follows.</p> <ol style="list-style-type: none"><li data-bbox="498 644 1270 739">1 Build-step: Each of k clusters is associated with a potential medoid. This assignment is performed using a technique specified by the 'Start' name-value pair argument.<li data-bbox="498 751 1325 907">2 Swap-step: Within each cluster, each point is tested as a potential medoid by checking if the sum of within-cluster distances gets smaller using that point as the medoid. If so, the point is defined as a new medoid. Every point is then assigned to the cluster with the closest medoid. <p>The algorithm iterates the build- and swap-steps until the medoids do not change, or other termination criteria are met.</p> <p>The algorithm can produce better solutions than the other algorithms in some situations, but it can be prohibitively long running.</p>

Algorithm	Description
'small'	<p>Use an algorithm similar to the k-means algorithm to find k medoids. This option employs a variant of the Lloyd's iterations based on [2].</p> <p>The algorithm proceeds as follows.</p> <ol style="list-style-type: none"> 1 For each point in each cluster, calculate the sum of distances from the point to every other point in the cluster. Choose the point that minimizes the sum as the new medoid. 2 Update the cluster membership for each data point to reflect the new medoid. <p>The algorithm repeats these steps until no further updates occur or other termination criteria are met. The algorithm has an optional PAM-like online update phase (specified by the 'OnlinePhase' name-value pair argument) that improves cluster quality. It tends to return higher quality solutions than the clara or large algorithms, but it may not be the best choice for very large data.</p>
'clara'	<p>Clustering LARge Applications (CLARA) [1] repeatedly performs the PAM algorithm on random subsets of the data. It aims to overcome scaling challenges posed by the PAM algorithm through sampling.</p> <p>The algorithm proceeds as follows.</p> <ol style="list-style-type: none"> 1 Select a subset of the data and apply the PAM algorithm to the subset. 2 Assign points of the full data set to clusters by picking the closest medoid. <p>The algorithm repeats these steps until the medoids do not change, or other termination criteria are met.</p> <p>For the best performance, it is recommended that you perform multiple replicates. By default, the program performs five replicates. Each replicate samples <i>s</i> rows from <i>X</i> (specified by 'NumSamples' name-value pair argument) to perform clustering on. By default, $40+2*k$ samples are selected.</p>

Algorithm	Description
'large'	This is similar to the <code>small</code> scale algorithm and repeatedly performs searches using a k-means like update. However, the algorithm examines only a random sample of cluster members during each iteration. The user-adjustable parameter, <code>'PercentNeighbors'</code> , controls the number of neighbors to examine. If there is no improvement after the neighbors are examined, the algorithm terminates the local search. The algorithm performs a total of r replicates (specified by <code>'Replicates'</code> name-value pair argument) and returns the best clustering result. The algorithm has an optional PAM-like online phase (specified by the <code>'OnlinePhase'</code> name-value pair argument) that improves cluster quality.

Example: `'Algorithm','pam'`

OnlinePhase — Flag to perform PAM-like online update phase

`'on'` (default) | `'off'`

A flag to perform PAM-like online update phase, specified as a comma-separated pair consisting of `'OnlinePhase'` and `'on'` or `'off'`.

If it is `on`, then `kmedoids` performs a PAM-like update to the medoids after the Lloyd iterations in the `small` and `large` algorithms. During this online update phase, the algorithm chooses a small subset of data points in each cluster that are the furthest from and nearest to medoid. For each chosen point, it reassigns the clustering of the entire data set and check if this creates a smaller sum of distances than the best known.

In other words, the swap considerations are limited to the points near the medoids and far from the medoids. The near points are considered in order to refine the clustering. The far points are considered in order to escape local minima. Turning on this feature tends to improve the quality of solutions generated by both algorithms. Total run time tends to increase as well, but the increase typically is less than one iteration of PAM.

Example: `OnlinePhase,'off'`

Distance — Distance metric

`'sqeuclidean'` (default) | `'euclidean'` | `'seuclidean'` | `'cityblock'` | `'minkowski'` | `'chebychev'` | `'mahalanobis'` | `'cosine'` | `'correlation'` | `'spearman'` | `'hamming'` | `'jaccard'` | custom distance function

Distance metric, in p-dimensional space, specified as the comma-separated pair consisting of 'Distance' and 'euclidean', 'seuclidean', 'cityblock', 'minkowski', 'chebychev', 'mahalanobis', 'cosine', 'correlation', 'spearman', 'hamming', 'jaccard', or a custom distance function.

kmedoids minimizes the sum of medoid to cluster member distances. See `pdist` for the definition of each distance metric. kmedoids supports all distance metrics supported by `pdist`.

Example: 'Distance', 'hamming'

Options — Options to control iterative algorithm to minimize fitting criteria

[] (default) | structure array returned by `statset`

Options to control the iterative algorithm to minimize fitting criteria, specified as the comma-separated pair consisting of 'Options' and a structure array returned by `statset`. Supported fields of the structure array specify options for controlling the iterative algorithm. This table summarizes the supported fields.

Field	Description
Display	Level of display output. Choices are 'off' (default) and 'iter'.
MaxIter	Maximum number of iterations allowed. The default is 100.
UseParallel	If <code>true</code> , compute in parallel. If Parallel Computing Toolbox is not available, then computation occurs in serial mode. The default is <code>false</code> , meaning serial computation.
UseSubstreams	Set to <code>true</code> to compute in parallel in a reproducible fashion. The default is <code>false</code> . To compute reproducibly, you must also set <code>Streams</code> to a type allowing substreams: 'mlfg6331_64' or 'mrg32k3a'.
Streams	A <code>RandStream</code> object or cell array of such objects. For details about these options and parallel computing in Statistics and Machine Learning Toolbox, see "Speed Up Statistical Computations" or enter <code>help parallelstats</code> at the command line.

Example: 'Options', `statset('Display','off')`

Replicates — Number of times to repeat clustering using new initial cluster medoid positions

positive integer

Number of times to repeat clustering using new initial cluster medoid positions, specified as a positive integer. The default value depends on the choice of algorithm. For `pam` and `small`, the default is 1. For `clara`, the default is 5. For `large`, the default is 3.

Example: `'Replicates',4`

NumSamples — Number of samples to take from data when executing clara algorithm

`40+2*k` (default) | positive integer

Number of samples to take from the data when executing the `clara` algorithm, specified as a positive integer. The default number of samples is calculated as $40+2*k$.

Example: `'NumSamples',160`

PercentNeighbors — Percent of data set to examine using large algorithm

`0.001` (default) | scalar value between 0 and 1

Percent of the data set to examine using the `large` algorithm, specified as a positive number.

The program examines `percentneighbors*size(X,1)` number of neighbors for the medoids. If there is no improvement in the within-cluster sum of distances, then the algorithm terminates.

The value of this parameter between 0 and 1, where a value closer to 1 tends to give higher quality solutions, but the algorithm takes longer to run, and a value closer to 0 tends to give lower quality solutions, but finishes faster.

Example: `'PercentNeighbors',0.01`

Start — Method for choosing initial cluster medoid positions

`'plus'` (default) | `'sample'` | `'cluster'` | matrix

Method for choosing initial cluster medoid positions, specified as the comma-separated pair consisting of `'Start'` and `'plus'`, `'sample'`, `'cluster'`, or a matrix. This table summarizes the available methods.

Method	Description
<code>'plus'</code> (default)	Select k observations from X according to the k -means++ algorithm on page 32-3538 for cluster center initialization.

Method	Description
'sample'	Select k observations from X at random.
'cluster'	Perform preliminary clustering phase on a random subsample (10%) of X . This preliminary phase is itself initialized using <code>sample</code> , that is, the observations are selected at random.
matrix	A custom k -by- p matrix of starting locations. In this case, you can pass in <code>[]</code> for the k input argument, and <code>kmedoids</code> infers k from the first dimension of the matrix. You can also supply a 3-D array, implying a value for 'Replicates' from the array's third dimension.

Example: 'Start', 'sample'

Data Types: char | string | single | double

Output Arguments

idx — Medoid indices

numeric column vector

Medoid indices, returned as a numeric column vector. `idx` has as many rows as X , and each row indicates the medoid assignment of the corresponding observation.

C — Cluster medoid locations

numeric matrix

Cluster medoid locations, returned as a numeric matrix. C is a k -by- p matrix, where row j is the medoid of cluster j

sumd — Within-cluster sums of point-to-medoid distances

numeric column vector

Within-cluster sums of point-to-medoid distances, returned as a numeric column vector. `sumd` is a k -by-1 vector, where element j is the sum of point-to-medoid distances within cluster j .

D — Distances from each point to every medoid

numeric matrix

Distances from each point to every medoid, returned as a numeric matrix. D is an n -by- k matrix, where element (j,m) is the distance from observation j to medoid m .

midx — Index to X

column vector

Index to X , returned as a column vector of indices. $midx$ is a k -by-1 vector and the indices satisfy $C = X(midx, :)$.

info — Algorithm information

struct

Algorithm information, returned as a struct. `info` contains options used by the function when executed such as k -medoid clustering algorithm (`algorithm`), method used to choose initial cluster medoid positions (`start`), distance metric (`distance`), number of iterations taken in the best replicate (`iterations`) and the replicate number of the returned results (`bestReplicate`).

Definitions

k -medoids Clustering

k -medoids clustering is a partitioning method commonly used in domains that require robustness to outlier data, arbitrary distance metrics, or ones for which the mean or median does not have a clear definition.

It is similar to k -means, and the goal of both methods is to divide a set of measurements or observations into k subsets or clusters so that the subsets minimize the sum of distances between a measurement and a center of the measurement's cluster. In the k -means algorithm, the center of the subset is the mean of measurements in the subset, often called a centroid. In the k -medoids algorithm, the center of the subset is a member of the subset, called a medoid.

The k -medoids algorithm returns medoids which are the actual data points in the data set. This allows you to use the algorithm in situations where the mean of the data does not exist within the data set. This is the main difference between k -medoids and k -means

where the centroids returned by k -means may not be within the data set. Hence k -medoids is useful for clustering categorical data where a mean is impossible to define or interpret.

The function `kmedoids` provides several iterative algorithms that minimize the sum of distances from each object to its cluster medoid, over all clusters. One of the algorithms is called partitioning around medoids (PAM) [1] which proceeds in two steps.

- 1 Build-step: Each of k clusters is associated with a potential medoid. This assignment is performed using a technique specified by the 'Start' name-value pair argument.
- 2 Swap-step: Within each cluster, each point is tested as a potential medoid by checking if the sum of within-cluster distances gets smaller using that point as the medoid. If so, the point is defined as a new medoid. Every point is then assigned to the cluster with the closest medoid.

The algorithm iterates the build- and swap-steps until the medoids do not change, or other termination criteria are met.

You can control the details of the minimization using several optional input parameters to `kmedoids`, including ones for the initial values of the cluster medoids, and for the maximum number of iterations. By default, `kmedoids` uses the k -means++ algorithm on page 32-3538 for cluster medoid initialization and the squared Euclidean metric to determine distances.

Extended Capabilities

Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the `'UseParallel'` option to `true`.

Set the `'UseParallel'` field of the options structure to `true` using `statset` and specify the `'Options'` name-value pair argument in the call to this function.

For example: `'Options',statset('UseParallel',true)`

For more information, see the `'Options'` name-value pair argument.

For more general information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

Introduced in R2014b

knnsearch

Find k -nearest neighbors using searcher object

Syntax

```
Idx = knnsearch(Mdl,Y)
Idx = knnsearch(Mdl,Y,Name,Value)
[Idx,D] = knnsearch( ___ )
```

Description

`Idx = knnsearch(Mdl,Y)` searches for the nearest neighbor (i.e., the closest point, row, or observation) in `Mdl.X` to each point (i.e., row or observation) in the query data `Y` using an exhaustive search or a *Kd-tree*. `knnsearch` returns `Idx`, which is a column vector of the indices in `Mdl.X` representing the nearest neighbors.

`Idx = knnsearch(Mdl,Y,Name,Value)` returns the indices of the closest points in `Mdl.X` to `Y` with additional options specified by one or more `Name,Value` pair arguments. For example, specify the number of nearest neighbors to search for, distance metric different from the one stored in `Mdl.Distance`. You can also specify which action to take if the closest distances are tied.

`[Idx,D] = knnsearch(___)` additionally returns the matrix `D` using any of the input arguments in the previous syntaxes. `D` contains the distances between each observation in `Y` that correspond to the closest observations in `Mdl.X`. By default, the function arranges the columns of `D` in ascending order by closeness, with respect to the distance metric.

Examples

Search for Nearest Neighbors Using *Kd-tree* and Exhaustive Search

`knnsearch` accepts `ExhaustiveSearcher` or `KDTreeSearcher` model objects to search the training data for the nearest neighbors to the query data. An

ExhaustiveSearcher model invokes the exhaustive searcher algorithm, and a KDTreeSearcher model defines a Kd-tree, which knnsearch uses to search for nearest neighbors.

Load Fisher's iris data set. Randomly reserve five observations from the data for query data.

```
load fisheriris
rng(1); % For reproducibility
n = size(meas,1);
idx = randsample(n,5);
X = meas(~ismember(1:n,idx),:); % Training data
Y = meas(idx,:); % Query data
```

The variable `meas` contains 4 predictors.

Grow a default four-dimensional Kd-tree.

```
MdLKDT = KDTreeSearcher(X)
```

```
MdLKDT =
  KDTreeSearcher with properties:
    BucketSize: 50
    Distance: 'euclidean'
    DistParameter: []
    X: [145x4 double]
```

`MdLKDT` is a `KDTreeSearcher` model object. You can alter its writable properties using dot notation.

Prepare an exhaustive nearest neighbor searcher.

```
MdLES = ExhaustiveSearcher(X)
```

```
MdLES =
  ExhaustiveSearcher with properties:
    Distance: 'euclidean'
    DistParameter: []
    X: [145x4 double]
```

MdlKDT is an `ExhaustiveSearcher` model object. It contains the options, such as the distance metric, to use to find nearest neighbors.

Alternatively, you can grow a *Kd-tree* or prepare an exhaustive nearest neighbor searcher using `createns`.

Search the training data for the nearest neighbors indices that correspond to each query observation. Conduct both types of searches using the default settings. By default, the number of neighbors to search for per query observation is 1.

```
IdxKDT = knnsearch(MdlKDT,Y);
IdxES = knnsearch(MdlES,Y);
[IdxKDT IdxES]
```

```
ans = 5x2
```

```
    17    17
     6     6
     1     1
    89    89
   124   124
```

In this case, the results of the search are the same.

Search for Nearest Neighbors of Query Data Using Minkowski Distance

Grow a *Kd-tree* nearest neighbor searcher object by using the `createns` function. Pass the object and query data to the `knnsearch` function to find *k*-nearest neighbors.

Load Fisher's iris data set.

```
load fisheriris
```

Remove five irises randomly from the predictor data to use as a query set.

```
rng(1); % For reproducibility
n = size(meas,1); % Sample size
qIdx = randsample(n,5); % Indices of query data
tIdx = ~ismember(1:n,qIdx); % Indices of training data
Q = meas(qIdx,:);
X = meas(tIdx,:);
```

Grow a four-dimensional Kd-tree using the training data. Specify the Minkowski distance for finding nearest neighbors.

```
Mdl = createns(X, 'Distance', 'minkowski')
```

```
Mdl =  
  KDTreeSearcher with properties:  
  
    BucketSize: 50  
    Distance: 'minkowski'  
    DistParameter: 2  
    X: [145x4 double]
```

Because `X` has four columns and the distance metric is Minkowski, `createns` creates a `KDTreeSearcher` model object by default. The Minkowski distance exponent is 2 by default.

Find the indices of the training data (`Mdl.X`) that are the two nearest neighbors of each point in the query data (`Q`).

```
IdxNN = knnsearch(Mdl, Q, 'K', 2)
```

```
IdxNN = 5x2
```

```
    17     4  
     6     2  
     1    12  
    89    66  
   124   100
```

Each row of `IdxNN` corresponds to a query data observation, and the column order corresponds to the order of the nearest neighbors, with respect to ascending distance. For example, based on the Minkowski distance, the second nearest neighbor of `Q(3, :)` is `X(12, :)`.

Include Ties in Nearest Neighbor Search

Load Fisher's iris data set.

```
load fisheriris
```

Remove five irises randomly from the predictor data to use as a query set.

```
rng(4); % For reproducibility
n = size(meas,1); % Sample size
qIdx = randsample(n,5); % Indices of query data
X = meas(~ismember(1:n,qIdx),:);
Y = meas(qIdx,:);
```

Grow a four-dimensional Kd-tree using the training data. Specify the Minkowski distance for finding nearest neighbors.

```
Mdl = KDTreeSearcher(X);
```

Mdl is a KDTreeSearcher model object. By default, the distance metric for finding nearest neighbors is the Euclidean metric.

Find the indices of the training data (X) that are the seven nearest neighbors of each point in the query data (Y).

```
[Idx,D] = knnsearch(Mdl,Y,'K',7,'IncludeTies',true);
```

Idx and D are five-element cell arrays of vectors, with each vector having at least seven elements.

Display the lengths of the vectors in Idx.

```
cellfun('length',Idx)
```

```
ans = 5×1
```

```
8
7
7
7
7
```

Because cell 1 contains a vector with length greater than $k = 7$, query observation 1 ($Y(1,:)$) is equally close to at least two observations in X.

Display the indices of the nearest neighbors to $Y(1,:)$ and their distances.

```
nn5 = Idx{1}
```

```
nn5 = 1×8
```

```
          91    98    67    69    71    93    88    95

nn5d = D{1}
nn5d = 1×8
      0.1414    0.2646    0.2828    0.3000    0.3464    0.3742    0.3873    0.3873
```

Training observations 88 and 95 are 0.3873 cm away from query observation 1.

Compare k -Nearest Neighbors Using Different Distance Metrics

Train two `KDTreeSearcher` models using different distance metrics, and compare k -nearest neighbors of query data for the two models.

Load Fisher's iris data set. Consider the petal measurements as predictors.

```
load fisheriris
X = meas(:,3:4); % Predictors
Y = species;    % Response
```

Train a `KDTreeSearcher` model object by using the predictors. Specify the Minkowski distance with exponent 5.

```
KDTreeMdl = KDTreeSearcher(X, 'Distance', 'minkowski', 'P', 5)

KDTreeMdl =
  KDTreeSearcher with properties:
    BucketSize: 50
    Distance: 'minkowski'
    DistParameter: 5
    X: [150x2 double]
```

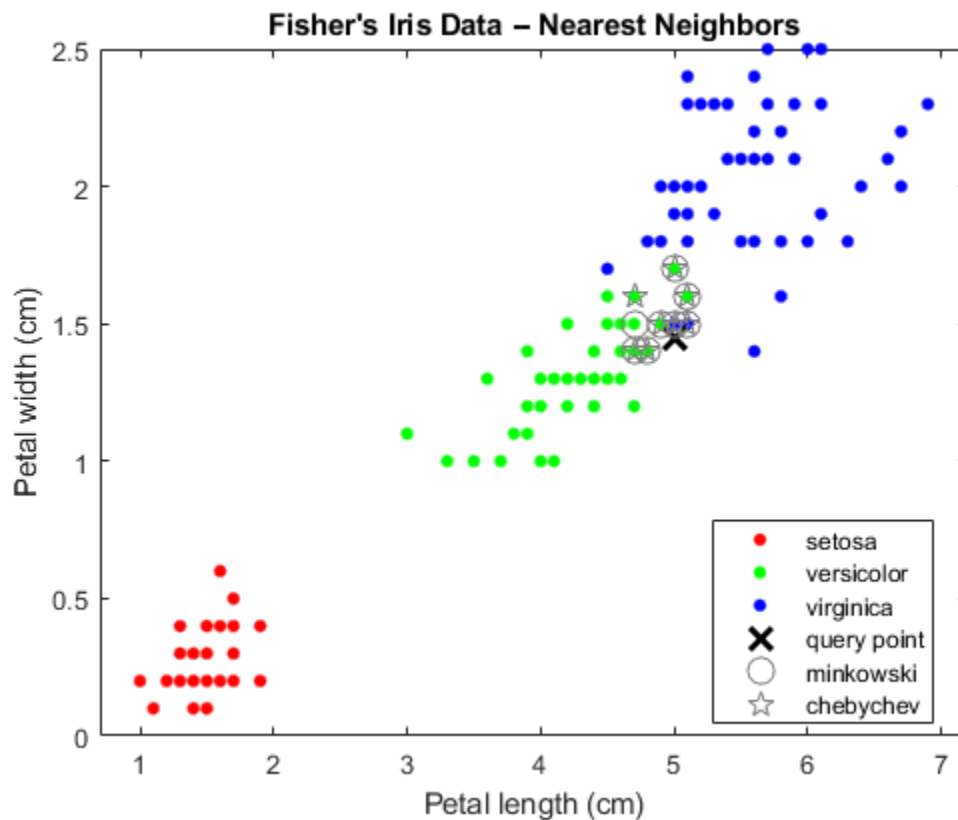

Find the 10 nearest neighbors from `X` to a query point (`newpoint`), first using Minkowski then Chebychev distance metrics. The query point must have the same column dimension as the data used to train the model.

```
newpoint = [5 1.45];
[IdxMk, DMk] = knnsearch(KDTreeMdl, newpoint, 'k', 10);
[IdxCb, DCb] = knnsearch(KDTreeMdl, newpoint, 'k', 10, 'Distance', 'chebychev');
```

IdxMk and IdxCb are 1-by-10 matrices containing the row indices of X corresponding to the nearest neighbors to newpoint using Minkowski and Chebychev distances, respectively. Element (1,1) is the nearest, element (1,2) is the next nearest, and so on.

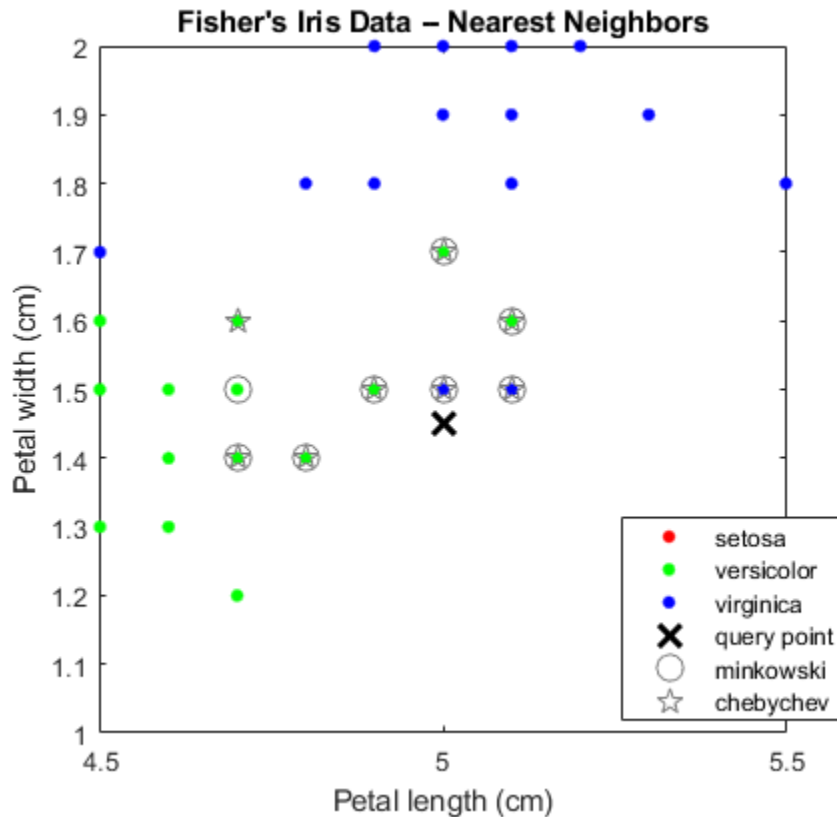

Plot the training data, query point, and nearest neighbors.

```
figure;
gscatter(X(:,1),X(:,2),Y);
title('Fisher''s Iris Data -- Nearest Neighbors');
xlabel('Petal length (cm)');
ylabel('Petal width (cm)');
hold on
plot(newpoint(1),newpoint(2),'kx','MarkerSize',10,'LineWidth',2); % Query point
plot(X(IdxMk,1),X(IdxMk,2),'o','Color',[.5 .5 .5],'MarkerSize',10); % Minkowski nearest
plot(X(IdxCb,1),X(IdxCb,2),'p','Color',[.5 .5 .5],'MarkerSize',10); % Chebychev nearest
legend('setosa','versicolor','virginica','query point',...
      'minkowski','chebychev','Location','Best');
```

Zoom in on the points of interest.

```
h = gca; % Get current axis handle.
h.XLim = [4.5 5.5];
h.YLim = [1 2];
axis square;
```

Several observations are equal, which is why only eight nearest neighbors are identified in the plot.

Input Arguments

Mdl – Nearest neighbor searcher

ExhaustiveSearcher model object | KDTreeSearcher model object

Nearest neighbor searcher, specified as an ExhaustiveSearcher or KDTreeSearcher model object, respectively.

If `Mdl` is an `ExhaustiveSearcher` model, then `knnsearch` searches for nearest neighbors using an exhaustive search. Otherwise, `knnsearch` uses the grown Kd-tree to search for nearest neighbors.

Y — Query data

numeric matrix

Query data, specified as a numeric matrix.

`Y` is an m -by- K matrix. Rows of `Y` correspond to observations (i.e., examples), and columns correspond to predictors (i.e., variables or features). `Y` must have the same number of columns as the training data stored in `Mdl.X`.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'K', 2, 'Distance', 'minkowski'` specifies to find the two nearest neighbors of `Mdl.X` to each point in `Y` and to use the Minkowski distance metric.

For Both Nearest Neighbor Searchers

Distance — Distance metric

`Mdl.Distance` (default) | `'cityblock'` | `'euclidean'` | `'mahalanobis'` | `'minkowski'` | `'seuclidean'` | function handle | ...

Distance metric used to find neighbors of the training data to the query observations, specified as the comma-separated pair consisting of `'Distance'` and a character vector, string scalar, or function handle.

For both types of nearest neighbor searchers, `knnsearch` supports these distance metrics.

Value	Description
<code>'chebychev'</code>	Chebychev distance (maximum coordinate difference).
<code>'cityblock'</code>	City block distance.

Value	Description
'euclidean'	Euclidean distance.
'minkowski'	Minkowski distance. The default exponent is 2. To specify a different exponent, use the 'P' name-value pair argument.

If `Mdl` is an `ExhaustiveSearcher` model object, then `knnsearch` also supports these distance metrics.

Value	Description
'correlation'	One minus the sample linear correlation between observations (treated as sequences of values).
'cosine'	One minus the cosine of the included angle between observations (treated as row vectors).
'hamming'	Hamming distance, which is the percentage of coordinates that differ.
'jaccard'	One minus the Jaccard coefficient, which is the percentage of nonzero coordinates that differ.
'mahalanobis'	Mahalanobis distance, computed using a positive definite covariance matrix. To change the value of the covariance matrix, use the 'Cov' name-value pair argument.
'seuclidean'	Standardized Euclidean distance. Each coordinate difference between rows in <code>Mdl.X</code> and the query matrix is scaled by dividing by the corresponding element of the standard deviation computed from <code>Mdl.X</code> . To specify another scaling, use the 'Scale' name-value pair argument.
'spearman'	One minus the sample Spearman's rank correlation between observations (treated as sequences of values).

If `Mdl` is an `ExhaustiveSearcher` model object, then you can also specify a function handle for a custom distance metric by using `@` (for example, `@distfun`). The custom distance function must:

- Have the form function `D2 = distfun(ZI,ZJ)`.
- Take as arguments:
 - A 1-by- K vector `ZI` containing a single row from `Mdl.X` or `Y`, where K is the number of columns of `Mdl.X`.
 - An m -by- K matrix `ZJ` containing multiple rows of `Mdl.X` or `Y`, where m is a positive integer.
- Return an m -by-1 vector of distances `D2`, where `D2(j)` is the distance between the observations `ZI` and `ZJ(j,:)`.

For more details, see “Distance Metrics” on page 18-16.

Example: `'Distance','minkowski'`

IncludeTies — Flag to include all nearest neighbors

`false (0) (default) | true (1)`

Flag to include nearest neighbors that have the same distance from query observations, specified as the comma-separated pair consisting of `'IncludeTies'` and `false (0)` or `true (1)`.

If `IncludeTies` is `true`, then:

- `knnsearch` includes all nearest neighbors whose distances are equal to the k th smallest distance in the output arguments, where k is the number of searched nearest neighbors specified by the `'K'` name-value pair argument.
- `Idx` and `D` are m -by-1 cell arrays such that each cell contains a vector of at least k indices and distances, respectively. Each vector in `D` contains arranged distances in ascending order. Each row in `Idx` contains the indices of the nearest neighbors corresponding to the distances in `D`.

If `IncludeTies` is `false`, then `knnsearch` chooses the observation with the smallest index among the observations that have the same distance from a query point.

Example: `'IncludeTies',true`

K — Number of nearest neighbors

`1 (default) | positive integer`

Number of nearest neighbors to search for in the training data per query observation, specified as the comma-separated pair consisting of 'K' and a positive integer.

Example: 'K',2

Data Types: single | double

P — Exponent for Minkowski distance metric

2 (default) | positive scalar

Exponent for the Minkowski distance metric, specified as the comma-separated pair consisting of 'P' and a positive scalar. This argument is valid only if 'Distance' is 'minkowski'.

Example: 'P',3

Data Types: single | double

For Kd-Tree Nearest Neighbor Searchers

SortIndices — Flag to sort returned indices according to distance

true (1) (default) | false (0)

Flag to sort returned indices according to distance, specified as the comma-separated pair consisting of 'SortIndices' and either true (1) or false (0).

For faster performance, you can set `SortIndices` to false when the following are true:

- `Y` contains many observations that have many nearest neighbors in `X`.
- `Mdl` is a `KDTreeSearcher` model object.
- `IncludeTies` is false.

In this case, `knnsearch` returns the indices of the nearest neighbors in no particular order. When `SortIndices` is true, the function arranges the nearest-neighbor indices in ascending order by distance.

`SortIndices` is true by default. When `Mdl` is an `ExhaustiveSearcher` model object or `IncludeTies` is true, the function always sorts the indices.

Example: 'SortIndices',false

Data Types: logical

For Exhaustive Nearest Neighbor Searchers**Cov — Covariance matrix for Mahalanobis distance metric**`nancov(Mdl.X)` (default) | positive definite matrix

Covariance matrix for the Mahalanobis distance metric, specified as the comma-separated pair consisting of 'Cov' and a positive definite matrix. Cov is a K -by- K matrix, where K is the number of columns of `Mdl.X`. If you specify Cov and do not specify 'Distance', 'mahalanobis', then `knnsearch` returns an error message.

Example: 'Cov', `eye(3)`

Data Types: `single` | `double`

Scale — Scale parameter value for standardized Euclidean distance metric`nanstd(Mdl.X)` (default) | nonnegative numeric vector

Scale parameter value for the standardized Euclidean distance metric, specified as the comma-separated pair consisting of 'Scale' and a nonnegative numeric vector. Scale has length K , where K is the number of columns of `Mdl.X`.

The software scales each difference between the training and query data using the corresponding element of Scale. If you specify Scale and do not specify 'Distance', 'seuclidean', then `knnsearch` returns an error message.

Example: 'Scale', `quantile(Mdl.X,0.75) - quantile(Mdl.X,0.25)`

Data Types: `single` | `double`

Note If you specify 'Distance', 'Cov', 'P', or 'Scale', then `Mdl.Distance` and `Mdl.DistanceParameter` do not change value.

Output Arguments

Idx — Training data indices of nearest neighbors

numeric matrix | cell array of numeric vectors

Training data indices of nearest neighbors, returned as a numeric matrix or cell array of numeric vectors.

- If you do not specify `IncludeTies` (`false` by default), then `Idx` is an m -by- k numeric matrix, where m is the number of rows in `Y` and k is the number of searched nearest

neighbors specified by the 'K' name-value pair argument. $\text{Idx}(j, i)$ indicates that $\text{Mdl}.X(\text{Idx}(j, i), :)$ is one of the k closest observations in $\text{Mdl}.X$ to the query observation $Y(j, :)$.

- If you specify 'IncludeTies', true, then Idx is an m -by-1 cell array such that cell j ($\text{Idx}\{j\}$) contains a vector of at least k indices of the closest observations in $\text{Mdl}.X$ to the query observation $Y(j, :)$.

If `SortIndices` is true, then `knnsearch` arranges the indices in ascending order by distance.

D — Distances of nearest neighbors

numeric matrix | cell array of numeric vectors

Distances of the nearest neighbors to the query data, returned as a numeric matrix or cell array of numeric vectors.

- If you do not specify `IncludeTies` (false by default), then D is an m -by- k numeric matrix, where m is the number of rows in Y and k is the number of searched nearest neighbors specified by the 'K' name-value pair argument. $D(j, i)$ is the distance between $\text{Mdl}.X(\text{Idx}(j, i), :)$ and the query observation $Y(j, :)$ with respect to the distance metric.
- If you specify 'IncludeTies', true, then D is an m -by-1 cell array such that cell j ($D\{j\}$) contains a vector of at least k distances of the closest observations in $\text{Mdl}.X$ to the query observation $Y(j, :)$.

If `SortIndices` is true, then `knnsearch` arranges the distances in ascending order.

Tips

`knnsearch` finds the k (positive integer) points in $\text{Mdl}.X$ that are k -nearest for each Y point. In contrast, `rangesearch` finds all the points in $\text{Mdl}.X$ that are within distance r (positive scalar) of each Y point.

Alternative Functionality

- `knnsearch` is an object function that requires an `ExhaustiveSearcher` or a `KDTreeSearcher` model object and query data. Under equivalent conditions, the `knnsearch` object function returns the same results as the `knnsearch` function when

you specify the name-value pair argument 'NSMethod', 'exhaustive' or 'NSMethod', 'kdtree', respectively.

- For k -nearest neighbors classification, see `fitcknn` and `ClassificationKNN`.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- This table contains notes about the arguments of `knnsearch`. Arguments not included in this table are fully supported.

Argument	Notes and Limitations
Mdl	<p>There are two ways to use Mdl in code generation. For an example, see “Code Generation for Nearest Neighbor Searcher” on page 31-15.</p> <ul style="list-style-type: none"> • Use <code>saveCompactModel</code>, <code>loadCompactModel</code>, and <code>codegen</code> to generate code for the <code>knnsearch</code> function. Save a trained model by using <code>saveCompactModel</code>. Define an entry-point function that loads the saved model by using <code>loadCompactModel</code> and calls the <code>knnsearch</code> function. Then use <code>codegen</code> to generate code for the entry-point function. • Include <code>coder.Constant(Mdl)</code> in the <code>-args</code> value of <code>codegen</code>. <p>If Mdl is a <code>KDTreeSearcher</code> object, and the code generation build type is a MEX function, then <code>codegen</code> generates a MEX function using Intel Threading Building Blocks (TBB) for parallel computation. Otherwise, <code>codegen</code> generates code using <code>parfor</code>.</p> <ul style="list-style-type: none"> • MEX function for the kd-tree search algorithm — <code>codegen</code> generates an optimized MEX function using Intel TBB for parallel computation on multicore platforms. You can use the MEX function to accelerate MATLAB algorithms. For details on Intel TBB, see https://software.intel.com/en-us/intel-tbb. <p>If you generate the MEX function to test the generated code of the <code>parfor</code> version, you can disable the usage of Intel TBB. Set the <code>ExtrinsicCalls</code> property of the MEX configuration object to <code>false</code>. For details, see <code>coder.MexCodeConfig</code>.</p> <ul style="list-style-type: none"> • MEX function for the exhaustive search algorithm and standalone C/C++ code for both algorithms — The generated code of <code>knnsearch</code> uses <code>parfor</code> to create loops that run in parallel on supported shared-memory multicore platforms in the generated code. If your compiler does not support the Open Multiprocessing (OpenMP) application interface or you disable OpenMP

Argument	Notes and Limitations
	library, MATLAB Coder treats the <code>parfor</code> -loops as <code>for</code> -loops. To find supported compilers, see https://www.mathworks.com/support/compilers/current_release/ . To disable OpenMP library, set the <code>EnableOpenMP</code> property of the configuration object to <code>false</code> . For details, see <code>coder.CodeConfig</code> .
'Distance'	<ul style="list-style-type: none"> • Cannot be a custom distance function. • Must be a compile-time constant; its value cannot change in the generated code.
'IncludeTies'	Must be a compile-time constant; its value cannot change in the generated code.
'SortIndices'	Not supported. The output arguments are always sorted.
Name-value pair arguments	Names in name-value pair arguments must be compile-time constants. For example, to allow a user-defined exponent for the Minkowski distance in the generated code, include <code>{coder.Constant('Distance'), coder.Constant('Minkowski'), coder.Constant('P'), 0}</code> in the <code>-args</code> value of <code>codegen</code> .
Idx	When you specify 'IncludeTies' as <code>true</code> , the sorted order of tied distances in the generated code can be different from the order in MATLAB due to numerical precision.

For more information, see “Introduction to Code Generation” on page 31-2 and “Code Generation for Nearest Neighbor Searcher” on page 31-15.

Topics

“k-Nearest Neighbor Search and Radius Search” on page 18-18
“Distance Metrics” on page 18-16

Introduced in R2010a

knnsearch

Find k -nearest neighbors using input data

Syntax

```
Idx = knnsearch(X,Y)  
Idx = knnsearch(X,Y,Name,Value)  
[Idx,D] = knnsearch( ___ )
```

Description

`Idx = knnsearch(X,Y)` finds the nearest neighbor in X for each query point in Y and returns the indices of the nearest neighbors in `Idx`, a column vector. `Idx` has the same number of rows as Y .

`Idx = knnsearch(X,Y,Name,Value)` returns `Idx` with additional options specified using one or more name-value pair arguments. For example, you can specify the number of nearest neighbors to search for and the distance metric used in the search.

`[Idx,D] = knnsearch(___)` additionally returns the matrix `D`, using any of the input arguments in the previous syntaxes. `D` contains the distances between each observation in Y and the corresponding closest observations in X .

Examples

Find Nearest Neighbors

Find the patients in the `hospital` data set that most closely resemble the patients in Y , according to age and weight.

Load the `hospital` data set.

```
load hospital;
X = [hospital.Age hospital.Weight];
Y = [20 162; 30 169; 40 168; 50 170; 60 171]; % New patients
```

Perform a `knnsearch` between `X` and `Y` to find indices of nearest neighbors.

```
Idx = knnsearch(X,Y);
```

Find the patients in `X` closest in age and weight to those in `Y`.

```
X(Idx,:)
```

```
ans = 5×2
```

```
25 171
25 171
39 164
49 170
50 172
```

Find k-Nearest Neighbors Using Different Distance Metrics

Find the 10 nearest neighbors in `X` to each point in `Y`, first using the Minkowski distance metric and then using the Chebychev distance metric.

Load Fisher's iris data set.

```
load fisheriris
X = meas(:,3:4); % Measurements of original flowers
Y = [5 1.45;6 2;2.75 .75]; % New flower data
```

Perform a `knnsearch` between `X` and the query points `Y` using Minkowski and Chebychev distance metrics.

```
[mIdx,mD] = knnsearch(X,Y,'K',10,'Distance','minkowski','P',5);
[cIdx,cD] = knnsearch(X,Y,'K',10,'Distance','chebychev');
```

Visualize the results of the two nearest neighbor searches. Plot the training data. Plot the query points with the marker `X`. Use circles to denote the Minkowski nearest neighbors. Use pentagrams to denote the Chebychev nearest neighbors.

```

gscatter(X(:,1),X(:,2),species)
line(Y(:,1),Y(:,2),'Marker','x','Color','k',...
      'Markersize',10,'Linewidth',2,'LineStyle','none')
line(X(mIdx,1),X(mIdx,2),'Color',[.5 .5 .5],'Marker','o',...
      'LineStyle','none','Markersize',10)
line(X(cIdx,1),X(cIdx,2),'Color',[.5 .5 .5],'Marker','p',...
      'LineStyle','none','Markersize',10)
legend('setosa','versicolor','virginica','query point',...
      'minkowski','chebychev','Location','best')

```

Input Arguments

X — Input data

numeric matrix

Input data, specified as a numeric matrix. Rows of `X` correspond to observations, and columns correspond to variables.

Data Types: `single` | `double`

Y — Query points

numeric matrix

Query points, specified as a numeric matrix. Rows of `Y` correspond to observations, and columns correspond to variables. `Y` must have the same number of columns as `X`.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example:

```
knnsearch(X,Y,'K',10,'IncludeTies',true,'Distance','cityblock')
```

searches for 10 nearest neighbors, including ties and using the city block distance.

K — Number of nearest neighbors

1 (default) | positive integer

Number of nearest neighbors to find in `X` for each point in `Y`, specified as the comma-separated pair consisting of `'K'` and a positive integer.

Example: `'K',10`

Data Types: `single` | `double`

IncludeTies — Flag to include all nearest neighbors

false (0) (default) | true (1)

Flag to include all nearest neighbors that have the same distance from query points, specified as the comma-separated pair consisting of `'IncludeTies'` and `false (0)` or `true (1)`.

If `'IncludeTies'` is `false`, then `knnsearch` chooses the observation with the smallest index among the observations that have the same distance from a query point.

If `'IncludeTies'` is `true`, then:

- `knnsearch` includes all nearest neighbors whose distances are equal to the k th smallest distance in the output arguments. To specify k , use the `'K'` name-value pair argument.
- `Idx` and `D` are m -by-1 cell arrays such that each cell contains a vector of at least k indices and distances, respectively. Each vector in `D` contains distances arranged in ascending order. Each row in `Idx` contains the indices of the nearest neighbors corresponding to the distances in `D`.

Example: `'IncludeTies',true`

NSMethod — Nearest neighbor search method

`'kdtree'` | `'exhaustive'`

Nearest neighbor search method, specified as the comma-separated pair consisting of `'NSMethod'` and one of these values.

- `'kdtree'` — Creates and uses a Kd-tree to find nearest neighbors. `'kdtree'` is the default value when the number of columns in `X` is less than or equal to 10, `X` is not sparse, and the distance metric is `'euclidean'`, `'cityblock'`, `'chebychev'`, or `'minkowski'`. Otherwise, the default value is `'exhaustive'`.

The value `'kdtree'` is valid only when the distance metric is one of the four metrics noted above.

- `'exhaustive'` — Uses the exhaustive search algorithm by computing the distance values from all the points in `X` to each point in `Y`.

Example: `'NSMethod','exhaustive'`

Distance — Distance metric

`'euclidean'` (default) | `'seuclidean'` | `'cityblock'` | `'chebychev'` | `'minkowski'` | `'mahalanobis'` | function handle | ...

Distance metric `knnsearch` uses, specified as the comma-separated pair consisting of 'Distance' and one of the values in this table or a function handle.

Value	Description
'euclidean'	Euclidean distance.
'seuclidean'	Standardized Euclidean distance. Each coordinate difference between the query matrix Y and the reference matrix X is scaled by dividing by the corresponding standard deviation computed from X . To specify another scaling factor, use the 'P' name-value pair argument.
'cityblock'	City block distance.
'chebychev'	Chebychev distance (maximum coordinate difference).
'minkowski'	Minkowski distance. The default exponent is 2. To specify a different exponent, use the 'P' name-value pair argument.
'mahalanobis'	Mahalanobis distance, computed using a positive definite covariance matrix. To change the value of the covariance matrix, use the 'Cov' name-value pair argument.
'cosine'	One minus the cosine of the included angle between observation vectors).
'correlation'	One minus the sample linear correlation between observations (for sequences of values).
'spearman'	One minus the sample Spearman's rank correlation between observations (for sequences of values).
'hamming'	Hamming distance, which is the percentage of coordinates that differ.
'jaccard'	One minus the Jaccard coefficient, which is the percentage of coordinates that differ.

You can also specify a function handle for a custom distance metric by using @ (for example, @distfun). A custom distance function must:

- Have the form `function D2 = distfun(ZI,ZJ)`.
- Take as arguments:
 - A 1-by- n vector ZI containing a single row from X or from the query points Y .
 - An m_2 -by- n matrix ZJ containing multiple rows of X or Y .
- Return an m_2 -by-1 vector of distances $D2$, whose j th element is the distance between the observations ZI and $ZJ(j, :)$.

For more information, see “Distance Metrics” on page 18-16.

Example: 'Distance', 'chebychev'

P — Exponent for Minkowski distance metric

2 (default) | positive scalar

Exponent for the Minkowski distance metric, specified as the comma-separated pair consisting of 'P' and a positive scalar. This argument is valid only if 'Distance' is 'minkowski'.

Example: 'P', 4

Data Types: single | double

Cov — Covariance matrix for Mahalanobis distance metric

nancov(X) (default) | positive definite matrix

Covariance matrix for the Mahalanobis distance metric, specified as the comma-separated pair consisting of 'Cov' and a positive definite matrix. This argument is valid only when 'Distance' is 'mahalanobis'.

Example: 'Cov', eye(4)

Data Types: single | double

Scale — Scale parameter value for standardized Euclidean distance metric

nanstd(X) (default) | nonnegative numeric vector

Scale parameter value for the standardized Euclidean distance metric, specified as the comma-separated pair consisting of 'Scale' and a nonnegative numeric vector. 'Scale' has length equal to the number of columns in X. When knnsearch computes the standardized Euclidean distance, each coordinate of X is scaled by the corresponding element of 'Scale', as is each query point. This argument is valid only when 'Distance' is 'seuclidean'.

Example: 'Scale', quantile(X,0.75) - quantile(X,0.25)

Data Types: single | double

BucketSize — Maximum number of data points in leaf node of Kd-tree

50 (default) | positive integer

Maximum number of data points in the leaf node of the Kd-tree, specified as the comma-separated pair consisting of 'BucketSize' and a positive integer. This argument is valid only when NSMethod is 'kdtree'.

Example: `'BucketSize',20`

Data Types: `single` | `double`

SortIndices — Flag to sort returned indices according to distance

`true` (1) (default) | `false` (0)

Flag to sort returned indices according to distance, specified as the comma-separated pair consisting of `'SortIndices'` and either `true` (1) or `false` (0).

For faster performance, you can set `SortIndices` to `false` when the following are true:

- `Y` contains many observations that have many nearest neighbors in `X`.
- `NSMethod` is `'kdtree'`.
- `IncludeTies` is `false`.

In this case, `knnsearch` returns the indices of the nearest neighbors in no particular order. When `SortIndices` is `true`, the function arranges the nearest-neighbor indices in ascending order by distance.

`SortIndices` is `true` by default. When `NSMethod` is `'exhaustive'` or `IncludeTies` is `true`, the function always sorts the indices.

Example: `'SortIndices',false`

Data Types: `logical`

Output Arguments

Idx — Input data indices of nearest neighbors

numeric matrix | cell array of numeric vectors

Input data indices of the nearest neighbors, returned as a numeric matrix or cell array of numeric vectors.

- If you do not specify `IncludeTies` (`false` by default), then `Idx` is an m -by- k numeric matrix, where m is the number of rows in `Y` and k is the number of searched nearest neighbors. `Idx(j,i)` indicates that `X(Idx(j,i),:)` is one of the k closest observations in `X` to the query point `Y(j,:)`.

- If you specify 'IncludeTies', true, then Idx is an m -by-1 cell array such that cell j (Idx{j}) contains a vector of at least k indices of the closest observations in X to the query point $Y(j, :)$.

If SortIndices is true, then knnsearch arranges the indices in ascending order by distance.

D — Distances of nearest neighbors

numeric matrix | cell array of numeric vectors

Distances of the nearest neighbors to the query points, returned as a numeric matrix or cell array of numeric vectors.

- If you do not specify IncludeTies (false by default), then D is an m -by- k numeric matrix, where m is the number of rows in Y and k is the number of searched nearest neighbors. $D(j, i)$ is the distance between $X(\text{Idx}(j, i), :)$ and $Y(j, :)$ with respect to the distance metric.
- If you specify 'IncludeTies', true, then D is an m -by-1 cell array such that cell j (D{j}) contains a vector of at least k distances of the closest observations in X to the query point $Y(j, :)$.

If SortIndices is true, then knnsearch arranges the distances in ascending order.

Tips

- For a fixed positive integer k , knnsearch finds the k points in X that are the nearest to each point in Y . To find all points in X within a fixed distance of each point in Y , use rangesearch.
- knnsearch does not save a search object. To create a search object, use createns.

Algorithms

For information on a specific search algorithm, see “k-Nearest Neighbor Search and Radius Search” on page 18-18.

Alternative Functionality

If you set the `knnsearch` function's `'NSMethod'` name-value pair argument to the appropriate value (`'exhaustive'` for an exhaustive search algorithm or `'kdtree'` for a Kd-tree algorithm), then the search results are equivalent to the results obtained by conducting a distance search using the `knnsearch` object function. Unlike the `knnsearch` function, the `knnsearch` object function requires an `ExhaustiveSearcher` or a `KDTreeSearcher` model object.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- For code generation, the default value of the `'NSMethod'` name-value pair argument is `'exhaustive'` when the number of columns in `X` is greater than 7.
- The value of the `'Distance'` name-value pair argument must be a compile-time constant and cannot be a custom distance function.
- The value of the `'IncludeTies'` name-value pair argument must be a compile-time constant.
- The `'SortIndices'` name-value pair argument is not supported. The output arguments are always sorted.
- Names in name-value pair arguments must be compile-time constants. For example, to allow a user-defined exponent for the Minkowski distance in the generated code, include `{coder.Constant('Distance'),coder.Constant('Minkowski'),coder.Constant('P'),0}` in the `-args` value of `codegen`.

- When you specify `'IncludeTies'` as `true`, the sorted order of tied distances in the generated code can be different from the order in MATLAB due to numerical precision.
- When `knnsearch` uses the `kd`-tree search algorithm, and the code generation build type is a MEX function, `codegen` generates a MEX function using Intel Threading Building Blocks (TBB) for parallel computation. Otherwise, `codegen` generates code using `parfor`.
 - MEX function for the `kd`-tree search algorithm — `codegen` generates an optimized MEX function using Intel TBB for parallel computation on multicore platforms. You can use the MEX function to accelerate MATLAB algorithms. For details on Intel TBB, see <https://software.intel.com/en-us/intel-tbb>.

If you generate the MEX function to test the generated code of the `parfor` version, you can disable the usage of Intel TBB. Set the `ExtrinsicCalls` property of the MEX configuration object to `false`. For details, see `coder.MexCodeConfig`.

- MEX function for the exhaustive search algorithm and standalone C/C++ code for both algorithms — The generated code of `knnsearch` uses `parfor` to create loops that run in parallel on supported shared-memory multicore platforms in the generated code. If your compiler does not support the Open Multiprocessing (OpenMP) application interface or you disable OpenMP library, MATLAB Coder treats the `parfor`-loops as `for`-loops. To find supported compilers, see https://www.mathworks.com/support/compilers/current_release/. To disable OpenMP library, set the `EnableOpenMP` property of the configuration object to `false`. For details, see `coder.CodeConfig`.

For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “General Code Generation Workflow” on page 31-5.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Usage notes and limitations:

- The `'IncludeTies'`, `'NSMethod'`, and `'SortIndices'` name-value pair arguments are not supported.

For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

Introduced in R2010a

kruskalwallis

Kruskal-Wallis test

Syntax

```
p = kruskalwallis(x)
p = kruskalwallis(x,group)
p = kruskalwallis(x,group,displayopt)
[p,tbl,stats] = kruskalwallis( ___ )
```

Description

`p = kruskalwallis(x)` returns the p -value for the null hypothesis that the data in each column of the matrix `x` comes from the same distribution, using a Kruskal-Wallis test on page 32-3601. The alternative hypothesis is that not all samples come from the same distribution. `kruskalwallis` also returns an ANOVA table and a box plot.

`p = kruskalwallis(x,group)` returns the p -value for a test of the null hypothesis that the data in each categorical group, as specified by the grouping variable `group` comes from the same distribution. The alternative hypothesis is that not all groups come from the same distribution.

`p = kruskalwallis(x,group,displayopt)` returns the p -value of the test and lets you display or suppress the ANOVA table and box plot.

`[p,tbl,stats] = kruskalwallis(___)` also returns the ANOVA table as the cell array `tbl` and the structure `stats` containing information about the test statistics.

Examples

Test Data Samples for the Same Distribution

Create two different normal probability distribution objects. The first distribution has $\mu = 0$ and $\sigma = 1$, and the second distribution has $\mu = 2$ and $\sigma = 1$.

```
pd1 = makedist('Normal');  
pd2 = makedist('Normal','mu',2,'sigma',1);
```

Create a matrix of sample data by generating random numbers from these two distributions.

```
rng('default'); % for reproducibility  
x = [random(pd1,20,2), random(pd2,20,1)];
```

The first two columns of `x` contain data generated from the first distribution, while the third column contains data generated from the second distribution.

Test the null hypothesis that the sample data from each column in `x` comes from the same distribution.

```
p = kruskalwallis(x)
```

Kruskal-Wallis ANOVA Table

Source	SS	df	MS	Chi-sq	Prob>Chi-sq
Columns	7631.1	2	3815.55	25.02	3.68957e-06
Error	10363.9	57	181.82		
Total	17995	59			

$p = 3.6896e-06$

The returned value of p indicates that `kruskalwallis` rejects the null hypothesis that all three data samples come from the same distribution at a 1% significance level. The ANOVA table provides additional test results, and the box plot visually presents the summary statistics for each column in x .

Conduct Followup Tests for Unequal Medians

Create two different normal probability distribution objects. The first distribution has $\mu = 0$ and $\sigma = 1$. The second distribution has $\mu = 2$ and $|\sigma = 1$.

```
pd1 = makedist('Normal');
pd2 = makedist('Normal','mu',2,'sigma',1);
```

Create a matrix of sample data by generating random numbers from these two distributions.

```
rng('default'); % for reproducibility
x = [random(pd1,20,2), random(pd2,20,1)];
```

The first two columns of `x` contain data generated from the first distribution, while the third column contains data generated from the second distribution.

Test the null hypothesis that the sample data from each column in `x` comes from the same distribution. Suppress the output displays, and generate the structure `stats` to use in further testing.

```
[p,tbl,stats] = kruskalwallis(x,[],'off')
```

```
p = 3.6896e-06
```

```
tbl = 4x6 cell array
  Columns 1 through 5
```

{'Source' }	{'SS' }	{'df' }	{'MS' }	{'Chi-sq' }
{'Columns' }	{[7.6311e+03]}	{[2]}	{[3.8155e+03]}	{[25.0200]}
{'Error' }	{[1.0364e+04]}	{[57]}	{[181.8228]}	{0x0 double}
{'Total' }	{[17995]}	{[59]}	{0x0 double }	{0x0 double }

```
Column 6
```

{'Prob>Chi-sq' }
{[3.6896e-06]}
{0x0 double }
{0x0 double }

```
stats = struct with fields:
  gnames: [3x1 char]
  n: [20 20 20]
  source: 'kruskalwallis'
  meanranks: [26.7500 18.9500 45.8000]
  sumt: 0
```

The returned value of `p` indicates that the test rejects the null hypothesis at the 1% significance level. You can use the structure `stats` to perform additional followup testing.

The cell array `tbl` contains the same data as the graphical ANOVA table, including column and row labels.

Conduct a followup test to identify which data sample comes from a different distribution.

```
c = multcompare(stats)
```

Note: Intervals can be used for testing but are not simultaneous confidence intervals.

```
c = 3×6
```

1.0000	2.0000	-5.1435	7.8000	20.7435	0.3345
1.0000	3.0000	-31.9935	-19.0500	-6.1065	0.0016
2.0000	3.0000	-39.7935	-26.8500	-13.9065	0.0000

The results indicate that there is a significant difference between groups 1 and 3, so the test rejects the null hypothesis that the data in these two groups comes from the same distribution. The same is true for groups 2 and 3. However, there is not a significant difference between groups 1 and 2, so the test does not reject the null hypothesis that these two groups come from the same distribution. Therefore, these results suggest that the data in groups 1 and 2 come from the same distribution, and the data in group 3 comes from a different distribution.

Test for the Same Distribution Across Groups

Create a vector, `strength`, containing measurements of the strength of metal beams. Create a second vector, `alloy`, indicating the type of metal alloy from which the corresponding beam is made.

```
strength = [82 86 79 83 84 85 86 87 74 82 ...
            78 75 76 77 79 79 77 78 82 79];

alloy = {'st', 'st', 'st', 'st', 'st', 'st', 'st', 'st', ...
        'al1', 'al1', 'al1', 'al1', 'al1', 'al1', ...
        'al2', 'al2', 'al2', 'al2', 'al2', 'al2'};
```

Test the null hypothesis that the beam strength measurements have the same distribution across all three alloys.

```
p = kruskalwallis(strength, alloy, 'off')
p = 0.0018
```

The returned value of `p` indicates that the test rejects the null hypothesis at the 1% significance level.

Input Arguments

x — Sample data

vector | matrix

Sample data for the hypothesis test, specified as a vector or an m -by- n matrix. If `x` is an m -by- n matrix, each of the n columns represents an independent sample containing m mutually independent observations.

Data Types: `single` | `double`

group — Grouping variable

numeric vector | logical vector | character array | string array | cell array of character vectors

Grouping variable, specified as a numeric or logical vector, a character or string array, or a cell array of character vectors.

- If `x` is a vector, then each element in `group` identifies the group to which the corresponding element in `x` belongs, and `group` must be a vector of the same length as `x`. If a row of `group` contains an empty value, that row and the corresponding observation in `x` are disregarded. NaN values in either `x` or `group` are similarly ignored.
- If `x` is a matrix, then each column in `x` represents a different group, and you can use `group` to specify labels for these columns. The number of elements in `group` and the number of columns in `x` must be equal.

The labels contained in `group` also annotate the box plot.

Example:

```
{'red', 'blue', 'green', 'blue', 'red', 'blue', 'green', 'green', 'red'}
```

Data Types: `single` | `double` | `logical` | `char` | `string` | `cell`

displayopt — Display option

'on' (default) | 'off'

Display option, specified as 'on' or 'off'. If `displayopt` is 'on', `kruskalwallis` displays the following figures:

- An ANOVA table containing the sums of squares, degrees of freedom, and other quantities calculated based on the ranks of the data in `x`.
- A box plot of the data in each column of the data matrix `x`. The box plots are based on the actual data values, rather than on the ranks.

If `displayopt` is 'off', `kruskalwallis` does not display these figures.

If you specify a value for `displayopt`, you must also specify a value for `group`. If you do not have a grouping variable, specify `group` as `[]`.

Example: 'off'

Output Arguments

p — *p*-value

scalar value in the range [0,1]

p-value of the test, returned as a scalar value in the range [0,1]. *p* is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. Small values of *p* cast doubt on the validity of the null hypothesis.

tbl — ANOVA table

cell array

ANOVA table of test results, returned as a cell array. **tbl** includes the sums of squares, degrees of freedom, and other quantities calculated based on the ranks of the data in *x*, as well as column and row labels.

stats — Test data

structure

Test data, returned as a structure. You can perform followup multiple comparison tests on pairs of sample medians by using `multcompare`, with **stats** as the input value.

Definitions

Kruskal-Wallis Test

The Kruskal-Wallis test is a nonparametric version of classical one-way ANOVA, and an extension of the Wilcoxon rank sum test to more than two groups. It compares the medians of the groups of data in *x* to determine if the samples come from the same population (or, equivalently, from different populations with the same distribution).

The Kruskal-Wallis test uses ranks of the data, rather than numeric values, to compute the test statistics. It finds ranks by ordering the data from smallest to largest across all groups, and taking the numeric index of this ordering. The rank for a tied observation is equal to the average rank of all observations tied with it. The *F*-statistic used in classical one-way ANOVA is replaced by a chi-square statistic, and the *p*-value measures the significance of the chi-square statistic.

The Kruskal-Wallis test assumes that all samples come from populations having the same continuous distribution, apart from possibly different locations due to group effects, and

that all observations are mutually independent. By contrast, classical one-way ANOVA replaces the first assumption with the stronger assumption that the populations have normal distributions.

Introduced before R2006a

ksdensity

Kernel smoothing function estimate for univariate and bivariate data

Syntax

```
[f,xi] = ksdensity(x)
[f,xi] = ksdensity(x,pts)
[f,xi] = ksdensity( ___,Name,Value)
[f,xi,bw] = ksdensity( ___ )
```

```
ksdensity( ___ )
ksdensity(ax, ___ )
```

Description

`[f,xi] = ksdensity(x)` returns a probability density estimate, `f`, for the sample data in the vector or two-column matrix `x`. The estimate is based on a normal kernel function, and is evaluated at equally-spaced points, `xi`, that cover the range of the data in `x`. `ksdensity` estimates the density at 100 points for univariate data, or 900 points for bivariate data.

`ksdensity` works best with continuously distributed samples.

`[f,xi] = ksdensity(x,pts)` specifies points (`pts`) to evaluate `f`. Here, `xi` and `pts` contain identical values.

`[f,xi] = ksdensity(___,Name,Value)` uses additional options specified by one or more name-value pair arguments in addition to any of the input arguments in the previous syntaxes. For example, you can define the function type `ksdensity` evaluates, such as probability density, cumulative probability, survivor function, and so on. Or you can specify the bandwidth of the smoothing window.

`[f,xi,bw] = ksdensity(___)` also returns the bandwidth of the kernel smoothing window, `bw`. The default bandwidth is the optimal for normal densities.

`ksdensity(___)` plots the kernel smoothing function estimate.

`ksdensity(ax, ___)` plots the results using axes with the handle, `ax`, instead of the current axes returned by `gca`.

Examples

Estimate Density

Generate a sample data set from a mixture of two normal distributions.

```
rng('default') % For reproducibility
x = [randn(30,1); 5+randn(30,1)];
```

Plot the estimated density.

```
[f,xi] = ksdensity(x);
figure
plot(xi,f);
```

The density estimate shows the bimodality of the sample.

Estimate Density with Boundary Correction

Generate a nonnegative sample data set from the half-normal distribution.

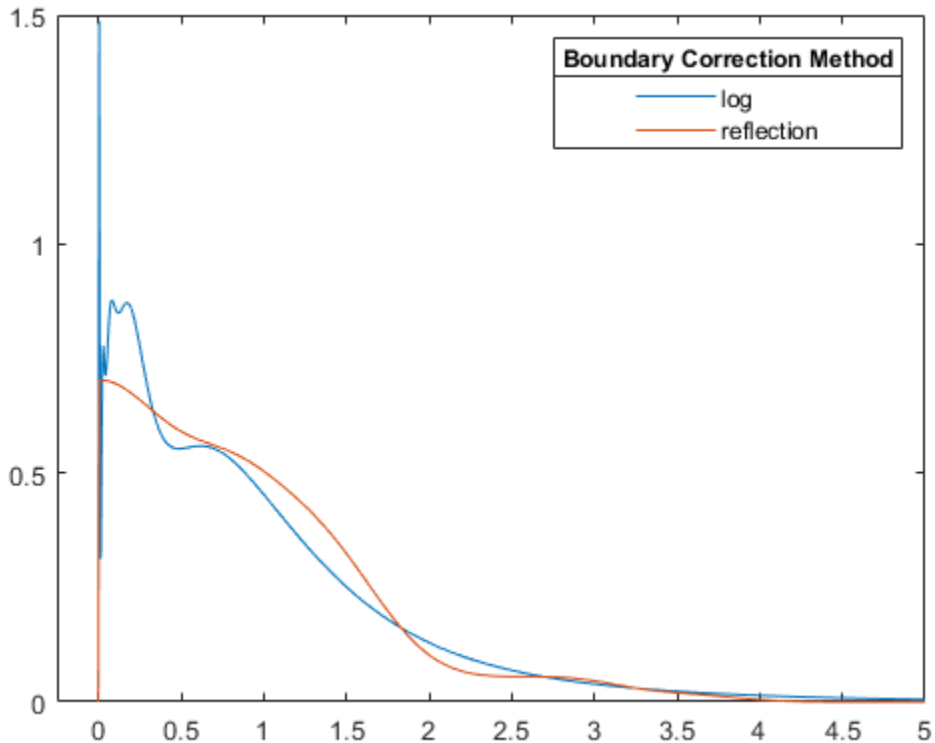

```
rng('default') % For reproducibility
pd = makedist('HalfNormal','mu',0,'sigma',1);
x = random(pd,100,1);
```

Estimate pdfs with two different boundary correction methods, log transformation and reflection, by using the 'BoundaryCorrection' name-value pair argument.

```
pts = linspace(0,5,1000); % points to evaluate the estimator
[f1,xi1] = ksdensity(x,pts,'Support','positive');
[f2,xi2] = ksdensity(x,pts,'Support','positive','BoundaryCorrection','reflection');
```

Plot the two estimated pdfs.

```
plot(xi1,f1,xi2,f2)
lgd = legend('log','reflection');
title(lgd, 'Boundary Correction Method')
xl = xlim;
xlim([xl(1)-0.25 xl(2)])
```

`ksdensity` uses a boundary correction method when you specify either positive or bounded support. The default boundary correction method is log transformation. When

ksdensity transforms the support back, it introduces the $1/x$ term in the kernel density estimator. Therefore, the estimate has a peak near $x = 0$. On the other hand, the reflection method does not cause undesirable peaks near the boundary.

Estimate Cumulative Distribution Function at Specified Values

Load the sample data.

```
load hospital
```

Compute and plot the estimated cdf evaluated at a specified set of values.

```
pts = (min(hospital.Weight):2:max(hospital.Weight));  
figure()  
ecdf(hospital.Weight)  
hold on  
[f,xi,bw] = ksdensity(hospital.Weight,pts,'Support','positive',...  
    'Function','cdf');  
plot(xi,f,'-g','LineWidth',2)  
legend('empirical cdf','kernel-bw:default','Location','northwest')  
xlabel('Patient weights')  
ylabel('Estimated cdf')
```

`ksdensity` seems to smooth the cumulative distribution function estimate too much. An estimate with a smaller bandwidth might produce a closer estimate to the empirical cumulative distribution function.

Return the bandwidth of the smoothing window.

```
bw
```

```
bw = 0.1070
```

Plot the cumulative distribution function estimate using a smaller bandwidth.

```
[f,xi] = ksdensity(hospital.Weight,pts,'Support','positive',...
    'Function','cdf','Bandwidth',0.05);
```

```
plot(xi,f,'--r','LineWidth',2)
legend('empirical cdf','kernel-bw:default','kernel-bw:0.05',...
      'Location','northwest')
hold off
```

The `ksdensity` estimate with a smaller bandwidth matches the empirical cumulative distribution function better.

Plot Estimated Cumulative Density Function for Given Number of Points

Load the sample data.

```
load hospital
```

Plot the estimated cdf evaluated at 50 equally spaced points.

```
figure()  
ksdensity(hospital.Weight, 'Support', 'positive', 'Function', 'cdf', ...  
          'NumPoints', 50)  
xlabel('Patient weights')  
ylabel('Estimated cdf')
```

Estimate Survivor and Cumulative Hazard for Censored Failure Data

Generate sample data from an exponential distribution with mean 3.

```
rng('default') % For reproducibility  
x = random('exp',3,100,1);
```

Create a logical vector that indicates censoring. Here, observations with lifetimes longer than 10 are censored.

```
T = 10;  
cens = (x>T);
```

Compute and plot the estimated density function.

```
figure  
ksdensity(x, 'Support', 'positive', 'Censoring', cens);
```

Compute and plot the survivor function.

```
figure  
ksdensity(x, 'Support', 'positive', 'Censoring', cens, ...  
          'Function', 'survivor');
```

Compute and plot the cumulative hazard function.

```
figure
ksdensity(x,'Support','positive','Censoring',cens,...
'Function','cumhazard');
```

Estimate Inverse Cumulative Distribution Function for Specified Probability Values

Generate a mixture of two normal distributions, and plot the estimated inverse cumulative distribution function at a specified set of probability values.

```
rng('default') % For reproducibility
x = [randn(30,1); 5+randn(30,1)];
pi = linspace(.01,.99,99);
figure
ksdensity(x,pi,'Function','icdf');
```

Return Bandwidth of Smoothing Window

Generate a mixture of two normal distributions.

```
rng('default') % For reproducibility  
x = [randn(30,1); 5+randn(30,1)];
```

Return the bandwidth of the smoothing window for the probability density estimate.

```
[f,xi,bw] = ksdensity(x);  
bw
```

```
bw = 1.5141
```

The default bandwidth is optimal for normal densities.

Plot the estimated density.

```
figure  
plot(xi,f);  
xlabel('xi')  
ylabel('f')  
hold on
```

Plot the density using an increased bandwidth value.

```
[f,xi] = ksdensity(x,'Bandwidth',1.8);  
plot(xi,f,'--r','LineWidth',1.5)
```

A higher bandwidth further smooths the density estimate, which might mask some characteristics of the distribution.

Now, plot the density using a decreased bandwidth value.

```
[f,xi] = ksdensity(x,'Bandwidth',0.8);  
plot(xi,f,'-.k','LineWidth',1.5)  
legend('bw = default','bw = 1.8','bw = 0.8')  
hold off
```

A smaller bandwidth smooths the density estimate less, which exaggerates some characteristics of the sample.

Plot Kernel Density Estimate of Bivariate Data

Create a two-column vector of points at which to evaluate the density.

```
gridx1 = -0.25:.05:1.25;  
gridx2 = 0:.1:15;  
[x1,x2] = meshgrid(gridx1, gridx2);  
x1 = x1(:);
```

```
x2 = x2(:);  
xi = [x1 x2];
```

Generate a 30-by-2 matrix containing random numbers from a mixture of bivariate normal distributions.

```
rng('default') % For reproducibility  
x = [0+.5*rand(20,1) 5+2.5*rand(20,1);  
     .75+.25*rand(10,1) 8.75+1.25*rand(10,1)];
```

Plot the estimated density of the sample data.

```
figure  
ksdensity(x,xi);
```

Input Arguments

x — Sample data

column vector | two-column matrix

Sample data for which `ksdensity` returns `f` values, specified as a column vector or two-column matrix. Use a column vector for univariate data, and a two-column matrix for bivariate data.

Example: `[f,xi] = ksdensity(x)`

Data Types: `single` | `double`

pts — Points at which to evaluate `f`

vector | two-column matrix

Points at which to evaluate `f`, specified as a vector or two-column matrix. For univariate data, `pts` can be a row or column vector. The length of the returned output `f` is equal to the number of points in `pts`.

Example: `pts = (0:1:25); ksdensity(x,pts);`

Data Types: `single` | `double`

ax — Axes handle

handle

Axes handle for the figure `ksdensity` plots to, specified as a handle.

For example, if `h` is a handle for a figure, then `ksdensity` can plot to that figure as follows.

Example: `ksdensity(h,x)`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example:

```
'Censoring',cens,'Kernel','triangle','NumPoints',20,'Function','cdf'
```

specifies that `ksdensity` estimates the cdf by evaluating at 20 equally spaced points that covers the range of data, using the triangle kernel smoothing function and accounting for the censored data information in vector `cens`.

Bandwidth — Bandwidth of the kernel smoothing window

optimal value for normal densities (default) | scalar value | two-element vector

The bandwidth of the kernel-smoothing window, which is a function of the number of points in `x`, specified as the comma-separated pair consisting of `'Bandwidth'` and a scalar value. If the sample data is bivariate, `Bandwidth` can also be a two-element vector. The default is optimal for estimating normal densities [1], but you might want to choose a larger or smaller value to smooth more or less.

If you specify `'BoundaryCorrection'` as `'log'` (default) and `'Support'` as either `'positive'` or a vector [L U], `ksdensity` converts bounded data to be unbounded by using log transformation. The value of `'Bandwidth'` is on the scale of the transformed values.

Example: `'Bandwidth',0.8`

Data Types: `single` | `double`

BoundaryCorrection — Boundary correction method

`'log'` (default) | `'reflection'`

Boundary correction method, specified as the comma-separated pair consisting of `'BoundaryCorrection'` and `'log'` or `'reflection'`.

Value	Description
'log'	<p>ksdensity converts bounded data x to be unbounded by one of the following transformations. Then, it transforms back to the original bounded scale after density estimation.</p> <ul style="list-style-type: none"> For univariate data, if you specify 'Support', 'positive', then ksdensity applies $\log(x)$. For univariate data, if you specify 'Support', [L U], where L and U are numeric scalars and $L < U$, then ksdensity applies $\log((x-L)/(U-x))$. For bivariate data, ksdensity transforms each column of x in the same way with the univariate data. <p>The value of 'Bandwidth' and the bw output are on the scale of the transformed values.</p>
'reflection'	<p>ksdensity augments bounded data by adding reflected data near the boundaries, then it returns estimates corresponding to the original support. For details, see “Reflection Method” on page 32-3627.</p>

ksdensity applies boundary correction only when you specify 'Support' as a value other than 'unbounded'.

Example: 'BoundaryCorrection', 'reflection'

Censoring — Logical vector

vector of 0s (default) | vector of 0s and 1s

Logical vector indicating which entries are censored, specified as the comma-separated pair consisting of 'Censoring' and a vector of binary values. A value of 0 indicates there is no censoring, 1 indicates that observation is censored. Default is there is no censoring. This name-value pair is only valid for univariate data.

Example: 'Censoring', censdata

Data Types: logical

Function — Function to estimate

'pdf' (default) | 'cdf' | 'icdf' | 'survivor' | 'cumhazard'

Function to estimate, specified as the comma-separated pair consisting of 'Function' and one of the following.

Value	Description
'pdf'	Probability density function.
'cdf'	Cumulative distribution function.
'icdf'	Inverse cumulative distribution function. <code>ksdensity</code> computes the estimated inverse cdf of the values in <code>x</code> , and evaluates it at the probability values specified in <code>pi</code> . This value is valid only for univariate data.
'survivor'	Survivor function.
'cumhazard'	Cumulative hazard function. This value is valid only for univariate data.

Example: 'Function','icdf'

Kernel — Type of kernel smoother

'normal' (default) | 'box' | 'triangle' | 'epanechnikov' | function handle | character vector | string scalar

Type of kernel smoother, specified as the comma-separated pair consisting of 'Kernel' and one of the following.

- 'normal' (default)
- 'box'
- 'triangle'
- 'epanechnikov'
- A kernel function that is a custom or built-in function. Specify the function as a function handle (for example, `@myfunction` or `@normpdf`) or as a character vector or string scalar (for example, 'myfunction' or 'normpdf'). The software calls the specified function with one argument that is an array of distances between data values and locations where the density is evaluated. The function must return an array of the same size containing corresponding values of the kernel function.

When 'Function' is 'pdf', the kernel function returns density values. Otherwise, it returns cumulative probability values.

Specifying a custom kernel when 'Function' is 'icdf' returns an error.

For bivariate data, `ksdensity` applies the same kernel to each dimension.

Example: 'Kernel', 'box'

NumPoints — Number of equally spaced points

100 (default) | scalar value

Number of equally spaced points in x_i , specified as the comma-separated pair consisting of 'NumPoints' and a scalar value. This name-value pair is only valid for univariate data.

For example, for a kernel smooth estimate of a specified function at 80 equally spaced points within the range of sample data, input:

Example: 'NumPoints', 80

Data Types: single | double

Support — Support for the density

'unbounded' (default) | 'positive' | two-element vector, [L U] | two-by-two matrix, [L1 L2; U1 U2]

Support for the density, specified as the comma-separated pair consisting of 'support' and one of the following.

Value	Description
'unbounded'	Default. Allow the density to extend over the whole real line.
'positive'	Restrict the density to positive values.
Two-element vector, [L U]	Give the finite lower and upper bounds for the support of the density. This option is only valid for univariate sample data.
Two-by-two matrix, [L1 L2; U1 U2]	Give the finite lower and upper bounds for the support of the density. The first row contains the lower limits and the second row contains the upper limits. This option is only valid for bivariate sample data.

For bivariate data, 'Support' can be a combination of positive, unbounded, or bounded variables specified as [0 -Inf; Inf Inf] or [0 L; Inf U].

Example: 'Support', 'positive'

Example: 'Support', [0 10]

Data Types: single | double | char | string

PlotFcn — Function used to create kernel density plot

'surf' (default) | 'contour' | 'plot3' | 'surfc'

Function used to create kernel density plot, specified as the comma-separated pair consisting of 'PlotFcn' and one of the following.

Value	Description
'surf'	3-D shaded surface plot, created using <code>surf</code>
'contour'	Contour plot, created using <code>contour</code>
'plot3'	3-D line plot, created using <code>plot3</code>
'surfc'	Contour plot under a 3-D shaded surface plot, created using <code>surfc</code>

This name-value pair is only valid for bivariate sample data.

Example: 'PlotFcn', 'contour'

Weights — Weights for sample data

vector

Weights for sample data, specified as the comma-separated pair consisting of 'Weights' and a vector of length `size(x,1)`, where `x` is the sample data.

Example: 'Weights', `xw`

Data Types: `single` | `double`

Output Arguments

f — Estimated function values

vector

Estimated function values, returned as a vector whose length is equal to the number of points in `xi` or `pts`.

xi — Evaluation points

100 equally spaced points | 900 equally spaced points | vector | two-column matrix

Evaluation points at which `ksdensity` calculates `f`, returned as a vector or a two-column matrix. For univariate data, the default is 100 equally-spaced points that cover the range of data in `x`. For bivariate data, the default is 900 equally-spaced points created using `meshgrid` from 30 equally-spaced points in each dimension.

bw — Bandwidth of smoothing window

scalar value

Bandwidth of smoothing window, returned as a scalar value.

If you specify 'BoundaryCorrection' as 'log' (default) and 'Support' as either 'positive' or a vector [L U], `ksdensity` converts bounded data to be unbounded by using log transformation. The value of `bw` is on the scale of the transformed values.

Definitions

Kernel Distribution

A kernel distribution is a nonparametric representation of the probability density function (pdf) of a random variable. You can use a kernel distribution when a parametric distribution cannot properly describe the data, or when you want to avoid making assumptions about the distribution of the data. A kernel distribution is defined by a smoothing function and a bandwidth value, which control the smoothness of the resulting density curve.

The kernel density estimator is the estimated pdf of a random variable. For any real values of x , the kernel density estimator's formula is given by

$$\hat{f}_h(x) = \frac{1}{nh} \sum_{i=1}^n K\left(\frac{x - x_i}{h}\right),$$

where x_1, x_2, \dots, x_n are random samples from an unknown distribution, n is the sample size, $K(\cdot)$ is the kernel smoothing function, and h is the bandwidth.

The kernel estimator for the cumulative distribution function (cdf), for any real values of x , is given by

$$\hat{F}_h(x) = \int_{-\infty}^x \hat{f}_h(t) dt = \frac{1}{n} \sum_{i=1}^n G\left(\frac{x - x_i}{h}\right),$$

where $G(x) = \int_{-\infty}^x K(t) dt$.

For more details, see “Kernel Distribution” on page B-80.

Reflection Method

The reflection method is a boundary correction method that accurately finds kernel density estimators when a random variable has bounded support. If you specify 'BoundaryCorrection', 'reflection', `ksdensity` uses the reflection method. This method augments bounded data by adding reflected data near the boundaries, and estimates the pdf. Then, `ksdensity` returns the estimated pdf corresponding to the original support with proper normalization, so that the estimated pdf's integral over the original support is equal to one.

If you additionally specify 'Support', [L U], then `ksdensity` finds the kernel estimator as follows.

- If 'Function' is 'pdf', then the kernel density estimator is

$$\hat{f}_h(x) = \frac{1}{nh} \sum_{i=1}^n \left[K\left(\frac{x - x_i^-}{h}\right) + K\left(\frac{x - x_i}{h}\right) + K\left(\frac{x - x_i^+}{h}\right) \right] \text{ for } L \leq x \leq U,$$

where $x_i^- = 2L - x_i$, $x_i^+ = 2U - x_i$, and x_i is the i th sample data.

- If 'Function' is 'cdf', then the kernel estimator for cdf is

$$\begin{aligned} \hat{F}_h(x) = & \frac{1}{n} \sum_{i=1}^n \left[G\left(\frac{x - x_i^-}{h}\right) + G\left(\frac{x - x_i}{h}\right) + G\left(\frac{x - x_i^+}{h}\right) \right] \text{ for } L \leq x \leq U. \\ & - \frac{1}{n} \sum_{i=1}^n \left[G\left(\frac{L - x_i^-}{h}\right) + G\left(\frac{L - x_i}{h}\right) + G\left(\frac{L - x_i^+}{h}\right) \right] \end{aligned}$$

- To obtain a kernel estimator for an inverse cdf, a survivor function, or a cumulative hazard function (when 'Function' is 'icdf', 'survivor', or 'cumhazrd'), `ksdensity` uses both $\hat{f}_h(x)$ and $\hat{F}_h(x)$.

If you additionally specify 'Support' as 'positive' or [0 inf], then `ksdensity` finds the kernel estimator by replacing [L U] with [0 inf] in the above equations.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function supports tall arrays for out-of-memory data with some limitations.

- Some options that require extra passes or sorting of the input data are not supported:
 - 'BoundaryCorrection'
 - 'Censoring'
 - 'Support' (support is always unbounded).
- Uses standard deviation (instead of median absolute deviation) to compute the bandwidth.

For more information, see "Tall Arrays" (MATLAB).

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Plotting is not supported.
- Names in name-value pair arguments must be compile-time constants.
- Values in the following name-value pair arguments must also be compile-time constants: 'BoundaryCorrection', 'Function', and 'Kernel'. For example, to

use the 'Function', 'cdf' name-value pair argument in the generated code, include `{coder.Constant('Function'),coder.Constant('cdf')}` in the `-args` value of `codegen`.

- The value of the 'Kernel' name-value pair argument cannot be a custom function handle. To specify a custom kernel function, use a character vector or string scalar.
- For the value of the 'Support' name-value pair argument, the compile-time data type must match the runtime data type.

For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “General Code Generation Workflow” on page 31-5.

kstest

One-sample Kolmogorov-Smirnov test

Syntax

```
h = kstest(x)
h = kstest(x,Name,Value)
[h,p] = kstest( ___ )
[h,p,ksstat,cv] = kstest( ___ )
```

Description

`h = kstest(x)` returns a test decision for the null hypothesis that the data in vector `x` comes from a standard normal distribution, against the alternative that it does not come from such a distribution, using the one-sample Kolmogorov-Smirnov test on page 32-3639. The result `h` is 1 if the test rejects the null hypothesis at the 5% significance level, or 0 otherwise.

`h = kstest(x,Name,Value)` returns a test decision for the one-sample Kolmogorov-Smirnov test with additional options specified by one or more name-value pair arguments. For example, you can test for a distribution other than standard normal, change the significance level, or conduct a one-sided test.

`[h,p] = kstest(___)` also returns the *p*-value `p` of the hypothesis test, using any of the input arguments from the previous syntaxes.

`[h,p,ksstat,cv] = kstest(___)` also returns the value of the test statistic `ksstat` and the approximate critical value `cv` of the test.

Examples

Test for Standard Normal Distribution

Perform the one-sample Kolmogorov-Smirnov test by using `kstest`. Confirm the test decision by visually comparing the empirical cumulative distribution function (cdf) to the standard normal cdf.

Load the `examgrades` data set. Create a vector containing the first column of the exam grade data.

```
load examgrades
test1 = grades(:,1);
```

Test the null hypothesis that the data comes from a normal distribution with a mean of 75 and a standard deviation of 10. Use these parameters to center and scale each element of the data vector, because `kstest` tests for a standard normal distribution by default.

```
x = (test1-75)/10;
h = kstest(x)
```

```
h = logical
    0
```

The returned value of `h = 0` indicates that `kstest` fails to reject the null hypothesis at the default 5% significance level.

Plot the empirical cdf and the standard normal cdf for a visual comparison.

```
cdfplot(x)
hold on
x_values = linspace(min(x),max(x));
plot(x_values,normcdf(x_values,0,1),'r-')
legend('Empirical CDF','Standard Normal CDF','Location','best')
```

The figure shows the similarity between the empirical cdf of the centered and scaled data vector and the cdf of the standard normal distribution.

Specify the Hypothesized Distribution Using a Two-Column Matrix

Load the sample data. Create a vector containing the first column of the students' exam grades data.

```
load examgrades;  
x = grades(:,1);
```

Specify the hypothesized distribution as a two-column matrix. Column 1 contains the data vector x . Column 2 contains cdf values evaluated at each value in x for a hypothesized Student's t distribution with a location parameter of 75, a scale parameter of 10, and one degree of freedom.

```
test_cdf = [x, cdf('tlocation', x, 75, 10, 1)];
```

Test if the data are from the hypothesized distribution.

```
h = kstest(x, 'CDF', test_cdf)
```

```
h = logical  
    1
```

The returned value of $h = 1$ indicates that `kstest` rejects the null hypothesis at the default 5% significance level.

Specify the Hypothesized Distribution Using a Probability Distribution Object

Load the sample data. Create a vector containing the first column of the students' exam grades data.

```
load examgrades;  
x = grades(:,1);
```

Create a probability distribution object to test if the data comes from a Student's t distribution with a location parameter of 75, a scale parameter of 10, and one degree of freedom.

```
test_cdf = makedist('tlocation', 'mu', 75, 'sigma', 10, 'nu', 1);
```

Test the null hypothesis that the data comes from the hypothesized distribution.

```
h = kstest(x, 'CDF', test_cdf)
```

```
h = logical  
    1
```

The returned value of $h = 1$ indicates that `kstest` rejects the null hypothesis at the default 5% significance level.

Test the Hypothesis at Different Significance Levels

Load the sample data. Create a vector containing the first column of the students' exam grades.

```
load examgrades;  
x = grades(:,1);
```

Create a probability distribution object to test if the data comes from a Student's t distribution with a location parameter of 75, a scale parameter of 10, and one degree of freedom.

```
test_cdf = makedist('tlocationscale','mu',75,'sigma',10,'nu',1);
```

Test the null hypothesis that data comes from the hypothesized distribution at the 1% significance level.

```
[h,p] = kstest(x,'CDF',test_cdf,'Alpha',0.01)
```

```
h = logical  
    1
```

```
p = 0.0021
```

The returned value of $h = 1$ indicates that `kstest` rejects the null hypothesis at the 1% significance level.

Conduct a One-Sided Hypothesis Test

Load the sample data. Create a vector containing the third column of the stock return data matrix.

```
load stockreturns;  
x = stocks(:,3);
```

Test the null hypothesis that the data comes from a standard normal distribution, against the alternative hypothesis that the population cdf of the data is larger than the standard normal cdf.

```
[h,p,k,c] = kstest(x, 'Tail', 'larger')
```

```
h = logical  
    1
```

```
p = 5.0854e-05
```

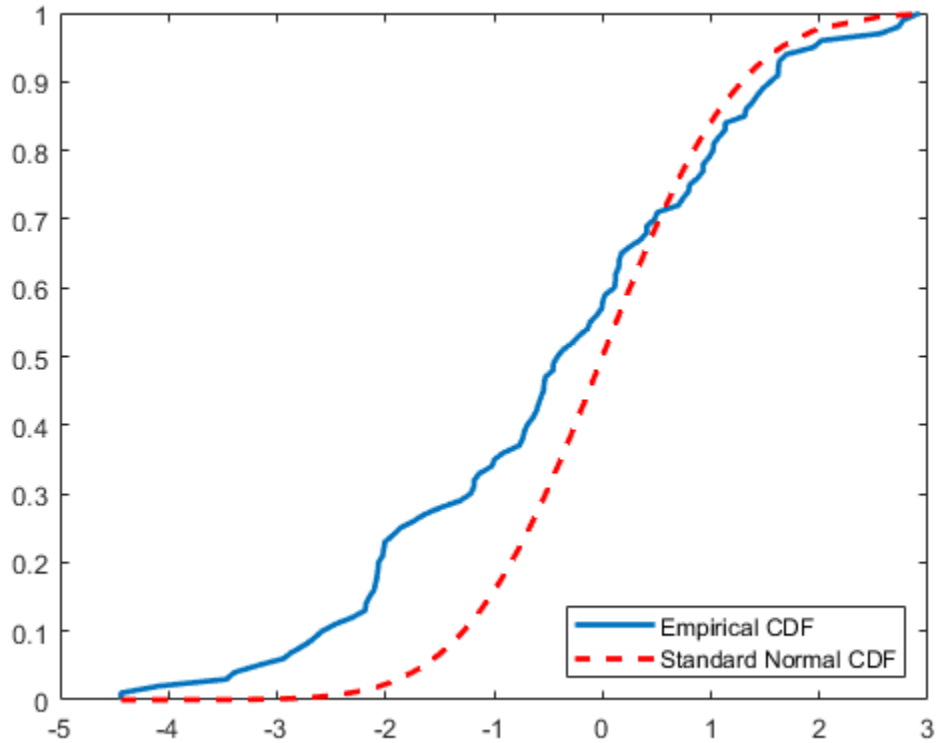

```
k = 0.2197
```

```
c = 0.1207
```

The returned value of $h = 1$ indicates that `kstest` rejects the null hypothesis in favor of the alternative hypothesis at the default 5% significance level.

Plot the empirical cdf and the standard normal cdf for a visual comparison.

```
[f,x_values] = ecdf(x);  
J = plot(x_values,f);  
hold on;  
K = plot(x_values,normcdf(x_values),'r--');  
set(J,'LineWidth',2);  
set(K,'LineWidth',2);  
legend([J K], 'Empirical CDF', 'Standard Normal CDF', 'Location', 'SE');
```

The plot shows the difference between the empirical cdf of the data vector x and the cdf of the standard normal distribution.

Input Arguments

x — Sample data

vector

Sample data, specified as a vector.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'Tail', 'larger', 'Alpha', 0.01` specifies a test using the alternative hypothesis that the cdf of the population from which the sample data is drawn is greater than the cdf of the hypothesized distribution, conducted at the 1% significance level.

Alpha — Significance level

`0.05` (default) | scalar value in the range (0,1)

Significance level of the hypothesis test, specified as the comma-separated pair consisting of `'Alpha'` and a scalar value in the range (0,1).

Example: `'Alpha', 0.01`

Data Types: `single` | `double`

CDF — cdf of hypothesized continuous distribution

matrix | probability distribution object

cdf of hypothesized continuous distribution, specified the comma-separated pair consisting of `'CDF'` and either a two-column matrix or a continuous probability distribution object. When CDF is a matrix, column 1 contains a set of possible x values, and column 2 contains the corresponding hypothesized cumulative distribution function values $G(x)$. The calculation is most efficient if CDF is specified such that column 1 contains the values in the data vector x . If there are values in x not found in column 1 of CDF, `kstest` approximates $G(x)$ by interpolation. All values in x must lie in the interval between the smallest and largest values in the first column of CDF. By default, `kstest` tests for a standard normal distribution.

The one-sample Kolmogorov-Smirnov test on page 32-3639 is only valid for continuous cumulative distribution functions, and requires CDF to be predetermined. The result is not accurate if CDF is estimated from the data. To test x against the normal, lognormal, extreme value, Weibull, or exponential distribution without specifying distribution parameters, use `lillietest` instead.

Data Types: `single` | `double`

Tail — Type of alternative hypothesis

`'unequal'` (default) | `'larger'` | `'smaller'`

Type of alternative hypothesis to evaluate, specified as the comma-separated pair consisting of 'Tail' and one of the following.

'unequal'	Test the alternative hypothesis that the cdf of the population from which x is drawn is not equal to the cdf of the hypothesized distribution.
'larger'	Test the alternative hypothesis that the cdf of the population from which x is drawn is greater than the cdf of the hypothesized distribution.
'smaller'	Test the alternative hypothesis that the cdf of the population from which x is drawn is less than the cdf of the hypothesized distribution.

If the values in the data vector x tend to be larger than expected from the hypothesized distribution, the empirical distribution function of x tends to be smaller, and vice versa.

Example: 'Tail', 'larger'

Output Arguments

h — Hypothesis test result

1 | 0

Hypothesis test result, returned as a logical value.

- If $h = 1$, this indicates the rejection of the null hypothesis at the Alpha significance level.
- If $h = 0$, this indicates a failure to reject the null hypothesis at the Alpha significance level.

p — *p*-value

scalar value in the range [0,1]

p-value of the test, returned as a scalar value in the range [0,1]. *p* is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. Small values of *p* cast doubt on the validity of the null hypothesis.

ksstat — Test statistic

nonnegative scalar value

Test statistic of the hypothesis test, returned as a nonnegative scalar value.

cv — Critical value

nonnegative scalar value

Critical value, returned as a nonnegative scalar value.

Definitions

One-Sample Kolmogorov-Smirnov Test

The one-sample Kolmogorov-Smirnov test is a nonparametric test of the null hypothesis that the population cdf of the data is equal to the hypothesized cdf.

The two-sided test for “unequal” cdf functions tests the null hypothesis against the alternative that the population cdf of the data is not equal to the hypothesized cdf. The test statistic is the maximum absolute difference between the empirical cdf calculated from x and the hypothesized cdf:

$$D^* = \max_x \left(\left| \widehat{F}(x) - G(x) \right| \right),$$

where $\widehat{F}(x)$ is the empirical cdf and $G(x)$ is the cdf of the hypothesized distribution.

The one-sided test for a “larger” cdf function tests the null hypothesis against the alternative that the population cdf of the data is greater than the hypothesized cdf. The test statistic is the maximum amount by which the empirical cdf calculated from x exceeds the hypothesized cdf:

$$D^* = \max_x \left(\widehat{F}(x) - G(x) \right).$$

The one-sided test for a “smaller” cdf function tests the null hypothesis against the alternative that the population cdf of the data is less than the hypothesized cdf. The test statistic is the maximum amount by which the hypothesized cdf exceeds the empirical cdf calculated from x :

$$D^* = \max_x \left(G(x) - \widehat{F}(x) \right).$$

`kstest` computes the critical value `cv` using an approximate formula or by interpolation in a table. The formula and table cover the range $0.01 \leq \alpha \leq 0.2$ for two-sided tests

and $0.005 \leq \alpha \leq 0.1$ for one-sided tests. `cv` is returned as `NaN` if `alpha` is outside this range.

Algorithms

`kstest` decides to reject the null hypothesis by comparing the p -value `p` with the significance level `Alpha`, not by comparing the test statistic `ksstat` with the critical value `cv`. Since `cv` is approximate, comparing `ksstat` with `cv` occasionally leads to a different conclusion than comparing `p` with `Alpha`.

`adtest` | `kstest2` | `lillietest`

Introduced before R2006a

kstest2

Two-sample Kolmogorov-Smirnov test

Syntax

```
h = kstest2(x1,x2)
h = kstest2(x1,x2,Name,Value)
[h,p] = kstest2(____)
[h,p,ks2stat] = kstest2(____)
```

Description

`h = kstest2(x1,x2)` returns a test decision for the null hypothesis that the data in vectors `x1` and `x2` are from the same continuous distribution, using the two-sample Kolmogorov-Smirnov test on page 32-3645. The alternative hypothesis is that `x1` and `x2` are from different continuous distributions. The result `h` is 1 if the test rejects the null hypothesis at the 5% significance level, and 0 otherwise.

`h = kstest2(x1,x2,Name,Value)` returns a test decision for a two-sample Kolmogorov-Smirnov test with additional options specified by one or more name-value pair arguments. For example, you can change the significance level or conduct a one-sided test.

`[h,p] = kstest2(____)` also returns the asymptotic p -value `p`, using any of the input arguments from the previous syntaxes.

`[h,p,ks2stat] = kstest2(____)` also returns the test statistic `ks2stat`.

Examples

Test Two Samples for the Same Distribution

Generate sample data from two different Weibull distributions.

```
rng(1);      % For reproducibility
x1 = wblrnd(1,1,1,50);
x2 = wblrnd(1.2,2,1,50);
```

Test the null hypothesis that data in vectors `x1` and `x2` comes from populations with the same distribution.

```
h = kstest2(x1,x2)
```

```
h = logical
    1
```

The returned value of `h = 1` indicates that `kstest` rejects the null hypothesis at the default 5% significance level.

Test the Hypothesis at Different Significance Levels

Generate sample data from two different Weibull distributions.

```
rng(1);      % For reproducibility
x1 = wblrnd(1,1,1,50);
x2 = wblrnd(1.2,2,1,50);
```

Test the null hypothesis that data vectors `x1` and `x2` are from populations with the same distribution at the 1% significance level.

```
[h,p] = kstest2(x1,x2,'Alpha',0.01)
```

```
h = logical
    0
```

```
p = 0.0317
```

The returned value of `h = 0` indicates that `kstest` does not reject the null hypothesis at the 1% significance level.

One-Sided Hypothesis Test

Generate sample data from two different Weibull distributions.

```
rng(1);      % For reproducibility
x1 = wblrnd(1,1,1,50);
x2 = wblrnd(1.2,2,1,50);
```

Test the null hypothesis that data in vectors `x1` and `x2` comes from populations with the same distribution, against the alternative hypothesis that the cdf of the distribution of `x1` is larger than the cdf of the distribution of `x2`.

```
[h,p,k] = kstest2(x1,x2,'Tail','larger')
```

```
h = logical
    1
```

```
p = 0.0158
```

```
k = 0.2800
```

The returned value of `h = 1` indicates that `kstest` rejects the null hypothesis, in favor of the alternative hypothesis that the cdf of the distribution of `x1` is larger than the cdf of the distribution of `x2`, at the default 5% significance level. The returned value of `k` is the test statistic for the two-sample Kolmogorov-Smirnov test.

Input Arguments

x1 — Sample data

vector

Sample data from the first sample, specified as a vector. Data vectors `x1` and `x2` do not need to be the same size.

Data Types: `single` | `double`

x2 — Sample data

vector

Sample data from the second sample, specified as a vector. Data vectors `x1` and `x2` do not need to be the same size.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'Tail', 'larger', 'Alpha', 0.01` specifies a test using the alternative hypothesis that the empirical cdf of `x1` is larger than the empirical cdf of `x2`, conducted at the 1% significance level.

Alpha — Significance level

`0.05` (default) | scalar value in the range (0,1)

Significance level of the hypothesis test, specified as the comma-separated pair consisting of `'Alpha'` and a scalar value in the range (0,1).

Example: `'Alpha', 0.01`

Data Types: `single` | `double`

Tail — Type of alternative hypothesis

`'unequal'` (default) | `'larger'` | `'smaller'`

Type of alternative hypothesis to evaluate, specified as the comma-separated pair consisting of `'Tail'` and one of the following.

- `'unequal'` Test the alternative hypothesis that the empirical cdf of `x1` is unequal to the empirical cdf of `x2`.
- `'larger'` Test the alternative hypothesis that the empirical cdf of `x1` is larger than the empirical cdf of `x2`.
- `'smaller'` Test the alternative hypothesis that the empirical cdf of `x1` is smaller than the empirical cdf of `x2`.

If the data values in `x1` tend to be larger than those in `x2`, the empirical distribution function of `x1` tends to be smaller than that of `x2`, and vice versa.

Example: `'Tail', 'larger'`

Output Arguments

h — Hypothesis test result

1 | 0

Hypothesis test result, returned as a logical value.

- If $h = 1$, this indicates the rejection of the null hypothesis at the Alpha significance level.
- If $h = 0$, this indicates a failure to reject the null hypothesis at the Alpha significance level.

p — Asymptotic *p*-value

scalar value in the range (0,1)

Asymptotic *p*-value of the test, returned as a scalar value in the range (0,1). *p* is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. The asymptotic *p*-value becomes very accurate for large sample sizes, and is believed to be reasonably accurate for sample sizes n_1 and n_2 , such that $(n_1 * n_2) / (n_1 + n_2) \geq 4$.

ks2stat — Test statistic

nonnegative scalar value

Test statistic, returned as a nonnegative scalar value.

Definitions

Two-Sample Kolmogorov-Smirnov Test

The two-sample Kolmogorov-Smirnov test is a nonparametric hypothesis test that evaluates the difference between the cdfs of the distributions of the two sample data vectors over the range of x in each data set.

The two-sided test uses the maximum absolute difference between the cdfs of the distributions of the two data vectors. The test statistic is

$$D^* = \max_x \left(\left| \widehat{F}_1(x) - \widehat{F}_2(x) \right| \right),$$

where $\widehat{F}_1(x)$ is the proportion of x_1 values less than or equal to x and $\widehat{F}_2(x)$ is the proportion of x_2 values less than or equal to x .

The one-sided test uses the actual value of the difference between the cdfs of the distributions of the two data vectors rather than the absolute value. The test statistic is

$$D^* = \max_x (\widehat{F}_1(x) - \widehat{F}_2(x)).$$

Algorithms

In `kstest2`, the decision to reject the null hypothesis is based on comparing the p -value `p` with the significance level `Alpha`, not by comparing the test statistic `ks2stat` with a critical value.

Introduced before R2006a

kurtosis

Kurtosis

Syntax

```
k = kurtosis(X)
k = kurtosis(X,flag)
k = kurtosis(X,flag,'all')
k = kurtosis(X,flag,dim)
k = kurtosis(X,flag,vecdim)
```

Description

`k = kurtosis(X)` returns the sample kurtosis of `X`.

- If `X` is a vector, then `kurtosis(X)` returns a scalar value that is the kurtosis of the elements in `X`.
- If `X` is a matrix, then `kurtosis(X)` returns a row vector that contains the sample kurtosis of each column in `X`.
- If `X` is a multidimensional array, then `kurtosis(X)` operates along the first nonsingleton dimension of `X`.

`k = kurtosis(X,flag)` specifies whether to correct for bias (`flag` is `0`) or not (`flag` is `1`, the default). When `X` represents a sample from a population, the kurtosis of `X` is biased, meaning it tends to differ from the population kurtosis by a systematic amount based on the sample size. You can set `flag` to `0` to correct for this systematic bias.

`k = kurtosis(X,flag,'all')` returns the kurtosis of all elements of `X`.

`k = kurtosis(X,flag,dim)` returns the kurtosis along the operating dimension `dim` of `X`.

`k = kurtosis(X,flag,vecdim)` returns the kurtosis over the dimensions specified in the vector `vecdim`. For example, if `X` is a 2-by-3-by-4 array, then `kurtosis(X,1,[1 2])` returns a 1-by-1-by-4 array. Each element of the output array is the biased kurtosis of the elements on the corresponding page of `X`.

Examples

Find Kurtosis of Matrix

Set the random seed for reproducibility of the results.

```
rng('default')
```

Generate a matrix with 5 rows and 4 columns.

```
X = randn(5,4)
```

```
X = 5×4
```

```
    0.5377    -1.3077    -1.3499    -0.2050  
    1.8339    -0.4336     3.0349    -0.1241  
   -2.2588     0.3426     0.7254     1.4897  
    0.8622     3.5784    -0.0631     1.4090  
    0.3188     2.7694     0.7147     1.4172
```

Find the sample kurtosis of X.

```
k = kurtosis(X)
```

```
k = 1×4
```

```
    2.7067    1.4069    2.3783    1.1759
```

k is a row vector containing the sample kurtosis of each column in X.

Correct for Bias in Sample Kurtosis

For an input vector, correct for bias in the calculation of kurtosis by specifying the `flag` input argument.

Set the random seed for reproducibility of the results.

```
rng('default')
```

Generate a vector of length 10.

```
x = randn(10,1)
```

```
x = 10×1
```

```
    0.5377  
    1.8339  
   -2.2588  
    0.8622  
    0.3188  
   -1.3077  
   -0.4336  
    0.3426  
    3.5784  
    2.7694
```

Find the biased kurtosis of x . By default, `kurtosis` sets the value of `flag` to 1 for computing the biased kurtosis.

```
k1 = kurtosis(x) % flag is 1 by default
```

```
k1 = 2.3121
```

Find the bias-corrected kurtosis of x by setting the value of `flag` to 0.

```
k2 = kurtosis(x,0)
```

```
k2 = 2.7483
```

Find Kurtosis Along Given Dimension

Find the kurtosis along different dimensions for a multidimensional array.

Set the random seed for reproducibility of the results.

```
rng('default')
```

Create a 4-by-3-by-2 array of random numbers.

```
X = randn([4,3,2])
```

```
X =  
X(:,:,1) =  
  
    0.5377    0.3188    3.5784  
    1.8339   -1.3077    2.7694  
   -2.2588   -0.4336   -1.3499  
    0.8622    0.3426    3.0349
```

```
X(:,:,2) =  
  
    0.7254   -0.1241    0.6715  
   -0.0631    1.4897   -1.2075  
    0.7147    1.4090    0.7172  
   -0.2050    1.4172    1.6302
```

Find the kurtosis of X along the default dimension.

```
k1 = kurtosis(X)  
  
k1 =  
k1(:,:,1) =  
  
    2.1350    1.7060    2.2789  
  
k1(:,:,2) =  
  
    1.0542    2.3278    2.0996
```

By default, `kurtosis` operates along the first dimension of X whose size does not equal 1. In this case, this dimension is the first dimension of X. Therefore, k1 is a 1-by-3-by-2 array.

Find the biased kurtosis of X along the second dimension.

```
k2 = kurtosis(X,1,2)  
  
k2 =  
k2(:,:,1) =  
  
    1.5000  
    1.5000
```

```
1.5000
1.5000
```

```
k2(:,:,2) =
```

```
1.5000
1.5000
1.5000
1.5000
```

k2 is a 4-by-1-by-2 array.

Find the biased kurtosis of X along the third dimension.

```
k3 = kurtosis(X,1,3)
```

```
k3 = 4×3
```

```
1.0000    1.0000    1.0000
1.0000    1.0000    1.0000
1.0000    1.0000    1.0000
1.0000    1.0000    1.0000
```

k3 is a 4-by-3 matrix.

Find Kurtosis Along Vector of Dimensions

Find the kurtosis over multiple dimensions by using the 'all' and vecdim input arguments.

Set the random seed for reproducibility of the results.

```
rng('default')
```

Create a 4-by-3-by-2 array of random numbers.

```
X = randn([4 3 2])
```

```
X =
X(:,:,1) =
```

```
0.5377    0.3188    3.5784
1.8339   -1.3077    2.7694
-2.2588   -0.4336   -1.3499
0.8622    0.3426    3.0349
```

```
X(:,:,2) =
```

```
0.7254   -0.1241    0.6715
-0.0631    1.4897   -1.2075
0.7147    1.4090    0.7172
-0.2050    1.4172    1.6302
```

Find the biased kurtosis of X.

```
kall = kurtosis(X,1,'all')
```

```
kall = 2.8029
```

kall is the biased kurtosis of the entire input data set X.

Find the biased kurtosis of each page of X by specifying the first and second dimensions.

```
kpage = kurtosis(X,1,[1 2])
```

```
kpage =
kpage(:,:,1) =
```

```
1.9345
```

```
kpage(:,:,2) =
```

```
2.5877
```

For example, kpage(1,1,2) is the biased kurtosis of the elements in X(:,:,2).

Find the biased kurtosis of the elements in each X(i, :, :) slice by specifying the second and third dimensions.

```
krow = kurtosis(X,1,[2 3])
```

```
krow = 4×1  
  
    3.8457  
    1.4306  
    1.7094  
    2.3378
```

For example, `krow(3)` is the biased kurtosis of the elements in `X(3, :, :)`.

Input Arguments

X — Input data

vector | matrix | multidimensional array

Input data that represents a sample from a population, specified as a vector, matrix, or multidimensional array.

- If `X` is a vector, then `kurtosis(X)` returns a scalar value that is the kurtosis of the elements in `X`.
- If `X` is a matrix, then `kurtosis(X)` returns a row vector that contains the sample kurtosis of each column in `X`.
- If `X` is a multidimensional array, then `kurtosis(X)` operates along the first nonsingleton dimension of `X`.

To specify the operating dimension when `X` is a matrix or an array, use the `dim` input argument.

`kurtosis` treats NaN values in `X` as missing values and removes them.

Data Types: `single` | `double`

flag — Indicator for bias

1 (default) | 0

Indicator for the bias, specified as `0` or `1`.

- If `flag` is `1` (default), then the kurtosis of `X` is biased, meaning it tends to differ from the population kurtosis by a systematic amount based on the sample size.

- If `flag` is 0, then `kurtosis` corrects for the systematic bias.

Data Types: `single` | `double` | `logical`

dim — Dimension

positive integer

Dimension along which to operate, specified as a positive integer. If you do not specify a value for `dim`, then the default is the first dimension of `X` whose size does not equal 1.

Consider the `kurtosis` of a matrix `X`:

- If `dim` is equal to 1, then `kurtosis` returns a row vector that contains the sample kurtosis of each column in `X`.
- If `dim` is equal to 2, then `kurtosis` returns a column vector that contains the sample kurtosis of each row in `X`.

If `dim` is greater than `ndims(X)` or if `size(X, dim)` is 1, then `kurtosis` returns an array of NaNs the same size as `X`.

Data Types: `single` | `double`

vecdim — Vector of dimensions

positive integer vector

Vector of dimensions, specified as a positive integer vector. Each element of `vecdim` represents a dimension of the input array `X`. The output `k` has length 1 in the specified operating dimensions. The other dimension lengths are the same for `X` and `k`.

For example, if `X` is a 2-by-3-by-3 array, then `kurtosis(X, 1, [1 2])` returns a 1-by-1-by-3 array. Each element of the output is the biased kurtosis of the elements on the corresponding page of `X`.

Data Types: `single` | `double`

Output Arguments

k — Kurtosis

scalar | vector | matrix | multidimensional array

Kurtosis, returned as a scalar, vector, matrix, or multidimensional array.

Algorithms

Kurtosis is a measure of how outlier-prone a distribution is. The kurtosis of the normal distribution on page B-136 is 3. Distributions that are more outlier-prone than the normal distribution have kurtosis greater than 3; distributions that are less outlier-prone have kurtosis less than 3. Some definitions of kurtosis subtract 3 from the computed value, so that the normal distribution has kurtosis of 0. The `kurtosis` function does not use this convention.

The kurtosis of a distribution is defined as

$$k = \frac{E(x - \mu)^4}{\sigma^4},$$

where μ is the mean of x , σ is the standard deviation of x , and $E(t)$ represents the expected value of the quantity t . The `kurtosis` function computes a sample version of this population value.

When you set `flag` to 1, the kurtosis is biased, and the following equation applies:

$$k_1 = \frac{\frac{1}{n} \sum_{i=1}^n (x_i - \bar{x})^4}{\left(\frac{1}{n} \sum_{i=1}^n (x_i - \bar{x})^2\right)^2}.$$

When you set `flag` to 0, kurtosis corrects for the systematic bias, and the following equation applies:

$$k_0 = \frac{n-1}{(n-2)(n-3)}((n+1)k_1 - 3(n-1)) + 3.$$

This bias-corrected equation requires that `X` contain at least four elements.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. For more information, see “Tall Arrays” (MATLAB).

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The `'all'` and `vecdim` input arguments are not supported.
- The `dim` input argument must be a compile-time constant.
- If you do not specify the `dim` input argument, the working (or operating) dimension can be different in the generated code. As a result, run-time errors can occur. For more details, see “Automatic dimension restriction” (MATLAB Coder).

For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “General Code Generation Workflow” on page 31-5.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Usage notes and limitations:

- The 'all' and vecdim input arguments are not supported.

For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

Topics

“Normal Distribution” on page B-136

Introduced before R2006a

lasso

Lasso or elastic net regularization for linear models

Syntax

```
B = lasso(X,y)
B = lasso(X,y,Name,Value)
[B,FitInfo] = lasso( ___ )
```

Description

`B = lasso(X,y)` returns fitted least-squares regression coefficients for linear models of the predictor data `X` and the response `y`. Each column of `B` corresponds to a particular regularization coefficient in `Lambda`. By default, `lasso` performs lasso regularization using a geometric sequence of `Lambda` values.

`B = lasso(X,y,Name,Value)` fits regularized regressions with additional options specified by one or more name-value pair arguments. For example, `'Alpha',0.5` sets elastic net as the regularization method, with the parameter `Alpha` equal to 0.5.

`[B,FitInfo] = lasso(___)` also returns the structure `FitInfo`, which contains information about the fit of the models, using any of the input arguments in the previous syntaxes.

Examples

Remove Redundant Predictors Using Lasso Regularization

Construct a data set with redundant predictors and identify those predictors by using `lasso`.

Create a matrix `X` of 100 five-dimensional normal variables. Create a response vector `y` from just two components of `X`, and add a small amount of noise.

```

rng default % For reproducibility
X = randn(100,5);
weights = [0;2;0;-3;0]; % Only two nonzero coefficients
y = X*weights + randn(100,1)*0.1; % Small added noise

```

Construct the default lasso fit.

```
B = lasso(X,y);
```

Find the coefficient vector for the 25th Lambda value in B.

```
B(:,25)
```

```
ans = 5×1
```

```

    0
  1.6093
    0
 -2.5865
    0

```

lasso identifies and removes the redundant predictors.

Remove Redundant Predictors by Using Cross-Validated Fits

Construct a data set with redundant predictors and identify those predictors by using cross-validated lasso.

Create a matrix X of 100 five-dimensional normal variables. Create a response vector y from two components of X, and add a small amount of noise.

```

rng default % For reproducibility
X = randn(100,5);
weights = [0;2;0;-3;0]; % Only two nonzero coefficients
y = X*weights + randn(100,1)*0.1; % Small added noise

```

Construct the lasso fit by using 10-fold cross-validation with labeled predictor variables.

```
[B,FitInfo] = lasso(X,y,'CV',10,'PredictorNames',{'x1','x2','x3','x4','x5'});
```

Display the variables in the model that corresponds to the minimum cross-validated mean squared error (MSE).

```
idxLambdaMinMSE = FitInfo.IndexMinMSE;
minMSEModelPredictors = FitInfo.PredictorNames(B(:,idxLambdaMinMSE)~=0)

minMSEModelPredictors = 1x2 cell array
    {'x2'}    {'x4'}
```

Display the variables in the sparsest model within one standard error of the minimum MSE.

```
idxLambda1SE = FitInfo.Index1SE;
sparseModelPredictors = FitInfo.PredictorNames(B(:,idxLambda1SE)~=0)

sparseModelPredictors = 1x2 cell array
    {'x2'}    {'x4'}
```

In this example, `lasso` identifies the same predictors for the two models and removes the redundant predictors.

Lasso Plot with Cross-Validated Fits

Visually examine the cross-validated error of various levels of regularization.

Load the sample data.

```
load acetylene
```

Create a design matrix with interactions and no constant term.

```
X = [x1 x2 x3];
D = x2fx(X, 'interaction');
D(:,1) = []; % No constant term
```

Construct the lasso fit using 10-fold cross-validation. Include the `FitInfo` output so you can plot the result.

```
rng default % For reproducibility
[B,FitInfo] = lasso(D,y, 'CV',10);
```

Plot the cross-validated fits.

```
lassoPlot(B,FitInfo,'PlotType','CV');
legend('show') % Show legend
```

The green circle and dotted line locate the λ with minimum cross-validation error. The blue circle and dotted line locate the point with minimum cross-validation error plus one standard deviation.

Predict Values Using Elastic Net Regularization

Predict students' exam scores using `lasso` and the elastic net method.

Load the `examgrades` data set.

```
load examgrades
X = grades(:,1:4);
y = grades(:,5);
```

Split the data into training and test sets.

```
n = length(y);
c = cvpartition(n, 'HoldOut', 0.3);
idxTrain = training(c,1);
idxTest = ~idxTrain;
XTrain = X(idxTrain,:);
yTrain = y(idxTrain);
XTest = X(idxTest,:);
yTest = y(idxTest);
```

Find the coefficients of a regularized linear regression model using 10-fold cross-validation and the elastic net method with $\text{Alpha} = 0.75$. Use the largest Lambda value such that the mean squared error (MSE) is within one standard error of the minimum MSE.

```
[B,FitInfo] = lasso(XTrain,yTrain, 'Alpha', 0.75, 'CV', 10);
idxLambda1SE = FitInfo.Index1SE;
coef = B(:,idxLambda1SE);
coef0 = FitInfo.Intercept(idxLambda1SE);
```

Predict exam scores for the test data. Compare the predicted values to the actual exam grades using a reference line.

```
yhat = XTest*coef + coef0;
hold on
scatter(yTest,yhat)
plot(yTest,yTest)
xlabel('Actual Exam Grades')
ylabel('Predicted Exam Grades')
hold off
```

Input Arguments

X — Predictor data

numeric matrix

Predictor data, specified as a numeric matrix. Each row represents one observation, and each column represents one predictor variable.

Data Types: `single` | `double`

y — Response data

numeric vector

Response data, specified as a numeric vector. `y` has length n , where n is the number of rows of `X`. The response `y(i)` corresponds to the i th row of `X`.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `lasso(X,y, 'Alpha', 0.75, 'CV', 10)` performs elastic net regularization with 10-fold cross-validation. The `'Alpha', 0.75` name-value pair argument sets the parameter used in the elastic net optimization.

AbsTol — Absolute error tolerance

`1e-4` (default) | positive scalar

Absolute error tolerance used to determine the convergence of the “ADMM Algorithm” on page 32-3672, specified as the comma-separated pair consisting of `'AbsTol'` and a positive scalar. The algorithm converges when successive estimates of the coefficient vector differ by an amount less than `AbsTol`.

Note This option applies only when you use `lasso` on tall arrays. See “Extended Capabilities” on page 32-0 for more information.

Example: `'AbsTol', 1e-3`

Data Types: `single` | `double`

Alpha — Weight of lasso versus ridge optimization

`1` (default) | positive scalar

Weight of lasso (L^1) versus ridge (L^2) optimization, specified as the comma-separated pair consisting of `'Alpha'` and a positive scalar value in the interval $(0, 1]$. The value `Alpha = 1` represents lasso regression, `Alpha` close to `0` approaches ridge regression on page 11-135, and other values represent elastic net optimization. See “Elastic Net” on page 32-3671.

Example: `'Alpha', 0.5`

Data Types: `single` | `double`

B0 — Initial values for x-coefficients in ADMM Algorithm

vector of zeros (default) | numeric vector

Initial values for x-coefficients in “ADMM Algorithm” on page 32-3672, specified as the comma-separated pair consisting of 'B0' and a numeric vector.

Note This option applies only when you use `lasso` on tall arrays. See “Extended Capabilities” on page 32-0 for more information.

Data Types: `single` | `double`

CV — Cross-validation specification for estimating mean squared error

'resubstitution' (default) | positive integer scalar | `cvpartition` object

Cross-validation specification for estimating the mean squared error (MSE), specified as the comma-separated pair consisting of 'CV' and one of the following:

- 'resubstitution' — `lasso` uses X and y to fit the model and to estimate the MSE without cross-validation.
- Positive scalar integer K — `lasso` uses K -fold cross-validation.
- `cvpartition` object `cvp` — `lasso` uses the cross-validation method expressed in `cvp`. You cannot use a 'leaveout' partition with `lasso`.

Example: 'CV',3

DFmax — Maximum number of nonzero coefficients

Inf (default) | positive integer scalar

Maximum number of nonzero coefficients in the model, specified as the comma-separated pair consisting of 'DFmax' and a positive integer scalar. `lasso` returns results only for `Lambda` values that satisfy this criterion.

Example: 'DFmax',5

Data Types: `single` | `double`

Lambda — Regularization coefficients

nonnegative vector

Regularization coefficients, specified as the comma-separated pair consisting of 'Lambda' and a vector of nonnegative values. See “Lasso” on page 32-3671.

- If you do not supply Lambda, then `lasso` calculates the largest value of Lambda that gives a nonnull model. In this case, `LambdaRatio` gives the ratio of the smallest to the largest value of the sequence, and `NumLambda` gives the length of the vector.
- If you supply Lambda, then `lasso` ignores `LambdaRatio` and `NumLambda`.
- If `Standardize` is `true`, then Lambda is the set of values used to fit the models with the X data standardized to have zero mean and a variance of one.

The default is a geometric sequence of `NumLambda` values, with only the largest value able to produce $B = 0$.

Example: 'Lambda', `linspace(0,1)`

Data Types: `single` | `double`

LambdaRatio — Ratio of smallest to largest Lambda values

`1e-4` (default) | positive scalar

Ratio of the smallest to the largest Lambda values when you do not supply Lambda, specified as the comma-separated pair consisting of 'LambdaRatio' and a positive scalar.

If you set `LambdaRatio = 0`, then `lasso` generates a default sequence of Lambda values and replaces the smallest one with 0 .

Example: 'LambdaRatio', `1e-2`

Data Types: `single` | `double`

MaxIter — Maximum number of iterations allowed

positive integer scalar

Maximum number of iterations allowed, specified as the comma-separated pair consisting of 'MaxIter' and a positive integer scalar.

If the algorithm executes `MaxIter` iterations before reaching the convergence tolerance `RelTol`, then the function stops iterating and returns a warning message.

The function can return more than one warning when `NumLambda` is greater than 1.

Default values are `1e5` for standard data and `1e4` for tall arrays.

Example: 'MaxIter', 1e3

Data Types: single | double

MCREps — Number of Monte Carlo repetitions for cross-validation

1 (default) | positive integer scalar

Number of Monte Carlo repetitions for cross-validation, specified as the comma-separated pair consisting of 'MCREps' and a positive integer scalar.

- If CV is 'resubstitution' or a cvpartition of type 'resubstitution', then MCREps must be 1.
- If CV is a cvpartition of type 'holdout', then MCREps must be greater than 1.

Example: 'MCREps', 5

Data Types: single | double

NumLambda — Number of Lambda values

100 (default) | positive integer scalar

Number of Lambda values lasso uses when you do not supply Lambda, specified as the comma-separated pair consisting of 'NumLambda' and a positive integer scalar. lasso can return fewer than NumLambda fits if the residual error of the fits drops below a threshold fraction of the variance of y .

Example: 'NumLambda', 50

Data Types: single | double

Options — Option to cross-validate in parallel and specify random streams

structure

Option to cross-validate in parallel and specify the random streams, specified as the comma-separated pair consisting of 'Options' and a structure. This option requires Parallel Computing Toolbox.

Create the Options structure with `statset`. The option fields are:

- `UseParallel` — Set to `true` to compute in parallel. The default is `false`.
- `UseSubstreams` — Set to `true` to compute in parallel in a reproducible fashion. For reproducibility, set `Streams` to a type allowing substreams: 'mlfg6331_64' or 'mrg32k3a'. The default is `false`.

- **Streams** — A `RandStream` object or cell array consisting of one such object. If you do not specify `Streams`, then `lasso` uses the default stream.

Example: `'Options',statset('UseParallel',true)`

Data Types: `struct`

PredictorNames — Names of predictor variables

`{}` (default) | string array | cell array of character vectors

Names of the predictor variables, in the order in which they appear in `X`, specified as the comma-separated pair consisting of `'PredictorNames'` and a string array or cell array of character vectors.

Example: `'PredictorNames',{'x1','x2','x3','x4'}`

Data Types: `string` | `cell`

RelTol — Convergence threshold for coordinate descent algorithm

`1e-4` (default) | positive scalar

Convergence threshold for the coordinate descent algorithm [3], specified as the comma-separated pair consisting of `'RelTol'` and a positive scalar. The algorithm terminates when successive estimates of the coefficient vector differ in the L^2 norm by a relative amount less than `RelTol`.

Example: `'RelTol',5e-3`

Data Types: `single` | `double`

Rho — Augmented Lagrangian parameter

positive scalar

Augmented Lagrangian parameter ρ for the “ADMM Algorithm” on page 32-3672, specified as the comma-separated pair consisting of `'Rho'` and a positive scalar. The default is automatic selection.

Note This option applies only when you use `lasso` on tall arrays. See “Extended Capabilities” on page 32-0 for more information.

Example: `'Rho',2`

Data Types: `single` | `double`

Standardize — Flag for standardizing predictor data before fitting models

true (default) | false

Flag for standardizing the predictor data X before fitting the models, specified as the comma-separated pair consisting of 'Standardize' and either true or false. If Standardize is true, then the X data is scaled to have zero mean and a variance of one. Standardize affects whether the regularization is applied to the coefficients on the standardized scale or the original scale. The results are always presented on the original data scale.

X and y are always centered.

Example: 'Standardize', false

Data Types: logical

U0 — Initial value of scaled dual variable

vector of zeros (default) | numeric vector

Initial value of the scaled dual variable u in the “ADMM Algorithm” on page 32-3672, specified as the comma-separated pair consisting of 'U0' and a numeric vector.

Note This option applies only when you use lasso on tall arrays. See “Extended Capabilities” on page 32-0 for more information.

Data Types: single | double

Weights — Observation weights

1/n*ones(n,1) (default) | nonnegative vector

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a nonnegative vector. Weights has length n , where n is the number of rows of X . The lasso function scales Weights to sum to 1.

Data Types: single | double

Output Arguments**B — Fitted coefficients**

numeric matrix

Fitted coefficients, returned as a numeric matrix. **B** is a p -by- L matrix, where p is the number of predictors (columns) in **X**, and L is the number of **Lambda** values. You can specify the number of **Lambda** values using the **NumLambda** name-value pair argument.

The coefficient corresponding to the intercept term is a field in **FitInfo**.

Data Types: `single` | `double`

FitInfo — Fit information of models

structure

Fit information of the linear models, returned as a structure with the fields described in this table.

Field in FitInfo	Description
Intercept	Intercept term β_0 for each linear model, a 1-by- L vector
Lambda	Lambda parameters in ascending order, a 1-by- L vector
Alpha	Value of the Alpha parameter, a scalar
DF	Number of nonzero coefficients in B for each value of Lambda , a 1-by- L vector
MSE	Mean squared error (MSE), a 1-by- L vector
PredictorNames	Value of the PredictorNames parameter, stored as a cell array of character vectors

If you set the **CV** name-value pair argument to cross-validate, the **FitInfo** structure contains these additional fields.

Field in FitInfo	Description
SE	Standard error of MSE for each Lambda , as calculated during cross-validation, a 1-by- L vector
LambdaMinMSE	Lambda value with the minimum MSE, a scalar
Lambda1SE	Largest Lambda value such that MSE is within one standard error of the minimum MSE, a scalar
IndexMinMSE	Index of Lambda with the value LambdaMinMSE , a scalar
Index1SE	Index of Lambda with the value Lambda1SE , a scalar

Definitions

Lasso

For a given value of λ , a nonnegative parameter, lasso solves the problem

$$\min_{\beta_0, \beta} \left(\frac{1}{2N} \sum_{i=1}^N (y_i - \beta_0 - x_i^T \beta)^2 + \lambda \sum_{j=1}^p |\beta_j| \right).$$

- N is the number of observations.
- y_i is the response at observation i .
- x_i is data, a vector of length p at observation i .
- λ is a nonnegative regularization parameter corresponding to one value of Λ .
- The parameters β_0 and β are a scalar and a vector of length p , respectively.

As λ increases, the number of nonzero components of β decreases.

The lasso problem involves the L^1 norm of β , as contrasted with the elastic net algorithm.

Elastic Net

For α strictly between 0 and 1, and nonnegative λ , elastic net solves the problem

$$\min_{\beta_0, \beta} \left(\frac{1}{2N} \sum_{i=1}^N (y_i - \beta_0 - x_i^T \beta)^2 + \lambda P_\alpha(\beta) \right),$$

where

$$P_\alpha(\beta) = \frac{(1-\alpha)}{2} \|\beta\|_2^2 + \alpha \|\beta\|_1 = \sum_{j=1}^p \left(\frac{(1-\alpha)}{2} \beta_j^2 + \alpha |\beta_j| \right).$$

Elastic net is the same as lasso when $\alpha = 1$. For other values of α , the penalty term $P_\alpha(\beta)$ interpolates between the L^1 norm of β and the squared L^2 norm of β . As α shrinks toward 0, elastic net approaches ridge regression.

Algorithms

ADMM Algorithm

When operating on tall arrays, `lasso` uses an algorithm based on the Alternating Direction Method of Multipliers (ADMM) [5]. The notation used here is the same as in the reference paper. This method solves problems of the form

Minimize $l(x) + g(z)$

Subject to $Ax + Bz = c$

Using this notation, the lasso regression problem is

Minimize $l(x) + g(z) = \frac{1}{2}\|Ax - b\|_2^2 + \lambda\|z\|_1$

Subject to $x - z = 0$

Because the loss function $l(x) = \frac{1}{2}\|Ax - b\|_2^2$ is quadratic, the iterative updates performed by the algorithm amount to solving a linear system of equations with a single coefficient matrix but several right-hand sides. The updates performed by the algorithm during each iteration are

$$x^{k+1} = (A^T A + \rho I)^{-1} (A^T b + \rho(z^k - u^k))$$

$$z^{k+1} = S_{\lambda/\rho}(x^{k+1} + u^k)$$

$$u^{k+1} = u^k + x^{k+1} - z^{k+1}$$

A is the dataset (a tall array), x contains the coefficients, ρ is the penalty parameter (augmented Lagrangian parameter), b is the response (a tall array), and S is the soft thresholding operator.

$$S_{\kappa}(a) = \begin{cases} a - \kappa, & a > \kappa \\ 0, & |a| \leq \kappa \\ a + \kappa, & a < -\kappa \end{cases} .$$

lasso solves the linear system using Cholesky factorization because the coefficient matrix $A^T A + \rho I$ is symmetric and positive definite. Because ρ does not change between iterations, the Cholesky factorization is cached between iterations.

Even though A and b are tall arrays, they appear only in the terms $A^T A$ and $A^T b$. The results of these two matrix multiplications are small enough to fit in memory, so they are precomputed and the iterative updates between iterations are performed entirely within memory.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function supports tall arrays for out-of-memory data with some limitations.

- With tall arrays, `lasso` uses an algorithm based on ADMM (Alternating Direction Method of Multipliers).
- No elastic net support. The `'Alpha'` parameter is always 1.
- No cross-validation (`'CV'` parameter) support, which includes the related parameter `'MCReps'`.
- The output `FitInfo` does not contain the additional fields `'SE'`, `'LambdaMinMSE'`, `'Lambda1SE'`, `'IndexMinMSE'`, and `'Index1SE'`.
- The `'Options'` parameter is not supported because it does not contain options that apply to the ADMM algorithm. You can tune the ADMM algorithm using name-value pair arguments.
- Supported name-value pair arguments are:
 - `'Lambda'`
 - `'LambdaRatio'`
 - `'NumLambda'`
 - `'Standardize'`
 - `'PredictorNames'`
 - `'RelTol'`
 - `'Weights'`
- Additional name-value pair arguments to control the ADMM algorithm are:
 - `'Rho'` — Augmented Lagrangian parameter, ρ . The default value is automatic selection.
 - `'AbsTol'` — Absolute tolerance used to determine convergence. The default value is $1e-4$.
 - `'MaxIter'` — Maximum number of iterations. The default value is $1e4$.
 - `'B0'` — Initial values for the coefficients x . The default value is a vector of zeros.
 - `'U0'` — Initial values of the scaled dual variable u . The default value is a vector of zeros.

For more information, see “Tall Arrays” (MATLAB).

Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the 'UseParallel' option to true.

Set the 'UseParallel' field of the options structure to true using `statset` and specify the 'Options' name-value pair argument in the call to this function.

For example: `'Options',statset('UseParallel',true)`

For more information, see the 'Options' name-value pair argument.

For more general information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

Topics

“Lasso and Elastic Net” on page 11-140

Introduced in R2011b

lassoglm

Lasso or elastic net regularization for generalized linear models

Syntax

```
B = lassoglm(X,y)
B = lassoglm(X,y,distr)
B = lassoglm(X,y,distr,Name,Value)
[B,FitInfo] = lassoglm( ___ )
```

Description

`B = lassoglm(X,y)` returns penalized, maximum-likelihood fitted coefficients for generalized linear models of the predictor data `X` and the response `y`, where the values in `y` are assumed to have a normal probability distribution. Each column of `B` corresponds to a particular regularization coefficient in `Lambda`. By default, `lassoglm` performs lasso regularization using a geometric sequence of `Lambda` values.

`B = lassoglm(X,y,distr)` performs lasso regularization to fit the models using the probability distribution `distr` for `y`.

`B = lassoglm(X,y,distr,Name,Value)` fits regularized generalized linear regressions with additional options specified by one or more name-value pair arguments. For example, `'Alpha', 0.5` sets elastic net as the regularization method, with the parameter `Alpha` equal to 0.5.

`[B,FitInfo] = lassoglm(___)` also returns the structure `FitInfo`, which contains information about the fit of the models, using any of the input arguments in the previous syntaxes.

Examples

Remove Redundant Predictors Using Lasso Regularization

Construct a data set with redundant predictors and identify those predictors by using `lassoglm`.

Create a random matrix X with 100 observations and 10 predictors. Create the normally distributed response y using only four of the predictors and a small amount of noise.

```
rng default
X = randn(100,10);
weights = [0.6;0.5;0.7;0.4];
y = X(:, [2 4 5 7])*weights + randn(100,1)*0.1; % Small added noise
```

Perform lasso regularization.

```
B = lassoglm(X,y);
```

Find the coefficient vector for the 75th Lambda value in B .

```
B(:,75)
```

```
ans = 10×1
```

```
    0
  0.5431
    0
  0.3944
  0.6173
    0
  0.3473
    0
    0
    0
```

`lassoglm` identifies and removes the redundant predictors.

Cross-Validated Lasso Regularization of Generalized Linear Model

Construct data from a Poisson model, and identify the important predictors by using `lassoglm`.

Create data with 20 predictors. Create a Poisson response variable using only three of the predictors plus a constant.

```
rng default % For reproducibility
X = randn(100,20);
weights = [.4;.2;.3];
mu = exp(X(:,[5 10 15])*weights + 1);
y = poissrnd(mu);
```

Construct a cross-validated lasso regularization of a Poisson regression model of the data.

```
[B,FitInfo] = lassoglm(X,y,'poisson','CV',10);
```

Examine the cross-validation plot to see the effect of the Lambda regularization parameter.

```
lassoPlot(B,FitInfo,'plottype','CV');
legend('show') % Show legend
```

The green circle and dotted line locate the Lambda with minimum cross-validation error. The blue circle and dotted line locate the point with minimum cross-validation error plus one standard deviation.

Find the nonzero model coefficients corresponding to the two identified points.

```
idxLambdaMinDeviance = FitInfo.IndexMinDeviance;
mincoefs = find(B(:,idxLambdaMinDeviance))

mincoefs = 7×1

     3
     5
     6
```

```
10
11
15
16
```

```
idxLambda1SE = FitInfo.Index1SE;
min1coefs = find(B(:,idxLambda1SE))
```

```
min1coefs = 3×1
```

```
5
10
15
```

The coefficients from the minimum-plus-one standard error point are exactly those coefficients used to create the data.

Predict Values Using Lasso Regularization

Predict whether students got a B or above on their last exam by using `lassoglm`.

Load the `examgrades` data set. Convert the last exam grades to a logical vector, where 1 represents a grade of 80 or above and 0 represents a grade below 80.

```
load examgrades
X = grades(:,1:4);
y = grades(:,5);
yBinom = (y>=80);
```

Partition the data into training and test sets.

```
rng default % Set the seed for reproducibility
c = cvpartition(yBinom,'HoldOut',0.3);
idxTrain = training(c,1);
idxTest = ~idxTrain;
XTrain = X(idxTrain,:);
yTrain = yBinom(idxTrain);
XTest = X(idxTest,:);
yTest = yBinom(idxTest);
```

Perform lasso regularization for generalized linear model regression with 3-fold cross-validation on the training data. Assume the values in y are binomially distributed. Choose model coefficients corresponding to the Lambda with minimum expected deviance.

```
[B,FitInfo] = lassoglm(XTrain,yTrain,'binomial','CV',3);  
idxLambdaMinDeviance = FitInfo.IndexMinDeviance;  
B0 = FitInfo.Intercept(idxLambdaMinDeviance);  
coef = [B0; B(:,idxLambdaMinDeviance)]
```

```
coef = 5×1
```

```
-21.1911  
 0.0235  
 0.0670  
 0.0693  
 0.0949
```

Predict exam grades for the test data using the model coefficients found in the previous step. Specify the link function for a binomial response using 'logit'. Convert the prediction values to a logical vector.

```
yhat = glmval(coef,XTest,'logit');  
yhatBinom = (yhat>=0.5);
```

Determine the accuracy of the predictions using a confusion matrix.

```
c = confusionchart(yTest,yhatBinom);
```

True Class	false	29	1
	true	4	2
		false	true
		Predicted Class	

The function correctly predicts 31 exam grades. However, the function incorrectly predicts that 1 student receives a B or above and 4 students receive a grade below a B.

Input Arguments

X — Predictor data

numeric matrix

Predictor data, specified as a numeric matrix. Each row represents one observation, and each column represents one predictor variable.

Data Types: `single` | `double`

y — Response data

numeric vector | logical vector | categorical array | numeric matrix

Response data, specified as a numeric vector, logical vector, categorical array, or two-column numeric matrix.

- When `distr` is not `'binomial'`, `y` is a numeric vector or categorical array of length `n`, where `n` is the number of rows in `X`. The response `y(i)` corresponds to row `i` in `X`.
- When `distr` is `'binomial'`, `y` is one of the following:
 - Numeric vector of length `n`, where each entry represents success (1) or failure (0)
 - Logical vector of length `n`, where each entry represents success or failure
 - Categorical array of length `n`, where each entry represents success or failure
 - Two-column numeric matrix, where the first column contains the number of successes for each observation and the second column contains the total number of trials

Data Types: single | double | logical | categorical

distr — Distribution of response data

`'normal'` | `'binomial'` | `'poisson'` | `'gamma'` | `'inverse gaussian'`

Distribution of response data, specified as one of the following:

- `'normal'`
- `'binomial'`
- `'poisson'`
- `'gamma'`
- `'inverse gaussian'`

`lassoglm` uses the default link function on page 32-3690 corresponding to `distr`. Specify another link function using the `Link` name-value pair argument.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `lassoglm(X,y,'poisson','Alpha',0.5)` performs elastic net regularization assuming that the response values are Poisson distributed. The `'Alpha',0.5` name-value pair argument sets the parameter used in the elastic net optimization.

Alpha — Weight of lasso versus ridge optimization

1 (default) | positive scalar

Weight of lasso (L^1) versus ridge (L^2) optimization, specified as the comma-separated pair consisting of `'Alpha'` and a positive scalar value in the interval $(0, 1]$. The value `Alpha = 1` represents lasso regression, `Alpha` close to 0 approaches ridge regression, and other values represent elastic net optimization. See “Elastic Net” on page 32-3691.

Example: `'Alpha',0.75`

Data Types: `single` | `double`

CV — Cross-validation specification for estimating deviance

`'resubstitution'` (default) | positive integer scalar | `cvpartition` object

Cross-validation specification for estimating the deviance, specified as the comma-separated pair consisting of `'CV'` and one of the following:

- `'resubstitution'` — `lassoglm` uses X and y to fit the model and to estimate the deviance without cross-validation.
- Positive scalar integer K — `lassoglm` uses K -fold cross-validation.
- `cvpartition` object `cvp` — `lassoglm` uses the cross-validation method expressed in `cvp`. You cannot use a `'leaveout'` partition with `lassoglm`.

Example: `'CV',10`

DFmax — Maximum number of nonzero coefficients

Inf (default) | positive integer scalar

Maximum number of nonzero coefficients in the model, specified as the comma-separated pair consisting of `'DFmax'` and a positive integer scalar. `lassoglm` returns results only for `Lambda` values that satisfy this criterion.

Example: `'DFmax',25`

Data Types: `single` | `double`

Lambda — Regularization coefficients

nonnegative vector

Regularization coefficients, specified as the comma-separated pair consisting of 'Lambda' and a vector of nonnegative values. See “Lasso” on page 32-3691.

- If you do not supply Lambda, then lassoglm estimates the largest value of Lambda that gives a nonnull model. In this case, LambdaRatio gives the ratio of the smallest to the largest value of the sequence, and NumLambda gives the length of the vector.
- If you supply Lambda, then lassoglm ignores LambdaRatio and NumLambda.
- If Standardize is true, then Lambda is the set of values used to fit the models with the X data standardized to have zero mean and a variance of one.

The default is a geometric sequence of NumLambda values, with only the largest value able to produce $B = 0$.

Data Types: single | double

LambdaRatio — Ratio of smallest to largest Lambda values

1e-4 (default) | positive scalar

Ratio of the smallest to the largest Lambda values when you do not supply Lambda, specified as the comma-separated pair consisting of 'LambdaRatio' and a positive scalar.

If you set LambdaRatio = 0, then lassoglm generates a default sequence of Lambda values and replaces the smallest one with 0.

Example: 'LambdaRatio', 1e-2

Data Types: single | double

Link — Mapping between mean of response and linear predictor

'comploglog' | 'identity' | 'log' | 'logit' | 'loglog' | ...

Mapping between the mean μ of the response and the linear predictor Xb , specified as the comma-separated pair consisting of 'Link' and one of the values in this table.

Value	Description
'comploglog'	$\log(-\log((1 - \mu))) = Xb$
'identity', default for the distribution 'normal'	$\mu = Xb$
'log', default for the distribution 'poisson'	$\log(\mu) = Xb$

Value	Description
'logit', default for the distribution 'binomial'	$\log(\mu/(1 - \mu)) = Xb$
'loglog'	$\log(-\log(\mu)) = Xb$
'probit'	$\Phi^{-1}(\mu) = Xb$, where Φ is the normal (Gaussian) cumulative distribution function
'reciprocal', default for the distribution 'gamma'	$\mu^{-1} = Xb$
p (a number), default for the distribution 'inverse gaussian' (with $p = -2$)	$\mu^p = Xb$
A cell array of the form {FL FD FI}, containing three function handles created using @, which define the link (FL), the derivative of the link (FD), and the inverse link (FI). Or, a structure of function handles with the field Link containing FL, the field Derivative containing FD, and the field Inverse containing FI.	User-specified link function (see “Custom Link Function” on page 12-16)

Example: 'Link', 'probit'

Data Types: char | string | single | double | cell

MaxIter — Maximum number of iterations allowed

1e4 (default) | positive integer scalar

Maximum number of iterations allowed, specified as the comma-separated pair consisting of 'MaxIter' and a positive integer scalar.

If the algorithm executes `MaxIter` iterations before reaching the convergence tolerance `RelTol`, then the function stops iterating and returns a warning message.

The function can return more than one warning when `NumLambda` is greater than 1.

Example: 'MaxIter', 1e3

Data Types: single | double

MCREps — Number of Monte Carlo repetitions for cross-validation

1 (default) | positive integer scalar

Number of Monte Carlo repetitions for cross-validation, specified as the comma-separated pair consisting of 'MCREps' and a positive integer scalar.

- If CV is 'resubstitution' or a cvpartition of type 'resubstitution', then MCREps must be 1.
- If CV is a cvpartition of type 'holdout', then MCREps must be greater than 1.

Example: 'MCREps',2

Data Types: single | double

NumLambda — Number of Lambda values

100 (default) | positive integer scalar

Number of Lambda values `lassoglm` uses when you do not supply Lambda, specified as the comma-separated pair consisting of 'NumLambda' and a positive integer scalar. `lassoglm` can return fewer than NumLambda fits if the deviance of the fits drops below a threshold fraction of the null deviance (deviance of the fit without any predictors X).

Example: 'NumLambda',150

Data Types: single | double

Offset — Additional predictor variable

numeric vector

Additional predictor variable, specified as the comma-separated pair consisting of 'Offset' and a numeric vector with the same number of rows as X. The `lassoglm` function keeps the coefficient value of Offset fixed at 1.0.

Data Types: single | double

Options — Option to cross-validate in parallel and specify random streams

structure

Option to cross-validate in parallel and specify the random streams, specified as the comma-separated pair consisting of 'Options' and a structure. This option requires Parallel Computing Toolbox.

Create the Options structure with `statset`. The option fields are:

- `UseParallel` — Set to `true` to compute in parallel. The default is `false`.
- `UseSubstreams` — Set to `true` to compute in parallel in a reproducible fashion. For reproducibility, set `Streams` to a type allowing substreams: `'mlfg6331_64'` or `'mrg32k3a'`. The default is `false`.
- `Streams` — A `RandStream` object or cell array consisting of one such object. If you do not specify `Streams`, then `lassoglm` uses the default stream.

Example: `'Options', statset('UseParallel', true)`

Data Types: `struct`

PredictorNames — Names of predictor variables

`{}` (default) | `string array` | `cell array of character vectors`

Names of the predictor variables, in the order in which they appear in X , specified as the comma-separated pair consisting of `'PredictorNames'` and a `string array` or `cell array of character vectors`.

Example: `'PredictorNames', {'Height', 'Weight', 'Age'}`

Data Types: `string` | `cell`

RelTol — Convergence threshold for coordinate descent algorithm

`1e-4` (default) | `positive scalar`

Convergence threshold for the coordinate descent algorithm [3], specified as the comma-separated pair consisting of `'RelTol'` and a positive scalar. The algorithm terminates when successive estimates of the coefficient vector differ in the L^2 norm by a relative amount less than `RelTol`.

Example: `'RelTol', 2e-3`

Data Types: `single` | `double`

Standardize — Flag for standardizing predictor data before fitting models

`true` (default) | `false`

Flag for standardizing the predictor data X before fitting the models, specified as the comma-separated pair consisting of `'Standardize'` and either `true` or `false`. If `Standardize` is `true`, then the X data is scaled to have zero mean and a variance of one. `Standardize` affects whether the regularization is applied to the coefficients on the standardized scale or the original scale. The results are always presented on the original data scale.

Example: 'Standardize', false

Data Types: logical

Weights — Observation weights

$1/n \times \text{ones}(n, 1)$ (default) | nonnegative vector

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a nonnegative vector. `Weights` has length n , where n is the number of rows of X . At least two values must be positive.

Data Types: single | double

Output Arguments

B — Fitted coefficients

numeric matrix

Fitted coefficients, returned as a numeric matrix. B is a p -by- L matrix, where p is the number of predictors (columns) in X , and L is the number of `Lambda` values. You can specify the number of `Lambda` values using the `NumLambda` name-value pair argument.

The coefficient corresponding to the intercept term is a field in `FitInfo`.

Data Types: single | double

FitInfo — Fit information of models

structure

Fit information of the generalized linear models, returned as a structure with the fields described in this table.

Field in <code>FitInfo</code>	Description
<code>Intercept</code>	Intercept term β_0 for each linear model, a 1-by- L vector
<code>Lambda</code>	<code>Lambda</code> parameters in ascending order, a 1-by- L vector
<code>Alpha</code>	Value of the <code>Alpha</code> parameter, a scalar
<code>DF</code>	Number of nonzero coefficients in B for each value of <code>Lambda</code> , a 1-by- L vector

Field in FitInfo	Description
Deviance	Deviance of the fitted model for each value of Lambda, a 1-by-L vector If the model is cross-validated, then the values for Deviance represent the estimated expected deviance of the model applied to new data, as calculated by cross-validation. Otherwise, Deviance is the deviance of the fitted model applied to the data used to perform the fit.
PredictorNames	Value of the PredictorNames parameter, stored as a cell array of character vectors

If you set the CV name-value pair argument to cross-validate, the FitInfo structure contains these additional fields.

Field in FitInfo	Description
SE	Standard error of Deviance for each Lambda, as calculated during cross-validation, a 1-by-L vector
LambdaMinDeviance	Lambda value with minimum expected deviance, as calculated by cross-validation, a scalar
Lambda1SE	Largest Lambda value such that Deviance is within one standard error of the minimum, a scalar
IndexMinDeviance	Index of Lambda with the value LambdaMinDeviance, a scalar
Index1SE	Index of Lambda with the value Lambda1SE, a scalar

Definitions

Link Function

A link function $f(\mu)$ maps a distribution with mean μ to a linear model with data X and coefficient vector b using the formula

$$f(\mu) = Xb.$$

You can find the formulas for the link functions in the `Link` name-value pair argument description. This table lists the link functions that are typically used for each distribution.

Distribution Family	Default Link Function	Other Typical Link Functions
'normal'	'identity'	
'binomial'	'logit'	'comprologlog', 'loglog', 'probit'
'poisson'	'log'	
'gamma'	'reciprocal'	
'inverse gaussian'	-2	

Lasso

For a nonnegative value of λ , `lassoglm` solves the problem

$$\min_{\beta_0, \beta} \left(\frac{1}{N} \text{Deviance}(\beta_0, \beta) + \lambda \sum_{j=1}^p |\beta_j| \right).$$

- The function `Deviance` in this equation is the deviance of the model fit to the responses using the intercept β_0 and the predictor coefficients β . The formula for `Deviance` depends on the `dist` parameter you supply to `lassoglm`. Minimizing the λ -penalized deviance is equivalent to maximizing the λ -penalized loglikelihood.
- N is the number of observations.
- λ is a nonnegative regularization parameter corresponding to one value of `Lambda`.
- The parameters β_0 and β are a scalar and a vector of length p , respectively.

As λ increases, the number of nonzero components of β decreases.

The lasso problem involves the L^1 norm of β , as contrasted with the elastic net algorithm.

Elastic Net

For α strictly between 0 and 1, and nonnegative λ , elastic net solves the problem

$$\min_{\beta_0, \beta} \left(\frac{1}{N} \text{Deviance}(\beta_0, \beta) + \lambda P_\alpha(\beta) \right),$$

where

$$P_\alpha(\beta) = \frac{(1 - \alpha)}{2} \|\beta\|_2^2 + \alpha \|\beta\|_1 = \sum_{j=1}^p \left(\frac{(1 - \alpha)}{2} \beta_j^2 + \alpha |\beta_j| \right).$$

Elastic net is the same as lasso when $\alpha = 1$. For other values of α , the penalty term $P_\alpha(\beta)$ interpolates between the L^1 norm of β and the squared L^2 norm of β . As α shrinks toward 0, elastic net approaches ridge regression.

Extended Capabilities

Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the 'UseParallel' option to true.

Set the 'UseParallel' field of the options structure to true using `statset` and specify the 'Options' name-value pair argument in the call to this function.

For example: `'Options',statset('UseParallel',true)`

For more information, see the 'Options' name-value pair argument.

For more general information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

lassoPlot

Trace plot of lasso fit

Syntax

```
lassoPlot(B)  
lassoPlot(B,FitInfo)  
lassoPlot(B,FitInfo,Name,Value)  
[ax,figh] = lassoPlot(____)
```

Description

`lassoPlot(B)` creates a trace plot of the values in `B` against the L^1 norm of `B`.

`lassoPlot(B,FitInfo)` creates a plot with type depending on the data type of `FitInfo` and the value, if any, of the `PlotType` name-value pair.

`lassoPlot(B,FitInfo,Name,Value)` creates a plot with additional options specified by one or more `Name,Value` pair arguments.

`[ax,figh] = lassoPlot(____)`, for any previous input syntax, returns a handle `ax` to the plot axis, and a handle `figh` to the figure window.

Input Arguments

B

Coefficients of a sequence of regression fits, as returned from the `lasso` or `lassoglm` functions. `B` is a `p`-by-`N``Lambda` matrix, where `p` is the number of predictors, and each column of `B` is a set of coefficients `lasso` calculates using one `Lambda` penalty value.

FitInfo

Information controlling the plot:

- `FitInfo` is a structure, especially as returned from `lasso` or `lassoglm` — `lassoPlot` creates a plot based on the `PlotType` name-value pair.
- `FitInfo` is a vector — `lassoPlot` forms the x-axis of the plot from the values in `FitInfo`. The length of `FitInfo` must equal the number of columns of `B`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Parent

Axis in which to draw the plot.

Default: New plot

PlotType

Plot type when you specify a `FitInfo` vector or structure:

PlotType	Plot
'L1'	<code>lassoPlot</code> creates the x-axis from the L^1 norm of the coefficients in <code>B</code> . The x-axis at the top of the plot contains the degrees of freedom (<code>df</code>), meaning the number of nonzero coefficients of <code>B</code> .
'Lambda' When you choose this value, <code>FitInfo</code> must be a structure.	<code>lassoPlot</code> creates the x-axis from the <code>Lambda</code> field of <code>FitInfo</code> . The x-axis at the top of the plot contains the degrees of freedom (<code>df</code>), meaning the number of nonzero coefficients of <code>B</code> .

PlotType	Plot
'CV' When you choose this value, <code>FitInfo</code> must be a cross-validated structure.	<ul style="list-style-type: none"> • For each <code>Lambda</code>, <code>lassoPlot</code> plots an estimate of the mean squared prediction error on new data for the model fitted by <code>lasso</code> with that value of <code>Lambda</code>. • <code>lassoPlot</code> plots error bars for the estimates.

If you include a cross-validated `FitInfo` structure, `lassoPlot` also indicates two specific `Lambda` values with green and blue dashed lines.

- A green, dashed line indicates the value of `Lambda` with a minimum cross-validated mean squared error (MSE).
- A blue, dashed line indicates the greatest `Lambda` that is within one standard error of the minimum MSE. This `Lambda` value makes the sparsest model with relatively low MSE.

To display the label for each plot in the legend of the figure, type `legend('show')` in the Command Window.

Default: 'L1'

PredictorNames

String array or cell array of character vectors to label each coefficient of `B`. If the length of `PredictorNames` is less than the number of rows of `B`, the remaining labels are padded with default values.

`lassoPlot` uses `PredictorNames` in `FitInfo` only if:

- You created `FitInfo` with a call to `lasso` that included a `PredictorNames` name-value pair.
- You call `lassoPlot` *without* a `PredictorNames` name-value pair.
- You include `FitInfo` in your `lassoPlot` call.

For an example, see “Lasso Plot with Default Plot Type” on page 32-3697.

Default: {'B1', 'B2', ...}

XScale

- 'linear' for linear x-axis
- 'log' for logarithmic scaled x-axis

Default: 'linear', except 'log' for the 'CV' plot type

Output Arguments

ax

Handle to the axis of the plot (see “Axes Appearance” (MATLAB)).

figh

Handle to the figure window (see “Special Object Identifiers” (MATLAB)).

Examples

Lasso Plot with Default Plot Type

Load the sample data

```
load acetylene
```

Prepare the design matrix for lasso fit with interactions.

```
X = [x1 x2 x3];
D = x2fx(X, 'interaction');
D(:,1) = []; % No constant term
```

The `x2fx` function returns the quadratic model in the order of a constant term, linear terms and interaction terms: constant term, x_1 , x_2 , x_3 , $x_1 \cdot x_2$, $x_1 \cdot x_3$, and $x_2 \cdot x_3$

Fit a regularized model of the data using `lasso`.

```
B = lasso(D,y);
```

Plot the lasso fits with labeled coefficients by using the PredictorNames name-value pair.

```
lassoPlot(B, 'PredictorNames', {'x1', 'x2', 'x3', 'x1.*x2', 'x1.*x3', 'x2.*x3'});
legend('show', 'Location', 'NorthWest') % Show legend
```

Each line represents a trace of the values in B for a single predictor variable: x1, x2, x3, x1.*x2, x1.*x3, and x2.*x3.

Display a data tip for the trace plot. A data tip appears when you hover over a data tip.

A data tip displays these lines of information: the name of the selected coefficient with a fitted value, the L1 norm of a set of coefficients including the selected coefficient, and the index of the corresponding Lambda.

Lasso Plot with Lambda Plot Type

Load the sample data.

load `acetylene`

Prepare the data for lasso fit with interactions.

```
X = [x1 x2 x3];  
D = x2fx(X, 'interaction');  
D(:,1) = []; % No constant term
```

Fit a regularized model of the data with lasso.

```
[B,FitInfo] = lasso(D,y);
```

Plot the fits with the Lambda plot type and logarithmic scaling.

```
lassoPlot(B,FitInfo, 'PlotType', 'Lambda', 'XScale', 'log');
```

Lasso Plot with Cross-Validated Fits

Visually examine the cross-validated error of various levels of regularization.

Load the sample data.

```
load acetylene
```

Create a design matrix with interactions and no constant term.

```
X = [x1 x2 x3];  
D = x2fx(X, 'interaction');  
D(:,1) = []; % No constant term
```

Construct the lasso fit using 10-fold cross-validation. Include the FitInfo output so you can plot the result.

```
rng default % For reproducibility  
[B,FitInfo] = lasso(D,y,'CV',10);
```

Plot the cross-validated fits.

```
lassoPlot(B,FitInfo,'PlotType','CV');  
legend('show') % Show legend
```

The green circle and dotted line locate the Lambda with minimum cross-validation error. The blue circle and dotted line locate the point with minimum cross-validation error plus one standard deviation.

Introduced in R2011b

le

Class: grandstream

Less than or equal relation for handles

Syntax

`h1 <= h2`

Description

Handles are equal if they are handles for the same object. All comparisons use a number associated with each handle object. Nothing can be assumed about the result of a handle comparison except that the repeated comparison of two handles in the same MATLAB session will yield the same result. The order of handle values is purely arbitrary and has no connection to the state of the handle objects being compared.

`h1 <= h2` performs element-wise comparisons between handle arrays `h1` and `h2`. `h1` and `h2` must be of the same dimensions unless one is a scalar. The result is a logical array of the same dimensions, where each element is an element-wise `<=` result.

If one of `h1` or `h2` is scalar, scalar expansion is performed and the result will match the dimensions of the array that is not scalar.

`tf = le(h1, h2)` stores the result in a logical array of the same dimensions.

learnerCoderConfigurer

Create coder configurer of machine learning model

After training a machine learning model, create a coder configurer for the model by using `learnerCoderConfigurer`. Use the object functions and properties of the configurer to specify code generation options and to generate C/C++ code for the `predict` and `update` functions of the machine learning model. Generating C/C++ code requires MATLAB Coder.

This flow chart shows the code generation workflow using a coder configurer. Use `learnerCoderConfigurer` for the highlighted step.

Syntax

```

configurer = learnerCoderConfigurer(Mdl,X)
configurer = learnerCoderConfigurer(Mdl,X,Name,Value)

```

Description

`configurer = learnerCoderConfigurer(Mdl,X)` returns the coder configurer configurer for the machine learning model `Mdl`. Specify the predictor data `X` for the `predict` function of `Mdl`.

`configurer = learnerCoderConfigurer(Mdl,X,Name,Value)` returns a coder configurer with additional options specified by one or more name-value pair arguments.

For example, you can specify the number of output arguments in the `predict` function, the file name of generated C/C++ code, and the verbosity level of the coder configurer.

Examples

Generate Code Using Coder Configurer

Train a machine learning model, and then generate code for the `predict` and `update` functions of the model by using a coder configurer.

Load the `carsmall` data set and train a support vector machine (SVM) regression model.

```
load carsmall
X = [Horsepower,Weight];
Y = MPG;
Mdl = fitrsvm(X,Y);
```

`Mdl` is a `RegressionSVM` object.

Create a coder configurer for the `RegressionSVM` model by using `learnerCoderConfigurer`. Specify the predictor data `X`. The `learnerCoderConfigurer` function uses the input `X` to configure the coder attributes of the `predict` function input.

```
configurer = learnerCoderConfigurer(Mdl,X)

configurer =
  RegressionSVMCoderConfigurer with properties:

  Update Inputs:
    Alpha: [1x1 LearnerCoderInput]
    SupportVectors: [1x1 LearnerCoderInput]
    Scale: [1x1 LearnerCoderInput]
    Bias: [1x1 LearnerCoderInput]

  Predict Inputs:
    X: [1x1 LearnerCoderInput]

  Code Generation Parameters:
    NumOutputs: 1
    OutputFileName: 'RegressionSVMModel'
```

Properties, Methods

`configurer` is a `RegressionSVMCoderConfigurer` object, which is a coder configurer of a `RegressionSVM` object.

To generate C/C++ code, you must have access to a C/C++ compiler that is configured properly. MATLAB Coder locates and uses a supported, installed compiler. You can use `mex -setup` to view and change the default compiler. For more details, see “Change Default Compiler” (MATLAB).

Generate code for the `predict` and `update` functions of the SVM regression model (`Mdl`) with default settings.

```
generateCode(configurer)
```

`generateCode` creates these files in output folder:
'initialize.m', 'predict.m', 'update.m', 'RegressionSVMModel.mat'

The `generateCode` function completes these actions:

- Generate the MATLAB files required to generate code, including the two entry-point functions `predict.m` and `update.m` for the `predict` and `update` functions of `Mdl`, respectively.
- Create a MEX function named `RegressionSVMModel` for the two entry-point functions.
- Create the code for the MEX function in the `codegen\mex\RegressionSVMModel` folder.
- Copy the MEX function to the current folder.

Display the contents of the `predict.m`, `update.m`, and `initialize.m` files by using the `type` function.

```
type predict.m
```

```
function varargout = predict(X,varargin) %#codegen
% Autogenerated by MATLAB, 03-Mar-2019 15:58:37
[varargout{1:nargout}] = initialize('predict',X,varargin{:});
end
```

```
type update.m
```

```
function update(varargin) %#codegen
% Autogenerated by MATLAB, 03-Mar-2019 15:58:37
initialize('update',varargin{:});
end
```

type `initialize.m`

```
function [varargout] = initialize(command,varargin) %#codegen
% Autogenerated by MATLAB, 03-Mar-2019 15:58:37
coder.inline('always');
persistent model;
if isempty(model)
    model = loadCompactModel('RegressionSVMModel.mat');
end
switch(command)
    case 'update'
        % Update struct fields: Alpha
        %                               SupportVectors
        %                               Scale
        %                               Bias

        model = update(model,varargin{:});
    case 'predict'
        % Predict Inputs: X

        X = varargin{1};
        if nargin == 2
            [varargout{1:nargout}] = predict(model,X);
        else
            PVPairs = cell(1,nargin-2);
            for i = 1:nargin-2
                PVPairs{1,i} = varargin{i+1};
            end
            [varargout{1:nargout}] = predict(model,X,PVPairs{:});
        end
end
end
end
```

Update Parameters of SVM Classification Model in Generated Code

Train a SVM model using a partial data set and create a coder configurer for the model. Use the properties of the coder configurer to specify coder attributes of the SVM model

parameters. Use the object function of the coder configurer to generate C code that predicts labels for new predictor data. Then retrain the model using the whole data set and update parameters in the generated code without regenerating the code.

Train Model

Load the `ionosphere` data set. This data set has 34 predictors and 351 binary responses for radar returns, either bad ('b') or good ('g'). Train a binary SVM classification model using the first 50 observations.

```
load ionosphere
Mdl = fitcsvm(X(1:50,:),Y(1:50));
```

`Mdl` is a `ClassificationSVM` object.

Create Coder Configurer

Create a coder configurer for the `ClassificationSVM` model by using `learnerCoderConfigurer`. Specify the predictor data `X`. The `learnerCoderConfigurer` function uses the input `X` to configure the coder attributes of the `predict` function input. Also, set the number of outputs to 2 so that the generated code returns predicted labels and scores.

```
configurer = learnerCoderConfigurer(Mdl,X(1:50:),'NumOutputs',2);
```

`configurer` is a `ClassificationSVMCoderConfigurer` object, which is a coder configurer of a `ClassificationSVM` object.

Specify Coder Attributes of Parameters

Specify the coder attributes of the SVM classification model parameters so that you can update the parameters in the generated code after retraining the model. This example specifies the coder attributes of predictor data that you want to pass to the generated code and the coder attributes of the support vectors of the SVM model.

First, specify the coder attributes of `X` so that the generated code accepts any number of observations. Modify the `SizeVector` and `VariableDimensions` attributes. The `SizeVector` attribute specifies the upper bound of the predictor data size, and the `VariableDimensions` attribute specifies whether each dimension of the predictor data has a variable size or fixed size.

```
configurer.X.SizeVector = [Inf 34];
configurer.X.VariableDimensions = [true false];
```

The size of the first dimension is the number of observations. In this case, the code specifies that the upper bound of the size is `Inf` and the size is variable, meaning that `X` can have any number of observations. This specification is convenient if you do not know the number of observations when generating code.

The size of the second dimension is the number of predictor variables. This value must be fixed for a machine learning model. `X` contains 34 predictors, so the value of the `SizeVector` attribute must be 34 and the value of the `VariableDimensions` attribute must be `false`.

If you retrain the SVM model using new data or different settings, the number of support vectors can vary. Therefore, specify the coder attributes of `SupportVectors` so that you can update the support vectors in the generated code.

```
configurer.SupportVectors.SizeVector = [250 34];
```

`SizeVector` attribute for `Alpha` has been modified to satisfy configuration constraints.
`SizeVector` attribute for `SupportVectorLabels` has been modified to satisfy configuration

```
configurer.SupportVectors.VariableDimensions = [true false];
```

`VariableDimensions` attribute for `Alpha` has been modified to satisfy configuration const
`VariableDimensions` attribute for `SupportVectorLabels` has been modified to satisfy conf

If you modify the coder attributes of `SupportVectors`, then the software modifies the coder attributes of `Alpha` and `SupportVectorLabels` to satisfy configuration constraints. If the modification of the coder attributes of one parameter requires subsequent changes to other dependent parameters to satisfy configuration constraints, then the software changes the coder attributes of the dependent parameters.

Generate Code

To generate C/C++ code, you must have access to a C/C++ compiler that is configured properly. MATLAB Coder locates and uses a supported, installed compiler. You can use `mex -setup` to view and change the default compiler. For more details, see “Change Default Compiler” (MATLAB).

Use `generateCode` to generate code for the `predict` and `update` functions of the SVM classification model (Mdl) with default settings.

```
generateCode(configurer)
```

`generateCode` creates these files in output folder:
'initialize.m', 'predict.m', 'update.m', 'ClassificationSVMModel.mat'

`generateCode` generates the MATLAB files required to generate code, including the two entry-point functions `predict.m` and `update.m` for the `predict` and `update` functions of `Mdl`, respectively. Then `generateCode` creates a MEX function named `ClassificationSVMModel` for the two entry-point functions in the `codegen\mex\ClassificationSVMModel` folder and copies the MEX function to the current folder.

Verify Generated Code

Pass some predictor data to verify whether the `predict` function of `Mdl` and the `predict` function in the MEX function return the same labels. To call an entry-point function in a MEX function that has more than one entry point, specify the function name as the first input argument.

```
[label,score] = predict(Mdl,X);
[label_mex,score_mex] = ClassificationSVMModel('predict',X);
```

Compare `label` and `label_mex` by using `isequal`.

```
isequal(label,label_mex)
```

```
ans = logical
     1
```

`isequal` returns logical 1 (true) if all the inputs are equal. The comparison confirms that the `predict` function of `Mdl` and the `predict` function in the MEX function return the same labels.

`score_mex` might include round-off differences compared with `score`. In this case, compare `score_mex` and `score`, allowing a small tolerance.

```
find(abs(score-score_mex) > 1e-8)
```

```
ans =
```

```
0x1 empty double column vector
```

The comparison confirms that `score` and `score_mex` are equal within the tolerance $1e-8$.

Retrain Model and Update Parameters in Generated Code

Retrain the model using the entire data set.

```
retrainedMdl = fitcsvm(X,Y);
```

Extract parameters to update by using `validatedUpdateInputs`. This function detects the modified model parameters in `retrainedMdl` and validates whether the modified parameter values satisfy the coder attributes of the parameters.

```
params = validatedUpdateInputs(configurer,retrainedMdl);
```

Update parameters in the generated code.

```
ClassificationSVMModel('update',params)
```

Verify Generated Code

Compare the outputs from the `predict` function of `retrainedMdl` and the `predict` function in the updated MEX function.

```
[label,score] = predict(retrainedMdl,X);  
[label_mex,score_mex] = ClassificationSVMModel('predict',X);  
isequal(label,label_mex)
```

```
ans = logical  
     1
```

```
find(abs(score-score_mex) > 1e-8)
```

```
ans =
```

```
     0x1 empty double column vector
```

The comparison confirms that `labels` and `labels_mex` are equal, and the score values are equal within the tolerance.

Input Arguments

Mdl — Machine learning model

full model object | compact model object

Machine learning model, specified as a full or compact model object, as given in this table of supported models.

Model	Full/Compact Model Object	Training Function
Support vector machine (SVM) regression	RegressionSVM, CompactRegressionSVM	fitrsvm
SVM for one-class and binary classification	ClassificationSVM, CompactClassificationSVM	fitcsvm
Multiclass model for SVMs	ClassificationECOC, CompactClassificationECOC	fitcecoc

For the code generation usage notes and limitations of a machine learning model, see the Code Generation section of the model object page.

X — Predictor data

numeric matrix

Predictor data for the `predict` function of `Mdl`, specified as an n -by- p numeric matrix, where n is the number of observations and p is the number of predictor variables.

The `predict` function of a machine learning model predicts labels for classification and responses for regression for given predictor data. After creating the coder configurer `configurer`, you can use the `generateCode` function to generate C/C++ code for the `predict` function of `Mdl`. The generated code accepts predictor data that has the same size and data type of `X`. You can specify whether each dimension has a variable size or fixed size after creating `configurer`.

For example, if you want to generate C/C++ code that predicts labels using 100 observations with three predictor variables, then specify `X` as `zeros(100,3)`. The `learnerCoderConfigurer` function uses only the size and data type of `X`, not its values. Therefore, `X` can be predictor data or a MATLAB expression that represents the set of values with a certain data type. The output `configurer` stores the size and data type of `X` in the `X` property of `configurer`. You can modify the size and data type of `X` after creating `configurer`. For example, change the number of observations to 200 and the data type to `single`.

```
configurer.X.SizeVector = [200 3];
configurer.X.DataType = 'single';
```

To allow the generated C/C++ code to accept predictor data with up to 100 observations, specify `X` as `zeros(100,3)` and change the `VariableDimensions` property.

```
configurer.X.VariableDimensions = [1 0];
```

[1 0] indicates that the first dimension of X (number of observations) has a variable size and the second dimension of X (number of predictor variables) has a fixed size. The specified number of observations, 100 in this example, becomes the maximum allowed number of observations in the generated C/C++ code. To allow any number of observations, specify the bound as `Inf`.

```
configurer.X.SizeVector = [Inf 3];
```

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `configurer = learnerCoderConfigurer(Mdl,X, 'NumOutputs',2, 'OutputFileName', 'myModel')` sets the number of outputs in `predict` to 2 and specifies the file name 'myModel' for the generated C/C++ code.

NumOutputs — Number of outputs in predict

1 (default) | positive integer

Number of output arguments in the `predict` function of the machine learning model `Mdl`, specified as the comma-separated pair consisting of 'NumOutputs' and a positive integer `n`.

This table lists the outputs for the `predict` function of different models. `predict` in the generated C/C++ code returns the first `n` outputs of the `predict` function in the order of given in the Outputs column.

Model	predict Function of Model	Outputs
SVM regression	<code>predict</code>	<code>yfit</code> (predicted responses)

Model	predict Function of Model	Outputs
SVM for one-class and binary classification	predict	label (predicted class labels), score (scores or posterior probabilities)
Multiclass model for SVMs	predict	label (predicted class labels), NegLoss (negated average binary losses), PBScore (positive-class scores)

For example, if you specify 'NumOutputs', 1 for an SVM classification model, then predict returns predicted class labels in the generated C/C++ code.

After creating the coder configurer configurer, you can modify the number of outputs by using dot notation.

```
configurer.NumOutputs = 2;
```

The 'NumOutputs' name-value pair argument is equivalent to the '-nargout' compiler option of codegen. This option specifies the number of output arguments in the entry-point function of code generation. The object function generateCode of a coder configurer generates two entry-point functions—predict.m and update.m for the predict and update functions of MdL, respectively—and generates C/C++ code for the two entry-point functions. The specified value for 'NumOutputs' corresponds to the number of output arguments in predict.m.

Example: 'NumOutputs', 2

Data Types: single | double

OutputFileName — File name of generated C/C++ code

MdL object name plus 'Model' (default) | character vector | string scalar

File name of the generated C/C++ code, specified as the comma-separated pair consisting of 'OutputFileName' and a character vector or string scalar.

The object function generateCode of a coder configurer generates C/C++ code using this file name.

The file name must not contain spaces because they can lead to code generation failures in certain operating system configurations. Also, the name must be a valid MATLAB function name.

The default file name is the object name of `Mdl` followed by `'Model'`. For example, if `Mdl` is a `CompactClassificationSVM` or `ClassificationSVM` object, then the default name is `'ClassificationSVMModel'`.

After creating the coder configurer `configurer`, you can modify the file name by using dot notation.

```
configurer.OutputFileName = 'myModel';
```

Example: `'OutputFileName', 'myModel'`

Data Types: `char` | `string`

Verbose — Verbosity level

`true` (logical 1) (default) | `false` (logical 0)

Verbosity level, specified as the comma-separated pair consisting of `'Verbose'` and either `true` (logical 1) or `false` (logical 0). The verbosity level controls the display of notification messages at the command line for the coder configurer `configurer`.

Value	Description
<code>true</code> (logical 1)	The software displays notification messages when your changes to the coder attributes of a parameter result in changes for other dependent parameters.
<code>false</code> (logical 0)	The software does not display notification messages.

To enable updating machine learning model parameters in the generated code, you need to configure the coder attributes of the parameters before generating code. The coder attributes of parameters are dependent on each other, so the software stores the dependencies as configuration constraints. If you modify the coder attributes of a parameter by using a coder configurer, and the modification requires subsequent changes to other dependent parameters to satisfy configuration constraints, then the software changes the coder attributes of the dependent parameters. The verbosity level determines whether or not the software displays notification messages for these subsequent changes.

After creating the coder configurer `configurer`, you can modify the verbosity level by using dot notation.

```
configurer.Verbose = false;
```

Example: `'Verbose', false`

Data Types: `logical`

Output Arguments

configurer — **Coder configurer**

coder configurer object

Coder configurer of a machine learning model, returned as one of the coder configurer objects in this table.

Model	Coder Configurer Object
Support vector machine (SVM) regression	RegressionSVMCoderConfigurer
SVM for one-class and binary classification	ClassificationSVMCoderConfigurer
Multiclass model for SVMs	ClassificationECOCCoderConfigurer

Use the object functions and properties of a coder configurer object to configure code generation options and to generate C/C++ code for the `predict` and `update` functions of the machine learning model.

“Code Generation for Prediction and Update Using Coder Configurer” on page 31-96

Introduced in R2018b

length

Class: dataset

Length of dataset array

Note The dataset data type might be removed in a future release. To work with heterogeneous data, use the MATLAB® table data type instead. See MATLAB table documentation for more information.

Syntax

`n = length(A)`

Description

`n = length(A)` returns the number of observations in the dataset A. `length` is equivalent to `size(A,1)`.

See Also

`size`

levelcounts

Element counts by level of a nominal or ordinal array

Note The `nominal` and `ordinal` array data types might be removed in a future release. To represent ordered and unordered discrete, nonnumeric data, use the “Categorical Arrays” (MATLAB) data type instead.

Syntax

```
C = levelcounts(A)
C = levelcounts(A,dim)
```

Description

`C = levelcounts(A)` returns counts of the number of elements in the nominal or ordinal array `A` equal to each possible level in `A`.

- If `A` is a vector, then `C` is a vector containing as many elements as the number of levels in `A`.
- If `A` is a matrix, then `C` is a matrix of column counts.
- If `A` is an N -dimensional array, then `levelcounts` operates along the first nonsingleton dimension.

`C = levelcounts(A,dim)` operates along the dimension `dim`.

Examples

Count Observations in Each Level

Create a nominal array from data in a cell array.

```
colors = nominal({'r','b','g';'g','r','b';'b','r','g'},...
                 {'blue','green','red'})
```

```
colors = 3x3 nominal array
  red      blue      green
  green    red       blue
  blue     red       green
```

Count the number of observations of each level in each column.

```
levelcounts(colors)
```

```
ans = 3x3
```

```
  1    1    1
  1    0    2
  1    2    0
```

Count the number of observations of each level in each row.

```
levelcounts(colors,2)
```

```
ans = 3x3
```

```
  1    1    1
  1    1    1
  1    1    1
```

Alternatively, you can use `summary` to display the counts with their labels. The default is to count elements in each column.

```
summary(colors)
```

```
  blue      1      1      1
  green     1      0      2
  red       1      2      0
```

You can also count elements in each row.

```
summary(colors,2)
```

```
  blue      green      red
  1         1         1
  1         1         1
  1         1         1
```

Input Arguments

A — Nominal or ordinal array

`nominal` array | `ordinal` array

Nominal or ordinal array, specified as a `nominal` or `ordinal` array object created with `nominal` or `ordinal`.

dim — Dimension along which to count

positive integer value

Dimension along which to count the number of elements in each level, specified as a positive integer value. For example, if the dimension is 1, then `levelcounts` counts along each column, while if the dimension is 2, then `levelcounts` counts along each row.

Data Types: `double` | `single`

See Also

`nominal` | `ordinal` | `summary`

Introduced in R2007a

leverage

Leverage

Syntax

```
h = leverage(data)
h = leverage(data, model)
```

Description

`h = leverage(data)` finds the leverage of each row (point) in the matrix `data` for a linear additive regression model.

`h = leverage(data, model)` finds the leverage on a regression, using a specified model type, where `model` can be one of the following:

- 'linear' - includes constant and linear terms
- 'interaction' - includes constant, linear, and cross product terms
- 'quadratic' - includes interactions and squared terms
- 'purequadratic' - includes constant, linear, and squared terms

Leverage is a measure of the influence of a given observation on a regression due to its location in the space of the inputs.

Examples

One rule of thumb is to compare the leverage to $2p/n$ where n is the number of observations and p is the number of parameters in the model. For the Hald data set this value is 0.7692.

```
load hald
h = max(leverage(ingredients, 'linear'))
h =
    0.7004
```

Since $0.7004 < 0.7692$, there are no high leverage points using this rule.

Algorithms

```
[Q,R] = qr(x2fx(data,'model'),0);
```

```
leverage = (sum(Q' .* Q'))'
```

lhsdesign

Latin hypercube sample

Syntax

```
X = lhsdesign(n,p)
X = lhsdesign(...,'smooth','off')
X = lhsdesign(...,'criterion',criterion)
X = lhsdesign(...,'iterations',k)
```

Description

`X = lhsdesign(n,p)` returns an n -by- p matrix, X , containing a latin hypercube sample of n values on each of p variables. For each column of X , the n values are randomly distributed with one from each interval $(0, 1/n)$, $(1/n, 2/n)$, ..., $(1-1/n, 1)$, and they are randomly permuted.

`X = lhsdesign(...,'smooth','off')` produces points at the midpoints of the above intervals: $0.5/n$, $1.5/n$, ..., $1-0.5/n$. The default is 'on'.

`X = lhsdesign(...,'criterion',criterion)` iteratively generates latin hypercube samples to find the best one according to *criterion*, which can be 'none', 'maximin', or 'correlation'.

Criterion	Description
'none'	No iteration.
'maximin'	Maximize minimum distance between points. This is the default.
'correlation'	Reduce correlation.

`X = lhsdesign(...,'iterations',k)` iterates up to k times in an attempt to improve the design according to the specified criterion. The default is $k = 5$.

haltonset | lhsnorm | sobolset | unifrnd

Introduced before R2006a

lhsnorm

Latin hypercube sample from normal distribution

Syntax

```
X = lhsnorm(mu, sigma, n)
X = lhsnorm(mu, sigma, n, flag)
[X, Z] = lhsnorm(...)
```

Description

`X = lhsnorm(mu, sigma, n)` returns an n -by- p matrix, X , containing a latin hypercube sample of size n from a p -dimensional multivariate normal distribution with mean vector, μ , and covariance matrix, σ .

X is similar to a random sample from the multivariate normal distribution, but the marginal distribution of each column is adjusted so that its sample marginal distribution is close to its theoretical normal distribution.

`X = lhsnorm(mu, sigma, n, flag)` controls the amount of smoothing in the sample. If *flag* is 'off', each column has points equally spaced on the probability scale. In other words, each column is a permutation of the values $G(0.5/n)$, $G(1.5/n)$, ..., $G(1-0.5/n)$, where G is the inverse normal cumulative distribution for that column's marginal distribution. If *flag* is 'on' (the default), each column has points uniformly distributed on the probability scale. For example, in place of $0.5/n$ you use a value having a uniform distribution on the interval $(0/n, 1/n)$.

`[X, Z] = lhsnorm(...)` also returns Z , the original multivariate normal sample before the marginals are adjusted to obtain X .

`lhsdesign` | `mvnrnd`

Introduced before R2006a

lillietest

Lilliefors test

Syntax

```
h = lillietest(x)
h = lillietest(x,Name,Value)
[h,p] = lillietest( ___ )
[h,p,kstat,critval] = lillietest( ___ )
```

Description

`h = lillietest(x)` returns a test decision for the null hypothesis that the data in vector `x` comes from a distribution in the normal family, against the alternative that it does not come from such a distribution, using a Lilliefors test. The result `h` is `1` if the test rejects the null hypothesis at the 5% significance level, and `0` otherwise.

`h = lillietest(x,Name,Value)` returns a test decision with additional options specified by one or more name-value pair arguments. For example, you can test the data against a different distribution family, change the significance level, or calculate the p -value using a Monte Carlo approximation.

`[h,p] = lillietest(___)` also returns the p -value `p`, using any of the input arguments from the previous syntaxes.

`[h,p,kstat,critval] = lillietest(___)` also returns the test statistic `kstat` and the critical value `critval` for the test.

Examples

Test for Normal Distribution

Load the sample data. Test the null hypothesis that car mileage, in miles per gallon (MPG), follows a normal distribution across different makes of cars.

```
load carbig
[h,p,k,c] = lillietest(MPG)
```

Warning: P is less than the smallest tabulated value, returning 0.001.

```
h = 1
```

```
p = 1.0000e-03
```

```
k = 0.0789
```

```
c = 0.0451
```

The test statistic k is greater than the critical value c , so `lillietest` returns a result of $h = 1$ to indicate rejection of the null hypothesis at the default 5% significance level. The warning indicates that the returned p -value is less the smallest value in the table of precomputed values. To find a more accurate p -value, use `MCTol` to run a Monte Carlo approximation. See “Determine the p -value Using Monte Carlo Approximation” on page 32-3732.

Test the Hypothesis at Different Significance Levels

Load the sample data. Create a vector containing the first column of the students’ exam grades data.

```
load examgrades
x = grades(:,1);
```

Test the null hypothesis that the sample data comes from a normal distribution at the 1% significance level.

```
[h,p] = lillietest(x, 'Alpha', 0.01)
```

```
h = 0
```

```
p = 0.0348
```

The returned value of $h = 0$ indicates that `lillietest` does not reject the null hypothesis at the 1% significance level.

Test for Exponential Distribution

Load the sample data. Test the null hypothesis that car mileage, in miles per gallon (MPG), follows an exponential distribution across different makes of cars.

```
load carbig
h = lillietest(MPG, 'Distribution', 'exponential')

h = 1
```

The returned value of `h = 1` indicates that `lillietest` rejects the null hypothesis at the default 5% significance level.

Test for Weibull Distribution

Generate two sample data sets, one from a Weibull distribution and another from a lognormal distribution. Perform the Lilliefors test to assess whether each data set is from a Weibull distribution. Confirm the test decision by performing a visual comparison using a Weibull probability plot (`wblplot`).

Generate samples from a Weibull distribution.

```
rng('default')
data1 = wblrnd(0.5, 2, [500, 1]);
```

Perform the Lilliefors test by using the `lillietest`. To test data for a Weibull distribution, test if the logarithm of the data has an extreme value distribution.

```
h1 = lillietest(log(data1), 'Distribution', 'extreme value')

h1 = 0
```

The returned value of `h1 = 0` indicates that `lillietest` fails to reject the null hypothesis at the default 5% significance level. Confirm the test decision using a Weibull probability plot.

```
wblplot(data1)
```

The plot indicates that the data follows a Weibull distribution.

Generate samples from a lognormal distribution.

```
data2 =lognrnd(5,2,[500,1]);
```

Perform the Lilliefors test.

```
h2 = lillietest(log(data2), 'Distribution', 'extreme value')
```

```
h2 = 1
```

The returned value of $h2 = 1$ indicates that `lillietest` rejects the null hypothesis at the default 5% significance level. Confirm the test decision using a Weibull probability plot.

```
wblplot(data2)
```

The plot indicates that the data does not follow a Weibull distribution.

Determine the p-value Using Monte Carlo Approximation

Load the sample data. Test the null hypothesis that car mileage, in miles per gallon (MPG), follows a normal distribution across different makes of cars. Determine the p -value using a Monte Carlo approximation with a maximum Monte Carlo standard error of $1e-4$.

```
load carbig
[h,p] = lillietest(MPG,'MCTol',1e-4)
```

```
h = 1
```

```
p = 8.3333e-06
```

The returned value of `h = 1` indicates that `lillietest` rejects the null hypothesis that the data comes from a normal distribution at the 5% significance level.

Input Arguments

x — Sample data

vector

Sample data, specified as a vector.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'Distribution', 'exponential', 'Alpha', 0.01` tests the null hypothesis that the population distribution belongs to the exponential distribution family at the 1% significance level.

Alpha — Significance level

`0.05` (default) | scalar value in the range (0,1)

Significance level of the hypothesis test, specified as the comma-separated pair consisting of `'Alpha'` and a scalar value in the range (0,1).

- If `MCTol` is not used, `Alpha` must be in the range [0.001,0.50].
- If `MCTol` is used, `Alpha` must be in the range (0,1).

Example: `'Alpha', 0.01`

Data Types: `single` | `double`

Distribution — Distribution family`'normal' (default) | 'exponential' | 'extreme value'`

Distribution family for the hypothesis test, specified as the comma-separated pair consisting of 'Distr' and one of the following.

```
'normal'    Normal distribution
'exponential' Exponential distribution
'l'
'extreme    Extreme value distribution
value'
```

- To test x for a lognormal distribution, test if $\log(x)$ has a normal distribution.
- To test x for a Weibull distribution, test if $\log(x)$ has an extreme value distribution.

Example: `'Distribution','exponential'`

MCTol — Maximum Monte Carlo standard error

scalar value in the range (0,1)

Maximum Monte Carlo standard error on page 32-3736 for p , the p -value of the test, specified as the comma-separated pair consisting of 'MCTol' and a scalar value in the range (0,1).

Example: `'MCTol',0.001`

Data Types: `single | double`

Output Arguments

h — Hypothesis test result`1 | 0`

Hypothesis test result, returned as 1 or 0.

- If $h = 1$, this indicates the rejection of the null hypothesis at the Alpha significance level.
- If $h = 0$, this indicates a failure to reject the null hypothesis at the Alpha significance level.

p — p-value

scalar value in the range (0,1)

p-value of the test, returned as a scalar value in the range (0,1). *p* is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. Small values of *p* cast doubt on the validity of the null hypothesis.

- If `MCTol` is not used, *p* is computed using inverse interpolation into the table of critical values, and is returned as a scalar value in the range [0.001,0.50]. `lillietest` warns when *p* is not found within the tabulated range and returns either the smallest or largest tabulated value.
- If `MCTol` is used, `lillietest` conducts a Monte Carlo simulation to compute a more accurate *p*-value, and *p* is returned as a scalar value in the range (0,1).

kstat — Test statistic

nonnegative scalar value

Test statistic, returned as a nonnegative scalar value.

critval — Critical value

nonnegative scalar value

Critical value for the hypothesis test, returned as a nonnegative scalar value.

Definitions

Lilliefors Test

The Lilliefors test is a two-sided goodness-of-fit test suitable when the parameters of the null distribution are unknown and must be estimated. This is in contrast to the one-sample Kolmogorov-Smirnov test, which requires the null distribution to be completely specified.

The Lilliefors test statistic is:

$$D^* = \max_x |\hat{F}(x) - G(x)|,$$

where $\hat{F}(x)$ is the empirical cdf of the sample data and $G(x)$ is the cdf of the hypothesized distribution with estimated parameters equal to the sample parameters.

`lillietest` can be used to test whether the data vector `x` has a lognormal or Weibull distribution by applying a transformation to the data vector and running the appropriate Lilliefors test:

- To test `x` for a lognormal distribution, test if $\log(x)$ has a normal distribution.
- To test `x` for a Weibull distribution, test if $\log(x)$ has an extreme value distribution.

The Lilliefors test cannot be used when the null hypothesis is not a location-scale family of distributions.

Monte Carlo Standard Error

The Monte Carlo standard error is the error due to simulating the p -value.

The Monte Carlo standard error is calculated as:

$$SE = \sqrt{\frac{(\hat{p})(1 - \hat{p})}{\text{mc reps}}},$$

where \hat{p} is the estimated p -value of the hypothesis test, and `mc reps` is the number of Monte Carlo replications performed.

The number of Monte Carlo replications, `mc reps`, is determined such that the Monte Carlo standard error for \hat{p} less than the value specified for `MCTol`.

Algorithms

To compute the critical value for the hypothesis test, `lillietest` interpolates into a table of critical values pre-computed using Monte Carlo simulation for sample sizes less than 1000 and significance levels between 0.001 and 0.50. The table used by `lillietest` is larger and more accurate than the table originally introduced by Lilliefors. If a more accurate p -value is desired, or if the desired significance level is less than 0.001 or greater than 0.50, the `MCTol` input argument can be used to run a Monte Carlo simulation to calculate the p -value more exactly.

When the computed value of the test statistic is greater than the critical value, `lillietest` rejects the null hypothesis at significance level `Alpha`.

`lillietest` treats NaN values in `x` as missing values and ignores them.

Introduced before R2006a

LinearModel

Linear regression model

Description

`LinearModel` is a fitted linear regression model object. A regression model describes the relationship between a response and predictors. The linearity in a linear regression model refers to the linearity of the predictor coefficients.

Use the properties of a `LinearModel` object to investigate a fitted linear regression model. The object properties include information about coefficient estimates, summary statistics, fitting method, and input data. Use the object functions to predict responses and to modify, evaluate, and visualize the linear regression model.

Creation

Create a `LinearModel` object by using `fitlm` or `stepwiselm`.

`fitlm` fits a linear regression model to data using a fixed model specification. Use `addTerms`, `removeTerms`, or `step` to add or remove terms from the model. Alternatively, use `stepwiselm` to fit a model using stepwise linear regression.

Properties

Coefficient Estimates

CoefficientCovariance — Covariance matrix of coefficient estimates

numeric matrix

This property is read-only.

Covariance matrix of coefficient estimates, specified as a p -by- p matrix of numeric values. p is the number of coefficients in the fitted model.

For details, see “Coefficient Standard Errors and Confidence Intervals” on page 11-73.

Data Types: `single` | `double`

CoefficientNames — Coefficient names

cell array of character vectors

This property is read-only.

Coefficient names, specified as a cell array of character vectors, each containing the name of the corresponding term.

Data Types: `cell`

Coefficients — Coefficient values

table

This property is read-only.

Coefficient values, specified as a table. `Coefficients` contains one row for each coefficient and these columns:

- `Estimate` — Estimated coefficient value
- `SE` — Standard error of the estimate
- `tStat` — t -statistic for a test that the coefficient is zero
- `pValue` — p -value for the t -statistic

Use `anova` (only for a linear regression model) or `coefTest` to perform other tests on the coefficients. Use `coefCI` to find the confidence intervals of the coefficient estimates.

To obtain any of these columns as a vector, index into the property using dot notation. For example, obtain the estimated coefficient vector in the model `mdl`:

```
beta = mdl.Coefficients.Estimate
```

Data Types: `table`

NumCoefficients — Number of model coefficients

positive integer

This property is read-only.

Number of model coefficients, specified as a positive integer. `NumCoefficients` includes coefficients that are set to zero when the model terms are rank deficient.

Data Types: `double`

NumEstimatedCoefficients — Number of estimated coefficients

positive integer

This property is read-only.

Number of estimated coefficients in the model, specified as a positive integer. `NumEstimatedCoefficients` does not include coefficients that are set to zero when the model terms are rank deficient. `NumEstimatedCoefficients` is the degrees of freedom for regression.

Data Types: `double`

Summary Statistics

DFE — Degrees of freedom for error

positive integer

This property is read-only.

Degrees of freedom for the error (residuals), equal to the number of observations minus the number of estimated coefficients, specified as a positive integer.

Data Types: `double`

Diagnostics — Observation diagnostics

table

This property is read-only.

Observation diagnostics, specified as a table that contains one row for each observation and the columns described in this table.

Column	Meaning	Description
Leverage	Diagonal elements of HatMatrix	Leverage for each observation indicates to what extent the fit is determined by the observed predictor values. A value close to 1 indicates that the fit is largely determined by that observation, with little contribution from the other observations. A value close to 0 indicates that the fit is largely determined by the other observations. For a model with P coefficients and N observations, the average value of Leverage is P/N. A Leverage value greater than 2*P/N indicates high leverage.
CooksDistance	Cook's distance	CooksDistance is a measure of scaled change in fitted values. An observation with CooksDistance greater than three times the mean Cook's distance can be an outlier.
Dffits	Delete-1 scaled differences in fitted values	Dffits is the scaled change in the fitted values for each observation that results from excluding that observation from the fit. Values greater than 2*sqrt(P/N) in absolute value can be considered influential.
S2_i	Delete-1 variance	S2_i is a set of residual variance estimates obtained by deleting each observation in turn. These estimates can be compared with the mean squared error (MSE) value, stored in the MSE property.
CovRatio	Delete-1 ratio of determinant of covariance	CovRatio is the ratio of the determinant of the coefficient covariance matrix, with each observation deleted in turn, to the determinant of the covariance matrix for the full model. Values greater than $1 + 3*P/N$ or less than $1 - 3*P/N$ indicate influential points.

Column	Meaning	Description
Dfbetas	Delete-1 scaled differences in coefficient estimates	Dfbetas is an N-by-P matrix of the scaled change in the coefficient estimates that results from excluding each observation in turn. Values greater than $3/\sqrt{N}$ in absolute value indicate that the observation has a significant influence on the corresponding coefficient.
HatMatrix	Projection matrix to compute fitted from observed responses	HatMatrix is an N-by-N matrix such that $\text{Fitted} = \text{HatMatrix} * Y$, where Y is the response vector and Fitted is the vector of fitted response values.

`Diagnostics` contains information that is helpful in finding outliers and influential observations. Delete-1 diagnostics capture the changes that result from excluding each observation in turn from the fit. For more details, see “Hat Matrix and Leverage” on page 11-99, “Cook’s Distance” on page 11-69, and “Delete-1 Statistics” on page 11-80.

Use `plotDiagnostics` to plot observation diagnostics.

Rows not used in the fit because of missing values (in `ObservationInfo.Missing`) or excluded values (in `ObservationInfo.Excluded`) contain NaN values in the `CooksDistance`, `Dffits`, `S2_i`, and `CovRatio` columns and zeros in the `Leverage`, `Dfbetas`, and `HatMatrix` columns.

To obtain any of these columns as an array, index into the property using dot notation. For example, obtain the delete-1 variance vector in the model `mdl`:

```
S2i = mdl.Diagnostics.S2_i;
```

Data Types: `table`

Fitted — Fitted response values based on input data

numeric vector

This property is read-only.

Fitted (predicted) response values based on input data, specified as an n -by-1 numeric vector. n is the number of observations in the input data. Use `predict` to compute predictions for other predictor values, or to compute confidence bounds on `Fitted`.

Data Types: `single` | `double`

LogLikelihood — Loglikelihood

numeric value

This property is read-only.

Loglikelihood of response values, specified as a numeric value, based on the assumption that each response value follows a normal distribution. The mean of the normal distribution is the fitted (predicted) response value, and the variance is the MSE.

Data Types: `single` | `double`

ModelCriterion — Criterion for model comparison

structure

This property is read-only.

Criterion for model comparison, specified as a structure with these fields:

- **AIC** — Akaike information criterion. $AIC = -2 \cdot \log L + 2 \cdot m$, where $\log L$ is the loglikelihood and m is the number of estimated parameters.
- **AICc** — Akaike information criterion corrected for the sample size. $AICc = AIC + (2 \cdot m \cdot (m + 1)) / (n - m - 1)$, where n is the number of observations.
- **BIC** — Bayesian information criterion. $BIC = -2 \cdot \log L + m \cdot \log(n)$.
- **CAIC** — Consistent Akaike information criterion. $CAIC = -2 \cdot \log L + m \cdot (\log(n) + 1)$.

Information criteria are model selection tools that you can use to compare multiple models fit to the same data. These criteria are likelihood-based measures of model fit that include a penalty for complexity (specifically, the number of parameters). Different information criteria are distinguished by the form of the penalty.

When you compare multiple models, the model with the lowest information criterion value is the best-fitting model. The best-fitting model can vary depending on the criterion used for model comparison.

To obtain any of the criterion values as a scalar, index into the property using dot notation. For example, obtain the AIC value `aic` in the model `mdl`:

```
aic = mdl.ModelCriterion.AIC
```

Data Types: `struct`

MSE — Mean squared error

numeric value

This property is read-only.

Mean squared error (residuals), specified as a numeric value.

$$MSE = SSE / DFE,$$

where *MSE* is the mean squared error, *SSE* is the sum of squared errors, and *DFE* is the degrees of freedom.

Data Types: `single` | `double`

Residuals — Residuals for fitted model

table

This property is read-only.

Residuals for the fitted model, specified as a table that contains one row for each observation and the columns described in this table.

Column	Description
Raw	Observed minus fitted values
Pearson	Raw residuals divided by the root mean squared error (RMSE)
Standardized	Raw residuals divided by their estimated standard deviation
Studentized	Raw residual divided by an independent estimate of the residual standard deviation. The residual for observation <i>i</i> is divided by an estimate of the error standard deviation based on all observations except observation <i>i</i> .

Use `plotResiduals` to create a plot of the residuals. For details, see “Residuals” on page 11-104.

Rows not used in the fit because of missing values (in `ObservationInfo.Missing`) or excluded values (in `ObservationInfo.Excluded`) contain NaN values.

To obtain any of these columns as a vector, index into the property using dot notation. For example, obtain the raw residual vector `r` in the model `mdl`:

```
r = mdl.Residuals.Raw
```

Data Types: `table`

RMSE — Root mean squared error

numeric value

This property is read-only.

Root mean squared error (residuals), specified as a numeric value.

$$RMSE = \sqrt{MSE},$$

where *RMSE* is the root mean squared error and *MSE* is the mean squared error.

Data Types: `single` | `double`

Rsquared — R-squared value for model

structure

This property is read-only.

R-squared value for the model, specified as a structure with two fields:

- **Ordinary** — Ordinary (unadjusted) R-squared
- **Adjusted** — R-squared adjusted for the number of coefficients

The R-squared value is the proportion of the total sum of squares explained by the model. The ordinary R-squared value relates to the *SSR* and *SST* properties:

$$Rsquared = SSR/SST = 1 - SSE/SST,$$

where *SST* is the total sum of squares, *SSE* is the sum of squared errors, and *SSR* is the regression sum of squares.

For details, see “Coefficient of Determination (R-Squared)” on page 11-77.

To obtain either of these values as a scalar, index into the property using dot notation. For example, obtain the adjusted R-squared value in the model `mdl`:

```
r2 = mdl.Rsquared.Adjusted
```

Data Types: `struct`

SSE — Sum of squared errors

numeric value

This property is read-only.

Sum of squared errors (residuals), specified as a numeric value.

The Pythagorean theorem implies

$$SST = SSE + SSR,$$

where SST is the total sum of squares, SSE is the sum of squared errors, and SSR is the regression sum of squares.

Data Types: `single` | `double`

SSR — Regression sum of squares

numeric value

This property is read-only.

Regression sum of squares, specified as a numeric value. The regression sum of squares is equal to the sum of squared deviations of the fitted values from their mean.

The Pythagorean theorem implies

$$SST = SSE + SSR,$$

where SST is the total sum of squares, SSE is the sum of squared errors, and SSR is the regression sum of squares.

Data Types: `single` | `double`

SST — Total sum of squares

numeric value

This property is read-only.

Total sum of squares, specified as a numeric value. The total sum of squares is equal to the sum of squared deviations of the response vector y from the mean (\bar{y}).

The Pythagorean theorem implies

$$SST = SSE + SSR,$$

where SST is the total sum of squares, SSE is the sum of squared errors, and SSR is the regression sum of squares.

Data Types: `single` | `double`

Fitting Method

Robust — Robust fit information

structure

This property is read-only.

Robust fit information, specified as a structure with the fields described in this table.

Field	Description
WgtFun	Robust weighting function, such as 'bisquare' (see 'RobustOpts')
Tune	Tuning constant. This field is empty ([]) if WgtFun is 'ols' or if WgtFun is a function handle for a custom weight function with the default tuning constant 1.
Weights	Vector of weights used in the final iteration of robust fit. This field is empty for a CompactLinearModel object.

This structure is empty unless you fit the model using robust regression.

Data Types: struct

Steps — Stepwise fitting information

structure

This property is read-only.

Stepwise fitting information, specified as a structure with the fields described in this table.

Field	Description
Start	Formula representing the starting model
Lower	Formula representing the lower bound model. The terms in Lower must remain in the model.
Upper	Formula representing the upper bound model. The model cannot contain more terms than Upper.
Criterion	Criterion used for the stepwise algorithm, such as 'sse'
PEnter	Threshold for Criterion to add a term
PRemove	Threshold for Criterion to remove a term
History	Table representing the steps taken in the fit

The History table contains one row for each step, including the initial fit, and the columns described in this table.

Column	Description
Action	Action taken during the step: <ul style="list-style-type: none"> 'Start' — First step 'Add' — A term is added 'Remove' — A term is removed
TermName	<ul style="list-style-type: none"> If Action is 'Start', TermName specifies the starting model specification. If Action is 'Add' or 'Remove', TermName specifies the term added or removed in the step.
Terms	Model specification in a “Terms Matrix” on page 32-3762
DF	Regression degrees of freedom after the step
delDF	Change in regression degrees of freedom from the previous step (negative for steps that remove a term)
Deviance	Deviance (residual sum of squares) at the step (only for a generalized linear regression model)
FStat	<i>F</i> -statistic that leads to the step
PValue	<i>p</i> -value of the <i>F</i> -statistic

The structure is empty unless you fit the model using stepwise regression.

Data Types: struct

Input Data

Formula — Model information

LinearFormula object

This property is read-only.

Model information, specified as a LinearFormula object.

Display the formula of the fitted model mdl using dot notation:

```
mdl.Formula
```

NumObservations — Number of observations

positive integer

This property is read-only.

Number of observations the fitting function used in fitting, specified as a positive integer. `NumObservations` is the number of observations supplied in the original table, dataset, or matrix, minus any excluded rows (set with the 'Exclude' name-value pair argument) or rows with missing values.

Data Types: double

NumPredictors — Number of predictor variables

positive integer

This property is read-only.

Number of predictor variables used to fit the model, specified as a positive integer.

Data Types: double

NumVariables — Number of variables

positive integer

This property is read-only.

Number of variables in the input data, specified as a positive integer. `NumVariables` is the number of variables in the original table or dataset, or the total number of columns in the predictor matrix and response vector.

`NumVariables` also includes any variables that are not used to fit the model as predictors or as the response.

Data Types: double

ObservationInfo — Observation information

table

This property is read-only.

Observation information, specified as an n -by-4 table, where n is equal to the number of rows of input data. The `ObservationInfo` contains the columns described in this table.

Column	Description
Weights	Observation weight, specified as a numeric value. The default value is 1.

Column	Description
Excluded	Indicator of excluded observation, specified as a logical value. The value is <code>true</code> if you exclude the observation from the fit by using the 'Exclude' name-value pair argument.
Missing	Indicator of missing observation, specified as a logical value. The value is <code>true</code> if the observation is missing.
Subset	Indicator of whether or not a fitting function uses the observation, specified as a logical value. The value is <code>true</code> if the observation is not excluded or missing, meaning that fitting function uses the observation.

To obtain any of these columns as a vector, index into the property using dot notation. For example, obtain the weight vector `w` of the model `mdl`:

```
w = mdl.ObservationInfo.Weights
```

Data Types: `table`

ObservationNames — Observation names

cell array of character vectors

This property is read-only.

Observation names, specified as a cell array of character vectors containing the names of the observations used in the fit.

- If the fit is based on a table or dataset containing observation names, `ObservationNames` uses those names.
- Otherwise, `ObservationNames` is an empty cell array.

Data Types: `cell`

PredictorNames — Names of predictors used to fit model

cell array of character vectors

This property is read-only.

Names of predictors used to fit the model, specified as a cell array of character vectors.

Data Types: `cell`

ResponseName — Response variable name

character vector

This property is read-only.

Response variable name, specified as a character vector.

Data Types: char

VariableInfo — Information about variables

table

This property is read-only.

Information about variables contained in `Variables`, specified as a table with one row for each variable and the columns described in this table.

Column	Description
Class	Variable class, specified as a cell array of character vectors, such as 'double' and 'categorical'
Range	Variable range, specified as a cell array of vectors <ul style="list-style-type: none"> • Continuous variable — Two-element vector [<i>min</i>, <i>max</i>], the minimum and maximum values • Categorical variable — Vector of distinct variable values
InModel	Indicator of which variables are in the fitted model, specified as a logical vector. The value is <code>true</code> if the model includes the variable.
IsCategorical	Indicator of categorical variables, specified as a logical vector. The value is <code>true</code> if the variable is categorical.

`VariableInfo` also includes any variables that are not used to fit the model as predictors or as the response.

Data Types: table

VariableNames — Names of variables

cell array of character vectors

This property is read-only.

Names of variables, specified as a cell array of character vectors.

- If the fit is based on a table or dataset, this property provides the names of the variables in the table or dataset.
- If the fit is based on a predictor matrix and response vector, `VariableNames` contains the values specified by the 'VarNames' name-value pair argument of the fitting method. The default value of 'VarNames' is {'x1', 'x2', ..., 'xn', 'y'}.

`VariableNames` also includes any variables that are not used to fit the model as predictors or as the response.

Data Types: `cell`

Variables — Input data

`table`

This property is read-only.

Input data, specified as a table. `Variables` contains both predictor and response values. If the fit is based on a table or dataset array, `Variables` contains all the data from the table or dataset array. Otherwise, `Variables` is a table created from the input data matrix X and response the vector y .

`Variables` also includes any variables that are not used to fit the model as predictors or as the response.

Data Types: `table`

Object Functions

Create `CompactLinearModel`

`compact` Compact linear regression model

Add or Remove Terms from Linear Model

`addTerms` Add terms to linear regression model

`removeTerms` Remove terms from linear regression model

`step` Improve linear regression model by adding or removing terms

Predict Responses

<code>feval</code>	Predict responses of linear regression model using one input for each predictor
<code>predict</code>	Predict responses of linear regression model
<code>random</code>	Simulate responses with random noise for linear regression model

Evaluate Linear Model

<code>anova</code>	Analysis of variance for linear regression model
<code>coefCI</code>	Confidence intervals of coefficient estimates of linear regression model
<code>coefTest</code>	Linear hypothesis test on linear regression model coefficients
<code>dwtest</code>	Durbin-Watson test with linear regression model object

Visualize Linear Model and Summary Statistics

<code>plot</code>	Scatter plot or added variable plot of linear regression model
<code>plotAdded</code>	Added variable plot of linear regression model
<code>plotAdjustedResponse</code>	Adjusted response plot of linear regression model
<code>plotDiagnostics</code>	Plot observation diagnostics of linear regression model
<code>plotEffects</code>	Plot main effects of predictors in linear regression model
<code>plotInteraction</code>	Plot interaction effects of two predictors in linear regression model
<code>plotPartialDependence</code>	Create partial dependence plot (PDP) and individual conditional expectation (ICE) plots
<code>plotResiduals</code>	Plot residuals of linear regression model
<code>plotSlice</code>	Plot of slices through fitted linear regression surface

Examples

Fit Linear Regression Using Data in Matrix

Fit a linear regression model using a matrix input data set.

Load the `carsmall` data set, a matrix input data set.

```
load carsmall
X = [Weight,Horsepower,Acceleration];
```

Fit a linear regression model by using `fitlm`.

```
mdl = fitlm(X,MPG)
```

```
mdl =
Linear regression model:
  y ~ 1 + x1 + x2 + x3

Estimated Coefficients:

```

	Estimate	SE	tStat	pValue
(Intercept)	47.977	3.8785	12.37	4.8957e-21
x1	-0.0065416	0.0011274	-5.8023	9.8742e-08
x2	-0.042943	0.024313	-1.7663	0.08078
x3	-0.011583	0.19333	-0.059913	0.95236

```
Number of observations: 93, Error degrees of freedom: 89
Root Mean Squared Error: 4.09
R-squared: 0.752, Adjusted R-Squared: 0.744
F-statistic vs. constant model: 90, p-value = 7.38e-27
```

The model display includes the model formula, estimated coefficients, and model summary statistics.

The model formula in the display, $y \sim 1 + x1 + x2 + x3$, corresponds to $y = \beta_0 + \beta_1 X_1 + \beta_2 X_2 + \beta_3 X_3 + e$.

The model display also shows the estimated coefficient information, which is stored in the `Coefficients` property. Display the `Coefficients` property.

```
mdl.Coefficients
ans=4x4 table
```

	Estimate	SE	tStat	pValue
(Intercept)	47.977	3.8785	12.37	4.8957e-21
x1	-0.0065416	0.0011274	-5.8023	9.8742e-08
x2	-0.042943	0.024313	-1.7663	0.08078
x3	-0.011583	0.19333	-0.059913	0.95236

The `Coefficient` property includes these columns:

- **Estimate** — Coefficient estimates for each corresponding term in the model. For example, the estimate for the constant term (`intercept`) is 47.977.

- **SE** — Standard error of the coefficients.
- **tStat** — t -statistic for each coefficient to test the null hypothesis that the corresponding coefficient is zero against the alternative that it is different from zero, given the other predictors in the model. Note that $tStat = Estimate/SE$. For example, the t -statistic for the intercept is $47.977/3.8785 = 12.37$.
- **pValue** — p -value for the t -statistic of the hypothesis test that the corresponding coefficient is equal to zero or not. For example, the p -value of the t -statistic for x_2 is greater than 0.05, so this term is not significant at the 5% significance level given the other terms in the model.

The summary statistics of the model are:

- **Number of observations** — Number of rows without any NaN values. For example, **Number of observations** is 93 because the **MPG** data vector has six NaN values and the **Horsepower** data vector has one NaN value for a different observation, where the number of rows in **X** and **MPG** is 100.
- **Error degrees of freedom** — $n - p$, where n is the number of observations, and p is the number of coefficients in the model, including the intercept. For example, the model has four predictors, so the **Error degrees of freedom** is $93 - 4 = 89$.
- **Root mean squared error** — Square root of the mean squared error, which estimates the standard deviation of the error distribution.
- **R-squared and Adjusted R-squared** — Coefficient of determination and adjusted coefficient of determination, respectively. For example, the **R-squared** value suggests that the model explains approximately 75% of the variability in the response variable **MPG**.
- **F-statistic vs. constant model** — Test statistic for the F -test on the regression model, which tests whether the model fits significantly better than a degenerate model consisting of only a constant term.
- **p-value** — p -value for the F -test on the model. For example, the model is significant with a p -value of $7.3816e-27$.

You can find these statistics in the model properties (**NumObservations**, **DFE**, **RMSE**, and **Rsquared**) and by using the `anova` function.

```
anova mdl, 'summary'
```

```
ans=3x5 table
```

SumSq	DF	MeanSq	F	pValue
-------	----	--------	---	--------

Total	6004.8	92	65.269		
Model	4516	3	1505.3	89.987	7.3816e-27
Residual	1488.8	89	16.728		

Linear Regression with Categorical Predictor

Fit a linear regression model that contains a categorical predictor. Reorder the categories of the categorical predictor to control the reference level in the model. Then, use `anova` to test the significance of the categorical variable.

Model with Categorical Predictor

Load the `carsmall` data set and create a linear regression model of MPG as a function of `Model_Year`. To treat the numeric vector `Model_Year` as a categorical variable, identify the predictor using the `'CategoricalVars'` name-value pair argument.

```
load carsmall
mdl = fitlm(Model_Year,MPG,'CategoricalVars',1,'VarNames',{'Model_Year','MPG'})
```

```
mdl =
Linear regression model:
MPG ~ 1 + Model_Year
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	17.69	1.0328	17.127	3.2371e-30
Model_Year_76	3.8839	1.4059	2.7625	0.0069402
Model_Year_82	14.02	1.4369	9.7571	8.2164e-16

```
Number of observations: 94, Error degrees of freedom: 91
Root Mean Squared Error: 5.56
R-squared: 0.531, Adjusted R-Squared: 0.521
F-statistic vs. constant model: 51.6, p-value = 1.07e-15
```

The model formula in the display, `MPG ~ 1 + Model_Year`, corresponds to

$$\text{MPG} = \beta_0 + \beta_1 I_{\text{Year} = 76} + \beta_2 I_{\text{Year} = 82} + \epsilon,$$

where $I_{\text{Year} = 76}$ and $I_{\text{Year} = 82}$ are indicator variables whose value is one if the value of `Model_Year` is 76 and 82, respectively. The `Model_Year` variable includes three distinct values, which you can check by using the `unique` function.

```
unique(Model_Year)
```

```
ans = 3×1
```

```
70
76
82
```

`fitlm` chooses the smallest value in `Model_Year` as a reference level ('70') and creates two indicator variables $I_{\text{Year} = 76}$ and $I_{\text{Year} = 82}$. The model includes only two indicator variables because the design matrix becomes rank deficient if the model includes three indicator variables (one for each level) and an intercept term.

Model with Full Indicator Variables

You can interpret the model formula of `mdl` as a model that has three indicator variables without an intercept term:

$$y = \beta_0 I_{x_1 = 70} + (\beta_0 + \beta_1) I_{x_1 = 76} + (\beta_0 + \beta_2) I_{x_2 = 82} + \epsilon.$$

Alternatively, you can create a model that has three indicator variables without an intercept term by manually creating indicator variables and specifying the model formula.

```
temp_Year = dummyvar(categorical(Model_Year));
Model_Year_70 = temp_Year(:,1);
Model_Year_76 = temp_Year(:,2);
Model_Year_82 = temp_Year(:,3);
tbl = table(Model_Year_70,Model_Year_76,Model_Year_82,MPG);
mdl = fitlm(tbl, 'MPG ~ Model_Year_70 + Model_Year_76 + Model_Year_82 - 1')
```

```
mdl =
```

```
Linear regression model:
```

```
MPG ~ Model_Year_70 + Model_Year_76 + Model_Year_82
```

```
Estimated Coefficients:
```

	Estimate	SE	tStat	pValue
Model_Year_70	17.69	1.0328	17.127	3.2371e-30

```
Model_Year_76    21.574    0.95387    22.617    4.0156e-39
Model_Year_82    31.71     0.99896    31.743    5.2234e-51
```

```
Number of observations: 94, Error degrees of freedom: 91
Root Mean Squared Error: 5.56
```

Choose Reference Level in Model

You can choose a reference level by modifying the order of categories in a categorical variable. First, create a categorical variable `Year`.

```
Year = categorical(Model_Year);
```

Check the order of categories by using the `categories` function.

```
categories(Year)

ans = 3x1 cell array
    {'70'}
    {'76'}
    {'82'}
```

If you use `Year` as a predictor variable, then `fitlm` chooses the first category `'70'` as a reference level. Reorder `Year` by using the `reordercats` function.

```
Year_reordered = reordercats(Year,{'76','70','82'});
categories(Year_reordered)
```

```
ans = 3x1 cell array
    {'76'}
    {'70'}
    {'82'}
```

The first category of `Year_reordered` is `'76'`. Create a linear regression model of `MPG` as a function of `Year_reordered`.

```
mdl2 = fitlm(Year_reordered,MPG,'VarNames',{'Model_Year','MPG'})
```

```
mdl2 =
Linear regression model:
    MPG ~ 1 + Model_Year
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	21.574	0.95387	22.617	4.0156e-39
Model_Year_70	-3.8839	1.4059	-2.7625	0.0069402
Model_Year_82	10.136	1.3812	7.3385	8.7634e-11

Number of observations: 94, Error degrees of freedom: 91

Root Mean Squared Error: 5.56

R-squared: 0.531, Adjusted R-Squared: 0.521

F-statistic vs. constant model: 51.6, p-value = 1.07e-15

mdl2 uses '76' as a reference level and includes two indicator variables $I_{\text{Year} = 70}$ and $I_{\text{Year} = 82}$.

Evaluate Categorical Predictor

The model display of mdl2 includes a p -value of each term to test whether or not the corresponding coefficient is equal to zero. Each p -value examines each indicator variable. To examine the categorical variable Model_Year as a group of indicator variables, use `anova`. Specify 'components' to return a component ANOVA table that includes ANOVA statistics for each variable in the model except the constant term.

```
anova(mdl2, 'components')
```

ans=2x5 table

	SumSq	DF	MeanSq	F	pValue
Model_Year	3190.1	2	1595.1	51.56	1.0694e-15
Error	2815.2	91	30.936		

The component ANOVA table includes the p -value of the Model_Year variable, which is smaller than the p -values of the indicator variables.

Fit Robust Linear Regression Model

Load the `hald` data set, which measures the effect of cement composition on its hardening heat.

```
load hald
```

This data set includes the variables `ingredients` and `heat`. The matrix `ingredients` contains the percent composition of four chemicals present in the cement. The vector `heat` contains the values for the heat hardening after 180 days for each cement sample.

Fit a robust linear regression model to the data.

```
mdl = fitlm(ingredients,heat,'RobustOpts','on')
```

```
mdl =  
Linear regression model (robust fit):  
y ~ 1 + x1 + x2 + x3 + x4
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	60.09	75.818	0.79256	0.4509
x1	1.5753	0.80585	1.9548	0.086346
x2	0.5322	0.78315	0.67957	0.51596
x3	0.13346	0.8166	0.16343	0.87424
x4	-0.12052	0.7672	-0.15709	0.87906

```
Number of observations: 13, Error degrees of freedom: 8  
Root Mean Squared Error: 2.65  
R-squared: 0.979, Adjusted R-Squared: 0.969  
F-statistic vs. constant model: 94.6, p-value = 9.03e-07
```

For more details, see the topic “Robust Regression — Reduce Outlier Effects” on page 11-132, which compares the results of a robust fit to a standard least-squares fit.

Fit Linear Model Using Stepwise Regression

Load the `hald` data set, which measures the effect of cement composition on its hardening heat.

```
load hald
```

This data set includes the variables `ingredients` and `heat`. The matrix `ingredients` contains the percent composition of four chemicals present in the cement. The vector `heat` contains the values for the heat hardening after 180 days for each cement sample.

Fit a stepwise linear regression model to the data. Specify 0.06 as the threshold for the criterion to add a term to the model.

```
mdl = stepwiselm(ingredients,heat,'PEnter',0.06)
```

1. Adding x4, FStat = 22.7985, pValue = 0.000576232
2. Adding x1, FStat = 108.2239, pValue = 1.105281e-06
3. Adding x2, FStat = 5.0259, pValue = 0.051687
4. Removing x4, FStat = 1.8633, pValue = 0.2054

```
mdl =  
Linear regression model:  
y ~ 1 + x1 + x2
```

Estimated Coefficients:

	Estimate	SE	tStat	pValue
(Intercept)	52.577	2.2862	22.998	5.4566e-10
x1	1.4683	0.1213	12.105	2.6922e-07
x2	0.66225	0.045855	14.442	5.029e-08

```
Number of observations: 13, Error degrees of freedom: 10  
Root Mean Squared Error: 2.41  
R-squared: 0.979, Adjusted R-Squared: 0.974  
F-statistic vs. constant model: 230, p-value = 4.41e-09
```

By default, the starting model is a constant model. `stepwiselm` performs forward selection and adds the `x4`, `x1`, and `x2` terms (in that order), because the corresponding p -values are less than the `PEnter` value of 0.06. `stepwiselm` then uses backward elimination and removes `x4` from the model because, once `x2` is in the model, the p -value of `x4` is greater than the default value of `PRemove`, 0.1.

Definitions

Terms Matrix

A terms matrix T is a t -by- $(p + 1)$ matrix specifying terms in a model, where t is the number of terms, p is the number of predictor variables, and $+1$ accounts for the response variable. The value of $T(i, j)$ is the exponent of variable j in term i .

For example, suppose that an input includes three predictor variables A , B , and C and the response variable Y in the order A , B , C , and Y . Each row of T represents one term:

- $[0 \ 0 \ 0 \ 0]$ — Constant term or intercept
- $[0 \ 1 \ 0 \ 0]$ — B ; equivalently, $A^0 * B^1 * C^0$
- $[1 \ 0 \ 1 \ 0]$ — $A * C$
- $[2 \ 0 \ 0 \ 0]$ — A^2
- $[0 \ 1 \ 2 \ 0]$ — $B * (C^2)$

The 0 at the end of each term represents the response variable. In general, a column vector of zeros in a terms matrix represents the position of the response variable. If you have the predictor and response variables in a matrix and column vector, then you must include 0 for the response variable in the last column of each row.

Alternative Functionality

- For reduced computation time on high-dimensional data sets, fit a linear regression model using the `fitrlinear` function.
- To regularize a regression, use `fitrlinear`, `lasso`, `ridge`, or `plsregress`.
 - `fitrlinear` regularizes a regression for high-dimensional data sets using lasso or ridge regression.
 - `lasso` removes redundant predictors in linear regression using lasso or elastic net.
 - `ridge` regularizes a regression with correlated terms using ridge regression.
 - `plsregress` regularizes a regression with correlated terms using partial least squares.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The `predict` and `random` functions support code generation.
- When you fit a model by using `fitlm` or `stepwiselm`, you cannot supply training data in a table that contains a logical vector, character array, categorical array, string array, or cell array of character vectors. Also, you cannot use the `'CategoricalVars'` name-value pair argument. Code generation does not support categorical predictors. To include categorical predictors in a model, preprocess the categorical predictors by using `dummyvar` before fitting the model.

For more information, see “Introduction to Code Generation” on page 31-2.

“What Is a Linear Regression Model?” on page 11-8

Introduced in R2012a

LinearMixedModel class

Linear mixed-effects model class

Description

A `LinearMixedModel` object represents a model of a response variable with fixed and random effects. It comprises data, a model description, fitted coefficients, covariance parameters, design matrices, residuals, residual plots, and other diagnostic information for a linear mixed-effects model. You can predict model responses with the `predict` function and generate random data at new design points using the `random` function.

Construction

You can fit a linear mixed-effects model using `fitlme(tbl, formula)` if your data is in a table or dataset array. Alternatively, if your model is not easily described using a formula, you can create matrices to define the fixed and random effects, and fit the model using `fitlmematrix(X, y, Z, G)`.

Input Arguments

tbl — Input data

table | dataset array

Input data, which includes the response variable, predictor variables, and grouping variables, specified as a table or dataset array. The predictor variables can be continuous or grouping variables (see “Grouping Variables” on page 2-57). You must specify the model for the variables using `formula`.

Data Types: table

formula — Formula for model specification

character vector or string scalar of the form 'y ~ fixed + (random1|grouping1) + ... + (randomR|groupingR)'

Formula for model specification, specified as a character vector or string scalar of the form `'y ~ fixed + (random1|grouping1) + ... + (randomR|groupingR)'`. For a full description, see “Formula” on page 32-3781.

Example: `'y ~ treatment +(1|block)'`

X — Fixed-effects design matrix

n-by-*p* matrix

Fixed-effects design matrix, specified as an *n*-by-*p* matrix, where *n* is the number of observations, and *p* is the number of fixed-effects predictor variables. Each row of *X* corresponds to one observation, and each column of *X* corresponds to one variable.

Data Types: `single` | `double`

y — Response values

n-by-1 vector

Response values, specified as an *n*-by-1 vector, where *n* is the number of observations.

Data Types: `single` | `double`

Z — Random-effects design

n-by-*q* matrix | cell array of *R* *n*-by-*q*(*r*) matrices, *r* = 1, 2, ..., *R*

Random-effects design, specified as either of the following.

- If there is one random-effects term in the model, then *Z* must be an *n*-by-*q* matrix, where *n* is the number of observations and *q* is the number of variables in the random-effects term.
- If there are *R* random-effects terms, then *Z* must be a cell array of length *R*. Each cell of *Z* contains an *n*-by-*q*(*r*) design matrix *Z*{*r*}, *r* = 1, 2, ..., *R*, corresponding to each random-effects term. Here, *q*(*r*) is the number of random effects term in the *r*th random effects design matrix, *Z*{*r*}.

Data Types: `single` | `double` | `cell`

G — Grouping variable or variables

n-by-1 vector | cell array of *R* *n*-by-1 vectors

Grouping variable or variables on page 2-57, specified as either of the following.

- If there is one random-effects term, then *G* must be an *n*-by-1 vector corresponding to a single grouping variable with *M* levels or groups.

G can be a categorical vector, logical vector, numeric vector, character array, string array, or cell array of character vectors.

- If there are multiple random-effects terms, then G must be a cell array of length R. Each cell of G contains a grouping variable $G\{r\}$, $r = 1, 2, \dots, R$, with $M(r)$ levels.

$G\{r\}$ can be a categorical vector, logical vector, numeric vector, character array, string array, or cell array of character vectors.

Data Types: `categorical` | `logical` | `single` | `double` | `char` | `string` | `cell`

Properties

Coefficients — Fixed-effects coefficient estimates

dataset array

Fixed-effects coefficient estimates and related statistics, stored as a dataset array containing the following fields.

Name	Name of the term.
Estimate	Estimated value of the coefficient.
SE	Standard error of the coefficient.
tStat	<i>t</i> -statistics for testing the null hypothesis that the coefficient is equal to zero.
DF	Degrees of freedom for the <i>t</i> -test. Method to compute DF is specified by the 'DFMethod' name-value pair argument. <code>Coefficients</code> always uses the 'Residual' method for 'DFMethod'.
pValue	<i>p</i> -value for the <i>t</i> -test.
Lower	Lower limit of the confidence interval for coefficient. <code>Coefficients</code> always uses the 95% confidence level, i.e. 'alpha' is 0.05.
Upper	Upper limit of confidence interval for coefficient. <code>Coefficients</code> always uses the 95% confidence level, i.e. 'alpha' is 0.05.

You can change 'DFMethod' and 'alpha' while computing confidence intervals for or testing hypotheses involving fixed- and random-effects, using the `coefCI` and `coefTest` methods.

CoefficientCovariance — Covariance of the estimated fixed-effects coefficients

p-by-*p* matrix

Covariance of the estimated fixed-effects coefficients of the linear mixed-effects model, stored as a *p*-by-*p* matrix, where *p* is the number of fixed-effects coefficients.

You can display the covariance parameters associated with the random effects using the `covarianceParameters` method.

Data Types: `double`

CoefficientNames — Names of the fixed-effects coefficients

1-by-*p* cell array of character vectors

Names of the fixed-effects coefficients of a linear mixed-effects model, stored as a 1-by-*p* cell array of character vectors.

Data Types: `cell`

DFE — Residual degrees of freedom

positive integer value

Residual degrees of freedom, stored as a positive integer value. $DFE = n - p$, where *n* is the number of observations, and *p* is the number of fixed-effects coefficients.

This corresponds to the 'Residual' method of calculating degrees of freedom in the `fixedEffects` and `randomEffects` methods.

Data Types: `double`

FitMethod — Method used to fit the linear mixed-effects model

ML | REML

Method used to fit the linear mixed-effects model, stored as either of the following.

- ML, if the fitting method is maximum likelihood
- REML, if the fitting method is restricted maximum likelihood

Data Types: `char`

Formula — Specification of the fixed- and random-effects terms, and grouping variables

object

Specification of the fixed-effects terms, random-effects terms, and grouping variables that define the linear mixed-effects model, stored as an object.

For more information on how to specify the model to fit using a formula, see “Formula” on page 32-3781.

LogLikelihood — Maximized log or restricted log likelihood

scalar value

Maximized log likelihood or maximized restricted log likelihood of the fitted linear mixed-effects model depending on the fitting method you choose, stored as a scalar value.

Data Types: double

ModelCriterion — Model criterion

dataset array

Model criterion to compare fitted linear mixed-effects models, stored as a dataset array with the following columns.

AIC	Akaike Information Criterion
BIC	Bayesian Information Criterion
Loglikelihood	Log likelihood value of the model
Deviance	-2 times the log likelihood of the model

If n is the number of observations used in fitting the model, and p is the number of fixed-effects coefficients, then for calculating AIC and BIC,

- The total number of parameters is $nc + p + 1$, where nc is the total number of parameters in the random-effects covariance excluding the residual variance
- The effective number of observations is
 - n , when the fitting method is maximum likelihood (ML)
 - $n - p$, when the fitting method is restricted maximum likelihood (REML)

MSE — ML or REML estimate

positive scalar value

ML or REML estimate, based on the fitting method used for estimating σ^2 , stored as a positive scalar value. σ^2 is the residual variance or variance of the observation error term of the linear mixed-effects model.

Data Types: double

NumCoefficients — Number of fixed-effects coefficients

positive integer value

Number of fixed-effects coefficients in the fitted linear mixed-effects model, stored as a positive integer value.

Data Types: double

NumEstimatedCoefficients — Number of estimated fixed-effects coefficients

positive integer value

Number of estimated fixed-effects coefficients in the fitted linear mixed-effects model, stored as a positive integer value.

Data Types: double

NumObservations — Number of observations

positive integer value

Number of observations used in the fit, stored as a positive integer value. This is the number of rows in the table or dataset array, or the design matrices minus the excluded rows or rows with NaN values.

Data Types: double

NumPredictors — Number of predictors

positive integer value

Number of variables used as predictors in the linear mixed-effects model, stored as a positive integer value.

Data Types: double

NumVariables — Total number of variables

positive integer value

Total number of variables including the response and predictors, stored as a positive integer value.

- If the sample data is in a table or dataset array `tbl`, `NumVariables` is the total number of variables in `tbl` including the response variable.
- If the fit is based on matrix input, `NumVariables` is the total number of columns in the predictor matrix or matrices, and response vector.

`NumVariables` includes variables, if there are any, that are not used as predictors or as the response.

Data Types: `double`

ObservationInfo — Information about the observations

table

Information about the observations used in the fit, stored as a table.

`ObservationInfo` has one row for each observation and the following four columns.

<code>Weights</code>	The value of the weighted variable for that observation. Default value is 1.
<code>Excluded</code>	<code>true</code> , if the observation was excluded from the fit using the 'Exclude' name-value pair argument, <code>false</code> , otherwise. 1 stands for <code>true</code> and 0 stands for <code>false</code> .
<code>Missing</code>	<code>true</code> , if the observation was excluded from the fit because any response or predictor value is missing, <code>false</code> , otherwise. Missing values include <code>NaN</code> for numeric variables, empty cells for cell arrays, blank rows for character arrays, and the <code><undefined></code> value for categorical arrays.
<code>Subset</code>	<code>true</code> , if the observation was used in the fit, <code>false</code> , if it was not used because it is missing or excluded.

Data Types: `table`

ObservationNames — Names of observations

cell array of character vectors

Names of observations used in the fit, stored as a cell array of character vectors.

- If the data is in a table or dataset array, `tbl`, containing observation names, `ObservationNames` has those names.
- If the data is provided in matrices, or a table or dataset array without observation names, then `ObservationNames` is an empty cell array.

Data Types: `cell`

PredictorNames — Names of predictors

cell array of character vectors

Names of the variables that you use as predictors in the fit, stored as a cell array of character vectors that has the same length as `NumPredictors`.

Data Types: `cell`

ResponseName — Names of response variable

character vector

Name of the variable used as the response variable in the fit, stored as a character vector.

Data Types: `char`

Rsquared — Proportion of variability in the response explained by the fitted model

structure

Proportion of variability in the response explained by the fitted model, stored as a structure. It is the multiple correlation coefficient or R-squared. `Rsquared` has two fields.

Ordinary

R-squared value, stored as a scalar value in a structure. `Rsquared.Ordinary = 1 - SSE./SST`

Adjusted

R-squared value adjusted for the number of fixed-effects coefficients, stored as a scalar value in a structure.

`Rsquared.Adjusted = 1 - (SSE./SST)*(DFT./DFE)`,

where $DFE = n - p$, $DFT = n - 1$, and n is the total number of observations, p is the number of fixed-effects coefficients.

Data Types: `struct`

SSE — Error sum of squares

positive scalar value

Error sum of squares, that is, sum of the squared conditional residuals, stored as a positive scalar value.

$SSE = \text{sum}((y - F).^2)$, where y is the response vector, and F is the fitted conditional response of the linear mixed-effects model. The conditional model has contributions from both fixed and random effects.

Data Types: `double`

SSR — Regression sum of squares

positive scalar value

Regression sum of squares, that is, the sum of squares explained by the linear mixed-effects regression, stored as a positive scalar value. It is the sum of squared deviations of the conditional fitted values from their mean.

$SSR = \text{sum}((F - \text{mean}(F)).^2)$, where F is the fitted conditional response of the linear mixed-effects model. The conditional model has contributions from both fixed and random effects.

Data Types: `double`

SST — Total sum of squares

positive scalar value

Total sum of squares, that is, the sum of the squared deviations of the observed response values from their mean, stored as a positive scalar value.

$SST = \text{sum}((y - \text{mean}(y)).^2) = SSR + SSE$, where y is the response vector.

Data Types: `double`

Variables — Variables

table

Variables, stored as a table.

- If the fit is based on a table or dataset array `tbl`, then `Variables` is identical to `tbl`.

- If the fit is based on matrix input, then `Variables` is a table containing all the variables in the predictor matrix or matrices, and response variable.

Data Types: `table`

VariableInfo — Information about the variables

`table`

Information about the variables used in the fit, stored as a table.

`VariableInfo` has one row for each variable and contains the following four columns.

<code>Class</code>	Class of the variable ('double', 'cell', 'nominal', and so on).
<code>Range</code>	Value range of the variable. <ul style="list-style-type: none"> • For a numerical variable, it is a two-element vector of the form <code>[min,max]</code>. • For a cell or categorical variable, it is a cell or categorical array containing all unique values of the variable.
<code>InModel</code>	<code>true</code> , if the variable is a predictor in the fitted model. <code>false</code> , if the variable is not in the fitted model.
<code>IsCategorical</code>	<code>true</code> , if the variable has a type that is treated as a categorical predictor, such as cell, logical, or categorical, or if it is specified as categorical by the 'Categorical' name-value pair argument of the <code>fit</code> method. <code>false</code> , if it is a continuous predictor.

Data Types: `table`

VariableNames — Names of the variables

cell array of character vectors

Names of the variables used in the fit, stored as a cell array of character vectors.

- If sample data is in a table or dataset array `tbl`, `VariableNames` contains the names of the variables in `tbl`.
- If sample data is in matrix format, then `VariableInfo` includes variable names you supply while fitting the model. If you do not supply the variable names, then `VariableInfo` contains the default names.

Data Types: `cell`

Methods

<code>anova</code>	Analysis of variance for linear mixed-effects model
<code>coefCI</code>	Confidence intervals for coefficients of linear mixed-effects model
<code>coefTest</code>	Hypothesis test on fixed and random effects of linear mixed-effects model
<code>compare</code>	Compare linear mixed-effects models
<code>covarianceParameters</code>	Extract covariance parameters of linear mixed-effects model
<code>designMatrix</code>	Fixed- and random-effects design matrices
<code>disp</code>	Display linear mixed-effects model
<code>fit</code>	(Not Recommended) Fit linear mixed-effects model using tables
<code>fitmatrix</code>	Fit linear mixed-effects model using design matrices
<code>fitted</code>	Fitted responses from a linear mixed-effects model
<code>fixedEffects</code>	Estimates of fixed effects and related statistics
<code>plotResiduals</code>	Plot residuals of linear mixed-effects model
<code>predict</code>	Predict response of linear mixed-effects model
<code>random</code>	Generate random responses from fitted linear mixed-effects model
<code>randomEffects</code>	Estimates of random effects and related statistics
<code>residuals</code>	Residuals of fitted linear mixed-effects model
<code>response</code>	Response vector of the linear mixed-effects model

Copy Semantics

Value. To learn how value classes affect copy operations, see Copying Objects (MATLAB).

Examples

Random Intercept Model with Categorical Predictor

Load the sample data.

```
load flu
```

The `flu` dataset array has a `Date` variable, and 10 variables containing estimated influenza rates (in 9 different regions, estimated from Google® searches, plus a nationwide estimate from the Center for Disease Control and Prevention, CDC).

To fit a linear-mixed effects model, your data must be in a properly formatted dataset array. To fit a linear mixed-effects model with the influenza rates as the responses and region as the predictor variable, combine the nine columns corresponding to the regions into an array. The new dataset array, `flu2`, must have the response variable, `FluRate`, the nominal variable, `Region`, that shows which region each estimate is from, and the grouping variable `Date`.

```
flu2 = stack(flu,2:10,'NewDataVarName','FluRate',...
    'IndVarName','Region');
flu2.Date = nominal(flu2.Date);
```

Fit a linear mixed-effects model with fixed effects for region and a random intercept that varies by `Date`.

Because region is a nominal variable, `fitlme` takes the first region, NE, as the reference and creates eight dummy variables representing the other eight regions. For example, `I[MidAtl]` is the dummy variable representing the region `MidAtl`. For details, see “Dummy Indicator Variables” on page 2-60.

The corresponding model is

$$y_{im} = \beta_0 + \beta_1 I[\text{MidAtl}]_i + \beta_2 I[\text{ENCentral}]_i + \beta_3 I[\text{WNCentral}]_i + \beta_4 I[\text{SAtl}]_i \\ + \beta_5 I[\text{ESCentral}]_i + \beta_6 I[\text{WSCentral}]_i + \beta_7 I[\text{Mtn}]_i + \beta_8 I[\text{Pac}]_i + b_{0m} + \varepsilon_{im}, \quad m = 1, 2, \dots, 52,$$

where y_{im} is the observation i for level m of grouping variable `Date`, β_j , $j = 0, 1, \dots, 8$, are the fixed-effects coefficients, b_{0m} is the random effect for level m of the grouping variable `Date`, and ε_{im} is the observation error for observation i . The random effect has the prior distribution, $b_{0m} \sim N(0, \sigma_b^2)$ and the error term has the distribution, $\varepsilon_{im} \sim N(0, \sigma^2)$.

```
lme = fitlme(flu2, 'FluRate ~ 1 + Region + (1|Date)')
```

```

    0.18705    -0.033621    0.17162
    0.37191    -0.055948    0.14929
    0.0022936  -0.26276    -0.057514

```

Random effects covariance parameters (95% CIs):

Group: Date (52 Levels)

Name1	Name2	Type	Estimate	Lower
'(Intercept)'	'(Intercept)'	'std'	0.6443	0.5297

Upper
0.78368

Group: Error

Name	Estimate	Lower	Upper
'Res Std'	0.26627	0.24878	0.285

The p -values $7.3324e-06$ and $2.1623e-10$ respectively show that the fixed effects of the flu rates in regions `WNCentral` and `ESCentral` are significantly different relative to the flu rates in region `NE`.

The confidence limits for the standard deviation of the random-effects term, σ_b , do not include 0 (0.5297, 0.78368), which indicates that the random-effects term is significant. You can also test the significance of the random-effects terms using the `compare` method.

The estimated value of an observation is the sum of the fixed effects and the random-effect value at the grouping variable level corresponding to that observation. For example, the estimated best linear unbiased predictor (BLUP) of the flu rate for region `WNCentral` in week 10/9/2005 is

$$\begin{aligned}
 \hat{y}_{\text{WNCentral}, 10/9/2005} &= \hat{\beta}_0 + \hat{\beta}_3 I[\text{WNCentral}] + \hat{b}_{10/9/2005} \\
 &= 1.2233 + 0.23687 - 0.1718 \\
 &= 1.28837.
 \end{aligned}$$

This is the fitted conditional response, since it includes contribution to the estimate from both the fixed and random effects. You can compute this value as follows.

```

beta = fixedEffects(lme);
[~,~,STATS] = randomEffects(lme); % Compute the random-effects statistics (STATS)
STATS.Level = nominal(STATS.Level);
y_hat = beta(1) + beta(4) + STATS.Estimate(STATS.Level=='10/9/2005')

```

```
y_hat = 1.2884
```

You can simply display the fitted value using the `fitted` method.

```
F = fitted(lme);  
F(flu2.Date == '10/9/2005' & flu2.Region == 'WNCentral')  
  
ans = 1.2884
```

Compute the fitted marginal response for region `WNCentral` in week `10/9/2005`.

```
F = fitted(lme, 'Conditional', false);  
F(flu2.Date == '10/9/2005' & flu2.Region == 'WNCentral')  
  
ans = 1.4602
```

Linear Mixed-Effects Model with a Random Slope

Load the sample data.

```
load carbig
```

Fit a linear mixed-effects model for miles per gallon (MPG), with fixed effects for acceleration, horsepower and the cylinders, and uncorrelated random-effect for intercept and acceleration grouped by the model year. This model corresponds to

$$\text{MPG}_{im} = \beta_0 + \beta_1 \text{Acc}_i + \beta_2 \text{HP} + b_{0m} + b_{1m} \text{Acc}_{im} + \varepsilon_{im}, \quad m = 1, 2, 3,$$

with the random-effects terms having the following prior distributions:

$$b_m = \begin{pmatrix} b_{0m} \\ b_{1m} \end{pmatrix} \sim N\left(0, \begin{pmatrix} \sigma_0^2 & \sigma_{0,1} \\ \sigma_{0,1} & \sigma_1^2 \end{pmatrix}\right),$$

where m represents the model year.

First, prepare the design matrices for fitting the linear mixed-effects model.

```
X = [ones(406,1) Acceleration Horsepower];  
Z = [ones(406,1) Acceleration];  
Model_Year = nominal(Model_Year);  
G = Model_Year;
```

Now, fit the model using `fitlmematrix` with the defined design matrices and grouping variables. Use the `'fminunc'` optimization algorithm.

```
lme = fitlmematrix(X,MPG,Z,G,'FixedEffectPredictors',...
{'Intercept','Acceleration','Horsepower'},'RandomEffectPredictors',...
{{'Intercept','Acceleration'}},'RandomEffectGroups',{'Model_Year'},...
'FitMethod','REML')
```

```
lme =
Linear mixed-effects model fit by REML
```

Model information:

Number of observations	392
Fixed effects coefficients	3
Random effects coefficients	26
Covariance parameters	4

Formula:

Linear Mixed Formula with 4 predictors.

Model fit statistics:

AIC	BIC	LogLikelihood	Deviance
2202.9	2230.7	-1094.5	2188.9

Fixed effects coefficients (95% CIs):

Name	Estimate	SE	tStat	DF	pValue
'Intercept'	50.064	2.3176	21.602	389	1.4185e-68
'Acceleration'	-0.57897	0.13843	-4.1825	389	3.5654e-05
'Horsepower'	-0.16958	0.0073242	-23.153	389	3.5289e-75

Lower	Upper
45.507	54.62
-0.85112	-0.30681
-0.18398	-0.15518

Random effects covariance parameters (95% CIs):

Group: Model_Year (13 Levels)

Name1	Name2	Type	Estimate
'Intercept'	'Intercept'	'std'	3.72
'Acceleration'	'Intercept'	'corr'	-0.8769
'Acceleration'	'Acceleration'	'std'	0.3593

Lower	Upper
-------	-------

```
    1.5215    9.0954
 -0.98274  -0.33846
  0.19418    0.66483
```

Group: Error

Name	Estimate	Lower	Upper
'Res Std'	3.6913	3.4331	3.9688

The fixed effects coefficients display includes the estimate, standard errors (SE), and the 95% confidence interval limits (Lower and Upper). The *p*-values for (`pValue`) indicate that all three fixed-effects coefficients are significant.

The confidence intervals for the standard deviations and the correlation between the random effects for intercept and acceleration do not include zeros, hence they seem significant. Use the `compare` method to test for the random effects.

Display the covariance matrix of the estimated fixed-effects coefficients.

```
lme.CoefficientCovariance
```

```
ans = 3x3
```

```
    5.3711    -0.2809    -0.0126
 -0.2809    0.0192     0.0005
 -0.0126    0.0005     0.0001
```

The diagonal elements show the variances of the fixed-effects coefficient estimates. For example, the variance of the estimate of the intercept is 5.3711. Note that the standard errors of the estimates are the square roots of the variances. For example, the standard error of the intercept is 2.3176, which is `sqrt(5.3711)`.

The off-diagonal elements show the correlation between the fixed-effects coefficient estimates. For example, the correlation between the intercept and acceleration is -0.2809 and the correlation between acceleration and horsepower is 0.0005.

Display the coefficient of determination for the model.

```
lme.Rsquared
```

```
ans = struct with fields:
  Ordinary: 0.7826
  Adjusted: 0.7815
```

The adjusted value is the R-squared value adjusted for the number of predictors in the model.

Definitions

Formula

In general, a formula for model specification is a character vector or string scalar of the form `'y ~ terms'`. For the linear mixed-effects models, this formula is in the form `'y ~ fixed + (random1|grouping1) + ... + (randomR|groupingR)'`, where `fixed` and `random` contain the fixed-effects and the random-effects terms.

Suppose a table `tbl` contains the following:

- A response variable, `y`
- Predictor variables, `Xj`, which can be continuous or grouping variables
- Grouping variables, `g1`, `g2`, ..., `gR`,

where the grouping variables in `Xj` and `gr` can be categorical, logical, character arrays, string arrays, or cell arrays of character vectors.

Then, in a formula of the form, `'y ~ fixed + (random1|g1) + ... + (randomR|gR)'`, the term `fixed` corresponds to a specification of the fixed-effects design matrix X , `random1` is a specification of the random-effects design matrix Z_1 corresponding to grouping variable `g1`, and similarly `randomR` is a specification of the random-effects design matrix Z_R corresponding to grouping variable `gR`. You can express the `fixed` and `random` terms using Wilkinson notation.

Wilkinson notation describes the factors present in models. The notation relates to factors present in models, not to the multipliers (coefficients) of those factors.

Wilkinson Notation	Factors in Standard Notation
1	Constant (intercept) term
X^k , where k is a positive integer	X, X^2, \dots, X^k
$X_1 + X_2$	X_1, X_2

Wilkinson Notation	Factors in Standard Notation
X1*X2	X1, X2, X1.*X2 (elementwise multiplication of X1 and X2)
X1:X2	X1.*X2 only
- X2	Do not include X2
X1*X2 + X3	X1, X2, X3, X1*X2
X1 + X2 + X3 + X1:X2	X1, X2, X3, X1*X2
X1*X2*X3 - X1:X2:X3	X1, X2, X3, X1*X2, X1*X3, X2*X3
X1*(X2 + X3)	X1, X2, X3, X1*X2, X1*X3

Statistics and Machine Learning Toolbox notation always includes a constant term unless you explicitly remove the term using -1. Here are some examples for linear mixed-effects model specification.

Examples:

Formula	Description
'y ~ X1 + X2'	Fixed effects for the intercept, X1 and X2. This is equivalent to 'y ~ 1 + X1 + X2'.
'y ~ -1 + X1 + X2'	No intercept and fixed effects for X1 and X2. The implicit intercept term is suppressed by including -1.
'y ~ 1 + (1 g1)'	Fixed effects for the intercept plus random effect for the intercept for each level of the grouping variable g1.
'y ~ X1 + (1 g1)'	Random intercept model with a fixed slope.
'y ~ X1 + (X1 g1)'	Random intercept and slope, with possible correlation between them. This is equivalent to 'y ~ 1 + X1 + (1 + X1 g1)'.
'y ~ X1 + (1 g1) + (-1 + X1 g1)'	Independent random effects terms for intercept and slope.

Formula	Description
'y ~ 1 + (1 g1) + (1 g2) + (1 g1:g2)'	Random intercept model with independent main effects for g1 and g2, plus an independent interaction effect.

linhpytest

Linear hypothesis test

Syntax

```
p = linhpytest(beta,COVB,c,H,dfe)
[p,t,r] = linhpytest(...)
```

Description

`p = linhpytest(beta,COVB,c,H,dfe)` returns the p value p of a hypothesis test on a vector of parameters. `beta` is a vector of k parameter estimates. `COVB` is the k -by- k estimated covariance matrix of the parameter estimates. `c` and `H` specify the null hypothesis in the form $H*\mathbf{b} = \mathbf{c}$, where \mathbf{b} is the vector of unknown parameters estimated by `beta`. `dfe` is the degrees of freedom for the `COVB` estimate, or `Inf` if `COVB` is known rather than estimated.

`beta` is required. The remaining arguments have default values:

- `COVB = eye(k)`
- `c = zeros(k,1)`
- `H = eye(K)`
- `dfe = Inf`

If `H` is omitted, `c` must have k elements and it specifies the null hypothesis values for the entire parameter vector.

Note The following functions return outputs suitable for use as the `COVB` input argument to `linhpytest`: `nlinfit`, `coxphfit`, `glmfit`, `mnrfit`, `regstats`, `robustfit`. `nlinfit` returns `COVB` directly; the other functions return `COVB` in `stats.covb`.

`[p,t,r] = linhpytest(...)` also returns the test statistic `t` and the rank `r` of the hypothesis matrix `H`. If `dfe` is `Inf` or is not given, `t*r` is a chi-square statistic with r

degrees of freedom . If `dfe` is specified as a finite value, `t` is an F statistic with `r` and `dfe` degrees of freedom.

`linhptest` performs a test based on an asymptotic normal distribution for the parameter estimates. It can be used after any estimation procedure for which the parameter covariances are available, such as `regstats` or `glmfit`. For linear regression, the p -values are exact. For other procedures, the p -values are approximate, and may be less accurate than other procedures such as those based on a likelihood ratio.

Examples

Fit a multiple linear model to the data in `hald.mat`:

```
load hald
stats = regstats(heat,ingredients,'linear');
beta = stats.beta
beta =
    62.4054
     1.5511
     0.5102
     0.1019
    -0.1441
```

Perform an F -test that the last two coefficients are both 0:

```
SIGMA = stats.covb;
dfe = stats.fstat.dfe;
H = [0 0 0 1 0;0 0 0 0 1];
c = [0;0];
[p,F] = linyptest(beta,SIGMA,c,H,dfe)
p =
    0.4668
F =
    0.8391
```

Introduced in R2007a

linkage

Agglomerative hierarchical cluster tree

Syntax

```
Z = linkage(X)
Z = linkage(X,method)
Z = linkage(X,method,metric)
Z = linkage(X,method,metric,'savememory',value)

Z = linkage(X,method,pdist_inputs)

Z = linkage(y)
Z = linkage(y,method)
```

Description

`Z = linkage(X)` returns a matrix `Z` that encodes a tree containing hierarchical clusters of the rows of the input data matrix `X`.

`Z = linkage(X,method)` creates the tree using the specified `method`, which describes how to measure the distance between clusters. For more information, see “Linkages” on page 32-3796.

`Z = linkage(X,method,metric)` performs clustering by passing `metric` to the `pdist` function, which computes the distance between the rows of `X`.

`Z = linkage(X,method,metric,'savememory',value)` uses a memory-saving algorithm when `value` is 'on', and uses the standard algorithm when `value` is 'off'.

`Z = linkage(X,method,pdist_inputs)` passes `pdist_inputs` to the `pdist` function, which computes the distance between the rows of `X`. The `pdist_inputs` argument consists of the 'seuclidean', 'minkowski', or 'mahalanobis' metric and an additional distance metric option.

`Z = linkage(y)` uses a vector representation `y` of a distance matrix. `y` is either computed by `pdist` or is a more general dissimilarity matrix conforming to the output format of `pdist`.

`Z = linkage(y,method)` creates the tree using the specified `method`, which describes how to measure the distance between clusters.

Examples

Cluster Data and Plot Result

Randomly generate sample data with 20,000 observations.

```
rng('default') % For reproducibility
X = rand(20000,3);
```

Create a hierarchical cluster tree using the `ward` linkage method. In this case, the `'SaveMemory'` option of the `clusterdata` function is set to `'on'` by default. In general, specify the best value for `'SaveMemory'` based on the dimensions of `X` and the available memory.

```
Z = linkage(X,'ward');
```

Cluster the data into a maximum of four groups and plot the result.

```
c = cluster(Z,'Maxclust',4);
scatter3(X(:,1),X(:,2),X(:,3),10,c)
```

cluster identifies four groups in the data.

Compare Cluster Assignments to Classes

Find a maximum of three clusters in the `fisheriris` data set and compare cluster assignments of the flowers to their known classification.

Load the sample data.

```
load fisheriris
```

Create a hierarchical cluster tree using the 'average' method and the 'chebychev' metric.

```
Z = linkage(meas, 'average', 'chebychev');
```

Find a maximum of three clusters in the data.

```
T = cluster(Z, 'maxclust', 3);
```

Create a dendrogram plot of Z. To see the three clusters, use 'ColorThreshold' with a cutoff halfway between the third-from-last and second-from-last linkages.

```
cutoff = median([Z(end-2,3) Z(end-1,3)]);
dendrogram(Z, 'ColorThreshold', cutoff)
```

Display the last two rows of Z to see how the three clusters are combined into one. linkage combines the 293rd (blue) cluster with the 297th (red) cluster to form the 298th

cluster with a linkage of 1.7583. `linkage` then combines the 296th (green) cluster with the 298th cluster.

```
lastTwo = Z(end-1:end,:)
```

```
lastTwo = 2×3
```

```
    293.0000    297.0000     1.7583
    296.0000    298.0000     3.4445
```

See how the cluster assignments correspond to the three species. For example, one of the clusters contains 50 flowers of the second species and 40 flowers of the third species.

```
crosstab(T,species)
```

```
ans = 3×3
```

```
     0     0    10
     0    50    40
    50     0     0
```

Observe Clustering Step in Hierarchical Tree

Load the `examgrades` data set.

```
load examgrades
```

Create a hierarchical tree using `linkage`. Use the 'single' method and the Minkowski metric with an exponent of 3.

```
Z = linkage(grades,'single',{'minkowski',3});
```

Observe the 25th clustering step.

```
Z(25,:)
```

```
ans = 1×3
```

```
    86.0000   137.0000    4.5307
```

`linkage` combines the 86th observation and the 137th cluster to form a cluster of index $120 + 25 = 145$, where 120 is the total number of observations in `grades` and 25 is the row number in `Z`. The shortest distance between the 86th observation and any of the points in the 137th cluster is 4.5307.

Cluster Data Using Dissimilarity Matrix

Create an agglomerative hierarchical cluster tree using a dissimilarity matrix.

Take a dissimilarity matrix `X` and convert it to a vector form that `linkage` accepts by using `squareform`.

```
X = [0 1 2 3; 1 0 4 5; 2 4 0 6; 3 5 6 0];
y = squareform(X);
```

Create a cluster tree using `linkage` with the `'complete'` method of calculating the distance between clusters. The first two columns of `Z` show how `linkage` combines clusters. The third column of `Z` gives the distance between clusters.

```
Z = linkage(y, 'complete')
```

```
Z = 3x3
```

```
    1     2     1
    3     5     4
    4     6     6
```

Create a dendrogram plot of `Z`. The x-axis corresponds to the leaf nodes of the tree, and the y-axis corresponds to the linkage distances between clusters.

```
dendrogram(Z)
```

Input Arguments

X — Input data

numeric matrix

Input data, specified as a numeric matrix with two or more rows. The rows represent observations, and the columns represent categories or dimensions.

Data Types: `single` | `double`

method — Algorithm for computing distance between clusters

'`single`' (default) | '`average`' | '`centroid`' | '`complete`' | ...

Algorithm for computing the distance between clusters, specified as one of the values in this table.

Method	Description
'average'	Unweighted average distance (UPGMA)
'centroid'	Centroid distance (UPGMC), appropriate for Euclidean distances only
'complete'	Farthest distance
'median'	Weighted center of mass distance (WPGMC), appropriate for Euclidean distances only
'single'	Shortest distance
'ward'	Inner squared distance (minimum variance algorithm), appropriate for Euclidean distances only
'weighted'	Weighted average distance (WPGMA)

For more information on these methods, see “Linkages” on page 32-3796.

metric – Distance metric

'euclidean' (default) | 'squaredeuclidean' | 'seuclidean' | 'mahalanobis' | function handle | ...

Distance metric, specified as any metric accepted by the `pdist` function. These metrics are described in the following table.

Value	Description
'euclidean'	Euclidean distance (default).
'squaredeuclidean'	Squared Euclidean distance. (This option is provided for efficiency only. It does not satisfy the triangle inequality.)
'seuclidean'	Standardized Euclidean distance. Each coordinate difference between observations is scaled by dividing by the corresponding element of the standard deviation, $S = \text{nanstd}(X)$. Use <code>DistParameter</code> to specify another value for S .
'mahalanobis'	Mahalanobis distance using the sample covariance of X , $C = \text{nancov}(X)$. Use <code>DistParameter</code> to specify another value for C , where the matrix C is symmetric and positive definite.

Value	Description
'cityblock'	City block distance.
'minkowski'	Minkowski distance. The default exponent is 2. Use <code>DistParameter</code> to specify a different exponent P , where P is a positive scalar value of the exponent.
'chebychev'	Chebychev distance (maximum coordinate difference).
'cosine'	One minus the cosine of the included angle between points (treated as vectors).
'correlation'	One minus the sample correlation between points (treated as sequences of values).
'hamming'	Hamming distance, which is the percentage of coordinates that differ.
'jaccard'	One minus the Jaccard coefficient, which is the percentage of nonzero coordinates that differ.
'spearman'	One minus the sample Spearman's rank correlation between observations (treated as sequences of values).
@ <i>distfun</i>	<p>Custom distance function handle. A distance function has the form</p> <pre>function D2 = distfun(ZI,ZJ) % calculation of distance ...</pre> <p>where</p> <ul style="list-style-type: none"> • ZI is a 1-by-n vector containing a single observation. • ZJ is an $m2$-by-n matrix containing multiple observations. <code>distfun</code> must accept a matrix ZJ with an arbitrary number of observations. • $D2$ is an $m2$-by-1 vector of distances, and $D2(k)$ is the distance between observations ZI and $ZJ(k, :)$. <p>If your data is not sparse, you can generally compute distance more quickly by using a built-in distance instead of a function handle.</p>

For more information, see “Distance Metrics” on page 32-4902.

Use `pdist_inputs` instead of `metric` to specify the additional input argument `DistParameter` of `pdist` for 'seuclidean', 'minkowski', or 'mahalanobis'.

Data Types: char | string | function_handle

pdist_inputs — Distance metric and distance metric option

cell array

Distance metric and distance metric option, specified as a cell array of the comma-separated pair consisting of the two input arguments `Distance` and `DistParameter` of the function `pdist`. This argument is valid only for specifying 'seuclidean', 'minkowski', or 'mahalanobis'.

Example: {'minkowski',5}

Data Types: cell

value — Flag for 'savememory' option

'on' | 'off'

Flag for the 'savememory' option, specified as either 'on' or 'off'. The 'on' setting causes `linkage` to construct clusters without computing the distance matrix. The 'on' setting is available only when `method` is 'centroid', 'median', or 'ward' and `metric` is 'euclidean'.

When `value` is 'on', the `linkage` run time is proportional to the number of dimensions (number of columns of `X`). When `value` is 'off', the `linkage` memory requirement is proportional to N^2 , where N is the number of observations. The best (least-time) setting to use for `value` depends on the problem dimensions, number of observations, and available memory. The default `value` setting is a rough approximation of an optimal setting.

The default is 'on' when `X` has 20 columns or fewer, or the computer does not have enough memory to store the distance matrix. Otherwise, the default is 'off'.

Example: 'savememory', 'on'

y — Distances

numeric vector

Distances, specified as a numeric vector with the same format as the output of the `pdist` function:

- A row vector of length $m(m - 1)/2$, corresponding to pairs of observations in a matrix with m rows

- Distances arranged in the order (2,1), (3,1), ..., (m,1), (3,2), ..., (m,2), ..., (m,m - 1))

y can be a more general dissimilarity matrix conforming to the output format of `pdist`.

Data Types: `single` | `double`

Output Arguments

Z — Agglomerative hierarchical cluster tree

numeric matrix

Agglomerative hierarchical cluster tree, returned as a numeric matrix. Z is an $(m - 1)$ -by-3 matrix, where m is the number of observations in the original data. Columns 1 and 2 of Z contain cluster indices linked in pairs to form a binary tree. The leaf nodes are numbered from 1 to m . Leaf nodes are the singleton clusters from which all higher clusters are built. Each newly formed cluster, corresponding to row $Z(I, :)$, is assigned the index $m + I$. The entries $Z(I, 1)$ and $Z(I, 2)$ contain the indices of the two component clusters that form cluster $m + I$. The $m - 1$ higher clusters correspond to the interior nodes of the clustering tree. $Z(I, 3)$ contains the linkage distance between the two clusters merged in row $Z(I, :)$.

For example, consider building a tree with 30 initial nodes. Suppose that cluster 5 and cluster 7 are combined at step 12, and that the distance between them at that step is 1.5. Then $Z(12, :)$ is $[5 \ 7 \ 1.5]$. The newly formed cluster has index $12 + 30 = 42$. If cluster 42 appears in a later row, then the function is combining the cluster created at step 12 into a larger cluster.

Data Types: `single` | `double`

Definitions

Linkages

A *linkage* is the distance between two clusters.

The following notation describes the linkages used by the various methods:

- Cluster r is formed from clusters p and q .

- n_r is the number of objects in cluster r .
- x_{ri} is the i th object in cluster r .
- *Single linkage*, also called *nearest neighbor*, uses the smallest distance between objects in the two clusters.

$$d(r, s) = \min(\text{dist}(x_{ri}, x_{sj}), i \in (1, \dots, n_r), j \in (1, \dots, n_s))$$

- *Complete linkage*, also called *farthest neighbor*, uses the largest distance between objects in the two clusters.

$$d(r, s) = \max(\text{dist}(x_{ri}, x_{sj}), i \in (1, \dots, n_r), j \in (1, \dots, n_s))$$

- *Average linkage* uses the average distance between all pairs of objects in any two clusters.

$$d(r, s) = \frac{1}{n_r n_s} \sum_{i=1}^{n_r} \sum_{j=1}^{n_s} \text{dist}(x_{ri}, x_{sj})$$

- *Centroid linkage* uses the Euclidean distance between the centroids of the two clusters.

$$d(r, s) = \|\bar{x}_r - \bar{x}_s\|_2,$$

where

$$\bar{x}_r = \frac{1}{n_r} \sum_{i=1}^{n_r} x_{ri}$$

- *Median linkage* uses the Euclidean distance between weighted centroids of the two clusters.

$$d(r, s) = \|\tilde{x}_r - \tilde{x}_s\|_2,$$

where \tilde{x}_r and \tilde{x}_s are weighted centroids for the clusters r and s . If cluster r was created by combining clusters p and q , \tilde{x}_r is defined recursively as

$$\tilde{x}_r = \frac{1}{2}(\tilde{x}_p + \tilde{x}_q)$$

- *Ward's linkage* uses the incremental sum of squares, that is, the increase in the total within-cluster sum of squares as a result of joining two clusters. The within-cluster sum of squares is defined as the sum of the squares of the distances between all

objects in the cluster and the centroid of the cluster. The sum of squares metric is equivalent to the following distance metric $d(r,s)$, which is the formula `linkage` uses.

$$d(r,s) = \sqrt{\frac{2n_r n_s}{(n_r + n_s)}} \|\bar{x}_r - \bar{x}_s\|_2,$$

where

- $\|\cdot\|_2$ is the Euclidean distance.
- \bar{x}_r and \bar{x}_s are the centroids of clusters r and s .
- n_r and n_s are the number of elements in clusters r and s .

In some references, Ward's linkage does not use the factor of 2 multiplying $n_r n_s$. The `linkage` function uses this factor so that the distance between two singleton clusters is the same as the Euclidean distance.

- *Weighted average linkage* uses a recursive definition for the distance between two clusters. If cluster r was created by combining clusters p and q , the distance between r and another cluster s is defined as the average of the distance between p and s and the distance between q and s .

$$d(r,s) = \frac{d(p,s) + d(q,s)}{2}$$

Tips

- Computing `linkage(y)` can be slow when y is a vector representation of the distance matrix. For the `'centroid'`, `'median'`, and `'ward'` methods, `linkage` checks whether y is a Euclidean distance. Avoid this time-consuming check by passing in X instead of y .
- The `'centroid'` and `'median'` methods can produce a cluster tree that is not monotonic. This result occurs when the distance from the union of two clusters, r and s , to a third cluster is less than the distance between r and s . In this case, in a dendrogram drawn with the default orientation, the path from a leaf to the root node takes some downward steps. To avoid this result, use another method. This figure shows a nonmonotonic cluster tree.

In this case, cluster 1 and cluster 3 are joined into a new cluster, and the distance between this new cluster and cluster 2 is less than the distance between cluster 1 and cluster 3. The result is a nonmonotonic tree.

- You can provide the output `Z` to other functions including `dendrogram` to display the tree, `cluster` to assign points to clusters, `inconsistent` to compute inconsistent measures, and `cophenet` to compute the cophenetic correlation coefficient.

loadCompactModel

Reconstruct model object from saved model for code generation

To generate C/C++ code for the object functions (`predict`, `random`, `knnsearch`, or `rangesearch`) of machine learning models, use `saveCompactModel`, `loadCompactModel`, and `codegen`. After training a machine learning model, save the model by using `saveCompactModel`. Define an entry-point function that loads the model by using `loadCompactModel` and calls an object function. Then use `codegen` or the MATLAB Coder app to generate C/C++ code. Generating C/C++ code requires MATLAB Coder.

This flow chart shows the code generation workflow for the object functions of machine learning models. Use `loadCompactModel` for the highlighted step.

Syntax

```
Mdl = loadCompactModel(filename)
```

Description

`Mdl = loadCompactModel(filename)` reconstructs a classification model, regression model, or nearest neighbor searcher (`Mdl`) from the saved model stored in the MATLAB formatted binary file (MAT-file) named `filename`. You must create the `filename` file by using `saveCompactModel`.

Examples

Generate C/C++ Code for Prediction

After training a machine learning model, save the model by using `saveCompactModel`. Define an entry-point function that loads the model by using `loadCompactModel` and calls the `predict` function of the trained model. Then use `codegen` to generate C/C++ code.

This example briefly explains the code generation workflow for the prediction of machine learning models at the command line. For more details, see “Code Generation for Prediction of Machine Learning Model at Command Line” on page 31-10. You can also generate code using the MATLAB Coder app. See “Code Generation for Prediction of Machine Learning Model Using MATLAB Coder App” on page 31-20 for details. To learn about the code generation for finding nearest neighbors using a nearest neighbor searcher model, see “Code Generation for Nearest Neighbor Searcher” on page 31-15.

Train Model

Load Fisher's iris data set. Remove all observed setosa irises data so that X and Y contain data for two classes only.

```
load fisheriris
inds = ~strcmp(species, 'setosa');
X = meas(inds,:);
Y = species(inds);
```

Train a support vector machine (SVM) classification model using the processed data set.

```
Mdl = fitcsvm(X,Y);
```

Mdl is a `ClassificationSVM` model.

Save Model

Save the SVM classification model to the file `SVMIris.mat` by using `saveCompactModel`.

```
saveCompactModel(Mdl, 'SVMIris');
```

Define Entry-Point Function

Define an entry-point function named `classifyIris` that does the following:

- Accept iris flower measurements with columns corresponding to `meas`, and return predicted labels.

- Load a trained SVM classification model.
- Predict labels using the loaded classification model for the iris flower measurements.

type `classifyIris.m` % Display contents of `classifyIris.m` file

```
function label = classifyIris(X) %#codegen
%CLASSIFYIRISES Classify iris species using SVM Model
% CLASSIFYIRISES classifies the iris flower measurements in X using the
% compact SVM model in the file SVMIris.mat, and then returns class
% labels in label.
CompactMdl = loadCompactModel('SVMIris');
label = predict(CompactMdl,X);
end
```

Add the `%#codegen` compiler directive (or pragma) to the entry-point function after the function signature to indicate that you intend to generate code for the MATLAB algorithm. Adding this directive instructs the MATLAB Code Analyzer to help you diagnose and fix violations that would result in errors during code generation.

Note: If you click the button located in the upper-right section of this example and open this example in MATLAB®, then MATLAB® opens the example folder. This folder includes the entry-point function file.

Generate Code

Generate code for the entry-point function using `codegen`. Because C and C++ are statically typed languages, you must determine the properties of all variables in the entry-point function at compile time. Pass `X` as the value of the `-args` option to specify that the generated code must accept an input that has the same data type and array size as the training data `X`. If the number of observations is unknown at compile time, you can also specify the input as variable-size by using `coder.typeof`. For details, see “Specify Variable-Size Arguments for Code Generation” on page 31-58 and “Specify Properties of Entry-Point Function Inputs” (MATLAB Coder).

```
codegen classifyIris -args {X}
```

`codegen` generates the MEX function `classifyIris_mex` with a platform-dependent extension.

Verify Generated Code

Compare the labels classified using `predict`, `classifyIris`, and `classifyIris_mex`.

```
label1 = predict(Mdl,X);
label2 = classifyIrises(X);
label3 = classifyIrises_mex(X);
verify_label = isequal(label1,label2,label3)

verify_label = logical
    1
```

`isequal` returns logical 1 (true), which means all the inputs are equal. The labels classified all three ways are the same.

Input Arguments

filename — Name of MAT-file containing structure array representing a model object

character vector | string scalar

Name of MAT-file containing the structure array representing a model object, specified as a character vector. You must create the `filename` file using `saveCompactModel`.

`loadCompactModel` reconstructs the model stored in the `filename` file at compile time. For supported models, see the `Mdl` input argument of `saveCompactModel`.

The extension of the `filename` file must be `.mat`. If `filename` has no extension, then `loadCompactModel` appends `.mat`.

If `filename` does not include a full path, then `loadCompactModel` loads the file from the current folder.

Example: 'Mdl'

Data Types: char | string

Output Arguments

Mdl — Machine learning model

model object

Machine learning model, returned as one of these model objects:

- Classification model object
 - ClassificationKNN
 - ClassificationLinear
 - CompactClassificationDiscriminant
 - CompactClassificationECOC
 - CompactClassificationEnsemble
 - CompactClassificationNaiveBayes
 - CompactClassificationSVM — If you use `saveCompactModel` to save an SVM model that is equipped to predict posterior probabilities, and use `loadCompactModel` to load the model, then `loadCompactModel` cannot restore the `ScoreTransform` property into the MATLAB Workspace. However, `loadCompactModel` can load the model, including the `ScoreTransform` property, at compile time for code generation, within an entry-point function.
 - CompactClassificationTree
- Regression model object
 - CompactGeneralizedLinearModel
 - CompactLinearModel — Suppose you train a linear model by using `fitlm` and specifying `'RobustOpts'` as a structure with an anonymous function handle for the `RobustWgtFun` field, use `saveCompactModel` to save the model, and then use `loadCompactModel` to load the model. In this case, `loadCompactModel` cannot restore the `Robust` property into the MATLAB Workspace. However, `loadCompactModel` can load the model at compile time within an entry-point function for code generation.
 - CompactRegressionEnsemble
 - CompactRegressionGP
 - CompactRegressionSVM
 - CompactRegressionTree
 - RegressionLinear
- Nearest neighbor searcher object
 - ExhaustiveSearcher
 - KDTreeSearcher

Algorithms

`saveCompactModel` reduces the memory footprint of classification and regression models (Mdl) by removing properties that are not required for prediction.

- For a model that has a corresponding compact model, the `saveCompactModel` function applies the appropriate `compact` function to the model before saving it.
- For a model that does not have a corresponding compact model, such as `ClassificationLinear`, `RegressionLinear`, `ExhaustiveSearcher`, and `KDTreeSearcher`, the `saveCompactModel` function saves the model as it is.
- A `ClassificationKNN` model object is a full object that does not have a corresponding compact object. For this model, `saveCompactModel` saves a compact version that does not include the hyperparameter optimization properties.

`loadCompactModel` loads the reduced version saved by `saveCompactModel`.

Alternative Functionality

- Use a coder configurer created by `learnerCoderConfigurer` for the models listed in this table.

Model	Coder Configurer Object
Support vector machine (SVM) regression	<code>RegressionSVMCoderConfigurer</code>
SVM for one-class and binary classification	<code>ClassificationSVMCoderConfigurer</code>
Multiclass model for SVMs	<code>ClassificationECOCCoderConfigurer</code>

After training a machine learning model, create a coder configurer of the model. Use the object functions and properties of the configurer to configure code generation options and to generate code for the `predict` and `update` functions of the model. If you generate code using a coder configurer, you can update model parameters in the generated code without having to regenerate the code. For details, see “Code Generation for Prediction and Update Using Coder Configurer” on page 31-96.

Introduced in R2016b

logncdf

Lognormal cumulative distribution function

Syntax

```
p = logncdf(x)
p = logncdf(x,mu)
p = logncdf(x,mu,sigma)

[p,pLo,pUp] = logncdf(x,mu,sigma,pCov)
[p,pLo,pUp] = logncdf(x,mu,sigma,pCov,alpha)

___ = logncdf(___,'upper')
```

Description

`p = logncdf(x)` returns the cumulative distribution function (cdf) of the standard lognormal distribution, evaluated at the values in `x`. In the standard lognormal distribution, the mean and standard deviation of logarithmic values are 0 and 1, respectively.

`p = logncdf(x,mu)` returns the cdf of the lognormal distribution with the distribution parameters `mu` (mean of logarithmic values) and 1 (standard deviation of logarithmic values), evaluated at the values in `x`.

`p = logncdf(x,mu,sigma)` returns the cdf of the lognormal distribution with the distribution parameters `mu` (mean of logarithmic values) and `sigma` (standard deviation of logarithmic values), evaluated at the values in `x`.

`[p,pLo,pUp] = logncdf(x,mu,sigma,pCov)` also returns the 95% confidence bounds `[pLo,pUp]` of `p` using the estimated parameters (`mu` and `sigma`) and their covariance matrix `pCov`.

`[p,pLo,pUp] = logncdf(x,mu,sigma,pCov,alpha)` specifies the confidence level for the confidence interval `[pLo,pUp]` to be $100(1-\alpha)\%$.

`___ = logncdf(___, 'upper')` returns the complement of the cdf, evaluated at the values in `x`, using an algorithm that more accurately computes the extreme upper-tail probabilities. 'upper' can follow any of the input argument combinations in the previous syntaxes.

Examples

Compute Lognormal Distribution cdf

Compute the cdf values evaluated at the values in `x` for the lognormal distribution with mean `mu` and standard deviation `sigma`.

```
x = 0:0.2:10;  
mu = 0;  
sigma = 1;  
p = logncdf(x,mu,sigma);
```

Plot the cdf.

```
plot(x,p)  
grid on  
xlabel('x')  
ylabel('p')
```

Confidence Interval of Lognormal cdf Value

Find the maximum likelihood estimates (MLEs) of the lognormal distribution parameters, and then find the confidence interval of the corresponding cdf value.

Generate 1000 random numbers from the lognormal distribution with the parameters 5 and 2.

```
rng('default') % For reproducibility
n = 1000; % Number of samples
x = lognrnd(5,2,n,1);
```

Find the MLEs for the distribution parameters (mean and standard deviation of logarithmic values) by using `mle`.

```
phat = mle(x, 'distribution', 'LogNormal')
```

```
phat = 1×2
```

```
    4.9347    1.9969
```

```
muHat = phat(1);  
sigmaHat = phat(2);
```

Estimate the covariance of the distribution parameters by using `lognlike`. The function `lognlike` returns an approximation to the asymptotic covariance matrix if you pass the MLEs and the samples used to estimate the MLEs.

```
[~,pCov] = lognlike(phat,x)
```

```
pCov = 2×2
```

```
    0.0040    -0.0000  
   -0.0000     0.0020
```

Find the cdf value at 0.5 and its 95% confidence interval.

```
[p,pLo,pUp] = logncdf(0.5,muHat,sigmaHat,pCov)
```

```
p = 0.0024
```

```
pLo = 0.0016
```

```
pUp = 0.0037
```

`p` is the cdf value of the lognormal distribution with the parameters `muHat` and `sigmaHat`. The interval `[pLo,pUp]` is the 95% confidence interval of the cdf evaluated at 0.5, considering the uncertainty of `muHat` and `sigmaHat` using `pCov`. The 95% confidence interval means the probability that `[pLo,pUp]` contains the true cdf value is 0.95.

Complementary cdf (Tail Distribution)

Determine the probability that an observation from a standard lognormal distribution will fall on the interval $[\exp(10), \text{Inf}]$.

```
p1 = 1 - logncdf(exp(10))
```

```
p1 = 0
```

`logncdf(exp(10))` is nearly 1, so `p1` becomes 0. Specify `'upper'` so that `logncdf` computes the extreme upper-tail probabilities more accurately.

```
p2 = logncdf(exp(10), 'upper')
```

```
p2 = 7.6199e-24
```

You can also use `'upper'` to compute a right-tailed p -value.

Input Arguments

x — Values at which to evaluate cdf

positive scalar value | array of positive scalar values

Values at which to evaluate the cdf, specified as a positive scalar value or an array of positive scalar values.

If you specify `pCov` to compute the confidence interval $[pLo, pUp]$, then `x` must be a scalar value.

To evaluate the cdf at multiple values, specify `x` using an array. To evaluate the cdfs of multiple distributions, specify `mu` and `sigma` using arrays. If one or more of the input arguments `x`, `mu`, and `sigma` are arrays, then the array sizes must be the same. In this case, `logncdf` expands each scalar input into a constant array of the same size as the array inputs. Each element in `p` is the cdf value of the distribution specified by the corresponding elements in `mu` and `sigma`, evaluated at the corresponding element in `x`.

Example: `[-1,0,3,4]`

Data Types: `single` | `double`

mu — Mean of logarithmic values

0 (default) | scalar value | array of scalar values

Mean of logarithmic values for the lognormal distribution, specified as a scalar value or an array of scalar values.

If you specify `pCov` to compute the confidence interval `[pLo, pUp]`, then `mu` must be a scalar value.

To evaluate the cdf at multiple values, specify `x` using an array. To evaluate the cdfs of multiple distributions, specify `mu` and `sigma` using arrays. If one or more of the input arguments `x`, `mu`, and `sigma` are arrays, then the array sizes must be the same. In this case, `logncdf` expands each scalar input into a constant array of the same size as the array inputs. Each element in `p` is the cdf value of the distribution specified by the corresponding elements in `mu` and `sigma`, evaluated at the corresponding element in `x`.

Example: `[0 1 2; 0 1 2]`

Data Types: `single` | `double`

sigma — Standard deviation of logarithmic values

1 (default) | positive scalar value | array of positive scalar values

Standard deviation of logarithmic values for the lognormal distribution, specified as a positive scalar value or an array of positive scalar values.

If you specify `pCov` to compute the confidence interval `[pLo, pUp]`, then `sigma` must be a scalar value.

To evaluate the cdf at multiple values, specify `x` using an array. To evaluate the cdfs of multiple distributions, specify `mu` and `sigma` using arrays. If one or more of the input arguments `x`, `mu`, and `sigma` are arrays, then the array sizes must be the same. In this case, `logncdf` expands each scalar input into a constant array of the same size as the array inputs. Each element in `p` is the cdf value of the distribution specified by the corresponding elements in `mu` and `sigma`, evaluated at the corresponding element in `x`.

Example: `[1 1 1; 2 2 2]`

Data Types: `single` | `double`

pCov — Covariance of estimates

2-by-2 numeric matrix

Covariance of the estimates `mu` and `sigma`, specified as a 2-by-2 matrix.

If you specify `pCov` to compute the confidence interval `[pLo, pUp]`, then `x`, `mu`, and `sigma` must be scalar values.

You can estimate the maximum likelihood estimates of `mu` and `sigma` by using `mle`, and estimate the covariance of `mu` and `sigma` by using `lognlike`. For an example, see “Confidence Interval of Lognormal cdf Value” on page 32-3809.

Data Types: `single` | `double`

alpha — Significance level

0.05 (default) | scalar in the range (0,1)

Significance level for the confidence interval, specified as a scalar in the range (0,1). The confidence level is $100(1-\text{alpha})\%$, where `alpha` is the probability that the confidence interval does not contain the true value.

Example: 0.01

Data Types: `single` | `double`

Output Arguments

p — cdf values

scalar value | array of scalar values

cdf values, evaluated at the values in `x`, returned as a scalar value or an array of scalar values. `p` is the same size as `x`, `mu`, and `sigma` after any necessary scalar expansion. Each element in `p` is the cdf value of the distribution specified by the corresponding elements in `mu` and `sigma`, evaluated at the corresponding element in `x`.

pLo — Lower confidence bound for p

scalar value | array of scalar values

Lower confidence bound for `p`, returned as a scalar value or an array of scalar values. `pLo` has the same size as `p`.

pUp — Upper confidence bound for p

scalar value | array of scalar values

Upper confidence bound for `p`, returned as a scalar value or an array of scalar values. `pUp` has the same size as `p`.

Definitions

Lognormal Distribution

The lognormal distribution is a probability distribution whose logarithm has a normal distribution.

The cumulative distribution function (cdf) of the lognormal distribution is

$$p = F(x) \left| \mu, \sigma \right. = \frac{1}{\sigma\sqrt{2\pi}} \int_0^x \frac{1}{t} \exp\left\{-\frac{(\log t - \mu)^2}{2\sigma^2}\right\} dt, \quad \text{for } x > 0.$$

Algorithms

- The `logncdf` function uses the complementary error function `erfc`. The relationship between `logncdf` and `erfc` is

$$\text{logncdf}(x, 0, 1) = \frac{1}{2} \text{erfc}\left(-\frac{\log x}{\sqrt{2}}\right).$$

The complementary error function `erfc(x)` is defined as

$$\text{erfc}(x) = 1 - \text{erf}(x) = \frac{2}{\sqrt{\pi}} \int_x^\infty e^{-t^2} dt.$$

- The `logncdf` function computes confidence bounds for `p` by using the delta method. The normal distribution cdf value of `log(x)` with the parameters `mu` and `sigma` is equivalent to the cdf value of `(log(x)-mu)/sigma` with the parameters 0 and 1. Therefore, the `logncdf` function estimates the variance of `(log(x)-mu)/sigma` using the covariance matrix of `mu` and `sigma` by the delta method, and finds the confidence bounds of `(log(x)-mu)/sigma` using the estimates of this variance. Then, the function transforms the bounds to the scale of `p`. The computed bounds give approximately the desired confidence level when you estimate `mu`, `sigma`, and `pCov` from large samples.

Alternative Functionality

- `logncdf` is a function specific to lognormal distribution. Statistics and Machine Learning Toolbox also offers the generic function `cdf`, which supports various probability distributions. To use `cdf`, create a `LognormalDistribution` probability distribution object and pass the object as an input argument or specify the probability distribution name and its parameters. Note that the distribution-specific function `logncdf` is faster than the generic function `cdf`.
- Use the **Probability Distribution Function** app to create an interactive plot of the cumulative distribution function (cdf) or probability density function (pdf) for a probability distribution.

Topics

“Lognormal Distribution” on page B-94

Introduced before R2006a

lognfit

Lognormal parameter estimates

Syntax

```
pHat = lognfit(x)
```

```
[pHat,pCI] = lognfit(x)
```

```
[pHat,pCI] = lognfit(x,alpha)
```

```
[ ___ ] = lognfit(x,alpha,censoring)
```

```
[ ___ ] = lognfit(x,alpha,censoring,freq)
```

```
[ ___ ] = lognfit(x,alpha,censoring,freq,options)
```

Description

`pHat = lognfit(x)` returns unbiased estimates of lognormal distribution parameters, given the sample data in `x`. `pHat(1)` and `pHat(2)` are the mean and standard deviation of logarithmic values, respectively.

`[pHat,pCI] = lognfit(x)` also returns 95% confidence intervals for the parameter estimates.

`[pHat,pCI] = lognfit(x,alpha)` specifies the confidence level for the confidence intervals to be $100(1-\alpha)\%$.

`[___] = lognfit(x,alpha,censoring)` specifies whether each value in `x` is right-censored or not. Use the logical vector `censoring` in which 1 indicates observations that are right-censored and 0 indicates observations that are fully observed. With `censoring`, the `phat` values are the maximum likelihood estimates (MLEs).

`[___] = lognfit(x,alpha,censoring,freq)` specifies the frequency or weights of observations.

`[___] = lognfit(x,alpha,censoring,freq,options)` specifies optimization options for the iterative algorithm `lognfit` to use to compute MLEs with `censoring`. Create `options` by using the function `statset`.

You can pass in [] for alpha, censoring, and freq to use their default values.

Examples

Estimate Parameters and Confidence Intervals

Generate 1000 random numbers from the lognormal distribution with the parameters 5 and 2.

```
rng('default') % For reproducibility
n = 1000; % Number of samples
x = lognrnd(5,2,n,1);
```

Find the parameter estimates and the 99% confidence intervals.

```
[pHat,pCI] = lognfit(x,0.01)
```

```
pHat = 1×2
```

```
    4.9347    1.9979
```

```
pCI = 2×2
```

```
    4.7717    1.8887
    5.0978    2.1196
```

pHat(1) and pHat(2) are the mean and standard deviation of logarithmic values, respectively. pCI contains the 99% confidence intervals of the mean and standard deviation parameters. The values in the first row are the lower bounds, and the values in the second row are the upper bounds.

Change Algorithm Options

Find the MLEs of a data set with censoring by using lognfit. Use statset to specify the iterative algorithm options that lognfit uses to compute MLEs for censored data, and then find the MLEs again.

Generate the true times x that follow the lognormal distribution with the parameters 5 and 2.

```
rng('default') % For reproducibility
n = 1000; % Number of samples
x = lognrnd(5,2,n,1);
```

Generate the censoring times. Note that the censoring times must be independent of the true times x .

```
censtime = normrnd(150,20,size(x));
```

Specify the indicator for the censoring times and the observed times.

```
censoring = x>censtime;
y = min(x,censtime);
```

Find the MLEs of the lognormal distribution parameters. The second input argument of `lognfit` specifies the confidence level. Pass in `[]` to use its default value 0.05. The third input argument specifies the censorship information.

```
pHat = lognfit(y,[],censoring)
```

```
pHat = 1×2
```

```
    4.9535    1.9996
```

Display the default algorithm parameters that `lognfit` uses to estimate the lognormal distribution parameters.

```
statset('lognfit')
```

```
ans = struct with fields:
    Display: 'off'
    MaxFunEvals: 200
    MaxIter: 100
    TolBnd: 1.0000e-06
    TolFun: 1.0000e-08
    TolTypeFun: []
    TolX: 1.0000e-08
    TolTypeX: []
    GradObj: []
    Jacobian: []
    DerivStep: []
```

```
FunValCheck: []
  Robust: []
RobustWgtFun: []
  WgtFun: []
  Tune: []
UseParallel: []
UseSubstreams: []
  Streams: {}
OutputFcn: []
```

Save the options using a different name. Change how the results are displayed (`Display`) and the termination tolerance for the objective function (`TolFun`).

```
options = statset('lognfit');
options.Display = 'final';
options.TolFun = 1e-10;
```

Alternatively, you can specify algorithm parameters by using the name-value pair arguments of the function `statset`.

```
options = statset('Display','final','TolFun',1e-10);
```

Find the MLEs with the new algorithm parameters.

```
pHat = lognfit(y,[],censoring,[],options)
```

```
Successful convergence: Norm of gradient less than OPTIONS.TolFun
```

```
pHat = 1×2
```

```
    4.9535    1.9996
```

`lognfit` displays a report on the final iteration.

Input Arguments

x — Sample data

vector

Sample data, specified as a vector.

Data Types: `single` | `double`

alpha — Significance level

0.05 (default) | scalar in the range (0,1)

Significance level for the confidence intervals, specified as a scalar in the range (0,1). The confidence level is $100(1-\text{alpha})\%$, where `alpha` is the probability that the confidence intervals do not contain the true value.

Example: `0.01`

Data Types: `single` | `double`

censoring — Indicator for censoring

array of 0s (default) | logical vector

Indicator for the censoring of each value in `x`, specified as a logical vector of the same size as `x`. Use 1 for observations that are right-censored and 0 for observations that are fully observed.

The default is an array of 0s, meaning that all observations are fully observed.

Data Types: `logical`

freq — Frequency or weights of observations

array of 1s (default) | nonnegative vector

Frequency or weights of observations, specified as a nonnegative vector that is the same size as `x`. The `freq` input argument typically contains nonnegative integer counts for the corresponding elements in `x`, but can contain any nonnegative values.

To obtain the weighted MLEs for a data set with censoring, specify weights of observations, normalized to the number of observations in `x`.

The default is an array of 1s, meaning one observation per element of `x`.

Data Types: `single` | `double`

options — Optimization options

`statset('lognfit')` (default) | structure

Optimization options, specified as a structure. `options` determines the control parameters for the iterative algorithm that `lognfit` uses to compute MLEs for censored data.

Create options by using the function `statset` or by creating a structure array containing the fields and values described in this table.

Field Name	Value	Default Value
Display	Amount of information displayed by the algorithm. <ul style="list-style-type: none"> 'off' — Displays no information. 'final' — Displays the final output. 	'off'
MaxFunEvals	Maximum number of objective function evaluations allowed, specified as a positive integer.	200
MaxIter	Maximum number of iterations allowed, specified as a positive integer.	100
TolBnd	Lower bound of the standard deviation parameter estimate, specified as a positive scalar. The bounds for the mean and standard deviation parameter estimates are $[-Inf, Inf]$ and $[TolBnd, Inf]$, respectively.	1e-6
TolFun	Termination tolerance for the objective function value, specified as a positive scalar.	1e-8
TolX	Termination tolerance for the parameters, specified as a positive scalar.	1e-8

You can also enter `statset('lognfit')` in the Command Window to see the names and default values of the fields that `lognfit` accepts in the `options` structure.

Example: `statset('Display','final','MaxIter',1000)` specifies to display the final information of the iterative algorithm results, and change the maximum number of iterations allowed to 1000.

Data Types: `struct`

Output Arguments

pHat — Estimates of lognormal distribution parameters

1-by-2 vector

Estimates of lognormal distribution parameters, returned as a 1-by-2 vector. `pHat(1)` and `pHat(2)` are the mean and standard deviation of logarithmic values, respectively.

- With no censoring, the `pHat` values are unbiased estimates. To compute the MLEs with no censoring, use the `mle` function.
- With censoring, the `pHat` values are the MLEs. To compute the weighted MLEs, specify the weights of observations by using `freq`.

pCI — Confidence intervals for parameter estimates

2-by-2 matrix

Confidence intervals for parameter estimates of the lognormal distribution, returned as a 2-by-2 matrix containing the lower and upper bounds of the $100(1-\alpha)\%$ confidence intervals.

The first and second rows correspond to the lower and upper bounds of the confidence intervals, respectively.

Algorithms

To compute the confidence intervals, `lognfit` uses the exact method for uncensored data and the Wald method for censored data. The exact method provides exact coverage for uncensored samples based on t and chi-square distributions.

Alternative Functionality

`lognfit` is a function specific to lognormal distribution. Statistics and Machine Learning Toolbox also offers the generic functions `mle`, `fitdist`, and `paramci` and the **Distribution Fitter** app, which support various probability distributions.

- `mle` returns MLEs and the confidence intervals of MLEs for the parameters of various probability distributions. You can specify the probability distribution name or a custom probability density function.

- Create a `LognormalDistribution` probability distribution object by fitting the distribution to data using the `fitdist` function or the **Distribution Fitter** app. The object properties `mu` and `sigma` store the parameter estimates. To obtain the confidence intervals for the parameter estimates, pass the object to `paramci`.

Topics

“Lognormal Distribution” on page B-94

Introduced before R2006a

logninv

Lognormal inverse cumulative distribution function

Syntax

```
x = logninv(p)
x = logninv(p,mu)
x = logninv(p,mu,sigma)
```

```
[x,xLo,xUp] = logninv(p,mu,sigma,pCov)
[x,xLo,xUp] = logninv(p,mu,sigma,pCov,alpha)
```

Description

`x = logninv(p)` returns the inverse of the standard lognormal cumulative distribution function (cdf), evaluated at the probability values in `p`. In the standard lognormal distribution, the mean and standard deviation of logarithmic values are 0 and 1, respectively.

`x = logninv(p,mu)` returns the inverse of the lognormal cdf with the distribution parameters `mu` (mean of logarithmic values) and 1 (standard deviation of logarithmic values), evaluated at the probability values in `p`.

`x = logninv(p,mu,sigma)` returns the inverse of the lognormal cdf with the distribution parameters `mu` (mean of logarithmic values) and `sigma` (standard deviation of logarithmic values), evaluated at the probability values in `p`.

`[x,xLo,xUp] = logninv(p,mu,sigma,pCov)` also returns the 95% confidence bounds `[xLo,xUp]` of `x` using the estimated parameters (`mu` and `sigma`) and their covariance matrix `pCov`.

`[x,xLo,xUp] = logninv(p,mu,sigma,pCov,alpha)` specifies the confidence level for the confidence interval `[xLo,xUp]` to be $100(1-\alpha)\%$.

Examples

Inverse of Lognormal Distribution cdf

Compute the inverse of cdf values evaluated at the probability values in `p` for the lognormal distribution with mean `mu` and standard deviation `sigma`.

```
p = 0.005:0.01:0.995;  
mu = 1;  
sigma = 0.5;  
x = logninv(p,mu,sigma);
```

Plot the inverse cdf.

```
plot(p,x)  
grid on  
xlabel('p');  
ylabel('x');
```

Confidence Interval of Inverse Lognormal cdf Value

Find the maximum likelihood estimates (MLEs) of the lognormal distribution parameters, and then find the confidence interval of the corresponding inverse cdf value.

Generate 1000 random numbers from the lognormal distribution with the parameters 5 and 2.

```
rng('default') % For reproducibility
n = 1000; % Number of samples
x = lognrnd(5,2,[n,1]);
```

Find the MLEs for the distribution parameters (mean and standard deviation of logarithmic values) by using `mle`.

```
phat = mle(x, 'distribution', 'LogNormal')  
  
phat = 1×2  
  
    4.9347    1.9969
```

```
muHat = phat(1);  
sigmaHat = phat(2);
```

Estimate the covariance of the distribution parameters by using `lognlike`. The function `lognlike` returns an approximation to the asymptotic covariance matrix if you pass the MLEs and the samples used to estimate the MLEs.

```
[~,pCov] = lognlike(phat,x)  
  
pCov = 2×2  
  
    0.0040    -0.0000  
   -0.0000    0.0020
```

Find the inverse cdf value at 0.5 and its 99% confidence interval.

```
[x,xLo,xUp] = logninv(0.5,muHat,sigmaHat,pCov,0.01)  
  
x = 139.0364  
  
xLo = 118.1643  
  
xUp = 163.5953
```

`x` is the inverse cdf value using the lognormal distribution with the parameters `muHat` and `sigmaHat`. The interval `[xLo,xUp]` is the 99% confidence interval of the inverse cdf value evaluated at 0.5, considering the uncertainty of `muHat` and `sigmaHat` using `pCov`. The 99% confidence interval means the probability that `[xLo,xUp]` contains the true inverse cdf value is 0.99.

Input Arguments

p — Probability values at which to evaluate inverse of cdf

scalar value in $[0, 1]$ | array of scalar values

Probability values at which to evaluate the inverse of the cdf (icdf), specified as a scalar value or an array of scalar values, where each element is in the range $[0, 1]$.

If you specify `pCov` to compute the confidence interval $[xLo, xUp]$, then `p` must be a scalar value.

To evaluate the icdf at multiple values, specify `p` using an array. To evaluate the icdfs of multiple distributions, specify `mu` and `sigma` using arrays. If one or more of the input arguments `p`, `mu`, and `sigma` are arrays, then the array sizes must be the same. In this case, `logninv` expands each scalar input into a constant array of the same size as the array inputs. Each element in `x` is the icdf value of the distribution specified by the corresponding elements in `mu` and `sigma`, evaluated at the corresponding element in `p`.

Example: `[0.1, 0.5, 0.9]`

Data Types: `single` | `double`

mu — Mean of logarithmic values

0 (default) | scalar value | array of scalar values

Mean of logarithmic values for the lognormal distribution, specified as a scalar value or an array of scalar values.

If you specify `pCov` to compute the confidence interval $[xLo, xUp]$, then `mu` must be a scalar value.

To evaluate the icdf at multiple values, specify `p` using an array. To evaluate the icdfs of multiple distributions, specify `mu` and `sigma` using arrays. If one or more of the input arguments `p`, `mu`, and `sigma` are arrays, then the array sizes must be the same. In this case, `logninv` expands each scalar input into a constant array of the same size as the array inputs. Each element in `x` is the icdf value of the distribution specified by the corresponding elements in `mu` and `sigma`, evaluated at the corresponding element in `p`.

Example: `[0 1 2; 0 1 2]`

Data Types: `single` | `double`

sigma — Standard deviation of logarithmic values

1 (default) | positive scalar value | array of positive scalar values

Standard deviation of logarithmic values for the lognormal distribution, specified as a positive scalar value or an array of positive scalar values.

If you specify `pCov` to compute the confidence interval `[xLo,xUp]`, then `sigma` must be a scalar value.

To evaluate the `icdf` at multiple values, specify `p` using an array. To evaluate the `icdfs` of multiple distributions, specify `mu` and `sigma` using arrays. If one or more of the input arguments `p`, `mu`, and `sigma` are arrays, then the array sizes must be the same. In this case, `logninv` expands each scalar input into a constant array of the same size as the array inputs. Each element in `x` is the `icdf` value of the distribution specified by the corresponding elements in `mu` and `sigma`, evaluated at the corresponding element in `p`.

Example: `[1 1 1; 2 2 2]`

Data Types: `single` | `double`

pCov — Covariance of estimates

2-by-2 numeric matrix

Covariance of the estimates `mu` and `sigma`, specified as a 2-by-2 matrix.

If you specify `pCov` to compute the confidence interval `[xLo,xUp]`, then `p`, `mu`, and `sigma` must be scalar values.

You can estimate the maximum likelihood estimates of `mu` and `sigma` by using `mle`, and estimate the covariance of `mu` and `sigma` by using `lognlike`. For an example, see “Confidence Interval of Inverse Lognormal cdf Value” on page 32-3827.

Data Types: `single` | `double`

alpha — Significance level

0.05 (default) | scalar in the range (0,1)

Significance level for the confidence interval, specified as a scalar in the range (0,1). The confidence level is $100(1-\alpha)\%$, where `alpha` is the probability that the confidence interval does not contain the true value.

Example: `0.01`

Data Types: `single` | `double`

Output Arguments

x — icdf values

scalar value | array of scalar values

icdf values, evaluated at the probability values in `p`, returned as a scalar value or an array of scalar values. `x` is the same size as `p`, `mu`, and `sigma` after any necessary scalar expansion. Each element in `x` is the icdf value of the distribution specified by the corresponding elements in `mu` and `sigma`, evaluated at the corresponding element in `p`.

xLo — Lower confidence bound for x

scalar value | array of scalar values

Lower confidence bound for `x`, returned as a scalar value or an array of scalar values. `xLo` has the same size as `x`.

xUp — Upper confidence bound for x

scalar value | array of scalar values

Upper confidence bound for `x`, returned as a scalar value or an array of scalar values. `xUp` has the same size as `x`.

Definitions

Lognormal Distribution

The lognormal distribution is a probability distribution whose logarithm has a normal distribution.

The lognormal inverse function is defined in terms of the lognormal cdf as

$$x = F^{-1}(p | \mu, \sigma) = \{x: F(x | \mu, \sigma) = p\}$$

where

$$p = F(x | \mu, \sigma) = \frac{1}{\sigma\sqrt{2\pi}} \int_0^x \frac{1}{t} \exp\left\{-\frac{(\log t - \mu)^2}{2\sigma^2}\right\} dt, \quad \text{for } x > 0.$$

Algorithms

- The function `logninv` uses the inverse complementary error function `erfcinv`. The relationship between `logninv` and `erfcinv` is

$$\text{logninv}(p, 0, 1) = \exp(-\sqrt{2} \text{erfcinv}(2p)).$$

The inverse complementary error function `erfcinv(x)` is defined as `erfcinv(erfc(x))=x`, and the complementary error function `erfc(x)` is defined as

$$\text{erfc}(x) = 1 - \text{erf}(x) = \frac{2}{\sqrt{\pi}} \int_x^{\infty} e^{-t^2} dt.$$

- The `logninv` function computes confidence bounds for `x` by using the delta method. `log(logninv(p, mu, sigma))` is equivalent to `mu + sigma*log(logninv(p, 0, 1))`. Therefore, the `logninv` function estimates the variance of `mu + sigma*log(logninv(p, 0, 1))` using the covariance matrix of `mu` and `sigma` by the delta method, and finds the confidence bounds using the estimates of this variance. The computed bounds give approximately the desired confidence level when you estimate `mu`, `sigma`, and `pCov` from large samples.

Alternative Functionality

- `logninv` is a function specific to lognormal distribution. Statistics and Machine Learning Toolbox also offers the generic function `icdf`, which supports various probability distributions. To use `icdf`, create a `LognormalDistribution` probability distribution object and pass the object as an input argument or specify the probability distribution name and its parameters. Note that the distribution-specific function `logninv` is faster than the generic function `icdf`.

Topics

“Lognormal Distribution” on page B-94

Introduced before R2006a

lognlike

Lognormal negative loglikelihood

Syntax

```
nlogL = lognlike(params,x)
nlogL = lognlike(params,x,censoring)
nlogL = lognlike(params,x,censoring,freq)
```

```
[nlogL,aVar] = lognlike( ___ )
```

Description

`nlogL = lognlike(params,x)` returns the lognormal negative loglikelihood of the distribution parameters (`params`) given the sample data (`x`). `params(1)` and `params(2)` are the mean and standard deviation of logarithmic values, respectively.

`nlogL = lognlike(params,x,censoring)` specifies whether each value in `x` is right-censored or not. Use the logical vector `censoring` in which 1 indicates observations that are right-censored and 0 indicates observations that are fully observed.

`nlogL = lognlike(params,x,censoring,freq)` specifies the frequency or weights of observations. To specify `freq` without specifying `censoring`, you can pass `[]` for `censoring`.

`[nlogL,aVar] = lognlike(___)` also returns the inverse of the Fisher information matrix `aVar`, using any of the input argument combinations in the previous syntaxes. If values in `params` are the maximum likelihood estimates (MLEs) of the parameters, `aVar` is an approximation to the asymptotic covariance matrix.

Examples

Negative Loglikelihood of MLEs

Find the MLEs of a data set with censoring by using `mle`, and then find the negative loglikelihood of the MLEs by using `lognlike`.

Generate 1000 random numbers from the lognormal distribution with the parameters 5 and 2.

```
rng('default') % For reproducibility
n = 1000; % Number of samples
x = lognrnd(5,2,[n,1]);
```

Find the MLEs for the distribution parameters (mean and standard deviation of logarithmic values) by using `mle`.

```
phat = mle(x, 'distribution', 'LogNormal')
```

```
phat = 1×2
```

```
    4.9347    1.9969
```

Find the negative loglikelihood of the MLEs.

```
nlogL = lognlike(phat,x)
```

```
nlogL = 7.0453e+03
```

Confidence Interval of Lognormal cdf Value

Find the maximum likelihood estimates (MLEs) of the lognormal distribution parameters, and then find the confidence interval of the corresponding cdf value.

Generate 1000 random numbers from the lognormal distribution with the parameters 5 and 2.

```
rng('default') % For reproducibility
n = 1000; % Number of samples
x = lognrnd(5,2,n,1);
```

Find the MLEs for the distribution parameters (mean and standard deviation of logarithmic values) by using `mle`.

```
phat = mle(x, 'distribution', 'LogNormal')  
phat = 1×2  
    4.9347    1.9969
```

```
muHat = phat(1);  
sigmaHat = phat(2);
```

Estimate the covariance of the distribution parameters by using `lognlike`. The function `lognlike` returns an approximation to the asymptotic covariance matrix if you pass the MLEs and the samples used to estimate the MLEs.

```
[~,pCov] = lognlike(phat,x)  
pCov = 2×2  
    0.0040    -0.0000  
   -0.0000    0.0020
```

Find the cdf value at 0.5 and its 95% confidence interval.

```
[p,pLo,pUp] = logncdf(0.5,muHat,sigmaHat,pCov)  
p = 0.0024  
pLo = 0.0016  
pUp = 0.0037
```

`p` is the cdf value of the lognormal distribution with the parameters `muHat` and `sigmaHat`. The interval `[pLo,pUp]` is the 95% confidence interval of the cdf evaluated at 0.5, considering the uncertainty of `muHat` and `sigmaHat` using `pCov`. The 95% confidence interval means the probability that `[pLo,pUp]` contains the true cdf value is 0.95.

Input Arguments

params — Lognormal distribution parameters
vector of two numeric values

Lognormal distribution parameters, specified as a vector of two numeric values. `params(1)` and `params(2)` are the mean and standard deviation of logarithmic values, respectively. `params(2)` must be positive.

Example: `[0,1]`

Data Types: `single` | `double`

x — Sample data

vector

Sample data, specified as a vector.

Data Types: `single` | `double`

censoring — Indicator for censoring

array of 0s (default) | logical vector

Indicator for the censoring of each value in `x`, specified as a logical vector of the same size as `x`. Use 1 for observations that are right-censored and 0 for observations that are fully observed.

The default is an array of 0s, meaning that all observations are fully observed.

Data Types: `logical`

freq — Frequency or weights of observations

array of 1s (default) | nonnegative vector

Frequency or weights of observations, specified as a nonnegative vector that is the same size as `x`. The `freq` input argument typically contains nonnegative integer counts for the corresponding elements in `x`, but can contain any nonnegative values.

To obtain the weighted negative loglikelihood for a data set with censoring, specify weights of observations, normalized to the number of observations in `x`.

The default is an array of 1s, meaning one observation per element of `x`.

Data Types: `single` | `double`

Output Arguments

nlogL — Negative loglikelihood

numeric scalar

Negative loglikelihood value of the distribution parameters (`params`) given the sample data (`x`), returned as a numeric scalar.

aVar — Inverse of Fisher information matrix

numeric matrix

Inverse of the Fisher information matrix, returned as a 2-by-2 numeric matrix. `aVar` is based on the observed Fisher information given the observed data (`x`), not the expected information.

If values in `params` are the MLEs of the parameters, `aVar` is an approximation to the asymptotic variance-covariance matrix (also known as the asymptotic covariance matrix). To find the MLEs, use `mle`.

Alternative Functionality

`lognlike` is a function specific to lognormal distribution. Statistics and Machine Learning Toolbox also offers the generic functions `mlecov`, `fitdist`, `negloglik`, and `proflik` and the **Distribution Fitter** app, which support various probability distributions.

- `mlecov` returns the asymptotic covariance matrix of the MLEs of the parameters for a distribution specified by a custom probability density function. For example, `mlecov(params,x,'pdf',@lognpdf)` returns the asymptotic covariance matrix of the MLEs for the lognormal distribution.
- Create a `LognormalDistribution` probability distribution object by fitting the distribution to data using the `fitdist` function or the **Distribution Fitter** app. The object property `ParameterCovariance` stores the covariance matrix of the parameter estimates. To obtain the negative loglikelihood of the parameter estimates and the profile of the likelihood function, pass the object to `negloglik` and `proflik`, respectively.

lognpdf

Lognormal probability density function

Syntax

```
y = lognpdf(x)
y = lognpdf(x,mu)
y = lognpdf(x,mu,sigma)
```

Description

`y = lognpdf(x)` returns the probability density function (pdf) of the standard lognormal distribution, evaluated at the values in `x`. In the standard lognormal distribution, the mean and standard deviation of logarithmic values are 0 and 1, respectively.

`y = lognpdf(x,mu)` returns the pdf of the lognormal distribution with the distribution parameters `mu` (mean of logarithmic values) and 1 (standard deviation of logarithmic values), evaluated at the values in `x`.

`y = lognpdf(x,mu,sigma)` returns the pdf of the lognormal distribution with the distribution parameters `mu` (mean of logarithmic values) and `sigma` (standard deviation of logarithmic values), evaluated at the values in `x`.

Examples

Compute Lognormal Distribution pdf

Compute the pdf values evaluated at the values in `x` for the lognormal distribution with mean `mu` and standard deviation `sigma`.

```
x = 0:0.02:10;
mu = 0;
sigma = 1;
y = lognpdf(x,0,1);
```

Plot the pdf.

```
plot(x,y)
grid on
xlabel('x')
ylabel('y')
```

Input Arguments

x — Values at which to evaluate pdf

positive scalar value | array of positive scalar values

Values at which to evaluate the pdf, specified as a positive scalar value or an array of positive scalar values.

To evaluate the pdf at multiple values, specify `x` using an array. To evaluate the pdfs of multiple distributions, specify `mu` and `sigma` using arrays. If one or more of the input arguments `x`, `mu`, and `sigma` are arrays, then the array sizes must be the same. In this case, `lognpdf` expands each scalar input into a constant array of the same size as the array inputs. Each element in `y` is the pdf value of the distribution specified by the corresponding elements in `mu` and `sigma`, evaluated at the corresponding element in `x`.

Example: `[-1,0,3,4]`

Data Types: `single` | `double`

mu — Mean of logarithmic values

0 (default) | scalar value | array of scalar values

Mean of logarithmic values for the lognormal distribution, specified as a scalar value or an array of scalar values.

To evaluate the pdf at multiple values, specify `x` using an array. To evaluate the pdfs of multiple distributions, specify `mu` and `sigma` using arrays. If one or more of the input arguments `x`, `mu`, and `sigma` are arrays, then the array sizes must be the same. In this case, `lognpdf` expands each scalar input into a constant array of the same size as the array inputs. Each element in `y` is the pdf value of the distribution specified by the corresponding elements in `mu` and `sigma`, evaluated at the corresponding element in `x`.

Example: `[0 1 2; 0 1 2]`

Data Types: `single` | `double`

sigma — Standard deviation of logarithmic values

1 (default) | positive scalar value | array of positive scalar values

Standard deviation of logarithmic values for the lognormal distribution, specified as a positive scalar value or an array of positive scalar values.

To evaluate the pdf at multiple values, specify `x` using an array. To evaluate the pdfs of multiple distributions, specify `mu` and `sigma` using arrays. If one or more of the input arguments `x`, `mu`, and `sigma` are arrays, then the array sizes must be the same. In this case, `lognpdf` expands each scalar input into a constant array of the same size as the array inputs. Each element in `y` is the pdf value of the distribution specified by the corresponding elements in `mu` and `sigma`, evaluated at the corresponding element in `x`.

Example: [1 1 1; 2 2 2]

Data Types: single | double

Output Arguments

y — pdf values

scalar value | array of scalar values

pdf values, evaluated at the values in `x`, returned as a scalar value or an array of scalar values. `y` is the same size as `x`, `mu`, and `sigma` after any necessary scalar expansion. Each element in `y` is the pdf value of the distribution specified by the corresponding elements in `mu` and `sigma`, evaluated at the corresponding element in `x`.

Definitions

Lognormal Distribution

The lognormal distribution is a probability distribution whose logarithm has a normal distribution.

The probability density function (pdf) of the lognormal distribution is

$$y = f(x) \left| \mu, \sigma \right) = \frac{1}{x\sigma\sqrt{2\pi}} \exp\left\{ -\frac{(\log x - \mu)^2}{2\sigma^2} \right\}, \quad \text{for } x > 0.$$

Alternative Functionality

- `lognpdf` is a function specific to lognormal distribution. Statistics and Machine Learning Toolbox also offers the generic function `pdf`, which supports various probability distributions. To use `pdf`, create a `LognormalDistribution` probability distribution object and pass the object as an input argument or specify the probability distribution name and its parameters. Note that the distribution-specific function `lognpdf` is faster than the generic function `pdf`.

- Use the **Probability Distribution Function** app to create an interactive plot of the cumulative distribution function (cdf) or probability density function (pdf) for a probability distribution.

Introduced before R2006a

lognrnd

Lognormal random numbers

Syntax

```
r = lognrnd(mu, sigma)
r = lognrnd(mu, sigma, sz1, ..., szN)
r = lognrnd(mu, sigma, [sz1, ..., szN])
```

Description

`r = lognrnd(mu, sigma)` generates a random number from the lognormal distribution with the distribution parameters `mu` (mean of logarithmic values) and `sigma` (standard deviation of logarithmic values).

`r = lognrnd(mu, sigma, sz1, ..., szN)` or `r = lognrnd(mu, sigma, [sz1, ..., szN])` generates a `sz1`-by-...-by-`szN` array of lognormal random numbers.

Examples

Generate Lognormal Random Number

Find the distribution parameters from the mean and variance of a lognormal distribution and generate a lognormal random value from the distribution.

Find the distribution parameters `mu` and `sigma` from the mean and variance.

```
m = 1; % mean
v = 2; % variance
mu = log((m^2)/sqrt(v+m^2))

mu = -0.5493

sigma = sqrt(log(v/(m^2)+1))
```

```
sigma = 1.0481
```

Generate a lognormal random value.

```
rng('default') % For reproducibility
r = lognrnd(mu,sigma)

r = 1.0144
```

Reset Random Number Generator

Save the current state of the random number generator. Then create a 1-by-5 vector of lognormal random numbers from the lognormal distribution with the parameters 3 and 10.

```
s = rng;
r = lognrnd(3,10,[1,5])

r = 1×5
109 ×

    0.0000    1.8507    0.0000    0.0001    0.0000
```

Restore the state of the random number generator to `s`, and then create a new 1-by-5 vector of random numbers. The values are the same as before.

```
rng(s);
r1 = lognrnd(3,10,[1,5])

r1 = 1×5
109 ×

    0.0000    1.8507    0.0000    0.0001    0.0000
```

Clone Size from Existing Array

Create a matrix of lognormally distributed random numbers with the same size as an existing array.

```
A = [3 2; -2 1];
sz = size(A);
R = lognrnd(0,1,sz)

R = 2×2

    1.7120    0.1045
    6.2582    2.3683
```

You can combine the previous two lines of code into a single line.

```
R = lognrnd(1,0,size(A));
```

Input Arguments

mu — Mean of logarithmic values

scalar value | array of scalar values

Mean of logarithmic values for the lognormal distribution, specified as a scalar value or an array of scalar values.

To generate random numbers from multiple distributions, specify **mu** and **sigma** using arrays. If both **mu** and **sigma** are arrays, then the array sizes must be the same. If either **mu** or **sigma** is a scalar, then **lognrnd** expands the scalar argument into a constant array of the same size as the other argument. Each element in **r** is the random number generated from the distribution specified by the corresponding elements in **mu** and **sigma**.

Example: `[0 1 2; 0 1 2]`

Data Types: `single` | `double`

sigma — Standard deviation of logarithmic values

nonnegative scalar value | array of nonnegative scalar values

Standard deviation of logarithmic values for the lognormal distribution, specified as a nonnegative scalar value or an array of nonnegative scalar values.

If **sigma** is zero, then the output **r** is always equal to $\exp(\mu)$.

To generate random numbers from multiple distributions, specify **mu** and **sigma** using arrays. If both **mu** and **sigma** are arrays, then the array sizes must be the same. If either

`mu` or `sigma` is a scalar, then `lognrnd` expands the scalar argument into a constant array of the same size as the other argument. Each element in `r` is the random number generated from the distribution specified by the corresponding elements in `mu` and `sigma`.

Example: `[1 1 1; 2 2 2]`

Data Types: `single` | `double`

`sz1, ..., szN` — Size of each dimension

`integers` | `row vector of integers`

Size of each dimension, specified as integers or a row vector of integers. For example, specifying `5, 3, 2` or `[5, 3, 2]` generates a 5-by-3-by-2 array of random numbers from the probability distribution.

If either `mu` or `sigma` is an array, then the specified dimensions `sz1, ..., szN` must match the common dimensions of `mu` and `sigma` after any necessary scalar expansion. The default values of `sz1, ..., szN` are the common dimensions.

- If you specify a single value `sz1`, then `r` is a square matrix of size `sz1`.
- If the size of any dimension is 0 or negative, then `r` is an empty array.
- Beyond the second dimension, `lognrnd` ignores trailing dimensions with a size of 1. For example, `lognrnd(3, 1, 1, 1)` produces a 3-by-1 vector of random numbers.

Data Types: `single` | `double`

Output Arguments

`r` — Lognormal random numbers

`scalar value` | `array of scalar values`

Lognormal random numbers, returned as a scalar value or an array of scalar values with the dimensions specified by `sz1, ..., szN`. Each element in `r` is the random number generated from the distribution specified by the corresponding elements in `mu` and `sigma`.

Definitions

Lognormal Distribution

The lognormal distribution is a probability distribution whose logarithm has a normal distribution.

The mean m and variance v of a lognormal random variable are functions of the lognormal distribution parameters μ and σ :

$$m = \exp(\mu + \sigma^2/2)$$
$$v = \exp(2\mu + \sigma^2)(\exp(\sigma^2) - 1)$$

Also, you can compute the lognormal distribution parameters μ and σ from the mean m and variance v :

$$\mu = \log(m^2/\sqrt{v + m^2})$$
$$\sigma = \sqrt{\log(v/m^2 + 1)}$$

Alternative Functionality

- `lognrnd` is a function specific to lognormal distribution. Statistics and Machine Learning Toolbox also offers the generic function `random`, which supports various probability distributions. To use `random`, create a `LognormalDistribution` probability distribution object and pass the object as an input argument or specify the probability distribution name and its parameters. Note that the distribution-specific function `lognrnd` is faster than the generic function `random`.
- To generate random numbers interactively, use `randtool`, a random number generation user interface.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

The generated code can return a different sequence of numbers than MATLAB if either of the following is true:

- The output is nonscalar.
- An input parameter is invalid for the distribution.

For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “General Code Generation Workflow” on page 31-5.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU arrays. For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

lognstat

Lognormal mean and variance

Syntax

```
[m,v] = lognstat(mu,sigma)
```

Description

`[m,v] = lognstat(mu,sigma)` returns the mean and variance of the lognormal distribution with the distribution parameters `mu` (mean of logarithmic values) and `sigma` (standard deviation of logarithmic values).

Examples

Compute Mean and Variance

Compute the mean and variance of the lognormal distribution with parameters `mu` and `sigma`.

```
mu = 0;  
sigma = 1;  
[m,v] = lognstat(mu,sigma)
```

```
m = 1.6487
```

```
v = 4.6708
```

Input Arguments

mu — Mean of logarithmic values

scalar value | array of scalar values

Mean of logarithmic values for the lognormal distribution, specified as a scalar value or an array of scalar values.

To compute the means and variances of multiple distributions, specify distribution parameters using an array of scalar values. If both `mu` and `sigma` are arrays, then the array sizes must be the same. If either `mu` or `sigma` is a scalar, then `lognstat` expands the scalar argument into a constant array of the same size as the other argument. Each element in `m` and `v` is the mean and variance of the distribution specified by the corresponding elements in `mu` and `sigma`.

Example: `[0 1 2; 0 1 2]`

Data Types: `single` | `double`

sigma — Standard deviation of logarithmic values

positive scalar value | array of positive scalar values

Standard deviation of logarithmic values for the lognormal distribution, specified as a positive scalar value or an array of positive scalar values.

To compute the means and variances of multiple distributions, specify distribution parameters using an array of scalar values. If both `mu` and `sigma` are arrays, then the array sizes must be the same. If either `mu` or `sigma` is a scalar, then `lognstat` expands the scalar argument into a constant array of the same size as the other argument. Each element in `m` and `v` is the mean and variance of the distribution specified by the corresponding elements in `mu` and `sigma`.

Example: `[1 1 1; 2 2 2]`

Data Types: `single` | `double`

Output Arguments

m — Mean

scalar value | array of scalar values

Mean of the lognormal distribution, returned as a scalar value or an array of scalar values. `m` is the same size as `mu` and `sigma` after any necessary scalar expansion. Each element in `m` is the mean of the lognormal distribution specified by the corresponding elements in `mu` and `sigma`.

v — Variance

scalar value | array of scalar values

Variance of the lognormal distribution, returned as a scalar value or an array of scalar values. `v` is the same size as `mu` and `sigma` after any necessary scalar expansion. Each element in `v` is the variance of the lognormal distribution specified by the corresponding elements in `mu` and `sigma`.

Definitions

Lognormal Distribution

The lognormal distribution is a probability distribution whose logarithm has a normal distribution.

The mean m and variance v of a lognormal random variable are functions of the lognormal distribution parameters μ and σ :

$$m = \exp(\mu + \sigma^2/2)$$
$$v = \exp(2\mu + \sigma^2)(\exp(\sigma^2) - 1)$$

Also, you can compute the lognormal distribution parameters μ and σ from the mean m and variance v :

$$\mu = \log(m^2/\sqrt{v + m^2})$$
$$\sigma = \sqrt{\log(v/m^2 + 1)}$$

Alternative Functionality

- `lognstat` is a function specific to lognormal distribution. Statistics and Machine Learning Toolbox also offers generic functions to compute summary statistics, including mean (`mean`), median (`median`), interquartile range (`iqr`), variance (`var`), and standard deviation (`std`). These generic functions support various probability distributions. To use these functions, create a `LognormalDistribution` probability distribution object and pass the object as an input argument.

logP

Log unconditional probability density for discriminant analysis classifier

Syntax

$\text{lp} = \text{logP}(\text{obj}, X_{\text{new}})$

Description

$\text{lp} = \text{logP}(\text{obj}, X_{\text{new}})$ returns the log of the unconditional probability density of each row of X_{new} , computed using the discriminant analysis model obj .

Input Arguments

obj

Discriminant analysis classifier, produced using `fitcdiscr`.

Xnew

Matrix where each row represents an observation, and each column represents a predictor. The number of columns in X_{new} must equal the number of predictors in obj .

Output Arguments

lp

Column vector with the same number of rows as X_{new} . Each entry is the logarithm of the unconditional probability density of the corresponding row of X_{new} .

Examples

Compute Log Unconditional Probability Density of an Observation

Construct a discriminant analysis classifier for Fisher's iris data, and examine its prediction for an average measurement.

Load Fisher's iris data and construct a default discriminant analysis classifier.

```
load fisheriris
Mdl = fitcdiscr(meas,species);
```

Find the log probability of the discriminant model applied to an average iris.

```
logPAverage = logP(Mdl,mean(meas))
```

```
logPAverage = -1.7254
```

Definitions

Unconditional Probability Density

The unconditional probability density of a point x of a discriminant analysis model is

$$P(x) = \sum_{k=1}^K P(x, k),$$

where $P(x, k)$ is the conditional density of the model at x for class k , when the total number of classes is K .

The conditional density $P(x, k)$ is

$$P(x, k) = P(k)P(x|k),$$

where $P(k)$ is the prior probability of class k , and $P(x|k)$ is the conditional density of x given class k . The conditional density function of the multivariate normal with mean μ_k and covariance Σ_k at a point x is

$$P(x|k) = \frac{1}{(2\pi|\Sigma_k|)^{1/2}} \exp\left(-\frac{1}{2}(x - \mu_k)^T \Sigma_k^{-1} (x - \mu_k)\right),$$

where $|\Sigma_k|$ is the determinant of Σ_k , and Σ_k^{-1} is the inverse matrix.

logP

Log unconditional probability density for naive Bayes classifier

Syntax

```
lp = logP(Mdl, tbl)
lp = logP(Mdl, X)
```

Description

`lp = logP(Mdl, tbl)` returns the log unconditional probability density on page 32-3862 of the observations (rows) in `tbl` using the naive Bayes model `Mdl`.

You can use `lp` to identify outliers in the training data.

`lp = logP(Mdl, X)` returns the log unconditional probability density on page 32-3862 of the observations (rows) in `X` using the naive Bayes model `Mdl`.

Input Arguments

Mdl — Naive Bayes classifier

`ClassificationNaiveBayes model` | `CompactClassificationNaiveBayes model`

Naive Bayes classifier, specified as a `ClassificationNaiveBayes model` or `CompactClassificationNaiveBayes model` returned by `fitcnb` or `compact`, respectively.

tbl — Sample data

table

Sample data, specified as a table. Each row of `tbl` corresponds to one observation, and each column corresponds to one predictor variable. Optionally, `tbl` can contain additional columns for the response variable and observation weights. `tbl` must contain all the predictors used to train `Mdl`. Multi-column variables and cell arrays other than cell arrays of character vectors are not allowed.

If you trained `Mdl` using sample data contained in a `table`, then the input data for this method must also be in a `table`.

Data Types: `table`

X — Predictor data

numeric matrix

Predictor data, specified as a numeric matrix.

Each row of `X` corresponds to one observation (also known as an instance or example), and each column corresponds to one variable (also known as a feature). The variables making up the columns of `X` must be the same as the variables that trained `Mdl`.

Data Types: `double` | `single`

Output Arguments

lp — Log of unconditional probability density

numeric column vector

Log of the unconditional probability density of the predictors, returned as a numeric column vector. `lp` has as many elements as rows in `X`, and each element is the log probability density of the corresponding row in `X`.

If any rows in `X` contain at least one `NaN`, then the corresponding element of `lp` is `NaN`.

Examples

Compute Unconditional Probability Densities of Observations

Load Fisher's iris data set.

```
load fisheriris
X = meas;    % Predictors
Y = species; % Response
```

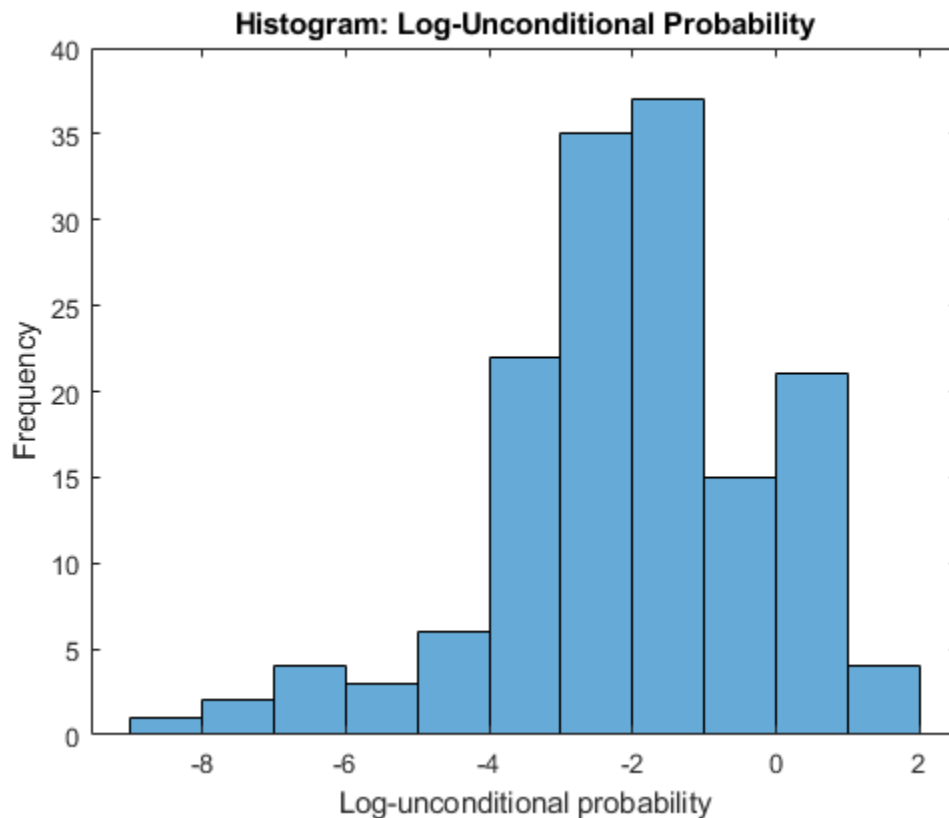

Train a naive Bayes classifier. It is good practice to specify the class order. Assume that each predictor is conditionally normally distributed given its label.

```
Mdl = fitcnb(X,Y,'ClassNames',{'setosa','versicolor','virginica'});
```

Mdl is a trained `ClassificationNaiveBayes` classifier.

Compute the unconditional probability densities of the in-sample observations.

```
lp = logP(Mdl,X);  
histogram(lp)  
xlabel 'Log-unconditional probability'  
ylabel 'Frequency'  
title 'Histogram: Log-Unconditional Probability'
```

Identify indices of observations having log-unconditional probability less than -7.

```
idx = find(lp < -7)
```

```
idx = 3×1
```

```
    61  
   118  
   132
```

Definitions

Unconditional Probability Density

The unconditional probability density of the predictors is its distribution marginalized over the classes.

In other words, the unconditional probability density is

$$P(X_1, \dots, X_P) = \sum_{k=1}^K P(X_1, \dots, X_P, Y = k) = \sum_{k=1}^K P(X_1, \dots, X_P \mid y = k) \pi(Y = k),$$

where $\pi(Y = k)$ is the class prior probability. The conditional distribution of the data given the class ($P(X_1, \dots, X_P \mid y = k)$) and the class prior probability distributions are training options (i.e., are specified when training the classifier).

Prior Probability

The prior probability of a class is the believed relative frequency with which observations from that class occur in a population.

loss

Loss of k -nearest neighbor classifier

Syntax

```
L = loss mdl, tbl, ResponseVarName)
```

```
L = loss mdl, tbl, Y)
```

```
L = loss mdl, X, Y)
```

```
L = loss( ____, Name, Value)
```

Description

`L = loss mdl, tbl, ResponseVarName)` returns a scalar representing how well `mdl` classifies the data in `tbl` when `tbl.ResponseVarName` contains the true classifications. If `tbl` contains the response variable used to train `mdl`, then you do not need to specify `ResponseVarName`.

When computing the loss, the `loss` function normalizes the class probabilities in `tbl.ResponseVarName` to the class probabilities used for training, which are stored in the `Prior` property of `mdl`.

The meaning of the classification loss (`L`) depends on the loss function and weighting scheme, but, in general, better classifiers yield smaller classification loss values. For more details, see “Classification Loss” on page 32-3868.

`L = loss mdl, tbl, Y)` returns a scalar representing how well `mdl` classifies the data in `tbl` when `Y` contains the true classifications.

When computing the loss, the `loss` function normalizes the class probabilities in `Y` to the class probabilities used for training, which are stored in the `Prior` property of `mdl`.

`L = loss mdl, X, Y)` returns a scalar representing how well `mdl` classifies the data in `X` when `Y` contains the true classifications.

When computing the loss, the `loss` function normalizes the class probabilities in `Y` to the class probabilities used for training, which are stored in the `Prior` property of `mdl`.

`L = loss(____, Name, Value)` specifies options using one or more name-value pair arguments in addition to the input arguments in previous syntaxes. For example, you can specify the loss function and the classification weights.

Examples

Loss Calculation

Create a k -nearest neighbor classifier for the Fisher iris data, where $k = 5$.

Load the Fisher iris data set.

```
load fisheriris
```

Create a classifier for five nearest neighbors.

```
mdl = fitcknn(meas,species,'NumNeighbors',5);
```

Examine the loss of the classifier for a mean observation classified as 'versicolor'.

```
X = mean(meas);  
Y = {'versicolor'};  
L = loss(mdl,X,Y)
```

```
L = 0
```

All five nearest neighbors classify as 'versicolor'.

Input Arguments

mdl — k -nearest neighbor classifier model

ClassificationKNN object

k -nearest neighbor classifier model, specified as a ClassificationKNN object.

tbl — Sample data

table

Sample data used to train the model, specified as a table. Each row of `tbl` corresponds to one observation, and each column corresponds to one predictor variable. Optionally, `tbl`

can contain one additional column for the response variable. Multicolumn variables and cell arrays other than cell arrays of character vectors are not allowed.

If `tbl` contains the response variable used to train `mdl`, then you do not need to specify `ResponseVarName` or `Y`.

If you train `mdl` using sample data contained in a `table`, then the input data for `loss` must also be in a `table`.

Data Types: `table`

ResponseVarName — Response variable name

name of a variable in `tbl`

Response variable name, specified as the name of a variable in `tbl`. If `tbl` contains the response variable used to train `mdl`, then you do not need to specify `ResponseVarName`.

You must specify `ResponseVarName` as a character vector or string scalar. For example, if the response variable is stored as `tbl.response`, then specify it as `'response'`. Otherwise, the software treats all columns of `tbl`, including `tbl.response`, as predictors.

The response variable must be a categorical, character, or string array, logical or numeric vector, or cell array of character vectors. If the response variable is a character array, then each element must correspond to one row of the array.

Data Types: `char` | `string`

X — Predictor data

numeric matrix

Predictor data, specified as a numeric matrix. Each row of `X` represents one observation, and each column represents one variable.

Data Types: `single` | `double`

Y — Class labels

categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Class labels, specified as a categorical, character, or string array, logical or numeric vector, or cell array of character vectors. Each row of `Y` represents the classification of the corresponding row of `X`.

Data Types: `categorical` | `char` | `string` | `logical` | `single` | `double` | `cell`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example:

`loss mdl, tbl, 'response', 'LossFun', 'exponential', 'Weights', 'w'` returns the weighted exponential loss of `mdl` classifying the data in `tbl`. Here, `tbl.response` is the response variable, and `tbl.w` is the weight variable.

LossFun — Loss function

'mincost' (default) | 'binodeviance' | 'classiferror' | 'exponential' | 'hinge' | 'logit' | 'quadratic' | function handle

Loss function, specified as the comma-separated pair consisting of 'LossFun' and a built-in loss function name or a function handle.

- The following table lists the available loss functions.

Value	Description
'binodeviance'	Binomial deviance
'classiferror'	Classification error
'exponential'	Exponential
'hinge'	Hinge
'logit'	Logistic
'mincost'	Minimal expected misclassification cost (for classification scores that are posterior probabilities)
'quadratic'	Quadratic

'mincost' is appropriate for classification scores that are posterior probabilities. By default, *k*-nearest neighbor models return posterior probabilities as classification scores (see `predict`).

- You can specify a function handle for a custom loss function using @ (for example, @lossfun). Let n be the number of observations in X and K be the number of distinct classes (`numel mdl.ClassNames`). Your custom loss function must have this form:

```
function lossvalue = lossfun(C,S,W,Cost)
```

- C is an n -by- K logical matrix with rows indicating the class to which the corresponding observation belongs. The column order corresponds to the class order in `mdl.ClassNames`. Construct C by setting $C(p,q) = 1$, if observation p is in class q , for each row. Set all other elements of row p to 0.
- S is an n -by- K numeric matrix of classification scores. The column order corresponds to the class order in `mdl.ClassNames`. The argument S is a matrix of classification scores, similar to the output of `predict`.
- W is an n -by-1 numeric vector of observation weights. If you pass W , the software normalizes the weights to sum to 1.
- $Cost$ is a K -by- K numeric matrix of misclassification costs. For example, $Cost = ones(K) - eye(K)$ specifies a cost of 0 for correct classification and 1 for misclassification.
- The output argument `lossvalue` is a scalar.

For more details on loss functions, see “Classification Loss” on page 32-3868.

Data Types: `char` | `string` | `function_handle`

Weights — Observation weights

`ones(size(X,1),1)` (default) | numeric vector | name of a variable in `tbl`

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a numeric vector or the name of a variable in `tbl`.

If you specify `Weights` as a numeric vector, then the size of `Weights` must be equal to the number of rows in X or `tbl`.

If you specify `Weights` as the name of a variable in `tbl`, the name must be a character vector or string scalar. For example, if the weights are stored as `tbl.w`, then specify `Weights` as 'w'. Otherwise, the software treats all columns of `tbl`, including `tbl.w`, as predictors.

`loss` normalizes the weights so that observation weights in each class sum to the prior probability of that class. When you supply `Weights`, `loss` computes the weighted classification loss.

Example: 'Weights', 'w'

Data Types: single | double | char | string

Algorithms

Classification Loss

Classification loss functions measure the predictive inaccuracy of classification models. When you compare the same type of loss among many models, a lower loss indicates a better predictive model.

Consider the following scenario.

- L is the weighted average classification loss.
- n is the sample size.
- For binary classification:
 - y_j is the observed class label. The software codes it as -1 or 1, indicating the negative or positive class, respectively.
 - $f(X_j)$ is the raw classification score for observation (row) j of the predictor data X .
 - $m_j = y_j f(X_j)$ is the classification score for classifying observation j into the class corresponding to y_j . Positive values of m_j indicate correct classification and do not contribute much to the average loss. Negative values of m_j indicate incorrect classification and contribute significantly to the average loss.
- For algorithms that support multiclass classification (that is, $K \geq 3$):
 - y_j^* is a vector of $K - 1$ zeros, with 1 in the position corresponding to the true, observed class y_j . For example, if the true class of the second observation is the third class and $K = 4$, then $y_2^* = [0 \ 0 \ 1 \ 0]$. The order of the classes corresponds to the order in the `ClassNames` property of the input model.
 - $f(X_j)$ is the length K vector of class scores for observation j of the predictor data X . The order of the scores corresponds to the order of the classes in the `ClassNames` property of the input model.
 - $m_j = y_j^* f(X_j)$. Therefore, m_j is the scalar classification score that the model predicts for the true, observed class.

- The weight for observation j is w_j . The software normalizes the observation weights so that they sum to the corresponding prior class probability. The software also normalizes the prior probabilities so they sum to 1. Therefore,

$$\sum_{j=1}^n w_j = 1.$$

Given this scenario, the following table describes the supported loss functions that you can specify by using the 'LossFun' name-value pair argument.

Loss Function	Value of LossFun	Equation
Binomial deviance	'binodeviance'	$L = \sum_{j=1}^n w_j \log\{1 + \exp[-2m_j]\}.$
Exponential loss	'exponential'	$L = \sum_{j=1}^n w_j \exp(-m_j).$
Classification error	'classiferror'	$L = \sum_{j=1}^n w_j I\{\hat{y}_j \neq y_j\}.$ <p>It is the weighted fraction of misclassified observations where \hat{y}_j is the class label corresponding to the class with the maximal posterior probability. $I\{x\}$ is the indicator function.</p>
Hinge loss	'hinge'	$L = \sum_{j=1}^n w_j \max\{0, 1 - m_j\}.$
Logit loss	'logit'	$L = \sum_{j=1}^n w_j \log(1 + \exp(-m_j)).$

Loss Function	Value of LossFun	Equation
Minimal cost	'mincost'	<p>Minimal cost. The software computes the weighted minimal cost using this procedure for observations $j = 1, \dots, n$.</p> <ol style="list-style-type: none"> 1 Estimate the 1-by-K vector of expected classification costs for observation j: $v_j = f(X_j)'C.$ <p>$f(X_j)$ is the column vector of class posterior probabilities for binary and multiclass classification. C is the cost matrix that the input model stores in the <code>Cost</code> property.</p> 2 For observation j, predict the class label corresponding to the minimum expected classification cost: $\hat{y}_j = \min_{j = 1, \dots, K} (v_j).$ 3 Using C, identify the cost incurred (c_j) for making the prediction. <p>The weighted, average, minimum cost loss is</p> $L = \sum_{j=1}^n w_j c_j.$
Quadratic loss	'quadratic'	$L = \sum_{j=1}^n w_j (1 - m_j)^2.$

This figure compares the loss functions (except 'mincost') for one observation over m . Some functions are normalized to pass through [0,1].

True Misclassification Cost

Two costs are associated with KNN classification: the true misclassification cost per class and the expected misclassification cost per observation.

You can set the true misclassification cost per class by using the 'Cost' name-value pair argument when you run `fitcknn`. The value `Cost(i, j)` is the cost of classifying an observation into class `j` if its true class is `i`. By default, `Cost(i, j) = 1` if `i ~= j`, and `Cost(i, j) = 0` if `i = j`. In other words, the cost is 0 for correct classification and 1 for incorrect classification.

Expected Cost

Two costs are associated with KNN classification: the true misclassification cost per class and the expected misclassification cost per observation. The third output of `predict` is the expected misclassification cost per observation.

Suppose you have `Nobs` observations that you want to classify with a trained classifier `mdl`, and you have `K` classes. You place the observations into a matrix `Xnew` with one observation per row. The command

```
[label,score,cost] = predict(mdl,Xnew)
```

returns a matrix `cost` of size `Nobs`-by-`K`, among other outputs. Each row of the `cost` matrix contains the expected (average) cost of classifying the observation into each of the `K` classes. `cost(n,j)` is

$$\sum_{i=1}^K \widehat{P}(i|Xnew(n))C(j|i),$$

where

- K is the number of classes.
- $\widehat{P}(i|Xnew(n))$ is the posterior probability on page 32-5188 of class i for observation $Xnew(n)$.
- $C(j|i)$ is the true misclassification cost of classifying an observation as j when its true class is i .

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. For more information, see “Tall Arrays” (MATLAB).

Introduced in R2012a

loss

Class: ClassificationLinear

Classification loss for linear classification models

Syntax

`L = loss(Mdl,X,Y)`

`L = loss(___,Name,Value)`

Description

`L = loss(Mdl,X,Y)` returns the classification losses on page 32-3884 for the binary, linear classification model `Mdl` using predictor data in `X` and corresponding class labels in `Y`. `L` contains classification error rates for each regularization strength in `Mdl`.

`L = loss(___,Name,Value)` uses any of the previous syntaxes and additional options specified by one or more `Name,Value` pair arguments. For example, you can specify that columns in the predictor data correspond to observations or specify the classification loss function.

Input Arguments

Mdl — Binary, linear classification model

ClassificationLinear model object

Binary, linear classification model, specified as a ClassificationLinear model object. You can create a ClassificationLinear model object using `fitlinear`.

X — Predictor data

full matrix | sparse matrix

Predictor data, specified as an n -by- p full or sparse matrix. This orientation of X indicates that rows correspond to individual observations, and columns correspond to individual predictor variables.

Note If you orient your predictor matrix so that observations correspond to columns and specify 'ObservationsIn', 'columns', then you might experience a significant reduction in computation time.

The length of Y and the number of observations in X must be equal.

Data Types: `single` | `double`

Y — Class labels

categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Class labels, specified as a categorical, character, or string array, logical or numeric vector, or cell array of character vectors.

- The data type of Y must be the same as the data type of `Mdl.ClassNames`. (The software treats string arrays as cell arrays of character vectors.)
- The distinct classes in Y must be a subset of `Mdl.ClassNames`.
- If Y is a character array, then each element must correspond to one row of the array.
- The length of Y and the number of observations in X must be equal.

Data Types: `categorical` | `char` | `string` | `logical` | `single` | `double` | `cell`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

LossFun — Loss function

'classiferror' (default) | 'binodeviance' | 'exponential' | 'hinge' | 'logit' | 'mincost' | 'quadratic' | function handle

Loss function, specified as the comma-separated pair consisting of 'LossFun' and a built-in, loss-function name or function handle.

- The following table lists the available loss functions. Specify one using its corresponding character vector or string scalar.

Value	Description
'binodeviance'	Binomial deviance
'classiferror'	Classification error
'exponential'	Exponential
'hinge'	Hinge
'logit'	Logistic
'mincost'	Minimal expected misclassification cost (for classification scores that are posterior probabilities)
'quadratic'	Quadratic

'mincost' is appropriate for classification scores that are posterior probabilities. For linear classification models, logistic regression learners return posterior probabilities as classification scores by default, but SVM learners do not (see `predict`).

- Specify your own function by using function handle notation.

Let n be the number of observations in X and K be the number of distinct classes (`numel(Mdl.ClassNames)`, where `Mdl` is the input model). Your function must have this signature:

```
lossvalue = lossfun(C,S,W,Cost)
```

- The output argument `lossvalue` is a scalar.
- You choose the function name (`lossfun`).
- `C` is an n -by- K logical matrix with rows indicating the class to which the corresponding observation belongs. The column order corresponds to the class order in `Mdl.ClassNames`.

Construct `C` by setting $C(p, q) = 1$, if observation p is in class q , for each row. Set all other elements of row p to 0 .

- `S` is an n -by- K numeric matrix of classification scores. The column order corresponds to the class order in `Mdl.ClassNames`. `S` is a matrix of classification scores, similar to the output of `predict`.

- W is an n -by-1 numeric vector of observation weights. If you pass W , the software normalizes the weights to sum to 1.
- $Cost$ is a K -by- K numeric matrix of misclassification costs. For example, $Cost = ones(K) - eye(K)$ specifies a cost of 0 for correct classification, and 1 for misclassification.

Example: 'LossFun', @lossfun

Data Types: char | string | function_handle

ObservationsIn — Predictor data observation dimension

'rows' (default) | 'columns'

Predictor data observation dimension, specified as the comma-separated pair consisting of 'ObservationsIn' and 'columns' or 'rows'.

Note If you orient your predictor matrix so that observations correspond to columns and specify 'ObservationsIn', 'columns', then you might experience a significant reduction in optimization-execution time.

Weights — Observation weights

numeric vector of positive values

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a numeric vector of positive values. If you supply weights, `loss` computes the weighted classification loss.

Let n be the number of observations in X .

- $numel(Weights)$ must be n .
- By default, $Weights$ is $ones(n, 1)$.

`loss` normalizes $Weights$ to sum up to the value of the prior probability in the respective class.

Data Types: double | single

Output Arguments

L — Classification losses

numeric scalar | numeric row vector

Classification losses, returned as a numeric scalar or row vector. The interpretation of L depends on `Weights` and `LossFun`.

L is the same size as `Mdl.Lambda`. $L(j)$ is the classification loss of the linear classification model trained using the regularization strength `Mdl.Lambda(j)`.

Examples

Estimate Test-Sample Classification Loss

Load the NLP data set.

```
load nlpdata
```

X is a sparse matrix of predictor data, and Y is a categorical vector of class labels. There are more than two classes in the data.

The models should identify whether the word counts in a web page are from the Statistics and Machine Learning Toolbox™ documentation. So, identify the labels that correspond to the Statistics and Machine Learning Toolbox™ documentation web pages.

```
Ystats = Y == 'stats';
```

Train a binary, linear classification model that can identify whether the word counts in a documentation web page are from the Statistics and Machine Learning Toolbox™ documentation. Specify to hold out 30% of the observations. Optimize the objective function using `SpaRSA`.

```
rng(1); % For reproducibility  
CVMdl = fitlinear(X,Ystats,'Solver','sparsa','Holdout',0.30);  
Cmdl = CVMdl.Trained{1};
```

`CVMdl` is a `ClassificationPartitionedLinear` model. It contains the property `Trained`, which is a 1-by-1 cell array holding a `ClassificationLinear` model that the software trained using the training set.

Extract the training and test data from the partition definition.

```
trainIdx = training(CVMdl.Partition);
testIdx = test(CVMdl.Partition);
```

Estimate the training- and test-sample classification error.

```
ceTrain = loss(CMdl,X(trainIdx,:),Ystats(trainIdx))
```

```
ceTrain = 1.3572e-04
```

```
ceTest = loss(CMdl,X(testIdx,:),Ystats(testIdx))
```

```
ceTest = 5.2804e-04
```

Because there is one regularization strength in CMdl, ceTrain and ceTest are numeric scalars.

Specify Custom Classification Loss

Load the NLP data set. Preprocess the data as in “Estimate Test-Sample Classification Loss” on page 32-3878, and transpose the predictor data.

```
load nlpdata
Ystats = Y == 'stats';
X = X';
```

Train a binary, linear classification model. Specify to hold out 30% of the observations. Optimize the objective function using SpaRSA. Specify that the predictor observations correspond to columns.

```
rng(1); % For reproducibility
CVMdl = fitlinear(X,Ystats,'Solver','sparsa','Holdout',0.30,...
    'ObservationsIn','columns');
CMdl = CVMdl.Trained{1};
```

CVMdl is a ClassificationPartitionedLinear model. It contains the property Trained, which is a 1-by-1 cell array holding a ClassificationLinear model that the software trained using the training set.

Extract the training and test data from the partition definition.

```
trainIdx = training(CVMdl.Partition);  
testIdx = test(CVMdl.Partition);
```

Create an anonymous function that measures linear loss, that is,

$$L = \frac{\sum_j -w_j y_j f_j}{\sum_j w_j}.$$

w_j is the weight for observation j , y_j is response j (-1 for the negative class, and 1 otherwise), and f_j is the raw classification score of observation j . Custom loss functions must be written in a particular form. For rules on writing a custom loss function, see the `LossFun` name-value pair argument.

```
linearloss = @(C,S,W,Cost)sum(-W.*sum(S.*C,2))/sum(W);
```

Estimate the training- and test-sample classification loss using the linear loss function.

```
ceTrain = loss(CMdl,X(:,trainIdx),Ystats(trainIdx),'LossFun',linearloss,...  
    'ObservationsIn','columns')
```

```
ceTrain = -7.8330
```

```
ceTest = loss(CMdl,X(:,testIdx),Ystats(testIdx),'LossFun',linearloss,...  
    'ObservationsIn','columns')
```

```
ceTest = -7.7383
```

Find Good Lasso Penalty Using Classification Loss

To determine a good lasso-penalty strength for a linear classification model that uses a logistic regression learner, compare test-sample classification error rates.

Load the NLP data set. Preprocess the data as in “Specify Custom Classification Loss” on page 32-3879.

```
load nlpdata  
Ystats = Y == 'stats';  
X = X';  
  
rng(10); % For reproducibility  
Partition = cvpartition(Ystats,'Holdout',0.30);
```

```
testIdx = test(Partition);
XTest = X(:,testIdx);
YTest = Ystats(testIdx);
```

Create a set of 11 logarithmically-spaced regularization strengths from 10^{-6} through $10^{-0.5}$.

```
Lambda = logspace(-6, -0.5, 11);
```

Train binary, linear classification models that use each of the regularization strengths. Optimize the objective function using SpaRSA. Lower the tolerance on the gradient of the objective function to $1e-8$.

```
CVMdl = fitlinear(X, Ystats, 'ObservationsIn', 'columns', ...
    'CVPartition', Partition, 'Learner', 'logistic', 'Solver', 'sparsa', ...
    'Regularization', 'lasso', 'Lambda', Lambda, 'GradientTolerance', 1e-8)
```

```
CVMdl =
classreg.learning.partition.ClassificationPartitionedLinear
  CrossValidatedModel: 'Linear'
  ResponseName: 'Y'
  NumObservations: 31572
  KFold: 1
  Partition: [1x1 cvpartition]
  ClassNames: [0 1]
  ScoreTransform: 'none'
```

Properties, Methods

Extract the trained linear classification model.

```
Mdl = CVMdl.Trained{1}
```

```
Mdl =
ClassificationLinear
  ResponseName: 'Y'
  ClassNames: [0 1]
  ScoreTransform: 'logit'
  Beta: [34023x11 double]
  Bias: [1x11 double]
  Lambda: [1x11 double]
  Learner: 'logistic'
```

Properties, Methods

`Mdl` is a `ClassificationLinear` model object. Because `Lambda` is a sequence of regularization strengths, you can think of `Mdl` as 11 models, one for each regularization strength in `Lambda`.

Estimate the test-sample classification error.

```
ce = loss(Mdl,X(:,testIdx),Ystats(testIdx),'ObservationsIn','columns');
```

Because there are 11 regularization strengths, `ce` is a 1-by-11 vector of classification error rates.

Higher values of `Lambda` lead to predictor variable sparsity, which is a good quality of a classifier. For each regularization strength, train a linear classification model using the entire data set and the same options as when you cross-validated the models. Determine the number of nonzero coefficients per model.

```
Mdl = fitclinear(X,Ystats,'ObservationsIn','columns',...  
    'Learner','logistic','Solver','sparsa','Regularization','lasso',...  
    'Lambda',Lambda,'GradientTolerance',1e-8);  
numNZCoeff = sum(Mdl.Beta~=0);
```

In the same figure, plot the test-sample error rates and frequency of nonzero coefficients for each regularization strength. Plot all variables on the log scale.

```
figure;  
[h,hL1,hL2] = plotyy(log10(Lambda),log10(ce),...  
    log10(Lambda),log10(numNZCoeff + 1));  
hL1.Marker = 'o';  
hL2.Marker = 'o';  
ylabel(h(1),'log_{10} classification error')  
ylabel(h(2),'log_{10} nonzero-coefficient frequency')  
xlabel('log_{10} Lambda')  
title('Test-Sample Statistics')  
hold off
```

Choose the index of the regularization strength that balances predictor variable sparsity and low classification error. In this case, a value between 10^{-4} to 10^{-1} should suffice.

```
idxFinal = 7;
```

Select the model from `Mdl` with the chosen regularization strength.

```
MdlFinal = selectModels(Mdl,idxFinal);
```

`MdlFinal` is a `ClassificationLinear` model containing one regularization strength. To estimate labels for new observations, pass `MdlFinal` and the new data to `predict`.

Definitions

Classification Loss

Classification loss functions measure the predictive inaccuracy of classification models. When you compare the same type of loss among many models, a lower loss indicates a better predictive model.

Consider the following scenario.

- L is the weighted average classification loss.
- n is the sample size.
- For binary classification:
 - y_j is the observed class label. The software codes it as -1 or 1 , indicating the negative or positive class, respectively.
 - $f(X_j)$ is the raw classification score for observation (row) j of the predictor data X .
 - $m_j = y_j f(X_j)$ is the classification score for classifying observation j into the class corresponding to y_j . Positive values of m_j indicate correct classification and do not contribute much to the average loss. Negative values of m_j indicate incorrect classification and contribute significantly to the average loss.
- For algorithms that support multiclass classification (that is, $K \geq 3$):
 - y_j^* is a vector of $K - 1$ zeros, with 1 in the position corresponding to the true, observed class y_j . For example, if the true class of the second observation is the third class and $K = 4$, then $y_2^* = [0 \ 0 \ 1 \ 0]$. The order of the classes corresponds to the order in the `ClassNames` property of the input model.
 - $f(X_j)$ is the length K vector of class scores for observation j of the predictor data X . The order of the scores corresponds to the order of the classes in the `ClassNames` property of the input model.
 - $m_j = y_j^* f(X_j)$. Therefore, m_j is the scalar classification score that the model predicts for the true, observed class.
- The weight for observation j is w_j . The software normalizes the observation weights so that they sum to the corresponding prior class probability. The software also normalizes the prior probabilities so they sum to 1 . Therefore,

$$\sum_{j=1}^n w_j = 1.$$

Given this scenario, the following table describes the supported loss functions that you can specify by using the 'LossFun' name-value pair argument.

Loss Function	Value of LossFun	Equation
Binomial deviance	'binodeviance'	$L = \sum_{j=1}^n w_j \log\{1 + \exp[-2m_j]\}.$
Exponential loss	'exponential'	$L = \sum_{j=1}^n w_j \exp(-m_j).$
Classification error	'classiferror'	$L = \sum_{j=1}^n w_j I\{\hat{y}_j \neq y_j\}.$ <p>It is the weighted fraction of misclassified observations where \hat{y}_j is the class label corresponding to the class with the maximal posterior probability. $I\{x\}$ is the indicator function.</p>
Hinge loss	'hinge'	$L = \sum_{j=1}^n w_j \max\{0, 1 - m_j\}.$
Logit loss	'logit'	$L = \sum_{j=1}^n w_j \log(1 + \exp(-m_j)).$

Loss Function	Value of LossFun	Equation
Minimal cost	'mincost'	<p>Minimal cost. The software computes the weighted minimal cost using this procedure for observations $j = 1, \dots, n$.</p> <ol style="list-style-type: none"> Estimate the 1-by-K vector of expected classification costs for observation j: $v_j = f(X_j)'C.$ <p>$f(X_j)$ is the column vector of class posterior probabilities for binary and multiclass classification. C is the cost matrix that the input model stores in the <code>Cost</code> property.</p> For observation j, predict the class label corresponding to the minimum expected classification cost: $\hat{y}_j = \min_{j = 1, \dots, K} (v_j).$ Using C, identify the cost incurred (c_j) for making the prediction. <p>The weighted, average, minimum cost loss is</p> $L = \sum_{j=1}^n w_j c_j.$
Quadratic loss	'quadratic'	$L = \sum_{j=1}^n w_j (1 - m_j)^2.$

This figure compares the loss functions (except 'mincost') for one observation over m . Some functions are normalized to pass through [0,1].

Algorithms

By default, observation weights are prior class probabilities. If you supply weights using `Weights`, then the software normalizes them to sum to the prior probabilities in the respective classes. The software uses the renormalized weights to estimate the weighted classification loss.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. For more information, see “Tall Arrays” (MATLAB).

`ClassificationLinear` | `fitclinear` | `predict`

Introduced in R2016a

loss

Classification error

Syntax

```
L = loss(obj,X,Y)
L = loss(obj,X,Y,Name,Value)
```

Description

`L = loss(obj,X,Y)` returns the classification loss on page 32-3892, which is a scalar representing how well `obj` classifies the data in `X`, when `Y` contains the true classifications.

When computing the loss, `loss` normalizes the class probabilities in `Y` to the class probabilities used for training, stored in the `Prior` property of `obj`.

`L = loss(obj,X,Y,Name,Value)` returns the loss with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

`obj`

Discriminant analysis classifier of class `ClassificationDiscriminant` or `CompactClassificationDiscriminant`, typically constructed with `fitcdiscr`.

`X`

Matrix where each row represents an observation, and each column represents a predictor. The number of columns in `X` must equal the number of predictors in `obj`.

Y

Class labels, with the same data type as exists in `obj`. The number of elements of `Y` must equal the number of rows of `X`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

LossFun

Built-in, loss-function name (character vector or string scalar in the table) or function handle.

- The following table lists the available loss functions. Specify one using the corresponding value.

Value	Description
'binodeviance'	Binomial deviance
'classiferror'	Classification error
'exponential'	Exponential
'hinge'	Hinge
'logit'	Logistic
'mincost'	Minimal expected misclassification cost (for classification scores that are posterior probabilities)
'quadratic'	Quadratic

'mincost' is appropriate for classification scores that are posterior probabilities. Discriminant analysis models return posterior probabilities as classification scores by default (see `predict`).

- Specify your own function using function handle notation.

Suppose that n be the number of observations in `X` and K be the number of distinct classes (`numel(Mdl.ClassNames)`). Your function must have this signature

```
lossvalue = lossfun(C,S,W,Cost)
```

where:

- The output argument `lossvalue` is a scalar.
- You choose the function name (*lossfun*).
- `C` is an n -by- K logical matrix with rows indicating which class the corresponding observation belongs. The column order corresponds to the class order in `Mdl.ClassNames`.

Construct `C` by setting $C(p, q) = 1$ if observation p is in class q , for each row. Set all other elements of row p to 0 .

- `S` is an n -by- K numeric matrix of classification scores. The column order corresponds to the class order in `Mdl.ClassNames`. `S` is a matrix of classification scores, similar to the output of `predict`.
- `W` is an n -by-1 numeric vector of observation weights. If you pass `W`, the software normalizes them to sum to 1.
- `Cost` is a K -by- K numeric matrix of misclassification costs. For example, `Cost = ones(K) - eye(K)` specifies a cost of 0 for correct classification, and 1 for misclassification.

Specify your function using `'LossFun', @lossfun`.

For more details on loss functions, see “Classification Loss” on page 32-3892.

Default: `'mincost'`

Weights

Numeric vector of length N , where N is the number of rows of `X`. `weights` are nonnegative. `loss` normalizes the weights so that observation weights in each class sum to the prior probability of that class. When you supply `weights`, `loss` computes weighted classification loss.

Default: `ones(N, 1)`

Output Arguments

L

Classification loss on page 32-3892, a scalar. The interpretation of **L** depends on the values in `weights` and `lossfun`.

Examples

Estimate Classification Error

Load Fisher's iris data set.

```
load fisheriris
```

Train a discriminant analysis model using all observations in the data.

```
Mdl = fitcdiscr(meas,species);
```

Estimate the classification error of the model using the training observations.

```
L = loss(Mdl,meas,species)
```

```
L = 0.0200
```

Alternatively, if `Mdl` is not compact, then you can estimate the training-sample classification error by passing `Mdl` to `resubLoss`.

Definitions

Classification Loss

Classification loss functions measure the predictive inaccuracy of classification models. When you compare the same type of loss among many models, a lower loss indicates a better predictive model.

Consider the following scenario.

- L is the weighted average classification loss.
- n is the sample size.
- For binary classification:
 - y_j is the observed class label. The software codes it as -1 or 1, indicating the negative or positive class, respectively.
 - $f(X_j)$ is the raw classification score for observation (row) j of the predictor data X .
 - $m_j = y_j f(X_j)$ is the classification score for classifying observation j into the class corresponding to y_j . Positive values of m_j indicate correct classification and do not contribute much to the average loss. Negative values of m_j indicate incorrect classification and contribute significantly to the average loss.
- For algorithms that support multiclass classification (that is, $K \geq 3$):
 - y_j^* is a vector of $K - 1$ zeros, with 1 in the position corresponding to the true, observed class y_j . For example, if the true class of the second observation is the third class and $K = 4$, then $y_2^* = [0 \ 0 \ 1 \ 0]$. The order of the classes corresponds to the order in the `ClassNames` property of the input model.
 - $f(X_j)$ is the length K vector of class scores for observation j of the predictor data X . The order of the scores corresponds to the order of the classes in the `ClassNames` property of the input model.
 - $m_j = y_j^* f(X_j)$. Therefore, m_j is the scalar classification score that the model predicts for the true, observed class.
- The weight for observation j is w_j . The software normalizes the observation weights so that they sum to the corresponding prior class probability. The software also normalizes the prior probabilities so they sum to 1. Therefore,

$$\sum_{j=1}^n w_j = 1.$$

Given this scenario, the following table describes the supported loss functions that you can specify by using the 'LossFun' name-value pair argument.

Loss Function	Value of LossFun	Equation
Binomial deviance	'binodeviance'	$L = \sum_{j=1}^n w_j \log\{1 + \exp[-2m_j]\}.$

Loss Function	Value of LossFun	Equation
Exponential loss	'exponential'	$L = \sum_{j=1}^n w_j \exp(-m_j).$
Classification error	'classiferror'	$L = \sum_{j=1}^n w_j I\{\hat{y}_j \neq y_j\}.$ <p>It is the weighted fraction of misclassified observations where \hat{y}_j is the class label corresponding to the class with the maximal posterior probability. $I\{x\}$ is the indicator function.</p>
Hinge loss	'hinge'	$L = \sum_{j=1}^n w_j \max\{0, 1 - m_j\}.$
Logit loss	'logit'	$L = \sum_{j=1}^n w_j \log(1 + \exp(-m_j)).$

Loss Function	Value of LossFun	Equation
Minimal cost	'mincost'	<p>Minimal cost. The software computes the weighted minimal cost using this procedure for observations $j = 1, \dots, n$.</p> <ol style="list-style-type: none"> 1 Estimate the 1-by-K vector of expected classification costs for observation j: $v_j = f(X_j)'C.$ <p>$f(X_j)$ is the column vector of class posterior probabilities for binary and multiclass classification. C is the cost matrix that the input model stores in the <code>Cost</code> property.</p> 2 For observation j, predict the class label corresponding to the minimum expected classification cost: $\hat{y}_j = \min_{j=1, \dots, K} (v_j).$ 3 Using C, identify the cost incurred (c_j) for making the prediction. <p>The weighted, average, minimum cost loss is</p> $L = \sum_{j=1}^n w_j c_j.$
Quadratic loss	'quadratic'	$L = \sum_{j=1}^n w_j (1 - m_j)^2.$

This figure compares the loss functions (except 'mincost') for one observation over m . Some functions are normalized to pass through [0,1].

Posterior Probability

The posterior probability that a point z belongs to class j is the product of the prior probability and the multivariate normal density. The density function of the multivariate normal with mean μ_j and covariance Σ_j at a point z is

$$P(x|k) = \frac{1}{(2\pi|\Sigma_k|)^{1/2}} \exp\left(-\frac{1}{2}(x - \mu_k)^T \Sigma_k^{-1} (x - \mu_k)\right),$$

where $|\Sigma_k|$ is the determinant of Σ_k , and Σ_k^{-1} is the inverse matrix.

Let $P(k)$ represent the prior probability of class k . Then the posterior probability that an observation x is of class k is

$$\hat{P}(k|x) = \frac{P(x|k)P(k)}{P(x)},$$

where $P(x)$ is a normalization constant, the sum over k of $P(x|k)P(k)$.

Prior Probability

The prior probability is one of three choices:

- 'uniform' — The prior probability of class k is one over the total number of classes.
- 'empirical' — The prior probability of class k is the number of training samples of class k divided by the total number of training samples.
- Custom — The prior probability of class k is the k th element of the `prior` vector. See `fitcdiscr`.

After creating a classification model (`Mdl`) you can set the prior using dot notation:

```
Mdl.Prior = v;
```

where v is a vector of positive elements representing the frequency with which each element occurs. You do not need to retrain the classifier when you set a new prior.

Cost

The matrix of expected costs per observation is defined in “Cost” on page 20-7.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. For more information, see “Tall Arrays” (MATLAB).

Topics

“Discriminant Analysis Classification” on page 20-2

loss

Package:

Classification loss for multiclass error-correcting output codes (ECOC) model

Syntax

`L = loss(Mdl, tbl, ResponseVarName)`

`L = loss(Mdl, tbl, Y)`

`L = loss(Mdl, X, Y)`

`L = loss(____, Name, Value)`

Description

`L = loss(Mdl, tbl, ResponseVarName)` returns the classification loss (L), a scalar representing how well the trained multiclass error-correcting output codes (ECOC) model `Mdl` classifies the predictor data in `tbl` compared to the true class labels in `tbl.ResponseVarName`. By default, `loss` uses the classification error on page 32-3908 to compute L.

`L = loss(Mdl, tbl, Y)` returns the classification loss for the predictor data in table `tbl` and the true class labels in `Y`.

`L = loss(Mdl, X, Y)` returns the classification loss for the predictor data in matrix `X` and the true class labels in `Y`.

`L = loss(____, Name, Value)` specifies options using one or more name-value pair arguments in addition to any of the input argument combinations in previous syntaxes. For example, you can specify a decoding scheme, classification loss function, and verbosity level.

Examples

Determine Test-Sample Loss of ECOC Model

Load Fisher's iris data set. Specify the predictor data X , the response data Y , and the order of the classes in Y .

```
load fisheriris
X = meas;
Y = categorical(species);
classOrder = unique(Y); % Class order
rng(1); % For reproducibility
```

Train an ECOC model using SVM binary classifiers. Specify a 15% holdout sample, standardize the predictors using an SVM template, and specify the class order.

```
t = templateSVM('Standardize',true);
PMdl = fitcecoc(X,Y,'Holdout',0.15,'Learners',t,'ClassNames',classOrder);
Mdl = PMdl.Trained{1}; % Extract trained, compact classifier
```

`PMdl` is a `ClassificationPartitionedECOC` model. It has the property `Trained`, a 1-by-1 cell array containing the `CompactClassificationECOC` model that the software trained using the training set.

Estimate the test-sample classification error, which is the default classification loss.

```
testInds = test(PMdl.Partition); % Extract the test indices
XTest = X(testInds,:);
YTest = Y(testInds,:);
L = loss(Mdl,XTest,YTest)

L = 0
```

The ECOC model correctly classifies all irises in the test sample.

Determine ECOC Model Quality Using Custom Loss

Determine the quality of an ECOC model by using a custom loss function that considers the minimal binary loss for each observation.

Load Fisher's iris data set. Specify the predictor data X , the response data Y , and the order of the classes in Y .

```
load fisheriris
X = meas;
```

```
Y = categorical(species);
classOrder = unique(Y); % Class order
rng(1) % For reproducibility
```

Train an ECOC model using SVM binary classifiers. Specify a 15% holdout sample, standardize the predictors using an SVM template, and define the class order.

```
t = templateSVM('Standardize',true);
PMdl = fitcecoc(X,Y,'Holdout',0.15,'Learners',t,'ClassNames',classOrder);
Mdl = PMdl.Trained{1}; % Extract trained, compact classifier
```

PMdl is a `ClassificationPartitionedECOC` model. It has the property `Trained`, a 1-by-1 cell array containing the `CompactClassificationECOC` model that the software trained using the training set.

Create a function that takes the minimal loss for each observation, then averages the minimal losses for all observations. `S` corresponds to the `NegLoss` output of `predict`.

```
lossfun = @(~,S,~,~)mean(min(-S,[],2));
```

Compute the test-sample custom loss.

```
testInds = test(PMdl.Partition); % Extract the test indices
XTest = X(testInds,:);
YTest = Y(testInds,:);
loss(Mdl,XTest,YTest,'LossFun',lossfun)
```

```
ans = 0.0033
```

The average minimal binary loss for the test-sample observations is 0.0033.

Input Arguments

Mdl — Full or compact multiclass ECOC model

`ClassificationECOC` model object | `CompactClassificationECOC` model object

Full or compact multiclass ECOC model, specified as a `ClassificationECOC` or `CompactClassificationECOC` model object.

To create a full or compact ECOC model, see `ClassificationECOC` or `CompactClassificationECOC`.

tbl — Sample data

table

Sample data, specified as a table. Each row of `tbl` corresponds to one observation, and each column corresponds to one predictor variable. Optionally, `tbl` can contain additional columns for the response variable and observation weights. `tbl` must contain all the predictors used to train `Mdl`. Multicolumn variables and cell arrays other than cell arrays of character vectors are not allowed.

If you train `Mdl` using sample data contained in a `table`, then the input data for `loss` must also be in a table.

Note If `Mdl.BinaryLearners` contains linear or kernel classification models (`ClassificationLinear` or `ClassificationKernel` model objects), then you cannot specify sample data in a `table`. Instead, pass a matrix (X) and class labels (Y).

When training `Mdl`, assume that you set `'Standardize', true` for a template object specified in the `'Learners'` name-value pair argument of `fitcecoc`. In this case, for the corresponding binary learner j , the software standardizes the columns of the new predictor data using the corresponding means in `Mdl.BinaryLearner{j}.Mu` and standard deviations in `Mdl.BinaryLearner{j}.Sigma`.

Data Types: `table`

ResponseVarName — Response variable namename of variable in `tbl`

Response variable name, specified as the name of a variable in `tbl`. If `tbl` contains the response variable used to train `Mdl`, then you do not need to specify `ResponseVarName`.

If you specify `ResponseVarName`, then you must do so as a character vector or string scalar. For example, if the response variable is stored as `tbl.y`, then specify `ResponseVarName` as `'y'`. Otherwise, the software treats all columns of `tbl`, including `tbl.y`, as predictors.

The response variable must be a categorical, character, or string array, a logical or numeric vector, or a cell array of character vectors. If the response variable is a character array, then each element must correspond to one row of the array.

Data Types: `char` | `string`

X — Predictor data

numeric matrix

Predictor data, specified as a numeric matrix.

Each row of `X` corresponds to one observation, and each column corresponds to one variable. The variables in the columns of `X` must be the same as the variables that trained the classifier `Mdl`.

The number of rows in `X` must equal the number of rows in `Y`.

When training `Mdl`, assume that you set `'Standardize', true` for a template object specified in the `'Learners'` name-value pair argument of `fitcecoc`. In this case, for the corresponding binary learner `j`, the software standardizes the columns of the new predictor data using the corresponding means in `Mdl.BinaryLearner{j}.Mu` and standard deviations in `Mdl.BinaryLearner{j}.Sigma`.

Data Types: `double` | `single`

Y — Class labels

categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Class labels, specified as a categorical, character, or string array, a logical or numeric vector, or a cell array of character vectors. `Y` must have the same data type as `Mdl.ClassNames`. (The software treats string arrays as cell arrays of character vectors.)

The number of rows in `Y` must equal the number of rows in `tbl` or `X`.

Data Types: `categorical` | `char` | `string` | `logical` | `single` | `double` | `cell`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `loss(Mdl,X,Y,'BinaryLoss','hinge','LossFun',@lossfun)` specifies `'hinge'` as the binary learner loss function and the custom function handle `@lossfun` as the overall loss function.

BinaryLoss — Binary learner loss function

'hamming' | 'linear' | 'logit' | 'exponential' | 'binodeviance' | 'hinge' | 'quadratic' | function handle

Binary learner loss function, specified as the comma-separated pair consisting of 'BinaryLoss' and a built-in loss function name or function handle.

- This table describes the built-in functions, where y_j is a class label for a particular binary learner (in the set $\{-1, 1, 0\}$), s_j is the score for observation j , and $g(y_j, s_j)$ is the binary loss formula.

Value	Description	Score Domain	$g(y_j, s_j)$
'binodeviance'	Binomial deviance	$(-\infty, \infty)$	$\log[1 + \exp(-2y_j s_j)] / [2\log(2)]$
'exponential'	Exponential	$(-\infty, \infty)$	$\exp(-y_j s_j) / 2$
'hamming'	Hamming	$[0, 1]$ or $(-\infty, \infty)$	$[1 - \text{sign}(y_j s_j)] / 2$
'hinge'	Hinge	$(-\infty, \infty)$	$\max(0, 1 - y_j s_j) / 2$
'linear'	Linear	$(-\infty, \infty)$	$(1 - y_j s_j) / 2$
'logit'	Logistic	$(-\infty, \infty)$	$\log[1 + \exp(-y_j s_j)] / [2\log(2)]$
'quadratic'	Quadratic	$[0, 1]$	$[1 - y_j(2s_j - 1)]^2 / 2$

The software normalizes binary losses so that the loss is 0.5 when $y_j = 0$. Also, the software calculates the mean binary loss for each class.

- For a custom binary loss function, for example `customFunction`, specify its function handle 'BinaryLoss', @customFunction.

`customFunction` has this form:

```
bLoss = customFunction(M,s)
```

where:

- M is the K -by- L coding matrix stored in `Mdl.CodingMatrix`.
- s is the 1-by- L row vector of classification scores.
- `bLoss` is the classification loss. This scalar aggregates the binary losses for every learner in a particular class. For example, you can use the mean binary loss to aggregate the loss over the learners for each class.

- K is the number of classes.
- L is the number of binary learners.

For an example of passing a custom binary loss function, see “Predict Test-Sample Labels of ECOC Model Using Custom Binary Loss Function” on page 32-5219.

The default `BinaryLoss` value depends on the score ranges returned by the binary learners. This table describes some default `BinaryLoss` values based on the given assumptions.

Assumption	Default Value
All binary learners are SVMs or either linear or kernel classification models of SVM learners.	'hinge'
All binary learners are ensembles trained by <code>AdaboostM1</code> or <code>GentleBoost</code> .	'exponential'
All binary learners are ensembles trained by <code>LogitBoost</code> .	'binodeviance'
All binary learners are linear or kernel classification models of logistic regression learners. Or, you specify to predict class posterior probabilities by setting <code>'FitPosterior', true</code> in <code>fitcecoc</code> .	'quadratic'

To check the default value, use dot notation to display the `BinaryLoss` property of the trained model at the command line.

Example: `'BinaryLoss', 'binodeviance'`

Data Types: `char` | `string` | `function_handle`

Decoding — Decoding scheme

`'lossweighted'` (default) | `'lossbased'`

Decoding scheme that aggregates the binary losses, specified as the comma-separated pair consisting of `'Decoding'` and `'lossweighted'` or `'lossbased'`. For more information, see “Binary Loss” on page 32-3909.

Example: `'Decoding', 'lossbased'`

LossFun — Loss function

`'classiferror'` (default) | `function_handle`

Loss function, specified as the comma-separated pair consisting of `'LossFun'` and `'classiferror'` or a function handle.

- Specify the built-in function 'classiferror'. In this case, the loss function is the classification error on page 32-3908, which is the proportion of misclassified observations.
- Or, specify your own function using function handle notation.

Assume that $n = \text{size}(X,1)$ is the sample size and K is the number of classes. Your function must have the signature `lossvalue = lossfun(C,S,W,Cost)`, where:

- The output argument `lossvalue` is a scalar.
- You specify the function name (*lossfun*).
- C is an n -by- K logical matrix with rows indicating the class to which the corresponding observation belongs. The column order corresponds to the class order in `Mdl.ClassNames`.

Construct C by setting $C(p,q) = 1$ if observation p is in class q , for each row. Set all other elements of row p to 0.

- S is an n -by- K numeric matrix of negated loss values for the classes. Each row corresponds to an observation. The column order corresponds to the class order in `Mdl.ClassNames`. The input S resembles the output argument `NegLoss` of `predict`.
- W is an n -by-1 numeric vector of observation weights. If you pass W , the software normalizes its elements to sum to 1.
- $Cost$ is a K -by- K numeric matrix of misclassification costs. For example, `Cost = ones(K) - eye(K)` specifies a cost of 0 for correct classification and 1 for misclassification.

Specify your function using 'LossFun',@lossfun.

Data Types: char | string | function_handle

ObservationsIn — Predictor data observation dimension

'rows' (default) | 'columns'

Predictor data observation dimension, specified as the comma-separated pair consisting of 'ObservationsIn' and 'columns' or 'rows'. `Mdl.BinaryLearners` must contain `ClassificationLinear` models.

Note If you orient your predictor matrix so that observations correspond to columns and specify 'ObservationsIn', 'columns', you can experience a significant reduction in execution time.

Options — Estimation options

[] (default) | structure array returned by `statset`

Estimation options, specified as the comma-separated pair consisting of 'Options' and a structure array returned by `statset`.

To invoke parallel computing:

- You need a Parallel Computing Toolbox license.
- Specify 'Options', `statset('UseParallel',true)`.

Verbose — Verbosity level

0 (default) | 1

Verbosity level, specified as the comma-separated pair consisting of 'Verbose' and 0 or 1. Verbose controls the number of diagnostic messages that the software displays in the Command Window.

If Verbose is 0, then the software does not display diagnostic messages. Otherwise, the software displays diagnostic messages.

Example: 'Verbose',1

Data Types: single | double

Weights — Observation weights

`ones(size(X,1),1)` (default) | numeric vector | name of variable in `tbl`

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a numeric vector or the name of a variable in `tbl`. If you supply weights, then `loss` computes the weighted loss.

If you specify `Weights` as a numeric vector, then the size of `Weights` must be equal to the number of rows in `X` or `tbl`.

If you specify `Weights` as the name of a variable in `tbl`, you must do so as a character vector or string scalar. For example, if the weights are stored as `tbl.w`, then specify

Weights as 'w'. Otherwise, the software treats all columns of `tbl`, including `tbl.w`, as predictors.

If you do not specify your own loss function (using `LossFun`), then the software normalizes `Weights` to sum up to the value of the prior probability in the respective class.

Data Types: `single` | `double` | `char` | `string`

Output Arguments

L — Classification loss

numeric scalar | numeric row vector

Classification loss, returned as a numeric scalar or row vector. `L` is a generalization or resubstitution quality measure. Its interpretation depends on the loss function and weighting scheme, but in general, better classifiers yield smaller classification loss values.

If `Mdl.BinaryLearners` contains `ClassificationLinear` models, then `L` is a 1-by- ℓ vector, where ℓ is the number of regularization strengths in the linear classification models (`numel(Mdl.BinaryLearners{1}.Lambda)`). The value `L(j)` is the loss for the model trained using regularization strength `Mdl.BinaryLearners{1}.Lambda(j)`.

Otherwise, `L` is a scalar value.

Definitions

Classification Error

The classification error is a binary classification error measure that has the form

$$L = \frac{\sum_{j=1}^n w_j e_j}{\sum_{j=1}^n w_j},$$

where:

- w_j is the weight for observation j . The software renormalizes the weights to sum to 1.
- $e_j = 1$ if the predicted class of observation j differs from its true class, and 0 otherwise.

In other words, the classification error is the proportion of observations misclassified by the classifier.

Binary Loss

A binary loss is a function of the class and classification score that determines how well a binary learner classifies an observation into the class.

Suppose the following:

- m_{kj} is element (k,j) of the coding design matrix M (that is, the code corresponding to class k of binary learner j).
- s_j is the score of binary learner j for an observation.
- g is the binary loss function.
- \hat{k} is the predicted class for the observation.

In loss-based decoding [Escalera et al.] on page 18-228, the class producing the minimum sum of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \operatorname{argmin}_k \sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j).$$

In loss-weighted decoding [Escalera et al.] on page 18-228, the class producing the minimum average of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \operatorname{argmin}_k \frac{\sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j)}{\sum_{j=1}^L |m_{kj}|}.$$

Allwein et al. on page 18-227 suggest that loss-weighted decoding improves classification accuracy by keeping loss values for all classes in the same dynamic range.

This table summarizes the supported loss functions, where y_j is a class label for a particular binary learner (in the set $\{-1,1,0\}$), s_j is the score for observation j , and $g(y_j, s_j)$.

Value	Description	Score Domain	$g(y_j, s_j)$
'binodeviance'	Binomial deviance	$(-\infty, \infty)$	$\log[1 + \exp(-2y_j s_j)] / [2\log(2)]$
'exponential'	Exponential	$(-\infty, \infty)$	$\exp(-y_j s_j) / 2$
'hamming'	Hamming	$[0,1]$ or $(-\infty, \infty)$	$[1 - \text{sign}(y_j s_j)] / 2$
'hinge'	Hinge	$(-\infty, \infty)$	$\max(0, 1 - y_j s_j) / 2$
'linear'	Linear	$(-\infty, \infty)$	$(1 - y_j s_j) / 2$
'logit'	Logistic	$(-\infty, \infty)$	$\log[1 + \exp(-y_j s_j)] / [2\log(2)]$
'quadratic'	Quadratic	$[0,1]$	$[1 - y_j(2s_j - 1)]^2 / 2$

The software normalizes binary losses such that the loss is 0.5 when $y_j = 0$, and aggregates using the average of the binary learners [Allwein et al.] on page 18-227.

Do not confuse the binary loss with the overall classification loss (specified by the 'LossFun' name-value pair argument of the `loss` and `predict` object functions), which measures how well an ECOC classifier performs as a whole.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. For more information, see “Tall Arrays” (MATLAB).

Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the 'UseParallel' option to true.

Set the 'UseParallel' field of the options structure to true using `statset` and specify the 'Options' name-value pair argument in the call to this function.

For example: `'Options',statset('UseParallel',true)`

For more information, see the 'Options' name-value pair argument.

For more general information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

Introduced in R2014b

loss

Classification error

Syntax

```
L = loss(ens, tbl, ResponseVarName)
```

```
L = loss(ens, tbl, Y)
```

```
L = loss(ens, X, Y)
```

```
L = loss( ____, Name, Value)
```

Description

`L = loss(ens, tbl, ResponseVarName)` returns the classification error for ensemble `ens` computed using table of predictors `tbl` and true class labels `tbl.ResponseVarName`.

`L = loss(ens, tbl, Y)` returns the classification error for ensemble `ens` computed using table of predictors `tbl` and true class labels `Y`.

`L = loss(ens, X, Y)` returns the classification error for ensemble `ens` computed using matrix of predictors `X` and true class labels `Y`.

`L = loss(____, Name, Value)` computes classification error with additional options specified by one or more `Name, Value` pair arguments, using any of the previous syntaxes.

When computing the loss, `loss` normalizes the class probabilities in `ResponseVarName` or `Y` to the class probabilities used for training, stored in the `Prior` property of `ens`.

Input Arguments

ens

Classification ensemble created with `fitcensemble`, or a compact classification ensemble created with `compact`.

tbl

Sample data, specified as a table. Each row of `tbl` corresponds to one observation, and each column corresponds to one predictor variable. `tbl` must contain all of the predictors used to train the model. Multi-column variables and cell arrays other than cell arrays of character vectors are not allowed.

If you trained `ens` using sample data contained in a `table`, then the input data for this method must also be in a table.

ResponseVarName

Response variable name, specified as the name of a variable in `tbl`.

You must specify `ResponseVarName` as a character vector or string scalar. For example, if the response variable `Y` is stored as `tbl.Y`, then specify it as `'Y'`. Otherwise, the software treats all columns of `tbl`, including `Y`, as predictors when training the model.

X

Matrix of data to classify. Each row of `X` represents one observation, and each column represents one predictor. `X` must have the same number of columns as the data used to train `ens`. `X` should have the same number of rows as the number of elements in `Y`.

If you trained `ens` using sample data contained in a matrix, then the input data for this method must also be in a matrix.

Y

Class labels of observations in `tbl` or `X`. `Y` should be of the same type as the classification used to train `ens`, and its number of elements should equal the number of rows of `tbl` or `X`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Learners

Indices of weak learners in the ensemble ranging from 1 to `ens.NumTrained`. `loss` uses only these learners for calculating loss.

Default: `1:NumTrained`

Lossfun

Loss function, specified as the comma-separated pair consisting of 'LossFun' and a built-in, loss-function name or function handle.

- The following table lists the available loss functions. Specify one using its corresponding character vector or string scalar.

Value	Description
'binodeviance'	Binomial deviance
'classiferror'	Classification error
'exponential'	Exponential
'hinge'	Hinge
'logit'	Logistic
'mincost'	Minimal expected misclassification cost (for classification scores that are posterior probabilities)
'quadratic'	Quadratic

'mincost' is appropriate for classification scores that are posterior probabilities.

- Bagged and subspace ensembles return posterior probabilities by default (`ens.Method` is 'Bag' or 'Subspace').
- If the ensemble method is 'AdaBoostM1', 'AdaBoostM2', 'GentleBoost', or 'LogitBoost', then, to use posterior probabilities as classification scores, you must specify the double-logit score transform by entering

```
ens.ScoreTransform = 'doublelogit';
```
- For all other ensemble methods, the software does not support posterior probabilities as classification scores.
- Specify your own function using function handle notation.

Suppose that n be the number of observations in X and K be the number of distinct classes (`numel(ens.ClassNames)`, `ens` is the input model). Your function must have this signature

```
lossvalue = lossfun(C,S,W,Cost)
```

where:

- The output argument `lossvalue` is a scalar.
- You choose the function name (`lossfun`).
- C is an n -by- K logical matrix with rows indicating which class the corresponding observation belongs. The column order corresponds to the class order in `ens.ClassNames`.

Construct C by setting $C(p, q) = 1$ if observation p is in class q , for each row. Set all other elements of row p to 0 .

- S is an n -by- K numeric matrix of classification scores. The column order corresponds to the class order in `ens.ClassNames`. S is a matrix of classification scores, similar to the output of `predict`.
- W is an n -by-1 numeric vector of observation weights. If you pass W , the software normalizes them to sum to 1.
- $Cost$ is a K -by- K numeric matrix of misclassification costs. For example, $Cost = ones(K) - eye(K)$ specifies a cost of 0 for correct classification, and 1 for misclassification.

Specify your function using `'LossFun', @lossfun`.

For more details on loss functions, see “Classification Loss” on page 32-3917.

Default: `'classiferror'`

mode

Meaning of the output L :

- `'ensemble'` — L is a scalar value, the loss for the entire ensemble.
- `'individual'` — L is a vector with one element per trained learner.
- `'cumulative'` — L is a vector in which element J is obtained by using learners $1:J$ from the input list of learners.

Default: `'ensemble'`

UseObsForLearner

A logical matrix of size N-by-T, where:

- N is the number of rows of X.
- T is the number of weak learners in ens.

When `UseObsForLearner(i, j)` is `true`, learner `j` is used in predicting the class of row `i` of X.

Default: `true(N, T)`

weights

Vector of observation weights, with nonnegative entries. The length of `weights` must equal the number of rows in X. When you specify `weights`, `loss` normalizes the weights so that observation weights in each class sum to the prior probability of that class.

Default: `ones(size(X, 1), 1)`

Output Arguments

L

Classification loss on page 32-3917, by default the fraction of misclassified data. L can be a vector, and can mean different things, depending on the name-value pair settings.

Examples

Estimate Classification Error

Load Fisher's iris data set.

```
load fisheriris
```

Train a classification ensemble of 100 decision trees using AdaBoostM2. Specify tree stumps as the weak learners.

```
t = templateTree('MaxNumSplits',1);
ens = fitcensemble(meas,species,'Method','AdaBoostM2','Learners',t);
```

Estimate the classification error of the model using the training observations.

```
L = loss(ens,meas,species)
```

```
L = 0.0333
```

Alternatively, if `ens` is not compact, then you can estimate the training-sample classification error by passing `ens` to `resubLoss`.

Definitions

Classification Loss

Classification loss functions measure the predictive inaccuracy of classification models. When you compare the same type of loss among many models, a lower loss indicates a better predictive model.

Consider the following scenario.

- L is the weighted average classification loss.
- n is the sample size.
- For binary classification:
 - y_j is the observed class label. The software codes it as -1 or 1, indicating the negative or positive class, respectively.
 - $f(X_j)$ is the raw classification score for observation (row) j of the predictor data X .
 - $m_j = y_j f(X_j)$ is the classification score for classifying observation j into the class corresponding to y_j . Positive values of m_j indicate correct classification and do not contribute much to the average loss. Negative values of m_j indicate incorrect classification and contribute significantly to the average loss.
- For algorithms that support multiclass classification (that is, $K \geq 3$):
 - y_j^* is a vector of $K - 1$ zeros, with 1 in the position corresponding to the true, observed class y_j . For example, if the true class of the second observation is the third class and $K = 4$, then $y_2^* = [0 \ 0 \ 1 \ 0]$. The order of the classes corresponds to the order in the `ClassNames` property of the input model.

- $f(X_j)$ is the length K vector of class scores for observation j of the predictor data X . The order of the scores corresponds to the order of the classes in the `ClassNames` property of the input model.
- $m_j = y_j^* f(X_j)$. Therefore, m_j is the scalar classification score that the model predicts for the true, observed class.
- The weight for observation j is w_j . The software normalizes the observation weights so that they sum to the corresponding prior class probability. The software also normalizes the prior probabilities so they sum to 1. Therefore,

$$\sum_{j=1}^n w_j = 1.$$

Given this scenario, the following table describes the supported loss functions that you can specify by using the 'LossFun' name-value pair argument.

Loss Function	Value of LossFun	Equation
Binomial deviance	'binodeviance'	$L = \sum_{j=1}^n w_j \log\{1 + \exp[-2m_j]\}.$
Exponential loss	'exponential'	$L = \sum_{j=1}^n w_j \exp(-m_j).$
Classification error	'classiferror'	$L = \sum_{j=1}^n w_j I\{\hat{y}_j \neq y_j\}.$ <p>It is the weighted fraction of misclassified observations where \hat{y}_j is the class label corresponding to the class with the maximal posterior probability. $I\{x\}$ is the indicator function.</p>
Hinge loss	'hinge'	$L = \sum_{j=1}^n w_j \max\{0, 1 - m_j\}.$

loss

Classification error for naive Bayes classifier

Syntax

```
L = loss(Mdl,tbl,ResponseVarName)
```

```
L = loss(Mdl,tbl,Y)
```

```
L = loss(Mdl,X,Y)
```

```
L = loss( ___,Name,Value)
```

Description

`L = loss(Mdl,tbl,ResponseVarName)` returns the minimum classification loss (see “Classification Loss” on page 32-3928), a scalar representing how well the trained naive Bayes classifier `Mdl` classifies the predictor data in table `tbl`) as compared to the true class labels in `tbl.ResponseVarName`.

`loss` normalizes the class probabilities in `tbl.ResponseVarName` to the prior class probabilities `fitcnb` used for training, stored in the `Prior` property of `Mdl`.

`L = loss(Mdl,tbl,Y)` returns the minimum classification loss (`L`), a scalar representing how well the trained naive Bayes classifier `Mdl` classifies the predictor data in table `tbl`) as compared to the true class labels in `Y`.

`loss` normalizes the class probabilities in `Y` to the prior class probabilities `fitcnb` used for training, stored in the `Prior` property of `Mdl`.

`L = loss(Mdl,X,Y)` returns the minimum classification loss (`L`), a scalar representing how well the trained naive Bayes classifier `Mdl` classifies the predictor data (`X`) as compared to the true class labels (`Y`).

`loss` normalizes the class probabilities in `Y` to the prior class probabilities `fitcnb` used for training, stored in the `Prior` property of `Mdl`.

`L = loss(____, Name, Value)` returns the classification loss with additional options specified by one or more `Name, Value` pair arguments, using any of the previous syntaxes.

Input Arguments

Mdl — Naive Bayes classifier

`ClassificationNaiveBayes` model | `CompactClassificationNaiveBayes` model

Naive Bayes classifier, specified as a `ClassificationNaiveBayes` model or `CompactClassificationNaiveBayes` model returned by `fitcnb` or `compact`, respectively.

tbl — Sample data

table

Sample data, specified as a table. Each row of `tbl` corresponds to one observation, and each column corresponds to one predictor variable. Optionally, `tbl` can contain additional columns for the response variable and observation weights. `tbl` must contain all the predictors used to train `Mdl`. Multi-column variables and cell arrays other than cell arrays of character vectors are not allowed.

If you trained `Mdl` using sample data contained in a `table`, then the input data for this method must also be in a table.

Data Types: `table`

ResponseVarName — Response variable name

name of a variable in `tbl`

Response variable name, specified as the name of a variable in `tbl`.

You must specify `ResponseVarName` as a character vector or string scalar. For example, if the response variable `y` is stored as `tbl.y`, then specify it as `'y'`. Otherwise, the software treats all columns of `tbl`, including `y`, as predictors when training the model.

The response variable must be a categorical, character, or string array, logical or numeric vector, or cell array of character vectors. If the response variable is a character array, then each element must correspond to one row of the array.

Data Types: `char` | `string`

X — Predictor data

numeric matrix

Predictor data, specified as a numeric matrix.

Each row of `X` corresponds to one observation (also known as an instance or example), and each column corresponds to one variable (also known as a feature). The variables making up the columns of `X` should be the same as the variables that trained `Mdl`.

The length of `Y` and the number of rows of `X` must be equal.

Data Types: `double` | `single`

Y — Class labels

categorical array | character array | string array | logical vector | vector of numeric values
| cell array of character vectors

Class labels, specified as a categorical, character, or string array, logical or numeric vector, or cell array of character vectors. `Y` must be the same as the data type of `Mdl.ClassNames`. (The software treats string arrays as cell arrays of character vectors.)

The length of `Y` and the number of rows of `tbl` or `X` must be equal.

Data Types: `categorical` | `char` | `string` | `logical` | `single` | `double` | `cell`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

LossFun — Loss function

'`classiferror`' (default) | '`binodeviance`' | '`exponential`' | '`hinge`' | '`logit`' | '`mincost`' | '`quadratic`' | function handle

Loss function, specified as the comma-separated pair consisting of '`LossFun`' and a built-in, loss-function name or function handle.

- The following table lists the available loss functions. Specify one using its corresponding character vector or string scalar.

Value	Description
'binodeviance'	Binomial deviance
'classiferror'	Classification error
'exponential'	Exponential
'hinge'	Hinge
'logit'	Logistic
'mincost'	Minimal expected misclassification cost (for classification scores that are posterior probabilities)
'quadratic'	Quadratic

'mincost' is appropriate for classification scores that are posterior probabilities. Naive Bayes models return posterior probabilities as classification scores by default (see `predict`).

- Specify your own function using function handle notation.

Suppose that n be the number of observations in X and K be the number of distinct classes (`numel(Mdl.ClassNames)`, Mdl is the input model). Your function must have this signature

```
lossvalue = lossfun(C,S,W,Cost)
```

where:

- The output argument `lossvalue` is a scalar.
- You choose the function name (`lossfun`).
- C is an n -by- K logical matrix with rows indicating which class the corresponding observation belongs. The column order corresponds to the class order in `Mdl.ClassNames`.

Construct C by setting $C(p, q) = 1$ if observation p is in class q , for each row. Set all other elements of row p to 0 .

- S is an n -by- K numeric matrix of classification scores. The column order corresponds to the class order in `Mdl.ClassNames`. S is a matrix of classification scores, similar to the output of `predict`.
- W is an n -by-1 numeric vector of observation weights. If you pass W , the software normalizes them to sum to 1.

- `Cost` is a K -by- K numeric matrix of misclassification costs. For example, `Cost = ones(K) - eye(K)` specifies a cost of 0 for correct classification, and 1 for misclassification.

Specify your function using `'LossFun', @lossfun`.

For more details on loss functions, see “Classification Loss” on page 32-3928.

Data Types: `char` | `string` | `function_handle`

Weights — Observation weights

`ones(size(X,1),1)` (default) | numeric vector | name of a variable in `tbl`

Observation weights, specified as the comma-separated pair consisting of `'Weights'` and a numeric vector or the name of a variable in `tbl`. The software weighs the observations in each row of `X` or `tbl` with the corresponding weight in `Weights`.

If you specify `Weights` as a vector, then the size of `Weights` must be equal to the number of rows of `X` or `tbl`.

If you specify `Weights` as the name of a variable in `tbl`, you must do so as a character vector or string scalar. For example, if the weights are stored as `tbl.w`, then specify `Weights` as `'w'`. Otherwise, the software treats all columns of `tbl`, including `tbl.w`, as predictors.

If you do not specify your own loss function, then the software normalizes `Weights` to add up to 1.

Data Types: `double` | `char` | `string`

Output Arguments

L — Classification loss

scalar

Classification loss, returned as a scalar. `L` is a generalization or resubstitution quality measure. Its interpretation depends on the loss function and weighting scheme, but, in general, better classifiers yield smaller loss values.

Examples

Determine Test Sample Minimum Cost Loss of Naive Bayes Classifiers

Load Fisher's iris data set.

```
load fisheriris
X = meas;      % Predictors
Y = species;  % Response
rng(1);       % For reproducibility
```

Train a naive Bayes classifier. Specify a 15% holdout sample for testing. It is good practice to specify the class order. Assume that each predictor is conditionally normally distributed given its label.

```
CVMdl = fitcnb(X,Y,'ClassNames',{'setosa','versicolor','virginica'},...
    'Holdout',0.15);
CMdl = CVMdl.Trained{1}; % Extract the trained, compact classifier
testInds = test(CVMdl.Partition); % Extract the test indices
XTest = X(testInds,:);
YTest = Y(testInds);
```

CVMdl is a `ClassificationPartitionedModel` classifier. It contains the property `Trained`, which is a 1-by-1 cell array holding a `CompactClassificationNaiveBayes` classifier that the software trained using the training set.

Determine how well the algorithm generalizes by estimating the test sample minimum cost loss.

```
L = loss(CMdl,XTest,YTest)
```

```
L = 0.0476
```

The test sample average classification cost is approximately 0.05.

You might improve the classification error by specifying better predictor distributions when you train the classifier.

Determine the Test Sample Classification Error of Naive Bayes Classifiers

Load Fisher's iris data set.

```
load fisheriris
X = meas;    % Predictors
Y = species; % Response
rng(1); % For reproducibility
```

Train a naive Bayes classifier. Specify a 15% holdout sample for testing. It is good practice to specify the class order. Assume that each predictor is conditionally normally distributed given its label.

```
CVMDL = fitcnb(X,Y,'ClassNames',{'setosa','versicolor','virginica'},...
    'Holdout',0.15);
CMDL = CVMDL.Trained{1}; % Extract the trained, compact classifier
testInds = test(CVMDL.Partition); % Extract the test indices
XTest = X(testInds,:);
YTest = Y(testInds);
```

CVMDL is a `ClassificationPartitionedModel` classifier. It contains the property `Trained`, which is a 1-by-1 cell array holding a `CompactClassificationNaiveBayes` classifier that the software trained using the training set.

Determine how well the algorithm generalizes by estimating the test sample classification error.

```
L = loss(CMDL,XTest,YTest,'LossFun','classiferror')
L = 0.0476
```

The classifier misclassified approximately 5% of the test sample observations.

Definitions

Classification Loss

Classification loss functions measure the predictive inaccuracy of classification models. When you compare the same type of loss among many models, a lower loss indicates a better predictive model.

Consider the following scenario.

- L is the weighted average classification loss.
- n is the sample size.
- For binary classification:
 - y_j is the observed class label. The software codes it as -1 or 1 , indicating the negative or positive class, respectively.
 - $f(X_j)$ is the raw classification score for observation (row) j of the predictor data X .
 - $m_j = y_j f(X_j)$ is the classification score for classifying observation j into the class corresponding to y_j . Positive values of m_j indicate correct classification and do not contribute much to the average loss. Negative values of m_j indicate incorrect classification and contribute significantly to the average loss.
- For algorithms that support multiclass classification (that is, $K \geq 3$):
 - y_j^* is a vector of $K - 1$ zeros, with 1 in the position corresponding to the true, observed class y_j . For example, if the true class of the second observation is the third class and $K = 4$, then $y_2^* = [0 \ 0 \ 1 \ 0]$. The order of the classes corresponds to the order in the `ClassNames` property of the input model.
 - $f(X_j)$ is the length K vector of class scores for observation j of the predictor data X . The order of the scores corresponds to the order of the classes in the `ClassNames` property of the input model.
 - $m_j = y_j^* f(X_j)$. Therefore, m_j is the scalar classification score that the model predicts for the true, observed class.
- The weight for observation j is w_j . The software normalizes the observation weights so that they sum to the corresponding prior class probability. The software also normalizes the prior probabilities so they sum to 1 . Therefore,

$$\sum_{j=1}^n w_j = 1.$$

Given this scenario, the following table describes the supported loss functions that you can specify by using the 'LossFun' name-value pair argument.

Loss Function	Value of LossFun	Equation
Binomial deviance	'binodeviance'	$L = \sum_{j=1}^n w_j \log\{1 + \exp[-2m_j]\}.$

Loss Function	Value of LossFun	Equation
Exponential loss	'exponential'	$L = \sum_{j=1}^n w_j \exp(-m_j).$
Classification error	'classiferror'	$L = \sum_{j=1}^n w_j I\{\hat{y}_j \neq y_j\}.$ <p>It is the weighted fraction of misclassified observations where \hat{y}_j is the class label corresponding to the class with the maximal posterior probability. $I\{x\}$ is the indicator function.</p>
Hinge loss	'hinge'	$L = \sum_{j=1}^n w_j \max\{0, 1 - m_j\}.$
Logit loss	'logit'	$L = \sum_{j=1}^n w_j \log(1 + \exp(-m_j)).$

Loss Function	Value of LossFun	Equation
Minimal cost	'mincost'	<p>Minimal cost. The software computes the weighted minimal cost using this procedure for observations $j = 1, \dots, n$.</p> <ol style="list-style-type: none"> 1 Estimate the 1-by-K vector of expected classification costs for observation j: $\nu_j = f(X_j)'C.$ <p>$f(X_j)$ is the column vector of class posterior probabilities for binary and multiclass classification. C is the cost matrix that the input model stores in the <code>Cost</code> property.</p> 2 For observation j, predict the class label corresponding to the minimum expected classification cost: $\hat{y}_j = \min_{j=1, \dots, K} (\nu_j).$ 3 Using C, identify the cost incurred (c_j) for making the prediction. <p>The weighted, average, minimum cost loss is</p> $L = \sum_{j=1}^n w_j c_j.$
Quadratic loss	'quadratic'	$L = \sum_{j=1}^n w_j (1 - m_j)^2.$

This figure compares the loss functions (except 'mincost') for one observation over m . Some functions are normalized to pass through [0,1].

Misclassification Cost

A misclassification cost is the relative severity of a classifier labeling an observation into the wrong class.

There are two types of misclassification costs: true and expected. Let K be the number of classes.

- True misclassification cost — A K -by- K matrix, where element (i, j) indicates the misclassification cost of predicting an observation into class j if its true class is i . The software stores the misclassification cost in the property `Mdl.Cost`, and used in computations. By default, $\text{Mdl.Cost}(i, j) = 1$ if $i \neq j$, and $\text{Mdl.Cost}(i, j) = 0$ if $i = j$.

= j . In other words, the cost is θ for correct classification, and 1 for any incorrect classification.

- Expected misclassification cost — A K -dimensional vector, where element k is the weighted average misclassification cost of classifying an observation into class k , weighted by the class posterior probabilities. In other words,

$$c_k = \sum_{j=1}^K \widehat{P}(Y = j | x_1, \dots, x_P) \text{Cost}_{jk}.$$

the software classifies observations to the class corresponding with the lowest expected misclassification cost.

Posterior Probability

The posterior probability is the probability that an observation belongs in a particular class, given the data.

For naive Bayes, the posterior probability that a classification is k for a given observation (x_1, \dots, x_P) is

$$\widehat{P}(Y = k | x_1, \dots, x_P) = \frac{P(X_1, \dots, X_P | y = k) \pi(Y = k)}{P(X_1, \dots, X_P)},$$

where:

- $P(X_1, \dots, X_P | y = k)$ is the conditional joint density of the predictors given they are in class k . `Mdl.DistributionNames` stores the distribution names of the predictors.
- $\pi(Y = k)$ is the class prior probability distribution. `Mdl.Prior` stores the prior distribution.
- $P(X_1, \dots, X_P)$ is the joint density of the predictors. The classes are discrete, so

$$P(X_1, \dots, X_P) = \sum_{k=1}^K P(X_1, \dots, X_P | y = k) \pi(Y = k).$$

Prior Probability

The prior probability of a class is the believed relative frequency with which observations from that class occur in a population.

loss

Package: classreg.learning.classif

Find classification error for support vector machine (SVM) classifier

Syntax

`L = loss(SVMModel, TBL, ResponseVarName)`

`L = loss(SVMModel, TBL, Y)`

`L = loss(SVMModel, X, Y)`

`L = loss(____, Name, Value)`

Description

`L = loss(SVMModel, TBL, ResponseVarName)` returns the classification error (see “Classification Loss” on page 32-3941), a scalar representing how well the trained support vector machine (SVM) classifier (`SVMModel`) classifies the predictor data in table `TBL` compared to the true class labels in `TBL.ResponseVarName`.

`loss` normalizes the class probabilities in `TBL.ResponseVarName` to the prior class probabilities that `fitcsvm` used for training, stored in the `Prior` property of `SVMModel`.

The classification loss (`L`) is a generalization or resubstitution quality measure. Its interpretation depends on the loss function and weighting scheme, but, in general, better classifiers yield smaller classification loss values.

`L = loss(SVMModel, TBL, Y)` returns the classification error for the predictor data in table `TBL` and the true class labels in `Y`.

`loss` normalizes the class probabilities in `Y` to the prior class probabilities that `fitcsvm` used for training, stored in the `Prior` property of `SVMModel`.

`L = loss(SVMModel, X, Y)` returns the classification error based on the predictor data in matrix `X` compared to the true class labels in `Y`.

`L = loss(____, Name, Value)` specifies options using one or more name-value pair arguments in addition to the input arguments in previous syntaxes. For example, you can specify the loss function and the classification weights.

Examples

Determine Test Sample Classification Error of SVM Classifiers

Load the ionosphere data set.

```
load ionosphere
rng(1); % For reproducibility
```

Train an SVM classifier. Specify a 15% holdout sample for testing, standardize the data, and specify that 'g' is the positive class.

```
CVSVMModel = fitcsvm(X,Y,'Holdout',0.15,'ClassNames',{'b','g'},...
    'Standardize',true);
CompactSVMModel = CVSVMModel.Trained{1}; % Extract the trained, compact classifier
testInds = test(CVSVMModel.Partition); % Extract the test indices
XTest = X(testInds,:);
YTest = Y(testInds,:);
```

`CVSVMModel` is a `ClassificationPartitionedModel` classifier. It contains the property `Trained`, which is a 1-by-1 cell array holding a `CompactClassificationSVM` classifier that the software trained using the training set.

Determine how well the algorithm generalizes by estimating the test sample classification error.

```
L = loss(CompactSVMModel,XTest,YTest)
```

```
L = 0.0787
```

The SVM classifier misclassifies approximately 8% of the test sample.

Determine Test Sample Hinge Loss of SVM Classifiers

Load the ionosphere data set.

```
load ionosphere
rng(1); % For reproducibility
```

Train an SVM classifier. Specify a 15% holdout sample for testing, standardize the data, and specify that 'g' is the positive class.

```
CVSVMModel = fitcsvm(X,Y,'Holdout',0.15,'ClassNames',{'b','g'},...
    'Standardize',true);
CompactSVMModel = CVSVMModel.Trained{1}; % Extract the trained, compact classifier
testInds = test(CVSVMModel.Partition); % Extract the test indices
XTest = X(testInds,:);
YTest = Y(testInds,:);
```

CVSVMModel is a `ClassificationPartitionedModel` classifier. It contains the property `Trained`, which is a 1-by-1 cell array holding a `CompactClassificationSVM` classifier that the software trained using the training set.

Determine how well the algorithm generalizes by estimating the test sample hinge loss.

```
L = loss(CompactSVMModel,XTest,YTest,'LossFun','hinge')
L = 0.2998
```

The hinge loss is approximately 0.3. Classifiers with hinge losses close to 0 are preferred.

Input Arguments

SVMModel — SVM classification model

`ClassificationSVM` model object | `CompactClassificationSVM` model object

SVM classification model, specified as a `ClassificationSVM` model object or `CompactClassificationSVM` model object returned by `fitcsvm` or `compact`, respectively.

TBL — Sample data

table

Sample data, specified as a table. Each row of TBL corresponds to one observation, and each column corresponds to one predictor variable. Optionally, TBL can contain additional columns for the response variable and observation weights. TBL must contain all of the predictors used to train `SVMModel`. Multicolumn variables and cell arrays other than cell arrays of character vectors are not allowed.

If TBL contains the response variable used to train `SVMMoDel`, then you do not need to specify `ResponseVarName` or `Y`.

If you trained `SVMMoDel` using sample data contained in a table, then the input data for `loss` must also be in a table.

If you set `'Standardize', true` in `fitcsvm` when training `SVMMoDel`, then the software standardizes the columns of the predictor data using the corresponding means in `SVMMoDel.Mu` and the standard deviations in `SVMMoDel.Sigma`.

Data Types: `table`

ResponseVarName — Response variable name

name of variable in TBL

Response variable name, specified as the name of a variable in TBL.

You must specify `ResponseVarName` as a character vector or string scalar. For example, if the response variable `Y` is stored as `TBL.Y`, then specify `ResponseVarName` as `'Y'`. Otherwise, the software treats all columns of TBL, including `Y`, as predictors when training the model.

The response variable must be a categorical, character, or string array, logical or numeric vector, or cell array of character vectors. If the response variable is a character array, then each element must correspond to one row of the array.

Data Types: `char` | `string`

X — Predictor data

numeric matrix

Predictor data, specified as a numeric matrix.

Each row of `X` corresponds to one observation (also known as an instance or example), and each column corresponds to one variable (also known as a feature). The variables in the columns of `X` must be the same as the variables that trained the `SVMMoDel` classifier.

The length of `Y` and the number of rows in `X` must be equal.

If you set `'Standardize', true` in `fitcsvm` to train `SVMMoDel`, then the software standardizes the columns of `X` using the corresponding means in `SVMMoDel.Mu` and the standard deviations in `SVMMoDel.Sigma`.

Data Types: `double` | `single`

Y — Class labels

categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Class labels, specified as a categorical, character, or string array, logical or numeric vector, or cell array of character vectors. Y must be the same as the data type of `SVMModel.ClassNames`. (The software treats string arrays as cell arrays of character vectors.)

The length of Y must equal the number of rows in TBL or the number of rows in X.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `loss(SVMModel, TBL, Y, 'Weights', W)` weighs the observations in each row of TBL using the corresponding weight in each row of the variable W in TBL.

LossFun — Loss function

'classiferror' (default) | 'binodeviance' | 'exponential' | 'hinge' | 'logit' | 'mincost' | 'quadratic' | function handle

Loss function, specified as the comma-separated pair consisting of 'LossFun' and a built-in loss function name or a function handle.

- This table lists the available loss functions. Specify one using its corresponding character vector or string scalar.

Value	Description
'binodeviance'	Binomial deviance
'classiferror'	Classification error
'exponential'	Exponential
'hinge'	Hinge
'logit'	Logistic

Value	Description
'mincost'	Minimal expected misclassification cost (for classification scores that are posterior probabilities)
'quadratic'	Quadratic

'mincost' is appropriate for classification scores that are posterior probabilities. You can specify to use posterior probabilities as classification scores for SVM models by setting 'FitPosterior', true when you cross-validate the model using `fitcsvm`.

- Specify your own function by using function handle notation.

Suppose that n is the number of observations in X , and K is the number of distinct classes (`numel(SVMModel.ClassNames)`) used to create the input model (`SVMModel`). Your function must have this signature

```
lossvalue = lossfun(C,S,W,Cost)
```

where:

- The output argument `lossvalue` is a scalar.
- You choose the function name (`lossfun`).
- C is an n -by- K logical matrix with rows indicating the class to which the corresponding observation belongs. The column order corresponds to the class order in `SVMModel.ClassNames`.

Construct C by setting $C(p, q) = 1$ if observation p is in class q , for each row. Set all other elements of row p to 0 .

- S is an n -by- K numeric matrix of classification scores, similar to the output of `predict`. The column order corresponds to the class order in `SVMModel.ClassNames`.
- W is an n -by-1 numeric vector of observation weights. If you pass W , the software normalizes the weights to sum to 1.
- $Cost$ is a K -by- K numeric matrix of misclassification costs. For example, $Cost = \text{ones}(K) - \text{eye}(K)$ specifies a cost of 0 for correct classification and 1 for misclassification.

Specify your function using 'LossFun', @`lossfun`.

For more details on loss functions, see "Classification Loss" on page 32-3941.

Example: 'LossFun', 'binodeviance'

Data Types: char | string | function_handle

Weights — Observation weights

ones(size(X,1),1) (default) | numeric vector | name of variable in TBL

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a numeric vector or the name of a variable in TBL. The software weighs the observations in each row of X or TBL with the corresponding weight in Weights.

If you specify Weights as a numeric vector, then the size of Weights must be equal to the number of rows in X or TBL.

If you specify Weights as the name of a variable in TBL, you must do so as a character vector or string scalar. For example, if the weights are stored as TBL.W, then specify Weights as 'W'. Otherwise, the software treats all columns of TBL, including TBL.W, as predictors.

If you do not specify your own loss function, then the software normalizes Weights to sum up to the value of the prior probability in the respective class.

Example: 'Weights', 'W'

Data Types: single | double | char | string

Definitions

Classification Loss

Classification loss functions measure the predictive inaccuracy of classification models. When you compare the same type of loss among many models, a lower loss indicates a better predictive model.

Consider the following scenario.

- L is the weighted average classification loss.
- n is the sample size.
- For binary classification:

- y_j is the observed class label. The software codes it as -1 or 1, indicating the negative or positive class, respectively.
- $f(X_j)$ is the raw classification score for observation (row) j of the predictor data X .
- $m_j = y_j f(X_j)$ is the classification score for classifying observation j into the class corresponding to y_j . Positive values of m_j indicate correct classification and do not contribute much to the average loss. Negative values of m_j indicate incorrect classification and contribute significantly to the average loss.
- For algorithms that support multiclass classification (that is, $K \geq 3$):
 - y_j^* is a vector of $K - 1$ zeros, with 1 in the position corresponding to the true, observed class y_j . For example, if the true class of the second observation is the third class and $K = 4$, then $y_2^* = [0 \ 0 \ 1 \ 0]$. The order of the classes corresponds to the order in the `ClassNames` property of the input model.
 - $f(X_j)$ is the length K vector of class scores for observation j of the predictor data X . The order of the scores corresponds to the order of the classes in the `ClassNames` property of the input model.
 - $m_j = y_j^* f(X_j)$. Therefore, m_j is the scalar classification score that the model predicts for the true, observed class.
- The weight for observation j is w_j . The software normalizes the observation weights so that they sum to the corresponding prior class probability. The software also normalizes the prior probabilities so they sum to 1. Therefore,

$$\sum_{j=1}^n w_j = 1.$$

Given this scenario, the following table describes the supported loss functions that you can specify by using the 'LossFun' name-value pair argument.

Loss Function	Value of LossFun	Equation
Binomial deviance	'binodeviance'	$L = \sum_{j=1}^n w_j \log\{1 + \exp[-2m_j]\}.$
Exponential loss	'exponential'	$L = \sum_{j=1}^n w_j \exp(-m_j).$

Loss Function	Value of LossFun	Equation
Classification error	'classiferror'	$L = \sum_{j=1}^n w_j I\{\hat{y}_j \neq y_j\}.$ <p>It is the weighted fraction of misclassified observations where \hat{y}_j is the class label corresponding to the class with the maximal posterior probability. $I\{x\}$ is the indicator function.</p>
Hinge loss	'hinge'	$L = \sum_{j=1}^n w_j \max\{0, 1 - m_j\}.$
Logit loss	'logit'	$L = \sum_{j=1}^n w_j \log(1 + \exp(-m_j)).$

Loss Function	Value of LossFun	Equation
Minimal cost	'mincost'	<p>Minimal cost. The software computes the weighted minimal cost using this procedure for observations $j = 1, \dots, n$.</p> <ol style="list-style-type: none"> Estimate the 1-by-K vector of expected classification costs for observation j: $\nu_j = f(X_j)'C.$ <p>$f(X_j)$ is the column vector of class posterior probabilities for binary and multiclass classification. C is the cost matrix that the input model stores in the <code>Cost</code> property.</p> For observation j, predict the class label corresponding to the minimum expected classification cost: $\hat{y}_j = \min_{j = 1, \dots, K} (\nu_j).$ Using C, identify the cost incurred (c_j) for making the prediction. <p>The weighted, average, minimum cost loss is</p> $L = \sum_{j=1}^n w_j c_j.$
Quadratic loss	'quadratic'	$L = \sum_{j=1}^n w_j (1 - m_j)^2.$

This figure compares the loss functions (except 'mincost') for one observation over m . Some functions are normalized to pass through [0,1].

Classification Score

The SVM classification score for classifying observation x is the signed distance from x to the decision boundary ranging from $-\infty$ to $+\infty$. A positive score for a class indicates that x is predicted to be in that class. A negative score indicates otherwise.

The positive class classification score $f(x)$ is the trained SVM classification function. $f(x)$ is also the numerical, predicted response for x , or the score for predicting x into the positive class.

$$f(x) = \sum_{j=1}^n \alpha_j y_j G(x_j, x) + b,$$

where $(\alpha_1, \dots, \alpha_n, b)$ are the estimated SVM parameters, $G(x_j, x)$ is the dot product in the predictor space between x and the support vectors, and the sum includes the training set observations. The negative class classification score for x , or the score for predicting x into the negative class, is $-f(x)$.

If $G(x_j, x) = x_j'x$ (the linear kernel), then the score function reduces to

$$f(x) = (x/s)\beta + b.$$

s is the kernel scale and β is the vector of fitted linear coefficients.

For more details, see “Understanding Support Vector Machines” on page 18-189.

Introduced in R2014a

loss

Classification error

Syntax

```
L = loss(tree, TBL, ResponseVarName)
```

```
L = loss(tree, TBL, Y)
```

```
L = loss(tree, X, Y)
```

```
L = loss( ____, Name, Value)
```

```
[L, se, NLeaf, bestlevel] = loss( ____ )
```

Description

`L = loss(tree, TBL, ResponseVarName)` returns a scalar representing how well `tree` classifies the data in `TBL`, when `TBL.ResponseVarName` contains the true classifications.

When computing the loss, `loss` normalizes the class probabilities in `Y` to the class probabilities used for training, stored in the `Prior` property of `tree`.

`L = loss(tree, TBL, Y)` returns a scalar representing how well `tree` classifies the data in `TBL`, when `Y` contains the true classifications.

`L = loss(tree, X, Y)` returns a scalar representing how well `tree` classifies the data in `X`, when `Y` contains the true classifications.

`L = loss(____, Name, Value)` returns the loss with additional options specified by one or more `Name, Value` pair arguments, using any of the previous syntaxes. For example, you can specify the loss function or observation weights.

`[L, se, NLeaf, bestlevel] = loss(____)` also returns the vector of standard errors of the classification errors (`se`), the vector of numbers of leaf nodes in the trees of the pruning sequence (`NLeaf`), and the best pruning level as defined in the `TreeSize` name-value pair (`bestlevel`).

Note `loss` returns `se` and further outputs only when the `LossFun` name-value pair is the default `'classiferror'`.

Input Arguments

tree — Trained classification tree

`ClassificationTree` model object | `CompactClassificationTree` model object

Trained classification tree, specified as a `ClassificationTree` or `CompactClassificationTree` model object. That is, `tree` is a trained classification model returned by `fitctree` or `compact`.

TBL — Sample data

table

Sample data, specified as a table. Each row of TBL corresponds to one observation, and each column corresponds to one predictor variable. Optionally, TBL can contain additional columns for the response variable and observation weights. TBL must contain all the predictors used to train `tree`. Multi-column variables and cell arrays other than cell arrays of character vectors are not allowed.

If TBL contains the response variable used to train `tree`, then you do not need to specify `ResponseVarName` or `Y`.

If you train `tree` using sample data contained in a table, then the input data for this method must also be in a table.

Data Types: table

X — Data to classify

numeric matrix

Data to classify, specified as a numeric matrix. Each row of `X` represents one observation, and each column represents one predictor. `X` must have the same number of columns as the data used to train `tree`. `X` must have the same number of rows as the number of elements in `Y`.

Data Types: single | double

ResponseVarName — Response variable name

name of a variable in TBL

Response variable name, specified as the name of a variable in TBL. If TBL contains the response variable used to train `tree`, then you do not need to specify `ResponseVarName`.

If you specify `ResponseVarName`, then you must do so as a character vector or string scalar. For example, if the response variable is stored as `TBL.Response`, then specify it as `'Response'`. Otherwise, the software treats all columns of TBL, including `TBL.ResponseVarName`, as predictors.

The response variable must be a categorical, character, or string array, logical or numeric vector, or cell array of character vectors. If the response variable is a character array, then each element must correspond to one row of the array.

Data Types: `char` | `string`

Y — Class labels

categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Class labels, specified as a categorical, character, or string array, a logical or numeric vector, or a cell array of character vectors. `Y` must be of the same type as the classification used to train `tree`, and its number of elements must equal the number of rows of `X`.

Data Types: `categorical` | `char` | `string` | `logical` | `single` | `double` | `cell`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

LossFun — Loss function

`'mincost'` (default) | `'binodeviance'` | `'classiferror'` | `'exponential'` | `'hinge'` | `'logit'` | `'quadratic'` | function handle

Loss function, specified as the comma-separated pair consisting of `'LossFun'` and a built-in, loss-function name or function handle.

- The following table lists the available loss functions. Specify one using its corresponding character vector or string scalar.

Value	Description
'binodeviance'	Binomial deviance
'classiferror'	Classification error
'exponential'	Exponential
'hinge'	Hinge
'logit'	Logistic
'mincost'	Minimal expected misclassification cost (for classification scores that are posterior probabilities)
'quadratic'	Quadratic

'mincost' is appropriate for classification scores that are posterior probabilities. Classification trees return posterior probabilities as classification scores by default (see `predict`).

- Specify your own function using function handle notation.

Suppose that n be the number of observations in X and K be the number of distinct classes (`numel(tree.ClassNames)`). Your function must have this signature

```
lossvalue = lossfun(C,S,W,Cost)
```

where:

- The output argument `lossvalue` is a scalar.
- You choose the function name (`lossfun`).
- C is an n -by- K logical matrix with rows indicating which class the corresponding observation belongs. The column order corresponds to the class order in `tree.ClassNames`.

Construct C by setting $C(p, q) = 1$ if observation p is in class q , for each row. Set all other elements of row p to 0 .

- S is an n -by- K numeric matrix of classification scores. The column order corresponds to the class order in `tree.ClassNames`. S is a matrix of classification scores, similar to the output of `predict`.
- W is an n -by-1 numeric vector of observation weights. If you pass W , the software normalizes them to sum to 1.

- `Cost` is a K -by- K numeric matrix of misclassification costs. For example, `Cost = ones(K) - eye(K)` specifies a cost of 0 for correct classification, and 1 for misclassification.

Specify your function using `'LossFun', @lossfun`.

For more details on loss functions, see “Classification Loss” on page 32-3957.

Data Types: `char` | `string` | `function_handle`

Weights — Observation weights

`ones(size(X,1),1)` (default) | name of a variable in TBL | numeric vector of positive values

Observation weights, specified as the comma-separated pair consisting of `'Weights'` and a numeric vector of positive values or the name of a variable in TBL.

If you specify `Weights` as a numeric vector, then the size of `Weights` must be equal to the number of rows in `X` or TBL.

If you specify `Weights` as the name of a variable in TBL, you must do so as a character vector or string scalar. For example, if the weights are stored as `TBL.W`, then specify it as `'W'`. Otherwise, the software treats all columns of TBL, including `TBL.W`, as predictors.

`loss` normalizes the weights so that observation weights in each class sum to the prior probability of that class. When you supply `Weights`, `loss` computes weighted classification loss.

Data Types: `single` | `double` | `char` | `string`

Name, Value arguments associated with pruning subtrees:

Subtrees — Pruning level

0 (default) | vector of nonnegative integers | `'all'`

Pruning level, specified as the comma-separated pair consisting of `'Subtrees'` and a vector of nonnegative integers in ascending order or `'all'`.

If you specify a vector, then all elements must be at least 0 and at most `max(tree.PruneList)`. 0 indicates the full, unpruned tree and `max(tree.PruneList)` indicates the completely pruned tree (i.e., just the root node).

If you specify `'all'`, then `loss` operates on all subtrees (i.e., the entire pruning sequence). This specification is equivalent to using `0:max(tree.PruneList)`.

loss prunes tree to each level indicated in Subtrees, and then estimates the corresponding output arguments. The size of Subtrees determines the size of some output arguments.

To invoke Subtrees, the properties PruneList and PruneAlpha of tree must be nonempty. In other words, grow tree by setting 'Prune', 'on', or by pruning tree using prune.

Example: 'Subtrees', 'all'

Data Types: single | double | char | string

TreeSize — Tree size

'se' (default) | 'min'

Tree size, specified as the comma-separated pair consisting of 'TreeSize' and one of the following values:

- 'se' — loss returns the highest pruning level with loss within one standard deviation of the minimum ($L + se$, where L and se relate to the smallest value in Subtrees).
- 'min' — loss returns the element of Subtrees with smallest loss, usually the smallest element of Subtrees.

Output Arguments

L — Classification loss

vector of scalar values

Classification loss on page 32-3957, returned as a vector the length of Subtrees. The meaning of the error depends on the values in Weights and LossFun.

se — Standard error of loss

vector of scalar values

Standard error of loss, returned as a vector the length of Subtrees.

NLeaf — Number of leaf nodes

vector of integer values

Number of leaves (terminal nodes) in the pruned subtrees, returned as a vector the length of Subtrees.

bestlevel — Best pruning level

scalar value

Best pruning level as defined in the `TreeSize` name-value pair, returned as a scalar whose value depends on `TreeSize`:

- `TreeSize = 'se'` — `loss` returns the highest pruning level with loss within one standard deviation of the minimum ($L + se$, where L and se relate to the smallest value in `Subtrees`).
- `TreeSize = 'min'` — `loss` returns the element of `Subtrees` with smallest loss, usually the smallest element of `Subtrees`.

By default, `bestlevel` is the pruning level that gives loss within one standard deviation of minimal loss.

Examples

Compute the In-sample Classification Error

Compute the resubstituted classification error for the `ionosphere` data set.

```
load ionosphere
tree = fitctree(X,Y);
L = loss(tree,X,Y)
```

```
L = 0.0114
```

Examine the Classification Error for Each Subtree

Unpruned decision trees tend to overfit. One way to balance model complexity and out-of-sample performance is to prune a tree (or restrict its growth) so that in-sample and out-of-sample performance are satisfactory.

Load Fisher's iris data set. Partition the data into training (50%) and validation (50%) sets.

```
load fisheriris
n = size(meas,1);
```

```

rng(1) % For reproducibility
idxTrn = false(n,1);
idxTrn(randsample(n,round(0.5*n))) = true; % Training set logical indices
idxVal = idxTrn == false; % Validation set logical indices

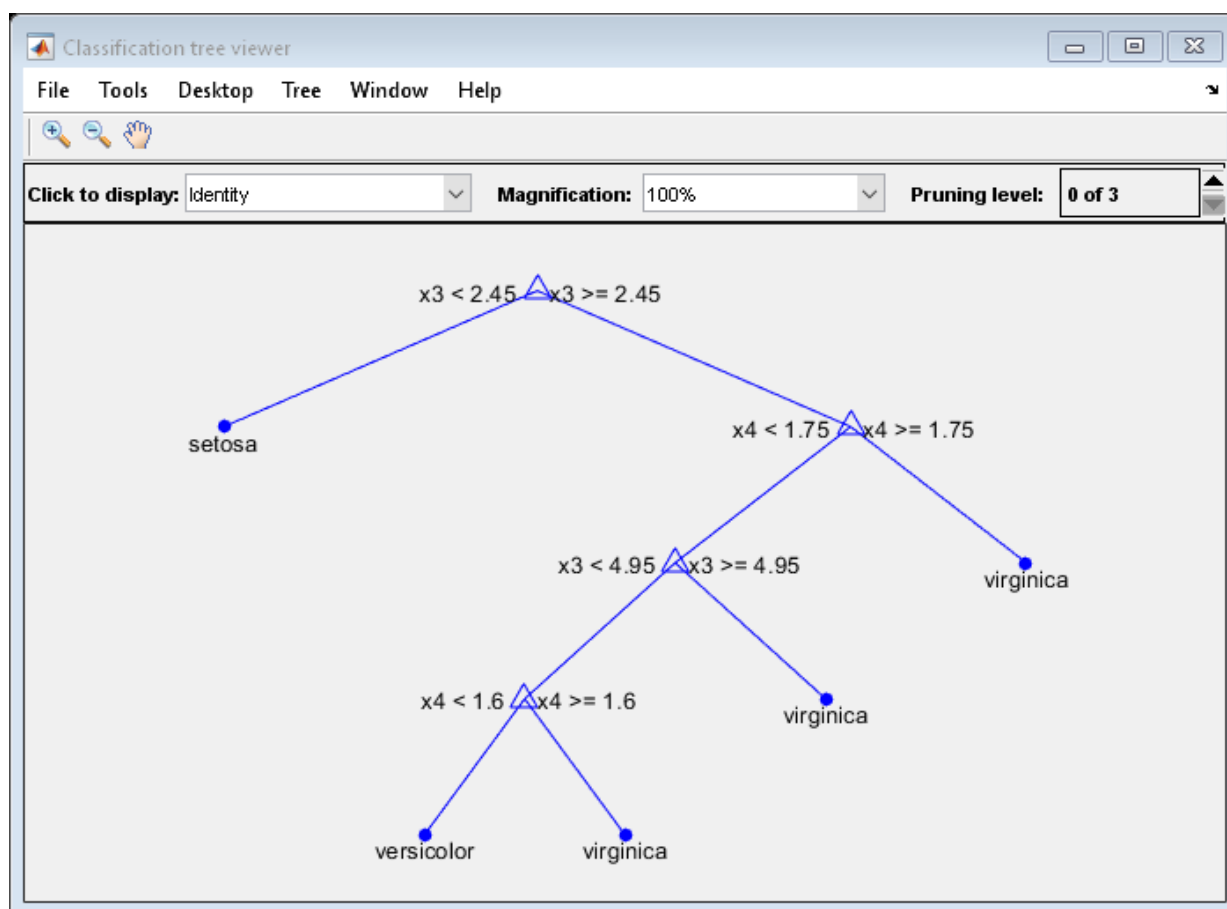

```

Grow a classification tree using the training set.

```
Mdl = fitctree(meas(idxTrn,:),species(idxTrn));
```

View the classification tree.

```
view(Mdl, 'Mode', 'graph');
```

The classification tree has four pruning levels. Level 0 is the full, unpruned tree (as displayed). Level 3 is just the root node (i.e., no splits).

Examine the training sample classification error for each subtree (or pruning level) excluding the highest level.

```
m = max(Mdl.PruneList) - 1;  
trnLoss = resubLoss(Mdl, 'SubTrees', 0:m)
```

```
trnLoss = 3×1
```

```
0.0267  
0.0533  
0.3067
```

- The full, unpruned tree misclassifies about 2.7% of the training observations.
- The tree pruned to level 1 misclassifies about 5.3% of the training observations.
- The tree pruned to level 2 (i.e., a stump) misclassifies about 30.6% of the training observations.

Examine the validation sample classification error at each level excluding the highest level.

```
valLoss = loss(Mdl, meas(idxVal, :), species(idxVal), 'SubTrees', 0:m)
```

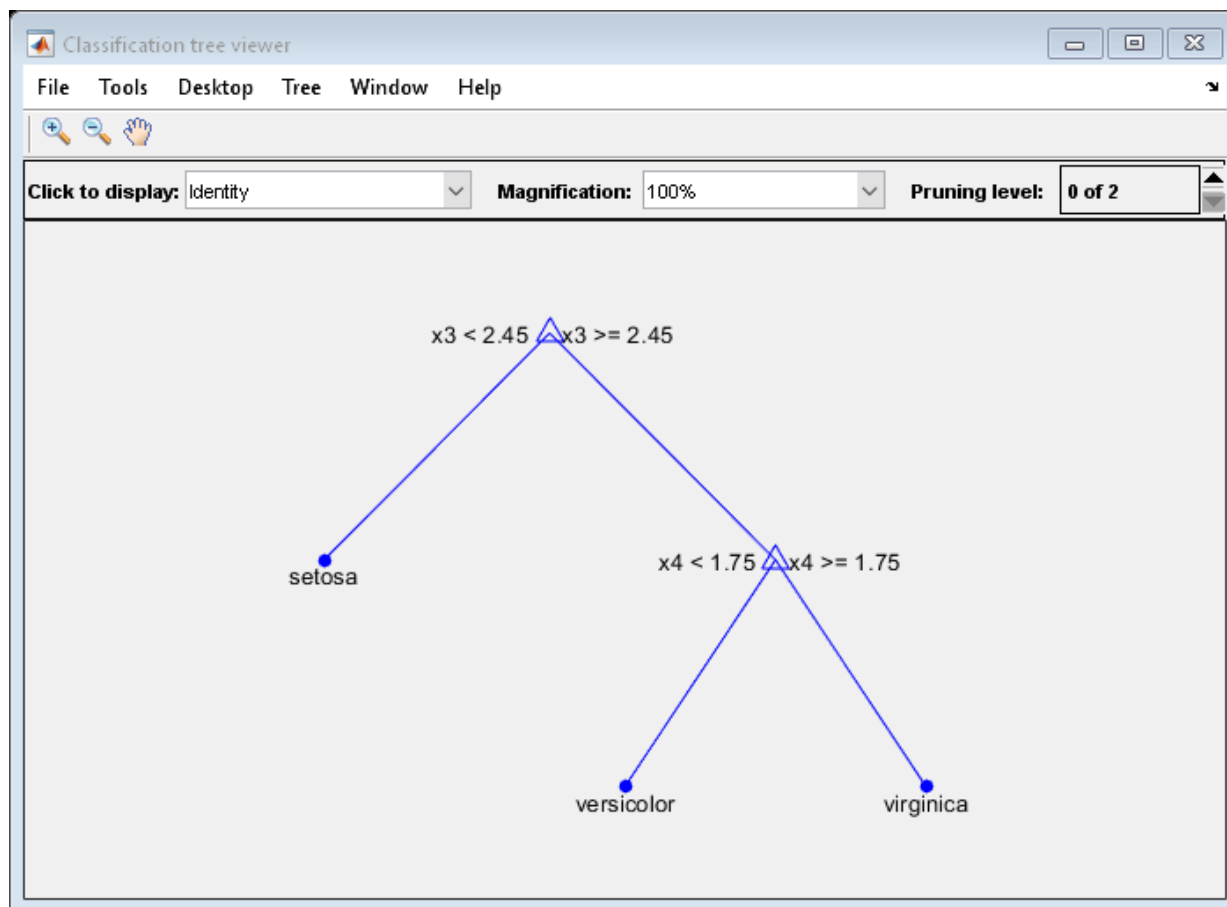

```
valLoss = 3×1
```

```
0.0369  
0.0237  
0.3067
```

- The full, unpruned tree misclassifies about 3.7% of the validation observations.
- The tree pruned to level 1 misclassifies about 2.4% of the validation observations.
- The tree pruned to level 2 (i.e., a stump) misclassifies about 30.7% of the validation observations.

To balance model complexity and out-of-sample performance, consider pruning `Mdl` to level 1.

```
pruneMdl = prune(Mdl, 'Level', 1);  
view(pruneMdl, 'Mode', 'graph')
```

Definitions

Classification Loss

Classification loss functions measure the predictive inaccuracy of classification models. When you compare the same type of loss among many models, a lower loss indicates a better predictive model.

Consider the following scenario.

- L is the weighted average classification loss.
- n is the sample size.
- For binary classification:
 - y_j is the observed class label. The software codes it as -1 or 1, indicating the negative or positive class, respectively.
 - $f(X_j)$ is the raw classification score for observation (row) j of the predictor data X .
 - $m_j = y_j f(X_j)$ is the classification score for classifying observation j into the class corresponding to y_j . Positive values of m_j indicate correct classification and do not contribute much to the average loss. Negative values of m_j indicate incorrect classification and contribute significantly to the average loss.
- For algorithms that support multiclass classification (that is, $K \geq 3$):
 - y_j^* is a vector of $K - 1$ zeros, with 1 in the position corresponding to the true, observed class y_j . For example, if the true class of the second observation is the third class and $K = 4$, then $y_2^* = [0 \ 0 \ 1 \ 0]$. The order of the classes corresponds to the order in the `ClassNames` property of the input model.
 - $f(X_j)$ is the length K vector of class scores for observation j of the predictor data X . The order of the scores corresponds to the order of the classes in the `ClassNames` property of the input model.
 - $m_j = y_j^* f(X_j)$. Therefore, m_j is the scalar classification score that the model predicts for the true, observed class.
- The weight for observation j is w_j . The software normalizes the observation weights so that they sum to the corresponding prior class probability. The software also normalizes the prior probabilities so they sum to 1. Therefore,

$$\sum_{j=1}^n w_j = 1.$$

Given this scenario, the following table describes the supported loss functions that you can specify by using the 'LossFun' name-value pair argument.

Loss Function	Value of LossFun	Equation
Binomial deviance	'binodeviance'	$L = \sum_{j=1}^n w_j \log \{1 + \exp[-2m_j]\}.$

Loss Function	Value of LossFun	Equation
Exponential loss	'exponential'	$L = \sum_{j=1}^n w_j \exp(-m_j).$
Classification error	'classiferror'	$L = \sum_{j=1}^n w_j I\{\hat{y}_j \neq y_j\}.$ <p>It is the weighted fraction of misclassified observations where \hat{y}_j is the class label corresponding to the class with the maximal posterior probability. $I\{x\}$ is the indicator function.</p>
Hinge loss	'hinge'	$L = \sum_{j=1}^n w_j \max\{0, 1 - m_j\}.$
Logit loss	'logit'	$L = \sum_{j=1}^n w_j \log(1 + \exp(-m_j)).$

Loss Function	Value of LossFun	Equation
Minimal cost	'mincost'	<p>Minimal cost. The software computes the weighted minimal cost using this procedure for observations $j = 1, \dots, n$.</p> <ol style="list-style-type: none"> 1 Estimate the 1-by-K vector of expected classification costs for observation j: $v_j = f(X_j)'C.$ <p>$f(X_j)$ is the column vector of class posterior probabilities for binary and multiclass classification. C is the cost matrix that the input model stores in the <code>Cost</code> property.</p> 2 For observation j, predict the class label corresponding to the minimum expected classification cost: $\hat{y}_j = \min_{j = 1, \dots, K} (v_j).$ 3 Using C, identify the cost incurred (c_j) for making the prediction. <p>The weighted, average, minimum cost loss is</p> $L = \sum_{j=1}^n w_j c_j.$
Quadratic loss	'quadratic'	$L = \sum_{j=1}^n w_j (1 - m_j)^2.$

This figure compares the loss functions (except 'mincost') for one observation over m . Some functions are normalized to pass through [0,1].

True Misclassification Cost

There are two costs associated with classification: the true misclassification cost per class, and the expected misclassification cost per observation.

You can set the true misclassification cost per class in the `Cost` name-value pair when you create the classifier using the `fitctree` method. `Cost(i, j)` is the cost of classifying an observation into class j if its true class is i . By default, `Cost(i, j) = 1` if $i \neq j$, and `Cost(i, j) = 0` if $i = j$. In other words, the cost is 0 for correct classification, and 1 for incorrect classification.

Expected Misclassification Cost

There are two costs associated with classification: the true misclassification cost per class, and the expected misclassification cost per observation.

Suppose you have `Nobs` observations that you want to classify with a trained classifier. Suppose you have `K` classes. You place the observations into a matrix `Xnew` with one observation per row.

The expected cost matrix `CE` has size `Nobs`-by-`K`. Each row of `CE` contains the expected (average) cost of classifying the observation into each of the `K` classes. `CE(n, k)` is

$$\sum_{i=1}^K \widehat{P}(i|Xnew(n))C(k|i),$$

where

- `K` is the number of classes.
- $\widehat{P}(i|Xnew(n))$ is the posterior probability of class `i` for observation `Xnew(n)`.
- `C(k|i)` is the true misclassification cost of classifying an observation as `k` when its true class is `i`.

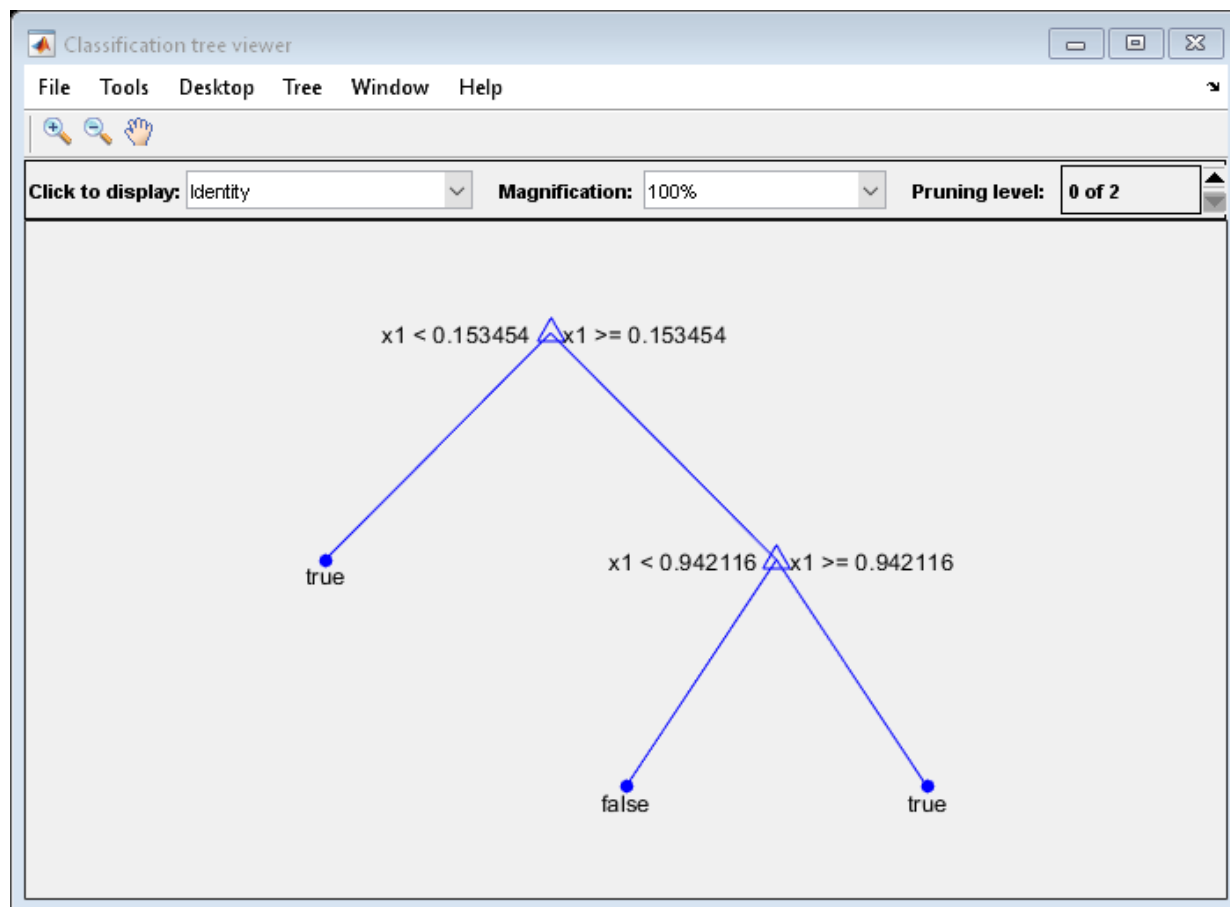

Score (tree)

For trees, the score of a classification of a leaf node is the posterior probability of the classification at that node. The posterior probability of the classification at a node is the number of training sequences that lead to that node with the classification, divided by the number of training sequences that lead to that node.

For example, consider classifying a predictor `X` as `true` when `X < 0.15` or `X > 0.95`, and `X` is false otherwise.

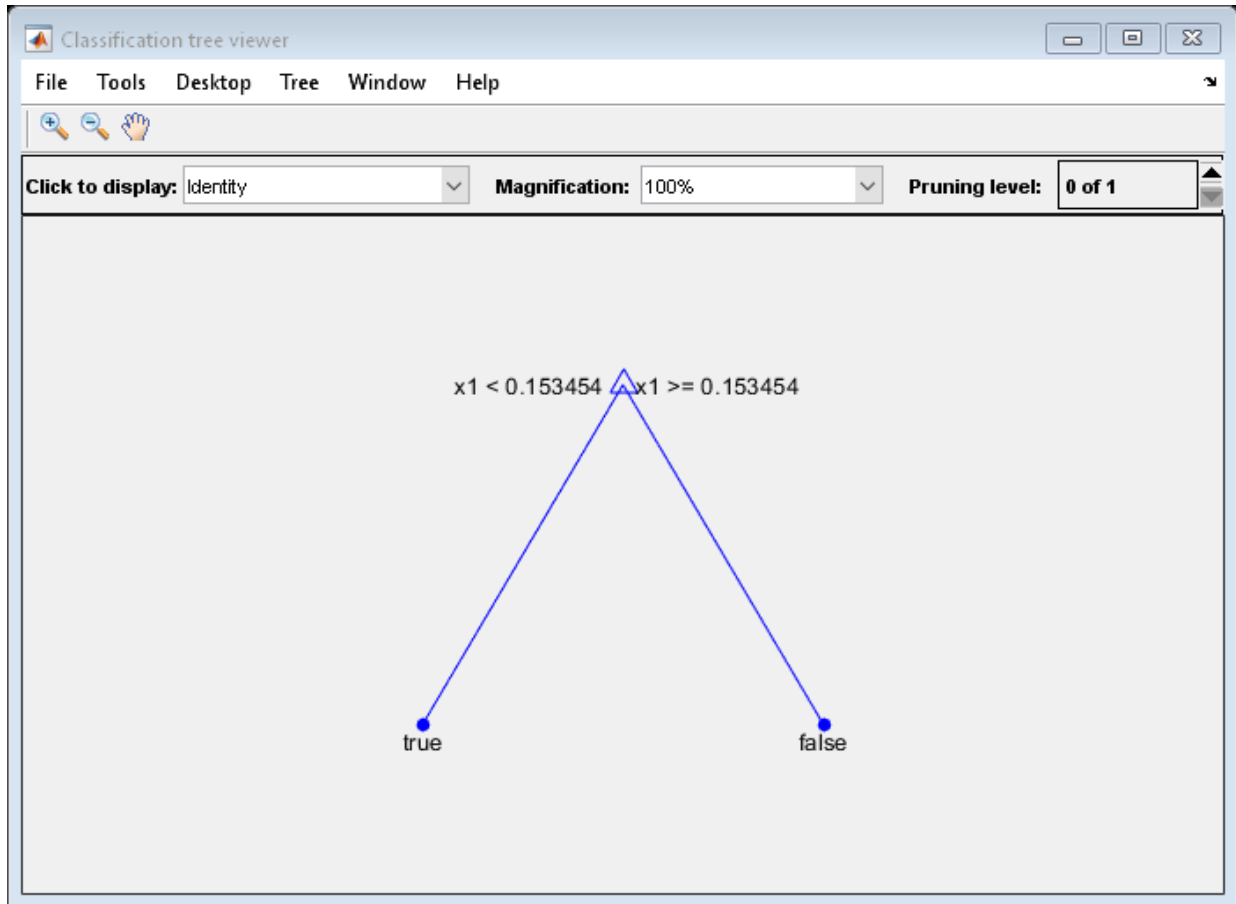

Generate 100 random points and classify them:

```
rng(0, 'twister') % for reproducibility
X = rand(100,1);
Y = (abs(X - .55) > .4);
tree = fitctree(X,Y);
view(tree, 'Mode', 'Graph')
```

Prune the tree:

```
tree1 = prune(tree, 'Level', 1);  
view(tree1, 'Mode', 'Graph')
```

The pruned tree correctly classifies observations that are less than 0.15 as `true`. It also correctly classifies observations from .15 to .94 as `false`. However, it incorrectly classifies observations that are greater than .94 as `false`. Therefore, the score for observations that are greater than .15 should be about $.05/.85=.06$ for `true`, and about $.8/.85=.94$ for `false`.

Compute the prediction scores for the first 10 rows of `X`:

```
[~,score] = predict(tree1,X(1:10));
[score X(1:10,:)]
```

```
ans = 10x3
    0.9059    0.0941    0.8147
    0.9059    0.0941    0.9058
         0     1.0000    0.1270
    0.9059    0.0941    0.9134
    0.9059    0.0941    0.6324
         0     1.0000    0.0975
    0.9059    0.0941    0.2785
    0.9059    0.0941    0.5469
    0.9059    0.0941    0.9575
    0.9059    0.0941    0.9649
```

Indeed, every value of X (the right-most column) that is less than 0.15 has associated scores (the left and center columns) of 0 and 1, while the other values of X have associated scores of 0.91 and 0.09. The difference (score 0.09 instead of the expected .06) is due to a statistical fluctuation: there are 8 observations in X in the range (.95, 1) instead of the expected 5 observations.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function supports tall arrays for out-of-memory data with the limitation:

- Only one output is supported.

For more information, see “Tall Arrays” (MATLAB).

edge | fitctree | margin | predict

loss

Regression error

Syntax

```
L = loss(ens, tbl, ResponseVarName)
L = loss(ens, tbl, Y)
L = loss(ens, X, Y)
L = loss( ____, Name, Value)
```

Description

`L = loss(ens, tbl, ResponseVarName)` returns the mean squared error between the predictions of `ens` to the data in `tbl`, compared to the true responses `tbl.ResponseVarName`.

`L = loss(ens, tbl, Y)` returns the mean squared error between the predictions of `ens` to the data in `tbl`, compared to the true responses `Y`.

`L = loss(ens, X, Y)` returns the mean squared error between the predictions of `ens` to the data in `X`, compared to the true responses `Y`.

`L = loss(____, Name, Value)` computes the error in prediction with additional options specified by one or more `Name, Value` pair arguments, using any of the previous syntaxes.

Input Arguments

ens

A regression ensemble created with `fitrensemble`, or the `compact` method.

tbl

Sample data, specified as a table. Each row of `tbl` corresponds to one observation, and each column corresponds to one predictor variable. `tbl` must contain all of the predictors

used to train the model. Multi-column variables and cell arrays other than cell arrays of character vectors are not allowed.

If you trained `ens` using sample data contained in a `table`, then the input data for this method must also be in a `table`.

ResponseVarName

Response variable name, specified as the name of a variable in `tbl`. The response variable must be a numeric vector.

You must specify `ResponseVarName` as a character vector or string scalar. For example, if the response variable `Y` is stored as `tbl.Y`, then specify it as `'Y'`. Otherwise, the software treats all columns of `tbl`, including `Y`, as predictors when training the model.

X

A matrix of predictor values. Each column of `X` represents one variable, and each row represents one observation.

`NaN` values in `X` are taken to be missing values. Observations with all missing values for `X` are not used in the calculation of loss.

If you trained `ens` using sample data contained in a matrix, then the input data for this method must also be in a matrix.

Y

A numeric column vector with the same number of rows as `tbl` or `X`. Each entry in `Y` is the response to the data in the corresponding row of `tbl` or `X`.

`NaN` values in `Y` are taken to be missing values. Observations with missing values for `Y` are not used in the calculation of loss.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Learners

Indices of weak learners in the ensemble ranging from 1 to `ens.NumTrained`. `oobEdge` uses only these learners for calculating loss.

Default: `1:NumTrained`

lossfun

Function handle for loss function, or 'mse', meaning mean squared error. If you pass a function handle `fun`, `loss` calls it as

```
fun(Y,Yfit,W)
```

where `Y`, `Yfit`, and `W` are numeric vectors of the same length.

- `Y` is the observed response.
- `Yfit` is the predicted response.
- `W` is the observation weights.

The returned value `fun(Y,Yfit,W)` should be a scalar.

Default: 'mse'

mode

Meaning of the output `L`:

- 'ensemble' — `L` is a scalar value, the loss for the entire ensemble.
- 'individual' — `L` is a vector with one element per trained learner.
- 'cumulative' — `L` is a vector in which element `J` is obtained by using learners `1:J` from the input list of learners.

Default: 'ensemble'

UseObsForLearner

A logical matrix of size `N-by-NumTrained`, where `N` is the number of observations in `ens.X`, and `NumTrained` is the number of weak learners. When `UseObsForLearner(I,J)` is true, `predict` uses learner `J` in predicting observation `I`.

Default: `true(N,NumTrained)`

weights

Numeric vector of observation weights with the same number of elements as `Y`. The formula for `loss` with `weights` is in “Weighted Mean Squared Error” on page 32-3970.

Default: `ones(size(Y))`

Output Arguments

L

Weighted mean squared error of predictions. The formula for `loss` is in “Weighted Mean Squared Error” on page 32-3970.

Examples

Find Mean-Squared Error of Ensemble Predictions

Find the loss of an ensemble predictor using the `carsmall` data set.

Load the `carsmall` data set and select engine displacement, horsepower, and vehicle weight as predictors.

```
load carsmall
X = [Displacement Horsepower Weight];
```

Train an ensemble of regression trees and find the regression error for predicting MPG.

```
ens = fitensemble(X,MPG);
L = loss(ens,X,MPG)
```

```
L = 0.3463
```

Definitions

Weighted Mean Squared Error

Let n be the number of rows of data, x_j be the j th row of data, y_j be the true response to x_j , and let $f(x_j)$ be the response prediction of `ens` to x_j . Let w be the vector of weights (all one by default).

First the weights are divided by their sum so they add to one: $w \rightarrow w/\Sigma w$. The mean squared error L is

$$L = \sum_{j=1}^n w_j (f(x_j) - y_j)^2.$$

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. For more information, see “Tall Arrays” (MATLAB).

`fitensemble` | `predict`

loss

Regression error for Gaussian process regression model

Syntax

```
L = loss(gprMdl, Xnew, Ynew)
L = loss(gprMdl, Xnew, Ynew, Name, Value)
```

Description

`L = loss(gprMdl, Xnew, Ynew)` returns the mean squared error for the Gaussian process regression (GPR) model `gpr`, using the predictors in `Xnew` and observed response in `Ynew`.

`L = loss(gprMdl, Xnew, Ynew, Name, Value)` returns the mean squared error for the GPR model, `gpr`, with additional options specified by one or more `Name, Value` pair arguments. For example, you can specify a custom loss function or the observation weights.

Input Arguments

gprMdl — Gaussian process regression model

RegressionGP object | CompactRegressionGP object

Gaussian process regression model, specified as a `RegressionGP` (full) or `CompactRegressionGP` (compact) object.

Xnew — New observed data

table | *m*-by-*d* matrix

New data, specified as a `table` or an *n*-by-*d* matrix, where *m* is the number of observations, and *d* is the number of predictor variables in the training data.

If you trained `gprMdl` on a `table`, then `Xnew` must be a `table` that contains all the predictor variables used to train `gprMdl`.

If `Xnew` is a table, then it can also contain `Ynew`. And if it does, then you do not have to specify `Ynew`.

If you trained `gprMdl` on a matrix, then `Xnew` must be a numeric matrix with d columns, and can only contain values for the predictor variables.

Data Types: `single` | `double` | `table`

Ynew — New response values

n -by-1 vector

New observed response values, that correspond to the predictor values in `Xnew`, specified as an n -by-1 vector. n is the number of rows in `Xnew`. Each entry in `Ynew` is the observed response based on the predictor data in the corresponding row of `Xnew`.

If `Xnew` is a table containing new response values, you do not have to specify `Ynew`.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

lossfun — Loss function

'mse' (default) | function handle

Loss function, specified as 'mse' (mean squared error) or a function handle.

If you pass a function handle, say `fun`, `loss` calls it as shown below: `fun(Y, Ypred, W)`, where `Y`, `Ypred` and `W` are numeric vectors of length n , and n is the number of rows in `Xnew`. `Y` is the observed response, `Ypred` is the predicted response, and `W` is the observation weights.

Example: `'lossfun', Fct` calls the loss function `Fct`.

Data Types: `char` | `string` | `function_handle`

weights — Observation weights

vector of 1s (default) | n -by-1 vector

Observation weights, specified as n -by-1 vector, where n is the number of rows in X_{new} . By default, the weight of each observation is 1.

Example: 'weights', W uses the observation weights in vector W .

Data Types: double | single

Output Arguments

L — Regression error

scalar value

Regression error for the trained Gaussian process regression model, `gprMdl`, returned as a scalar value.

Examples

Compute Regression Loss for Test Data

Load the sample data.

```
load(fullfile(matlabroot, 'examples', 'stats', 'gprdata.mat'))
```

The data has 8 predictor variables and contains 500 observations in training data and 100 observations in test data. This is simulated data.

Fit a GPR model using the squared exponential kernel function with separate length scales for each predictor. Standardize the predictor values in the training data. Use the exact method for fitting and prediction.

```
gprMdl = fitrgp(Xtrain,ytrain,'FitMethod','exact',...  
'PredictMethod','exact','KernelFunction','ardsquaredexponential',...  
'Standardize',1);
```

Compute the regression error for the test data.

```
L = loss(gprMdl,Xtest,ytest)
```

```
L = 0.6928
```

Predict the responses for test data.

```
ypredtest = predict(gprMdl,Xtest);
```

Plot the test response along with the predictions.

```
figure;  
plot(ytest,'r');  
hold on;  
plot(ypredtest,'b');  
legend('Data','Predictions','Location','Best');
```

Manually compute the regression loss.

```
L = (ytest - ypredtest)'*(ytest - ypredtest)/length(ytest)
```

```
L = 0.6928
```

Specify Custom Loss Function

Load the sample data and store in a table.

```
load fisheriris
tbl = table(meas(:,1),meas(:,2),meas(:,3),meas(:,4),species,...
'VariableNames',{'meas1','meas2','meas3','meas4','species'});
```

Fit a GPR model using the first measurement as the response and the other variables as the predictors.

```
mdl = fitrgp(tbl,'meas1');
```

Predict the responses using the trained model.

```
ypred = predict(mdl,tbl);
```

Compute the mean absolute error.

```
n = height(tbl);
y = tbl.meas1;
fun = @(y,ypred,w) sum(abs(y-ypred))/n;
L = loss(mdl,tbl,'lossfun',fun)
```

```
L = 0.2345
```

Alternatives

You can use `resubLoss` to compute the regression error for the trained GPR model at the observations in the training data.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. For more information, see “Tall Arrays” (MATLAB).

Introduced in R2015b

loss

Regression error for support vector machine regression model

Syntax

```
L = loss mdl, tbl, ResponseVarName
L = loss mdl, tbl, Y
L = loss mdl, X, Y
L = loss( ___, Name, Value)
```

Description

`L = loss(mdl, tbl, ResponseVarName)` returns the loss for the predictions of the support vector machine (SVM) regression model, `mdl`, based on the predictor data in the table `tbl` and the true response values in `tbl.ResponseVarName`.

`L = loss(mdl, tbl, Y)` returns the loss for the predictions of the support vector machine (SVM) regression model, `mdl`, based on the predictor data in the table `X` and the true response values in the vector `Y`.

`L = loss(mdl, X, Y)` returns the loss for the predictions of the support vector machine (SVM) regression model, `mdl`, based on the predictor data in `X` and the true responses in `Y`.

`L = loss(___, Name, Value)` returns the loss with additional options specified by one or more `Name, Value` pair arguments, using any of the previous syntaxes. For example, you can specify the loss function or observation weights.

Input Arguments

mdl — SVM regression model

RegressionSVM model | CompactRegressionSVM model

SVM regression model, specified as a `RegressionSVM` model or `CompactRegressionSVM` model returned by `fitrsvm` or `compact`, respectively.

tbl — Sample data

table

Sample data, specified as a table. Each row of `tbl` corresponds to one observation, and each column corresponds to one predictor variable. Optionally, `tbl` can contain additional columns for the response variable and observation weights. `tbl` must contain all of the predictors used to train `mdl`. Multi-column variables and cell arrays other than cell arrays of character vectors are not allowed.

If you trained `mdl` using sample data contained in a `table`, then the input data for this method must also be in a table.

Data Types: `table`

ResponseVarName — Response variable namename of a variable in `tbl`

Response variable name, specified as the name of a variable in `tbl`. The response variable must be a numeric vector.

You must specify `ResponseVarName` as a character vector or string scalar. For example, if the response variable `Y` is stored as `tbl.Y`, then specify `ResponseVarName` as `'Y'`. Otherwise, the software treats all columns of `tbl`, including `Y`, as predictors when training the model.

Data Types: `char` | `string`

X — Predictor data

numeric matrix

Predictor data, specified as a numeric matrix or table. Each row of `X` corresponds to one observation (also known as an instance or example), and each column corresponds to one variable (also known as a feature).

If you trained `mdl` using a matrix of predictor values, then `X` must be a numeric matrix with p columns. p is the number of predictors used to train `mdl`.

The length of `Y` and the number of rows of `X` must be equal.

Data Types: `single` | `double`

Y — Observed response values

vector of numeric values

Observed response values, specified as a vector of length n containing numeric values. Each entry in Y is the observed response based on the predictor data in the corresponding row of X .

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

LossFun — Loss function

'mse' (default) | 'epsiloninsensitive' | function handle

Loss function, specified as the comma-separated pair consisting of 'LossFun' and 'mse', 'epsiloninsensitive', or a function handle.

- The following table lists the available loss functions.

Value	Loss Function
'mse'	"Weighted Mean Squared Error" on page 32-3981
'epsiloninsensitive'	"Epsilon-Insensitive Loss Function" on page 32-3982

- Specify your own function using function handle notation.

Your function must have the signature `lossvalue = lossfun(Y,Yfit,W)`, where:

- The output argument `lossvalue` is a scalar value.
- You choose the function name (*lossfun*).
- Y is an n -by-1 numeric vector of observed response values.
- $Yfit$ is an n -by-1 numeric vector of predicted response values, calculated using the corresponding predictor values in X (similar to the output of `predict`).
- W is an n -by-1 numeric vector of observation weights. If you pass W , the software normalizes them to sum to 1.

Specify your function using 'LossFun', `@lossfun`.

Example: 'LossFun', 'epsiloninsensitive'

Data Types: char | string | function_handle

Weights — Observation weights

ones(size(X,1),1) (default) | numeric vector

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a numeric vector. **Weights** must be the same length as the number of rows in X. The software weighs the observations in each row of X using the corresponding weight value in **Weights**.

Weights are normalized to sum to 1.

Data Types: single | double

Output Arguments

L — Regression loss

scalar value

Regression loss, returned as a scalar value.

Examples

Calculate Test Sample Loss for SVM Regression Model

This example shows how to train an SVM regression model, then calculate the resubstitution mean square error and epsilon-insensitive error.

Load the carsmall sample data.

```
load carsmall
rng default % for reproducibility
```

Specify Horsepower and Weight as the predictor variables (X), and MPG as the response variable (Y).

```
X = [Horsepower,Weight];
Y = MPG;
```

Train a linear SVM regression model. Standardize the data.

```
mdl = fitrsvm(X,Y,'Standardize',true);
```

mdl is a RegressionSVM model.

Determine how well the trained model generalizes to new predictor values by estimating the test sample mean square error and epsilon-insensitive error.

```
lossMSE = loss(mdl,X,Y)
lossEI = loss(mdl,X,Y,'LossFun','epsiloninsensitive')
```

```
lossMSE =
```

```
17.0256
```

```
lossEI =
```

```
2.2506
```

Definitions

Weighted Mean Squared Error

The weighted mean squared error is calculated as follows:

$$\text{mse} = \frac{\sum_{j=1}^n w_j (f(x_j) - y_j)^2}{\sum_{j=1}^n w_j},$$

where:

- n is the number of rows of data
- x_j is the j th row of data
- y_j is the true response to x_j
- $f(x_j)$ is the response prediction of the SVM regression model mdl to x_j

- w is the vector of weights.

The weights in w are all equal to one by default. You can specify different values for weights using the 'Weights' name-value pair argument. If you specify weights, each value is divided by the sum of all weights, such that the normalized weights add to one.

Epsilon-Insensitive Loss Function

The epsilon-insensitive loss function ignores errors that are within the distance epsilon (ε) of the function value. It is formally described as:

$$Loss_{\varepsilon} = \begin{cases} 0, & \text{if } |y - f(x)| \leq \varepsilon \\ |y - f(x)| - \varepsilon, & \text{otherwise.} \end{cases}$$

The mean epsilon-insensitive loss is calculated as follows:

$$Loss = \frac{\sum_{j=1}^n w_j \max(0, |y_j - f(x_j)| - \varepsilon)}{\sum_{j=1}^n w_j},$$

where:

- n is the number of rows of data
- x_j is the j th row of data
- y_j is the true response to x_j
- $f(x_j)$ is the response prediction of the SVM regression model `mdl` to x_j
- w is the vector of weights.

The weights in w are all equal to one by default. You can specify different values for weights using the 'Weights' name-value pair argument. If you specify weights, each value is divided by the sum of all weights, such that the normalized weights add to one.

Tips

- If `mdl` is a cross-validated `RegressionPartitionedSVM` model, use `kfoldLoss` instead of `loss` to calculate the regression error.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. For more information, see “Tall Arrays” (MATLAB).

`CompactRegressionSVM` | `RegressionSVM` | `fitrsvm` | `kfoldLoss`

Introduced in R2015b

loss

Regression error

Syntax

```
L = loss(tree, tbl, ResponseVarName)
L = loss(tree, x, y)
L = loss( ____, Name, Value)
[L, se, NLeaf, bestlevel] = loss( ____ )
```

Description

`L = loss(tree, tbl, ResponseVarName)` returns the mean squared error between the predictions of `tree` to the data in `tbl`, compared to the true responses `tbl.ResponseVarName`.

`L = loss(tree, x, y)` returns the mean squared error between the predictions of `tree` to the data in `x`, compared to the true responses `y`.

`L = loss(____, Name, Value)` computes the error in prediction with additional options specified by one or more `Name, Value` pair arguments, using any of the previous syntaxes.

`[L, se, NLeaf, bestlevel] = loss(____)` also returns the standard error of the loss (`se`), the number of leaves (terminal nodes) in the tree (`NLeaf`), and the optimal pruning level for `tree` (`bestlevel`).

Input Arguments

tree — Trained regression tree

RegressionTree object | CompactRegressionTree object

Trained regression tree, specified as a `RegressionTree` object constructed by `fitrtree` or a `CompactRegressionTree` object constructed by `compact`.

x — Predictor values

matrix of floating-point values

Predictor values, specified as matrix of floating-point values. Each column of `x` represents one variable, and each row represents one observation.

Data Types: `single` | `double`

ResponseVarName — Response variable name

name of a variable in `tbl`

Response variable name, specified as the name of a variable in `tbl`.

You must specify `ResponseVarName` as a character vector or string scalar. For example, if the response variable `y` is stored as `tbl.y`, then specify `ResponseVarName` as `'y'`. Otherwise, the software treats all columns of `tbl`, including `y`, as predictors when training the model.

Data Types: `char` | `string`

y — Response data

numeric column vector

Response data, specified as a numeric column vector with the same number of rows as `x`. Each entry in `y` is the response to the data in the corresponding row of `x`.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

LossFun — Loss function

`'mse'` (default) | function handle

Loss function, specified as the comma-separated pair consisting of `'LossFun'` and a function handle for loss, or `'mse'` representing mean-squared error. If you pass a function handle `fun`, `loss` calls `fun` as:

```
fun(Y,Yfit,W)
```

- Y is the vector of true responses.
- Y_{fit} is the vector of predicted responses.
- W is the observation weights. If you pass W , the elements are normalized to sum to 1.

All the vectors have the same number of rows as Y .

Example: `'LossFun', 'mse'`

Data Types: `function_handle | char | string`

Subtrees — Pruning level

0 (default) | vector of nonnegative integers | `'all'`

Pruning level, specified as the comma-separated pair consisting of `'Subtrees'` and a vector of nonnegative integers in ascending order or `'all'`.

If you specify a vector, then all elements must be at least 0 and at most `max(tree.PruneList)`. 0 indicates the full, unpruned tree and `max(tree.PruneList)` indicates the completely pruned tree (i.e., just the root node).

If you specify `'all'`, then `loss` operates on all subtrees (i.e., the entire pruning sequence). This specification is equivalent to using `0:max(tree.PruneList)`.

`loss` prunes `tree` to each level indicated in `Subtrees`, and then estimates the corresponding output arguments. The size of `Subtrees` determines the size of some output arguments.

To invoke `Subtrees`, the properties `PruneList` and `PruneAlpha` of `tree` must be nonempty. In other words, grow `tree` by setting `'Prune', 'on'`, or by pruning `tree` using `prune`.

Example: `'Subtrees', 'all'`

Data Types: `single | double | char | string`

TreeSize — Tree size

`'se'` (default) | `'min'`

Tree size, specified as the comma-separated pair consisting of `'TreeSize'` and one of the following:

- `'se'` — `loss` returns `bestlevel` that corresponds to the smallest tree whose mean squared error (MSE) is within one standard error of the minimum MSE.

- `'min'` — `loss` returns `bestlevel` that corresponds to the minimal MSE tree.

Example: `'TreeSize', 'min'`

Weights — Observation weights

`ones(size(X,1),1)` (default) | vector of scalar values | name of a variable in `tbl`

Observation weights, specified as the comma-separated pair consisting of `'Weights'` and a vector of scalar values. The software weights the observations in each row of `x` or `tbl` with the corresponding value in `Weights`. The size of `Weights` must equal the number of rows in `x` or `tbl`.

If you specify the input data as a table `tbl`, then `Weights` can be the name of a variable in `tbl` that contains a numeric vector. In this case, you must specify `Weights` as a variable name. For example, if weights vector `W` is stored as `tbl.W`, then specify `Weights` as `'W'`. Otherwise, the software treats all columns of `tbl`, including `W`, as predictors when training the model.

Data Types: `single` | `double` | `char` | `string`

Output Arguments

L — Classification error

vector of scalar values

Classification error, returned as a vector the length of `Subtrees`. The error for each tree is the mean squared error, weighted with `Weights`. If you include `LossFun`, `L` reflects the loss calculated with `LossFun`.

se — Standard error of loss

vector of scalar values

Standard error of loss, returned as a vector the length of `Subtrees`.

NLeaf — Number of leaf nodes

vector of integer values

Number of leaves (terminal nodes) in the pruned subtrees, returned as a vector the length of `Subtrees`.

bestlevel — Best pruning level

scalar value

Best pruning level as defined in the `TreeSize` name-value pair, returned as a scalar whose value depends on `TreeSize`:

- `TreeSize = 'se'` — `loss` returns the highest pruning level with loss within one standard deviation of the minimum ($L+se$, where L and se relate to the smallest value in `Subtrees`).
- `TreeSize = 'min'` — `loss` returns the element of `Subtrees` with smallest loss, usually the smallest element of `Subtrees`.

Examples

Compute the In-Sample MSE

Load the `carsmall` data set. Consider `Displacement`, `Horsepower`, and `Weight` as predictors of the response `MPG`.

```
load carsmall
X = [Displacement Horsepower Weight];
```

Grow a regression tree using all observations.

```
tree = fitrtree(X,MPG);
```

Estimate the in-sample MSE.

```
L = loss(tree,X,MPG)
```

```
L = 4.8952
```

Find the Pruning Level Yielding the Optimal In-sample Loss

Load the `carsmall` data set. Consider `Displacement`, `Horsepower`, and `Weight` as predictors of the response `MPG`.

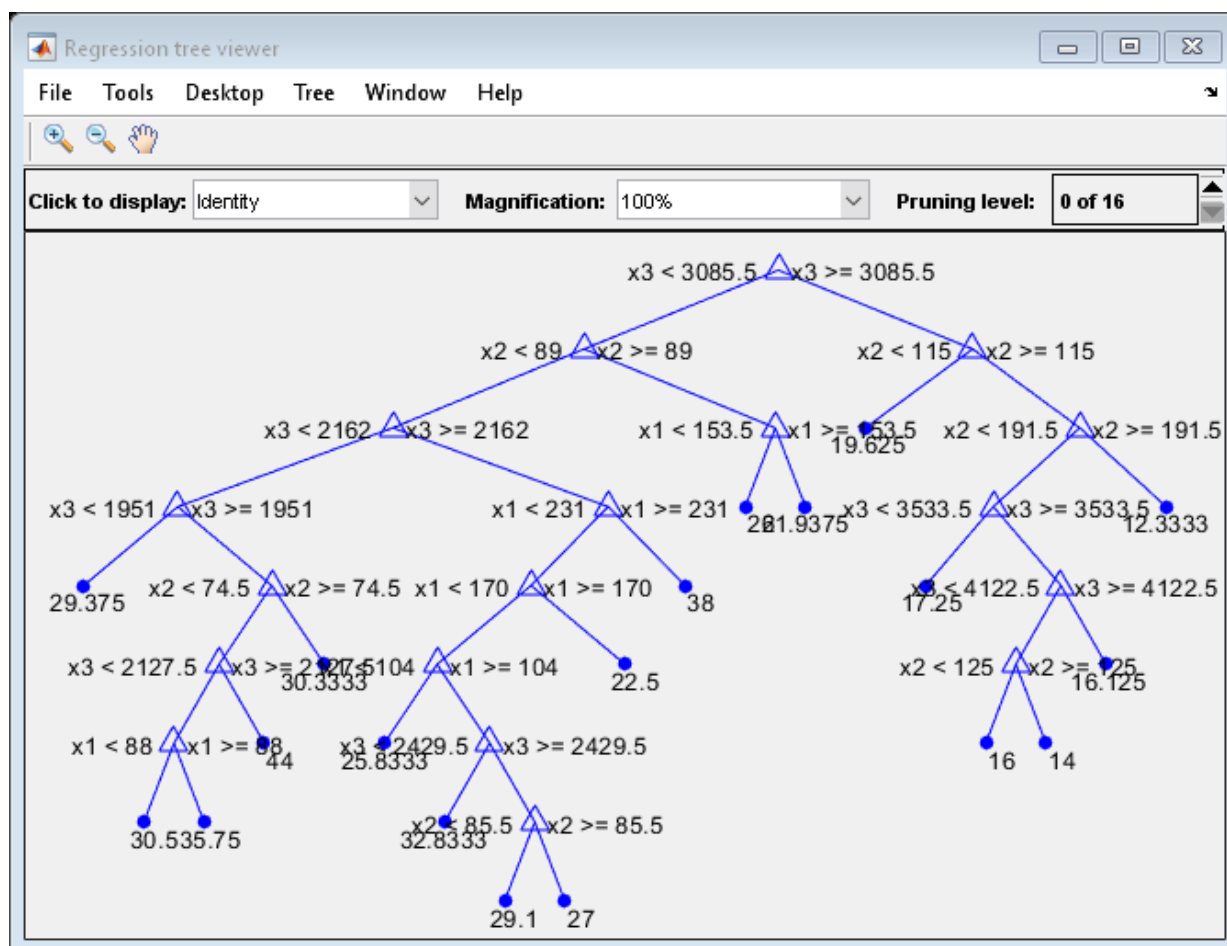

```
load carsmall
X = [Displacement Horsepower Weight];
```

Grow a regression tree using all observations.

```
Mdl = fitrtree(X,MPG);
```

View the regression tree.

```
view(Mdl, 'Mode', 'graph');
```

Find the best pruning level that yields the optimal in-sample loss.

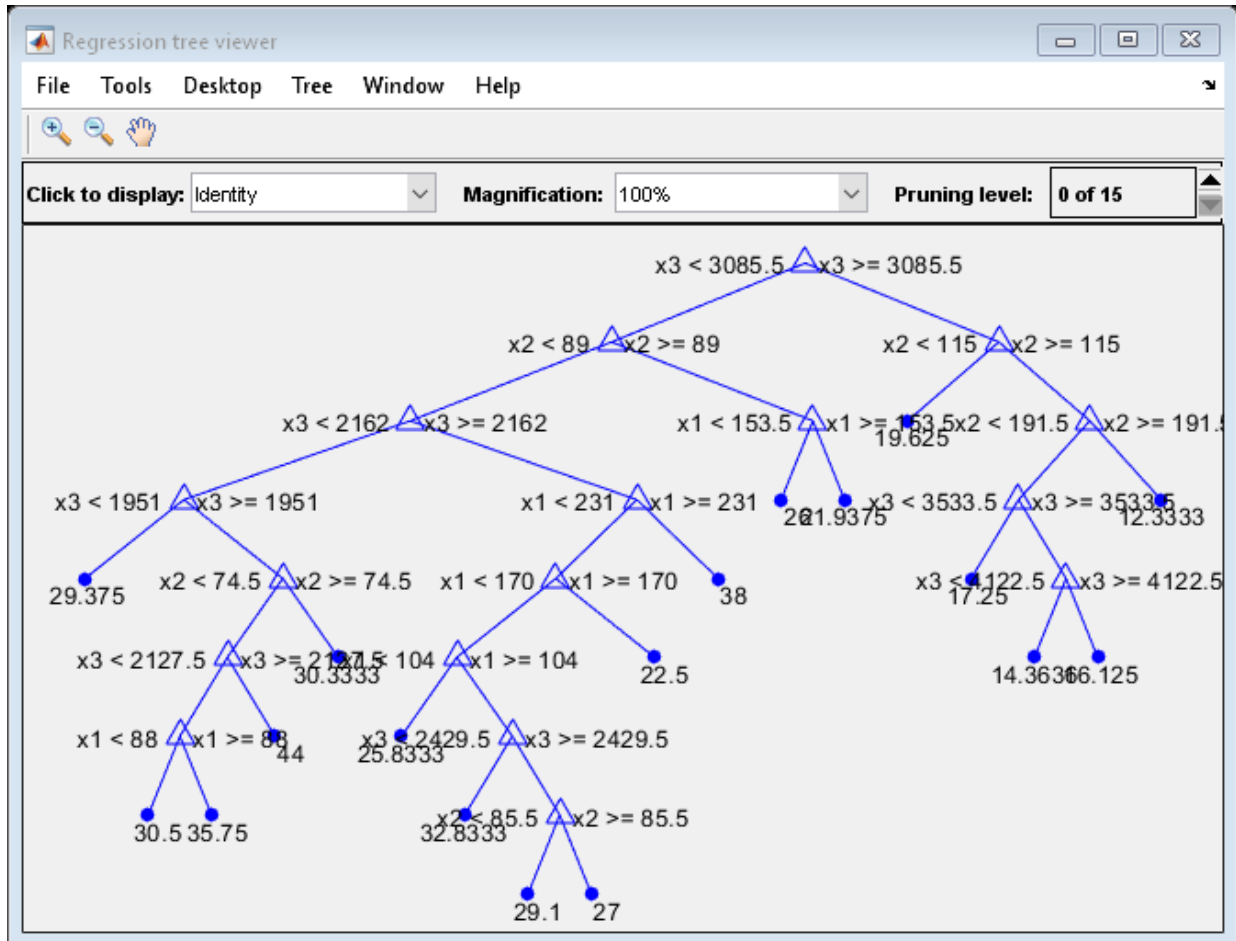

```
[L,se,NLeaf,bestLevel] = loss(Mdl,X,MPG, 'Subtrees', 'all');
```

```
bestLevel = 1
```

The best pruning level is level 1.

Prune the tree to level 1.

```
pruneMdl = prune(Mdl, 'Level', bestLevel);
view(pruneMdl, 'Mode', 'graph');
```

Examine the MSE for Each Subtree

Unpruned decision trees tend to overfit. One way to balance model complexity and out-of-sample performance is to prune a tree (or restrict its growth) so that in-sample and out-of-sample performance are satisfactory.

Load the `carsmall` data set. Consider Displacement, Horsepower, and Weight as predictors of the response MPG.

```
load carsmall
X = [Displacement Horsepower Weight];
Y = MPG;
```

Partition the data into training (50%) and validation (50%) sets.

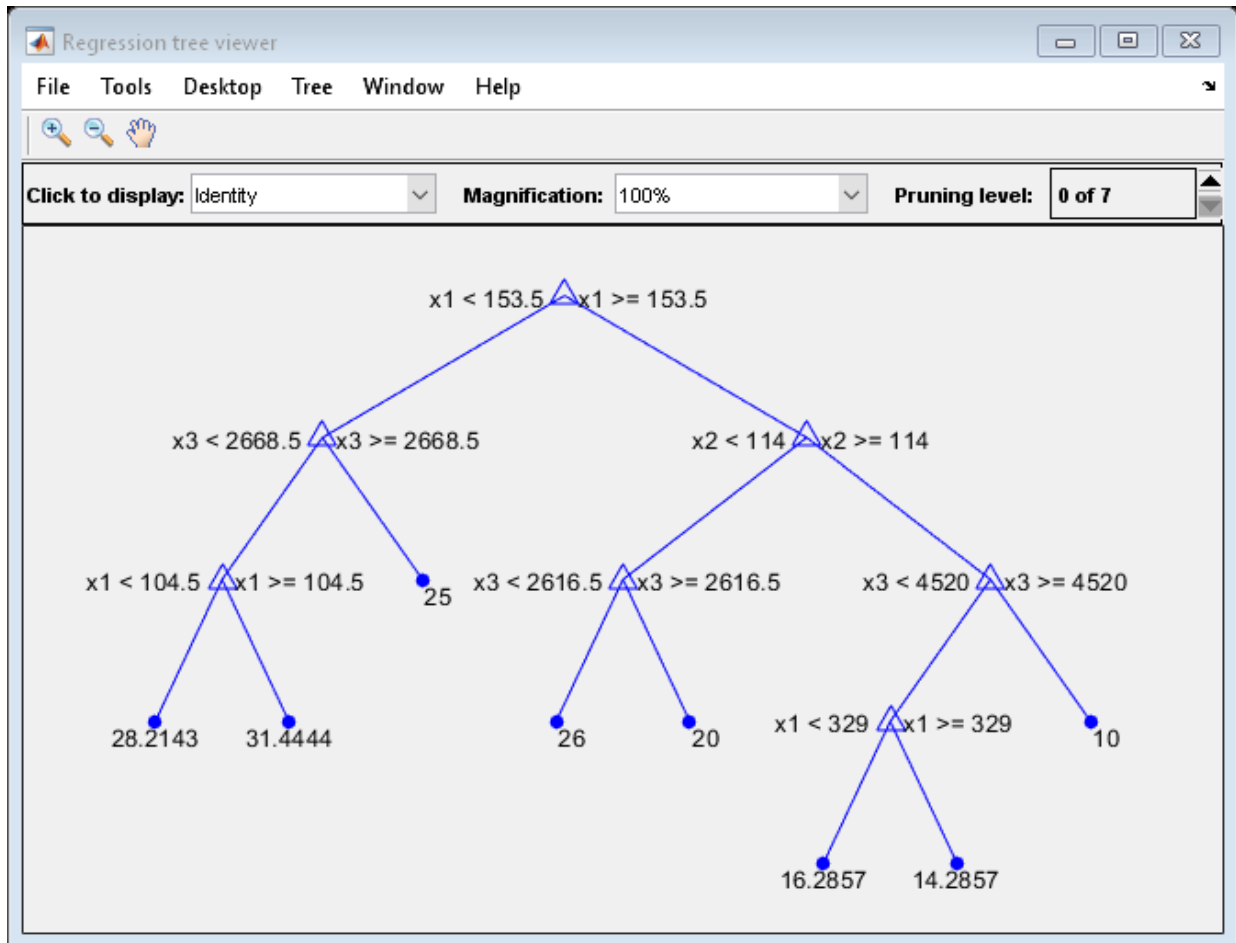

```
n = size(X,1);
rng(1) % For reproducibility
idxTrn = false(n,1);
idxTrn(randsample(n,round(0.5*n))) = true; % Training set logical indices
idxVal = idxTrn == false; % Validation set logical indices
```

Grow a regression tree using the training set.

```
Mdl = fitrtree(X(idxTrn,:),Y(idxTrn));
```

View the regression tree.

```
view(Mdl, 'Mode', 'graph');
```

The regression tree has seven pruning levels. Level 0 is the full, unpruned tree (as displayed). Level 7 is just the root node (i.e., no splits).

Examine the training sample MSE for each subtree (or pruning level) excluding the highest level.

```
m = max(Mdl.PruneList) - 1;
trnLoss = resubLoss(Mdl, 'SubTrees', 0:m)
```

```
trnLoss = 7x1
```

```
5.9789
6.2768
6.8316
7.5209
8.3951
10.7452
14.8445
```

- The MSE for the full, unpruned tree is about 6 units.
- The MSE for the tree pruned to level 1 is about 6.3 units.
- The MSE for the tree pruned to level 6 (i.e., a stump) is about 14.8 units.

Examine the validation sample MSE at each level excluding the highest level.

```
valLoss = loss(Mdl,X(idxVal,:),Y(idxVal),'SubTrees',0:m)
```

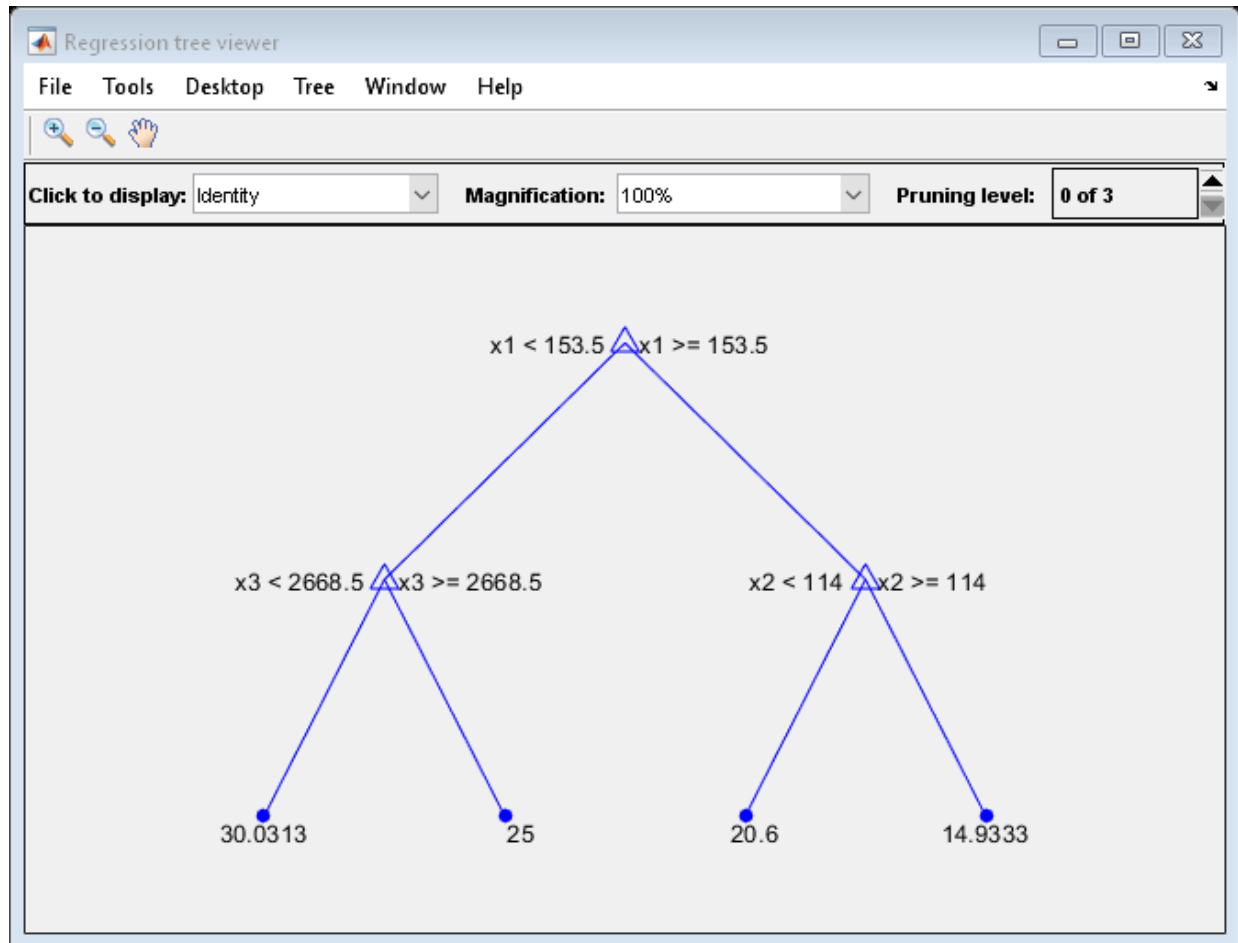

```
valLoss = 7×1
```

```
32.1205
31.5035
32.0541
30.8183
26.3535
30.0137
38.4695
```

- The MSE for the full, unpruned tree (level 0) is about 32.1 units.
- The MSE for the tree pruned to level 4 is about 26.4 units.
- The MSE for the tree pruned to level 5 is about 30.0 units.
- The MSE for the tree pruned to level 6 (i.e., a stump) is about 38.5 units.

To balance model complexity and out-of-sample performance, consider pruning Mdl to level 4.

```
pruneMdl = prune(Mdl,'Level',4);
view(pruneMdl,'Mode','graph')
```

Definitions

Mean Squared Error

The mean squared error m of the predictions $f(X_n)$ with weight vector w is

$$m = \frac{\sum w_n (f(X_n) - Y_n)^2}{\sum w_n}.$$

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function supports tall arrays for out-of-memory data with the limitation:

- Only one output is supported.

For more information, see “Tall Arrays” (MATLAB).

See Also

`fitrtree` | `predict`

loss

Class: FeatureSelectionNCAClassification

Evaluate accuracy of learned feature weights on test data

Syntax

```
err = loss mdl, X, Y
err = loss mdl, X, Y, Name, Value
```

Description

`err = loss mdl, X, Y` computes the misclassification error of the model `mdl`, for the predictors in `X` and the class labels in `Y`.

`err = loss mdl, X, Y, Name, Value` computes the classification error with additional options specified by one or more `Name, Value` pair arguments.

Input Arguments

mdl — Neighborhood component analysis model for classification

FeatureSelectionNCAClassification object

Neighborhood component analysis model for classification, returned as a FeatureSelectionNCAClassification object.

X — Predictor variable values

n-by-*p* matrix

Predictor variable values, specified as an *n*-by-*p* matrix, where *n* is the number of observations and *p* is the number of predictor variables.

Data Types: single | double

Y — Class labels

categorical vector | logical vector | numeric vector | string array | cell array of character vectors of length n | character matrix with n rows

Class labels, specified as a categorical vector, logical vector, numeric vector, string array, cell array of character vectors of length n , or character matrix with n rows, where n is the number of observations. Element i or row i of Y is the class label corresponding to row i of X (observation i).

Data Types: single | double | logical | char | string | cell | categorical

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

LossFunction — Loss function type

'classiferror' (default) | 'quadratic'

Loss function type, specified as a comma-separated pair consisting of 'Loss Function' and one of the following.

- 'classiferror' — Misclassification error, defined as

$$\frac{1}{n} \sum_{i=1}^n I(k_i \neq t_i),$$

where k_i is the predicted class and t_i is the true class for observation i . $I(k_i \neq t_i)$ is the indicator for when the k_i is not the same as t_i .

- 'quadratic' — Quadratic loss function, defined as

$$\frac{1}{n} \sum_{i=1}^n \sum_{k=1}^c (p_{ik} - I(i, k))^2,$$

where c is the number of classes, p_{ik} is the estimate probability that i th observation belongs to class k , and $I(i, k)$ is the indicator that i th observation belongs to class k .

Example: 'LossFunction', 'quadratic'

Output Arguments

err — Smaller-the-better accuracy measure for learned feature weights

scalar value

Smaller-the-better accuracy measure for learned feature weights, returned as a scalar value. You can specify the measure of accuracy using the `LossFunction` name-value pair argument.

Examples

Tune NCA Model for Classification

Load the sample data.

```
load(fullfile(matlabroot, 'examples', 'stats', 'twodimclassdata.mat'));
```

This data set is simulated using the scheme described in [1]. This is a two-class classification problem in two dimensions. Data from the first class (class -1) are drawn from two bivariate normal distributions $N(\mu_1, \Sigma)$ or $N(\mu_2, \Sigma)$ with equal probability, where $\mu_1 = [-0.75, -1.5]$, $\mu_2 = [0.75, 1.5]$, and $\Sigma = I_2$. Similarly, data from the second class (class 1) are drawn from two bivariate normal distributions $N(\mu_3, \Sigma)$ or $N(\mu_4, \Sigma)$ with equal probability, where $\mu_3 = [1.5, -1.5]$, $\mu_4 = [-1.5, 1.5]$, and $\Sigma = I_2$. The normal distribution parameters used to create this data set result in tighter clusters in data than the data used in [1].

Create a scatter plot of the data grouped by the class.

```
figure  
gscatter(X(:,1),X(:,2),y)  
xlabel('x1')  
ylabel('x2')
```

Add 100 irrelevant features to X . First generate data from a Normal distribution with a mean of 0 and a variance of 20.

```
n = size(X,1);
rng('default')
XwithBadFeatures = [X,randn(n,100)*sqrt(20)];
```

Normalize the data so that all points are between 0 and 1.

```
XwithBadFeatures = bsxfun(@rdivide,...
    bsxfun(@minus,XwithBadFeatures,min(XwithBadFeatures,[],1)), ...
    range(XwithBadFeatures,1));
X = XwithBadFeatures;
```

Fit a neighborhood component analysis (NCA) model to the data using the default Lambda (regularization parameter, λ) value. Use the LBFGS solver and display the convergence information.

```
ncaMdl = fscnca(X,y,'FitMethod','exact','Verbose',1, ...
               'Solver','lbfgs');
```

```
o Solver = LBFGS, HessianHistorySize = 15, LineSearchMethod = weakwolfe
```

10	-4.974874e-01	9.404e-08	8.947e-04	OK	1.670e+02	1.000e+00

```
Infinity norm of the final gradient = 9.404e-08
```

```
Two norm of the final step = 8.947e-04, TolX = 1.000e-06
```

```
Relative infinity norm of the final gradient = 9.404e-08, TolFun = 1.000e-06
```

```
EXIT: Local minimum found.
```

Plot the feature weights. The weights of the irrelevant features should be very close to zero.

```
figure
semilogx(ncaMdl.FeatureWeights,'ro')
xlabel('Feature index')
ylabel('Feature weight')
grid on
```

Predict the classes using the NCA model and compute the confusion matrix.

```
y_pred = predict(ncaMdl,X);  
confusionchart(y,y_pred);
```

Confusion matrix shows that 40 of the data that are in class -1 are predicted as belonging to class -1. 60 of the data from class -1 are predicted to be in class 1. Similarly, 94 of the data from class 1 are predicted to be from class 1 and 6 of them are predicted to be from class -1. The prediction accuracy for class -1 is not good.

All weights are very close to zero, which indicates that the value of λ used in training the model is too large. When $\lambda \rightarrow \infty$, all features weights approach to zero. Hence, it is important to tune the regularization parameter in most cases to detect the relevant features.

Use five-fold cross-validation to tune λ for feature selection by using `fscnca`. Tuning λ means finding the λ value that will produce the minimum classification loss. To tune λ using cross-validation:

1. Partition the data into five folds. For each fold, `cvpartition` assigns four-fifths of the data as a training set and one-fifth of the data as a test set. Again for each fold, `cvpartition` creates a stratified partition, where each partition has roughly the same proportion of classes.

```
cvp = cvpartition(y,'kfold',5);
numtestsets = cvp.NumTestSets;
lambdavalues = linspace(0,2,20)/length(y);
lossvalues = zeros(length(lambdavalues),numtestsets);
```

2. Train the neighborhood component analysis (nca) model for each λ value using the training set in each fold.

3. Compute the classification loss for the corresponding test set in the fold using the nca model. Record the loss value.

4. Repeat this process for all folds and all λ values.

```
for i = 1:length(lambdavalues)
    for k = 1:numtestsets

        % Extract the training set from the partition object
        Xtrain = X(cvp.training(k),:);
        ytrain = y(cvp.training(k),:);

        % Extract the test set from the partition object
        Xtest = X(cvp.test(k),:);
        ytest = y(cvp.test(k),:);

        % Train an NCA model for classification using the training set
        ncaMdl = fscnca(Xtrain,ytrain,'FitMethod','exact', ...
            'Solver','lbfgs','Lambda',lambdavalues(i));

        % Compute the classification loss for the test set using the NCA
        % model
        lossvalues(i,k) = loss(ncaMdl,Xtest,ytest, ...
            'LossFunction','quadratic');

    end
end
```

Plot the average loss values of the folds versus the λ values. If the λ value that corresponds to the minimum loss falls on the boundary of the tested λ values, the range of λ values should be reconsidered.

```

figure
plot(lambdavalues,mean(lossvalues,2),'ro-')
xlabel('Lambda values')
ylabel('Loss values')
grid on

```

Find the λ value that corresponds to the minimum average loss.

```

[~,idx] = min(mean(lossvalues,2)); % Find the index
bestlambda = lambdavalues(idx) % Find the best lambda value

```

```
bestlambda =
```

0.0037

Fit the NCA model to all of the data using the best λ value. Use the LBFGS solver and display the convergence information.

```
ncaMdl = fscnca(X,y,'FitMethod','exact','Verbose',1, ...
               'Solver','lbfgs','Lambda',bestlambda);
```

```
o Solver = LBFGS, HessianHistorySize = 15, LineSearchMethod = weakwolfe
```

ITER	FUN VALUE	NORM GRAD	NORM STEP	CURV	GAMMA	ALPH

15	-6.149996e-01	7.763e-06	5.206e-03	OK	2.919e+02	1.000
16	-6.149997e-01	8.374e-06	1.679e-02	OK	6.878e+02	1.000
17	-6.149997e-01	9.387e-06	9.542e-03	OK	1.284e+02	5.000
18	-6.149997e-01	3.250e-06	5.114e-03	OK	1.225e+02	1.000
19	-6.149997e-01	1.574e-06	1.275e-03	OK	1.808e+02	1.000

ITER	FUN VALUE	NORM GRAD	NORM STEP	CURV	GAMMA	ALPH
20	-6.149997e-01	5.764e-07	6.765e-04	OK	2.905e+02	1.000

```

Infinity norm of the final gradient = 5.764e-07
Two norm of the final step = 6.765e-04, TolX = 1.000e-06
Relative infinity norm of the final gradient = 5.764e-07, TolFun = 1.000e-06
EXIT: Local minimum found.
```

Plot the feature weights.

```
figure
semilogx(ncaMdl.FeatureWeights,'ro')
xlabel('Feature index')
ylabel('Feature weight')
grid on
```

`fscnca` correctly figures out that the first two features are relevant and that the rest are not. The first two features are not individually informative, but when taken together result in an accurate classification model.

Predict the classes using the new model and compute the accuracy.

```
ypred = predict(ncaMdl,X);  
confusionchart(y,ypred);
```

Confusion matrix shows that prediction accuracy for class -1 has improved. 88 of the data from class -1 are predicted to be from -1, and 12 of them are predicted to be from class 1. 92 of the data from class 1 are predicted to be from class 1 and 8 of them are predicted to be from class -1.

`FeatureSelectionNCAClassification` | `fscnca` | `predict` | `refit`

Introduced in R2016b

loss

Class: FeatureSelectionNCARegression

Evaluate accuracy of learned feature weights on test data

Syntax

```
err = loss mdl, X, Y
err = loss mdl, X, Y, Name, Value
```

Description

`err = loss(mdl, X, Y)` returns the mean squared error as the measure of accuracy in `err`, for the model `mdl`, predictor values in `X`, and response values in `Y`.

`err = loss(mdl, X, Y, Name, Value)` returns the measure of accuracy, `err`, with the additional option specified by the `Name, Value` pair argument.

Input Arguments

mdl — Neighborhood component analysis model for regression

FeatureSelectionNCARegression object

Neighborhood component analysis model for regression, specified as a FeatureSelectionNCARegression object.

X — Predictor variable values

n-by-*p* matrix

Predictor variable values, specified as an *n*-by-*p* matrix, where *n* is the number of observations and *p* is the number of predictor variables.

Data Types: single | double

Y — Response values

numeric real vector of length *n*

Response values, specified as a numeric real vector of length n , where n is the number of observations.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

LossFunction — Loss function type

`'mse'` (default) | `'mad'`

Loss function type, specified as a comma-separated pair consisting of `'Loss Function'` and one of the following.

Loss Function Type	Description
<code>'mse'</code>	Mean squared error
<code>'mad'</code>	Mean absolute deviation

Example: `'LossFunction', 'mse'`

Output Arguments

err — Smaller-the-better accuracy measure for learned feature weights

scalar value

Smaller-the-better accuracy measure for learned feature weights, returned as a scalar value. You can specify the measure of accuracy using the `LossFunction` name-value pair argument.

Examples

Tune NCA Model for Regression Using Loss and predict

Load the sample data.

Download the housing data [1], from the UCI Machine Learning Repository [2]. The dataset has 506 observations. The first 13 columns contain the predictor values and the last column contains the response values. The goal is to predict the median value of owner-occupied homes in suburban Boston as a function of 13 predictors.

Load the data and define the response vector and the predictor matrix.

```
load('housing.data');  
X = housing(:,1:13);  
y = housing(:,end);
```

Divide the data into training and test sets using the 4th predictor as the grouping variable for a stratified partitioning. This ensures that each partition includes similar amount of observations from each group.

```
rng(1) % For reproducibility  
cvp = cvpartition(X(:,4), 'Holdout', 56);  
Xtrain = X(cvp.training, :);  
ytrain = y(cvp.training, :);  
Xtest = X(cvp.test, :);  
ytest = y(cvp.test, :);
```

cvpartition randomly assigns 56 observations into a test set and the rest of the data into a training set.

Perform Feature Selection Using Default Settings

Perform feature selection using NCA model for regression. Standardize the predictor values.

```
nca = fsrnca(Xtrain, ytrain, 'Standardize', 1);
```

Plot the feature weights.

```
figure()  
plot(nca.FeatureWeights, 'ro')
```

The weights of irrelevant features are expected to approach zero. `fsrnca` identifies two features as irrelevant.

Compute the regression loss.

```
L = loss(nca,Xtest,ytest,'LossFunction','mad')
```

```
L = 2.5394
```

Compute the predicted response values for the test set and plot them versus the actual response.

```
ypred = predict(nca,Xtest);  
figure()
```

```
plot(ypred,ytest,'bo')
xlabel('Predicted response')
ylabel('Actual response')
```

A perfect fit versus the actual values forms a 45 degree straight line. In this plot, the predicted and actual response values seem to be scattered around this line. Tuning λ (regularization parameter) value usually helps improve the performance.

Tune the regularization parameter using 10-fold cross-validation

Tuning λ means finding the λ value that will produce the minimum regression loss. Here are the steps for tuning λ using 10-fold cross-validation:

1. First partition the data into 10 folds. For each fold, `cvpartition` assigns 1/10th of the data as a training set, and 9/10th of the data as a test set.

```
n = length(ytrain);  
cvp = cvpartition(Xtrain(:,4), 'kfold', 10);  
numvalidsets = cvp.NumTestSets;
```

Assign the λ values for the search. Create an array to store the loss values.

```
lambdaval = linspace(0, 2, 30) * std(ytrain) / n;  
lossvals = zeros(length(lambdaval), numvalidsets);
```

2. Train the neighborhood component analysis (nca) model for each λ value using the training set in each fold.

3. Fit a Gaussian process regression (gpr) model using the selected features. Next, compute the regression loss for the corresponding test set in the fold using the gpr model. Record the loss value.

4. Repeat this for each λ value and each fold.

```
for i = 1:length(lambdaval)  
    for k = 1:numvalidsets  
        X = Xtrain(cvp.training(k), :);  
        y = ytrain(cvp.training(k), :);  
        Xvalid = Xtrain(cvp.test(k), :);  
        yvalid = ytrain(cvp.test(k), :);  
  
        nca = fsrnca(X, y, 'FitMethod', 'exact', ...  
                   'Lambda', lambdaval(i), ...  
                   'Standardize', 1, 'LossFunction', 'mad');  
  
        % Select features using the feature weights and a relative  
        % threshold.  
        tol = 1e-3;  
        selidx = nca.FeatureWeights > tol * max(1, max(nca.FeatureWeights));  
  
        % Fit a non-ARD GPR model using selected features.  
        gpr = fitrgp(X(:, selidx), y, 'Standardize', 1, ...  
                   'KernelFunction', 'squareexponential', 'Verbose', 0);  
  
        lossvals(i, k) = loss(gpr, Xvalid(:, selidx), yvalid);  
    end  
end
```

```
end  
end
```

Compute the average loss obtained from the folds for each λ value. Plot the mean loss versus the λ values.

```
meanloss = mean(lossvals,2);  
figure;  
plot(lambdaval,meanloss,'ro-');  
xlabel('Lambda');  
ylabel('Loss (MSE)');  
grid on;
```

Find the λ value that produces the minimum loss value.

```
[~,idx] = min(meanloss);  
bestlambda = lambdaval(idx)
```

```
bestlambda = 0.0251
```

Perform feature selection for regression using the best λ value. Standardize the predictor values.

```
nca2 = fsrnca(Xtrain,ytrain,'Standardize',1,'Lambda',bestlambda,...  
             'LossFunction','mad');
```

Plot the feature weights.

```
figure()  
plot(nca.FeatureWeights,'ro')
```

Compute the loss using the new nca model on the test data, which is not used to select the features.

```
L2 = loss(nca2,Xtest,ytest,'LossFunction','mad')
```

```
L2 = 2.0560
```

Tuning the regularization parameter helps identify the relevant features and reduces the loss.

Plot the predicted versus the actual response values in the test set.

```
ypred = predict(nca2,Xtest);  
figure;  
plot(ypred,ytest,'bo');
```

The predicted response values seem to be closer to the actual values as well.

`FeatureSelectionNCARegression` | `fsrnca` | `predict` | `refit`

Introduced in R2016b

loss

Class: RegressionLinear

Regression loss for linear regression models

Syntax

```
L = loss(Mdl,X,Y)
```

```
L = loss(___,Name,Value)
```

Description

`L = loss(Mdl,X,Y)` returns the mean squared error (MSE) for the linear regression model `Mdl` using predictor data in `X` and corresponding responses in `Y`. `L` contains an MSE for each regularization strength in `Mdl`.

`L = loss(___,Name,Value)` uses any of the previous syntaxes and additional options specified by one or more `Name,Value` pair arguments. For example, specify that columns in the predictor data correspond to observations or specify the regression loss function.

Input Arguments

Mdl — Linear regression model

RegressionLinear model object

Linear regression model, specified as a RegressionLinear model object. You can create a RegressionLinear model object using `fitrlinear`.

X — Predictor data

full matrix | sparse matrix

Predictor data, specified as an n -by- p full or sparse matrix. This orientation of `X` indicates that rows correspond to individual observations, and columns correspond to individual predictor variables.

Note If you orient your predictor matrix so that observations correspond to columns and specify 'ObservationsIn', 'columns', then you might experience a significant reduction in computation time.

The length of `Y` and the number of observations in `X` must be equal.

Data Types: `single` | `double`

Y — Response data

numeric vector

Response data, specified as an n -dimensional numeric vector. The length of `Y` and the number of observations in `X` must be equal.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

LossFun — Loss function

'mse' (default) | 'epsiloninsensitive' | function handle

Loss function, specified as the comma-separated pair consisting of 'LossFun' and a built-in loss function name or function handle.

- The following table lists the available loss functions. Specify one using its corresponding value. Also, in the table, $f(x) = x\beta + b$.
 - β is a vector of p coefficients.
 - x is an observation from p predictor variables.
 - b is the scalar bias.

Value	Description
'epsiloninsensitive'	Epsilon-insensitive loss: $\ell[y, f(x)] = \max[0, y - f(x) - \varepsilon]$

Value	Description
'mse'	MSE: $\ell[y, f(x)] = [y - f(x)]^2$

'epsiloninsensitive' is appropriate for SVM learners only.

- Specify your own function using function handle notation.

Let n be the number of observations in X . Your function must have this signature

```
lossvalue = lossfun(Y,Yhat,W)
```

where:

- The output argument `lossvalue` is a scalar.
- You choose the function name (*lossfun*).
- Y is an n -dimensional vector of observed responses. `loss` passes the input argument Y in for Y .
- $Yhat$ is an n -dimensional vector of predicted responses, which is similar to the output of `predict`.
- W is an n -by-1 numeric vector of observation weights.

Specify your function using 'LossFun', @*lossfun*.

Data Types: char | string | function_handle

ObservationsIn — Predictor data observation dimension

'rows' (default) | 'columns'

Predictor data observation dimension, specified as the comma-separated pair consisting of 'ObservationsIn' and 'columns' or 'rows'.

Note If you orient your predictor matrix so that observations correspond to columns and specify 'ObservationsIn', 'columns', then you might experience a significant reduction in optimization-execution time.

Weights — Observation weights

numeric vector of positive values

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a numeric vector of positive values. If you supply weights, `loss` computes the weighted classification loss.

Let n be the number of observations in X .

- `numel(Weights)` must be n .
- By default, `Weights` is `ones(n,1)`.

Data Types: `double` | `single`

Output Arguments

L — Regression losses

numeric scalar | numeric row vector

Regression losses, returned as a numeric scalar or row vector. The interpretation of L depends on `Weights` and `LossFun`.

L is the same size as `Mdl.Lambda`. $L(j)$ is the regression loss of the linear regression model trained using the regularization strength `Mdl.Lambda(j)`.

Note If `Mdl.FittedLoss` is 'mse', then the loss term in the objective function is half of the MSE. `loss` returns the MSE by default. Therefore, if you use `loss` to check the resubstitution (training) error, then there is a discrepancy between the MSE and optimization results that `fitrlinear` returns.

Examples

Estimate Test-Sample Mean Squared Error

Simulate 10000 observations from this model

$$y = x_{100} + 2x_{200} + e.$$

- $X = x_1, \dots, x_{1000}$ is a 10000-by-1000 sparse matrix with 10% nonzero standard normal elements.

- e is random normal error with mean 0 and standard deviation 0.3.

```
rng(1) % For reproducibility
n = 1e4;
d = 1e3;
nz = 0.1;
X = sprandn(n,d,nz);
Y = X(:,100) + 2*X(:,200) + 0.3*randn(n,1);
```

Train a linear regression model. Reserve 30% of the observations as a holdout sample.

```
CVMdl = fitrlinear(X,Y,'Holdout',0.3);
Mdl = CVMdl.Trained{1}
```

```
Mdl =
  RegressionLinear
    ResponseName: 'Y'
  ResponseTransform: 'none'
           Beta: [1000x1 double]
           Bias: -0.0066
           Lambda: 1.4286e-04
           Learner: 'svm'
```

Properties, Methods

`CVMdl` is a `RegressionPartitionedLinear` model. It contains the property `Trained`, which is a 1-by-1 cell array holding a `RegressionLinear` model that the software trained using the training set.

Extract the training and test data from the partition definition.

```
trainIdx = training(CVMdl.Partition);
testIdx = test(CVMdl.Partition);
```

Estimate the training- and test-sample MSE.

```
mseTrain = loss(Mdl,X(trainIdx,:),Y(trainIdx))

mseTrain = 0.1496

mseTest = loss(Mdl,X(testIdx,:),Y(testIdx))

mseTest = 0.1798
```

Because there is one regularization strength in `Mdl`, `mseTrain` and `mseTest` are numeric scalars.

Specify Custom Regression Loss

Simulate 10000 observations from this model

$$y = x_{100} + 2x_{200} + e.$$

- $X = x_1, \dots, x_{1000}$ is a 10000-by-1000 sparse matrix with 10% nonzero standard normal elements.
- e is random normal error with mean 0 and standard deviation 0.3.

```
rng(1) % For reproducibility
n = 1e4;
d = 1e3;
nz = 0.1;
X = sprandn(n,d,nz);
Y = X(:,100) + 2*X(:,200) + 0.3*randn(n,1);
X = X'; % Put observations in columns for faster training
```

Train a linear regression model. Reserve 30% of the observations as a holdout sample.

```
CVMdl = fitrlinear(X,Y,'Holdout',0.3,'ObservationsIn','columns');
Mdl = CVMdl.Trained{1}
```

```
Mdl =
  RegressionLinear
    ResponseName: 'Y'
  ResponseTransform: 'none'
           Beta: [1000x1 double]
           Bias: -0.0066
           Lambda: 1.4286e-04
           Learner: 'svm'
```

Properties, Methods

`CVMdl` is a `RegressionPartitionedLinear` model. It contains the property `Trained`, which is a 1-by-1 cell array holding a `RegressionLinear` model that the software trained using the training set.

Extract the training and test data from the partition definition.

```
trainIdx = training(CVMdl.Partition);
testIdx = test(CVMdl.Partition);
```

Create an anonymous function that measures Huber loss ($\delta = 1$), that is,

$$L = \frac{1}{\sum w_j} \sum_{j=1}^n w_j \ell_j,$$

where

$$\ell_j = \begin{cases} 0.5\widehat{e}_j^2; & |\widehat{e}_j| \leq 1 \\ |\widehat{e}_j| - 0.5; & |\widehat{e}_j| > 1 \end{cases}$$

\widehat{e}_j is the residual for observation j . Custom loss functions must be written in a particular form. For rules on writing a custom loss function, see the 'LossFun' name-value pair argument.

```
huberloss = @(Y,Yhat,W) sum(W.*((0.5*(abs(Y-Yhat)<=1).*(Y-Yhat).^2) + ...
    (abs(Y-Yhat)>1).*abs(Y-Yhat)-0.5))/sum(W);
```

Estimate the training set and test set regression loss using the Huber loss function.

```
eTrain = loss(Mdl,X(:,trainIdx),Y(trainIdx),'LossFun',huberloss,...
    'ObservationsIn','columns')
```

```
eTrain = -0.4186
```

```
eTest = loss(Mdl,X(:,testIdx),Y(testIdx),'LossFun',huberloss,...
    'ObservationsIn','columns')
```

```
eTest = -0.4010
```

Find Good Lasso Penalty Using Regression Loss

Simulate 10000 observations from this model

$$y = x_{100} + 2x_{200} + e.$$

- $X = \{x_1, \dots, x_{1000}\}$ is a 10000-by-1000 sparse matrix with 10% nonzero standard normal elements.
- e is random normal error with mean 0 and standard deviation 0.3.

```
rng(1) % For reproducibility
n = 1e4;
d = 1e3;
nz = 0.1;
X = sprandn(n,d,nz);
Y = X(:,100) + 2*X(:,200) + 0.3*randn(n,1);
```

Create a set of 15 logarithmically-spaced regularization strengths from 10^{-4} through 10^{-1} .

```
Lambda = logspace(-4, -1, 15);
```

Hold out 30% of the data for testing. Identify the test-sample indices.

```
cvp = cvpartition(numel(Y), 'Holdout', 0.30);
idxTest = test(cvp);
```

Train a linear regression model using lasso penalties with the strengths in `Lambda`. Specify the regularization strengths, optimizing the objective function using `SpaRSA`, and the data partition. To increase execution speed, transpose the predictor data and specify that the observations are in columns.

```
X = X';
CVMdl = fitrlinear(X,Y, 'ObservationsIn', 'columns', 'Lambda', Lambda, ...
    'Solver', 'sparsa', 'Regularization', 'lasso', 'CVPartition', cvp);
Mdl1 = CVMdl.Trained{1};
numel(Mdl1.Lambda)
```

```
ans = 15
```

`Mdl1` is a `RegressionLinear` model. Because `Lambda` is a 15-dimensional vector of regularization strengths, you can think of `Mdl1` as 15 trained models, one for each regularization strength.

Estimate the test-sample mean squared error for each regularized model.

```
mse = loss(Mdl1,X(:,idxTest),Y(idxTest), 'ObservationsIn', 'columns');
```

Higher values of `Lambda` lead to predictor variable sparsity, which is a good quality of a regression model. Retrain the model using the entire data set and all options used

previously, except the data-partition specification. Determine the number of nonzero coefficients per model.

```
Mdl = fitrlinear(X,Y,'ObservationsIn','columns','Lambda',Lambda,...  
    'Solver','sparsa','Regularization','lasso');  
numNZCoeff = sum(Mdl.Beta~=0);
```

In the same figure, plot the MSE and frequency of nonzero coefficients for each regularization strength. Plot all variables on the log scale.

```
figure;  
[h,hL1,hL2] = plotyy(log10(Lambda),log10(mse),...  
    log10(Lambda),log10(numNZCoeff));  
hL1.Marker = 'o';  
hL2.Marker = 'o';  
ylabel(h(1),'log_{10} MSE')  
ylabel(h(2),'log_{10} nonzero-coefficient frequency')  
xlabel('log_{10} Lambda')  
hold off
```

Select the index or indices of `Lambda` that balance minimal classification error and predictor-variable sparsity (for example, `Lambda(11)`).

```
idx = 11;
MdlFinal = selectModels(Mdl,idx);
```

`MdlFinal` is a trained `RegressionLinear` model object that uses `Lambda(11)` as a regularization strength.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. For more information, see “Tall Arrays” (MATLAB).

See Also

`RegressionLinear` | `fitrlinear` | `predict`

Introduced in R2016a

lowerparams

Lower Pareto tail parameters

Syntax

```
params = lowerparams(pd)
```

Description

`params = lowerparams(pd)` returns the two-element vector `params`, which includes the shape and scale parameters of the generalized Pareto distribution (GPD) in the lower tail of `pd`.

`lowerparams` does not return the location parameter of the GPD. The location parameter is the quantile value corresponding to the lower tail cumulative probability. Use the `boundary` function to return the location parameter.

Examples

Parameters of Lower Pareto Tail

Generate a sample data set and fit a piecewise distribution with Pareto tails to the data by using `paretotails`. Find the distribution parameters of the lower Pareto tail by using the object function `lowerparams`.

Generate a sample data set containing 20% outliers.

```
rng('default'); % For reproducibility
left_tail = -exprnd(1,100,1);
right_tail = exprnd(5,100,1);
center = randn(800,1);
x = [left_tail;center;right_tail];
```

Create a `paretotails` object by fitting a piecewise distribution to `x`. Specify the boundaries of the tails using the lower and upper tail cumulative probabilities so that a

fitted object consists of the empirical distribution for the middle 80% of the data set and GPDs for the lower and upper 10% of the data set.

```
pd = paretotails(x,0.1,0.9)

pd =
Piecewise distribution with 3 segments
  -Inf < x < -1.33251    (0 < p < 0.1): lower tail, GPD(-0.0063504,0.567017)
 -1.33251 < x < 1.80149 (0.1 < p < 0.9): interpolated empirical cdf
  1.80149 < x < Inf     (0.9 < p < 1): upper tail, GPD(0.24874,3.00974)
```

Return the shape and scale parameters of the fitted GPD of the lower tail by using the `lowerparams` function.

```
params = lowerparams(pd)

params = 1x2

    -0.0064    0.5670
```

You can also get the lower Pareto tail parameters by using the `LowerParameters` property. Access the `LowerParameters` property by using dot notation.

```
pd.LowerParameters

ans = 1x2

    -0.0064    0.5670
```

The location parameter of the GPD is equal to the quantile value of the lower tail cumulative probability. Return the location parameter by using the `boundary` function.

```
[p,q] = boundary(pd)

p = 2x1

    0.1000
    0.9000

q = 2x1

    -1.3325
```

1.8015

The values in `p` are the cumulative probabilities at the boundaries, and the values in `q` are the corresponding quantiles. `q(2)` is the location parameter of the GPD of the lower tail.

Use the `upperparams` function or the `UpperParameters` property to get the upper Pareto tail parameters.

Input Arguments

pd — Piecewise distribution with Pareto tails

`paretotails` object

Piecewise distribution with Pareto tails, specified as a `paretotails` object.

Introduced in R2007a

lt

Class: grandstream

Less than relation for handles

Syntax

`h1 < h2`

Description

`h1 < h2` performs element-wise comparisons between handle arrays `h1` and `h2`. `h1` and `h2` must be of the same dimensions unless one is a scalar. The result is a logical array of the same dimensions, where each element is an element-wise `<` result.

If one of `h1` or `h2` is scalar, scalar expansion is performed and the result will match the dimensions of the array that is not scalar.

`tf = lt(h1, h2)` stores the result in a logical array of the same dimensions.

See Also

`eq` | `ge` | `gt` | `le` | `ne` | `grandstream`

lsline

Add least-squares line to scatter plot

Syntax

```
lsline  
lsline(ax)  
h = lsline(____)
```

Description

`lsline` superimposes a least-squares line on each scatter plot in the current axes.

`lsline` ignores data points that are connected with solid, dashed, or dash-dot lines ('-', '--', or '-.') because it does not consider them to be scatter plots. To produce scatter plots, use the MATLAB `scatter` and `plot` functions.

`lsline(ax)` superimposes a least-squares line on the scatter plot in the axes specified by `ax` instead of the current axes (`gca`).

`h = lsline(____)` returns a column vector of least-squares line objects `h` using any of the previous syntaxes. Use `h` to modify the properties of a specific least-squares line after you create it. For a list of properties, see [Line Properties](#).

Examples

Plot Least-Squares Line

Generate three sets of sample data and plot each set on the same figure.

```
x = 1:10;  
rng default; % For reproducibility  
figure;
```

```
y1 = x + randn(1,10);  
scatter(x,y1,25,'b','*')  
hold on  
  
y2 = 2*x + randn(1,10);  
plot(x,y2,'mo')  
  
y3 = 3*x + randn(1,10);  
plot(x,y3,'rx:')
```

Add a least-squares line for each set of sample data.

```
lsline
```

Specify Axes for Least-Squares and Reference Lines

Define the x-variable and two different y-variables to use for the plots.

```
rng default % For reproducibility
x = 1:10;
y1 = x + randn(1,10);
y2 = 2*x + randn(1,10);
```

Define `ax1` as the top half of the figure, and `ax2` as the bottom half of the figure. Create the first scatter plot on the top axis using `y1`, and the second scatter plot on the bottom axis using `y2`.

```
figure
ax1 = subplot(2,1,1);
ax2 = subplot(2,1,2);

scatter(ax1,x,y1)
scatter(ax2,x,y2)
```

Superimpose a least-squares line on the top plot, and a reference line at the mean of the y_2 values in the bottom plot.

```
lsline(ax1) % This is equivalent to reffline(ax1)

mu = mean(y2);
reffline(ax2,[0 mu])
```

Use Least-Squares Line Object to Modify Line Properties

Define the x-variable and two different y-variables to use for the plots.

```
rng default % For reproducibility
x = 1:10;
y1 = x + randn(1,10);
y2 = 2*x + randn(1,10);
```

Define `ax1` as the top half of the figure, and `ax2` as the bottom half of the figure. Create the first scatter plot on the top axis using `y1`, and the second scatter plot on the bottom axis using `y2`.

```
figure  
ax1 = subplot(2,1,1);  
ax2 = subplot(2,1,2);
```

```
scatter(ax1,x,y1)  
scatter(ax2,x,y2)
```

Superimpose a least-squares line on the top plot. Then, use the least-squares line object `h1` to change the line color to red.

```
h1 = lsline(ax1);  
h1.Color = 'r';
```

Superimpose a least-squares line on the bottom plot. Then, use the least-squares line object `h2` to increase the line width to 5.

```
h2 = lsline(ax2);  
h2.LineWidth = 5;
```

Input Arguments

ax — Target axes

`gca` (default) | axes object

Target axes, specified as an axes object. If you do not specify the axes and if the current axes are Cartesian axes, then the `lsline` function uses the current axes.

Output Arguments

h — One or more least-squares line objects

scalar | vector

One or more least-squares line objects, returned as a scalar or a vector. These objects are unique identifiers, which you can use to query and modify properties of a specific least-squares line. For a list of properties, see [Chart Line](#).

[gca](#) | [gline](#) | [plot](#) | [refcurve](#) | [refline](#) | [scatter](#)

Introduced before R2006a

mad

Mean or median absolute deviation

Syntax

```
y = mad(X)
y = mad(X, flag)
y = mad(X, flag, 'all')
y = mad(X, flag, dim)
y = mad(X, flag, vecdim)
```

Description

`y = mad(X)` returns the mean absolute deviation of the values in `X`.

- If `X` is a vector, then `mad` returns the mean or median absolute deviation of the values in `X`.
- If `X` is a matrix, then `mad` returns a row vector containing the mean or median absolute deviation of each column of `X`.
- If `X` is a multidimensional array, then `mad` operates along the first nonsingleton dimension of `X`.

`y = mad(X, flag)` specifies whether to compute the mean absolute deviation (`flag = 0`, the default) or the median absolute deviation (`flag = 1`).

`y = mad(X, flag, 'all')` returns the mean or median absolute deviation of all elements of `X`.

`y = mad(X, flag, dim)` returns the mean or median absolute deviation along the operating dimension `dim` of `X`.

`y = mad(X, flag, vecdim)` returns the mean or median absolute deviation over the dimensions specified in the vector `vecdim`. For example, if `X` is a 2-by-3-by-4 array, then `mad(X, 0, [1 2])` returns a 1-by-1-by-4 array. Each element of the output array is the mean absolute deviation of the elements on the corresponding page of `X`.

Examples

Compare Robustness of Scale Estimates

Compare the robustness of the standard deviation, mean absolute deviation, and median absolute deviation in the presence of outliers.

Create a data set x of normally distributed data. Create another data set x_0 that contains the elements of x and an additional outlier.

```
rng('default') % For reproducibility
x = normrnd(0,1,1,50);
x0 = [x 10];
```

Compute the ratio of the standard deviations of the two data sets.

```
r1 = std(x0)/std(x)
```

```
r1 = 1.4633
```

Compute the ratio of the mean absolute deviations of the two data sets.

```
r2 = mad(x0)/mad(x)
```

```
r2 = 1.1833
```

Compute the ratio of the median absolute deviations of the two data sets.

```
r3 = mad(x0,1)/mad(x,1)
```

```
r3 = 1.0336
```

In this case, the median absolute deviation is less influenced by the outlier compared to the other two scale estimates.

Mean and Median Absolute Deviations of All Values

Find the mean and median absolute deviations of all the values in an array.

Create a 3-by-5-by-2 array X and add an outlier.

```
X = reshape(1:30,[3 5 2]);  
X(6) = 100
```

```
X =  
X(:, :, 1) =
```

```
     1     4     7    10    13  
     2     5     8    11    14  
     3    100     9    12    15
```

```
X(:, :, 2) =
```

```
    16    19    22    25    28  
    17    20    23    26    29  
    18    21    24    27    30
```

Find the mean and median absolute deviations of the elements in X.

```
meandev = mad(X,0,'all')
```

```
meandev = 10.1178
```

```
mediandev = mad(X,1,'all')
```

```
mediandev = 7.5000
```

`meandev` is the mean absolute deviation of all the elements in X, and `mediandev` is the median absolute deviation of all the elements in X.

Find Median Absolute Deviation Along Given Dimension

Find the median absolute deviation along different dimensions for a multidimensional array.

Set the random seed for reproducibility of the results.

```
rng('default')
```

Create a 1-by-3-by-2 array of random numbers.

```
X = randn([1,3,2])
```

```
X =  
X(:,:,1) =  
    0.5377    1.8339   -2.2588  
  
X(:,:,2) =  
    0.8622    0.3188   -1.3077
```

Find the median absolute deviation of X along the default dimension.

```
Y2 = mad(X,1) % Flag is set to 1 for the median absolute deviation
```

```
Y2 =  
Y2(:,:,1) =  
    1.2962  
  
Y2(:,:,2) =  
    0.5434
```

By default, `mad` operates along the first dimension of X whose size does not equal 1. In this case, this dimension is the second dimension of X. Therefore, Y2 is a 1-by-1-by-2 array.

Find the median absolute deviation of X along the third dimension.

```
Y3 = mad(X,1,3)  
Y3 = 1×3  
    0.1623    0.7576    0.4756
```

Y3 is a 1-by-3 matrix.

Find Mean Absolute Deviation Along Vector of Dimensions

Find the mean absolute deviation over multiple dimensions by using the `vecdim` input argument.

Set the random seed for reproducibility of the results.

```
rng('default')
```

Create a 4-by-3-by-2 array of random numbers.

```
X = randn([4 3 2])
```

```
X =
```

```
X(:,:,1) =
```

```
    0.5377    0.3188    3.5784  
    1.8339   -1.3077    2.7694  
   -2.2588   -0.4336   -1.3499  
    0.8622    0.3426    3.0349
```

```
X(:,:,2) =
```

```
    0.7254   -0.1241    0.6715  
   -0.0631    1.4897   -1.2075  
    0.7147    1.4090    0.7172  
   -0.2050    1.4172    1.6302
```

Find the mean absolute deviation of each page of `X` by specifying the first and second dimensions.

```
ypage = mad(X,0,[1 2])
```

```
ypage =
```

```
ypage(:,:,1) =
```

```
    1.4626
```

```
ypage(:,:,2) =
```

```
    0.6652
```

For example, `ypage(:, :, 2)` is the mean absolute deviation of all the elements in `X(:, :, 2)`, and is equivalent to specifying `mad(X(:, :, 2), 0, 'all')`.

Find the mean absolute deviation of the elements in each `X(:, i, :)` slice by specifying the first and third dimensions.

```
ycol = mad(X, 0, [1 3])
ycol = 1×3
    0.8330    0.7872    1.5227
```

For example, `ycol(3)` is the mean absolute deviation of all the elements in `X(:, 3, :)`, and is equivalent to specifying `mad(X(:, 3, :), 0, 'all')`.

Input Arguments

X — Input data

vector | matrix | multidimensional array

Input data that represents a sample from a population, specified as a vector, matrix, or multidimensional array.

- If `X` is a vector, then `mad` returns the mean or median absolute deviation of the values in `X`.
- If `X` is a matrix, then `mad` returns a row vector containing the mean or median absolute deviation of each column of `X`.
- If `X` is a multidimensional array, then `mad` operates along the first nonsingleton dimension of `X`.

To specify the operating dimension when `X` is a matrix or an array, use the `dim` input argument.

`mad` treats NaNs as missing values and removes them.

Data Types: `single` | `double`

flag — Indicator for the type of deviation

0 (default) | 1

Indicator for the type of deviation, specified as 0 or 1.

- If `flag` is 0 (default), then `mad` computes the mean absolute deviation, `mean(abs(X - mean(X)))`.
- If `flag` is 1, then `mad` computes the median absolute deviation, `median(abs(X - median(X)))`.

Data Types: `single` | `double` | `logical`

dim — Dimension

positive integer

Dimension along which to operate, specified as a positive integer. If you do not specify a value for `dim`, then the default is the first dimension of `X` whose size does not equal 1.

Consider the mean absolute deviation of a matrix `X`:

- If `dim` is equal to 1, then `mad(X)` returns a row vector that contains the mean absolute deviation of each column in `X`.
- If `dim` is equal to 2, then `mad(X)` returns a column vector that contains the mean absolute deviation of each row in `X`.

Data Types: `single` | `double`

vecdim — Vector of dimensions

positive integer vector

Vector of dimensions, specified as a positive integer vector. Each element of `vecdim` represents a dimension of the input array `X`. The output `y` has length 1 in the specified operating dimensions. The other dimension lengths are the same for `X` and `y`.

For example, if `X` is a 2-by-3-by-3 array, then `mad(X, 0, [1 2])` returns a 1-by-1-by-3 array. Each element of the output array is the mean absolute deviation of the elements on the corresponding page of `X`.

Data Types: `single` | `double`

Output Arguments

y — Mean or median absolute deviation

scalar | vector | matrix | multidimensional array

Mean or median absolute deviation, returned as a scalar, vector, matrix, or multidimensional array. If `flag` is 0 (default), then `y` is the mean absolute deviation of the values in `X`, $\text{mean}(\text{abs}(X - \text{mean}(X)))$. If `flag` is 1, then `y` is the median absolute deviation of the values in `X`, $\text{median}(\text{abs}(X - \text{median}(X)))$.

Tips

- For normally distributed data, multiply `mad` by one of the following factors to obtain an estimate of the normal scale parameter σ :
 - $\text{sigma} = 1.253 * \text{mad}(X, 0)$ — For mean absolute deviation
 - $\text{sigma} = 1.4826 * \text{mad}(X, 1)$ — For median absolute deviation

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The 'all' and `vecdim` input arguments are not supported.
- Empty `dim` input is not supported.
- The `dim` input argument must be a compile-time constant.
- If you do not specify the `dim` input argument, the working (or operating) dimension can be different in the generated code. As a result, run-time errors can occur. For more details, see “Automatic dimension restriction” (MATLAB Coder).

For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “General Code Generation Workflow” on page 31-5.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Usage notes and limitations:

- The 'all' and `vecdim` input arguments are not supported.

For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

Introduced before R2006a

mahal

Mahalanobis distance

Syntax

```
d2 = mahal(Y,X)
```

Description

`d2 = mahal(Y,X)` returns the squared Mahalanobis distance on page 32-4055 of each observation in `Y` to the reference samples in `X`.

Examples

Compare Mahalanobis and Squared Euclidean Distances

Generate a correlated bivariate sample data set.

```
rng('default') % For reproducibility  
X = mvnrnd([0;0],[1 .9;.9 1],1000);
```

Specify four observations that are equidistant from the mean of `X` in Euclidean distance.

```
Y = [1 1;1 -1;-1 1;-1 -1];
```

Compute the Mahalanobis distance of each observation in `Y` to the reference samples in `X`.

```
d2_mahal = mahal(Y,X)
```

```
d2_mahal = 4×1
```

```
    1.1095  
   20.3632  
   19.5939  
    1.0137
```

Compute the squared Euclidean distance of each observation in Y from the mean of X .

```
d2_Euclidean = sum((Y-mean(X)).^2,2)
```

```
d2_Euclidean = 4×1
```

```
2.0931
```

```
2.0399
```

```
1.9625
```

```
1.9094
```

Plot X and Y by using `scatter` and use marker color to visualize the Mahalanobis distance of Y to the reference samples in X.

```
scatter(X(:,1),X(:,2),10, '.') % Scatter plot with points of size 10
```

```
hold on
```

```
scatter(Y(:,1),Y(:,2),100,d2_mahal, 'o', 'filled')
```

```
hb = colorbar;
```

```
ylabel(hb, 'Mahalanobis Distance')
```

```
legend('X', 'Y', 'Location', 'best')
```

All observations in Y ($[1, 1]$, $[-1, -1]$, $[1, -1]$, and $[-1, 1]$) are equidistant from the mean of X in Euclidean distance. However, $[1, 1]$ and $[-1, -1]$ are much closer to X than $[1, -1]$ and $[-1, 1]$ in Mahalanobis distance. Because Mahalanobis distance considers the covariance of the data and the scales of the different variables, it is useful for detecting outliers.

Input Arguments

Y — Data

n-by-*m* numeric matrix

Data, specified as an n -by- m numeric matrix, where n is the number of observations and m is the number of variables in each observation.

X and Y must have the same number of columns, but can have different numbers of rows.

Data Types: `single` | `double`

X — Reference samples

p -by- m numeric matrix

Reference samples, specified as a p -by- m numeric matrix, where p is the number of samples and m is the number of variables in each sample.

X and Y must have the same number of columns, but can have different numbers of rows. X must have more rows than columns.

Data Types: `single` | `double`

Output Arguments

d2 — Squared Mahalanobis distance

n -by-1 numeric vector

Squared Mahalanobis distance on page 32-4055 of each observation in Y to the reference samples in X , returned as an n -by-1 numeric vector, where n is the number of observations in X .

Definitions

Mahalanobis Distance

The Mahalanobis distance is a measure between a sample point and a distribution.

The Mahalanobis distance from a vector y to a distribution with mean μ and covariance Σ is

$$d = \sqrt{(y - \mu) \Sigma^{-1} (y - \mu)'}$$

This distance represents how far y is from the mean in number of standard deviations.

`mahal` returns the squared Mahalanobis distance d^2 from an observation in Y to the reference samples in X . In the `mahal` function, μ and Σ are the sample mean and covariance of the reference samples, respectively.

`mahal` | `pdist`

Introduced before R2006a

mahal

Mahalanobis distance to class means

Syntax

```
M = mahal(obj,X)
M = mahal(obj,X,Name,Value)
```

Description

`M = mahal(obj,X)` returns the squared Mahalanobis distances from observations in `X` to the class means in `obj`.

`M = mahal(obj,X,Name,Value)` computes the squared Mahalanobis distance with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

obj

Discriminant analysis classifier of class `ClassificationDiscriminant` or `CompactClassificationDiscriminant`, typically constructed with `fitcdiscr`.

X

Numeric matrix of size `n-by-p`, where `p` is the number of predictors in `obj`, and `n` is any positive integer. `mahal` computes the Mahalanobis distances from the rows of `X` to each of the `K` means of the classes in `obj`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes.

You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

ClassLabels

Class labels consisting of `n` elements of `obj.Y`, where `n` is the number of rows of `X`.

Output Arguments

M

Size and meaning of output `M` depends on whether the `ClassLabels` name-value pair is present:

- No `ClassLabels` — `M` is a numeric matrix of size `n`-by-`K`, where `K` is the number of classes in `obj`, and `n` is the number of rows in `X`. `M(i, j)` is the squared Mahalanobis distance from the `i`th row of `X` to the mean of class `j`.
- `ClassLabels` exists — `M` is a column vector with `n` elements. `M(i)` is the squared Mahalanobis distance from the `i`th row of `X` to the mean for the class of the `i`th element of `ClassLabels`.

Examples

Find the Mahalanobis distances from the mean of the Fisher iris data to the class means, using distinct covariance matrices for each class:

```
load fisheriris
obj = fitcdiscr(meas,species,...
    'DiscrimType','quadratic');
mahadist = mahal(obj,mean(meas))

mahadist =
    220.0667    5.0254    30.5804
```

Definitions

Mahalanobis Distance

The Mahalanobis distance $d(x,y)$ between n -dimensional points x and y , with respect to a given n -by- n covariance matrix S , is

$$d(x, y) = \sqrt{(x - y)^T S^{-1} (x - y)}.$$

`CompactClassificationDiscriminant` | `fitcdiscr` | `gmdistribution` | `mahal`

Topics

“Discriminant Analysis Classification” on page 20-2

mahal

Mahalanobis distance to Gaussian mixture component

Syntax

```
d2 = mahal(gm,X)
```

Description

`d2 = mahal(gm,X)` returns the squared Mahalanobis distance of each observation in `X` to each Gaussian mixture component in `gm`.

Examples

Measure Mahalanobis Distance

Generate random variates that follow a mixture of two bivariate Gaussian distributions by using the `mvnrnd` function. Fit a Gaussian mixture model (GMM) to the generated data by using the `fitgmdist` function, and then compute Mahalanobis distances between the generated data and the mixture components of the fitted GMM.

Define the distribution parameters (means and covariances) of two bivariate Gaussian mixture components.

```
rng('default') % For reproducibility
mu1 = [1 2]; % Mean of the 1st component
sigma1 = [2 0; 0 .5]; % Covariance of the 1st component
mu2 = [-3 -5]; % Mean of the 2nd component
sigma2 = [1 0; 0 1]; % Covariance of the 2nd component
```

Generate an equal number of random variates from each component, and combine the two sets of random variates.

```
r1 = mvnrnd(mu1,sigma1,1000);  
r2 = mvnrnd(mu2,sigma2,1000);  
X = [r1; r2];
```

The combined data set X contains random variates following a mixture of two bivariate Gaussian distributions.

Fit a two-component GMM to X.

```
gm = fitgmdist(X,2)
```

```
gm =
```

```
Gaussian mixture distribution with 2 components in 2 dimensions
```

```
Component 1:
```

```
Mixing proportion: 0.500000
```

```
Mean:    -2.9617    -4.9727
```

```
Component 2:
```

```
Mixing proportion: 0.500000
```

```
Mean:     0.9539     2.0261
```

`fitgmdist` fits a GMM to X using two mixture components. The means of Component 1 and Component 2 are [-2.9617, -4.9727] and [0.9539, 2.0261], which are close to μ_2 and μ_1 , respectively.

Compute the Mahalanobis distance of each point in X to each component of gm.

```
d2 = mahal(gm,X);
```

Plot X by using `scatter` and use marker color to visualize the Mahalanobis distance to Component 1.

```
scatter(X(:,1),X(:,2),10,d2(:,1),'.') % Scatter plot with points of size 10  
c = colorbar;  
ylabel(c,'Mahalanobis Distance to Component 1')
```

Input Arguments

gm — Gaussian mixture distribution

`gmdistribution` object

Gaussian mixture distribution, also called Gaussian mixture model (GMM), specified as a `gmdistribution` object.

You can create a `gmdistribution` object using `gmdistribution` or `fitgmdist`. Use the `gmdistribution` function to create a `gmdistribution` object by specifying the

distribution parameters. Use the `fitgmdist` function to fit a `gmdistribution` model to data given a fixed number of components.

X — Data

n-by-*m* numeric matrix

Data, specified as an *n*-by-*m* numeric matrix, where *n* is the number of observations and *m* is the number of variables in each observation.

If a row of *X* contains NaNs, then `mahal` excludes the row from the computation. The corresponding value in `d2` is NaN.

Data Types: `single` | `double`

Output Arguments

d2 — Squared Mahalanobis distance

n-by-*k* numeric matrix

Squared Mahalanobis distance of each observation in *X* to each Gaussian mixture component in `gm`, returned as an *n*-by-*k* numeric matrix, where *n* is the number of observations in *X* and *k* is the number of mixture components in `gm`.

`d2(i, j)` is the squared distance of observation *i* to the *j*th Gaussian mixture component.

Definitions

Mahalanobis Distance

The Mahalanobis distance is a measure between a sample point and a distribution.

The Mahalanobis distance from a vector *x* to a distribution with mean μ and covariance Σ is

$$d = \sqrt{(x - \mu) \Sigma^{-1} (x - \mu)'}$$

This distance represents how far *x* is from the mean in number of standard deviations.

`mahal` returns the squared Mahalanobis distance d^2 from an observation in `X` to a mixture component in `gm`.

maineffectsplot

Main effects plot for grouped data

Syntax

```
maineffectsplot(Y,GROUP)
maineffectsplot(Y,GROUP,param1,val1,param2,val2,...)
[figh,AXESH] = maineffectsplot(...)
```

Description

`maineffectsplot(Y,GROUP)` displays main effects plots for the group means of matrix `Y` with groups defined by entries in `GROUP`, which can be a cell array or a matrix. `Y` is a numeric matrix or vector. If `Y` is a matrix, the rows represent different observations and the columns represent replications of each observation. If `GROUP` is a cell array, then each cell of `GROUP` must contain a grouping variable that is a categorical variable, numeric vector, character matrix, string array, or single-column cell array of character vectors. If `GROUP` is a matrix, then its columns represent different grouping variables. Each grouping variable must have the same number of rows as `Y`. The number of grouping variables must be greater than 1.

The display has one subplot per grouping variable, with each subplot showing the group means of `Y` as a function of one grouping variable.

`maineffectsplot(Y,GROUP,param1,val1,param2,val2,...)` specifies one or more of the following name/value pairs:

- `'varnames'` — Grouping variable names in a character matrix, a string array, or a cell array of character vectors, one per grouping variable. Default names are `'X1'`, `'X2'`, ...
- `'statistic'` — Values that indicate whether the group mean or the group standard deviation should be plotted. Use `'mean'` or `'std'`. The default is `'mean'`. If the value is `'std'`, `Y` is required to have multiple columns.
- `'parent'` — A handle to the figure window for the plots. The default is the current figure window.

`[figh,AXESH] = maineffectsplo(...)` returns the handle `figh` to the figure window and an array of handles `AXESH` to the subplot axes.

Examples

Main Effects Plot

Load the sample data.

```
load carsmall;
```

Display main effects plots for car weight with two grouping variables, model year and number of cylinders.

```
maineffectsplo(Weight,{Model_Year,Cylinders}, ...  
               'varnames',{'Model Year','# of Cylinders'})
```

ClassificationDiscriminant.make

Class: ClassificationDiscriminant

(Not Recommended) Construct discriminant analysis classifier from parameters

Note ClassificationDiscriminant.make is not recommended. Use makecdiscr instead.

Syntax

```
cobj = ClassificationDiscriminant.make(Mu, Sigma)
cobj = ClassificationDiscriminant.make(Mu, Sigma, Name, Value)
```

Description

cobj = ClassificationDiscriminant.make(Mu, Sigma) constructs a compact discriminant analysis classifier from the class means Mu and covariance matrix Sigma.

cobj = ClassificationDiscriminant.make(Mu, Sigma, Name, Value) constructs a compact classifier with additional options specified by one or more Name, Value pair arguments.

Input Arguments

Mu — Class means

matrix of scalar values

Class means, specified as a K-by-p matrix of scalar values class means of size. K is the number of classes, and p is the number of predictors. Each row of Mu represents the mean of the multivariate normal distribution of the corresponding class. The class indices are in the ClassNames attribute.

Data Types: single | double

Sigma — Within-class covariance

matrix of scalar values

Within-class covariance, specified as a matrix of scalar values.

- For a linear discriminant, `Sigma` is a symmetric, positive semidefinite matrix of size p -by- p , where p is the number of predictors.
- For a quadratic discriminant, `Sigma` is an array of size p -by- p -by- K , where K is the number of classes. For each i , `Sigma(:, :, i)` is a symmetric, positive semidefinite matrix.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

ClassNames — Class names

numeric vector | categorical vector | logical vector | character array | cell array of character vectors

Class names as ordered in `Mu`, specified as the comma-separated pair consisting of `'ClassNames'` and an array containing grouping variables. Use any data type for a grouping variable, including numeric vector, categorical vector, logical vector, character array, or cell array of character vectors.

`ClassNames` names the classes, as ordered in `Mu`.

Default is `1:K`, where K is the number of classes (the number of rows of `Mu`).

Data Types: `single` | `double` | `logical` | `char` | `cell`

Cost — Cost of misclassification

square matrix | structure

Cost of misclassification, specified as the comma-separated pair consisting of `'Cost'` and a square matrix, where `Cost(i, j)` is the cost of classifying a point into class j if its true class is i . Alternatively, `Cost` can be a structure `S` having two fields: `S.ClassNames`

containing the group names as a variable of the same type as `y`, and `S.ClassificationCosts` containing the cost matrix.

The default is $\text{Cost}(i, j) = 1$ if $i \neq j$, and $\text{Cost}(i, j) = 0$ if $i = j$.

Data Types: `single` | `double` | `struct`

PredictorNames — Predictor variable names

`{'X1', 'X2', ...}` (default) | cell array of character vectors

Predictor variable names, specified as the comma-separated pair consisting of `'PredictorNames'` and a cell array of character vectors containing the names for the predictor variables, in the order in which they appear in `X`.

Data Types: `cell`

Prior — Prior probabilities

`'uniform'` (default) | vector of scalar values | structure

Prior probabilities for each class, specified as the comma-separated pair consisting of `'Prior'` and one of the following.

- `'uniform'`, a character vector meaning all class prior probabilities are equal.
- A vector containing one scalar value for each class.
- A structure `S` with two fields:
 - `S.ClassNames` containing the class names as a variable of the same type as `ClassNames`.
 - `S.ClassProbs` containing a vector of corresponding probabilities.

Data Types: `single` | `double` | `struct`

ResponseName — Response variable name

`'Y'` (default) | character vector

Response variable name, specified as the comma-separated pair consisting of `'ResponseName'` and a character vector containing the name of the response variable `y`.

Example: `'ResponseName', 'Response'`

Data Types: `char`

Output Arguments

cobj — Discriminant analysis classifier

discriminant analysis classifier object

Discriminant analysis classifier, returned as a discriminant analysis classifier object of class `CompactClassificationDiscriminant`. You can use the `predict` method to predict classification labels for new data.

Examples

Construct a Compact Linear Discriminant Analysis Classifier

Construct a compact linear discriminant analysis classifier from the means and covariances of the Fisher iris data.

```
load fisheriris
mu(1,:) = mean(meas(1:50,:));
mu(2,:) = mean(meas(51:100,:));
mu(3,:) = mean(meas(101:150,:));

mm1 = repmat(mu(1,:),50,1);
mm2 = repmat(mu(2,:),50,1);
mm3 = repmat(mu(3,:),50,1);
cc = meas;
cc(1:50,:) = cc(1:50,:) - mm1;
cc(51:100,:) = cc(51:100,:) - mm2;
cc(101:150,:) = cc(101:150,:) - mm3;
sigstar = cc' * cc / 147; % unbiased estimator of sigma
cpct = ClassificationDiscriminant.make(mu,sigstar,...
    'ClassNames',{'setosa','versicolor','virginica'})

cpct =
    classreg.learning.classif.CompactClassificationDiscriminant
        PredictorNames: {'x1' 'x2' 'x3' 'x4'}
        ResponseName: 'Y'
        CategoricalPredictors: []
        ClassNames: {'setosa' 'versicolor' 'virginica'}
        ScoreTransform: 'none'
        DiscrimType: 'linear'
        Mu: [3x4 double]
```

Coeffs: [3x3 struct]

makecdiscr

Construct discriminant analysis classifier from parameters

Syntax

```
cobj = makecdiscr(Mu,Sigma)
cobj = makecdiscr(Mu,Sigma,Name,Value)
```

Description

`cobj = makecdiscr(Mu,Sigma)` constructs a compact discriminant analysis classifier from the class means `Mu` and covariance matrix `Sigma`.

`cobj = makecdiscr(Mu,Sigma,Name,Value)` constructs a compact classifier with additional options specified by one or more name-value pair arguments. For example, you can specify the cost of misclassification or the prior probabilities for each class.

Examples

Construct a Compact Linear Discriminant Analysis Classifier

Construct a compact linear discriminant analysis classifier from the means and covariances of the Fisher iris data.

```
load fisheriris
mu(1,:) = mean(meas(1:50,:));
mu(2,:) = mean(meas(51:100,:));
mu(3,:) = mean(meas(101:150,:));

mm1 = repmat(mu(1,:),50,1);
mm2 = repmat(mu(2,:),50,1);
mm3 = repmat(mu(3,:),50,1);
cc = meas;
cc(1:50,:) = cc(1:50,:) - mm1;
```

```
cc(51:100,:) = cc(51:100,:) - mm2;
cc(101:150,:) = cc(101:150,:) - mm3;
sigstar = cc' * cc / 147; % unbiased estimator of sigma
cpct = makecdiscr(mu,sigstar,...
    'ClassNames',{'setosa','versicolor','virginica'})

cpct =
    classreg.learning.classif.CompactClassificationDiscriminant
        PredictorNames: {'x1' 'x2' 'x3' 'x4'}
        ResponseName: 'Y'
    CategoricalPredictors: []
        ClassNames: {'setosa' 'versicolor' 'virginica'}
        ScoreTransform: 'none'
        DiscrimType: 'linear'
            Mu: [3x4 double]
            Coeffs: [3x3 struct]
```

Properties, Methods

Input Arguments

Mu — Class means

matrix of scalar values

Class means, specified as a K -by- p matrix of scalar values class means of size. K is the number of classes, and p is the number of predictors. Each row of Mu represents the mean of the multivariate normal distribution of the corresponding class. The class indices are in the `ClassNames` attribute.

Data Types: `single` | `double`

Sigma — Within-class covariance

matrix of scalar values

Within-class covariance, specified as a matrix of scalar values.

- For a linear discriminant, **Sigma** is a symmetric, positive semidefinite matrix of size p -by- p , where p is the number of predictors.

- For a quadratic discriminant, `Sigma` is an array of size `p-by-p-by-K`, where `K` is the number of classes. For each `i`, `Sigma(:, :, i)` is a symmetric, positive semidefinite matrix.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'ClassNames', {'setosa' 'versicolor' 'virginica'}` specifies a discriminant analysis classifier that uses `'setosa'`, `'versicolor'`, and `'virginica'` as the grouping variables.

ClassNames — Class names

numeric vector | categorical vector | logical vector | character array | string array | cell array of character vectors

Class names as ordered in `Mu`, specified as the comma-separated pair consisting of `'ClassNames'` and an array containing grouping variables. Use any data type for a grouping variable, including numeric vector, categorical vector, logical vector, character array, string array, or cell array of character vectors.

The default is `1:K`, where `K` is the number of classes (the number of rows of `Mu`).

Example: `'ClassNames', {'setosa' 'versicolor' 'virginica'}`

Data Types: `single` | `double` | `logical` | `char` | `string` | `cell`

Cost — Cost of misclassification

square matrix | structure

Cost of misclassification, specified as the comma-separated pair consisting of `'Cost'` and a square matrix, where `Cost(i, j)` is the cost of classifying a point into class `j` if its true class is `i`. Alternatively, `Cost` can be a structure `S` having two fields: `S.ClassNames` containing the group names as a variable of the same type as `y`, and `S.ClassificationCosts` containing the cost matrix.

The default is `Cost(i, j)=1` if `i~=j`, and `Cost(i, j)=0` if `i=j`.

Data Types: `single` | `double` | `struct`

PredictorNames — Predictor variable names

`{'X1', 'X2', ...}` (default) | string array | cell array of character vectors

Predictor variable names, specified as the comma-separated pair consisting of 'PredictorNames' and a string array or cell array of character vectors containing the names for the predictor variables, in the order in which they appear in *X*.

Data Types: `string` | `cell`

Prior — Prior probabilities

'uniform' (default) | vector of scalar values | structure

Prior probabilities for each class, specified as the comma-separated pair consisting of 'Prior' and one of the following:

- 'uniform', meaning all class prior probabilities are equal
- A vector containing one scalar value for each class
- A structure *S* with two fields:
 - *S.ClassNames* containing the class names as a variable of the same type as *ClassNames*
 - *S.ClassProbs* containing a vector of corresponding probabilities

Data Types: `char` | `string` | `single` | `double` | `struct`

ResponseName — Response variable name

'Y' (default) | character vector | string scalar

Response variable name, specified as the comma-separated pair consisting of 'ResponseName' and a character vector or string scalar containing the name of the response variable *y*.

Example: 'ResponseName', 'Response'

Data Types: `char` | `string`

Output Arguments

cobj — Discriminant analysis classifier

discriminant analysis classifier object

Discriminant analysis classifier, returned as a discriminant analysis classifier object of class `CompactClassificationDiscriminant`. You can use the `predict` method to predict classification labels for new data.

Tips

- You can change the discriminant type using dot notation after constructing `cobj`:

```
cobj.DiscrimType = 'discrimType'
```

where *discrimType* is one of 'linear', 'quadratic', 'diagLinear', 'diagQuadratic', 'pseudoLinear', or 'pseudoQuadratic'. You can change between linear types or between quadratic types, but cannot change between a linear and a quadratic type.

- `cobj` is a linear classifier when `Sigma` is a matrix. `cobj` is a quadratic classifier when `Sigma` is a three-dimensional array.

Introduced in R2014a

makedist

Create probability distribution object

Syntax

```
pd = makedist(distname)
pd = makedist(distname,Name,Value)

list = makedist

makedist -reset
```

Description

`pd = makedist(distname)` creates a probability distribution object for the distribution `distname`, using the default parameter values.

`pd = makedist(distname,Name,Value)` creates a probability distribution object with one or more distribution parameter values specified by name-value pair arguments.

`list = makedist` returns a cell array `list` containing a list of the probability distributions that `makedist` can create.

`makedist -reset` resets the list of distributions by searching the path for files contained in a package named `prob` and implementing classes derived from `ProbabilityDistribution`. Use this syntax after you define a custom distribution function. For details, see “Define Custom Distributions Using the Distribution Fitter App” on page 5-111.

Examples

Create a Normal Distribution Object

Create a normal distribution object using the default parameter values.

```
pd = makedist('Normal')  
pd =  
  NormalDistribution  
  
  Normal distribution  
    mu = 0  
    sigma = 1
```

Compute the interquartile range of the distribution.

```
r = iqr(pd)  
r = 1.3490
```

Create a Gamma Distribution Object

Create a gamma distribution object using the default parameter values.

```
pd = makedist('Gamma')  
pd =  
  GammaDistribution  
  
  Gamma distribution  
    a = 1  
    b = 1
```

Compute the mean of the gamma distribution.

```
mean = mean(pd)  
mean = 1
```

Specify Parameters for a Normal Distribution Object

Create a normal distribution object with parameter values $\mu = 75$ and $\sigma = 10$.

```
pd = makedist('Normal', 'mu', 75, 'sigma', 10)
```

```
pd =  
  NormalDistribution  
  
  Normal distribution

```

Specify Parameters for a Gamma Distribution Object

Create a gamma distribution object with the parameter value $a = 3$ and the default value $b = 1$.

```
pd = makedist('Gamma','a',3)  
  
pd =  
  GammaDistribution  
  
  Gamma distribution  
    a = 3  
    b = 1
```

Input Arguments

distname — Distribution name

character vector | string scalar

Distribution name, specified as one of the following character vectors or string scalars. The distribution specified by `distname` determines the type of the returned probability distribution object.

Distribution Name	Description	Distribution Object
'Beta'	Beta distribution	BetaDistribution
'Binomial'	Binomial distribution	BinomialDistribution

Distribution Name	Description	Distribution Object
'BirnbauSaunders'	Birnbau-Saunders distribution	BirnbauSaundersDistribution
'Burr'	Burr distribution	BurrDistribution
'Exponential'	Exponential distribution	ExponentialDistribution
'ExtremeValue'	Extreme Value distribution	ExtremeValueDistribution
'Gamma'	Gamma distribution	GammaDistribution
'GeneralizedExtremeValue'	Generalized Extreme Value distribution	GeneralizedExtremeValueDistribution
'GeneralizedPareto'	Generalized Pareto distribution	GeneralizedParetoDistribution
'HalfNormal'	Half-normal distribution	HalfNormalDistribution
'InverseGaussian'	Inverse Gaussian distribution	InverseGaussianDistribution
'Logistic'	Logistic distribution	LogisticDistribution
'Loglogistic'	Loglogistic distribution	LoglogisticDistribution
'Lognormal'	Lognormal distribution	LognormalDistribution
'Multinomial'	Multinomial distribution	MultinomialDistribution
'Nakagami'	Nakagami distribution	NakagamiDistribution
'NegativeBinomial'	Negative Binomial distribution	NegativeBinomialDistribution
'Normal'	Normal distribution	NormalDistribution
'PiecewiseLinear'	Piecewise Linear distribution	PiecewiseLinearDistribution
'Poisson'	Poisson distribution	PoissonDistribution
'Rayleigh'	Rayleigh distribution	RayleighDistribution
'Rician'	Rician distribution	RicianDistribution

Distribution Name	Description	Distribution Object
'Stable'	Stable distribution	StableDistribution
'tLocationScale'	<i>t</i> Location-Scale distribution	tLocationScaleDistribution
'Triangular'	Triangular distribution	TriangularDistribution
'Uniform'	Uniform distribution	UniformDistribution
'Weibull'	Weibull distribution	WeibullDistribution

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `makedist('Normal', 'mu', 10)` specifies a normal distribution with parameter `mu` equal to 10, and parameter `sigma` equal to the default value of 1.

Beta Distribution

a — First shape parameter

1 (default) | positive scalar value

Example: 'a', 3

Data Types: single | double

b — Second shape parameter

1 (default) | positive scalar value

Example: 'b', 5

Data Types: single | double

Binomial Distribution

N — Number of trials

1 (default) | positive integer value

Example: 'N', 25

Data Types: single | double

p — Probability of success

0.5 (default) | scalar value in the range [0,1]

Example: 'p', 0.25

Data Types: single | double

Birnbaum-Saunders Distribution

beta — Scale parameter

1 (default) | positive scalar value

Example: 'beta', 2

Data Types: single | double

gamma — Shape parameter

1 (default) | nonnegative scalar value

Example: 'gamma', 0

Data Types: single | double

Burr Distribution

alpha — Scale parameter

1 (default) | positive scalar value

Example: 'alpha', 2

Data Types: single | double

c — First shape parameter

1 (default) | positive scalar value

Example: 'c', 2

Data Types: single | double

k — Second shape parameter

1 (default) | positive scalar value

Example: 'k', 5

Data Types: single | double

Exponential Distribution

mu — Mean parameter

1 (default) | positive scalar value

Example: 'mu', 5

Data Types: single | double

Extreme Value Distribution

mu — Location parameter

0 (default) | scalar value

Example: 'mu', -2

Data Types: single | double

sigma — Scale parameter

1 (default) | nonnegative scalar value

Example: 'sigma', 2

Data Types: single | double

Gamma Distribution

a — Shape parameter

1 (default) | positive scalar value

Example: 'a', 2

Data Types: single | double

b — Scale parameter

1 (default) | nonnegative scalar value

Example: 'b', 0

Data Types: single | double

Generalized Extreme Value Distribution

k — Shape parameter

0 (default) | scalar value

Example: 'k', 0

Data Types: single | double

sigma — Scale parameter

1 (default) | nonnegative scalar value

Example: 'sigma',2

Data Types: single | double

mu — Location parameter

0 (default) | scalar value

Example: 'mu',1

Data Types: single | double

Generalized Pareto Distribution**k — Shape parameter**

1 (default) | scalar value

Example: 'k',0

Data Types: single | double

sigma — Scale parameter

1 (default) | nonnegative scalar value

Example: 'sigma',2

Data Types: single | double

theta — Location parameter

1 (default) | scalar value

Example: 'theta',2

Data Types: single | double

Half-Normal Distribution**mu — Location parameter**

0 (default) | scalar value

Example: 'mu',1

Data Types: single | double

sigma — Shape parameter

1 (default) | nonnegative scalar value

Example: 'sigma',2

Data Types: single | double

Inverse Gaussian Distribution

mu — Scale parameter

1 (default) | positive scalar value

Example: 'mu',2

Data Types: single | double

lambda — Shape parameter

1 (default) | positive scalar value

Example: 'lambda',4

Data Types: single | double

Logistic Distribution

mu — Mean

0 (default) | scalar value

Example: 'mu',2

Data Types: single | double

sigma — Scale parameter

1 (default) | nonnegative scalar value

Example: 'sigma',4

Data Types: single | double

Loglogistic Distribution

mu — Mean of logarithmic values

0 (default) | scalar value

Example: 'mu',2

Data Types: single | double

sigma — Scale parameter of logarithmic values

1 (default) | nonnegative scalar value

Example: 'sigma',4

Data Types: single | double

Lognormal Distribution

mu — Mean of logarithmic values

0 (default) | scalar value

Example: 'mu',2

Data Types: single | double

sigma — Standard deviation of logarithmic values

1 (default) | nonnegative scalar value

Example: 'sigma',2

Data Types: single | double

Multinomial Distribution

probabilities — Outcome probabilities

[0.500 0.500] (default) | vector of scalar values in the range [0,1]

Outcome probabilities, specified as a vector of scalar values in the range [0,1]. The probabilities sum to 1 and correspond to outcomes [1, 2, ..., k], where k is the number of elements in the probabilities vector.

Example: 'probabilities', [0.1 0.2 0.5 0.2] gives the probabilities that the outcome is 1, 2, 3, or 4, respectively.

Data Types: single | double

Nakagami Distribution

mu — Shape parameter

1 (default) | positive scalar value

Example: 'mu',5

Data Types: single | double

omega — Scale parameter

1 (default) | positive scalar value

Example: 'omega',5

Data Types: single | double

Negative Binomial Distribution

R — Number of successes

1 (default) | positive scalar value

Example: 'R',5

Data Types: single | double

p — Probability of success

0.5 (default) | scalar value in the range (0,1]

Example: 'p',0.1

Data Types: single | double

Normal Distribution

mu — Mean

0 (default) | scalar value

Example: 'mu',2

Data Types: single | double

sigma — Standard deviation

1 (default) | nonnegative scalar value

Example: 'sigma',2

Data Types: single | double

Piecewise Linear Distribution

x — Data values

1 (default) | monotonically increasing vector of scalar values

Example: 'x',[1 2 3]

Data Types: single | double

Fx — cdf values

1 (default) | monotonically increasing vector of scalar values that start at 0 and end at 1

Example: 'Fx',[0.2 0.5 1]

Data Types: single | double

Poisson Distribution**lambda — Mean**

1 (default) | nonnegative scalar value

Example: 'lambda',5

Data Types: single | double

Rayleigh Distribution**b — Defining parameter**

1 (default) | positive scalar value

Example: 'b',3

Data Types: single | double

Rician Distribution**s — Noncentrality parameter**

1 (default) | nonnegative scalar value

Example: 's',0

Data Types: single | double

sigma — Scale parameter

1 (default) | positive scalar value

Example: 'sigma',2

Data Types: single | double

Stable Distribution**alpha — First shape parameter**

2 (default) | scalar value in the range (0,2]

Example: 'alpha',1

Data Types: single | double

beta — Second shape parameter

0 (default) | scalar value in the range [-1,1]

Example: 'beta',0.5

Data Types: single | double

gam — Scale parameter

1 (default) | scalar value in the range $(0, \infty)$

Example: 'gam', 2

Data Types: single | double

delta — Location parameter

0 (default) | scalar value

Example: 'delta', 5

Data Types: single | double

t Location-Scale Distribution

mu — Location parameter

0 (default) | scalar value

Example: 'mu', -2

Data Types: single | double

sigma — Scale parameter

1 (default) | positive scalar value

Example: 'sigma', 2

Data Types: single | double

nu — Degrees of freedom

5 (default) | positive scalar value

Example: 'nu', 20

Data Types: single | double

Triangular Distribution

a — Lower limit

0 (default) | scalar value

Example: 'a', -2

Data Types: single | double

b — Peak location

0.5 (default) | scalar value greater than or equal to a

Example: 'b',1

Data Types: single | double

c — Upper limit

1 (default) | scalar value greater than or equal to b

Example: 'c',5

Data Types: single | double

Uniform Distribution

lower — Lower parameter

0 (default) | scalar value

Example: 'lower',-4

Data Types: single | double

upper — Upper parameter

1 (default) | scalar value greater than lower

Example: 'upper',2

Data Types: single | double

Weibull Distribution

a — Scale parameter

1 (default) | positive scalar value

Example: 'a',2

Data Types: single | double

b — Shape parameter

1 (default) | positive scalar value

Example: 'b',5

Data Types: single | double

Output Arguments

pd — Probability distribution

probability distribution object

Probability distribution, returned as a probability distribution object of the type specified by `distname`.

list — List of probability distributions

cell array of character vectors

List of probability distributions that `makedist` can create, returned as a cell array of character vectors.

Alternative Functionality

App

The **Distribution Fitter** app opens a graphical user interface for you to import data from the workspace and interactively fit a probability distribution to that data. You can then save the distribution to the workspace as a probability distribution object. Open the Distribution Fitter app using `distributionFitter`, or click Distribution Fitter on the Apps tab.

Introduced in R2013a

manova

Class: RepeatedMeasuresModel

Multivariate analysis of variance

Syntax

```
manovatbl = manova(rm)
manovatbl = manova(rm,Name,Value)
[manovatbl,A,C,D] = manova(____)
```

Description

`manovatbl = manova(rm)` returns the results of multivariate analysis of variance (`manova`) for the repeated measures model `rm`.

`manovatbl = manova(rm,Name,Value)` also returns `manova` results with additional options, specified by one or more `Name,Value` pair arguments.

`[manovatbl,A,C,D] = manova(____)` also returns arrays `A`, `C`, and `D` for the hypotheses tests of the form $A*B*C = D$, where `D` is zero.

Input Arguments

rm — Repeated measures model

RepeatedMeasuresModel object

Repeated measures model, returned as a RepeatedMeasuresModel object.

For properties and methods of this object, see RepeatedMeasuresModel.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes.

You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

WithinModel — Model specifying within-subjects hypothesis test

'separatemeans' (default) | model specification using formula | *r*-by-*nc* matrix

Model specifying the within-subjects hypothesis test, specified as one of the following:

- 'separatemeans' — Compute a separate mean for each group, and test for equality among the means.
- Model specification — This is a model specification in the within-subject factors. Test each term in the model. In this case, `tbl` contains a separate manova for each term in the formula, with the multivariate response equal to the vector of coefficients of that term.
- An *r*-by-*nc* matrix, *C*, specifying *nc* contrasts among the *r* repeated measures. If *Y* represents the matrix of repeated measures you use in the repeated measures model `rm`, then the output `tbl` contains a separate manova for each column of $Y*C$.

Example: 'WithinModel', 'separatemeans'

Data Types: single | double | char | string

By — Single between-subjects factor

character vector | string scalar

Single between-subjects factor, specified as the comma-separated pair consisting of 'By' and a character vector or string scalar. `manova` performs a separate test of the within-subjects model for each value of this factor.

For example, if you have a between-subjects factor, `Drug`, then you can specify that factor to perform `manova` as follows.

Example: 'By', 'Drug'

Data Types: char | string

Output Arguments

manovatbl — Results of multivariate analysis of variance

table

Results of multivariate analysis of variance for the repeated measures model `rm`, returned as a `table`.

`manova` uses these methods to measure the contributions of the model terms to the overall covariance:

- Wilks' Lambda
- Pillai's trace
- Hotelling-Lawley trace
- Roy's maximum root statistic

For details, see "Multivariate Analysis of Variance for Repeated Measures" on page 9-83.

`manova` returns the results for these tests for each group. `manovatbl` contains the following columns.

Column Name	Definition
Within	Within-subject terms
Between	Between-subject terms
Statistic	Name of the statistic computed
Value	Value of the corresponding statistic
F	<i>F</i> -statistic value
RSquare	Measure for variance explained
df1	Numerator degrees of freedom
df2	Denominator degrees of freedom
pValue	<i>p</i> -value for the corresponding <i>F</i> -statistic value

Data Types: `table`

A — Specification based on between-subjects model

`matrix` | `cell array`

Specification based on the between-subjects model, returned as a matrix or a cell array. It permits the hypothesis on the elements within given columns of `B` (within time hypothesis). If `manovatbl` contains multiple hypothesis tests, `A` might be a cell array.

Data Types: `single` | `double` | `cell`

C — Specification based on within-subjects model

matrix | cell array

Specification based on the within-subjects model, returned as a matrix or a cell array. It permits the hypotheses on the elements within given rows of B (between time hypotheses). If `manovatbl` contains multiple hypothesis tests, C might be a cell array.

Data Types: single | double | cell

D — Hypothesis value

0

Hypothesis value, returned as 0.

Examples

Perform Multivariate Analysis of Variance

Load the sample data.

```
load fisheriris
```

The column vector `species` consists of iris flowers of three different species: `setosa`, `versicolor`, `virginica`. The double matrix `meas` consists of four types of measurements on the flowers: the length and width of sepals and petals in centimeters, respectively.

Store the data in a table array.

```
t = table(species,meas(:,1),meas(:,2),meas(:,3),meas(:,4),...  
'VariableNames',{'species','meas1','meas2','meas3','meas4'});  
Meas = table([1 2 3 4'],'VariableNames',{'Measurements'});
```

Fit a repeated measures model where the measurements are the responses and the species is the predictor variable.

```
rm = fitrm(t,'meas1-meas4~species','WithinDesign',Meas);
```

Perform multivariate analysis of variance.

```
manova(rm)
```

```
ans=8×9 table
```

manova1

One-way multivariate analysis of variance

Syntax

```
d = manova1(X,group)
d = manova1(X,group,alpha)
[d,p] = manova1(...)
[d,p,stats] = manova1(...)
```

Description

`d = manova1(X,group)` performs a one-way Multivariate Analysis of Variance (MANOVA) for comparing the multivariate means of the columns of `X`, grouped by `group`. `X` is an m -by- n matrix of data values, and each row is a vector of measurements on n variables for a single observation. `group` is a grouping variable defined as a categorical variable, vector, character array, string array, or cell array of character vectors. Two observations are in the same group if they have the same value in the `group` array. The observations in each group represent a sample from a population.

The function returns `d`, an estimate of the dimension of the space containing the group means. `manova1` tests the null hypothesis that the means of each group are the same n -dimensional multivariate vector, and that any difference observed in the sample `X` is due to random chance. If `d = 0`, there is no evidence to reject that hypothesis. If `d = 1`, then you can reject the null hypothesis at the 5% level, but you cannot reject the hypothesis that the multivariate means lie on the same line. Similarly, if `d = 2` the multivariate means may lie on the same plane in n -dimensional space, but not on the same line.

`d = manova1(X,group,alpha)` gives control of the significance level, `alpha`. The return value `d` will be the smallest dimension having $p > \alpha$, where `p` is a p -value for testing whether the means lie in a space of that dimension.

`[d,p] = manova1(...)` also returns a `p`, a vector of p -values for testing whether the means lie in a space of dimension 0, 1, and so on. The largest possible dimension is either the dimension of the space, or one less than the number of groups. There is one element of `p` for each dimension up to, but not including, the largest.

If the i th p -value is near zero, this casts doubt on the hypothesis that the group means lie on a space of $i-1$ dimensions. The choice of a critical p -value to determine whether the result is judged statistically significant is left to the researcher and is specified by the value of the input argument `alpha`. It is common to declare a result significant if the p -value is less than 0.05 or 0.01.

`[d,p,stats] = manova1(...)` also returns `stats`, a structure containing additional MANOVA results. The structure contains the following fields.

Field	Contents
<code>W</code>	Within-groups sum of squares and cross-products matrix
<code>B</code>	Between-groups sum of squares and cross-products matrix
<code>T</code>	Total sum of squares and cross-products matrix
<code>dfW</code>	Degrees of freedom for <code>W</code>
<code>dfB</code>	Degrees of freedom for <code>B</code>
<code>dfT</code>	Degrees of freedom for <code>T</code>
<code>lambda</code>	Vector of values of Wilk's lambda test statistic for testing whether the means have dimension 0, 1, etc.
<code>chisq</code>	Transformation of <code>lambda</code> to an approximate chi-square distribution
<code>chisqdf</code>	Degrees of freedom for <code>chisq</code>
<code>eigenval</code>	Eigenvalues of $W^{-1}B$
<code>eigenvec</code>	Eigenvectors of $W^{-1}B$; these are the coefficients for the canonical variables <code>C</code> , and they are scaled so the within-group variance of the canonical variables is 1
<code>canon</code>	Canonical variables <code>C</code> , equal to $XC * \text{eigenvec}$, where <code>XC</code> is <code>X</code> with columns centered by subtracting their means
<code>mdist</code>	A vector of Mahalanobis distances from each point to the mean of its group
<code>gmdist</code>	A matrix of Mahalanobis distances between each pair of group means

The canonical variables `C` are linear combinations of the original variables, chosen to maximize the separation between groups. Specifically, `C(:,1)` is the linear combination of the `X` columns that has the maximum separation between groups. This means that among all possible linear combinations, it is the one with the most significant F statistic in

a one-way analysis of variance. $C(:, 2)$ has the maximum separation subject to it being orthogonal to $C(:, 1)$, and so on.

You may find it useful to use the outputs from `manova1` along with other functions to supplement your analysis. For example, you may want to start with a grouped scatter plot matrix of the original variables using `gplotmatrix`. You can use `gscatter` to visualize the group separation using the first two canonical variables. You can use `manovacluster` to graph a dendrogram showing the clusters among the group means.

Assumptions

The MANOVA test makes the following assumptions about the data in X :

- The populations for each group are normally distributed.
- The variance-covariance matrix is the same for each population.
- All observations are mutually independent.

Examples

you can use `manova1` to determine whether there are differences in the averages of four car characteristics, among groups defined by the country where the cars were made.

```
load carbig
[d,p] = manova1([MPG Acceleration Weight Displacement],...
                Origin)
d =
     3
p =
     0
    0.0000
    0.0075
    0.1934
```

There are four dimensions in the input matrix, so the group means must lie in a four-dimensional space. `manova1` shows that you cannot reject the hypothesis that the means lie in a 3-D subspace.

Topics

“Grouping Variables” on page 2-57

Introduced before R2006a

manovacluster

Dendrogram of group mean clusters following MANOVA

Syntax

```
manovacluster(stats)
manovacluster(stats,method)
H = manovacluster(stats,method)
```

Description

`manovacluster(stats)` generates a dendrogram plot of the group means after a multivariate analysis of variance (MANOVA). `stats` is the output `stats` structure from `manova1`. The clusters are computed by applying the single linkage method to the matrix of Mahalanobis distances between group means.

See `dendrogram` for more information on the graphical output from this function. The dendrogram is most useful when the number of groups is large.

`manovacluster(stats,method)` uses the specified method in place of single linkage. `method` can be one of these values, which identify the methods used to create the cluster hierarchy. (See `linkage` for additional information.)

Method	Description
'single'	Shortest distance (default)
'complete'	Largest distance
'average'	Average distance
'centroid'	Centroid distance
'ward'	Incremental sum of squares

`H = manovacluster(stats,method)` returns a vector of handles to the lines in the figure.

Examples

Dendrogram of Group Means After MANOVA

Load the sample data.

```
load carbig
```

Define the variable matrix.

```
X = [MPG Acceleration Weight Displacement];
```

Perform one-way MANOVA to compare the means of MPG, Acceleration, Weight, and Displacement grouped by Origin.

```
[d,p,stats] = manoval(X,Origin);
```

Create a dendrogram plot of the group means.

```
manovacluster(stats)
```

Introduced before R2006a

margin

Margin of k -nearest neighbor classifier

Syntax

```
m = margin mdl, tbl, ResponseVarName
m = margin mdl, tbl, Y
m = margin mdl, X, Y
```

Description

`m = margin(mdl, tbl, ResponseVarName)` returns the classification margins on page 32-4109 for `mdl` with data `tbl` and classification `tbl.ResponseVarName`. If `tbl` contains the response variable used to train `mdl`, then you do not need to specify `ResponseVarName`.

`m` is returned as a numeric vector of length `size(tbl, 1)`. Each entry in `m` represents the margin for the corresponding row of `tbl` and the corresponding true class label in `tbl.ResponseVarName`, computed using `mdl`.

`m = margin(mdl, tbl, Y)` returns the classification margins for `mdl` with data `tbl` and classification `Y`.

`m = margin(mdl, X, Y)` returns the classification margins for `mdl` with data `X` and classification `Y`. `m` is returned as a numeric vector of length `size(X, 1)`.

Examples

Margin Calculation

Create a k -nearest neighbor classifier for the Fisher iris data, where $k = 5$.

Load the Fisher iris data set.

```
load fisheriris
```

Create a classifier for five nearest neighbors.

```
mdl = fitcknn(meas,species,'NumNeighbors',5);
```

Examine the margin of the classifier for a mean observation classified as 'versicolor'.

```
X = mean(meas);  
Y = {'versicolor'};  
m = margin(mdl,X,Y)
```

```
m = 1
```

All five nearest neighbors classify as 'versicolor'.

Input Arguments

mdl — *k*-nearest neighbor classifier model

ClassificationKNN object

k-nearest neighbor classifier model, specified as a ClassificationKNN object.

tbl — Sample data

table

Sample data used to train the model, specified as a table. Each row of `tbl` corresponds to one observation, and each column corresponds to one predictor variable. Optionally, `tbl` can contain one additional column for the response variable. Multicolumn variables and cell arrays other than cell arrays of character vectors are not allowed.

If `tbl` contains the response variable used to train `mdl`, then you do not need to specify `ResponseVarName` or `Y`.

If you train `mdl` using sample data contained in a table, then the input data for `margin` must also be in a table.

Data Types: table

ResponseVarName — Response variable name

name of a variable in `tbl`

Response variable name, specified as the name of a variable in `tbl`. If `tbl` contains the response variable used to train `mdl`, then you do not need to specify `ResponseVarName`.

You must specify `ResponseVarName` as a character vector or string scalar. For example, if the response variable is stored as `tbl.response`, then specify it as `'response'`. Otherwise, the software treats all columns of `tbl`, including `tbl.response`, as predictors.

The response variable must be a categorical, character, or string array, logical or numeric vector, or cell array of character vectors. If the response variable is a character array, then each element must correspond to one row of the array.

Data Types: `char` | `string`

X — Predictor data

numeric matrix

Predictor data, specified as a numeric matrix. Each row of `X` represents one observation, and each column represents one variable.

Data Types: `single` | `double`

Y — Class labels

categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Class labels, specified as a categorical, character, or string array, logical or numeric vector, or cell array of character vectors. Each row of `Y` represents the classification of the corresponding row of `X`.

Data Types: `categorical` | `char` | `string` | `logical` | `single` | `double` | `cell`

Definitions

Margin

The classification margin for each observation is the difference between the classification score for the true class and the maximal classification score for the false classes.

Score

The score of a classification is the posterior probability of the classification. The posterior probability is the number of neighbors with that classification divided by the number of neighbors. For a more detailed definition that includes weights and prior probabilities, see “Posterior Probability” on page 32-5188.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. For more information, see “Tall Arrays” (MATLAB).

Introduced in R2012a

margin

Class: ClassificationLinear

Classification margins for linear classification models

Syntax

```
m = margin(Mdl,X,Y)
```

```
m = margin(___,Name,Value)
```

Description

`m = margin(Mdl,X,Y)` returns the classification margins on page 32-4121 for the binary, linear classification model `Mdl` using predictor data in `X` and corresponding class labels in `Y`. `m` contains classification margins for each regularization strength in `Mdl`.

`m = margin(___,Name,Value)` uses any of the previous syntaxes and additional options specified by one or more `Name,Value` pair arguments. For example, you can specify that columns in the predictor data correspond to observations.

Input Arguments

Mdl — Binary, linear classification model

ClassificationLinear model object

Binary, linear classification model, specified as a `ClassificationLinear` model object. You can create a `ClassificationLinear` model object using `fitclinear`.

X — Predictor data

full matrix | sparse matrix

Predictor data, specified as an n -by- p full or sparse matrix. This orientation of `X` indicates that rows correspond to individual observations, and columns correspond to individual predictor variables.

Note If you orient your predictor matrix so that observations correspond to columns and specify 'ObservationsIn', 'columns', then you might experience a significant reduction in computation time.

The length of `Y` and the number of observations in `X` must be equal.

Data Types: `single` | `double`

Y — Class labels

categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Class labels, specified as a categorical, character, or string array, logical or numeric vector, or cell array of character vectors.

- The data type of `Y` must be the same as the data type of `Mdl.ClassNames`. (The software treats string arrays as cell arrays of character vectors.)
- The distinct classes in `Y` must be a subset of `Mdl.ClassNames`.
- If `Y` is a character array, then each element must correspond to one row of the array.
- The length of `Y` and the number of observations in `X` must be equal.

Data Types: `categorical` | `char` | `string` | `logical` | `single` | `double` | `cell`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

ObservationsIn — Predictor data observation dimension

'rows' (default) | 'columns'

Predictor data observation dimension, specified as the comma-separated pair consisting of 'ObservationsIn' and 'columns' or 'rows'.

Note If you orient your predictor matrix so that observations correspond to columns and specify 'ObservationsIn', 'columns', then you might experience a significant reduction in optimization-execution time.

Output Arguments

m — Classification margins

numeric column vector | numeric matrix

Classification margins on page 32-4121, returned as a numeric column vector or matrix.

m is n -by- L , where n is the number of observations in X and L is the number of regularization strengths in Mdl (that is, `numel(Mdl.Lambda)`).

$m(i, j)$ is the classification margin of observation i using the trained linear classification model that has regularization strength $Mdl.Lambda(j)$.

Examples

Estimate Test-Sample Margins

Load the NLP data set.

```
load nlpdata
```

X is a sparse matrix of predictor data, and Y is a categorical vector of class labels. There are more than two classes in the data.

The models should identify whether the word counts in a web page are from the Statistics and Machine Learning Toolbox™ documentation. So, identify the labels that correspond to the Statistics and Machine Learning Toolbox™ documentation web pages.

```
Ystats = Y == 'stats';
```

Train a binary, linear classification model that can identify whether the word counts in a documentation web page are from the Statistics and Machine Learning Toolbox™ documentation. Specify to hold out 30% of the observations. Optimize the objective function using SpARSA.

```
rng(1); % For reproducibility  
CVMdl = fitclinear(X, Ystats, 'Solver', 'sparsa', 'Holdout', 0.30);  
CMdl = CVMdl.Trained{1};
```

`CVMDL` is a `ClassificationPartitionedLinear` model. It contains the property `Trained`, which is a 1-by-1 cell array holding a `ClassificationLinear` model that the software trained using the training set.

Extract the training and test data from the partition definition.

```
trainIdx = training(CVMDL.Partition);  
testIdx = test(CVMDL.Partition);
```

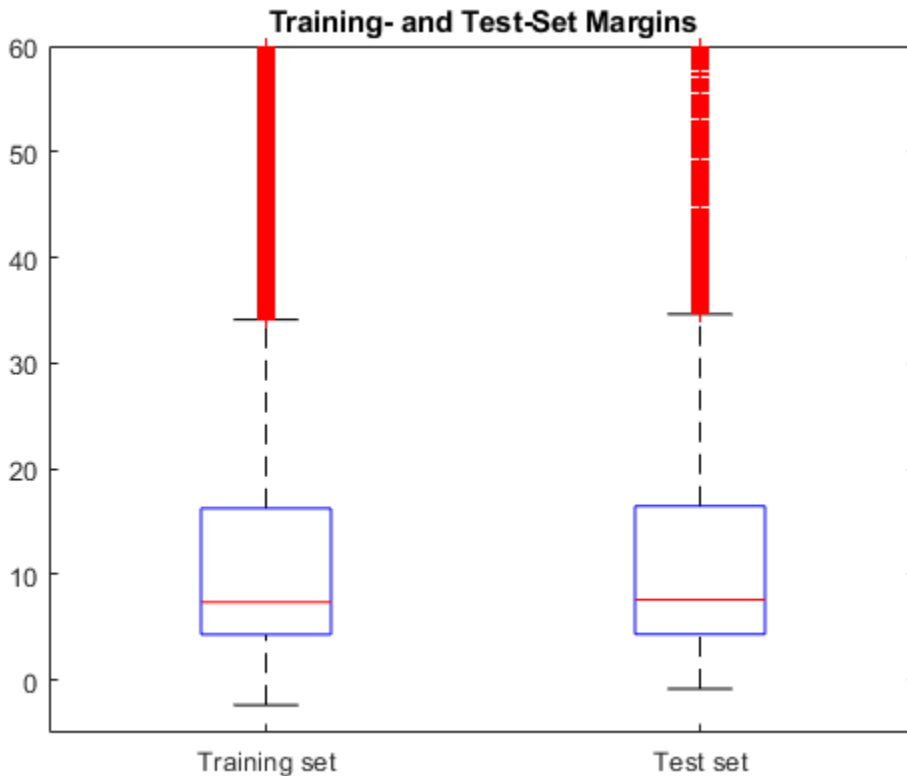

Estimate the training- and test-sample margins.

```
mTrain = margin(CMDL,X(trainIdx,:),Ystats(trainIdx));  
mTest = margin(CMDL,X(testIdx,:),Ystats(testIdx));
```

Because there is one regularization strength in `CMdl`, `mTrain` and `mTest` are column vectors with lengths equal to the number of training and test observations, respectively.

Plot both sets of margins using box plots.

```
figure;  
boxplot([mTrain; mTest],[zeros(size(mTrain,1),1); ones(size(mTest,1),1)], ...  
        'Labels',{'Training set','Test set'});  
h = gca;  
h.YLim = [-5 60];  
title 'Training- and Test-Set Margins'
```

The distributions of the margins between the training and test sets appear similar.

Feature Selection Using Test-Sample Margins

One way to perform feature selection is to compare test-sample margins from multiple models. Based solely on this criterion, the classifier with the larger margins is the better classifier.

Load the NLP data set. Preprocess the data as in “Estimate Test-Sample Margins” on page 32-4113.

```
load nlpdata
Ystats = Y == 'stats';
X = X';
rng(1); % For reproducibility
```

Create a data partition which holds out 30% of the observations for testing.

```
Partition = cvpartition(Ystats,'Holdout',0.30);
testIdx = test(Partition); % Test-set indices
XTest = X(:,testIdx);
YTest = Ystats(testIdx);
```

Partition is a `cvpartition` object that defines the data set partition.

Randomly choose 10% of the predictor variables.

```
p = size(X,1); % Number of predictors
idxPart = randsample(p,ceil(0.1*p));
```

Train two binary, linear classification models: one that uses the all of the predictors and one that uses the random 10%. Optimize the objective function using `SpaRSA`, and indicate that observations correspond to columns.

```
CVMDL = fitlinear(X,Ystats,'CVPartition',Partition,'Solver','sparsa',...
    'ObservationsIn','columns');
PCVMDL = fitlinear(X(idxPart,:),Ystats,'CVPartition',Partition,'Solver','sparsa',...
    'ObservationsIn','columns');
```

CVMDL and PCVMDL are `ClassificationPartitionedLinear` models.

Extract the trained `ClassificationLinear` models from the cross-validated models.

```
CMdl = CVMDL.Trained{1};
PCMDL = PCVMDL.Trained{1};
```

Estimate the test sample margins for each classifier. Plot the distribution of the margins sets using box plots.

```
fullMargins = margin(CMdl,XTest,YTest,'ObservationsIn','columns');
partMargins = margin(PCMDL,XTest(idxPart,:),YTest,...
    'ObservationsIn','columns');

figure;
boxplot([fullMargins partMargins],'Labels',...
    {'All Predictors','10% of the Predictors'});
```

```
h = gca;  
h.YLim = [-20 60];  
title('Test-Sample Margins')
```

The margin distribution of $\text{CMD}\lambda$ is situated higher than the margin distribution of $\text{PCMD}\lambda$.

Find Good Lasso Penalty Using Margins

To determine a good lasso-penalty strength for a linear classification model that uses a logistic regression learner, compare distributions of test-sample margins.

Load the NLP data set. Preprocess the data as in “Estimate Test-Sample Margins” on page 32-4113.

```
load nlpdata
Ystats = Y == 'stats';
X = X';

Partition = cvpartition(Ystats, 'Holdout', 0.30);
testIdx = test(Partition);
XTest = X(:, testIdx);
YTest = Ystats(testIdx);
```

Create a set of 11 logarithmically-spaced regularization strengths from 10^{-8} through 10^1 .

```
Lambda = logspace(-8, 1, 11);
```

Train binary, linear classification models that use each of the regularization strengths. Optimize the objective function using SpaRSA. Lower the tolerance on the gradient of the objective function to $1e-8$.

```
rng(10); % For reproducibility
CVMdl = fitlinear(X, Ystats, 'ObservationsIn', 'columns', ...
    'CVPartition', Partition, 'Learner', 'logistic', 'Solver', 'sparsa', ...
    'Regularization', 'lasso', 'Lambda', Lambda, 'GradientTolerance', 1e-8)
```

```
CVMdl =
  classreg.learning.partition.ClassificationPartitionedLinear
  CrossValidatedModel: 'Linear'
  ResponseName: 'Y'
  NumObservations: 31572
  KFold: 1
  Partition: [1x1 cvpartition]
  ClassNames: [0 1]
  ScoreTransform: 'none'
```

Properties, Methods

Extract the trained linear classification model.

```
Mdl = CVMdl.Trained{1}

Mdl =
  ClassificationLinear
```

```
ResponseName: 'Y'  
ClassNames: [0 1]  
ScoreTransform: 'logit'  
Beta: [34023x11 double]  
Bias: [1x11 double]  
Lambda: [1x11 double]  
Learner: 'logistic'
```

Properties, Methods

`Mdl` is a `ClassificationLinear` model object. Because `Lambda` is a sequence of regularization strengths, you can think of `Mdl` as 11 models, one for each regularization strength in `Lambda`.

Estimate the test-sample margins.

```
m = margin(Mdl,X(:,testIdx),Ystats(testIdx),'ObservationsIn','columns');  
size(m)
```

```
ans = 1×2
```

```
9471      11
```

Because there are 11 regularization strengths, `m` has 11 columns.

Plot the test-sample margins for each regularization strength. Because logistic regression scores are in $[0,1]$, margins are in $[-1,1]$. Rescale the margins to help identify the regularization strength that maximizes the margins over the grid.

```
figure;  
boxplot(10000.^m)  
ylabel('Exponentiated test-sample margins')  
xlabel('Lambda indices')
```

Several values of Lambda yield margin distributions that are compacted near 10000¹. Higher values of lambda lead to predictor variable sparsity, which is a good quality of a classifier.

Choose the regularization strength that occurs just before the centers of the margin distributions start decreasing.

```
LambdaFinal = Lambda(5);
```

Train a linear classification model using the entire data set and specify the desired regularization strength.

```
MdlFinal = fitlinear(X,Ystats,'ObservationsIn','columns',...
    'Learner','logistic','Solver','sparsa','Regularization','lasso',...
    'Lambda',LambdaFinal);
```

To estimate labels for new observations, pass `MdlFinal` and the new data to `predict`.

Definitions

Classification Margin

The classification margin for binary classification is, for each observation, the difference between the classification score for the true class and the classification score for the false class.

The software defines the classification margin for binary classification as

$$m = 2yf(x).$$

x is an observation. If the true label of x is the positive class, then y is 1, and -1 otherwise. $f(x)$ is the positive-class classification score for the observation x . The classification margin is commonly defined as $m = yf(x)$.

If the margins are on the same scale, then they serve as a classification confidence measure. Among multiple classifiers, those that yield greater margins are better.

Classification Score

For linear classification models, the raw classification score for classifying the observation x , a row vector, into the positive class is defined by

$$f_j(x) = x\beta_j + b_j.$$

For the model with regularization strength j , β_j is the estimated column vector of coefficients (the model property `Beta(:,j)`) and b_j is the estimated, scalar bias (the model property `Bias(j)`).

The raw classification score for classifying x into the negative class is $-f(x)$. The software classifies observations into the class that yields the positive score.

If the linear classification model consists of logistic regression learners, then the software applies the 'logit' score transformation to the raw classification scores (see `ScoreTransform`).

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. For more information, see “Tall Arrays” (MATLAB).

See Also

`ClassificationLinear` | `edge` | `fitclinear` | `predict`

Introduced in R2016a

margin

Classification margins

Syntax

```
m = margin(obj,X,Y)
```

Description

`m = margin(obj,X,Y)` returns the classification margins for the matrix of predictors `X` and class labels `Y`. For the definition, see “Definitions” on page 32-4125.

Input Arguments

obj

Discriminant analysis classifier of class `ClassificationDiscriminant` or `CompactClassificationDiscriminant`, typically constructed with `fitcdiscr`.

X

Matrix where each row represents an observation, and each column represents a predictor. The number of columns in `X` must equal the number of predictors in `obj`.

Y

Class labels, with the same data type as exists in `obj`. The number of elements of `Y` must equal the number of rows of `X`.

Output Arguments

m

Numeric column vector of length `size(X,1)`. Each entry in `m` represents the margin for the corresponding rows of `X` and (true class) `Y`, computed using `obj`.

Examples

Compute the classification margin for the Fisher iris data, trained on its first two columns of data, and view the last 10 entries:

```
load fisheriris
X = meas(:,1:2);
obj = fitcdiscr(X,species);
M = margin(obj,X,species);
M(end-10:end)
```

```
ans =
    0.6551
    0.4838
    0.6551
   -0.5127
    0.5659
    0.4611
    0.4949
    0.1024
    0.2787
   -0.1439
   -0.4444
```

The classifier trained on all the data is better:

```
obj = fitcdiscr(meas,species);
M = margin(obj,meas,species);
M(end-10:end)
```

```
ans =
    0.9983
    1.0000
    0.9991
    0.9978
```

```
1.0000
1.0000
0.9999
0.9882
0.9937
1.0000
0.9649
```

Definitions

Margin

The classification margin is the difference between the classification score for the true class and maximal classification score for the false classes.

The classification margin is a column vector with the same number of rows as in the matrix X . A high value of margin indicates a more reliable prediction than a low value.

Score (discriminant analysis)

For discriminant analysis, the score of a classification is the posterior probability of the classification. For the definition of posterior probability in discriminant analysis, see “Posterior Probability” on page 20-6.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. For more information, see “Tall Arrays” (MATLAB).

See Also

ClassificationDiscriminant | edge | fitcdiscr | loss | predict

Topics

“Discriminant Analysis Classification” on page 20-2

margin

Package:

Classification margins for multiclass error-correcting output codes (ECOC) model

Syntax

```
m = margin(Mdl,tbl,ResponseVarName)
```

```
m = margin(Mdl,tbl,Y)
```

```
m = margin(Mdl,X,Y)
```

```
m = margin( ____,Name,Value)
```

Description

`m = margin(Mdl,tbl,ResponseVarName)` returns the classification margins on page 32-4138 (m) for the trained multiclass error-correcting output codes (ECOC) model `Mdl` using the predictor data in table `tbl` and the class labels in `tbl.ResponseVarName`.

`m = margin(Mdl,tbl,Y)` returns the classification margins for the classifier `Mdl` using the predictor data in table `tbl` and the class labels in vector `Y`.

`m = margin(Mdl,X,Y)` returns the classification margins for the classifier `Mdl` using the predictor data in matrix `X` and the class labels `Y`.

`m = margin(____,Name,Value)` specifies options using one or more name-value pair arguments in addition to any of the input argument combinations in previous syntaxes. For example, you can specify a decoding scheme, binary learner loss function, and verbosity level.

Examples

Test-Sample Classification Margins of ECOC Model

Calculate the test-sample classification margins of an ECOC model with SVM binary learners.

Load Fisher's iris data set. Specify the predictor data X, the response data Y, and the order of the classes in Y.

```
load fisheriris
X = meas;
Y = categorical(species);
classOrder = unique(Y); % Class order
rng(1) % For reproducibility
```

Train an ECOC model using SVM binary classifiers. Specify a 30% holdout sample, standardize the predictors using an SVM template, and specify the class order.

```
t = templateSVM('Standardize',true);
PMdl = fitcecoc(X,Y,'Holdout',0.30,'Learners',t,'ClassNames',classOrder);
Mdl = PMdl.Trained{1}; % Extract trained, compact classifier
```

PMdl is a ClassificationPartitionedECOC model. It has the property Trained, a 1-by-1 cell array containing the CompactClassificationECOC model that the software trained using the training set.

Calculate the test-sample classification margins. Display the distribution of the margins using a boxplot.

```
testInds = test(PMdl.Partition); % Extract the test indices
XTest = X(testInds,:);
YTest = Y(testInds,:);
m = margin(Mdl,XTest,YTest);

boxplot(m)
title('Test-Sample Margins')
```

The classification margin of an observation is the positive-class negated loss minus the maximum negative-class negated loss. Choose classifiers that yield relatively large margins.

Select ECOC Model Features by Examining Test-Sample Margins

Perform feature selection by comparing test-sample margins from multiple models. Based solely on this comparison, the model with the greatest margins is the best model.

Load Fisher's iris data set. Specify the predictor data X , the response data Y , and the order of the classes in Y .

```
load fisheriris
X = meas;
Y = categorical(species);
classOrder = unique(Y); % Class order
rng(1); % For reproducibility
```

Partition the data set into training and test sets. Specify a 30% holdout sample for testing.

```
Partition = cvpartition(Y, 'Holdout', 0.30);
testInds = test(Partition); % Indices for the test set
XTest = X(testInds,:);
YTest = Y(testInds,:);
```

Partition defines the data set partition.

Define these two data sets:

- `fullX` contains all four predictors.
- `partX` contains the sepal measurements only.

```
fullX = X;
partX = X(:,1:2);
```

Train an ECOC model using SVM binary classifiers for each predictor set. Specify the partition definition, standardize the predictors using an SVM template, and define the class order.

```
t = templateSVM('Standardize', true);
fullPMDl = fitcecoc(fullX, Y, 'CVPartition', Partition, 'Learners', t, ...
    'ClassNames', classOrder);
partPMDl = fitcecoc(partX, Y, 'CVPartition', Partition, 'Learners', t, ...
    'ClassNames', classOrder);
fullMdl = fullPMDl.Trained{1};
partMdl = partPMDl.Trained{1};
```

`fullPMDl` and `partPMDl` are `ClassificationPartitionedECOC` models. Each model has the property `Trained`, a 1-by-1 cell array containing the `CompactClassificationECOC` model that the software trained using the corresponding training set.

Calculate the test-sample margins for each classifier. For each model, display the distribution of the margins using a boxplot.

```
fullMargins = margin(fullMdl, XTest, YTest);
partMargins = margin(partMdl, XTest(:,1:2), YTest);
```

```
boxplot([fullMargins partMargins], 'Labels', {'All Predictors', 'Two Predictors'})  
title('Boxplots of Test-Sample Margins')
```

The margin distribution of `fullMdl` is situated higher and has less variability than the margin distribution of `partMdl`.

Input Arguments

Mdl — Full or compact multiclass ECOC model

ClassificationECOC model object | CompactClassificationECOC model object

Full or compact multiclass ECOC model, specified as a `ClassificationECOC` or `CompactClassificationECOC` model object.

To create a full or compact ECOC model, see `ClassificationECOC` or `CompactClassificationECOC`.

tbl — Sample data

table

Sample data, specified as a table. Each row of `tbl` corresponds to one observation, and each column corresponds to one predictor variable. Optionally, `tbl` can contain additional columns for the response variable and observation weights. `tbl` must contain all the predictors used to train `Mdl`. Multicolumn variables and cell arrays other than cell arrays of character vectors are not allowed.

If you train `Mdl` using sample data contained in a `table`, then the input data for `margin` must also be in a table.

Note If `Mdl.BinaryLearners` contains linear or kernel classification models (`ClassificationLinear` or `ClassificationKernel` model objects), then you cannot specify sample data in a `table`. Instead, pass a matrix (X) and class labels (Y).

When training `Mdl`, assume that you set `'Standardize', true` for a template object specified in the `'Learners'` name-value pair argument of `fitcecoc`. In this case, for the corresponding binary learner j , the software standardizes the columns of the new predictor data using the corresponding means in `Mdl.BinaryLearner{j}.Mu` and standard deviations in `Mdl.BinaryLearner{j}.Sigma`.

Data Types: `table`

ResponseVarName — Response variable name

name of variable in `tbl`

Response variable name, specified as the name of a variable in `tbl`. If `tbl` contains the response variable used to train `Mdl`, then you do not need to specify `ResponseVarName`.

If you specify `ResponseVarName`, then you must do so as a character vector or string scalar. For example, if the response variable is stored as `tbl.y`, then specify `ResponseVarName` as `'y'`. Otherwise, the software treats all columns of `tbl`, including `tbl.y`, as predictors.

The response variable must be a categorical, character, or string array, a logical or numeric vector, or a cell array of character vectors. If the response variable is a character array, then each element must correspond to one row of the array.

Data Types: `char` | `string`

X — Predictor data

numeric matrix

Predictor data, specified as a numeric matrix.

Each row of `X` corresponds to one observation, and each column corresponds to one variable. The variables in the columns of `X` must be the same as the variables that trained the classifier `Mdl`.

The number of rows in `X` must equal the number of rows in `Y`.

When training `Mdl`, assume that you set `'Standardize', true` for a template object specified in the `'Learners'` name-value pair argument of `fitcecoc`. In this case, for the corresponding binary learner `j`, the software standardizes the columns of the new predictor data using the corresponding means in `Mdl.BinaryLearner{j}.Mu` and standard deviations in `Mdl.BinaryLearner{j}.Sigma`.

Data Types: `double` | `single`

Y — Class labels

categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Class labels, specified as a categorical, character, or string array, a logical or numeric vector, or a cell array of character vectors. `Y` must have the same data type as `Mdl.ClassNames`. (The software treats string arrays as cell arrays of character vectors.)

The number of rows in `Y` must equal the number of rows in `tbl` or `X`.

Data Types: `categorical` | `char` | `string` | `logical` | `single` | `double` | `cell`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `margin(Mdl,tbl,'y','BinaryLoss','exponential')` specifies an exponential binary learner loss function.

BinaryLoss — Binary learner loss function

'hamming' | 'linear' | 'logit' | 'exponential' | 'binodeviance' | 'hinge' | 'quadratic' | function handle

Binary learner loss function, specified as the comma-separated pair consisting of 'BinaryLoss' and a built-in loss function name or function handle.

- This table describes the built-in functions, where y_j is a class label for a particular binary learner (in the set $\{-1,1,0\}$), s_j is the score for observation j , and $g(y_j,s_j)$ is the binary loss formula.

Value	Description	Score Domain	$g(y_j,s_j)$
'binodeviance'	Binomial deviance	$(-\infty, \infty)$	$\log[1 + \exp(-2y_j s_j)] / [2\log(2)]$
'exponential'	Exponential	$(-\infty, \infty)$	$\exp(-y_j s_j) / 2$
'hamming'	Hamming	$[0,1]$ or $(-\infty, \infty)$	$[1 - \text{sign}(y_j s_j)] / 2$
'hinge'	Hinge	$(-\infty, \infty)$	$\max(0, 1 - y_j s_j) / 2$
'linear'	Linear	$(-\infty, \infty)$	$(1 - y_j s_j) / 2$
'logit'	Logistic	$(-\infty, \infty)$	$\log[1 + \exp(-y_j s_j)] / [2\log(2)]$
'quadratic'	Quadratic	$[0,1]$	$[1 - y_j(2s_j - 1)]^2 / 2$

The software normalizes binary losses so that the loss is 0.5 when $y_j = 0$. Also, the software calculates the mean binary loss for each class.

- For a custom binary loss function, for example `customFunction`, specify its function handle 'BinaryLoss',@`customFunction`.

`customFunction` has this form:

```
bLoss = customFunction(M,s)
```

where:

- M is the K -by- L coding matrix stored in `Mdl.CodingMatrix`.
- s is the 1-by- L row vector of classification scores.

- `bLoss` is the classification loss. This scalar aggregates the binary losses for every learner in a particular class. For example, you can use the mean binary loss to aggregate the loss over the learners for each class.
- `K` is the number of classes.
- `L` is the number of binary learners.

For an example of passing a custom binary loss function, see “Predict Test-Sample Labels of ECOC Model Using Custom Binary Loss Function” on page 32-5219.

The default `BinaryLoss` value depends on the score ranges returned by the binary learners. This table describes some default `BinaryLoss` values based on the given assumptions.

Assumption	Default Value
All binary learners are SVMs or either linear or kernel classification models of SVM learners.	'hinge'
All binary learners are ensembles trained by <code>AdaboostM1</code> or <code>GentleBoost</code> .	'exponential'
All binary learners are ensembles trained by <code>LogitBoost</code> .	'binodeviance'
All binary learners are linear or kernel classification models of logistic regression learners. Or, you specify to predict class posterior probabilities by setting ' <code>FitPosterior</code> ', true in <code>fitcecoc</code> .	'quadratic'

To check the default value, use dot notation to display the `BinaryLoss` property of the trained model at the command line.

Example: `'BinaryLoss', 'binodeviance'`

Data Types: `char | string | function_handle`

Decoding — Decoding scheme

`'lossweighted'` (default) | `'lossbased'`

Decoding scheme that aggregates the binary losses, specified as the comma-separated pair consisting of '`Decoding`' and '`lossweighted`' or '`lossbased`'. For more information, see “Binary Loss” on page 32-4137.

Example: `'Decoding', 'lossbased'`

ObservationsIn — Predictor data observation dimension`'rows' (default) | 'columns'`

Predictor data observation dimension, specified as the comma-separated pair consisting of `'ObservationsIn'` and `'columns'` or `'rows'`. `Mdl.BinaryLearners` must contain `ClassificationLinear` models.

Note If you orient your predictor matrix so that observations correspond to columns and specify `'ObservationsIn', 'columns'`, you can experience a significant reduction in execution time.

Options — Estimation options`[] (default) | structure array returned by statset`

Estimation options, specified as the comma-separated pair consisting of `'Options'` and a structure array returned by `statset`.

To invoke parallel computing:

- You need a Parallel Computing Toolbox license.
- Specify `'Options', statset('UseParallel', true)`.

Verbose — Verbosity level`0 (default) | 1`

Verbosity level, specified as the comma-separated pair consisting of `'Verbose'` and `0` or `1`. `Verbose` controls the number of diagnostic messages that the software displays in the Command Window.

If `Verbose` is `0`, then the software does not display diagnostic messages. Otherwise, the software displays diagnostic messages.

Example: `'Verbose', 1`

Data Types: `single` | `double`

Output Arguments

m — Classification margins`numeric column vector | numeric matrix`

Classification margins on page 32-4138, returned as a numeric column vector or numeric matrix.

If `Mdl.BinaryLearners` contains `ClassificationLinear` models, then `m` is an n -by- L vector, where n is the number of observations in `X` and L is the number of regularization strengths in the linear classification models (`numel(Mdl.BinaryLearners{1}.Lambda)`). The value `m(i,j)` is the margin of observation `i` for the model trained using regularization strength `Mdl.BinaryLearners{1}.Lambda(j)`.

Otherwise, `m` is a column vector of length n .

Definitions

Binary Loss

A binary loss is a function of the class and classification score that determines how well a binary learner classifies an observation into the class.

Suppose the following:

- m_{kj} is element (k,j) of the coding design matrix M (that is, the code corresponding to class k of binary learner j).
- s_j is the score of binary learner j for an observation.
- g is the binary loss function.
- \hat{k} is the predicted class for the observation.

In loss-based decoding [Escalera et al.] on page 18-228, the class producing the minimum sum of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \operatorname{argmin}_k \sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j).$$

In loss-weighted decoding [Escalera et al.] on page 18-228, the class producing the minimum average of the binary losses over binary learners determines the predicted class of an observation, that is,

$$\hat{k} = \operatorname{argmin}_k \frac{\sum_{j=1}^L |m_{kj}| g(m_{kj}, s_j)}{\sum_{j=1}^L |m_{kj}|}.$$

Allwein et al. on page 18-227 suggest that loss-weighted decoding improves classification accuracy by keeping loss values for all classes in the same dynamic range.

This table summarizes the supported loss functions, where y_j is a class label for a particular binary learner (in the set $\{-1, 1, 0\}$), s_j is the score for observation j , and $g(y_j, s_j)$.

Value	Description	Score Domain	$g(y_j, s_j)$
'binodeviance'	Binomial deviance	$(-\infty, \infty)$	$\log[1 + \exp(-2y_j s_j)] / [2\log(2)]$
'exponential'	Exponential	$(-\infty, \infty)$	$\exp(-y_j s_j) / 2$
'hamming'	Hamming	$[0, 1]$ or $(-\infty, \infty)$	$[1 - \operatorname{sign}(y_j s_j)] / 2$
'hinge'	Hinge	$(-\infty, \infty)$	$\max(0, 1 - y_j s_j) / 2$
'linear'	Linear	$(-\infty, \infty)$	$(1 - y_j s_j) / 2$
'logit'	Logistic	$(-\infty, \infty)$	$\log[1 + \exp(-y_j s_j)] / [2\log(2)]$
'quadratic'	Quadratic	$[0, 1]$	$[1 - y_j(2s_j - 1)]^2 / 2$

The software normalizes binary losses such that the loss is 0.5 when $y_j = 0$, and aggregates using the average of the binary learners [Allwein et al.] on page 18-227.

Do not confuse the binary loss with the overall classification loss (specified by the 'LossFun' name-value pair argument of the `loss` and `predict` object functions), which measures how well an ECOC classifier performs as a whole.

Classification Margin

The classification margin is, for each observation, the difference between the negative loss for the true class and the maximal negative loss among the false classes. If the margins are on the same scale, then they serve as a classification confidence measure. Among multiple classifiers, those that yield greater margins are better.

Tips

- To compare the margins or edges of several ECOC classifiers, use template objects to specify a common score transform function among the classifiers during training.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. For more information, see "Tall Arrays" (MATLAB).

Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the 'UseParallel' option to true.

Set the 'UseParallel' field of the options structure to true using `statset` and specify the 'Options' name-value pair argument in the call to this function.

For example: `'Options',statset('UseParallel',true)`

For more information, see the 'Options' name-value pair argument.

For more general information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

Introduced in R2014b

margin

Classification margins

Syntax

```
M = margin(ens,tbl,ResponseVarName)
```

```
M = margin(ens,tbl,Y)
```

```
M = margin(ens,X,Y)
```

```
M = margin( ___ Name,Value)
```

Description

`M = margin(ens,tbl,ResponseVarName)` returns the classification margin for the predictions of `ens` on data `tbl`, when the true classifications are `tbl.ResponseVarName`.

`M = margin(ens,tbl,Y)` returns the classification margin for the predictions of `ens` on data `tbl`, when the true classifications are `Y`.

`M = margin(ens,X,Y)` returns the classification margin for the predictions of `ens` on data `X`, when the true classifications are `Y`.

`M = margin(___ Name,Value)` calculates margin with additional options specified by one or more `Name,Value` pair arguments, using any of the previous syntaxes.

Input Arguments

ens

Classification ensemble created with `fitcensemble`, or a compact classification ensemble created with `compact`.

tbl

Sample data, specified as a table. Each row of `tbl` corresponds to one observation, and each column corresponds to one predictor variable. `tbl` must contain all of the predictors

used to train the model. Multi-column variables and cell arrays other than cell arrays of character vectors are not allowed.

If you trained `ens` using sample data contained in a `table`, then the input data for this method must also be in a `table`.

ResponseVarName

Response variable name, specified as the name of a variable in `tbl`.

You must specify `ResponseVarName` as a character vector or string scalar. For example, if the response variable `Y` is stored as `tbl.Y`, then specify it as `'Y'`. Otherwise, the software treats all columns of `tbl`, including `Y`, as predictors when training the model.

X

Matrix of data to classify. Each row of `X` represents one observation, and each column represents one predictor. `X` must have the same number of columns as the data used to train `ens`. `X` should have the same number of rows as the number of elements in `Y`.

If you trained `ens` using sample data contained in a matrix, then the input data for this method must also be in a matrix.

Y

Class labels of observations in `tbl` or `X`. `Y` should be of the same type as the classification used to train `ens`, and its number of elements should equal the number of rows of `tbl` or `X`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Learners

Indices of weak learners in the ensemble ranging from 1 to `ens.NumTrained`. `oobEdge` uses only these learners for calculating loss.

Default: `1:NumTrained`

UseObsForLearner

A logical matrix of size N-by-T, where:

- N is the number of rows of X.
- T is the number of weak learners in ens.

When `UseObsForLearner(i, j)` is true, learner j is used in predicting the class of row i of X.

Default: `true(N, T)`

Output Arguments

M

A numeric column vector with the same number of rows as `tbl` or X. Each row of M gives the classification margin for that row of `tbl` or X.

Examples

Find Classification Margin

Find the margin for classifying an average flower from the `fisheriris` data as 'versicolor'.

Load the Fisher iris data set.

```
load fisheriris
```

Train an ensemble of 100 boosted classification trees using `AdaBoostM2`.

```
t = templateTree('MaxNumSplits',1); % Weak learner template tree object
ens = fitcensemble(meas,species,'Method','AdaBoostM2','Learners',t);
```

Classify an average flower and find the classification margin.

```
flower = mean(meas);
predict(ens,flower)
```

```
ans = 1x1 cell array
    {'versicolor'}

margin(ens,flower,'versicolor')

ans = 3.2140
```

Definitions

Margin

The classification margin is the difference between the classification score for the true class and maximal classification score for the false classes. Margin is a column vector with the same number of rows as in the matrix X .

Score (ensemble)

For ensembles, a classification score represents the confidence of a classification into a class. The higher the score, the higher the confidence.

Different ensemble algorithms have different definitions for their scores. Furthermore, the range of scores depends on ensemble type. For example:

- AdaBoostM1 scores range from $-\infty$ to ∞ .
- Bag scores range from 0 to 1.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. For more information, see “Tall Arrays” (MATLAB).

margin

Classification margins for naive Bayes classifiers

Syntax

```
m = margin(Mdl,tbl,ResponseVarName)
m = margin(Mdl,tbl,Y)
m = margin(Mdl,X,Y)
```

Description

`m = margin(Mdl,tbl,ResponseVarName)` returns the classification margins on page 32-4152 (`m`) for the trained naive Bayes classifier `Mdl` using the predictor data in table `tbl` and the class labels in `tbl.ResponseVarName`.

`m = margin(Mdl,tbl,Y)` returns the classification margins (`m`) for the trained naive Bayes classifier `Mdl` using the predictor data in table `tbl` and the class labels in vector `Y`.

`m = margin(Mdl,X,Y)` returns the classification margins (`m`) for the trained naive Bayes classifier `Mdl` using the predictor data `X` and class labels `Y`.

Input Arguments

Mdl — Naive Bayes classifier

`ClassificationNaiveBayes model` | `CompactClassificationNaiveBayes model`

Naive Bayes classifier, specified as a `ClassificationNaiveBayes model` or `CompactClassificationNaiveBayes model` returned by `fitcnb` or `compact`, respectively.

tbl — Sample data

table

Sample data, specified as a table. Each row of `tbl` corresponds to one observation, and each column corresponds to one predictor variable. Optionally, `tbl` can contain additional

columns for the response variable and observation weights. `tbl` must contain all the predictors used to train `Mdl`. Multi-column variables and cell arrays other than cell arrays of character vectors are not allowed.

If you trained `Mdl` using sample data contained in a `table`, then the input data for this method must also be in a `table`.

Data Types: `table`

ResponseVarName — Response variable name

name of a variable in `tbl`

Response variable name, specified as the name of a variable in `tbl`.

You must specify `ResponseVarName` as a character vector or string scalar. For example, if the response variable `y` is stored as `tbl.y`, then specify it as `'y'`. Otherwise, the software treats all columns of `tbl`, including `y`, as predictors when training the model.

The response variable must be a categorical, character, or string array, logical or numeric vector, or cell array of character vectors. If the response variable is a character array, then each element must correspond to one row of the array.

Data Types: `char` | `string`

X — Predictor data

numeric matrix

Predictor data, specified as a numeric matrix.

Each row of `X` corresponds to one observation (also known as an instance or example), and each column corresponds to one variable (also known as a feature). The variables making up the columns of `X` should be the same as the variables that trained `Mdl`.

The length of `Y` and the number of rows of `X` must be equal.

Data Types: `double` | `single`

Y — Class labels

categorical array | character array | string array | logical vector | vector of numeric values | cell array of character vectors

Class labels, specified as a categorical, character, or string array, logical or numeric vector, or cell array of character vectors. `Y` must be the same as the data type of `Mdl.ClassNames`. (The software treats string arrays as cell arrays of character vectors.)

The length of `Y` and the number of rows of `tbl` or `X` must be equal.

Data Types: `categorical` | `char` | `string` | `logical` | `single` | `double` | `cell`

Output Arguments

`m` — Classification margins

numeric vector

Classification margins on page 32-4152, returned as a numeric vector.

`m` has the same length equal to `size(X,1)`. Each entry of `m` is the classification margin of the corresponding observation (row) of `X` and element of `Y`.

Examples

Estimate Test-Sample Classification Margins of Naive Bayes Classifiers

Load Fisher's iris data set.

```
load fisheriris
X = meas; % Predictors
Y = species; % Response
rng(1);
```

Train a naive Bayes classifier. Specify a 30% holdout sample for testing. It is good practice to specify the class order. Assume that each predictor is conditionally normally distributed given its label.

```
CVMdl = fitcnb(X,Y,'Holdout',0.30,...
    'ClassNames',{'setosa','versicolor','virginica'});
CMdl = CVMdl.Trained{1}; ...
% Extract the trained, compact classifier
testInds = test(CVMdl.Partition); % Extract the test indices
XTest = X(testInds,:);
YTest = Y(testInds);
```

`CVMdl` is a `ClassificationPartitionedModel` classifier. It contains the property `Trained`, which is a 1-by-1 cell array holding a `CompactClassificationNaiveBayes` classifier that the software trained using the training set.

Estimate the test sample classification margins. Display the distribution of the margins using a boxplot.

```
m = margin(CMdl,XTest,YTest);  
  
figure;  
boxplot(m);  
title 'Distribution of the Test-Sample Margins';
```

An observation margin is the observed true class score minus the maximum false class score among all scores in the respective class. Classifiers that yield relatively large margins are desirable.

Select Naive Bayes Classifier Features by Examining Test Sample Margins

The classifier margins measure, for each observation, the difference between the true class observed score and the maximal false class score for a particular class. One way to perform feature selection is to compare test sample margins from multiple models. Based solely on this criterion, the model with the highest margins is the best model.

Load Fisher's iris data set.

```
load fisheriris
X = meas;    % Predictors
Y = species; % Response
rng(1);
```

Partition the data set into training and test sets. Specify a 30% holdout sample for testing.

```
Partition = cvpartition(Y, 'Holdout', 0.30);
testInds = test(Partition); % Indices for the test set
XTest = X(testInds, :);
YTest = Y(testInds);
```

Partition defines the data set partition.

Define these two data sets:

- `fullX` contains all predictors.
- `partX` contains the last 2 predictors.

```
fullX = X;
partX = X(:, 3:4);
```

Train naive Bayes classifiers for each predictor set. Specify the partition definition.

```
FCVMdl = fitcnb(fullX, Y, 'CVPartition', Partition);
PCVMdl = fitcnb(partX, Y, 'CVPartition', Partition);
FCMdl = FCVMdl.Trained{1};
PCMdl = PCVMdl.Trained{1};
```

`FullCVMdl` and `PartCVMdl` are `ClassificationPartitionedModel` classifiers. They contain the property `Trained`, which is a 1-by-1 cell array holding a `CompactClassificationNaiveBayes` classifier that the software trained using the training set.

Estimate the test sample margins for each classifier. Display the distributions of the margins for each model using boxplots.

```
fullM = margin(FCmdl,XTest,YTest);  
partM = margin(PCmdl,XTest(:,3:4),YTest);  
  
figure;  
boxplot([fullM partM], 'Labels', {'All Predictors', 'Two Predictors'})  
h = gca;  
h.YLim = [0.98 1.01]; % Modify axis to see boxes.  
title 'Boxplots of Test-Sample Margins';
```

The margins have a similar distribution, but PCmdl is less complex.

Definitions

Classification Edge

The classification edge is the weighted mean of the classification margins.

If you supply weights, then the software normalizes them to sum to the prior probability of their respective class. The software uses the normalized weights to compute the weighted mean.

One way to choose among multiple classifiers, e.g., to perform feature selection, is to choose the classifier that yields the highest edge.

Classification Margin

The classification margins are, for each observation, the difference between the score for the true class and maximal score for the false classes. Provided that they are on the same scale, margins serve as a classification confidence measure, i.e., among multiple classifiers, those that yield larger margins are better.

Posterior Probability

The posterior probability is the probability that an observation belongs in a particular class, given the data.

For naive Bayes, the posterior probability that a classification is k for a given observation (x_1, \dots, x_p) is

$$\widehat{P}(Y = k | x_1, \dots, x_p) = \frac{P(X_1, \dots, X_p | y = k)\pi(Y = k)}{P(X_1, \dots, X_p)},$$

where:

- $P(X_1, \dots, X_p | y = k)$ is the conditional joint density of the predictors given they are in class k . `Mdl.DistributionNames` stores the distribution names of the predictors.
- $\pi(Y = k)$ is the class prior probability distribution. `Mdl.Prior` stores the prior distribution.

- $P(X_1, \dots, X_P)$ is the joint density of the predictors. The classes are discrete, so

$$P(X_1, \dots, X_P) = \sum_{k=1}^K P(X_1, \dots, X_P \mid Y = k) \pi(Y = k).$$

Prior Probability

The prior probability of a class is the believed relative frequency with which observations from that class occur in a population.

Score

The naive Bayes score is the class posterior probability given the observation.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. For more information, see “Tall Arrays” (MATLAB).

Topics

“Naive Bayes Classification” on page 21-2

margin

Package: classreg.learning.classif

Find classification margins for support vector machine (SVM) classifier

Syntax

```
m = margin(SVMModel, TBL, ResponseVarName)
```

```
m = margin(SVMModel, TBL, Y)
```

```
m = margin(SVMModel, X, Y)
```

Description

`m = margin(SVMModel, TBL, ResponseVarName)` returns the classification margins on page 32-4159 (`m`) for the trained support vector machine (SVM) classifier `SVMModel` using the sample data in table `TBL` and the class labels in `TBL.ResponseVarName`.

`m` is returned as a numeric vector with the same length as `Y`. The software estimates each entry of `m` using the trained SVM classifier `SVMModel`, the corresponding row of `X`, and the true class label `Y`.

`m = margin(SVMModel, TBL, Y)` returns the classification margins (`m`) for the trained SVM classifier `SVMModel` using the sample data in table `TBL` and the class labels in `Y`.

`m = margin(SVMModel, X, Y)` returns the classification margins for `SVMModel` using the predictor data in matrix `X` and the class labels in `Y`.

Examples

Estimate Test Sample Classification Margins of SVM Classifiers

Load the ionosphere data set.

```
load ionosphere
rng(1); % For reproducibility
```

Train an SVM classifier. Specify a 15% holdout sample for testing, standardize the data, and specify that 'g' is the positive class.

```
CVSVMModel = fitcsvm(X,Y,'Holdout',0.15,'ClassNames',{'b','g'},...
    'Standardize',true);
CompactSVMModel = CVSVMModel.Trained{1}; ...
    % Extract the trained, compact classifier
testInds = test(CVSVMModel.Partition); % Extract the test indices
XTest = X(testInds,:);
YTest = Y(testInds,:);
```

CVSVMModel is a `ClassificationPartitionedModel` classifier. It contains the property `Trained`, which is a 1-by-1 cell array holding a `CompactClassificationSVM` classifier that the software trained using the training set.

Estimate the test sample classification margins.

```
m = margin(CompactSVMModel,XTest,YTest);
m(10:20)
```

```
ans = 11x1
```

```
    3.5461
    5.5939
    4.9948
    4.5611
   -4.7963
    5.5127
   -2.8776
    1.8673
    9.4986
    9.5018
    :
```

An observation margin is the observed true class score minus the maximum false class score among all scores in the respective class. Classifiers that yield relatively large margins are preferred.

Select SVM Classifier Features by Examining Test Sample Margins

Perform feature selection by comparing test sample margins from multiple models. Based solely on this comparison, the model with the highest margins is the best model.

Load the `ionosphere` data set.

```
load ionosphere
rng(1); % For reproducibility
```

Partition the data set into training and test sets. Specify a 15% holdout sample for testing.

```
Partition = cvpartition(Y, 'Holdout', 0.15);
testInds = test(Partition); % Indices for the test set
XTest = X(testInds,:);
YTest = Y(testInds,:);
```

`Partition` defines the data set partition.

Define these two data sets:

- `fullX` contains all predictors (except the removed column of 0s).
- `partX` contains the last 20 predictors.

```
fullX = X;
partX = X(:,end-20:end);
```

Train SVM classifiers for each predictor set. Specify the partition definition.

```
FullCVSVMModel = fitcsvm(fullX,Y,'CVPartition',Partition);
PartCVSVMModel = fitcsvm(partX,Y,'CVPartition',Partition);
FCSVMModel = FullCVSVMModel.Trained{1};
PCSVMModel = PartCVSVMModel.Trained{1};
```

`FullCVSVMModel` and `PartCVSVMModel` are `ClassificationPartitionedModel` classifiers. They contain the property `Trained`, which is a 1-by-1 cell array holding a `CompactClassificationSVM` classifier that the software trained using the training set.

Estimate the test sample margins for each classifier.

```
fullM = margin(FCSVMModel,XTest,YTest);
partM = margin(PCSVMModel,XTest(:,end-20:end),YTest);
n = size(XTest,1);
p = sum(fullM < partM)/n
```

$p = 0.2500$

Approximately 25% of the margins from the full model are less than those from the model with fewer predictors. This result suggests that the model trained with all the predictors is better.

Input Arguments

SVMModel — SVM classification model

ClassificationSVM model object | CompactClassificationSVM model object

SVM classification model, specified as a `ClassificationSVM` model object or `CompactClassificationSVM` model object returned by `fitcsvm` or `compact`, respectively.

TBL — Sample data

table

Sample data, specified as a table. Each row of TBL corresponds to one observation, and each column corresponds to one predictor variable. Optionally, TBL can contain additional columns for the response variable and observation weights. TBL must contain all of the predictors used to train `SVMModel`. Multicolumn variables and cell arrays other than cell arrays of character vectors are not allowed.

If TBL contains the response variable used to train `SVMModel`, then you do not need to specify `ResponseVarName` or `Y`.

If you trained `SVMModel` using sample data contained in a table, then the input data for `margin` must also be in a table.

If you set `'Standardize', true` in `fitcsvm` when training `SVMModel`, then the software standardizes the columns of the predictor data using the corresponding means in `SVMModel.Mu` and the standard deviations in `SVMModel.Sigma`.

Data Types: table

X — Predictor data

numeric matrix

Predictor data, specified as a numeric matrix.

Each row of `X` corresponds to one observation (also known as an instance or example), and each column corresponds to one variable (also known as a feature). The variables in the columns of `X` must be the same as the variables that trained the `SVMModel` classifier.

The length of `Y` and the number of rows in `X` must be equal.

If you set `'Standardize', true` in `fitcsvm` to train `SVMModel`, then the software standardizes the columns of `X` using the corresponding means in `SVMModel.Mu` and the standard deviations in `SVMModel.Sigma`.

Data Types: `double` | `single`

ResponseVarName — Response variable name

name of variable in TBL

Response variable name, specified as the name of a variable in TBL. If TBL contains the response variable used to train `SVMModel`, then you do not need to specify `ResponseVarName`.

If you specify `ResponseVarName`, then you must do so as a character vector or string scalar. For example, if the response variable is stored as `TBL.Response`, then specify `ResponseVarName` as `'Response'`. Otherwise, the software treats all columns of TBL, including `TBL.Response`, as predictors.

The response variable must be a categorical, character, or string array, logical or numeric vector, or cell array of character vectors. If the response variable is a character array, then each element must correspond to one row of the array.

Data Types: `char` | `string`

Y — Class labels

categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Class labels, specified as a categorical, character, or string array, logical or numeric vector, or cell array of character vectors. `Y` must be the same as the data type of `SVMModel.ClassNames`. (The software treats string arrays as cell arrays of character vectors.)

The length of `Y` must equal the number of rows in TBL or the number of rows in `X`.

Definitions

Classification Edge

The edge is the weighted mean of the classification margins.

The weights are the prior class probabilities. If you supply weights, then the software normalizes them to sum to the prior probabilities in the respective classes. The software uses the renormalized weights to compute the weighted mean.

One way to choose among multiple classifiers, for example, to perform feature selection, is to choose the classifier that yields the highest edge.

Classification Margin

The classification margin for binary classification is, for each observation, the difference between the classification score for the true class and the classification score for the false class.

The software defines the classification margin for binary classification as

$$m = 2yf(x).$$

x is an observation. If the true label of x is the positive class, then y is 1, and -1 otherwise. $f(x)$ is the positive-class classification score for the observation x . The classification margin is commonly defined as $m = yf(x)$.

If the margins are on the same scale, then they serve as a classification confidence measure. Among multiple classifiers, those that yield greater margins are better.

Classification Score

The SVM classification score for classifying observation x is the signed distance from x to the decision boundary ranging from $-\infty$ to $+\infty$. A positive score for a class indicates that x is predicted to be in that class. A negative score indicates otherwise.

The positive class classification score $f(x)$ is the trained SVM classification function. $f(x)$ is also the numerical, predicted response for x , or the score for predicting x into the positive class.

$$f(x) = \sum_{j=1}^n \alpha_j y_j G(x_j, x) + b,$$

where $(\alpha_1, \dots, \alpha_n, b)$ are the estimated SVM parameters, $G(x_j, x)$ is the dot product in the predictor space between x and the support vectors, and the sum includes the training set observations. The negative class classification score for x , or the score for predicting x into the negative class, is $-f(x)$.

If $G(x_j, x) = x_j'x$ (the linear kernel), then the score function reduces to

$$f(x) = (x/s)'\beta + b.$$

s is the kernel scale and β is the vector of fitted linear coefficients.

For more details, see “Understanding Support Vector Machines” on page 18-189.

Algorithms

For binary classification, the software defines the margin for observation j , m_j , as

$$m_j = 2y_j f(x_j),$$

where $y_j \in \{-1, 1\}$, and $f(x_j)$ is the predicted score of observation j for the positive class. However, $m_j = y_j f(x_j)$ is commonly used to define the margin.

Introduced in R2014a

margin

Classification margins

Syntax

```
m = margin(tree, TBL, ResponseVarName)
m = margin(tree, TBL, Y)
m = margin(tree, X, Y)
```

Description

`m = margin(tree, TBL, ResponseVarName)` returns the classification margins for the table of predictors `TBL` and class labels `TBL.ResponseVarName`. For the definition, see “Margin” on page 32-4165.

`m = margin(tree, TBL, Y)` returns the classification margins for the table of predictors `TBL` and class labels `Y`.

`m = margin(tree, X, Y)` returns the classification margins for the matrix of predictors `X` and class labels `Y`.

Input Arguments

tree — Trained classification tree

`ClassificationTree` model object | `CompactClassificationTree` model object

Trained classification tree, specified as a `ClassificationTree` or `CompactClassificationTree` model object. That is, `tree` is a trained classification model returned by `fitctree` or `compact`.

TBL — Sample data

table

Sample data, specified as a table. Each row of `TBL` corresponds to one observation, and each column corresponds to one predictor variable. Optionally, `TBL` can contain additional

columns for the response variable and observation weights. `TBL` must contain all the predictors used to train `tree`. Multi-column variables and cell arrays other than cell arrays of character vectors are not allowed.

If `TBL` contains the response variable used to train `tree`, then you do not need to specify `ResponseVarName` or `Y`.

If you train `tree` using sample data contained in a `table`, then the input data for this method must also be in a `table`.

Data Types: `table`

X — Data to classify

numeric matrix

Data to classify, specified as a numeric matrix. Each row of `X` represents one observation, and each column represents one predictor. `X` must have the same number of columns as the data used to train `tree`. `X` must have the same number of rows as the number of elements in `Y`.

Data Types: `single` | `double`

ResponseVarName — Response variable name

name of a variable in `TBL`

Response variable name, specified as the name of a variable in `TBL`. If `TBL` contains the response variable used to train `tree`, then you do not need to specify `ResponseVarName`.

If you specify `ResponseVarName`, then you must do so as a character vector or string scalar. For example, if the response variable is stored as `TBL.Response`, then specify it as `'Response'`. Otherwise, the software treats all columns of `TBL`, including `TBL.ResponseVarName`, as predictors.

The response variable must be a categorical, character, or string array, logical or numeric vector, or cell array of character vectors. If the response variable is a character array, then each element must correspond to one row of the array.

Data Types: `char` | `string`

Y — Class labels

categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Class labels, specified as a categorical, character, or string array, a logical or numeric vector, or a cell array of character vectors. `Y` must be of the same type as the classification used to train `tree`, and its number of elements must equal the number of rows of `X`.

Data Types: `categorical` | `char` | `string` | `logical` | `single` | `double` | `cell`

Output Arguments

`m` — Margin

numeric column vector

Margin, returned as a numeric column vector of length `size(X,1)`. Each entry in `m` represents the margin for the corresponding rows of `X` and (true class) `Y`, computed using `tree`.

Examples

Compute the classification margin for the Fisher iris data, trained on its first two columns of data, and view the last 10 entries.

```
load fisheriris
X = meas(:,1:2);
tree = fitctree(X,species);
M = margin(tree,X,species);
M(end-10:end)
```

```
ans =
    0.1111
    0.1111
    0.1111
   -0.2857
    0.6364
    0.6364
    0.1111
    0.7500
    1.0000
    0.6364
    0.2000
```

The classification tree trained on all the data is better.

```
tree = fitctree(meas,species);
M = margin(tree,meas,species);
M(end-10:end)
```

```
ans =
    0.9565
    0.9565
    0.9565
    0.9565
    0.9565
    0.9565
    0.9565
    0.9565
    0.9565
    0.9565
```

Definitions

Margin

The classification margin is the difference between the classification score for the true class and maximal classification score for the false classes. Margin is a column vector with the same number of rows as in the matrix X.

Score (tree)

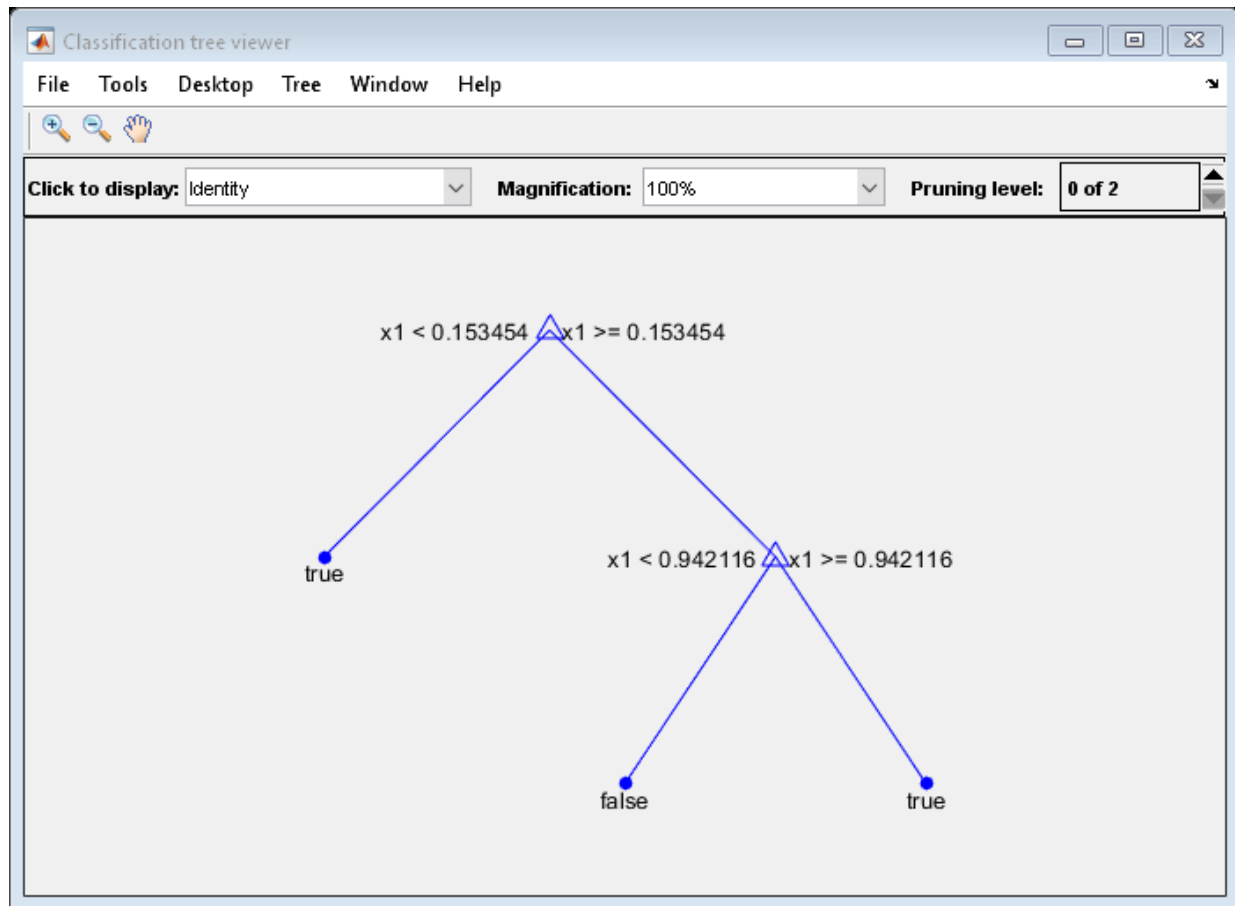

For trees, the score of a classification of a leaf node is the posterior probability of the classification at that node. The posterior probability of the classification at a node is the number of training sequences that lead to that node with the classification, divided by the number of training sequences that lead to that node.

For example, consider classifying a predictor X as true when $X < 0.15$ or $X > 0.95$, and X is false otherwise.

Generate 100 random points and classify them:

```
rng(0, 'twister') % for reproducibility
X = rand(100,1);
Y = (abs(X - .55) > .4);
```

```
tree = fitctree(X,Y);  
view(tree, 'Mode', 'Graph')
```

Prune the tree:

```
tree1 = prune(tree, 'Level', 1);  
view(tree1, 'Mode', 'Graph')
```

The pruned tree correctly classifies observations that are less than 0.15 as `true`. It also correctly classifies observations from .15 to .94 as `false`. However, it incorrectly classifies observations that are greater than .94 as `false`. Therefore, the score for observations that are greater than .15 should be about $.05/.85=.06$ for `true`, and about $.8/.85=.94$ for `false`.

Compute the prediction scores for the first 10 rows of `X`:

```
[~,score] = predict(tree1,X(1:10));
[score X(1:10,:)]
```

```
ans = 10x3
    0.9059    0.0941    0.8147
    0.9059    0.0941    0.9058
         0     1.0000    0.1270
    0.9059    0.0941    0.9134
    0.9059    0.0941    0.6324
         0     1.0000    0.0975
    0.9059    0.0941    0.2785
    0.9059    0.0941    0.5469
    0.9059    0.0941    0.9575
    0.9059    0.0941    0.9649
```

Indeed, every value of X (the right-most column) that is less than 0.15 has associated scores (the left and center columns) of 0 and 1, while the other values of X have associated scores of 0.91 and 0.09. The difference (score 0.09 instead of the expected .06) is due to a statistical fluctuation: there are 8 observations in X in the range (.95, 1) instead of the expected 5 observations.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. For more information, see “Tall Arrays” (MATLAB).

edge | fitctree | loss | predict

margin

Class: CompactTreeBagger

Classification margin

Syntax

```
mar = margin(B,TBLnew,Ynew)
mar = margin(B,Xnew,Ynew)
mar = margin(B,TBLnew,Ynew,'param1',val1,'param2',val2,...)
mar = margin(B,Xnew,Ynew,'param1',val1,'param2',val2,...)
```

Description

`mar = margin(B,TBLnew,Ynew)` computes the classification margins for the predictors contained in the table `TBLnew` given true response `Ynew`. You can omit `Ynew` if `TBLnew` contains the response variable. If you trained `B` using sample data contained in a table, then the input data for this method must also be in a table.

`mar = margin(B,Xnew,Ynew)` computes the classification margins for the predictors contained in the matrix `Xnew` given true response `Ynew`.

`Ynew` can be a numeric vector, character matrix, string array, cell array of character vectors, categorical vector or logical vector. `mar` is a numeric array of size `Nobs-by-NTrees`, where `Nobs` is the number of rows of `TBLnew` and `Ynew`, and `NTrees` is the number of trees in the ensemble `B`. For observation `I` and tree `J`, `mar(I,J)` is the difference between the score for the true class and the largest score for other classes. This method is available for classification ensembles only.

`mar = margin(B,TBLnew,Ynew,'param1',val1,'param2',val2,...)` or `mar = margin(B,Xnew,Ynew,'param1',val1,'param2',val2,...)` specifies optional parameter name-value pairs:

'Mode '	How the method computes errors. If set to 'cumulative' (default), <code>margin</code> computes cumulative errors and <code>mar</code> is an <code>Nobs</code> -by- <code>NTrees</code> matrix, where the first column gives error from <code>trees(1)</code> , second column gives error from <code>trees(1:2)</code> etc., up to <code>trees(1:NTrees)</code> . If set to 'individual', <code>mar</code> is a <code>Nobs</code> -by- <code>NTrees</code> matrix, where each element is an error from each tree in the ensemble. If set to 'ensemble', <code>mar</code> a single column of length <code>Nobs</code> showing the cumulative margins for the entire ensemble.
'Trees '	Vector of indices indicating what trees to include in this calculation. By default, this argument is set to 'all' and the method uses all trees. If 'Trees' is a numeric vector, the method returns a vector of length <code>NTrees</code> for 'cumulative' and 'individual' modes, where <code>NTrees</code> is the number of elements in the input vector, and a scalar for 'ensemble' mode. For example, in the 'cumulative' mode, the first element gives error from <code>trees(1)</code> , the second element gives error from <code>trees(1:2)</code> etc.
'TreeWeights '	Vector of tree weights. This vector must have the same length as the 'Trees' vector. The method uses these weights to combine output from the specified trees by taking a weighted average instead of the simple non-weighted majority vote. You cannot use this argument in the 'individual' mode.
'UseInstanceForTree '	Logical matrix of size <code>Nobs</code> -by- <code>NTrees</code> indicating which trees should be used to make predictions for each observation. By default the method uses all trees for all observations.

`margin`

margin

Class: TreeBagger

Classification margin

Syntax

```
mar = margin(B,TBLnew,Ynew)
mar = margin(B,Xnew,Ynew)
mar = margin(B,TBLnew,Ynew, 'param1',val1, 'param2',val2,...)
mar = margin(B,Xnew,Ynew, 'param1',val1, 'param2',val2,...)
```

Description

`mar = margin(B,TBLnew,Ynew)` computes the classification margins for the predictors contained in the table `TBLnew` given true response `Ynew`. You can omit `Ynew` if `TBLnew` contains the response variable. If you trained `B` using sample data contained in a table, then the input data for this method must also be in a table.

`mar = margin(B,Xnew,Ynew)` computes the classification margins for the predictors contained in the matrix `Xnew` given true response `Ynew`. If you trained `B` using sample data contained in a matrix, then the input data for this method must also be in a matrix.

`Ynew` can be a numeric vector, character matrix, string array, cell array of character vectors, categorical vector or logical vector. `mar` is a numeric array of size `Nobs-by-NTrees`, where `Nobs` is the number of rows of `TBLnew` and `Ynew`, and `NTrees` is the number of trees in the ensemble `B`. For observation `I` and tree `J`, `mar(I,J)` is the difference between the score for the true class and the largest score for other classes. This method is available for classification ensembles only.

`mar = margin(B,TBLnew,Ynew, 'param1',val1, 'param2',val2,...)` or `mar = margin(B,Xnew,Ynew, 'param1',val1, 'param2',val2,...)` specifies optional parameter name-value pairs:

'Mode '	Character vector or string scalar indicating how the method computes errors. If set to 'cumulative' (default), <code>margin</code> computes cumulative errors and <code>mar</code> is an <code>Nobs-by-NTrees</code> matrix, where the first column gives error from <code>trees(1)</code> , second column gives error from <code>trees(1:2)</code> etc., up to <code>trees(1:NTrees)</code> . If set to 'individual', <code>mar</code> is a <code>Nobs-by-NTrees</code> matrix, where each element is an error from each tree in the ensemble. If set to 'ensemble', <code>mar</code> a single column of length <code>Nobs</code> showing the cumulative margins for the entire ensemble.
'Trees '	Vector of indices indicating what trees to include in this calculation. By default, this argument is set to 'all' and the method uses all trees. If 'Trees' is a numeric vector, the method returns a vector of length <code>NTrees</code> for 'cumulative' and 'individual' modes, where <code>NTrees</code> is the number of elements in the input vector, and a scalar for 'ensemble' mode. For example, in the 'cumulative' mode, the first element gives error from <code>trees(1)</code> , the second element gives error from <code>trees(1:2)</code> etc.
'TreeWeights '	Vector of tree weights. This vector must have the same length as the 'Trees' vector. The method uses these weights to combine output from the specified trees by taking a weighted average instead of the simple non-weighted majority vote. You cannot use this argument in the 'individual' mode.
'UseInstanceForTree '	Logical matrix of size <code>Nobs-by-NTrees</code> indicating which trees should be used to make predictions for each observation. By default the method uses all trees for all observations.

`margin`

margmean

Class: RepeatedMeasuresModel

Estimate marginal means

Syntax

```
tbl = margmean(rm, vars)
tbl = margmean(rm, vars, 'alpha', alpha)
```

Description

`tbl = margmean(rm, vars)` returns the estimated marginal means for the variables `vars`, in the table `tbl`.

`tbl = margmean(rm, vars, 'alpha', alpha)` returns the $100*(1-\alpha)\%$ confidence intervals for the marginal means.

Input Arguments

rm — Repeated measures model

RepeatedMeasuresModel object

Repeated measures model, returned as a RepeatedMeasuresModel object.

For properties and methods of this object, see RepeatedMeasuresModel.

vars — Variables for which to compute the marginal means

character vector | string scalar | string array | cell array of character vectors

Variables for which to compute the marginal means, specified as a character vector or string scalar representing the name of a between or within-subjects factor in `rm`, or a string array or cell array of character vectors representing the names of multiple variables. Each between-subjects factor must be categorical.

For example, if you want to compute the marginal means for the variables Drug and Gender, then you can specify as follows.

Example: `{ 'Drug' , 'Gender' }`

Data Types: `char` | `string` | `cell`

alpha — Significance level

0.05 (default) | scalar value in the range of 0 to 1

Significance level of the confidence intervals for population marginal means, specified as a scalar value in the range of 0 to 1. The confidence level is $100*(1-\alpha)\%$.

For example, you can specify a 99% confidence level as follows.

Example: `'alpha',0.01`

Data Types: `double` | `single`

Output Arguments

tbl — Estimated marginal means

table

Estimated marginal means, returned as a table. `tbl` contains one row for each combination of the groups of the variables you specify in `vars`, one column for each variable, and the following columns.

Column name	Description
Mean	Estimated marginal means
StdErr	Standard errors of the estimates
Lower	Lower limit of a 95% confidence interval for the true population mean
Upper	Upper limit of a 95% confidence interval for the true population mean

Examples

Compute Marginal Means Grouped by Two Factors

Load the sample data.

```
load repeatedmeas
```

The table `between` includes the between-subject variables `age`, `IQ`, `group`, `gender`, and eight repeated measures `y1` to `y8` as responses. The table `within` includes the within-subject variables `w1` and `w2`. This is simulated data.

Fit a repeated measures model, where the repeated measures `y1` to `y8` are the responses, and `age`, `IQ`, `group`, `gender`, and the `group-gender` interaction are the predictor variables. Also specify the within-subject design matrix.

```
rm = fitrm(between, 'y1-y8 ~ Group*Gender + Age + IQ', 'WithinDesign', within);
```

Compute the marginal means grouped by the factors `Group` and `Gender`.

```
M = margmean(rm, {'Group' 'Gender'})
```

M=6×6 table

Group	Gender	Mean	StdErr	Lower	Upper
A	Female	15.946	5.6153	4.3009	27.592
A	Male	8.0726	5.7236	-3.7973	19.943
B	Female	11.758	5.7091	-0.08189	23.598
B	Male	2.2858	5.6748	-9.483	14.055
C	Female	-8.6183	5.871	-20.794	3.5574
C	Male	-13.551	5.7283	-25.431	-1.6712

Display the description for table `M`.

```
M.Properties.Description
```

```
ans =
    'Estimated marginal means
    Means computed with Age=13.7, IQ=98.2667'
```

Compute Estimated Marginal Means and Confidence Intervals

Load the sample data.

```
load fisheriris
```

The column vector, `species`, consists of iris flowers of three different species, `setosa`, `versicolor`, `virginica`. The double matrix `meas` consists of four types of measurements on the flowers, the length and width of sepals and petals in centimeters, respectively.

Store the data in a table array.

```
t = table(species,meas(:,1),meas(:,2),meas(:,3),meas(:,4),...
'VariableNames',{'species','meas1','meas2','meas3','meas4'});
Meas = dataset([1 2 3 4]','VarNames',{'Measurements'});
```

Fit a repeated measures model, where the measurements are the responses and the species is the predictor variable.

```
rm = fitrm(t,'meas1-meas4~species','WithinDesign',Meas);
```

Compute the marginal means grouped by the factor species.

```
margmean(rm,'species')
```

```
ans=3x5 table
    species      Mean      StdErr      Lower      Upper
    -----
    'setosa'      2.5355    0.042807    2.4509    2.6201
    'versicolor'  3.573     0.042807    3.4884    3.6576
    'virginica'   4.285     0.042807    4.2004    4.3696
```

`StdError` field shows the standard errors of the estimated marginal means. The `Lower` and `Upper` fields show the lower and upper bounds for the 95% confidence intervals of the group marginal means, respectively. None of the confidence intervals overlap, which indicates that marginal means differ with species. You can also plot the estimated marginal means using the `plotprofile` method.

Compute the 99% confidence intervals for the marginal means.

```
margmean(rm,'species','alpha',0.01)
```

```
ans=3x5 table
    species      Mean      StdErr      Lower      Upper
```

'setosa'	2.5355	0.042807	2.4238	2.6472
'versicolor'	3.573	0.042807	3.4613	3.6847
'virginica'	4.285	0.042807	4.1733	4.3967

See Also

`multcompare` | `fitrm` | `plotprofile`

mauchly

Class: RepeatedMeasuresModel

Mauchly's test for sphericity

Syntax

```
tbl = mauchly(rm)
tbl = mauchly(rm,C)
```

Description

`tbl = mauchly(rm)` returns the result of the Mauchly's test for sphericity for the repeated measures model `rm`.

It tests the null hypothesis that the sphericity assumption is true for the response variables in `rm`.

For more information, see “Mauchly's Test of Sphericity” on page 9-81.

`tbl = mauchly(rm,C)` returns the result of the Mauchly's test based on the contrast matrix `C`.

Input Arguments

rm — Repeated measures model

RepeatedMeasuresModel object

Repeated measures model, returned as a RepeatedMeasuresModel object.

For properties and methods of this object, see RepeatedMeasuresModel.

C — Contrasts

matrix

Contrasts, specified as a matrix. The default value of `C` is the `Q` factor in a QR decomposition of the matrix `M`, where `M` is defined so that `Y*M` is the difference between all successive pairs of columns of the repeated measures matrix `Y`.

Data Types: `single` | `double`

Output Arguments

tbl — Results of Mauchly's test of sphericity

table

Results of Mauchly's test for sphericity for the repeated measures model `rm`, returned as a table.

`tbl` contains the following columns.

Column Name	Definition
<code>W</code>	Value of Mauchly's <i>W</i> statistic
<code>ChiStat</code>	Chi-square statistic value
<code>DF</code>	Degrees of freedom of the Chi-square statistic
<code>pValue</code>	<i>p</i> -value corresponding to the Chi-square statistic

Data Types: `table`

Examples

Perform Mauchly's Test

Load the sample data.

```
load fisheriris
```

The column vector `species` consists of iris flowers of three different species: `setosa`, `versicolor`, and `virginica`. The double matrix `meas` consists of four types of measurements on the flowers: the length and width of sepals and petals in centimeters, respectively.

Store the data in a table array.

```
t = table(species,meas(:,1),meas(:,2),meas(:,3),meas(:,4),...  
'VariableNames',{'species','meas1','meas2','meas3','meas4'});  
Meas = dataset([1 2 3 4'],'VarNames',{'Measurements'});
```

Fit a repeated measures model, where the measurements are the responses and the species is the predictor variable.

```
rm = fitrm(t,'meas1-meas4~species','WithinDesign',Meas);
```

Perform Mauchly's test to assess the sphericity assumption.

```
mauchly(rm)
```

```
ans=1×4 table  
      W      ChiStat      DF      pValue  
-----  
  0.55814   84.976      5   7.6149e-17
```

The small p -value (in the `pValue` field) indicates that the sphericity, hence the compound symmetry assumption, does not hold. You should use epsilon corrections to compute the p -values for a repeated measures anova. You can compute the epsilon corrections using the `epsilon` method and perform the repeated measures anova with the corrected p -values using the `ranova` method.

mat2dataset

Convert matrix to dataset array

Note The dataset data type might be removed in a future release. To work with heterogeneous data, use the MATLAB® table data type instead. See MATLAB table documentation for more information.

Syntax

```
ds = mat2dataset(X)
ds = mat2dataset(X,Name,Value)
```

Description

`ds = mat2dataset(X)` converts a matrix to a dataset array.

`ds = mat2dataset(X,Name,Value)` performs the conversion using additional options specified by one or more Name, Value pair arguments.

Examples

Convert Matrix to Dataset Array

Convert a matrix to a dataset array using the default options.

Load sample data.

```
load('fisheriris')
X = meas;
size(X)
```

```
ans = 1×2
```

```
150      4
```

Convert the matrix to a dataset array.

```
ds = mat2dataset(X);  
size(ds)
```

```
ans = 1×2
```

```
150      4
```

```
ds(1:5, :)
```

```
ans =  
    X1    X2    X3    X4  
    5.1    3.5    1.4    0.2  
    4.9     3    1.4    0.2  
    4.7    3.2    1.3    0.2  
    4.6    3.1    1.5    0.2  
     5    3.6    1.4    0.2
```

When you do not specify variable names, `mat2dataset` uses the matrix name and column numbers to create default variable names.

Convert Matrix to Dataset Array with Variable Names

Load sample data.

```
load('fisheriris')  
X = meas;  
size(X)
```

```
ans = 1×2
```

```
150      4
```

Convert the matrix to a dataset array, providing a variable name for each of the four column of `X`.

```
ds = mat2dataset(X, 'VarNames', {'SLength', ...
'SWidth', 'PLength', 'PWidth'});
size(ds)
```

```
ans = 1×2
```

```
150    4
```

```
ds(1:5, :)
```

```
ans =
    SLength    SWidth    PLength    PWidth
    5.1         3.5         1.4         0.2
    4.9          3         1.4         0.2
    4.7         3.2         1.3         0.2
    4.6         3.1         1.5         0.2
    5           3.6         1.4         0.2
```

Create a Dataset Array with Multicolumn Variables

Convert a matrix to a dataset array containing multicolumn variables.

Load sample data.

```
load('fisheriris')
```

```
X = meas;
```

```
size(X)
```

```
ans = 1×2
```

```
150    4
```

Convert the matrix to a dataset array, combining the sepal measurements (the first two columns) into one variable named SepalMeas, and the petal measurements (third and fourth columns) into one variable names PetalMeas.

```
ds = mat2dataset(X, 'NumCols', [2,2], ...
'VarNames', {'SepalMeas', 'PetalMeas'});
ds(1:5, :)
```

```
ans =  
    SepalMeas      PetalMeas  
    5.1          3.5      1.4      0.2  
    4.9           3      1.4      0.2  
    4.7          3.2      1.3      0.2  
    4.6          3.1      1.5      0.2  
     5           3.6      1.4      0.2
```

The output dataset array has 150 observations and 2 variables.

```
size(ds)  
  
ans = 1×2  
  
    150     2
```

Input Arguments

X — Input matrix

matrix

Input matrix to convert to a dataset array, specified as an M -by- N numeric matrix. Each column of X becomes a variable in the output M -by- N dataset array.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'NumCols', [1, 1, 2, 1]` specifies that the 3rd and 4th columns of the input matrix should be combined into a single variable.

VarNames — Variable names for output dataset array

string array | cell array of character vectors

Variable names for the output dataset array, specified as the comma-separated pair consisting of 'VarNames' and a string array or cell array of character vectors. You must provide a variable name for each variable in `ds`. The names must be valid MATLAB identifiers, and must be unique.

Example: 'VarNames', {'myVar1', 'myVar2', 'myVar3'}

ObsNames — Observation names for output dataset array

string array | cell array of character vectors

Observation names for the output dataset array, specified as the comma-separated pair consisting of 'ObsNames' and a string array or cell array of character vectors. The names do not need to be valid MATLAB identifiers, but they must be unique.

NumCols — Number of columns for each variable

vector of nonnegative integers

Number of columns for each variable in `ds`, specified as the comma-separated pair consisting of 'NumCols' and a vector of nonnegative integers. When the number of columns for a variable is greater than one, `mat2dataset` combines multiple columns in `X` into a single variable in `ds`. The vector you assign to `NumCols` must sum to `size(X,2)`.

For example, to convert a matrix with eight columns into a dataset array with five variables, specify a vector with five elements that sum to eight, such as 'NumCols', [1, 1, 3, 1, 2].

Output Arguments

ds — Output dataset array

dataset array

Output dataset array, returned by default with a variable for each column of `X`, and an observation for each row of `X`. If you specify `NumCols`, then the number of variables in `ds` is equal to the length of the specified vector of column numbers.

Introduced in R2012b

mdscale

Nonclassical multidimensional scaling

Syntax

```
Y = mdscale(D,p)
[Y, stress] = mdscale(D,p)
[Y, stress, disparities] = mdscale(D,p)
[...] = mdscale(D,p, 'Name', value)
```

Description

`Y = mdscale(D,p)` performs nonmetric multidimensional scaling on the n -by- n dissimilarity matrix D , and returns Y , a configuration of n points (rows) in p dimensions (columns). The Euclidean distances between points in Y approximate a monotonic transformation of the corresponding dissimilarities in D . By default, `mdscale` uses Kruskal's normalized stress1 criterion.

You can specify D as either a full n -by- n matrix, or in upper triangle form such as is output by `pdist`. A full dissimilarity matrix must be real and symmetric, and have zeros along the diagonal and non-negative elements everywhere else. A dissimilarity matrix in upper triangle form must have real, non-negative entries. `mdscale` treats NaNs in D as missing values, and ignores those elements. `Inf` is not accepted.

You can also specify D as a full similarity matrix, with ones along the diagonal and all other elements less than one. `mdscale` transforms a similarity matrix to a dissimilarity matrix in such a way that distances between the points returned in Y approximate $\sqrt{1-D}$. To use a different transformation, transform the similarities prior to calling `mdscale`.

`[Y, stress] = mdscale(D,p)` returns the minimized stress, i.e., the stress evaluated at Y .

`[Y, stress, disparities] = mdscale(D,p)` returns the disparities, that is, the monotonic transformation of the dissimilarities D .

[...] = `mdscale(D,p,'Name',value)` specifies one or more optional parameter name/value pairs that control further details of `mdscale`. Specify *Name* in single quotes. Available parameters are

- **Criterion**— The goodness-of-fit criterion to minimize. This also determines the type of scaling, either non-metric or metric, that `mdscale` performs. Choices for non-metric scaling are:
 - `'stress'` — Stress normalized by the sum of squares of the inter-point distances, also known as `stress1`. This is the default.
 - `'sstress'` — Squared stress, normalized with the sum of 4th powers of the inter-point distances.

Choices for metric scaling are:

- `'metricstress'` — Stress, normalized with the sum of squares of the dissimilarities.
- `'metricsstress'` — Squared stress, normalized with the sum of 4th powers of the dissimilarities.
- `'sammon'` — Sammon's nonlinear mapping criterion. Off-diagonal dissimilarities must be strictly positive with this criterion.
- `'strain'` — A criterion equivalent to that used in classical multidimensional scaling.
- **Weights** — A matrix or vector the same size as `D`, containing nonnegative dissimilarity weights. You can use these to weight the contribution of the corresponding elements of `D` in computing and minimizing stress. Elements of `D` corresponding to zero weights are effectively ignored.

Note When you specify weights as a full matrix, its diagonal elements are ignored and have no effect, since the corresponding diagonal elements of `D` do not enter into the stress calculation.

- **Start** — Method used to choose the initial configuration of points for `Y`. The choices are
 - `'cmdscale'` — Use the classical multidimensional scaling solution. This is the default. `'cmdscale'` is not valid when there are zero weights.
 - `'random'` — Choose locations randomly from an appropriately scaled `p`-dimensional normal distribution with uncorrelated coordinates.

- An n -by- p matrix of initial locations, where n is the size of the matrix D and p is the number of columns of the output matrix Y . In this case, you can pass in `[]` for p and `mdscale` infers p from the second dimension of the matrix. You can also supply a 3-D array, implying a value for 'Replicates' from the array's third dimension.
- **Replicates** — Number of times to repeat the scaling, each with a new initial configuration. The default is 1.
- **Options** — Options for the iterative algorithm used to minimize the fitting criterion. Pass in an options structure created by `statset`. For example,

```
opts = statset(param1, val1, param2, val2, ...);
[...] = mdscale(..., 'Options', opts)
```

The choices of `statset` parameters are

- 'Display' — Level of display output. The choices are 'off' (the default), 'iter', and 'final'.
- 'MaxIter' — Maximum number of iterations allowed. The default is 200.
- 'TolFun' — Termination tolerance for the stress criterion and its gradient. The default is $1e-4$.
- 'TolX' — Termination tolerance for the configuration location step size. The default is $1e-4$.

Examples

```
load cereal.mat
X = [Calories Protein Fat Sodium Fiber ...
     Carbo Sugars Shelf Potass Vitamins];

% Take a subset from a single manufacturer.
X = X(strcmp('K', cellstr(Mfg)), :);

% Create a dissimilarity matrix.
dissimilarities = pdist(X);

% Use non-metric scaling to recreate the data in 2D,
% and make a Shepard plot of the results.
[Y, stress, disparities] = mdscale(dissimilarities, 2);
distances = pdist(Y);
[dum, ord] = sortrows([disparities(:) dissimilarities(:)]);
plot(dissimilarities, distances, 'bo', ...
```

```

dissimilarities(ord),disparities(ord),'r.-');
xlabel('Dissimilarities'); ylabel('Distances/Disparities')
legend({'Distances' 'Disparities'},'Location','NW');

```

```

% Do metric scaling on the same dissimilarities.
figure
[Y,stress] = ...
mdscale(dissimilarities,2,'criterion','metricsstress');
distances = pdist(Y);
plot(dissimilarities,distances,'bo', ...
[0 max(dissimilarities)],[0 max(dissimilarities)],'r.-');
xlabel('Dissimilarities'); ylabel('Distances')

```

Introduced before R2006a

mdsprox

Class: CompactTreeBagger

Multidimensional scaling of proximity matrix

Syntax

```
[SC,EIGEN] = mdsprox(B,X)
[SC,EIGEN] = mdsprox(B,X, 'param1',val1, 'param2',val2, ...)
```

Description

[SC,EIGEN] = mdsprox(B,X) applies classical multidimensional scaling to the proximity matrix computed for the data in the matrix X, and returns scaled coordinates SC and eigenvalues EIGEN of the scaling transformation. The method applies multidimensional scaling to the matrix of distances defined as $1 - \text{prox}$, where `prox` is the proximity matrix returned by the `proximity` method.

You can supply the proximity matrix directly by using the 'Data' parameter.

[SC,EIGEN] = mdsprox(B,X, 'param1',val1, 'param2',val2, ...) specifies optional parameter name/value pairs:

'Data'	Flag indicating how the method treats the X input argument. If set to 'predictors' (default), <code>mdsprox</code> assumes X to be a matrix of predictors and used for computation of the proximity matrix. If set to 'proximity', the method treats X as a proximity matrix returned by the <code>proximity</code> method.
--------	---

- 'Colors' If you supply this argument, `mdsprox` makes overlaid scatter plots of two scaled coordinates using specified colors for different classes. You must supply the colors as a character vector or a string scalar with one letter for each color. If there are more classes in the data than letters in the supplied value, `mdsprox` plots only the first `C` classes, where `C` is the number of letters in the supplied value. For regression or if you do not provide the vector of true class labels, the method uses the first color for all observations in `X`.
- 'Labels' Vector of true class labels for a classification ensemble. True class labels can be a numeric vector, character matrix, string array, or cell array of character vectors. If supplied, this vector must have as many elements as there are observations (rows) in `X`. This argument has no effect unless you also supply the 'Colors' argument.
- 'MDSCoordinates' Indices of the two scaled coordinates to plot. By default, `mdsprox` makes a scatter plot of the first and second scaled coordinates which correspond to the two largest eigenvalues. You can specify any other two or three indices not exceeding the dimensionality of the scaled data. This argument has no effect unless you also supply the 'Colors' argument.

mdsprox

Class: TreeBagger

Multidimensional scaling of proximity matrix

Syntax

```
[S,E] = mdsprox(B)
[S,E] = mdsprox(B, 'param1',val1, 'param2',val2,...)
```

Description

[S,E] = mdsprox(B) returns scaled coordinates, S, and eigenvalues, E, for the proximity matrix in the ensemble B. An earlier call to fillprox(B) must create the proximity matrix.

[S,E] = mdsprox(B, 'param1',val1, 'param2',val2,...) specifies optional parameter name/value pairs:

- | | |
|----------|--|
| 'Keep' | Array of indices of observations in the training data to use for multidimensional scaling. By default, this argument is set to 'all'. If you provide numeric or logical indices, the method uses only the subset of the training data specified by these indices to compute the scaled coordinates and eigenvalues. |
| 'Colors' | If you supply this argument, mdsprox makes overlaid scatter plots of two scaled coordinates using specified colors for different classes. You must supply the colors as a character vector or a string scalar with one letter for each color. If there are more classes in the data than letters in the supplied value, mdsprox plots only the first C classes, where C is the number of letters in the supplied value. For regression, the method uses the first color for all observations in X. |

'MDSCoordinate
s' Indices of the two scaled coordinates to plot. By default, `mdsprox` makes a scatter plot of the first and second scaled coordinates which correspond to the two largest eigenvalues. You can specify any other two or three indices not exceeding the dimensionality of the scaled data. This argument has no effect unless you also supply the 'Colors' argument.

mean

Package: prob

Mean of probability distribution

Syntax

```
m = mean(pd)
```

Description

`m = mean(pd)` returns the mean `m` of the probability distribution `pd`.

Examples

Mean of a Fitted Distribution

Load the sample data. Create a vector containing the first column of students' exam grade data.

```
load examgrades  
x = grades(:,1);
```

Create a normal distribution object by fitting it to the data.

```
pd = fitdist(x, 'Normal')  
  
pd =  
  NormalDistribution  
  
  Normal distribution  
      mu = 75.0083    [73.4321, 76.5846]  
      sigma = 8.7202    [7.7391, 9.98843]
```

Compute the mean of the fitted distribution.

```
m = mean(pd)
```

```
m = 75.0083
```

The mean of the normal distribution is equal to the parameter mu.

Mean of a Skewed Distribution

Create a Weibull probability distribution object.

```
pd = makedist('Weibull', 'a', 5, 'b', 2)
```

```
pd =  
WeibullDistribution  
  
Weibull distribution  
A = 5  
B = 2
```

Compute the mean of the distribution.

```
mean = mean(pd)
```

```
mean = 4.4311
```

Mean of a Uniform Distribution

Create a uniform distribution object

```
pd = makedist('Uniform', 'lower', -3, 'upper', 5)
```

```
pd =  
UniformDistribution  
  
Uniform distribution  
Lower = -3  
Upper = 5
```

Compute the mean of the distribution.

```
m = mean(pd)
```

```
m = 1
```

Mean of a Kernel Distribution

Load the sample data. Create a probability distribution object by fitting a kernel distribution to the miles per gallon (MPG) data.

```
load carsmall;
pd = fitdist(MPG, 'Kernel')

pd =
  KernelDistribution

  Kernel = normal
  Bandwidth = 4.11428
  Support = unbounded
```

Compute the mean of the distribution.

```
mean(pd)

ans = 23.7181
```

Input Arguments

pd — Probability distribution

probability distribution object

Probability distribution, specified as a probability distribution object created using one of the following.

Function or App	Description
<code>makedist</code>	Create a probability distribution object using specified parameter values.
<code>fitdist</code>	Fit a probability distribution object to sample data.

Function or App	Description
Distribution Fitter	Fit a probability distribution to sample data using the interactive Distribution Fitter app and export the fitted object to the workspace.

Output Arguments

m – Mean

scalar value

Mean of the probability distribution, returned as a scalar value.

Introduced in R2013a

meanMargin

Class: CompactTreeBagger

Mean classification margin

Syntax

```
mar = meanMargin(B, TBLnew, Ynew)
mar = meanMargin(B, Xnew, Ynew)
mar = meanMargin(B, TBLnew, Ynew, 'param1', val1, 'param2', val2, ...)
mar = meanMargin(B, Xnew, Ynew, 'param1', val1, 'param2', val2, ...)
```

Description

`mar = meanMargin(B, TBLnew, Ynew)` computes average classification margins for the predictors contained in the table `TBLnew` given the true response `Ynew`. You can omit `Ynew` if `TBLnew` contains the response variable. If you trained `B` using sample data contained in a table, then the input data for this method must also be in a table.

`mar = meanMargin(B, Xnew, Ynew)` computes average classification margins for the predictors contained in the matrix `Xnew` given true response `Ynew`. If you trained `B` using sample data contained in a matrix, then the input data for this method must also be in a matrix.

`Ynew` can be a numeric vector, character matrix, string array, cell array of character vectors, categorical vector, or logical vector. `meanMargin` averages the margins over all observations (rows) in `TBLnew` or `Xnew` for each tree. `mar` is a matrix of size 1-by-`NTrees`, where `NTrees` is the number of trees in the ensemble `B`. This method is available for classification ensembles only.

`mar = meanMargin(B, TBLnew, Ynew, 'param1', val1, 'param2', val2, ...)` or `mar = meanMargin(B, Xnew, Ynew, 'param1', val1, 'param2', val2, ...)` specifies optional parameter name-value pairs:

'Mode '	How meanMargin computes errors. If set to 'cumulative' (default), is a vector of length NTrees where the first element gives mean margin from trees(1), second column gives mean margins from trees(1:2) etc., up to trees(1:NTrees). If set to 'individual', mar is a vector of length NTrees, where each element is a mean margin from each tree in the ensemble. If set to 'ensemble', mar is a scalar showing the cumulative mean margin for the entire ensemble.
'Trees '	Vector of indices indicating what trees to include in this calculation. By default, this argument is set to 'all' and the method uses all trees. If 'Trees' is a numeric vector, the method returns a vector of length NTrees for 'cumulative' and 'individual' modes, where NTrees is the number of elements in the input vector, and a scalar for 'ensemble' mode. For example, in the 'cumulative' mode, the first element gives mean margin from trees(1), the second element gives mean margin from trees(1:2) etc.
'TreeWeights '	Vector of tree weights. This vector must have the same length as the 'Trees' vector. meanMargin uses these weights to combine output from the specified trees by taking a weighted average instead of the simple nonweighted majority vote. You cannot use this argument in the 'individual' mode.

meanMargin

meanMargin

Class: TreeBagger

Mean classification margin

Syntax

```
mar = meanMargin(B, TBLnew, Ynew)
mar = meanMargin(B, Xnew, Ynew)
mar = meanMargin(B, TBLnew, Ynew, 'param1', val1, 'param2', val2, ...)
mar = meanMargin(B, Xnew, Ynew, 'param1', val1, 'param2', val2, ...)
```

Description

`mar = meanMargin(B, TBLnew, Ynew)` computes average classification margins for the predictors contained in the table `TBLnew` given the true response `Ynew`. You can omit `Ynew` if `TBLnew` contains the response variable. If you trained `B` using sample data contained in a table, then the input data for this method must also be in a table.

`mar = meanMargin(B, Xnew, Ynew)` computes average classification margins for the predictors contained in the matrix `Xnew` given true response `Ynew`. If you trained `B` using sample data contained in a matrix, then the input data for this method must also be in a matrix.

`Ynew` can be a numeric vector, character matrix, string array, cell array of character vectors, categorical vector or logical vector. `meanMargin` averages the margins over all observations (rows) in `TBLnew` or `Xnew` for each tree. `mar` is a matrix of size 1-by-`NTrees`, where `NTrees` is the number of trees in the ensemble `B`. This method is available for classification ensembles only.

`mar = meanMargin(B, TBLnew, Ynew, 'param1', val1, 'param2', val2, ...)` or `mar = meanMargin(B, Xnew, Ynew, 'param1', val1, 'param2', val2, ...)` specifies optional parameter name-value pairs:

'Mode '	Character vector or string scalar indicating how <code>meanMargin</code> computes errors. If set to <code>'cumulative'</code> (default), is a vector of length <code>NTrees</code> where the first element gives mean margin from <code>trees(1)</code> , second column gives mean margins from <code>trees(1:2)</code> etc, up to <code>trees(1:NTrees)</code> . If set to <code>'individual'</code> , <code>mar</code> is a vector of length <code>NTrees</code> , where each element is a mean margin from each tree in the ensemble . If set to <code>'ensemble'</code> , <code>mar</code> is a scalar showing the cumulative mean margin for the entire ensemble .
'Trees '	Vector of indices indicating what trees to include in this calculation. By default, this argument is set to <code>'all'</code> and the method uses all trees. If <code>'Trees'</code> is a numeric vector, the method returns a vector of length <code>NTrees</code> for <code>'cumulative'</code> and <code>'individual'</code> modes, where <code>NTrees</code> is the number of elements in the input vector, and a scalar for <code>'ensemble'</code> mode. For example, in the <code>'cumulative'</code> mode, the first element gives mean margin from <code>trees(1)</code> , the second element gives mean margin from <code>trees(1:2)</code> etc.
'TreeWeights '	Vector of tree weights. This vector must have the same length as the <code>'Trees'</code> vector. <code>meanMargin</code> uses these weights to combine output from the specified trees by taking a weighted average instead of the simple nonweighted majority vote. You cannot use this argument in the <code>'individual'</code> mode.
'Weights '	Vector of observation weights to use for margin averaging. By default the weight of every observation is set to 1. The length of this vector must be equal to the number of rows in <code>X</code> .
'UseInstanceForTree '	Logical matrix of size <code>Nobs-by-NumTrees</code> indicating which trees to use to make predictions for each observation. By default the method uses all trees for all observations.

`meanMargin`

surrogateAssociation

Mean predictive measure of association for surrogate splits in decision tree

Syntax

```
ma = surrogateAssociation(tree)
ma = surrogateAssociation(tree,N)
```

Description

`ma = surrogateAssociation(tree)` returns a matrix of predictive measures of association for the predictors in `tree`.

`ma = surrogateAssociation(tree,N)` returns a matrix of predictive measures of association averaged over the nodes in vector `N`.

Input Arguments

tree

A classification tree constructed with `fitctree`, or a compact regression tree constructed with `compact`.

N

Vector of node numbers in `tree`.

Output Arguments

ma

- `ma = surrogateAssociation(tree)` returns a P-by-P matrix, where P is the number of predictors in `tree`. `ma(i,j)` is the predictive measure of association on

page 32-4206 between the optimal split on variable i and a surrogate split on variable j . For more details, see “Algorithms” on page 32-4207.

- `ma = surrogateAssociation(tree,N)` returns a P-by-P representing the predictive measure of association between variables averaged over nodes in the vector `N`. `N` contains node numbers from 1 to `max(tree.NumNodes)`.

Examples

Estimate Predictive Measures of Association for Surrogate Splits

Load Fisher's iris data set.

```
load fisheriris
```

Grow a classification tree using `species` as the response. Specify to use surrogate splits for missing values.

```
tree = fitctree(meas,species,'surrogate','on');
```

Find the mean predictive measure of association between the predictor variables.

```
ma = surrogateAssociation(tree)
```

```
ma = 4x4
```

```

1.0000         0         0         0
         0  1.0000         0         0
0.4633  0.2500  1.0000  0.5000
0.2065  0.1413  0.4022  1.0000

```

Find the mean predictive measure of association averaged over the odd-numbered nodes in `tree`.

```
N = 1:2:tree.NumNodes;
ma = surrogateAssociation(tree,N)
```

```
ma = 4x4
```

```

1.0000         0         0         0
         0  1.0000         0         0

```

0.4130	0.2826	0.8043	1.0000

Definitions

Predictive Measure of Association

The predictive measure of association is a value that indicates the similarity between decision rules that split observations. Among all possible decision splits that are compared to the optimal split (found by growing the tree), the best surrogate decision split on page 32-2176 yields the maximum predictive measure of association. The second-best surrogate split has the second-largest predictive measure of association.

Suppose x_j and x_k are predictor variables j and k , respectively, and $j \neq k$. At node t , the predictive measure of association between the optimal split $x_j < u$ and a surrogate split $x_k < v$ is

$$\lambda_{jk} = \frac{\min(P_L, P_R) - (1 - P_{L_j L_k} - P_{R_j R_k})}{\min(P_L, P_R)}.$$

- P_L is the proportion of observations in node t , such that $x_j < u$. The subscript L stands for the left child of node t .
- P_R is the proportion of observations in node t , such that $x_j \geq u$. The subscript R stands for the right child of node t .
- $P_{L_j L_k}$ is the proportion of observations at node t , such that $x_j < u$ and $x_k < v$.
- $P_{R_j R_k}$ is the proportion of observations at node t , such that $x_j \geq u$ and $x_k \geq v$.
- Observations with missing values for x_j or x_k do not contribute to the proportion calculations.

λ_{jk} is a value in $(-\infty, 1]$. If $\lambda_{jk} > 0$, then $x_k < v$ is a worthwhile surrogate split for $x_j < u$.

Surrogate Decision Splits

A surrogate decision split is an alternative to the optimal decision split at a given node in a decision tree. The optimal split is found by growing the tree; the surrogate split uses a similar or correlated predictor variable and split criterion.

When the value of the optimal split predictor for an observation is missing, the observation is sent to the left or right child node using the best surrogate predictor. When the value of the best surrogate split predictor for the observation is also missing, the observation is sent to the left or right child node using the second-best surrogate predictor, and so on. Candidate splits are sorted in descending order by their predictive measure of association on page 32-2680.

Algorithms

Element $ma(i, j)$ is the predictive measure of association averaged over surrogate splits on predictor j for which predictor i is the optimal split predictor. This average is computed by summing positive values of the predictive measure of association over optimal splits on predictor i and surrogate splits on predictor j and dividing by the total number of optimal splits on predictor i , including splits for which the predictive measure of association between predictors i and j is negative.

ClassificationTree | fitctree

surrogateAssociation

Mean predictive measure of association for surrogate splits in decision tree

Syntax

```
ma = surrogateAssociation(tree)
ma = surrogateAssociation(tree,N)
```

Description

`ma = surrogateAssociation(tree)` returns a matrix of predictive measures of association for the predictors in `tree`.

`ma = surrogateAssociation(tree,N)` returns a matrix of predictive measures of association averaged over the nodes in vector `N`.

Input Arguments

tree

A regression tree constructed with `fitrtree`, or a compact regression tree constructed with `compact`.

N

Vector of node numbers in `tree`.

Output Arguments

ma

- `ma = surrogateAssociation(tree)` returns a P-by-P matrix, where P is the number of predictors in `tree`. `ma(i,j)` is the predictive measure of association on

page 32-4210 between the optimal split on variable i and a surrogate split on variable j . For more details, see “Algorithms” on page 32-4211.

- `ma = surrogateAssociation(tree,N)` returns a P-by-P representing the predictive measure of association between variables averaged over nodes in the vector `N`. `N` contains node numbers from 1 to `max(tree.NumNodes)`.

Examples

Estimate Predictive Measures of Association for Surrogate Splits

Load the `carsmall` data set. Specify `Displacement`, `Horsepower`, and `Weight` as predictor variables.

```
load carsmall
X = [Displacement Horsepower Weight];
```

Grow a regression tree using `MPG` as the response. Specify to use surrogate splits for missing values.

```
tree = fitrtree(X,MPG,'surrogate','on');
```

Find the mean predictive measure of association between the predictor variables.

```
ma = surrogateAssociation(tree)
```

```
ma = 3×3
```

```
    1.0000    0.2167    0.5083
    0.4521    1.0000    0.3769
    0.2540    0.2659    1.0000
```

Find the mean predictive measure of association averaged over the odd-numbered nodes in `tree`.

```
N = 1:2:tree.NumNodes;
ma = surrogateAssociation(tree,N)
```

```
ma = 3×3
```

```
    1.0000    0.1250    0.6875
```

0.5632	1.0000	0.5861
0.3333	0.3148	1.0000

Definitions

Predictive Measure of Association

The predictive measure of association is a value that indicates the similarity between decision rules that split observations. Among all possible decision splits that are compared to the optimal split (found by growing the tree), the best surrogate decision split on page 32-2176 yields the maximum predictive measure of association. The second-best surrogate split has the second-largest predictive measure of association.

Suppose x_j and x_k are predictor variables j and k , respectively, and $j \neq k$. At node t , the predictive measure of association between the optimal split $x_j < u$ and a surrogate split $x_k < v$ is

$$\lambda_{jk} = \frac{\min(P_L, P_R) - (1 - P_{L_j L_k} - P_{R_j R_k})}{\min(P_L, P_R)}.$$

- P_L is the proportion of observations in node t , such that $x_j < u$. The subscript L stands for the left child of node t .
- P_R is the proportion of observations in node t , such that $x_j \geq u$. The subscript R stands for the right child of node t .
- $P_{L_j L_k}$ is the proportion of observations at node t , such that $x_j < u$ and $x_k < v$.
- $P_{R_j R_k}$ is the proportion of observations at node t , such that $x_j \geq u$ and $x_k \geq v$.
- Observations with missing values for x_j or x_k do not contribute to the proportion calculations.

λ_{jk} is a value in $(-\infty, 1]$. If $\lambda_{jk} > 0$, then $x_k < v$ is a worthwhile surrogate split for $x_j < u$.

Surrogate Decision Splits

A surrogate decision split is an alternative to the optimal decision split at a given node in a decision tree. The optimal split is found by growing the tree; the surrogate split uses a similar or correlated predictor variable and split criterion.

When the value of the optimal split predictor for an observation is missing, the observation is sent to the left or right child node using the best surrogate predictor. When the value of the best surrogate split predictor for the observation is also missing, the observation is sent to the left or right child node using the second-best surrogate predictor, and so on. Candidate splits are sorted in descending order by their predictive measure of association on page 32-2680.

Algorithms

Element $ma(i, j)$ is the predictive measure of association averaged over surrogate splits on predictor j for which predictor i is the optimal split predictor. This average is computed by summing positive values of the predictive measure of association over optimal splits on predictor i and surrogate splits on predictor j and dividing by the total number of optimal splits on predictor i , including splits for which the predictive measure of association between predictors i and j is negative.

median

Package: prob

Median of probability distribution

Syntax

```
m = median(pd)
```

Description

`m = median(pd)` returns the median `m` for the probability distribution `pd`

Examples

Median of a Fitted Distribution

Load the sample data. Create a vector containing the first column of students' exam grade data.

```
load examgrades
x = grades(:,1);
```

Create a normal distribution object by fitting it to the data.

```
pd = fitdist(x, 'Normal')

pd =
  NormalDistribution

  Normal distribution
      mu = 75.0083    [73.4321, 76.5846]
      sigma = 8.7202    [7.7391, 9.98843]
```

Compute the median of the fitted distribution.

```
m = median(pd)
```

```
m = 75.0083
```

For a symmetrical distribution such as the normal distribution, the median is equal to the mean, μ .

Median of a Skewed Distribution

Create a Weibull probability distribution object.

```
pd = makedist('Weibull','a',5,'b',2)
```

```
pd =  
  WeibullDistribution  
  
  Weibull distribution  
  A = 5  
  B = 2
```

Compute the median of the distribution.

```
m = median(pd)
```

```
m = 4.1628
```

For a skewed distribution such as the Weibull distribution, the median and the mean may not be equal.

Calculate the mean of the Weibull distribution and compare it to the median.

```
mean = mean(pd)
```

```
mean = 4.4311
```

The mean of the distribution is greater than the median.

Plot the pdf to visualize the distribution.

```
x = [0:.1:15];  
pdf = pdf(pd,x);  
plot(x,pdf)
```

Input Arguments

pd — Probability distribution

probability distribution object

Probability distribution, specified as a probability distribution object created using one of the following.

Function or App	Description
<code>makedist</code>	Create a probability distribution object using specified parameter values.
<code>fitdist</code>	Fit a probability distribution object to sample data.
Distribution Fitter	Fit a probability distribution to sample data using the interactive Distribution Fitter app and export the fitted object to the workspace.

Output Arguments

m — Median

scalar value

Median of the probability distribution, returned as a scalar value. The value of `m` is the 50th percentile of the probability distribution.

mergelevels

Merge levels of nominal or ordinal arrays

Note The `nominal` and `ordinal` array data types might be removed in a future release. To represent ordered and unordered discrete, nonnumeric data, use the “Categorical Arrays” (MATLAB) data type instead.

Syntax

```
B = mergelevels(A,oldlevels)
B = mergelevels(A,oldlevels,newlevel)
```

Description

`B = mergelevels(A,oldlevels)` merges two or more levels of `A`.

- If `A` is a nominal array, `mergelevels` uses the first label in `oldlevels` as the new level.
- If `A` is an ordinal array, the levels specified by `oldlevels` must be consecutive, and `mergelevels` uses the label corresponding to the lowest level in `oldlevels` as the label for the new level.

`B = mergelevels(A,oldlevels,newlevel)` merges two or more levels into the new level with label `newlevel`.

Examples

Create New Category From Merged Levels

Create a nominal array from data in a cell array.

```
colors = nominal({'r','b','g';'g','r','b';'b','r','g'},...
                 {'blue','green','red'})
```

```

colors = 3x3 nominal array
    red      blue      green
    green    red       blue
    blue     red       green

```

Merge the elements of the 'red' and 'blue' levels into a new level labeled 'purple'.

```

colors = mergelevels(colors,{'red','blue'},'purple')

```

```

colors = 3x3 nominal array
    purple    purple    green
    green     purple    purple
    purple    purple    green

```

Display the levels of colors.

```

getlevels(colors)

```

```

ans = 1x2 nominal array
    purple    green

```

Input Arguments

A — Nominal or ordinal array

nominal array | ordinal array

Nominal or ordinal array, specified as a nominal or ordinal array object created with nominal or ordinal.

oldlevels — Levels to merge

string array | cell array of character vectors | 2-D character array

Levels to merge, specified as a string array, cell array of character vectors, or 2-D character array. For ordinal arrays, the levels in `oldlevels` must be consecutive.

Data Types: char | string | cell

newlevel — Level to create

character vector | string scalar

Level to create from the merged levels, specified as a character vector or string scalar that gives the label for the new level.

Data Types: `char` | `string`

Output Arguments

B — **Nominal or ordinal array**

`nominal array` | `ordinal array`

Nominal or ordinal array, returned as a nominal or ordinal array object.

mhsample

Metropolis-Hastings sample

Syntax

```

smpl = mhsample(start,nsamples,'pdf',pdf,'proppdf',proppdf,
'proprnd',proprnd)
smpl = mhsample(...,'symmetric',sym)
smpl = mhsample(...,'burnin',K)
smpl = mhsample(...,'thin',m)
smpl = mhsample(...,'nchain',n)
[smpl,accept] = mhsample(...)

```

Description

`smpl = mhsample(start,nsamples,'pdf',pdf,'proppdf',proppdf,'proprnd',proprnd)` draws `nsamples` random samples from a target stationary distribution `pdf` using the Metropolis-Hastings algorithm.

`start` is a row vector containing the start value of the Markov Chain, `nsamples` is an integer specifying the number of samples to be generated, and `pdf`, `proppdf`, and `proprnd` are function handles created using `@`. `proppdf` defines the proposal distribution density, and `proprnd` defines the random number generator for the proposal distribution. `pdf` and `proprnd` take one argument as an input with the same type and size as `start`. `proppdf` takes two arguments as inputs with the same type and size as `start`.

`smpl` is a column vector or matrix containing the samples. If the log density function is preferred, `'pdf'` and `'proppdf'` can be replaced with `'logpdf'` and `'logproppdf'`. The density functions used in Metropolis-Hastings algorithm are not necessarily normalized.

The proposal distribution $q(x,y)$ gives the probability density for choosing x as the next point when y is the current point. It is sometimes written as $q(x|y)$.

If the `proppdf` or `logproppdf` satisfies $q(x,y) = q(y,x)$, that is, the proposal distribution is symmetric, `mhsample` implements Random Walk Metropolis-Hastings sampling. If the

`proppdf` or `logproppdf` satisfies $q(x,y) = q(x)$, that is, the proposal distribution is independent of current values, `mhsample` implements Independent Metropolis-Hastings sampling.

`smpl = mhsample(..., 'symmetric', sym)` draws `nsamples` random samples from a target stationary distribution `pdf` using the Metropolis-Hastings algorithm. `sym` is a logical value that indicates whether the proposal distribution is symmetric. The default value is `false`, which corresponds to the asymmetric proposal distribution. If `sym` is `true`, for example, the proposal distribution is symmetric, `proppdf` and `logproppdf` are optional.

`smpl = mhsample(..., 'burnin', K)` generates a Markov chain with values between the starting point and the k^{th} point omitted in the generated sequence. Values beyond the k^{th} point are kept. `k` is a nonnegative integer with default value of `0`.

`smpl = mhsample(..., 'thin', m)` generates a Markov chain with `m-1` out of `m` values omitted in the generated sequence. `m` is a positive integer with default value of `1`.

`smpl = mhsample(..., 'nchain', n)` generates `n` Markov chains using the Metropolis-Hastings algorithm. `n` is a positive integer with a default value of `1`. `smpl` is a matrix containing the samples. The last dimension contains the indices for individual chains.

`[smpl, accept] = mhsample(...)` also returns `accept`, the acceptance rate of the proposed distribution. `accept` is a scalar if a single chain is generated and is a vector if multiple chains are generated.

Examples

Estimate Moments Using Independent Metropolis-Hastings Sampling

Use Independent Metropolis-Hastings sampling to estimate the second order moment of a Gamma distribution.

```
rng default; % For reproducibility
alpha = 2.43;
beta = 1;
pdf = @(x)gampdf(x,alpha,beta); % Target distribution
proppdf = @(x,y)gampdf(x,floor(alpha),floor(alpha)/alpha);
proprnd = @(x)sum(...
```

```
        exprnd(floor(alpha)/alpha,floor(alpha),1));  
nsamples = 5000;  
smpl = mhsample(1,nsamples,'pdf',pdf,'proprnd',proprnd,...  
               'proppdf',proppdf);
```

Plot the results.

```
xxhat = cumsum(smpl.^2)./(1:nsamples)';  
figure;  
plot(1:nsamples,xxhat)
```

Random Walk Metropolis-Hastings Sampling

Use Random Walk Metropolis-Hastings sampling to generate sample data from a standard normal distribution.

```
rng default % For reproducibility
delta = .5;
pdf = @(x) normpdf(x);
proppdf = @(x,y) unifpdf(y-x,-delta,delta);
proprnd = @(x) x + rand*2*delta - delta;
nsamples = 15000;
x = mhsample(1,nsamples,'pdf',pdf,'proprnd',proprnd,'symmetric',1);
```

Plot the sample data.

```
figure;
h = histfit(x,50);
h(1).FaceColor = [.8 .8 1];
```

mle

Maximum likelihood estimates

Syntax

```
phat = mle(data)
phat = mle(data, 'distribution', dist)

phat = mle(data, 'pdf', pdf, 'start', start)
phat = mle(data, 'pdf', pdf, 'start', start, 'cdf', cdf)

phat = mle(data, 'logpdf', logpdf, 'start', start)
phat = mle(data, 'logpdf', logpdf, 'start', start, 'logsf', logsf)

phat = mle(data, 'nloglf', nloglf, 'start', start)

phat = mle( ____, Name, Value)
[phat, pci] = mle( ____, Name, Value)
```

Description

`phat = mle(data)` returns maximum likelihood estimates (MLEs) for the parameters of a normal distribution, using the sample data in the vector `data`.

`phat = mle(data, 'distribution', dist)` returns parameter estimates for a distribution specified by `dist`.

`phat = mle(data, 'pdf', pdf, 'start', start)` returns parameter estimates for a custom distribution specified by the probability density function `pdf`. You must also specify the initial parameter values, `start`.

`phat = mle(data, 'pdf', pdf, 'start', start, 'cdf', cdf)` returns parameter estimates for a custom distribution specified by the probability density function `pdf` and custom cumulative distribution function `cdf`.

`phat = mle(data, 'logpdf', logpdf, 'start', start)` returns parameter estimates for a custom distribution specified by the log probability density function `logpdf`. You must also specify the initial parameter values, `start`.

`phat = mle(data, 'logpdf', logpdf, 'start', start, 'logsf', logsf)` returns parameter estimates for a custom distribution specified by the log probability density function `logpdf` and custom log survival function on page 32-4242 `logsf`.

`phat = mle(data, 'nloglf', nloglf, 'start', start)` returns parameter estimates for the custom distribution specified by the negative loglikelihood function `nloglf`. You must also specify the initial parameter values, `start`.

`phat = mle(____, Name, Value)` specifies options using name-value pair arguments in addition to any of the input arguments in previous syntaxes. For example, you can specify the censored data, frequency of observations, and confidence level.

`[phat, pci] = mle(____)` also returns the 95% confidence intervals for the parameters.

Examples

Estimate Parameters of Burr Distribution

Load the sample data.

```
load carbig
```

The variable `MPG` has the miles per gallon for different models of cars.

Draw a histogram of `MPG` data.

```
histogram(MPG)
```

The distribution is somewhat right skewed. A symmetric distribution, such as normal distribution, might not be a good fit.

Estimate the parameters of the Burr Type XII distribution for the MPG data.

```
phat = mle(MPG, 'distribution', 'burr')
```

```
phat = 1×3
```

```
34.6447    3.7898    3.5722
```

The maximum likelihood estimates for the scale parameter α is 34.6447. The estimates for the two shape parameters c and k of the Burr Type XII distribution are 3.7898 and 3.5722, respectively.

Estimate Parameters of a Noncentral Chi-Square Distribution

Generate sample data of size 1000 from a noncentral chi-square distribution with degrees of freedom 8 and noncentrality parameter 3.

```
rng default % for reproducibility
x = ncx2rnd(8,3,1000,1);
```

Estimate the parameters of the noncentral chi-square distribution from the sample data. To do this, custom define the noncentral chi-square pdf using the pdf input argument.

```
[phat,pci] = mle(x,'pdf',@(x,v,d)ncx2pdf(x,v,d),'start',[1,1])
```

```
phat = 1×2
```

```
    8.1052    2.6693
```

```
pci = 2×2
```

```
    7.1121    1.6025
    9.0983    3.7362
```

The estimate for the degrees of freedom is 8.1052 and the noncentrality parameter is 2.6693. The 95% confidence interval for the degrees of freedom is (7.1121,9.0983) and the noncentrality parameter is (1.6025,3.7362). The confidence intervals include the true parameter values of 8 and 3, respectively.

Fit Custom Distribution to Censored Data

Load the sample data.

```
load(fullfile(matlabroot,'examples','stats','readmissiontimes.mat'));
```

The data includes `ReadmissionTime`, which has readmission times for 100 patients. The column vector `Censored` has the censorship information for each patient, where 1 indicates a censored observation, and 0 indicates the exact readmission time is observed. This is simulated data.

Define a custom probability density and cumulative distribution function.

```
custpdf = @(data,lambda) lambda*exp(-lambda*data);  
custcdf = @(data,lambda) 1-exp(-lambda*data);
```

Estimate the parameter, `lambda`, of the custom distribution for the censored sample data.

```
phat = mle(ReadmissionTime, 'pdf', custpdf, 'cdf', custcdf, 'start', 0.05, 'Censoring', Censored);  
phat = 0.1096
```

Fit Custom Log pdf and Survival Function

Load the sample data.

```
load(fullfile(matlabroot, 'examples', 'stats', 'readmissiontimes.mat'));
```

The data includes `ReadmissionTime`, which has readmission times for 100 patients. The column vector `Censored` has the censorship information for each patient, where 1 indicates a censored observation, and 0 indicates the exact readmission time is observed. This is simulated data.

Define a custom log probability density and survival function.

```
custlogpdf = @(data,lambda,k) log(k)-k*log(lambda)+(k-1)*log(data)-(data/lambda).^k;  
custlogsf = @(data,lambda,k) -(data/lambda).^k;
```

Estimate the parameters, `lambda` and `k`, of the custom distribution for the censored sample data.

```
phat = mle(ReadmissionTime, 'logpdf', custlogpdf, 'logsf', custlogsf, ...  
          'start', [1, 0.75], 'Censoring', Censored)
```

```
phat = 1×2  
    9.2090    1.4223
```

The scale and shape parameters of the custom-defined distribution are 9.2090 and 1.4223, respectively.

Fit Custom Log Negative Likelihood Function

Load the sample data.

```
load(fullfile(matlabroot, 'examples', 'stats', 'readmissiontimes.mat'));
```

The data includes `ReadmissionTime`, which has readmission times for 100 patients. This is simulated data.

Define a negative log likelihood function.

```
custnloglf = @(lambda,data,cens,freq) - length(data)*log(lambda) + nansum(lambda*data)
```

Estimate the parameters of the defined distribution.

```
phat = mle(ReadmissionTime, 'nloglf', custnloglf, 'start', 0.05)
```

```
phat = 0.1462
```

Estimate Probability of Success

Generate 100 random observations from a binomial distribution with the number of trials, $n = 20$, and the probability of success, $p = 0.75$.

```
data = binornd(20, 0.75, 100, 1);
```

Estimate the probability of success and 95% confidence limits using the simulated sample data.

```
[phat, pci] = mle(data, 'distribution', 'binomial', 'alpha', .05, 'ntrials', 20)
```

```
phat = 0.7615
```

```
pci = 2×1
```

```
0.7422
```

```
0.7800
```

The estimate of probability of success is 0.7615 and the lower and upper limits of the 95% confidence interval are 0.7422 and 0.78. This interval covers the true value used to simulate the data.

Fit Distribution with Known Parameter

Generate sample data of size 1000 from a noncentral chi-square distribution with degrees of freedom 10 and noncentrality parameter 5.

```
rng default % for reproducibility  
x = ncx2rnd(10,5,1000,1);
```

Suppose the noncentrality parameter is fixed at the value 5. Estimate the degrees of freedom of the noncentral chi-square distribution from the sample data. To do this, custom define the noncentral chi-square pdf using the `pdf` input argument.

```
[phat,pci] = mle(x, 'pdf', @(x,v,d)ncx2pdf(x,v,5), 'start', 1)
```

```
phat = 9.9307
```

```
pci = 2×1
```

```
9.5626  
10.2989
```

The estimate for the noncentrality parameter is 9.9307, with a 95% confidence interval of 9.5626 and 10.2989. The confidence interval includes the true parameter value of 10.

Fit Rician Distribution with Known Scale Parameter

Generate sample data of size 1000 from a Rician distribution with noncentrality parameter of 8 and scale parameter of 5. First create the Rician distribution.

```
r = makedist('Rician','s',8,'sigma',5);
```

Now, generate sample data from the distribution you created above.

```
rng default % For reproducibility
x = random(r,1000,1);
```

Suppose the scale parameter is known, and estimate the noncentrality parameter from sample data. To do this using `mle`, you must custom define the Rician probability density function.

```
[phat,pci] = mle(x,'pdf',@(x,s,sigma) pdf('rician',x,s,5),'start',10)

phat = 7.8953

pci = 2×1

    7.5405
    8.2501
```

The estimate for the noncentrality parameter is 7.8953, with a 95% confidence interval of 7.5404 and 8.2501. The confidence interval includes the true parameter value of 8.

Fit a Distribution with Additional Parameter

Add a scale parameter to the chi-square distribution for adapting to the scale of data and fit it. First, generate sample data of size 1000 from a chi-square distribution with degrees of freedom 5, and scale it by the factor of 100.

```
rng default % For reproducibility
x = 100*chi2rnd(5,1000,1);
```

Estimate the degrees of freedom and the scaling factor. To do this, custom define the chi-square probability density function using the `pdf` input argument. The density function requires a $1/s$ factor for data scaled by s .

```
[phat,pci] = mle(x,'pdf',@(x,v,s)chi2pdf(x/s,v)/s,'start',[1,200])

phat = 1×2

    5.1079    99.1681
```

```
pci = 2×2

    4.6862    90.1215
    5.5297   108.2146
```

The estimate for the degrees of freedom is 5.1079 and the scale is 99.1681. The 95% confidence interval for the degrees of freedom is (4.6862,5.5279) and the scale parameter is (90.1215,108.2146). The confidence intervals include the true parameter values of 5 and 100, respectively.

Input Arguments

data — Sample data

vector

Sample data `mle` uses to estimate the distribution parameters, specified as a vector.

Data Types: `single` | `double`

dist — Distribution type

'normal' (default) | character vector or string scalar of distribution type

Distribution type to estimate parameters for, specified as one of the following.

dist	Description	Parameter 1	Parameter 2	Parameter 3	Parameter 4
'Bernoulli'	"Bernoulli Distribution" on page B-2	p: probability of success for each trial	—	—	—
'Beta'	"Beta Distribution" on page B-4	a: first shape parameter	b: second shape parameter	—	—

Example: 'rician'

pdf — Custom probability density function

function handle

Custom probability distribution function, specified as a function handle created using @.

This custom function accepts the vector `data` and one or more individual distribution parameters as input parameters, and returns a vector of probability density values.

For example, if the name of the custom probability density function is `newpdf`, then you can specify the function handle in `mle` as follows.

Example: `@newpdf`

Data Types: `function_handle`

cdf — Custom cumulative distribution function

function handle

Custom cumulative distribution function, specified as a function handle created using @.

This custom function accepts the vector `data` and one or more individual distribution parameters as input parameters, and returns a vector of cumulative probability values.

You must define `cdf` with `pdf` if data is censored and you use the 'Censoring' name-value pair argument. If 'Censoring' is not present, you do not have to specify `cdf` while using `pdf`.

For example, if the name of the custom cumulative distribution function is `newcdf`, then you can specify the function handle in `mle` as follows.

Example: `@newcdf`

Data Types: `function_handle`

logpdf — Custom log probability density function

function handle

Custom log probability density function, specified as a function handle created using @.

This custom function accepts the vector `data` and one or more individual distribution parameters as input parameters, and returns a vector of log probability values.

For example, if the name of the custom log probability density function is `customlogpdf`, then you can specify the function handle in `mle` as follows.

Example: `@customlogpdf`

Data Types: `function_handle`

logsf — Custom log survival function

function handle

Custom log survival function on page 32-4242, specified as a function handle created using @.

This custom function accepts the vector `data` and one or more individual distribution parameters as input parameters, and returns a vector of log survival probability values.

You must define `logsf` with `logpdf` if data is censored and you use the `'Censoring'` name-value pair argument. If `'Censoring'` is not present, you do not have to specify `logsf` while using `logpdf`.

For example, if the name of the custom log survival function is `logsurvival`, then you can specify the function handle in `mle` as follows.

Example: `@logsurvival`

Data Types: `function_handle`

nloglf — Custom negative loglikelihood function

function handle

Custom negative loglikelihood function, specified as a function handle created using @.

This custom function accepts the following input arguments.

<code>params</code>	Vector of distribution parameter values. <code>mle</code> detects the number of parameters from the number of elements in <code>start</code> .
<code>data</code>	Vector of data.
<code>cens</code>	Boolean vector of censored values.
<code>freq</code>	Vector of integer data frequencies.

`nloglf` must accept all four arguments even if you do not use the 'Censoring' or 'Frequency' name-value pair arguments. You can write '`nloglf`' to ignore `cens` and `freq` arguments in that case.

`nloglf` returns a scalar negative loglikelihood value and optionally, a negative loglikelihood gradient vector (see the 'GradObj' field in 'Options').

If the name of the custom negative log likelihood function is `negloglik`, then you can specify the function handle in `mle` as follows.

Example: `@negloglik`

Data Types: `function_handle`

start — Initial parameter values

scalar | vector

Initial parameter values for the custom functions, specified as a scalar value or a vector of scalar values.

Use `start` when you fit custom distributions, that is, when you use `pdf` and `cdf`, `logpdf` and `logsf`, or `nloglf` input arguments.

Example: `0.05`

Example: `[100,2]`

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'Censoring', Cens, 'Alpha', 0.01, 'Options', Opt` specifies that `mle` estimates the parameters for the distribution of censored data specified by array `Cens`, computes the 99% confidence limits for the parameter estimates, and uses the algorithm control parameters specified by the structure `Opt`.

Censoring — Indicator for censoring

array of 0s (default) | array of 0s and 1s

Indicator for censoring, specified as the comma-separated pair consisting of `'Censoring'` and a Boolean array of the same size as `data`. Use 1 for observations that are right censored and 0 for observations that are fully observed. The default is all observations are fully observed.

For example, if the censored data information is in the binary array called `Censored`, then you can specify the censored data as follows.

Example: `'Censoring', Censored`

`mle` supports censoring for the following distributions:

Birnbaum-Saunders	Logistic
Burr	Lognormal
Exponential	Nakagami
Extreme Value	Normal
Gamma	Rician
Inverse Gaussian	t Location-Scale
Kernel	Weibull
Log-Logistic	

Data Types: `logical`

Frequency — Frequency of observations

array of 1s (default) | vector of nonnegative integer counts

Frequency of observations, specified as the comma-separated pair consisting of `'Frequency'` and an array containing nonnegative integer counts, which is the same size as `data`. The default is one observation per element of `data`.

For example, if the observation frequencies are stored in an array named `Freq`, you can specify the frequencies as follows.

Example: `'Frequency', Freq`

Data Types: `single` | `double`

Alpha — Significance level

0.05 (default) | scalar value in the range (0,1)

Significance level for the confidence interval of parameter estimates, `pci`, specified as the comma-separated pair consisting of 'Alpha' and a scalar value in the range (0,1). The confidence level of `pci` is $100(1-\text{Alpha})\%$. The default is 0.05 for 95% confidence.

For example, for 99% confidence limits, you can specify the confidence level as follows.

Example: `'Alpha',0.01`

Data Types: `single` | `double`

NTrials — Number of trials

scalar value | vector

Number of trials for the corresponding element of `data`, specified as the comma-separated pair consisting of 'Ntrials' and a scalar or a vector of the same size as `data`.

Applies only to binomial distribution.

Example: `'Ntrials',total`

Data Types: `single` | `double`

mu — Location parameter

0 (default) | scalar value

Location parameter for the half-normal distribution, specified as the comma-separated pair consisting of 'mu' and a scalar value.

Applies only to half-normal distribution.

Example: `'mu',1`

Data Types: `single` | `double`

Options — Fitting algorithm control parameters

structure

Fitting algorithm control parameters, specified as the comma-separated pair consisting of 'Options' and a structure returned by `statset`.

Not applicable to all distributions.

Use the 'Options' name-value pair argument to control details of the maximum likelihood optimization when fitting a custom distribution. For parameter names and default values, type `statset('mlecustom')`. You can set the options under a new name and use that in the name-value pair argument. `mle` interprets the following `statset` parameters for custom distribution fitting.

Parameter	Value
'GradObj'	<p>Default is 'off'.</p> <p>'on' or 'off', indicating whether or not <code>fmincon</code> can expect the custom function provided with the <code>nloglf</code> input argument to return the gradient vector of the negative log-likelihood as a second output.</p> <p><code>mle</code> ignores 'GradObj' when using <code>fminsearch</code>.</p>
'DerivStep'	<p>Default is $\text{eps}^{(1/3)}$.</p> <p>The relative difference, specified as a scalar or a vector the same size as <code>start</code>, used in finite difference derivative approximations when using <code>fmincon</code>, and 'GradObj' is 'off'.</p> <p><code>mle</code> ignores 'DerivStep' when using <code>fminsearch</code>.</p>
'FunValCheck'	<p>Default is 'on'.</p> <p>'on' or 'off', indicating whether or not <code>mle</code> should check the values returned by the custom distribution functions for validity.</p> <p>A poor choice of starting point can sometimes cause these functions to return NaNs, infinite values, or out-of-range values if they are written without suitable error checking.</p>
'TolBnd'	<p>Default is $1\text{e-}6$.</p> <p>An offset for lower and upper bounds when using <code>fmincon</code>.</p> <p><code>mle</code> treats lower and upper bounds as strict inequalities, that is, open bounds. With <code>fmincon</code>, this is approximated by creating closed bounds inset from the specified lower and upper bounds by <code>TolBnd</code>.</p>

Example: 'Options',statset('mlecustom')

Data Types: struct

LowerBound — Lower bounds for distribution parameters

$-\infty$ (default) | vector

Lower bounds for distribution parameters, specified as the comma-separated pair consisting of 'Lowerbound' and a vector the same size as start.

This name-value pair argument is valid only when you use the pdf and cdf, logpdf and logcdf, or nloglf input arguments.

Example: 'Lowerbound',0

Data Types: single | double

UpperBound — Upper bounds for distribution parameters

∞ (default) | vector

Upper bounds for distribution parameters, specified as the comma-separated pair consisting of 'Upperbound' and a vector the same size as start.

This name-value pair argument is valid only when you use the pdf and cdf, logpdf and logsf, or nloglf input arguments.

Example: 'Upperbound',1

Data Types: single | double

OptimFun — Optimization function

'fminsearch' (default) | 'fmincon'

Optimization function mle uses in maximizing the likelihood, specified as the comma-separated pair consisting of 'Optimfun' and either 'fminsearch' or 'fmincon'.

Default is 'fminsearch'.

You can only specify 'fmincon' if Optimization Toolbox is available.

The 'Optimfun' name-value pair argument is valid only when you fit custom distributions, that is, when you use the pdf and cdf, logpdf and logsf, or nloglf input arguments.

Example: 'Optimfun','fmincon'

Output Arguments

phat — Parameter estimates

scalar value | row vector

Parameter estimates, returned as a scalar value or a row vector.

pci — Confidence intervals for parameter estimates

2-by- k matrix

Confidence intervals for parameter estimates, returned as a column vector or a matrix depending on the number of parameters, hence the size of `phat`.

`pci` is a 2-by- k matrix, where k is the number of parameters `mle` estimates. The first and second rows of the `pci` show the lower and upper confidence limits, respectively.

Definitions

Survival Function

The survival function is the probability of survival as a function of time. It is also called the survivor function. It gives the probability that the survival time of an individual exceeds a certain value. Since the cumulative distribution function, $F(t)$, is the probability that the survival time is less than or equal to a given point in time, the survival function for a continuous distribution, $S(t)$, is the complement of the cumulative distribution function: $S(t) = 1 - F(t)$.

Tips

When you supply distribution functions, `mle` computes the parameter estimates using an iterative maximization algorithm. With some models and data, a poor choice of starting point can cause `mle` to converge to a local optimum that is not the global maximizer, or to fail to converge entirely. Even in cases for which the log-likelihood is well-behaved near the global maximum, the choice of starting point is often crucial to convergence of the algorithm. In particular, if the initial parameter values are far from the MLEs, underflow in the distribution functions can lead to infinite log-likelihoods.

Introduced before R2006a

mlecov

Asymptotic covariance of maximum likelihood estimators

Syntax

```
acov = mlecov(params,data,'pdf',pdf)
acov = mlecov(params,data,'pdf',pdf,'cdf',cdf)

acov = mlecov(params,data,'logpdf',logpdf)
acov = mlecov(params,data,'logpdf',logpdf,'logsf',logsf)

acov = mlecov(params,data,'nloglf',nloglf)

acov = mlecov( ____,Name,Value)
```

Description

`acov = mlecov(params,data,'pdf',pdf)` returns an approximation to the asymptotic covariance matrix of the maximum likelihood estimators of the parameters for a distribution specified by the custom probability density function `pdf`.

`mlecov` computes a finite difference approximation to the Hessian of the log-likelihood at the maximum likelihood estimates `params`, given the observed data, and returns the negative inverse of that Hessian.

`acov = mlecov(params,data,'pdf',pdf,'cdf',cdf)` returns `acov` for a distribution specified by the custom probability density function `pdf` and cumulative distribution function `cdf`.

`acov = mlecov(params,data,'logpdf',logpdf)` returns `acov` for a distribution specified by the custom log probability density function `logpdf`.

`acov = mlecov(params,data,'logpdf',logpdf,'logsf',logsf)` returns `acov` for a distribution specified by the custom log probability density function `logpdf` and custom log survival function on page 32-4253 `logsf`.

`acov = mlecov(params,data,'nloglf',nloglf)` returns `acov` for a distribution specified by the custom negative loglikelihood function `nloglf`.

`acov = mlecov(____,Name,Value)` specifies options using name-value pair arguments in addition to any of the input arguments in previous syntaxes. For example, you can specify the censored data and frequency of observations.

Examples

Custom Probability Density Function

Load the sample data.

```
load carbig
```

The vector `Weight` shows the weights of 406 cars.

In the MATLAB Editor, create a function that returns the probability density function (pdf) of a lognormal distribution. Save the file in your current working folder as `lognormpdf.m`.

```
function newpdf = lognormpdf(data,mu,sigma)
newpdf = exp(-(log(data)-mu).^2)/(2*sigma^2))./(data*sigma*sqrt(2*pi));
```

Estimate the parameters, `mu` and `sigma`, of the custom-defined distribution.

```
phat = mle(Weight,'pdf',@lognormpdf,'start',[4.5 0.3])
```

```
phat =
```

```
    7.9600    0.2804
```

Compute the approximate covariance matrix of the parameter estimates.

```
acov = mlecov(phat,Weight,'pdf',@lognormpdf)
```

```
acov =
```

```
    1.0e-03 *
    0.1937    -0.0000
   -0.0000    0.0968
```

Estimate the standard errors of estimates.

```
se = sqrt(diag(acov))  
se =  
  
    0.0139  
    0.0098
```

The standard error of the estimates of mu and sigma are 0.0139 and 0.0098, respectively.

Custom Log Probability Density Function

In the MATLAB Editor, create a function that returns the log probability density function of a beta distribution. Save the file in your current working folder as `betalogpdf.m`.

```
function logpdf = betalogpdf(x,a,b)  
logpdf = (a-1)*log(x)+(b-1)*log(1-x)-betaIn(a,b);
```

Generate sample data from a beta distribution with parameters 1.23 and 3.45 and estimate the parameters using the simulated data.

```
rng('default')  
x = betarnd(1.23,3.45,25,1);  
phat = mle(x,'dist','beta')  
  
phat =  
  
    1.1213    2.7182
```

Compute the approximate covariance matrix of the parameter estimates.

```
acov = mlecov(phat,x,'logpdf',@betalogpdf)  
acov =  
  
    0.0810    0.1646  
    0.1646    0.6074
```

Custom Log pdf and Survival Function

Load the sample data.

```
load(fullfile(matlabroot,'examples','stats','readmissiontimes.mat'));
```

The sample data includes `ReadmissionTime`, which has readmission times for 100 patients. The column vector `Censored` has the censorship information for each patient, where 1 indicates a censored observation, and 0 indicates the exact readmission time is observed. This is simulated data.

Define a custom log probability density and survival function.

```
custlogpdf = @(data,lambda,k) log(k)-k*log(lambda)...
             +(k-1)*log(data)-(data/lambda).^k;
custlogsf = @(data,lambda,k) -(data/lambda).^k;
```

Estimate the parameters, `lambda` and `k`, of the custom distribution for the censored sample data.

```
phat = mle(ReadmissionTime,'logpdf',custlogpdf,...
           'logsf',custlogsf,'start',[1,0.75],'Censoring',Censored)
```

```
phat = 1×2
```

```
    9.2090    1.4223
```

The scale and shape parameters of the custom-defined distribution are 9.2090 and 1.4223, respectively.

Compute the approximate covariance matrix of the parameter estimates.

```
acov = mlecov(phat,ReadmissionTime,...
              'logpdf',custlogpdf,'logsf',custlogsf,'Censoring',Censored)
```

```
acov = 2×2
```

```
    0.5653    0.0102
    0.0102    0.0163
```

Custom Log Negative Likelihood Function

Load the sample data.

```
load(fullfile(matlabroot,'examples','stats','readmissiontimes.mat'));
```

The sample data includes `ReadmissionTime`, which has readmission times for 100 patients. This is simulated data.

Define a negative log likelihood function.

```
custnloglf = @(lambda,data,cens,freq) -length(data)*log(lambda)...  
+ nansum(lambda*data);
```

Estimate the parameters of the defined distribution.

```
phat = mle(ReadmissionTime,'nloglf',custnloglf,'start',0.05)  
phat = 0.1462
```

Compute the variance of the parameter estimate.

```
acov = mlecov(phat,ReadmissionTime,'nloglf',custnloglf)  
acov = 2.1374e-04
```

Compute the standard error.

```
sqrt(acov)  
ans = 0.0146
```

Input Arguments

params — Parameter estimates

scalar value | vector

Parameter estimates, specified as a scalar value or vector of scalar values. These parameter estimates must be maximum likelihood estimates. For example, you can specify parameter estimates returned by `mle`.

Data Types: `single` | `double`

data — Sample data

vector

Sample data `mle` uses to estimate the distribution parameters, specified as a vector.

Data Types: `single` | `double`

pdf — Custom probability density function

function handle

Custom probability distribution function, specified as a function handle created using @.

This custom function accepts the vector `data` and one or more individual distribution parameters as input parameters, and returns a vector of probability density values.

For example, if the name of the custom probability density function is `newpdf`, then you can specify the function handle in `mlecov` as follows.

Example: `@newpdf`

Data Types: `function_handle`

cdf — Custom cumulative distribution function

function handle

Custom cumulative distribution function, specified as a function handle created using @.

This custom function accepts the vector `data` and one or more individual distribution parameters as input parameters, and returns a vector of cumulative probability values.

You must define `cdf` with `pdf` if data is censored and you use the 'Censoring' name-value pair argument. If 'Censoring' is not present, you do not have to specify `cdf` while using `pdf`.

For example, if the name of the custom cumulative distribution function is `newcdf`, then you can specify the function handle in `mlecov` as follows.

Example: `@newcdf`

Data Types: `function_handle`

logpdf — Custom log probability density function

function handle

Custom log probability density function, specified as a function handle created using @.

This custom function accepts the vector `data` and one or more individual distribution parameters as input parameters, and returns a vector of log probability values.

For example, if the name of the custom log probability density function is `customlogpdf`, then you can specify the function handle in `mlecov` as follows.

Example: `@customlogpdf`

Data Types: `function_handle`

logsf — Custom log survival function

`function handle`

Custom log survival function on page 32-4253, specified as a function handle created using `@`.

This custom function accepts the vector `data` and one or more individual distribution parameters as input parameters, and returns a vector of log survival probability values.

You must define `logsf` with `logpdf` if data is censored and you use the 'Censoring' name-value pair argument. If 'Censoring' is not present, you do not have to specify `logsf` while using `logpdf`.

For example, if the name of the custom log survival function is `logsurvival`, then you can specify the function handle in `mlecov` as follows.

Example: `@logsurvival`

Data Types: `function_handle`

nloglf — Custom negative loglikelihood function

`function handle`

Custom negative loglikelihood function, specified as a function handle created using `@`.

This custom function accepts the following input arguments.

<code>params</code>	Vector of distribution parameter values
<code>data</code>	Vector of data
<code>cens</code>	Boolean vector of censored values
<code>freq</code>	Vector of integer data frequencies

`nloglf` must accept all four arguments even if you do not use the 'Censoring' or 'Frequency' name-value pair arguments. You can write '`nloglf`' to ignore `cens` and `freq` arguments in that case.

`nloglf` returns a scalar negative loglikelihood value and optionally, a negative loglikelihood gradient vector (see the '`GradObj`' field in '`Options`').

If the name of the custom negative log likelihood function is `negloglik`, then you can specify the function handle in `mlecov` as follows.

Example: `@negloglik`

Data Types: `function_handle`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Censoring',cens,'Options',opt` specifies that `mlecov` reads the censored data information from the vector `cens` and performs according to the new options structure `opt`.

Censoring — Indicator for censoring

array of 0s (default) | array of 0s and 1s

Indicator for censoring, specified as the comma-separated pair consisting of `'Censoring'` and a Boolean array of the same size as `data`. Use 1 for observations that are right censored and 0 for observations that are fully observed. The default is all observations are fully observed.

For censored data, you must use `cdf` with `pdf`, or `logsf` with `logpdf`, or `nloglf` must be defined to account for censoring.

For example, if the censored data information is in the binary array called `Censored`, then you can specify the censored data as follows.

Example: `'Censoring',Censored`

Data Types: `logical`

Frequency — Frequency of observations

array of 1s (default) | vector of nonnegative integer counts

Frequency of observations, specified as the comma-separated pair consisting of `'Frequency'` and an array containing nonnegative integer counts, which is the same size as `data`. The default is one observation per element of `data`.

For example, if the observation frequencies are stored in an array named `Freq`, you can specify the frequencies as follows.

Example: `'Frequency', Freq`

Data Types: `single | double`

Options — Numerical options

structure

Numerical options for the finite difference Hessian calculation, specified as the comma-separated pair consisting of `'Options'` and a structure returned by `statset`.

You can set the options under a new name and use it in the name-value pair argument. The applicable `statset` parameters are as follows.

Parameter	Value
<code>'GradObj'</code>	Default is <code>'off'</code> . <code>'on'</code> or <code>'off'</code> , indicating whether or not the function provided with the <code>nloglf</code> input argument can return the gradient vector of the negative log-likelihood as a second output.
<code>'DerivStep'</code>	Default is <code>eps^(1/4)</code> . Relative step size used in finite difference for Hessian calculations. It can be a scalar, or the same size as <code>params</code> . A smaller value than the default might be appropriate if <code>'GradObj'</code> is <code>'on'</code> .

Example: `'Options', statset('mlecov')`

Data Types: `struct`

Output Arguments

acov — Approximation to asymptotic covariance matrix

p-by-*p* matrix

Approximation to asymptotic covariance matrix, returned as a *p*-by-*p* matrix, where *p* is the number of parameters in `params`.

Definitions

Survival Function

The survival function is the probability of survival as a function of time. It is also called the survivor function. It gives the probability that the survival time of an individual exceeds a certain value. Since the cumulative distribution function, $F(t)$, is the probability that the survival time is less than or equal to a given point in time, the survival function for a continuous distribution, $S(t)$, is the complement of the cumulative distribution function: $S(t) = 1 - F(t)$.

Introduced before R2006a

mnpdf

Multinomial probability density function

Syntax

```
Y = mnpdf(X,PROB)
```

Description

`Y = mnpdf(X,PROB)` returns the pdf for the multinomial distribution with probabilities `PROB`, evaluated at each row of `X`. `X` and `PROB` are m -by- k matrices or 1-by- k vectors, where k is the number of multinomial bins or categories. Each row of `PROB` must sum to one, and the sample sizes for each observation (rows of `X`) are given by the row sums `sum(X,2)`. `Y` is an m -by-1 vector, and `mnpdf` computes each row of `Y` using the corresponding rows of the inputs, or replicates them if needed.

Examples

Compute the Multinomial Distribution pdf

Compute the pdf of a multinomial distribution with a sample size of $n = 10$. The probabilities are $p = 1/2$ for outcome 1, $p = 1/3$ for outcome 2, and $p = 1/6$ for outcome 3.

```
p = [1/2 1/3 1/6];  
n = 10;  
x1 = 0:n;  
x2 = 0:n;  
[X1,X2] = meshgrid(x1,x2);  
X3 = n-(X1+X2);
```

Compute the pdf of the distribution.

```
Y = mnpdf([X1(:),X2(:),X3(:)], repmat(p, (n+1)^2, 1));
```

Plot the pdf on a 3-dimensional figure.

```
Y = reshape(Y,n+1,n+1);  
bar3(Y)  
h = gca;  
h.XTickLabel = [0:n];  
h.YTickLabel = [0:n];  
xlabel('x_1')  
ylabel('x_2')  
zlabel('Probability Mass')  
title('Trinomial Distribution')
```

Note that the visualization does not show x_3 , which is determined by the constraint $x_1 + x_2 + x_3 = n$.

mnrfit

Multinomial logistic regression

Syntax

```
B = mnrfi(X,Y)
B = mnrfi(X,Y,Name,Value)
[B,dev,stats] = mnrfi( ___ )
```

Description

`B = mnrfi(X,Y)` returns a matrix, `B`, of coefficient estimates for a multinomial logistic regression of the nominal responses in `Y` on the predictors in `X`.

`B = mnrfi(X,Y,Name,Value)` returns a matrix, `B`, of coefficient estimates for a multinomial model fit with additional options specified by one or more `Name, Value` pair arguments.

For example, you can fit a nominal, an ordinal, or a hierarchical model, or change the link function.

`[B,dev,stats] = mnrfi(___)` also returns the deviance of the fit, `dev`, and the structure `stats` for any of the previous input arguments. `stats` contains model statistics such as degrees of freedom, standard errors for coefficient estimates, and residuals.

Examples

Multinomial Regression for Nominal Responses

Fit a multinomial regression for nominal outcomes and interpret the results.

Load the sample data.

```
load fisheriris
```

The column vector, `species`, consists of iris flowers of three different species, `setosa`, `versicolor`, `virginica`. The double matrix `meas` consists of four types of measurements on the flowers, the length and width of sepals and petals in centimeters, respectively.

Define the nominal response variable using a categorical array.

```
sp = categorical(species);
```

Fit a multinomial regression model to predict the species using the measurements.

```
[B,dev,stats] = mnrfits(meas,sp);
```

```
B
```

```
B = 5×2  
103 ×
```

```
 2.3287    0.0426  
 0.7770    0.0025  
-0.6544    0.0067  
-0.5964   -0.0094  
-3.1815   -0.0183
```

This is a nominal model for the response category relative risks, with separate slopes on all four predictors, that is, each category of `meas`. The first row of `B` contains the intercept terms for the relative risk of the first two response categories, `setosa` and `versicolor` versus the reference category, `virginica`. The last four rows contain the slopes for the models for the first two categories. `mnrfits` accepts the third category as the reference category.

The relative risk of an iris flower being species 2 (`versicolor`) versus species 3 (`virginica`) is the ratio of the two probabilities (the probability of being species 2 and the probability of being species 3). The model for the relative risk is

$$\ln\left(\frac{\pi_{\text{versicolor}}}{\pi_{\text{virginica}}}\right) = 42.6 + 2.5X_1 + 6.7X_2 - 9.4X_3 - 18.3X_4.$$

The coefficients express both the effects of the predictor variables on the relative risk and the log odds of being in one category versus the reference category. For example, the estimated coefficient 2.5 indicates that the relative risk of being species 2 (`versicolor`) versus species 3 (`virginica`) increases $\exp(2.5)$ times for each unit increase in X_1 , the first measurement, given all else is equal. The relative log odds of being `versicolor` versus `virginica` increases 2.5 times with a one-unit increase in X_1 , given all else is equal.

If the coefficients are converging toward infinity or negative infinity, the estimated coefficients can vary slightly depending on your operating system.

Check the statistical significance of the model coefficients.

```
stats.p
```

```
ans = 5×2
```

```

0    0.0000
0    0.0281
0    0.0000
0    0.0000
0    0.0000

```

The small p -values indicate that all measures are significant on the relative risk of being a setosa versus a virginica (species 1 compared to species 3) and being a versicolor versus a virginica (species 2 compared to species 3).

Request the standard errors of coefficient estimates.

```

-22.3957 -14.1766
```

Multinomial Regression for Ordinal Responses

Fit a multinomial regression model for categorical responses with natural ordering among categories.

Load the sample data and define the predictor variables.

```
load carbig
X = [Acceleration Displacement Horsepower Weight];
```

The predictor variables are the acceleration, engine displacement, horsepower, and weight of the cars. The response variable is miles per gallon (mpg).

Create an ordinal response variable categorizing MPG into four levels from 9 to 48 mpg by labeling the response values in the range 9-19 as 1, 20-29 as 2, 30-39 as 3, and 40-48 as 4.

```
miles = ordinal(MPG,{'1','2','3','4'},[],[9,19,29,39,48]);
```

Fit an ordinal response model for the response variable miles.

```
[B,dev,stats] = mnrfity(X,miles,'model','ordinal');
B
```

```
B = 7x1
-16.6895
-11.7208
-8.0606
 0.1048
 0.0103
 0.0645
 0.0017
```

The first three elements of **B** are the intercept terms for the models, and the last four elements of **B** are the coefficients of the covariates, assumed common across all categories. This model corresponds to *parallel regression*, which is also called the *proportional odds* model, where there is a different intercept but common slopes among categories. You can specify this using the 'interactions', 'off' name-value pair argument, which is the default for ordinal models.

```
[B(1:3)'; repmat(B(4:end),1,3)]
```

```
ans = 5x3
-16.6895 -11.7208 -8.0606
 0.1048  0.1048  0.1048
 0.0103  0.0103  0.0103
 0.0645  0.0645  0.0645
 0.0017  0.0017  0.0017
```

The link function in the model is `logit('link','logit')`, which is the default for an ordinal model. The coefficients express the relative risk or log odds of the mpg of a car being less than or equal to one value versus greater than that value.

The proportional odds model in this example is

$$\ln\left(\frac{P(\text{mpg} \leq 19)}{P(\text{mpg} > 19)}\right) = -16.6895 + 0.1048X_A + 0.0103X_D + 0.0645X_H + 0.0017X_W$$

$$\ln\left(\frac{P(\text{mpg} \leq 29)}{P(\text{mpg} > 29)}\right) = -11.7208 + 0.1048X_A + 0.0103X_D + 0.0645X_H + 0.0017X_W$$

$$\ln\left(\frac{P(\text{mpg} \leq 39)}{P(\text{mpg} > 39)}\right) = -8.0606 + 0.1048X_A + 0.0103X_D + 0.0645X_H + 0.0017X_W$$

For example, the coefficient estimate of 0.1048 indicates that a unit change in acceleration would impact the odds of the mpg of a car being less than or equal to 19 versus more than 19, or being less than or equal to 29 versus greater than 29, or being less than or equal to 39 versus greater than 39, by a factor of $\exp(0.1048)$ given all else is equal.

Assess the significance of the coefficients.

```
stats.p
```

```
ans = 7×1
```

```
0.0000  
0.0000  
0.0000  
0.1899  
0.0350  
0.0000  
0.0118
```

The p -values of 0.035, 0.0000, and 0.0118 for engine displacement, horsepower, and weight of a car, respectively, indicate that these factors are significant on the odds of mpg of a car being less than or equal to a certain value versus being greater than that value.

Hierarchical Multinomial Regression Model

Fit a hierarchical multinomial regression model.

Load the sample data.

```
load(fullfile(matlabroot, 'examples', 'stats', 'smoking.mat'));
```

The data set `smoking` contains five variables: `sex`, `age`, `weight`, and systolic and diastolic blood pressure. `sex` is a binary variable where 1 indicates female patients, and 0 indicates male patients.

Define the response variable.

```
Y = categorical(smoking.Smoker);
```

The data in `Smoker` has four categories:

- 0: Nonsmoker, 0 cigarettes a day
- 1: Smoker, 1-5 cigarettes a day
- 2: Smoker, 6-10 cigarettes a day
- 3: Smoker, 11 or more cigarettes a day

Define the predictor variables.

```
X = [smoking.Sex smoking.Age smoking.Weight...
      smoking.SystolicBP smoking.DiastolicBP];
```

Fit a hierarchical multinomial model.

```
[B,dev,stats] = mnrfits(X,Y,'model','hierarchical');
B
```

```
B = 6x3
```

```
43.8148    5.9571    44.0712
 1.8709   -0.0230    0.0662
 0.0188    0.0625    0.1335
 0.0046   -0.0072   -0.0130
-0.2170    0.0416   -0.0324
-0.2273   -0.1449   -0.4824
```

The first column of `B` includes the intercept and the coefficient estimates for the model of the relative risk of being a nonsmoker versus a smoker. The second column includes the parameter estimates for modeling the log odds of smoking 1-5 cigarettes a day versus more than five cigarettes a day given that a person is a smoker. Finally, the third column includes the parameter estimates for modeling the log odds of a person smoking 6-10 cigarettes a day versus more than 10 cigarettes a day given he/she smokes more than 5 cigarettes a day.

The coefficients differ across categories. You can specify this using the 'interactions', 'on' name-value pair argument, which is the default for hierarchical models. So, the model in this example is

$$\ln\left(\frac{P(y=0)}{P(y>0)}\right) = 43.8148 + 1.8709X_S + 0.0188X_A + 0.0046X_W - 0.2170X_{SBP} - 0.2273X_{DBP}$$

$$\ln\left(\frac{P(1 \leq y \leq 5)}{P(y > 5)}\right) = 5.9571 - 0.0230X_S + 0.0625X_A - 0.0072X_W + 0.0416X_{SBP} - 0.1449X_{DBP}$$

$$\ln\left(\frac{P(6 \leq y \leq 10)}{P(y > 10)}\right) = 44.0712 + 0.0662X_S + 0.1335X_A - 0.0130X_W - 0.0324X_{SBP} - 0.4824X_{DBP}$$

For example, the coefficient estimate of 1.8709 indicates that the likelihood of being a smoker versus a nonsmoker increases by $\exp(1.8709) = 6.49$ times as the gender changes from female to male given everything else held constant.

Assess the statistical significance of the terms.

```
stats.p
```

```
ans = 6×3
```

0.0000	0.5363	0.2149
0.3549	0.9912	0.9835
0.6850	0.2676	0.2313
0.9032	0.8523	0.8514
0.0009	0.5187	0.8165
0.0004	0.0483	0.0545

Sex, age, or weight don't appear significant on any level. The p -values of 0.0009 and 0.0004 indicate that both types of blood pressure are significant on the relative risk of a person being a smoker versus a nonsmoker. The p -value of 0.0483 shows that only diastolic blood pressure is significant on the odds of a person smoking 0-5 cigarettes a day versus more than 5 cigarettes a day. Similarly, the p -value of 0.0545 indicates that diastolic blood pressure is significant on the odds of a person smoking 6-10 cigarettes a day versus more than 10 cigarettes a day.

Check if any nonsignificant factors are correlated to each other. Draw a scatterplot of age versus weight grouped by sex.

```
figure()  
gscatter(smoking.Age, smoking.Weight, smoking.Sex)  
legend('Male', 'Female')  
xlabel('Age')  
ylabel('Weight')
```

The range of weight of an individual seems to differ according to gender. Age does not seem to have any obvious correlation with sex or weight. Age is insignificant and weight seems to be correlated with sex, so you can eliminate both and reconstruct the model.

Eliminate age and weight from the model and fit a hierarchical model with sex, systolic blood pressure, and diastolic blood pressure as the predictor variables.

```
X = double([smoking.Sex smoking.SystolicBP...  
smoking.DiastolicBP]);  
[B,dev,stats] = mnrfits(X,Y,'model','hierarchical');  
B
```

```
B = 4×3
```

```
44.8456    5.3230    25.0248  
 1.6045    0.2330    0.4982  
-0.2161    0.0497    0.0179  
-0.2222   -0.1358   -0.3092
```

Here, a coefficient estimate of 1.6045 indicates that the likelihood of being a nonsmoker versus a smoker increases by $\exp(1.6045) = 4.97$ times as sex changes from male to female. A unit increase in the systolic blood pressure indicates an $\exp(-.2161) = 0.8056$ decrease in the likelihood of being a nonsmoker versus a smoker. Similarly, a unit increase in the diastolic blood pressure indicates an $\exp(-.2222) = 0.8007$ decrease in the relative rate of being a nonsmoker versus being a smoker.

Assess the statistical significance of the terms.

```
stats.p
```

```
ans = 4×3
```

```
0.0000    0.4715    0.2325  
0.0210    0.7488    0.6362  
0.0010    0.4107    0.8899  
0.0003    0.0483    0.0718
```

The p -values of 0.0210, 0.0010, and 0.0003 indicate that the terms sex and both types of blood pressure are significant on the relative risk of a person being a nonsmoker versus a smoker, given the other terms in the model. Based on the p -value of 0.0483, diastolic blood pressure appears significant on the relative risk of a person smoking 1–5 cigarettes versus more than 5 cigarettes a day, given that this person is a smoker. Because none of the p -values on the third column are less than 0.05, you can say that none of the variables are statistically significant on the relative risk of a person smoking from 6–10 cigarettes versus more than 10 cigarettes, given that this person smokes more than 5 cigarettes a day.

Input Arguments

X — Observations on predictor variables

n-by-*p* matrix

Observations on predictor variables, specified as an *n*-by-*p* matrix. *X* contains *n* observations for *p* predictors.

Note `mnrfit` automatically includes a constant term (intercept) in all models. Do not include a column of 1s in *X*.

Data Types: `single` | `double`

Y — Response values

n-by-*k* matrix | *n*-by-1 column vector

Response values, specified as a column vector or a matrix. *Y* can be one of the following:

- An *n*-by-*k* matrix, where $Y(i,j)$ is the number of outcomes of the multinomial category *j* for the predictor combinations given by $X(i,:)$. In this case, the number of observations are made at each predictor combination.
- An *n*-by-1 column vector of scalar integers from 1 to *k* indicating the value of the response for each observation. In this case, all sample sizes are 1.
- An *n*-by-1 categorical array indicating the nominal or ordinal value of the response for each observation. In this case, all sample sizes are 1.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'Model', 'ordinal', 'Link', 'probit'` specifies an ordinal model with a probit link function.

Model — Type of model to fit`'nominal'` (default) | `'ordinal'` | `'hierarchical'`

Type of model to fit, specified as the comma-separated pair consisting of `'Model'` and one of the following.

<code>'nominal'</code>	Default. There is no ordering among the response categories.
<code>'ordinal'</code>	There is a natural ordering among the response categories.
<code>'hierarchical'</code>	The choice of response category is sequential/nested.

Example: `'Model', 'ordinal'`

Interactions — Indicator for interaction between multinomial categories and coefficients`'on'` | `'off'`

Indicator for an interaction between the multinomial categories and coefficients, specified as the comma-separated pair consisting of `'Interactions'` and one of the following.

<code>'on'</code>	Default for nominal and hierarchical models. Fit a model with different coefficients across categories.
<code>'off'</code>	Default for ordinal models. Fit a model with a common set of coefficients for the predictor variables, across all multinomial categories. This is often described as <i>parallel regression</i> or the <i>proportional odds model</i> .

In all cases, the model has different intercepts across categories. The choice of `'Interactions'` determines the dimensions of the output array `B`.

Example: `'Interactions', 'off'`

Link — Link function`'logit'` (default) | `'probit'` | `'comloglog'` | `'loglog'`

Link function to use for ordinal and hierarchical models, specified as the comma-separated pair consisting of `'Link'` and one of the following.

<code>'logit'</code>	Default. $f(\gamma) = \ln(\gamma/(1-\gamma))$
<code>'probit'</code>	$f(\gamma) = \Phi^{-1}(\gamma)$ — error term is normally distributed with variance 1

'comploglog'	Complementary log-log $f(\gamma) = \ln(-\ln(1 - \gamma))$
'loglog'	$f(\gamma) = \ln(-\ln(\gamma))$

The link function defines the relationship between response probabilities and the linear combination of predictors, $X\beta$. The link functions might be functions of cumulative or conditional probabilities based on whether the model is for an ordinal or a sequential/nested response. For example, for an ordinal model, γ represents the cumulative probability of being in categories 1 to j and the model with a logit link function as follows:

$$\ln\left(\frac{\gamma}{1 - \gamma}\right) = \ln\left(\frac{\pi_1 + \pi_2 + \dots + \pi_j}{\pi_{j+1} + \dots + \pi_k}\right) = \beta_{0j} + \beta_1 X_1 + \beta_2 X_2 + \dots + \beta_p X_p,$$

where k represents the last category.

You cannot specify the 'Link' parameter for nominal models; these always use a multinomial logit link,

$$\ln\left(\frac{\pi_j}{\pi_r}\right) = \beta_{j0} + \beta_{j1} X_{j1} + \beta_{j2} X_{j2} + \dots + \beta_{jp} X_{jp}, \quad j = 1, \dots, k - 1,$$

where π stands for a categorical probability, and r corresponds to the reference category. `mnrfit` uses the last category as the reference category for nominal models.

Example: 'Link', 'loglog'

EstDisp — Indicator for estimating dispersion parameter

'off' (default) | 'on'

Indicator for estimating a dispersion parameter, specified as the comma-separated pair consisting of 'EstDisp' and one of the following.

'off'	Default. Use the theoretical dispersion value of 1.
'on'	Estimate a dispersion parameter for the multinomial distribution in computing standard errors.

Example: 'EstDisp', 'on'

Output Arguments

B — Coefficient estimates

vector | matrix

Coefficient estimates for a multinomial logistic regression of the responses in Y , returned as a vector or a matrix.

- If 'Interaction' is 'off', then B is a $k - 1 + p$ vector. The first $k - 1$ rows of B correspond to the intercept terms, one for each $k - 1$ multinomial categories, and the remaining p rows correspond to the predictor coefficients, which are common for all of the first $k - 1$ categories.
- If 'Interaction' is 'on', then B is a $(p + 1)$ -by- $(k - 1)$ matrix. Each column of B corresponds to the estimated intercept term and predictor coefficients, one for each of the first $k - 1$ multinomial categories.

The estimates for the k th category are taken to be zero as `mnrfit` takes the last category as the reference category.

dev — Deviance of the fit

scalar value

Deviance of the fit, returned as a scalar value. It is twice the difference between the maximum achievable log likelihood and that attained under the fitted model. This corresponds to the sum of deviance residuals,

$$dev = 2 * \sum_i^n \sum_j^k y_{ij} * \log\left(\frac{y_{ij}}{\hat{\pi}_{ij} * m_i}\right) = \sum_i^n rd_i,$$

where rd_i are the deviance residuals. For deviance residuals see `stats`.

stats — Model statistics

structure

Model statistics, returned as a structure that contains the following fields.

beta	The coefficient estimates. These are the same as <code>B</code> .
------	---

dfc	Degrees of freedom for error <ul style="list-style-type: none"> • If 'Interactions' is 'off', then degrees of freedom is $n*(k - 1) - (k - 1 + p)$. • If 'Interactions' is 'on', then degrees of freedom is $(n - p + 1)*(k - 1)$.
sfit	Estimated dispersion parameter.
s	Theoretical or estimated dispersion parameter. <ul style="list-style-type: none"> • If 'Estdisp' is 'off', then s is the theoretical dispersion parameter, 1. • If 'Estdisp' is 'on', then s is equal to the estimated dispersion parameter, sfit.
estdisp	Indicator for a theoretical or estimated dispersion parameter.
se	Standard errors of coefficient estimates, B.
coeffcorr	Estimated correlation matrix for B.
covb	Estimated covariance matrix for B.
t	t statistics for B.
p	p-values for B.
resid	Raw residuals. Observed minus fitted values, $r_{ij} = y_{ij} - \hat{\pi}_{ij} * m_i, \quad \begin{cases} i = 1, \dots, n \\ j = 1, \dots, k' \end{cases}$ <p>where π_{ij} is the categorical, cumulative or conditional probability, and m_i is the corresponding sample size.</p>
residp	Pearson residuals, which are the raw residuals scaled by the estimated standard deviation: $rp_{ij} = \frac{r_{ij}}{\hat{\sigma}_{ij}} = \frac{y_{ij} - \hat{\pi}_{ij} * m_i}{\sqrt{\hat{\pi}_{ij} * (1 - \hat{\pi}_{ij}) * m_i}}, \quad \begin{cases} i = 1, \dots, n \\ j = 1, \dots, k' \end{cases}$ <p>where π_{ij} is the categorical, cumulative, or conditional probability, and m_i is the corresponding sample size.</p>

residd	Deviance residuals: $rd_i = 2 * \sum_j^k y_{ij} * \log\left(\frac{y_{ij}}{\hat{\pi}_{ij} * m_i}\right), \quad i = 1, \dots, n.$ where π_{ij} is the categorical, cumulative, or conditional probability, and m_i is the corresponding sample size.
--------	---

Algorithms

mnrfit treats NaNs in either X or Y as missing values, and ignores them.

Introduced in R2006b

mnrnd

Multinomial random numbers

Syntax

```
r = mnrnd(n,p)
R = mnrnd(n,p,m)
R = mnrnd(N,P)
```

Description

`r = mnrnd(n,p)` returns random values `r` from the multinomial distribution with parameters `n` and `p`. `n` is a positive integer specifying the number of trials (sample size) for each multinomial outcome. `p` is a 1-by-`k` vector of multinomial probabilities, where `k` is the number of multinomial bins or categories. `p` must sum to one. (If `p` does not sum to one, `r` consists entirely of NaN values.) `r` is a 1-by-`k` vector, containing counts for each of the `k` multinomial bins.

`R = mnrnd(n,p,m)` returns `m` random vectors from the multinomial distribution with parameters `n` and `p`. `R` is a `m`-by-`k` matrix, where `k` is the number of multinomial bins or categories. Each row of `R` corresponds to one multinomial outcome.

`R = mnrnd(N,P)` generates outcomes from different multinomial distributions. `P` is a `m`-by-`k` matrix, where `k` is the number of multinomial bins or categories and each of the `m` rows contains a different set of multinomial probabilities. Each row of `P` must sum to one. (If any row of `P` does not sum to one, the corresponding row of `R` consists entirely of NaN values.) `N` is a `m`-by-1 vector of positive integers or a single positive integer (replicated by `mnrnd` to a `m`-by-1 vector). `R` is a `m`-by-`k` matrix. Each row of `R` is generated using the corresponding rows of `N` and `P`.

Examples

Generate 2 random vectors with the same probabilities:

```
n = 1e3;
p = [0.2,0.3,0.5];
R = mnrnd(n,p,2)
R =
    215    282    503
    194    303    503
```

Generate 2 random vectors with different probabilities:

```
n = 1e3;
P = [0.2, 0.3, 0.5; ...
     0.3, 0.4, 0.3;];
R = mnrnd(n,P)
R =
    186    290    524
    290    389    321
```

Introduced in R2006b

mnrval

Multinomial logistic regression values

Syntax

```
pihat = mnrvl(B,X)
[pihat,dlow,dhi] = mnrvl(B,X,stats)
[pihat,dlow,dhi] = mnrvl(B,X,stats,Name,Value)
```

```
yhat = mnrvl(B,X,ssize)
[yhat,dlow,dhi] = mnrvl(B,X,ssize,stats)
[yhat,dlow,dhi] = mnrvl(B,X,ssize,stats,Name,Value)
```

Description

`pihat = mnrvl(B,X)` returns the predicted probabilities for the multinomial logistic regression model with predictors, X , and the coefficient estimates, B .

`pihat` is an n -by- k matrix of predicted probabilities for each multinomial category. B is the vector or matrix that contains the coefficient estimates returned by `mnrfit`. And X is an n -by- p matrix which contains n observations for p predictors.

Note `mnrval` automatically includes a constant term in all models. Do not enter a column of 1s in X .

`[pihat,dlow,dhi] = mnrvl(B,X,stats)` also returns 95% error bounds on the predicted probabilities, `pihat`, using the statistics in the structure, `stats`, returned by `mnrfit`.

The lower and upper confidence bounds for `pihat` are `pihat` minus `dlow` and `pihat` plus `dhi`, respectively. Confidence bounds are nonsimultaneous and only apply to the fitted curve, not to new observations.

`[pihat,dlow,dhi] = mnrvl(B,X,stats,Name,Value)` returns the predicted probabilities and 95% error bounds on the predicted probabilities `pihat`, with additional options specified by one or more `Name,Value` pair arguments.

For example, you can specify the model type, link function, and the type of probabilities to return.

`yhat = mnrvl(B,X,ssize)` returns the predicted category counts for sample sizes, `ssize`.

`[yhat,dlow,dhi] = mnrvl(B,X,ssize,stats)` also computes 95% error bounds on the predicted counts `yhat`, using the statistics in the structure, `stats`, returned by `mnrfit`.

The lower and upper confidence bounds for `yhat` are `yhat` minus `dlo` and `yhat` plus `dhi`, respectively. Confidence bounds are nonsimultaneous and they apply to the fitted curve, not to new observations.

`[yhat,dlow,dhi] = mnrvl(B,X,ssize,stats,Name,Value)` returns the predicted category counts and 95% error bounds on the predicted counts `yhat`, with additional options specified by one or more `Name,Value` pair arguments.

For example, you can specify the model type, link function, and the type of predicted counts to return.

Examples

Estimate Category Probabilities for Nominal Responses

Fit a multinomial regression for nominal outcomes and estimate the category probabilities.

Load the sample data.

```
load fisheriris
```

The column vector, `species`, consists of iris flowers of three different species, `setosa`, `versicolor`, `virginica`. The double matrix `meas` consists of four types of measurements on the flowers, the length and width of sepals and petals in centimeters, respectively.

Define the nominal response variable.

```
sp = nominal(species);
sp = double(sp);
```

Now in `sp`, 1, 2, and 3 indicate the species *setosa*, *versicolor*, and *virginica*, respectively.

Fit a nominal model to estimate the species using the flower measurements as the predictor variables.

```
[B,dev,stats] = mnrfits(meas,sp);
```

Estimate the probability of being a certain kind of species for an iris flower having the measurements (6.3, 2.8, 4.9, 1.7).

```
x = [6.3, 2.8, 4.9, 1.7];
pihat = mnrval(B,x);
pihat

pihat = 1×3

    0    0.3977    0.6023
```

The probability of an iris flower having the measurements (6.3, 2.8, 4.9, 1.7) being a *setosa* is 0, a *versicolor* is 0.3977, and a *virginica* is 0.6023.

Estimate Upper and Lower Error Bounds for Probability Estimates of Ordinal Responses

Fit a multinomial regression model for categorical responses with natural ordering among categories. Then estimate the upper and lower confidence bounds for the category probability estimates.

Load the sample data and define the predictor variables.

```
load('carbig.mat')
X = [Acceleration Displacement Horsepower Weight];
```

The predictor variables are the acceleration, engine displacement, horsepower, and the weight of the cars. The response variable is miles per gallon (MPG).

Create an ordinal response variable categorizing MPG into four levels from 9 to 48 mpg.

```
miles = ordinal(MPG,{'1','2','3','4'},[],[9,19,29,39,48]);  
miles = double(miles);
```

Now in miles, 1 indicates the cars with miles per gallon from 9 to 19, and 2 indicates the cars with miles per gallon from 20 to 29. Similarly, 3 and 4 indicate the cars with miles per gallon from 30 to 39 and 40 to 48, respectively.

Fit a multinomial regression model for the response variable miles. For an ordinal model, the default 'link' is logit and the default 'interactions' is 'off'.

```
[B,dev,stats] = mnrfits(X,miles,'model','ordinal');
```

Compute the probability estimates and 95% error bounds for probability confidence intervals for miles per gallon of a car with $x = (12, 113, 110, 2670)$.

```
x = [12,113,110,2670];  
[pihat,dlow,hi] = mnrvl(B,x,stats,'model','ordinal');  
pihat
```

```
pihat = 1×4  
  
    0.0615    0.8426    0.0932    0.0027
```

Calculate the confidence bounds for the category probability estimates.

```
LL = pihat - dlow;  
UL = pihat + hi;  
[LL;UL]  
  
ans = 2×4  
  
    0.0073    0.7829    0.0283   -0.0003  
    0.1157    0.9022    0.1580    0.0057
```

Estimate Category Counts and Error Bounds for Nominal Responses

Fit a multinomial regression for nominal outcomes and estimate the category counts.

Load the sample data.

```
load fisheriris
```

The column vector, `species`, consists of iris flowers of three different species, `setosa`, `versicolor`, and `virginica`. The double matrix `meas` consists of four types of measurements on the flowers, the length and width of sepals and petals in centimeters, respectively.

Define the nominal response variable.

```
sp = nominal(species);
sp = double(sp);
```

Now in `sp`, 1, 2, and 3 indicate the species `setosa`, `versicolor`, and `virginica`, respectively.

Fit a nominal model to estimate the species based on the flower measurements.

```
[B,dev,stats] = mnrfits(meas,sp);
```

Estimate the number in each species category for a sample of 100 iris flowers all with the measurements (6.3, 2.8, 4.9, 1.7).

```
x = [6.3, 2.8, 4.9, 1.7];
yhat = mnrval(B,x,18)
```

```
yhat = 1×3
```

```
    0    7.1578    10.8422
```

Estimate the error bounds for the counts.

```
[yhat,dlow,hi] = mnrval(B,x,18,stats,'model','nominal');
```

Calculate the confidence bounds for the category probability estimates.

```
LL = yhat - dlow;
UL = yhat + hi;
[LL;UL]
```

```
ans = 2×3
```

```
    0    3.3019    6.9863
    0   11.0137   14.6981
```

Plot the Count Estimates

Create sample data with one predictor variable and a categorical response variable with three categories.

```
x = [-3 -2 -1 0 1 2 3]';
Y = [1 11 13; 2 9 14; 6 14 5; 5 10 10; ...
     5 14 6; 7 13 5; 8 11 6];
[Y x]

ans = 7x4
```

1	11	13	-3
2	9	14	-2
6	14	5	-1
5	10	10	0
5	14	6	1
7	13	5	2
8	11	6	3

There are observations on seven different values of the predictor variable x . The response variable Y has three categories and the data shows how many of the 25 individuals are in each category of Y for each observation of x . For example, when x is -3, 1 of 25 individuals is observed in category 1, 11 observed in category 2, and 13 observed in category 3. Similarly, when x is 1, 5 of the individuals are observed in category 1, 14 are observed in category 2, and 6 are observed in category 3.

Plot the number in each category versus the x values, on a stacked bar graph.

```
bar(x,Y, 'stacked');
ylim([0 25]);
```

Fit a nominal model for the individual response category probabilities, with separate slopes on the single predictor variable, x , for each category.

```
betaHatNom = mnrfits(x,Y,'model','nominal',...  
                    'interactions','on')
```

```
betaHatNom = 2x2
```

```
-0.6028    0.3832  
 0.4068    0.1948
```

The first row of `betaHatOrd` contains the intercept terms for the first two response categories. The second row contains the slopes. `mnrfit` accepts the third category as the reference category and hence assumes the coefficients for the third category are zero.

Compute the predicted probabilities for the three response categories.

```
xx = linspace(-4,4)';
piHatNom = mnrfval(betaHatNom,xx,'model','nominal',...
    'interactions','on');
```

The probability of being in the third category is simply $1 - P(y = 1) - P(y = 2)$.

Plot the estimated cumulative number in each category on the bar graph.

```
line(xx,cumsum(25*piHatNom,2),'LineWidth',2);
```

The cumulative probability for the third category is always 1.

Now, fit a "parallel" ordinal model for the cumulative response category probabilities, with a common slope on the single predictor variable, x , across all categories:

```
betaHat0rd = mnrfits(x,Y,'model','ordinal',...
    'interactions','off')
```

```
betaHat0rd = 3×1
```

```
-1.5001
 0.7266
 0.2642
```

The first two elements of `betaHat0rd` are the intercept terms for the first two response categories. The last element of `betaHat0rd` is the common slope.

Compute the predicted cumulative probabilities for the first two response categories. The cumulative probability for the third category is always 1.

```
piHat0rd = mnrvl(betaHat0rd,xx,'type','cumulative',...
    'model','ordinal','interactions','off');
```

Plot the estimated cumulative number on the bar graph of the observed cumulative number.

```
figure()
bar(x,cumsum(Y,2),'grouped');
ylim([0 25]);
line(xx,25*piHat0rd,'LineWidth',2);
```

Input Arguments

B — Coefficient estimates

vector or matrix returned by `mnrfit`

Coefficient estimates for the multinomial logistic regression model, specified as a vector or matrix returned by `mnrfit`. It is a vector or matrix depending on the model and interactions.

Example: `B = mnrfit(X,y); pihat = mnrval(B,X)`

Data Types: `single` | `double`

X — Sample data

matrix

Sample data on predictors, specified as an n -by- p . X contains n observations for p predictors.

Note `mnrval` automatically includes a constant term in all models. Do not enter a column of 1s in X .

Example: `pihat = mnrval(B,X)`

Data Types: `single` | `double`

stats — Model statisticsstructure returned by `mnrfit`

Model statistics, specified as a structure returned by `mnrfit`. You must use the `stats` input argument in `mnrval` to compute the lower and upper error bounds on the category probabilities and counts.

Example: `[B,dev,stats] = mnrfit(X,y);[pihat,dlo,dhi] = mnrval(B,X,stats)`

ssize — Sample sizes

column vector of positive integers

Sample sizes to return the number of items in response categories for each combination of the predictor variables, specified as an n -by-1 column vector of positive integers.

For example, for a response variable having three categories, if an observation of the number of individuals in each category is y_1 , y_2 , and y_3 , respectively, then the sample size, m , for that observation is $m = y_1 + y_2 + y_3$.

If the sample sizes for n observations are in vector `sample`, then you can enter the sample sizes as follows.

Example: `yhat = mnrval(B,X,sample)`

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example: `'model', 'ordinal', 'link', 'probit', 'type', 'cumulative'` specifies that `mnrval` returns the estimates for cumulative probabilities for an ordinal model with a probit link function.

model — Type of multinomial model

`'nominal'` (default) | `'ordinal'` | `'hierarchical'`

Type of multinomial model fit by `mnrfit`, specified as the comma-separated pair consisting of `'model'` and one of the following.

<code>'nominal'</code>	Default. Specify when there is no ordering among the response categories.
<code>'ordinal'</code>	Specify when there is a natural ordering among the response categories.
<code>'hierarchical'</code>	Specify when the choice of response category is sequential.

Example: `'model', 'ordinal'`

interactions — Indicator for interaction between multinomial categories and coefficients

`'on'` | `'off'`

Indicator for an interaction between the multinomial categories and coefficients in the model fit by `mnrfit`, specified as the comma-separated pair consisting of `'interactions'` and one of the following.

<code>'on'</code>	Default for nominal and hierarchical models. Specify to fit a model with different intercepts and coefficients across categories.
<code>'off'</code>	Default for ordinal models. Specify to fit a model with different intercepts, but a common set of coefficients for the predictor variables, across all multinomial categories. This is often described as <i>parallel regression</i> or <i>proportional odds model</i> .

Example: `'interactions', 'off'`

Data Types: logical

link — Link function

'logit' (default) | 'probit' | 'comploglog' | 'loglog'

Link function `mnrfit` uses for ordinal and hierarchical models, specified as the comma-separated pair consisting of 'link' and one of the following.

'logit'	Default. $f(\gamma) = \ln(\gamma/(1 - \gamma))$
'probit'	$f(\gamma) = \Phi^{-1}(\gamma)$ — error term is normally distributed with variance 1
'comploglog'	Complementary log-log $f(\gamma) = \ln(-\ln(1 - \gamma))$
'loglog'	$f(\gamma) = \ln(-\ln(\gamma))$

The link function defines the relationship between response probabilities and the linear combination of predictors, $X\beta$.

γ might be cumulative or conditional probabilities based on whether the model is for an ordinal or a sequential/nested response.

You cannot specify the 'link' parameter for nominal models; these always use a multinomial logit link,

$$\ln\left(\frac{\pi_j}{\pi_r}\right) = \beta_{j0} + \beta_{j1}X_{j1} + \beta_{j2}X_{j2} + \dots + \beta_{jp}X_{jp}, \quad j = 1, \dots, k - 1,$$

where π stands for a categorical probability, and r corresponds to the reference category, k is the total number of response categories, p is the number of predictor variables. `mnrfit` uses the last category as the reference category for nominal models.

Example: 'link','loglog'

type — Type of probabilities or counts to estimate

'category' (default) | 'cumulative' | 'conditional'

Type of probabilities or counts to estimate, specified as the comma-separated pair including 'type' and one of the following.

'category'	Default. Specify to return predictions and error bounds for the probabilities (or counts) of the k multinomial categories.
'cumulative'	Specify to return predictions and confidence bounds for the cumulative probabilities (or counts) of the first $k - 1$ multinomial categories, as an n -by- $(k - 1)$ matrix. The predicted cumulative probability for the k th category is always 1.
'conditional'	Specify to return predictions and error bounds in terms of the first $k - 1$ conditional category probabilities (counts), i.e., the probability (count) for category j , given an outcome in category j or higher. When 'type' is 'conditional', and you supply the sample size argument <code>ssize</code> , the predicted counts at each row of X are conditioned on the corresponding element of <code>ssize</code> , across all categories.

Example: 'type','cumulative'

confidence — Confidence level

0.95 (default) | scalar value in the range (0,1)

Confidence level for the error bounds, specified as the comma-separated pair consisting of 'confidence' and a scalar value in the range (0,1).

For example, for 99% error bounds, you can specify the confidence as follows:

Example: 'confidence',0.99

Data Types: single | double

Output Arguments

pihat — Probability estimates

n -by- $(k - 1)$ matrix

Probability estimates for each multinomial category, returned as an n -by- $(k - 1)$ matrix, where n is the number of observations, and k is the number of response categories.

yhat — Count estimates

n -by- $k - 1$ matrix

Count estimates for the number in each response category, returned as an n -by- $k - 1$ matrix, where n is the number of observations, and k is the number of response categories.

dlow — Lower error bound

column vector

Lower error bound to compute the lower confidence bound for `pihat` or `yhat`, returned as a column vector.

The lower confidence bound for `pihat` is `pihat` minus `dlow`. Similarly, the lower confidence bound for `yhat` is `yhat` minus `dlow`. Confidence bounds are nonsimultaneous and only apply to the fitted curve, not to new observations.

dhi — Upper error bound

column vector

Upper error bound to compute the upper confidence bound for `pihat` or `yhat`, returned as a column vector.

The upper confidence bound for `pihat` is `pihat` plus `dhi`. Similarly, the upper confidence bound for `yhat` is `yhat` plus `dhi`. Confidence bounds are nonsimultaneous and only apply to the fitted curve, not to new observations.

Introduced in R2006b

moment

Central moment

Syntax

```
m = moment(X,order)
m = moment(X,order,'all')
m = moment(X,order,dim)
m = moment(X,order,vecdim)
```

Description

`m = moment(X,order)` returns the central moment of `X` for the order specified by `order`.

- If `X` is a vector, then `moment(X,order)` returns a scalar value that is the k -order central moment of the elements in `X`.
- If `X` is a matrix, then `moment(X,order)` returns a row vector containing the k -order central moment of each column in `X`.
- If `X` is a multidimensional array, then `moment(X,order)` operates along the first nonsingleton dimension of `X`.

`m = moment(X,order,'all')` returns the central moment of the specified order for all elements of `X`.

`m = moment(X,order,dim)` takes the central moment along the operating dimension `dim` of `X`.

`m = moment(X,order,vecdim)` returns the central moment over the dimensions specified in the vector `vecdim`. For example, if `X` is a 2-by-3-by-4 array, then `moment(X,1,[1 2])` returns a 1-by-1-by-4 array. Each element of the output array is the first-order central moment of the elements on the corresponding page of `X`.

Examples

Find Central Moment for Specified Order

Set the random seed for reproducibility of the results.

```
rng('default')
```

Generate a matrix with 6 rows and 5 columns.

```
X = randn(6,5)
```

```
X = 6×5
```

```
    0.5377    -0.4336     0.7254     1.4090     0.4889
    1.8339     0.3426    -0.0631     1.4172     1.0347
   -2.2588     3.5784     0.7147     0.6715     0.7269
    0.8622     2.7694    -0.2050    -1.2075    -0.3034
    0.3188    -1.3499    -0.1241     0.7172     0.2939
   -1.3077     3.0349     1.4897     1.6302    -0.7873
```

Find the third-order central moment of X.

```
m = moment(X,3)
```

```
m = 1×5
```

```
   -1.1143   -0.9973    0.1234   -1.1023   -0.1045
```

m is a row vector containing the third-order central moment of each column in X.

Find Central Moment Along Given Dimension

Find the central moment along different dimensions for a multidimensional array.

Set the random seed for reproducibility of the results.

```
rng('default')
```

Create a 4-by-3-by-2 array of random numbers.

```
X = randn([4,3,2])
```

```
X =
```

```
X(:,:,1) =
```

```
    0.5377    0.3188    3.5784
    1.8339   -1.3077    2.7694
   -2.2588   -0.4336   -1.3499
    0.8622    0.3426    3.0349
```

```
X(:,:,2) =
```

```
    0.7254   -0.1241    0.6715
   -0.0631    1.4897   -1.2075
    0.7147    1.4090    0.7172
   -0.2050    1.4172    1.6302
```

Find the fourth-order central moment of X along the default dimension.

```
m1 = moment(X,4)
```

```
m1 =
```

```
m1(:,:,1) =
```

```
    11.4427    0.3553    33.6733
```

```
m1(:,:,2) =
```

```
    0.0360    0.4902    2.3821
```

By default, `moment` operates along the first dimension of X whose size does not equal 1. In this case, this dimension is the first dimension of X. Therefore, `m1` is a 1-by-3-by-2 array.

Find the fourth-order central moment of X along the second dimension.

```
m2 = moment(X,4,2)
```

```
m2 =
```

```
m2(:,:,1) =
```

```

7.3476
13.8702
0.4625

```

```
m2(:, :, 2) =
```

```

0.0341
2.2389
0.0171
0.6766

```

m2 is a 4-by-1-by-2 array.

Find the fourth-order central moment of X along the third dimension.

```
m3 = moment(X, 4, 3)
```

```
m3 = 4×3
```

```

0.0001    0.0024    4.4627
0.8093    3.8273   15.6340
4.8866    0.7205    1.1412
0.0811    0.0833    0.2433

```

m3 is a 4-by-3 matrix.

Find Central Moment Along Vector of Dimensions

Find the central moment over multiple dimensions by using the 'all' and vecdim input arguments.

Set the random seed for reproducibility of the results.

```
rng('default')
```

Create a 4-by-3-by-2 array of random numbers.

```
X = randn([4 3 2])
```

```
X =  
X(:, :, 1) =  
  
    0.5377    0.3188    3.5784  
    1.8339   -1.3077    2.7694  
   -2.2588   -0.4336   -1.3499  
    0.8622    0.3426    3.0349
```

```
X(:, :, 2) =  
  
    0.7254   -0.1241    0.6715  
   -0.0631    1.4897   -1.2075  
    0.7147    1.4090    0.7172  
   -0.2050    1.4172    1.6302
```

Find the third-order central moment of X.

```
mall = moment(X,3,'all')
```

```
mall = 0.2431
```

mall is the third-order central moment of the entire input data set X.

Find the third-order moment of each page of X by specifying the first and second dimensions.

```
mpage = moment(X,3,[1 2])
```

```
mpage =  
mpage(:, :, 1) =
```

```
    0.6002
```

```
mpage(:, :, 2) =
```

```
   -0.3475
```

For example, `mpage(1,1,2)` is the third-order central moment of the elements in `X(:, :, 2)`.

Find the third-order moment of the elements in each $X(i, :, :)$ slice by specifying the second and third dimensions.

```
mrow = moment(X,3,[2 3])
```

```
mrow = 4×1
```

```
    2.7552  
    0.0443  
   -0.7585  
    0.5340
```

For example, `mrow(1)` is the third-order central moment of the elements in $X(1, :, :)$.

Input Arguments

X — Input data

vector | matrix | multidimensional array

Input data that represents a sample from a population, specified as a vector, matrix, or multidimensional array.

- If X is a vector, then `moment(X,order)` returns a scalar value that is the k -order central moment of the elements in X .
- If X is a matrix, then `moment(X,order)` returns a row vector containing the k -order central moment of each column in X .
- If X is a multidimensional array, then `moment(X,order)` operates along the first nonsingleton dimension of X .

To specify the operating dimension when X is a matrix or an array, use the `dim` input argument.

Data Types: `single` | `double`

order — Order of central moment

positive integer

Order of the central moment, specified as a positive integer.

Data Types: `single` | `double`

dim — Dimension

positive integer

Dimension along which to operate, specified as a positive integer. If you do not specify a value for `dim`, then the default is the first nonsingleton dimension of `X`.

Consider the third-order central moment of a matrix `X`:

- If `dim` is equal to 1, then `moment(X,3,1)` returns a row vector that contains the third-order central moment of each column in `X`.
- If `dim` is equal to 2, then `moment(X,3,2)` returns a column vector that contains the third-order central moment of each row in `X`.

If `dim` is greater than `ndims(X)` or if `size(X,dim)` is 1, then `moment` returns an array of zeros the same size as `X`.

Data Types: `single` | `double`

vecdim — Vector of dimensions

positive integer vector

Vector of dimensions, specified as a positive integer vector. Each element of `vecdim` represents a dimension of the input array `X`. The output `m` has length 1 in the specified operating dimensions. The other dimension lengths are the same for `X` and `m`.

For example, if `X` is a 2-by-3-by-3 array, then `moment(X,1,[1 2])` returns a 1-by-1-by-3 array. Each element of the output array is the first-order central moment of the elements on the corresponding page of `X`.

Data Types: `single` | `double`

Output Arguments

m — Central moments

scalar | vector | matrix | multidimensional array

Central moments, returned as a scalar, vector, matrix, or multidimensional array.

Algorithms

The central moment of order k for a distribution is defined as

$$m_k = E(x - \mu)^k,$$

where μ is the mean of x , and $E(t)$ represents the expected value of the quantity t . The moment function computes a sample version of this population value.

$$m_k = \frac{1}{n} \sum_{i=1}^n (x_i - \bar{x})^k.$$

Note that the first-order central moment is zero, and the second-order central moment is the variance computed using a divisor of n rather than $n - 1$, where n is the length of the vector x or the number of rows in the matrix X .

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The 'all' and vecdim input arguments are not supported.
- The dim input argument must be a compile-time constant.
- If you do not specify the dim input argument, the working (or operating) dimension can be different in the generated code. As a result, run-time errors can occur. For more details, see “Automatic dimension restriction” (MATLAB Coder).

- If `order` is nonintegral and `X` is real, use `moment(complex(X),order)`.

For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “General Code Generation Workflow” on page 31-5.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Usage notes and limitations:

- The 'all' and `vecdim` input arguments are not supported.

For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

Introduced before R2006a

multcompare

Multiple comparison test

Syntax

```
c = multcompare(stats)
c = multcompare(stats,Name,Value)
[c,m] = multcompare( ___ )
[c,m,h] = multcompare( ___ )
[c,m,h,gnames] = multcompare( ___ )
```

Description

`c = multcompare(stats)` returns a matrix `c` of the pairwise comparison results from a multiple comparison test using the information contained in the `stats` structure. `multcompare` also displays an interactive graph of the estimates and comparison intervals. Each group mean is represented by a symbol, and the interval is represented by a line extending out from the symbol. Two group means are significantly different if their intervals are disjoint; they are not significantly different if their intervals overlap. If you use your mouse to select any group, then the graph will highlight all other groups that are significantly different, if any.

`c = multcompare(stats,Name,Value)` returns a matrix of pairwise comparison results, `c`, using additional options specified by one or more `Name,Value` pair arguments. For example, you can specify the confidence interval, or the type of critical value to use in the multiple comparison.

`[c,m] = multcompare(___)` also returns a matrix, `m`, which contains estimated values of the means (or whatever statistics are being compared) for each group and the corresponding standard errors. You can use any of the previous syntaxes.

`[c,m,h] = multcompare(___)` also returns a handle, `h`, to the comparison graph.

`[c,m,h,gnames] = multcompare(___)` also returns a cell array, `gnames`, which contains the names of the groups.

Examples

Multiple Comparison of Group Means

Load the sample data.

```
load carsmall
```

Perform a one-way analysis of variance (ANOVA) to see if there is any difference between the mileage of the cars by origin.

```
[p,t,stats] = anova1(MPG,Origin,'off');
```

Perform a multiple comparison of the group means.

```
[c,m,h,nms] = multcompare(stats);
```

multcompare displays the estimates with comparison intervals around them. You can click the graphs of each country to compare its mean to those of other countries.

Now display the mean estimates and the standard errors with the corresponding group names.

```
[nms num2cell(m)]
```

```
ans = 6x3 cell array
```

```

{'USA'   }    {[21.1328]}    {[0.8814]}
{'Japan' }    {[31.8000]}    {[1.8206]}
{'Germany'}  {[28.4444]}    {[2.3504]}
{'France' }  {[23.6667]}    {[4.0711]}
{'Sweden' }  {[22.5000]}    {[4.9860]}

```

```
{'Italy' } {[ 28]} {[7.0513]}
```

Multiple Comparisons for Two-Way ANOVA

Load the sample data.

```
load popcorn  
popcorn
```

```
popcorn = 6×3
```

```
5.5000  4.5000  3.5000  
5.5000  4.5000  4.0000  
6.0000  4.0000  3.0000  
6.5000  5.0000  4.0000  
7.0000  5.5000  5.0000  
7.0000  5.0000  4.5000
```

The data is from a study of popcorn brands and popper types (Hogg 1987). The columns of the matrix `popcorn` are brands (Gourmet, National, and Generic). The rows are popper types oil and air. In the study, researchers popped a batch of each brand three times with each popper. The values are the yield in cups of popped popcorn.

Perform a two-way ANOVA. Also compute the statistics that you need to perform a multiple comparison test on the main effects.

```
[~,~,stats] = anova2(popcorn,3,'off')
```

```
stats = struct with fields:  
  source: 'anova2'  
  sigmasq: 0.1389  
  colmeans: [6.2500 4.7500 4]  
  coln: 6  
  rowmeans: [4.5000 5.5000]  
  rown: 9  
  inter: 1  
  pval: 0.7462  
  df: 12
```

The `stats` structure includes

- The mean squared error (`sigmasq`)
- The estimates of the mean yield for each popcorn brand (`colmeans`)
- The number of observations for each popcorn brand (`coln`)
- The estimate of the mean yield for each popper type (`rowmeans`)
- The number of observations for each popper type (`rown`)
- The number of interactions (`inter`)
- The p -value that shows the significance level of the interaction term (`pval`)
- The error degrees of freedom (`df`).

Perform a multiple comparison test to see if the popcorn yield differs between pairs of popcorn brands (columns).

```
c = multcompare(stats)
```

Note: Your model includes an interaction term. A test of main effects can be difficult to interpret when the model includes interactions.

$c = 3 \times 6$

1.0000	2.0000	0.9260	1.5000	2.0740	0.0000
1.0000	3.0000	1.6760	2.2500	2.8240	0.0000
2.0000	3.0000	0.1760	0.7500	1.3240	0.0116

The first two columns of c show the groups that are compared. The fourth column shows the difference between the estimated group means. The third and fifth columns show the lower and upper limits for 95% confidence intervals for the true mean difference. The sixth column contains the p -value for a hypothesis test that the corresponding mean difference is equal to zero. All p -values (0, 0, and 0.0116) are very small, which indicates that the popcorn yield differs across all three brands.

The figure shows the multiple comparison of the means. By default, the group 1 mean is highlighted and the comparison interval is in blue. Because the comparison intervals for the other two groups do not intersect with the intervals for the group 1 mean, they are highlighted in red. This lack of intersection indicates that both means are different than group 1 mean. Select other group means to confirm that all group means are significantly different from each other.

Perform a multiple comparison test to see the popcorn yield differs between the two popper types (rows).

```
c = multcompare(stats, 'Estimate', 'row')
```

Note: Your model includes an interaction term. A test of main effects can be difficult to interpret when the model includes interactions.

```
c = 1×6
    1.0000    2.0000   -1.3828   -1.0000   -0.6172    0.0001
```

The small p -value of 0.0001 indicates that the popcorn yield differs between the two popper types (air and oil). The figure shows the same results. The disjoint comparison intervals indicate that the group means are significantly different from each other.

Multiple Comparisons for Three-Way ANOVA

Load the sample data.

```
y = [52.7 57.5 45.9 44.5 53.0 57.0 45.9 44.0]';
g1 = [1 2 1 2 1 2 1 2];
g2 = {'hi'; 'hi'; 'lo'; 'lo'; 'hi'; 'hi'; 'lo'; 'lo'};
g3 = {'may'; 'may'; 'may'; 'may'; 'june'; 'june'; 'june'; 'june'};
```

y is the response vector and $g1$, $g2$, and $g3$ are the grouping variables (factors). Each factor has two levels, and every observation in y is identified by a combination of factor levels. For example, observation $y(1)$ is associated with level 1 of factor $g1$, level 'hi' of factor $g2$, and level 'may' of factor $g3$. Similarly, observation $y(6)$ is associated with level 2 of factor $g1$, level 'hi' of factor $g2$, and level 'june' of factor $g3$.

Test if the response is the same for all factor levels. Also compute the statistics required for multiple comparison tests.

```
[~,~,stats] = anovan(y,{g1 g2 g3},'model','interaction',...
    'varnames',{'g1','g2','g3'});
```

Analysis of Variance

Source	Sum Sq.	d. f.	Mean Sq.	F	Prob>F
g1	3.781	1	3.781	336.11	0.0347
g2	199.001	1	199.001	17689	0.0048
g3	0.061	1	0.061	5.44	0.2578
g1*g2	18.301	1	18.301	1626.78	0.0158
g1*g3	0.211	1	0.211	18.78	0.1444
g2*g3	0.011	1	0.011	1	0.5
Error	0.011	1	0.011		
Total	221.379	7			

Constrained (Type III) sums of squares.

The p -value of 0.2578 indicates that the mean responses for levels 'may' and 'june' of factor g3 are not significantly different. The p -value of 0.0347 indicates that the mean responses for levels 1 and 2 of factor g1 are significantly different. Similarly, the p -value of 0.0048 indicates that the mean responses for levels 'hi' and 'lo' of factor g2 are significantly different.

Perform multiple comparison tests to find out which groups of the factors g1 and g2 are significantly different.

```
results = multcompare(stats, 'Dimension', [1 2])
```

results = 6x6

1.0000	2.0000	-6.8604	-4.4000	-1.9396	0.0280
1.0000	3.0000	4.4896	6.9500	9.4104	0.0177
1.0000	4.0000	6.1396	8.6000	11.0604	0.0143
2.0000	3.0000	8.8896	11.3500	13.8104	0.0108
2.0000	4.0000	10.5396	13.0000	15.4604	0.0095
3.0000	4.0000	-0.8104	1.6500	4.1104	0.0745

multcompare compares the combinations of groups (levels) of the two grouping variables, g1 and g2. In the results matrix, the number 1 corresponds to the combination of level 1 of g1 and level hi of g2, the number 2 corresponds to the combination of level 2 of g1 and level hi of g2. Similarly, the number 3 corresponds to

the combination of level 1 of `g1` and level `lo` of `g2`, and the number 4 corresponds to the combination of level 2 of `g1` and level `lo` of `g2`. The last column of the matrix contains the p -values.

For example, the first row of the matrix shows that the combination of level 1 of `g1` and level `hi` of `g2` has the same mean response values as the combination of level 2 of `g1` and level `hi` of `g2`. The p -value corresponding to this test is 0.0280, which indicates that the mean responses are significantly different. You can also see this result in the figure. The blue bar shows the comparison interval for the mean response for the combination of level 1 of `g1` and level `hi` of `g2`. The red bars are the comparison intervals for the mean response for other group combinations. None of the red bars overlap with the blue bar, which means the mean response for the combination of level 1 of `g1` and level `hi` of `g2` is significantly different from the mean response for other group combinations.

You can test the other groups by clicking on the corresponding comparison interval for the group. The bar you click on turns to blue. The bars for the groups that are significantly different are red. The bars for the groups that are not significantly different are gray. For example, if you click on the comparison interval for the combination of level 1 of `g1` and level `lo` of `g2`, the comparison interval for the combination of level 2 of `g1` and level `lo` of `g2` overlaps, and is therefore gray. Conversely, the other comparison intervals are red, indicating significant difference.

Input Arguments

stats — Test data

structure

Test data, specified as a structure. You can create a structure using one of the following functions:

- `anova1` — One-way analysis of variance.
- `anova2` — Two-way analysis of variance.
- `anovan` — N -way analysis of variance.
- `aoctool` — Interactive analysis of covariance tool.
- `friedman` — Friedman's test.
- `kruskalwallis` — Kruskal-Wallis test.

`multcompare` does not support multiple comparisons using `anovan` output for a model that includes random or nested effects. The calculations for a random effects model produce a warning that all effects are treated as fixed. Nested models are not accepted.

Data Types: `struct`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'Alpha', 0.01, 'CType', 'bonferroni', 'Display', 'off'` computes the Bonferroni critical values, conducts the hypothesis tests at the 1% significance level, and omits the interactive display.

Alpha — Significance level

`0.05` (default) | scalar value in the range (0,1)

Significance level of the multiple comparison test, specified as the comma-separated pair consisting of `'Alpha'` and a scalar value in the range (0,1). The value specified for `'Alpha'` determines the $100 \times (1 - \alpha)$ confidence levels of the intervals returned in the matrix `c` and in the figure.

Example: `'Alpha', 0.01`

Data Types: `single` | `double`

CType — Type of critical value

`'tukey-kramer'` (default) | `'hsd'` | `'lsd'` | `'bonferroni'` | `'dunn-sidak'` | `'scheffe'`

Type of critical value to use for the multiple comparison, specified as the comma-separated pair consisting of `'CType'` and one of the following.

Value	Description
<code>'tukey-kramer'</code> or <code>'hsd'</code>	Tukey's honest significant difference criterion on page 9-31
<code>'bonferroni'</code>	Bonferroni method on page 9-32
<code>'dunn-sidak'</code>	Dunn and Sidák's approach on page 9-32

Value	Description
'lsd'	Fisher's least significant difference procedure on page 9-33
'scheffe'	Scheffé's S procedure on page 9-33

Example: 'CType', 'bonferroni'

Display – Display toggle

'on' (default) | 'off'

Display toggle, specified as the comma-separated pair consisting of 'Display' and either 'on' or 'off'. If you specify 'on', then `multcompare` displays a graph of the estimates and their comparison intervals. If you specify 'off', then `multcompare` omits the graph.

Example: 'Display', 'off'

Dimension – Dimension over which to calculate marginal means

1 (default) | positive integer value | vector of positive integer values

A vector specifying the dimension or dimensions over which to calculate the population marginal means, specified as a positive integer value, or a vector of such values. Use the 'Dimension' name-value pair only if you create the input structure `stats` using the function `anovan`.

For example, if you specify 'Dimension' as 1, then `multcompare` compares the means for each value of the first grouping variable, adjusted by removing effects of the other grouping variables as if the design were balanced. If you specify 'Dimension' as [1,3], then `multcompare` computes the population marginal means for each combination of the first and third grouping variables, removing effects of the second grouping variable. If you fit a singular model, some cell means may not be estimable and any population marginal means that depend on those cell means will have the value NaN.

Population marginal means are described by Milliken and Johnson (1992) and by Searle, Speed, and Milliken (1980). The idea behind population marginal means is to remove any effect of an unbalanced design by fixing the values of the factors specified by 'Dimension', and averaging out the effects of other factors as if each factor combination occurred the same number of times. The definition of population marginal means does not depend on the number of observations at each factor combination. For designed experiments where the number of observations at each factor combination has no meaning, population marginal means can be easier to interpret than simple means ignoring other factors. For surveys and other studies where the number of observations at

each combination does have meaning, population marginal means may be harder to interpret.

Example: 'Dimension', [1,3]

Data Types: single | double

Estimate — Estimates to be compared

'column' (default) | 'row' | 'slope' | 'intercept' | 'pmm'

Estimates to be compared, specified as the comma-separated pair consisting of 'Estimate' and an allowable value. The allowable values for 'Estimate' depend on the function used to generate the input structure `stats`, according to the following table.

Source	Values
<code>anova1</code>	None. This name-value pair is ignored, and <code>multcompare</code> always compares the group means.
<code>anova2</code>	Either 'column' to compare column means, or 'row' to compare row means.
<code>anovan</code>	None. This name-value pair is ignored, and <code>multcompare</code> always compares the population marginal means as specified by the 'Dimension' name-value pair argument.
<code>aocool</code>	Either 'slope', 'intercept', or 'pmm' to compare slopes, intercepts, or population marginal means, respectively. If the analysis of covariance model did not include separate slopes, then 'slope' is not allowed. If it did not include separate intercepts, then no comparisons are possible.
<code>friedman</code>	None. This name-value pair is ignored, and <code>multcompare</code> always compares the average column ranks.
<code>kruskalwallis</code>	None. This name-value pair is ignored, and <code>multcompare</code> always compares the average group ranks.

Example: 'Estimate', 'row'

Output Arguments

c — Matrix of multiple comparison results

matrix of scalar values

Matrix of multiple comparison results, returned as a p -by-6 matrix of scalar values, where p is the number of pairs of groups. Each row of the matrix contains the result of one paired comparison test. Columns 1 and 2 contain the indices of the two samples being compared. Column 3 contains the lower confidence interval, column 4 contains the estimate, and column 5 contains the upper confidence interval. Column 6 contains the p -value for the hypothesis test that the corresponding mean difference is not equal to 0.

For example, suppose one row contains the following entries.

```
2.0000  5.0000  1.9442  8.2206  14.4971  0.0432
```

These numbers indicate that the mean of group 2 minus the mean of group 5 is estimated to be 8.2206, and a 95% confidence interval for the true difference of the means is [1.9442, 14.4971]. The p -value for the corresponding hypothesis test that the difference of the means of groups 2 and 5 is significantly different from zero is 0.0432.

In this example the confidence interval does not contain 0, so the difference is significant at the 5% significance level. If the confidence interval did contain 0, the difference would not be significant. The p -value of 0.0432 also indicates that the difference of the means of groups 2 and 5 is significantly different from 0.

m — Matrix of estimates

matrix of scalar values

Matrix of the estimates, returned as a matrix of scalar values. The first column of m contains the estimated values of the means (or whatever statistics are being compared) for each group, and the second column contains their standard errors.

h — Handle to the figure

handle

Handle to the figure containing the interactive graph, returned as a handle. The title of this graph contains instructions for interacting with the graph, and the x-axis label contains information about which means are significantly different from the selected mean. If you plan to use this graph for presentation, you may want to omit the title and the x-axis label. You can remove them using interactive features of the graph window, or you can use the following commands.

```
title('')  
xlabel('')
```

gnames — Group names

cell array of character vectors

Group names, returned as a cell array of character vectors. Each row of `gnames` contains the name of a group.

Definitions

Multiple Comparison Tests

Analysis of variance compares the means of several groups to test the hypothesis that they are all equal, against the general alternative that they are not all equal. Sometimes this alternative may be too general. You may need information about which pairs of means are significantly different, and which are not. A *multiple comparison test* can provide this information.

When you perform a simple *t*-test of one group mean against another, you specify a significance level that determines the cutoff value of the *t*-statistic. For example, you can specify the value `alpha = 0.05` to insure that when there is no real difference, you will incorrectly find a significant difference no more than 5% of the time. When there are many group means, there are also many pairs to compare. If you applied an ordinary *t*-test in this situation, the `alpha` value would apply to each comparison, so the chance of incorrectly finding a significant difference would increase with the number of comparisons. Multiple comparison procedures are designed to provide an upper bound on the probability that *any* comparison will be incorrectly found significant.

Introduced before R2006a

multcompare

Class: RepeatedMeasuresModel

Multiple comparison of estimated marginal means

Syntax

```
tbl = multcompare(rm,var)
tbl = multcompare(rm,var,Name,Value)
```

Description

`tbl = multcompare(rm,var)` returns multiple comparisons of the estimated marginal means based on the variable `var` in the repeated measures model `rm`.

`tbl = multcompare(rm,var,Name,Value)` returns multiple comparisons of the estimated marginal means with additional options specified by one or more `Name, Value` pair arguments.

For example, you can specify the comparison type or which variable to group by.

Input Arguments

rm — Repeated measures model

RepeatedMeasuresModel object

Repeated measures model, returned as a RepeatedMeasuresModel object.

For properties and methods of this object, see RepeatedMeasuresModel.

var — Variables for which to compute marginal means

character vector | string scalar

Variables for which to compute the marginal means, specified as a character vector or string scalar representing the name of a between- or within-subjects factor in `rm`. If `var` is a between-subjects factor, it must be categorical.

Data Types: `char` | `string`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Alpha — Significance level

0.05 (default) | scalar value in the range of 0 through 1

Significance level of the confidence intervals for population marginal means, specified as the comma-separated pair consisting of `'alpha'` and a scalar value in the range of 0 through 1. The confidence level is $100*(1-\alpha)\%$.

Example: `'alpha', 0.01`

Data Types: `double` | `single`

By — Factor to perform comparisons by

character vector | string scalar

Factor to do the comparisons by, specified as the comma-separated pair consisting of `'By'` and a character vector or string scalar. The comparison between levels of `var` occurs separately for each value of the factor you specify.

If you have more than one between-subjects factors, *A*, *B*, and *C*, and if you want to do the comparisons of *A* levels separately for each level of *C*, then specify *A* as the `var` argument and specify *C* using the `'By'` argument as follows.

Example: `'By', C`

Data Types: `char` | `string`

ComparisonType — Type of critical value to use

`'tukey-kramer'` (default) | `'dunn-sidak'` | `'bonferroni'` | `'scheffe'` | `'lsd'`

Type of critical value to use, specified as the comma-separated pair consisting of `'ComparisonType'` and one of the following.

Comparison Type	Definition
'tukey-kramer'	<p>Default. Also called Tukey's Honest Significant Difference procedure. It is based on the Studentized range distribution. According to the unproven Tukey-Kramer conjecture, it is also accurate for problems where the quantities being compared are correlated, as in analysis of covariance with unbalanced covariate values.</p>
'dunn-sidak'	<p>Use critical values from the t distribution, after an adjustment for multiple comparisons that was proposed by Dunn and proved accurate by Sidák. The critical value is</p> $ t = \frac{ \bar{y}_i - \bar{y}_j }{\sqrt{MSE\left(\frac{1}{n_i} + \frac{1}{n_j}\right)}} > t_{1 - \eta/2, v},$ <p>where</p> $\eta = 1 - (1 - \alpha)^{\frac{1}{\binom{k}{2}}}$ <p>and ng is the number of groups (marginal means). This procedure is similar to, but less conservative than, the Bonferroni procedure.</p>

Comparison Type	Definition
'bonferroni'	<p>Use critical values from the t distribution, after a Bonferroni adjustment to compensate for multiple comparisons. The critical value is</p> $t_{\alpha/2} \left(\frac{ng}{2} \right), v,$ <p>where ng is the number of groups (marginal means), and v is the error degrees of freedom. This procedure is conservative, but usually less so than the Scheffé procedure.</p>
'scheffe'	<p>Use critical values from Scheffé's S procedure, derived from the F distribution. The critical value is</p> $\sqrt{(ng - 1)F_{\alpha, ng - 1, v}},$ <p>where ng is the number of groups (marginal means), and v is the error degrees of freedom. This procedure provides a simultaneous confidence level for comparisons of all linear combinations of the means, and it is conservative for comparisons of simple differences of pairs.</p>
'lsd'	<p>Least significant difference. This option uses plain t-tests. The critical value is</p> $t_{\alpha/2, v},$ <p>where v is the error degrees of freedom. It provides no protection against the multiple comparison problem.</p>

Example: 'ComparisonType', 'dunn-sidak'

Output Arguments

tbl — Results of multiple comparison

table

Results of multiple comparisons of estimated marginal means, returned as a table. `tbl` has the following columns.

Column Name	Description
Difference	Estimated difference between the corresponding two marginal means
StdErr	Standard error of the estimated difference between the corresponding two marginal means
pValue	<i>p</i> -value for a test that the difference between the corresponding two marginal means is 0
Lower	Lower limit of simultaneous 95% confidence intervals for the true difference
Upper	Upper limit of simultaneous 95% confidence intervals for the true difference

Examples

Multiple Comparison of Estimated Marginal Means

Load the sample data.

```
load fisheriris
```

The column vector `species` consists of iris flowers of three different species: `setosa`, `versicolor`, and `virginica`. The double matrix `meas` consists of four types of measurements on the flowers: the length and width of sepals and petals in centimeters, respectively.

Store the data in a table array.

```
t = table(species,meas(:,1),meas(:,2),meas(:,3),meas(:,4),...
'VariableNames',{'species','meas1','meas2','meas3','meas4'});
Meas = dataset([1 2 3 4]','VarNames',{'Measurements'});
```

Fit a repeated measures model, where the measurements are the responses and the species is the predictor variable.

```
rm = fitrm(t, 'meas1-meas4~species', 'WithinDesign', Meas);
```

Perform a multiple comparison of the estimated marginal means of species.

```
tbl = multcompare(rm, 'species')
```

```
tbl=6x7 table
  species_1    species_2    Difference    StdErr    pValue    Lower
  _____    _____    _____    _____    _____    _____
  'setosa'      'versicolor'    -1.0375     0.060539    9.5606e-10    -1.1794
  'setosa'      'virginica'     -1.7495     0.060539    9.5606e-10    -1.8914
  'versicolor'  'setosa'        1.0375     0.060539    9.5606e-10     0.89562
  'versicolor'  'virginica'     -0.712     0.060539    9.5606e-10    -0.85388
  'virginica'   'setosa'        1.7495     0.060539    9.5606e-10     1.6076
  'virginica'   'versicolor'    0.712     0.060539    9.5606e-10     0.57012
```

The small *p*-values (in the `pValue` field) indicate that the estimated marginal means for the three species significantly differ from each other.

Perform Multiple Comparisons with Specified Options

Load the sample data.

```
load repeatedmeas
```

The table `between` includes the between-subject variables `age`, `IQ`, `group`, `gender`, and eight repeated measures `y1` through `y8` as responses. The table `within` includes the within-subject variables `w1` and `w2`. This is simulated data.

Fit a repeated measures model, where the repeated measures `y1` through `y8` are the responses, and `age`, `IQ`, `group`, `gender`, and the `group-gender` interaction are the predictor variables. Also specify the within-subject design matrix.

```
R = fitrm(between, 'y1-y8 ~ Group*Gender + Age + IQ', 'WithinDesign', within);
```

Perform a multiple comparison of the estimated marginal means based on the variable `Group`.

```
T = multcompare(R, 'Group')
```

T=6×7 table

Group_1	Group_2	Difference	StdErr	pValue	Lower	Upper
A	B	4.9875	5.6271	0.65436	-9.1482	19.123
A	C	23.094	5.9261	0.0021493	8.2074	37.981
B	A	-4.9875	5.6271	0.65436	-19.123	9.1482
B	C	18.107	5.8223	0.013588	3.4805	32.732
C	A	-23.094	5.9261	0.0021493	-37.981	-8.2074
C	B	-18.107	5.8223	0.013588	-32.732	-3.4805

The small p -value of 0.0021493 indicates that there is significant difference between the marginal means of groups A and C. The p -value of 0.65436 indicates that the difference between the marginal means for groups A and B is not significantly different from 0.

`multcompare` uses the Tukey-Kramer test statistic by default. Change the comparison type to the Scheffe procedure.

```
T = multcompare(R, 'Group', 'ComparisonType', 'Scheffe')
```

T=6×7 table

Group_1	Group_2	Difference	StdErr	pValue	Lower	Upper
A	B	4.9875	5.6271	0.67981	-9.7795	19.755
A	C	23.094	5.9261	0.0031072	7.5426	38.646
B	A	-4.9875	5.6271	0.67981	-19.755	9.7795
B	C	18.107	5.8223	0.018169	2.8273	33.386
C	A	-23.094	5.9261	0.0031072	-38.646	-7.5426
C	B	-18.107	5.8223	0.018169	-33.386	-2.8273

The Scheffe test produces larger p -values, but similar conclusions.

Perform multiple comparisons of estimated marginal means based on the variable `Group` for each gender separately.

```
T = multcompare(R, 'Group', 'By', 'Gender')
```

T=12×8 table

Gender	Group_1	Group_2	Difference	StdErr	pValue	Lower
--------	---------	---------	------------	--------	--------	-------

Female	A	B	4.1883	8.0177	0.86128	-15.953
Female	A	C	24.565	8.2083	0.017697	3.9449
Female	B	A	-4.1883	8.0177	0.86128	-24.329
Female	B	C	20.376	8.1101	0.049957	0.0033459
Female	C	A	-24.565	8.2083	0.017697	-45.184
Female	C	B	-20.376	8.1101	0.049957	-40.749
Male	A	B	5.7868	7.9498	0.74977	-14.183
Male	A	C	21.624	8.1829	0.038022	1.0676
Male	B	A	-5.7868	7.9498	0.74977	-25.757
Male	B	C	15.837	8.0511	0.14414	-4.3881
Male	C	A	-21.624	8.1829	0.038022	-42.179
Male	C	B	-15.837	8.0511	0.14414	-36.062

The results indicate that the difference between marginal means for groups A and B is not significant from 0 for either gender (corresponding p -values are 0.86128 for females and 0.74977 for males). The difference between marginal means for groups A and C is significant for both genders (corresponding p -values are 0.017697 for females and 0.038022 for males). While the difference between marginal means for groups B and C is significantly different from 0 for females (p -value is 0.049957), it is not significantly different from 0 for males (p -value is 0.14414).

multivarichart

Multivari chart for grouped data

Syntax

```
multivarichart(y, GROUP)
multivarichart(Y)
multivarichart(..., param1, val1, param2, val2, ...)
[charthandle, AXESH] = multivarichart(...)
```

Description

`multivarichart(y, GROUP)` displays the multivari chart for the vector `y` grouped by entries in `GROUP` that can be a cell array or a matrix. If `GROUP` is a cell array, then each cell in `GROUP` must contain a grouping variable that is a categorical vector, numeric vector, character matrix, string array, or single-column cell array of character vectors. If `GROUP` is a numeric matrix, then its columns represent different grouping variables. Each grouping variable must have the same number of elements as `y`. The number of grouping variables must be 2, 3, or 4.

Each subplot of the plot matrix contains a multivari chart for the first and second grouping variables. The x-axis in each subplot indicates values of the first grouping variable. The legend at the bottom of the figure window indicates values of the second grouping variable. The subplot at position (i, j) is the multivari chart for the subset of `y` at the i th level of the third grouping variable and the j th level of the fourth grouping variable. If the third or fourth grouping variable is absent, it is considered to have only one level.

`multivarichart(Y)` displays the multivari chart for a matrix `Y`. The data in different columns represent changes in one factor. The data in different rows represent changes in another factor.

`multivarichart(..., param1, val1, param2, val2, ...)` specifies one or more of the following name/value pairs:

- 'varnames' — Grouping variable names in a character matrix, a string array, or a cell array of character vectors, one per grouping variable. Default names are 'X1', 'X2', ...
- 'plotorder' — 'sorted' or a vector containing a permutation of the integers from 1 to the number of grouping variables.

If 'plotorder' is 'sorted', the grouping variables are rearranged in descending order according to the number of levels in each variable.

If 'plotorder' is a vector, it indicates the order in which each grouping variable should be plotted. For example, [2, 3, 1, 4] indicates that the second grouping variable should be used as the x-axis of each subplot, the third grouping variable should be used as the legend, the first grouping variable should be used as the columns of the plot, and the fourth grouping variable should be used as the rows of the plot.

[charthandle, AXESH] = multivarichart(...) returns a handle charthandle to the figure window and a matrix AXESH of handles to the subplot axes.

Examples

Multivari Chart for Grouped Data

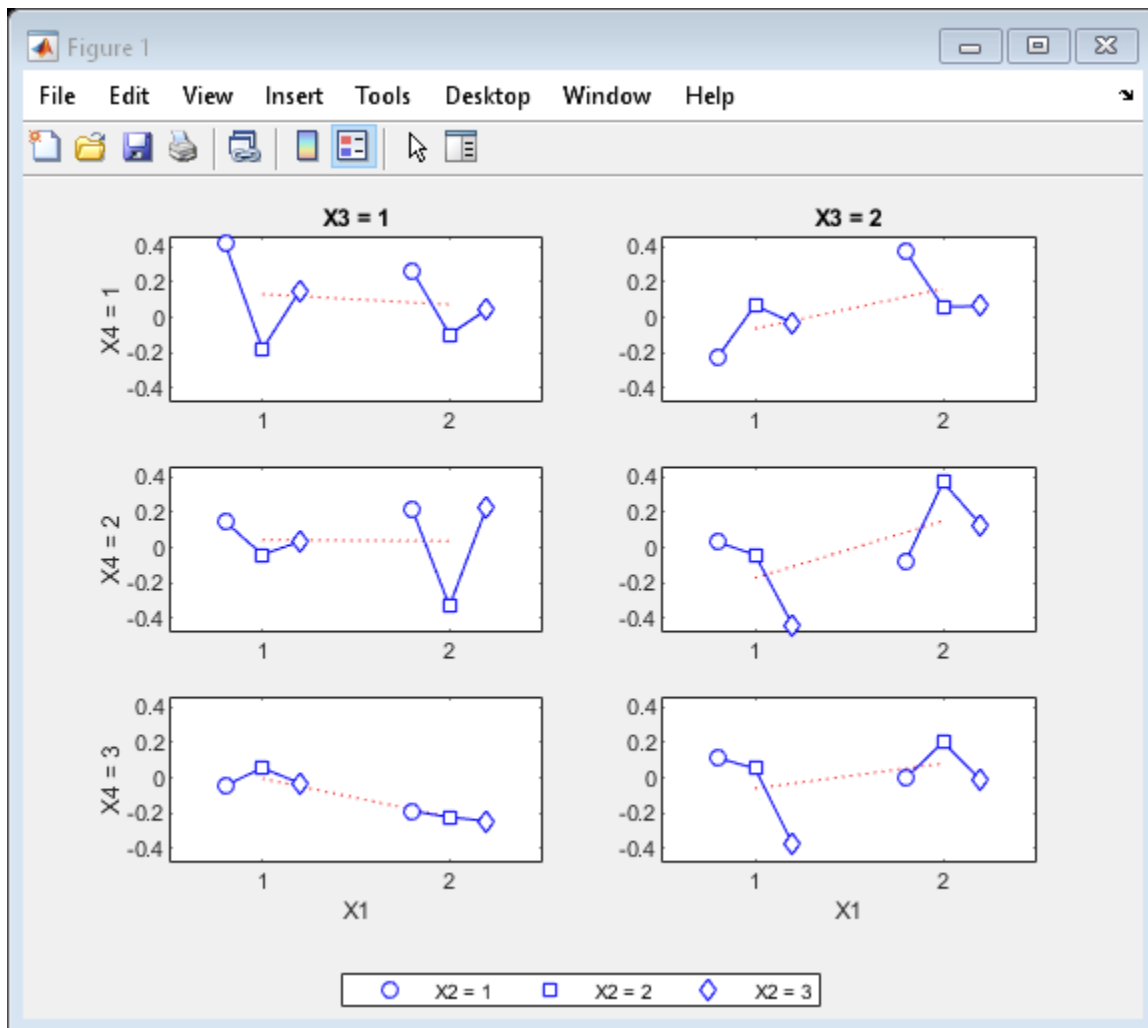

Display a multivari chart for data with two grouping variables.

```
rng default; % For reproducibility
y = randn(100,1); % Randomly generate response
group = [ceil(3*rand(100,1)) ceil(2*rand(100,1))];
multivarichart(y,group)
```

Display a multivari chart for data with four grouping variables.

```
y = randn(1000,1); % Randomly generate response
group = {ceil(2*rand(1000,1)),ceil(3*rand(1000,1)), ...
         ceil(2*rand(1000,1)),ceil(3*rand(1000,1))};
multivarichart(y,group)
```

mvksdensity

Kernel smoothing function estimate for multivariate data

Syntax

```
f = mvksdensity(x,pts,'Bandwidth',bw)
f = mvksdensity(x,pts,'Bandwidth',bw,Name,Value)
```

Description

`f = mvksdensity(x,pts,'Bandwidth',bw)` computes a probability density estimate of the sample data in the n -by- d matrix `x`, evaluated at the points in `pts` using the required name-value pair argument value `bw` for the bandwidth value. The estimation is based on a product Gaussian kernel function.

For univariate or bivariate data, use `ksdensity` instead.

`f = mvksdensity(x,pts,'Bandwidth',bw,Name,Value)` returns any of the previous output arguments, using additional options specified by one or more `Name,Value` pair arguments. For example, you can define the function type that `mvksdensity` evaluates, such as probability density, cumulative probability, or survivor function. You can also assign weights to the input values.

Examples

Estimate Multivariate Kernel Density

Load the Hald cement data.

```
load hald
```

The data measures the heat of hardening for 13 different cement compositions. The predictor matrix `ingredients` contains the percent composition for each of four cement

ingredients. The response matrix `heat` contains the heat of hardening (in cal/g) after 180 days.

Estimate the kernel density for the first three observations in `ingredients`.

```
xi = ingredients(1:3,:);  
f = mvksdensity(ingredients,xi,'Bandwidth',0.8);
```

Estimate Multivariate Kernel Density Using Grids

Load the Hald cement data.

```
load hald
```

The data measures the heat of hardening for 13 different cement compositions. The predictor matrix `ingredients` contains the percent composition for each of four cement ingredients. The response matrix `heat` contains the heat of hardening (in cal/g) after 180 days.

Create a array of points at which to estimate the density. First, define the range and spacing for each variable, using a similar number of points in each dimension.

```
gridx1 = 0:2:22;  
gridx2 = 20:5:80;  
gridx3 = 0:2:24;  
gridx4 = 5:5:65;
```

Next, use `ndgrid` to generate a full grid of points using the defined range and spacing.

```
[x1,x2,x3,x4] = ndgrid(gridx1,gridx2,gridx3,gridx4);
```

Finally, transform and concatenate to create an array that contains the points at which to estimate the density. This array has one column for each variable.

```
x1 = x1(:, :)';  
x2 = x2(:, :)';  
x3 = x3(:, :)';  
x4 = x4(:, :)';  
xi = [x1(:) x2(:) x3(:) x4(:)];
```

Estimate the density.

```
f = mvksdensity(ingredients,xi,...
    'Bandwidth',[4.0579 10.7345 4.4185 11.5466],...
    'Kernel','normpdf');
```

View the size of `xi` and `f` to confirm that `mvksdensity` calculates the density at each point in `xi`.

```
size_xi = size(xi)
```

```
size_xi = 1×2
```

```
    26364         4
```

```
size_f = size(f)
```

```
size_f = 1×2
```

```
    26364         1
```

Input Arguments

x — Sample data

numeric matrix

Sample data for which `mvksdensity` returns the probability density estimate, specified as an n -by- d matrix of numeric values. n is the number of data points (rows) in `x`, and d is the number of dimensions (columns).

Data Types: `single` | `double`

pts — Points at which to evaluate `f`

matrix

Points at which to evaluate the probability density estimate `f`, specified as a matrix with the same number of columns as `x`. The returned estimate `f` and `pts` have the same number of rows.

Data Types: `single` | `double`

bw — Value for the bandwidth of the kernel smoothing window

scalar value | d -element vector

Value for the bandwidth of the kernel-smoothing window, specified as a scalar value or d -element vector. d is the number of dimensions (columns) in the sample data x . If `bw` is a scalar value, it applies to all dimensions.

If you specify `'BoundaryCorrection'` as `'log'` (default) and `'Support'` as either `'positive'` or a two-row matrix, `mvksdensity` converts bounded data to be unbounded by using log transformation. The value of `bw` is on the scale of the transformed values.

Silverman's rule of thumb for the bandwidth is

$$b_i = \sigma_i \left\{ \frac{4}{(d+2)n} \right\}^{1/(d+4)}, \quad i = 1, 2, \dots, d,$$

where d is the number of dimensions, n is the number of observations, and σ_i is the standard deviation of the i^{th} variate [4].

Example: `'Bandwidth',0.8`

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1, ...,NameN,ValueN`.

Example: `'Kernel','triangle','Function','cdf'` specifies that `mvksdensity` estimates the cdf of the sample data using the triangle kernel function.

BoundaryCorrection — Boundary correction method

`'log'` (default) | `'reflection'`

Boundary correction method, specified as the comma-separated pair consisting of `'BoundaryCorrection'` and either `'log'` or `'reflection'`.

Value	Description
'log'	<p>mvksdensity converts bounded data to be unbounded by using one of the following transformations. Then, it transforms back to the original bounded scale after density estimation.</p> <ul style="list-style-type: none"> • If you specify 'Support', 'positive', then mvksdensity applies $\log(x_j)$ for each dimension, where x_j is the jth column of the input argument x. • If you specify 'Support' as a two-row matrix consisting of the lower and upper limits for each dimension, then mvksdensity applies $\log((x_j - L_j)/(U_j - x_j))$ for each dimension, where L_j and U_j are the lower and upper limits of the jth dimension, respectively. <p>The value of bw is on the scale of the transformed values.</p>
'reflection'	mvksdensity augments bounded data by adding reflected data near the boundaries, then it returns estimates corresponding to the original support. For details, see “Reflection Method” on page 32-4336.

mvksdensity applies boundary correction only when you specify 'Support' as a value other than 'unbounded'.

Example: 'BoundaryCorrection', 'reflection'

Function — Function to estimate

'pdf' (default) | 'cdf' | 'survivor'

Function to estimate, specified as the comma-separated pair consisting of 'Function' and one of the following.

Value	Description
'pdf'	Probability density function
'cdf'	Cumulative distribution function
'survivor'	Survivor function

Example: 'Function', 'cdf'

Kernel — Type of kernel smoother

'normal' (default) | 'box' | 'triangle' | 'epanechnikov' | function handle | character vector | string scalar

Type of kernel smoother, specified as the comma-separated pair consisting of 'Kernel' and one of the following.

Value	Description
'normal'	Normal (Gaussian) kernel
'box'	Box kernel
'triangle'	Triangular kernel
'epanechnikov'	Epanechnikov kernel

You can also specify a kernel function that is a custom or built-in function. Specify the function as a function handle (for example, @myfunction or @normpdf) or as a character vector or string scalar (for example, 'myfunction' or 'normpdf'). The software calls the specified function with one argument that is an array of distances between data values and locations where the density is evaluated, normalized by the bandwidth in that dimension. The function must return an array of the same size containing the corresponding values of the kernel function.

mvksdensity applies the same kernel to each dimension.

Example: 'Kernel', 'box'

Support — Support for the density

'unbounded' (default) | 'positive' | 2-by-*d* matrix

Support for the density, specified as the comma-separated pair consisting of 'support' and one of the following.

Value	Description
'unbounded'	Allow the density to extend over the whole real line
'positive'	Restrict the density to positive values
2-by- <i>d</i> matrix	Specify the finite lower and upper bounds for the support of the density. The first row contains the lower limits and the second row contains the upper limits. Each column contains the limits for one dimension of <i>x</i> .

'Support' can also be a combination of positive, unbounded, and bounded variables specified as [0 -Inf L; Inf Inf U].

Example: 'Support', 'positive'

Data Types: single | double | char | string

Weights — Weights for sample data

vector

Weights for sample data, specified as the comma-separated pair consisting of 'Weights' and a vector of length `size(x,1)`, where `x` is the sample data.

Example: 'Weights', `xw`

Data Types: single | double

Output Arguments

f — Estimated function values

vector

Estimated function values, returned as a vector. `f` and `pts` have the same number of rows.

Definitions

Multivariate Kernel Distribution

A multivariate kernel distribution is a nonparametric representation of the probability density function (pdf) of a random vector. You can use a kernel distribution when a parametric distribution cannot properly describe the data, or when you want to avoid making assumptions about the distribution of the data. A multivariate kernel distribution is defined by a smoothing function and a bandwidth matrix, which control the smoothness of the resulting density curve.

The multivariate kernel density estimator is the estimated pdf of a random vector. Let $x = (x_1, x_2, \dots, x_d)'$ be a d -dimensional random vector with a density function f and let $y_i = (y_{i1}, y_{i2}, \dots, y_{id})'$ be a random sample drawn from f for $i = 1, 2, \dots, n$, where n is the number of random samples. For any real vectors of x , the multivariate kernel density estimator is given by

$$\widehat{f}_H(x) = \frac{1}{n} \sum_{i=1}^n K_H(x - y_i),$$

where $K_H(x) = |H|^{-1/2} K(H^{-1/2}x)$, $K(\cdot)$ is the kernel smoothing function, and H is the d -by- d bandwidth matrix.

`mvksdensity` uses a diagonal bandwidth matrix and a product kernel. That is, $H^{1/2}$ is a square diagonal matrix with the elements of vector (h_1, h_2, \dots, h_d) on the main diagonal. $K(x)$ takes the product form $K(x) = k(x_1)k(x_2) \cdots k(x_d)$, where $k(\cdot)$ is a one-dimensional kernel smoothing function. Then, the multivariate kernel density estimator becomes

$$\begin{aligned} \widehat{f}_H(x) &= \frac{1}{n} \sum_{i=1}^n K_H(x - y_i) = \frac{1}{nh_1 h_2 \cdots h_d} \sum_{i=1}^n K\left(\frac{x_1 - y_{i1}}{h_1}, \frac{x_2 - y_{i2}}{h_2}, \dots, \frac{x_d - y_{id}}{h_d}\right) \\ &= \frac{1}{nh_1 h_2 \cdots h_d} \sum_{i=1}^n \prod_{j=1}^d k\left(\frac{x_j - y_{ij}}{h_j}\right). \end{aligned}$$

The kernel estimator for the cumulative distribution function (cdf), for any real vectors of x , is given by

$$\widehat{F}_H(x) = \int_{-\infty}^{x_1} \int_{-\infty}^{x_2} \cdots \int_{-\infty}^{x_d} \widehat{f}_H(t) dt_d \cdots dt_2 dt_1 = \frac{1}{n} \sum_{i=1}^n \prod_{j=1}^d G\left(\frac{x_j - y_{ij}}{h_j}\right),$$

where $G(x_j) = \int_{-\infty}^{x_j} k(t_j) dt_j$.

Reflection Method

The reflection method is a boundary correction method that accurately finds kernel density estimators when a random variable has bounded support. If you specify 'BoundaryCorrection', 'reflection', `mvksdensity` uses the reflection method.

If you additionally specify 'Support' as a two-row matrix consisting of the lower and upper limits for each dimension, then `mvksdensity` finds the kernel estimator as follows.

- If 'Function' is 'pdf', then the kernel density estimator is

$$\widehat{f}_H(x) = \frac{1}{nh_1 h_2 \cdots h_d} \sum_{i=1}^n \prod_{j=1}^d \left[k\left(\frac{x_j - y_{ij}^-}{h_j}\right) + k\left(\frac{x_j - y_{ij}}{h_j}\right) + k\left(\frac{x_j - y_{ij}^+}{h_j}\right) \right] \text{ for } L_j \leq x_j \leq U_j,$$

where $y_{ij}^- = 2L_j - y_{ij}$, $y_{ij}^+ = 2U_j - y_{ij}$, and y_{ij} is the j th element of the i th sample data corresponding to $x(i, j)$ of the input argument x . L_j and U_j are the lower and upper limits of the j th dimension, respectively.

- If 'Function' is 'cdf', then the kernel estimator for cdf is

$$\widehat{F}_H(x) = \frac{1}{n} \sum_{i=1}^n \prod_{j=1}^d \left[G\left(\frac{x_j - y_{ij}^-}{h_j}\right) + G\left(\frac{x_j - y_{ij}}{h_j}\right) + G\left(\frac{x_j - y_{ij}^+}{h_j}\right) - G\left(\frac{L_j - y_{ij}^-}{h_j}\right) - G\left(\frac{L_j - y_{ij}}{h_j}\right) - G\left(\frac{L_j - y_{ij}^+}{h_j}\right) \right]$$

for $L_j \leq x_j \leq U_j$.

- To obtain a kernel estimator for a survivor function (when 'Function' is 'survivor'), mvksdensity uses both $\widehat{f}_H(x)$ and $\widehat{F}_H(x)$.

If you additionally specify 'Support' as 'positive' or a matrix including $[0 \text{ inf}]$, then mvksdensity finds the kernel density estimator by replacing $[L_j \ U_j]$ with $[0 \text{ inf}]$ in the above equations.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Names in name-value pair arguments, including 'Bandwidth', must be compile-time constants.
- Values in the following name-value pair arguments must also be compile-time constants: 'BoundaryCorrection', 'Function', and 'Kernel'. For example, to use the 'Function', 'cdf' name-value pair argument in the generated code, include `{coder.Constant('Function'), coder.Constant('cdf')}` in the `-args` value of `codegen`.
- The value of the 'Kernel' name-value pair argument cannot be a custom function handle. To specify a custom kernel function, use a character vector or string scalar.
- For the value of the 'Support' name-value pair argument, the compile-time data type must match the runtime data type.

For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “General Code Generation Workflow” on page 31-5.

Introduced in R2016a

mvncdf

Multivariate normal cumulative distribution function

Syntax

```
p = mvncdf(X)
p = mvncdf(X,mu,sigma)

p = mvncdf(xl,xu,mu,sigma)

p = mvncdf( ____,options)

[p,err] = mvncdf( ____ )
```

Description

`p = mvncdf(X)` returns the cumulative distribution function (cdf) of the multivariate normal distribution with zero mean and identity covariance matrix, evaluated at each row of `X`. For more information, see “Multivariate Normal Distribution” on page 32-4348.

`p = mvncdf(X,mu,sigma)` returns the cdf of the multivariate normal distribution with mean `mu` and covariance `sigma`, evaluated at each row of `X`.

Specify `[]` for `mu` to use its default value of zero when you want to specify only `sigma`.

`p = mvncdf(xl,xu,mu,sigma)` returns the multivariate normal cdf evaluated over the multidimensional rectangle with lower and upper limits defined by `xl` and `xu`, respectively.

`p = mvncdf(____,options)` specifies control parameters for the numerical integration used to compute `p`, using any of the input argument combinations in the previous syntaxes. Create the `options` argument using the `statset` function with any combination of the parameters `'TolFun'`, `'MaxFunEvals'`, and `'Display'`.

`[p,err] = mvncdf(____)` additionally returns an estimate of the error in `p`. For more information, see “Algorithms” on page 32-4348.

Examples

Standard Multivariate Normal Distribution cdf

Evaluate the cdf of a standard four-dimensional multivariate normal distribution at points with increasing coordinates in every dimension.

Create a matrix X of five four-dimensional points with increasing coordinates.

```
firstDim = (-2:2)';  
X = repmat(firstDim,1,4)
```

```
X = 5×4
```

```
    -2    -2    -2    -2  
    -1    -1    -1    -1  
     0     0     0     0  
     1     1     1     1  
     2     2     2     2
```

Evaluate the cdf at the points in X .

```
p = mvncdf(X)
```

```
p = 5×1
```

```
    0.0000  
    0.0006  
    0.0625  
    0.5011  
    0.9121
```

The cdf values increase because the coordinates of the points are increasing in every dimension.

Bivariate Normal Distribution cdf

Compute and plot the cdf of a bivariate normal distribution.

Define the mean vector `mu` and the covariance matrix `sigma`.

```
mu = [1 -1];  
sigma = [.9 .4; .4 .3];
```

Create a grid of 625 evenly spaced points in two-dimensional space.

```
[X1,X2] = meshgrid(linspace(-1,3,25)',linspace(-3,1,25)');  
X = [X1(:) X2(:)];
```

Evaluate the cdf of the normal distribution at the grid points.

```
p = mvncdf(X,mu,sigma);
```

Plot the cdf values.

```
Z = reshape(p,25,25);  
surf(X1,X2,Z)
```

Probability over Rectangular Region

Compute the probability over the unit square of a bivariate normal distribution, and create a contour plot of the results.

Define the bivariate normal distribution parameters `mu` and `sigma`.

```
mu = [0 0];  
sigma = [0.25 0.3; 0.3 1];
```

Compute the probability over the unit square.

```
p = mvncdf([0 0],[1 1],mu,sigma)
```

```
p = 0.2097
```

To visualize the result, first create a grid of evenly spaced points in two-dimensional space.

```
x1 = -3:.2:3;  
x2 = -3:.2:3;  
[X1,X2] = meshgrid(x1,x2);  
X = [X1(:) X2(:)];
```

Then, evaluate the pdf of the normal distribution at the grid points.

```
y = mvnpdf(X,mu,sigma);  
y = reshape(y,length(x2),length(x1));
```

Finally, create a contour plot of the multivariate normal distribution that includes the unit square.

```
contour(x1,x2,y,[0.0001 0.001 0.01 0.05 0.15 0.25 0.35])  
xlabel('x')  
ylabel('y')  
line([0 0 1 1 0],[1 0 0 1 1], 'LineStyle','--', 'Color','k')
```

Computing a multivariate cumulative probability requires significantly more work than computing a univariate probability. By default, the `mvncdf` function computes values to less than full machine precision, and returns an estimate of the error as an optional second output. View the error estimate in this case.

```
[p,err] = mvncdf([0 0],[1 1],mu,sigma)
```

```
p = 0.2097
```

```
err = 1.0000e-08
```

Error Estimates in cdf Calculation

Evaluate the cdf of a multivariate normal distribution at random points, and display the error estimates associated with the cdf calculation.

Generate four random points from a five-dimensional multivariate normal distribution with mean vector `mu` and covariance matrix `sigma`.

```
mu = [0.5 -0.3 0.2 0.1 -0.4];
sigma = 0.5*eye(5);
rng('default') % For reproducibility
X = mvnrnd(mu,sigma,4);
```

Find the cdf values `p` at the points in `X` and the associated error estimates `err`. Display a summary of the numerical calculations.

```
[p,err] = mvncdf(X,mu,sigma,statset('Display','final'))
```

```
Successfully satisfied error tolerance of 0.0001 in 8650 function evaluations.
Successfully satisfied error tolerance of 0.0001 in 8650 function evaluations.
Successfully satisfied error tolerance of 0.0001 in 8650 function evaluations.
Successfully satisfied error tolerance of 0.0001 in 8650 function evaluations.
```

```
p = 4×1
```

```
    0.1520
    0.0407
    0.0002

```

```
    0
    0.0496
    0.0012
    0.5949
```

Input Arguments

X — Evaluation points

numeric matrix

Evaluation points, specified as an n -by- d numeric matrix, where n is a positive scalar integer and d is the dimension of a single multivariate normal distribution. The rows of X correspond to observations (or points), and the columns correspond to variables (or coordinates).

Data Types: `single` | `double`

mu — Mean vector of multivariate normal distribution

vector of zeros (default) | numeric vector | numeric scalar

Mean vector of a multivariate normal distribution, specified as a 1-by- d numeric vector or a numeric scalar, where d is the dimension of the multivariate normal distribution. If μ is a scalar, then `mvncdf` replicates the scalar to match the size of X .

Data Types: `single` | `double`

sigma — Covariance matrix of multivariate normal distribution

identity matrix (default) | symmetric, positive definite matrix | numeric vector of diagonal entries

Covariance matrix of a multivariate normal distribution, specified as a d -by- d symmetric, positive definite matrix, where d is the dimension of the multivariate normal distribution. If the covariance matrix is diagonal, containing variances along the diagonal and zero covariances off it, then you can also specify `sigma` as a 1-by- d vector containing just the diagonal entries.

Data Types: `single` | `double`

xl — Rectangle lower limit

numeric vector

Rectangle lower limit, specified as a 1-by- d numeric vector.

Data Types: `single` | `double`

xu — Rectangle upper limit

numeric vector

Rectangle upper limit, specified as a 1-by- d numeric vector.

Data Types: `single` | `double`

options — Numerical integration options

structure

Numerical integration options, specified as a structure. Create the `options` argument by calling the `statset` function with any combination of the following parameters:

- `'TolFun'` — Maximum absolute error tolerance. The default value is $1e-8$ when $d < 4$, and $1e-4$ when $d \geq 4$.
- `'MaxFunEvals'` — Maximum number of integrand evaluations allowed when $d \geq 4$. The default value is $1e7$. The function ignores `'MaxFunEvals'` when $d < 4$.
- `'Display'` — Level of display output. The choices are `'off'` (the default), `'iter'`, and `'final'`. The function ignores `'Display'` when $d < 4$.

Example: `statset('TolFun',1e-7,'Display','final')`

Data Types: `struct`

Output Arguments

p — cdf values

numeric vector | numeric scalar

cdf values, returned as either an n -by-1 numeric vector, where n is the number of rows in X , or a numeric scalar representing the probability over the rectangular region specified by x_l and x_u .

err — Absolute error tolerance

positive numeric scalar

Absolute error tolerance, returned as a positive numeric scalar. For bivariate and trivariate distributions, the default absolute error tolerance is $1e-8$. For four or more dimensions, the default absolute error tolerance is $1e-4$. For more information, see “Algorithms” on page 32-4348.

Definitions

Multivariate Normal Distribution

The multivariate normal distribution is a generalization of the univariate normal distribution to two or more variables. It has two parameters, a mean vector μ and a covariance matrix Σ , that are analogous to the mean and variance parameters of a univariate normal distribution. The diagonal elements of Σ contain the variances for each variable, and the off-diagonal elements of Σ contain the covariances between variables.

The probability density function (pdf) of the d -dimensional multivariate normal distribution is

$$y = f(x, \mu, \Sigma) = \frac{1}{\sqrt{|\Sigma|(2\pi)^d}} \exp\left(-\frac{1}{2}(x-\mu)' \Sigma^{-1}(x-\mu)\right)$$

where x and μ are 1-by- d vectors and Σ is a d -by- d symmetric, positive definite matrix. Only `mvnrnd` allows positive semi-definite Σ matrices, which can be singular. The pdf cannot have the same form when Σ is singular.

The multivariate normal cumulative distribution function (cdf) evaluated at x is the probability that a random vector v , distributed as multivariate normal, lies within the semi-infinite rectangle with upper limits defined by x :

$$\Pr\{v(1) \leq x(1), v(2) \leq x(2), \dots, v(d) \leq x(d)\}.$$

Although the multivariate normal cdf does not have a closed form, `mvncdf` can compute cdf values numerically.

Tips

- In the one-dimensional case, `sigma` is the variance, not the standard deviation. For example, `mvncdf(1, 0, 4)` is the same as `normcdf(1, 0, 2)`, where 4 is the variance and 2 is the standard deviation.

Algorithms

For bivariate and trivariate distributions, `mvncdf` uses adaptive quadrature on a transformation of the t density, based on methods developed by Drezner and Wesolowsky

[1] [2] and by Genz [3]. For four or more dimensions, mvncdf uses a quasi-Monte Carlo integration algorithm based on methods developed by Genz and Bretz [4] [5].

Topics

“Multivariate Normal Distribution” on page B-106

Introduced in R2006a

mvnpdf

Multivariate normal probability density function

Syntax

```
y = mvnpdf(X)
y = mvnpdf(X,mu)
y = mvnpdf(X,mu,sigma)
```

Description

`y = mvnpdf(X)` returns an n -by-1 vector `y` containing the probability density function (pdf) of the d -dimensional multivariate normal distribution with zero mean and identity covariance matrix, evaluated at each row of the n -by- d matrix `X`. For more information, see “Multivariate Normal Distribution” on page 32-4360.

`y = mvnpdf(X,mu)` returns pdf values of points in `X`, where `mu` determines the mean of each associated multivariate normal distribution.

`y = mvnpdf(X,mu,sigma)` returns pdf values of points in `X`, where `sigma` determines the covariance of each associated multivariate normal distribution.

Specify `[]` for `mu` to use its default value of zero when you want to specify only `sigma`.

Examples

Standard Multivariate Normal pdf

Evaluate the pdf of a standard five-dimensional normal distribution at a set of random points.

Randomly sample eight points from the standard five-dimensional normal distribution.

```
mu = zeros(1,5);
sigma = eye(5);
```

```
rng('default') % For reproducibility
X = mvnrnd(mu,sigma,8)

X = 8x5

    0.5377    3.5784   -0.1241    0.4889   -1.0689

   -0.4336    0.7147    0.7172    0.8884    1.3703
    0.3426   -0.2050    1.6302   -1.1471   -1.7115
```

Evaluate the pdf of the distribution at the points in X.

```
y = mvnpdf(X)
```

```
y = 8x1
```

```
    0.0000
    0.0000
    0.0000
    0.0000
    0.0054
    0.0011
    0.0015
    0.0003
```

Find the point in X with the greatest pdf value.

```
[maxpdf,idx] = max(y)
```

```
maxpdf = 0.0054
```

```
idx = 5
```

```
maxPoint = X(idx,:)
```

```
maxPoint = 1x5
```

```
    0.3188    0.7254    0.6715    0.2939    0.3252
```

The fifth point in X has a greater pdf value than any of the other randomly selected points.

Multivariate Normal pdfs Evaluated at Different Points

Create six three-dimensional normal distributions, each with a distinct mean. Evaluate the pdf of each distribution at a different random point.

Specify the means μ and covariances σ of the distributions. Each distribution has the same covariance matrix—the identity matrix.

```
firstDim = (1:6)';
mu = repmat(firstDim,1,3)
```

```
mu = 6×3
```

```
    1    1    1
    2    2    2
    3    3    3
    4    4    4
    5    5    5
    6    6    6
```

```
sigma = eye(3)
```

```
sigma = 3×3
```

```
    1    0    0
    0    1    0
    0    0    1
```

Randomly sample once from each of the six distributions.

```
rng('default') % For reproducibility
X = mvnrnd(mu,sigma)
```

```
X = 6×3
```

```
    1.5377    0.5664    1.7254
    3.8339    2.3426    1.9369
    0.7412    6.5784    3.7147
```

```
4.8622    6.7694    3.7950
5.3188    3.6501    4.8759
4.6923    9.0349    7.4897
```

Evaluate the pdfs of the distributions at the points in `X`. The pdf of the first distribution is evaluated at the point `X(1, :)`, the pdf of the second distribution is evaluated at the point `X(2, :)`, and so on.

```
y = mvnpdf(X,mu)
```

```
y = 6×1
```

```
0.0384
0.0111
0.0000
0.0009
0.0241
0.0001
```

Multivariate Normal pdf

Evaluate the pdf of a two-dimensional normal distribution at a set of given points.

Specify the mean `mu` and covariance `sigma` of the distribution.

```
mu = [1 -1];
sigma = [0.9 0.4; 0.4 0.3];
```

Randomly sample from the distribution 100 times. Specify `X` as the matrix of sampled points.

```
rng('default') % For reproducibility
X = mvnrnd(mu,sigma,100);
```

Evaluate the pdf of the distribution at the points in `X`.

```
y = mvnpdf(X,mu,sigma);
```

Plot the probability density values.

```
scatter3(X(:,1),X(:,2),y)
xlabel('X1')
ylabel('X2')
zlabel('Probability Density')
```

Multivariate Normal pdfs Evaluated at Same Point

Create ten different five-dimensional normal distributions, and compare the values of their pdfs at a specified point.

Set the dimensions n and d equal to 10 and 5, respectively.

```
n = 10;  
d = 5;
```

Specify the means `mu` and the covariances `sigma` of the multivariate normal distributions. Let all the distributions have the same mean vector, but vary the covariance matrices.

```
mu = ones(1,d)
```

```
mu = 1×5
```

```
    1    1    1    1    1
```

```
mat = eye(d);  
nMat = repmat(mat,1,1,n);  
var = reshape(1:n,1,1,n);  
sigma = nMat.*var;
```

Display the first two covariance matrices in `sigma`.

```
sigma(:,:,1:2)
```

```
ans =  
ans(:,:,1) =
```

```
    1    0    0    0    0  
    0    1    0    0    0  
    0    0    1    0    0  
    0    0    0    1    0  
    0    0    0    0    1
```

```
ans(:,:,2) =
```

```
    2    0    0    0    0  
    0    2    0    0    0  
    0    0    2    0    0  
    0    0    0    2    0  
    0    0    0    0    2
```

Set `x` to be a random point in five-dimensional space.

```
rng('default') % For reproducibility  
x = normrnd(0,1,1,5)
```

```
x = 1x5
    0.5377    1.8339   -2.2588    0.8622    0.3188
```

Evaluate the pdf at x for each of the ten distributions.

```
y = mvnpdf(x,mu,sigma)
```

```
y = 10x1
    10-4 x
```

```
    0.2490
    0.8867
    0.8755
    0.7035
    0.5438
    0.4211
    0.3305
    0.2635
    0.2134
    0.1753
```

Plot the results.

```
scatter(1:n,y,'filled')
xlabel('Distribution Index')
ylabel('Probability Density at x')
```

Input Arguments

X — Evaluation points

numeric vector | numeric matrix

Evaluation points, specified as a 1-by- d numeric vector or an n -by- d numeric matrix, where n is a positive scalar integer and d is the dimension of a single multivariate normal distribution. The rows of X correspond to observations (or points), and the columns correspond to variables (or coordinates).

If X is a vector, then `mvnpdf` replicates it to match the leading dimension of `mu` or the trailing dimension of `sigma`.

Data Types: `single` | `double`

mu — Means of multivariate normal distributions

vector of zeros (default) | numeric vector | numeric matrix

Means of multivariate normal distributions, specified as a 1-by- d numeric vector or an n -by- d numeric matrix.

- If `mu` is a vector, then `mvnpdf` replicates the vector to match the trailing dimension of `sigma`.
- If `mu` is a matrix, then each row of `mu` is the mean vector of a single multivariate normal distribution.

Data Types: `single` | `double`

sigma — Covariances of multivariate normal distributions

identity matrix (default) | symmetric, positive definite matrix | numeric array

Covariances of multivariate normal distributions, specified as a d -by- d symmetric, positive definite matrix or a d -by- d -by- n numeric array.

- If `sigma` is a matrix, then `mvnpdf` replicates the matrix to match the number of rows in `mu`.
- If `sigma` is an array, then each page of `sigma`, `sigma(:, :, i)`, is the covariance matrix of a single multivariate normal distribution and, therefore, is a symmetric, positive definite matrix.

If the covariance matrices are diagonal, containing variances along the diagonal and zero covariances off it, then you can also specify `sigma` as a 1-by- d vector or a 1-by- d -by- n array containing just the diagonal entries.

Data Types: `single` | `double`

Output Arguments

y — pdf values

numeric vector

pdf values, returned as an n -by-1 numeric vector, where n is one of the following:

- Number of rows in X if X is a matrix
- Number of times X is replicated if X is a vector

If X is a matrix, μ is a matrix, and σ is an array, then `mvnpdf` computes $y(i)$ using $X(i,:)$, $\mu(i,:)$, and $\sigma(:,:,i)$.

Data Types: `double`

Definitions

Multivariate Normal Distribution

The multivariate normal distribution is a generalization of the univariate normal distribution to two or more variables. It has two parameters, a mean vector μ and a covariance matrix Σ , that are analogous to the mean and variance parameters of a univariate normal distribution. The diagonal elements of Σ contain the variances for each variable, and the off-diagonal elements of Σ contain the covariances between variables.

The probability density function (pdf) of the d -dimensional multivariate normal distribution is

$$y = f(x, \mu, \Sigma) = \frac{1}{\sqrt{|\Sigma|(2\pi)^d}} \exp\left(-\frac{1}{2}(x-\mu) \Sigma^{-1}(x-\mu)'\right)$$

where x and μ are 1-by- d vectors and Σ is a d -by- d symmetric, positive definite matrix. Only `mvnrnd` allows positive semi-definite Σ matrices, which can be singular. The pdf cannot have the same form when Σ is singular.

The multivariate normal cumulative distribution function (cdf) evaluated at x is the probability that a random vector v , distributed as multivariate normal, lies within the semi-infinite rectangle with upper limits defined by x :

$$\Pr\{v(1) \leq x(1), v(2) \leq x(2), \dots, v(d) \leq x(d)\}.$$

Although the multivariate normal cdf does not have a closed form, `mvncdf` can compute cdf values numerically.

Tips

- In the one-dimensional case, `sigma` is the variance, not the standard deviation. For example, `mvnpdf(1,0,4)` is the same as `normpdf(1,0,2)`, where 4 is the variance and 2 is the standard deviation.

“Multivariate Normal Distribution” on page B-106

Introduced before R2006a

mvregress

Multivariate linear regression

Syntax

```
beta = mvregress(X,Y)
beta = mvregress(X,Y,Name,Value)
[beta,Sigma] = mvregress( ___ )
[beta,Sigma,E,CovB,logL] = mvregress( ___ )
```

Description

`beta = mvregress(X,Y)` returns the estimated coefficients for a multivariate normal regression on page 32-4377 of the d -dimensional responses in Y on the design matrices in X .

`beta = mvregress(X,Y,Name,Value)` returns the estimated coefficients using additional options specified by one or more name-value pair arguments. For example, you can specify the estimation algorithm, initial estimate values, or maximum number of iterations for the regression.

`[beta,Sigma] = mvregress(___)` also returns the estimated d -by- d variance-covariance matrix of Y , using any of the input arguments from the previous syntaxes.

`[beta,Sigma,E,CovB,logL] = mvregress(___)` also returns a matrix of residuals E , estimated variance-covariance matrix of the regression coefficients $CovB$, and the value of the log likelihood objective function after the last iteration $logL$.

Examples

Multivariate Regression Model for Panel Data with Different Intercepts

Fit a multivariate regression model to panel data, assuming different intercepts and common slopes.

Load the sample data.

```
load('flu')
```

The dataset array `flu` contains national CDC flu estimates, and nine separate regional estimates based on Google® query data.

Extract the response and predictor data.

```
Y = double(flu(:,2:end-1));  
[n,d] = size(Y);  
x = flu.WtdILI;
```

The responses in `Y` are the nine regional flu estimates. Observations exist for every week over a one-year period, so $n = 52$. The dimension of the responses corresponds to the regions, so $d = 9$. The predictors in `x` are the weekly national flu estimates.

Plot the flu data, grouped by region.

```
figure;  
regions = flu.Properties.VarNames(2:end-1);  
plot(x,Y,'x')  
legend(regions,'Location','NorthWest')
```

Fit the multivariate regression model

$$y_{ij} = \alpha_j + \beta x_{ij} + \epsilon_{ij},$$

where $i = 1, \dots, n$ and $j = 1, \dots, d$, with between-region concurrent correlation

$$COV(\epsilon_{ij}, \epsilon_{ij}) = \sigma_{jj}.$$

There are $K = 10$ regression coefficients to estimate: nine intercept terms and a common slope. The input argument X should be an n -element cell array of d -by- K design matrices.

```

X = cell(n,1);
for i = 1:n
    X{i} = [eye(d) repmat(x(i),d,1)];
end
[beta,Sigma] = mvregress(X,Y);

```

beta contains estimates of the K -dimensional coefficient vector

$$(\alpha_1, \alpha_2, \dots, \alpha_9, \beta)'$$

Sigma contains estimates of the d -by- d variance-covariance matrix $(\sigma_{ij})_{d \times d}$, $i, j = 1, \dots, d$ for the between-region concurrent correlations.

Plot the fitted regression model.

```

B = [beta(1:d)'; repmat(beta(end),1,d)];
xx = linspace(.5,3.5)';
fits = [ones(size(xx)),xx]*B;

figure;
h = plot(x,Y,'x',xx,fits,'-');
for i = 1:d
    set(h(d+i),'color',get(h(i),'color'));
end
legend(regions,'Location','NorthWest');

```

The plot shows that each regression line has a different intercept but the same slope. Upon visual inspection, some regression lines appear to fit the data better than others.

Multivariate Regression for Panel Data with Different Slopes

Fit a multivariate regression model to panel data using least squares, assuming different intercepts and slopes.

Load the sample data.

```
load('flu');
```

The dataset array `flu` contains national CDC flu estimates, and nine separate regional estimates based on Google® queries.

Extract the response and predictor data.

```
Y = double(flu(:,2:end-1));
[n,d] = size(Y);
x = flu.WtdILI;
```

The responses in Y are the nine regional flu estimates. Observations exist for every week over a one-year period, so $n = 52$. The dimension of the responses corresponds to the regions, so $d = 9$. The predictors in x are the weekly national flu estimates.

Fit the multivariate regression model

$$y_{ij} = \alpha_j + \beta_j x_{ij} + \epsilon_{ij},$$

where $i = 1, \dots, n$ and $j = 1, \dots, d$, with between-region concurrent correlation

$$COV(\epsilon_{ij}, \epsilon_{ij}) = \sigma_{jj}.$$

There are $K = 18$ regression coefficients to estimate: nine intercept terms, and nine slope terms. X is an n -element cell array of d -by- K design matrices.

```
X = cell(n,1);
for i = 1:n
    X{i} = [eye(d) x(i)*eye(d)];
end
[beta,Sigma] = mvregress(X,Y,'algorithm','cwls');
```

`beta` contains estimates of the K -dimensional coefficient vector

$$(\alpha_1, \alpha_2, \dots, \alpha_9, \beta_1, \beta_2, \dots, \beta_9)'$$

Plot the fitted regression model.

```
B = [beta(1:d)';beta(d+1:end)'];
xx = linspace(.5,3.5)';
fits = [ones(size(xx)),xx]*B;

figure;
h = plot(x,Y,'x',xx,fits,'-');
for i = 1:d
```

```

        set(h(d+i), 'color', get(h(i), 'color'));
    end

    regions = flu.Properties.VarNames(2:end-1);
    legend(regions, 'Location', 'NorthWest');

```

The plot shows that each regression line has a different intercept and slope.

Multivariate Regression With a Single Design Matrix

Fit a multivariate regression model using a single n -by- P design matrix for all response dimensions.

Load the sample data.

```
load('flu');
```

The dataset array `flu` contains national CDC flu estimates, and nine separate regional estimates based on Google® queries.

Extract the response and predictor data.

```
Y = double(flu(:,2:end-1));
[n,d] = size(Y);
x = flu.WtdILI;
```

The responses in Y are the nine regional flu estimates. Observations exist for every week over a one-year period, so $n = 52$. The dimension of the responses corresponds to the regions, so $d = 9$. The predictors in x are the weekly national flu estimates.

Create an n -by- P design matrix X . Add a column of ones to include a constant term in the regression.

```
X = [ones(size(x)),x];
```

Fit the multivariate regression model

$$y_{ij} = \alpha_j + \beta_j x_{ij} + \epsilon_{ij},$$

where $i = 1, \dots, n$ and $j = 1, \dots, d$, with between-region concurrent correlation

$$COV(\epsilon_{ij}, \epsilon_{ij}) = \sigma_{jj}.$$

There are 18 regression coefficients to estimate: nine intercept terms, and nine slope terms.

```
[beta,Sigma,E,CovB,logL] = mvregress(X,Y);
```

`beta` contains estimates of the P -by- d coefficient matrix. `Sigma` contains estimates of the d -by- d variance-covariance matrix for the between-region concurrent correlations. `E` is a matrix of the residuals. `CovB` is the estimated variance-covariance matrix of the regression coefficients. `logL` is the value of the log likelihood objective function after the last iteration.

Plot the fitted regression model.

```

B = beta;
xx = linspace(.5,3.5)';
fits = [ones(size(xx)),xx]*B;

figure;
h = plot(x,Y,'x', xx,fits,'-');
for i = 1:d
    set(h(d+i), 'color',get(h(i), 'color'));
end

regions = flu.Properties.VarNames(2:end-1);
legend(regions, 'Location', 'NorthWest');

```

The plot shows that each regression line has a different intercept and slope.

Input Arguments

X — Design matrices

matrix | cell array of matrices

Design matrices for the multivariate regression, specified as a matrix or cell array of matrices. n is the number of observations in the data, K is the number of regression coefficients to estimate, p is the number of predictor variables, and d is the number of dimensions in the response variable matrix Y .

- If $d = 1$, then specify X as a single n -by- K design matrix.
- If $d > 1$ and all d dimensions have the same design matrix, then you can specify X as a single n -by- p design matrix (not in a cell array).
- If $d > 1$ and all n observations have the same design matrix, then you can specify X as a cell array containing a single d -by- K design matrix.
- If $d > 1$ and all n observations do not have the same design matrix, then specify X as a cell array of length n containing d -by- K design matrices.

To include a constant term in the regression model, each design matrix should contain a column of ones.

`mvregress` treats NaN values in X as missing values, and ignores rows in X with missing values.

Data Types: `single` | `double` | `cell`

Y — Response variables

matrix

Response variables, specified as an n -by- d matrix. n is the number of observations in the data, and d is the number of dimensions in the response. When $d = 1$, `mvregress` treats the values in Y like n independent response values.

`mvregress` treats NaN values in Y as missing values, and handles them according to the estimation algorithm specified using the name-value pair argument `algorithm`.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'algorithm', 'cwl's', 'covar0'`, `C` specifies covariance-weighted least squares estimation using the covariance matrix `C`.

algorithm — Estimation algorithm

`'mvn' | 'ecm' | 'cwl's'`

Estimation algorithm, specified as the comma-separated pair consisting of `'algorithm'` and one of the following.

<code>'mvn'</code>	Ordinary multivariate normal maximum likelihood estimation.
<code>'ecm'</code>	Maximum likelihood estimation via the ECM algorithm.
<code>'cwl's'</code>	Covariance-weighted least squares estimation.

The default algorithm depends on the presence of missing data.

- For complete data, the default is `'mvn'`.
- If there are any missing responses (indicated by `NaN`), the default is `'ecm'`, provided the sample size is sufficient to estimate all parameters. Otherwise, the default algorithm is `'cwl's'`.

Note If `algorithm` has the value `'mvn'`, then `mvregress` removes observations with missing response values before estimation.

Example: `'algorithm', 'ecm'`

beta0 — Initial estimates for regression coefficients

vector

Initial estimates for the regression coefficients, specified as the comma-separated pair consisting of `'beta0'` and a vector with K elements. The default value is a vector of 0s.

The `beta0` argument is not used if the estimation algorithm is `'mvn'`.

covar0 — Initial estimate for variance-covariance matrix

Initial estimate for the variance-covariance matrix, `Sigma`, specified as the comma-separated pair consisting of `'covar0'` and a symmetric, positive definite, d -by- d matrix. The default value is the identity matrix.

If the estimation algorithm is `'cwls'`, then `mvregress` uses `covar0` as the weighting matrix at each iteration, without changing it.

covtype — Type of variance-covariance matrix

`'full'` (default) | `'diagonal'`

Type of variance-covariance matrix to estimate for Y , specified as the comma-separated pair consisting of `'covtype'` and one of the following.

<code>'full'</code>	Estimate all $d(d + 1)/2$ variance-covariance elements.
<code>'diagonal'</code>	Estimate only the d diagonal elements of the variance-covariance matrix.

Example: `'covtype', 'diagonal'`

maxiter — Maximum number of iterations

100 (default) | positive integer

Maximum number of iterations for the estimation algorithm, specified as the comma-separated pair consisting of `'maxiter'` and a positive integer.

Iterations continue until estimates are within the convergence tolerances `tolbeta` and `tolobj`, or the maximum number of iterations specified by `maxiter` is reached. If both `tolbeta` and `tolobj` are 0, then `mvregress` performs `maxiter` iterations with no convergence tests.

Example: `'maxiter', 50`

outputfcn — Function to evaluate each iteration

function handle

Function to evaluate at each iteration, specified as the comma-separated pair consisting of `'outputfcn'` and a function handle. The function must return a logical `true` or `false`. At each iteration, `mvregress` evaluates the function. If the result is `true`,

iterations stop. Otherwise, iterations continue. For example, you could specify a function that plots or displays current iteration results, and returns `true` if you close the figure.

The function must accept three input arguments, in this order:

- Vector of current coefficient estimates
- Structure containing these three fields:

<code>Covar</code>	Current value of the variance-covariance matrix
<code>iteration</code>	Current iteration number
<code>fval</code>	Current value of the loglikelihood objective function

- Text that takes these three values:

<code>'init'</code>	When the function is called during initialization
<code>'iter'</code>	When the function is called after an iteration
<code>'done'</code>	When the function is called after completion

tolbeta — Convergence tolerance for regression coefficients

`sqrt(eps)` (default) | positive scalar value

Convergence tolerance for regression coefficients, specified as the comma-separated pair consisting of `'tolbeta'` and a positive scalar value.

Let \mathbf{b}^t denote the estimate of the coefficient vector at iteration t , and τ_β be the tolerance specified by `tolbeta`. The convergence criterion for regression coefficient estimation is

$$\|\mathbf{b}^t - \mathbf{b}^{t-1}\| < \tau_\beta \sqrt{K}(1 + \|\mathbf{b}^t\|),$$

where K is the length of \mathbf{b}^t and $\|\mathbf{v}\|$ is the norm of a vector \mathbf{v} .

Iterations continue until estimates are within the convergence tolerances `tolbeta` and `tolobj`, or the maximum number of iterations specified by `maxiter` is reached. If both `tolbeta` and `tolobj` are 0, then `mvregress` performs `maxiter` iterations with no convergence tests.

Example: `'tolbeta', 1e-5`

tolobj — Convergence tolerance for loglikelihood objective function

`eps^(3/4)` (default) | positive scalar value

Convergence tolerance for the loglikelihood objective function, specified as the comma-separated pair consisting of `'tolobj'` and a positive scalar value.

Let L^t denote the value of the loglikelihood objective function at iteration t , and τ_ℓ be the tolerance specified by `tolobj`. The convergence criterion for the objective function is

$$|L^t - L^{t-1}| < \tau_\ell(1 + |L^t|).$$

Iterations continue until estimates are within the convergence tolerances `tolbeta` and `tolobj`, or the maximum number of iterations specified by `maxiter` is reached. If both `tolbeta` and `tolobj` are 0, then `mvregress` performs `maxiter` iterations with no convergence tests.

Example: `'tolobj', 1e-5`

varformat — Format for parameter estimate variance-covariance matrix

`'beta'` (default) | `'full'`

Format for the parameter estimate variance-covariance matrix, `CovB`, specified as the comma-separated pair consisting of `'varformat'` and one of the following.

<code>'beta'</code>	Return the variance-covariance matrix for only the regression coefficient estimates, <code>beta</code> .
<code>'full'</code>	Return the variance-covariance matrix for both the regression coefficient estimates, <code>beta</code> , and the variance-covariance matrix estimate, <code>Sigma</code> .

Example: `'varformat', 'full'`

vartype — Type of variance-covariance matrix for parameter estimates

`'hessian'` (default) | `'fisher'`

Type of variance-covariance matrix for parameter estimates, specified as the comma-separated pair consisting of `'vartype'` and either `'hessian'` or `'fisher'`.

- If the value is `'hessian'`, then `mvregress` uses the Hessian, or observed information, matrix to compute `CovB`.
- If the value is `'fisher'`, then `mvregress` uses the complete-data Fisher, or expected information, matrix to compute `CovB`.

The 'hessian' method takes into account the increase uncertainties due to missing data, while the 'fisher' method does not.

Example: 'vartype', 'fisher'

Output Arguments

beta — Estimated regression coefficients

column vector | matrix

Estimated regression coefficients, returned as a column vector or matrix.

- If you specify X as a single n -by- K design matrix, then `mvregress` returns **beta** as a column vector of length K . For example, if X is a 20-by-5 design matrix, then **beta** is a 5-by-1 column vector.
- If you specify X as a cell array containing one or more d -by- K design matrices, then `mvregress` returns **beta** as a column vector of length K . For example, if X is a cell array containing 2-by-10 design matrices, then **beta** is a 10-by-1 column vector.
- If you specify X as a single n -by- p design matrix (not in a cell array), and Y has dimension $d > 1$, then `mvregress` returns **beta** as a p -by- d matrix. For example, if X is a 20-by-5 design matrix, and Y has two dimensions such that $d = 2$, then **beta** is a 5-by-2 matrix, and the fitted Y values are $X \times \text{beta}$.

Sigma — Estimated variance-covariance matrix

square matrix

Estimated variance-covariance matrix for the responses in Y , returned as a d -by- d square matrix.

Note The estimated variance-covariance matrix, **Sigma**, is not the sample covariance matrix of the residual matrix, **E**.

E — Residuals

matrix

Residuals for the fitted regression model, returned as an n -by- d matrix.

If `algorithm` has the value 'ecm' or 'cwlsl', then `mvregress` computes the residual values corresponding to missing values in `Y` as the difference between the conditionally imputed values on page 32-4378 and the fitted values.

Note If `algorithm` has the value 'mvn', then `mvregress` removes observations with missing response values before estimation.

CovB — Parameter estimate variance-covariance matrix

square matrix

Parameter estimate variance-covariance matrix, returned as a square matrix.

- If `varformat` has the value 'beta' (default), then `CovB` is the estimated variance-covariance matrix of the coefficient estimates in `beta`.
- If `varformat` has the value 'full', then `CovB` is the estimated variance-covariance matrix of the combined estimates in `beta` and `Sigma`.

LogL — Loglikelihood objective function value

scalar value

Loglikelihood objective function value after the last iteration, returned as a scalar value.

Definitions

Multivariate Normal Regression

Multivariate normal regression is the regression of a d -dimensional response on a design matrix of predictor variables, with normally distributed errors. The errors can be heteroscedastic and correlated.

The model is

$$\mathbf{y}_i = \mathbf{X}_i\boldsymbol{\beta} + \mathbf{e}_i, \quad i = 1, \dots, n,$$

where

- \mathbf{y}_i is a d -dimensional vector of responses.

- \mathbf{X}_i is a design matrix of predictor variables.
- β is vector or matrix of regression coefficients.
- \mathbf{e}_i is a d -dimensional vector of error terms, with multivariate normal distribution

$$\mathbf{e}_i \sim MVN_d(\mathbf{0}, \Sigma).$$

Conditionally Imputed Values

The expectation/conditional maximization ('ecm') and covariance-weighted least squares ('cwlsls') estimation algorithms include imputation of missing response values.

Let $\tilde{\mathbf{y}}$ denote missing observations. The conditionally imputed values are the expected value of the missing observation given the observed data, $E(\tilde{\mathbf{y}}|\mathbf{y})$.

The joint distribution of the missing and observed responses is a multivariate normal distribution,

$$\begin{pmatrix} \tilde{\mathbf{y}} \\ \mathbf{y} \end{pmatrix} \sim MVN \left\{ \begin{pmatrix} \tilde{\mathbf{X}}\beta \\ \mathbf{X}\beta \end{pmatrix}, \begin{pmatrix} \Sigma_{\tilde{\mathbf{y}}} & \Sigma_{\tilde{\mathbf{y}}\mathbf{y}} \\ \Sigma_{\mathbf{y}\tilde{\mathbf{y}}} & \Sigma_{\mathbf{y}} \end{pmatrix} \right\}.$$

Using properties of the multivariate normal distribution, the imputed conditional expectation is given by

$$E(\tilde{\mathbf{y}}|\mathbf{y}) = \tilde{\mathbf{X}}\beta + \Sigma_{\tilde{\mathbf{y}}\mathbf{y}}\Sigma_{\mathbf{y}}^{-1}(\mathbf{y} - \mathbf{X}\beta).$$

Note `mvregress` only imputes missing response values. Observations with missing values in the design matrix are removed.

mvregresslike

Negative log-likelihood for multivariate regression

Syntax

```
nlogL = mvregresslike(X,Y,b,SIGMA,alg)
[nlogL,COVB] = mvregresslike(...)
[nlogL,COVB] = mvregresslike(...,type,format)
```

Description

`nlogL = mvregresslike(X,Y,b,SIGMA,alg)` computes the negative log-likelihood `nlogL` for a multivariate regression of the d -dimensional multivariate observations in the n -by- d matrix Y on the predictor variables in the matrix or cell array X , evaluated for the p -by-1 column vector b of coefficient estimates and the d -by- d matrix $SIGMA$ specifying the covariance of a row of Y . If $d = 1$, X can be an n -by- p design matrix of predictor variables. For any value of d , X can also be a cell array of length n , with each cell containing a d -by- p design matrix for one multivariate observation. If all observations have the same d -by- p design matrix, X can be a single cell.

NaN values in X or Y are taken as missing. Observations with missing values in X are ignored. Treatment of missing values in Y depends on the algorithm specified by `alg`.

`alg` should match the algorithm used by `mvregress` to obtain the coefficient estimates b , and must be one of the following:

- 'ecm' — ECM algorithm
- 'cwlsls' — Least squares conditionally weighted by $SIGMA$
- 'mvn' — Multivariate normal estimates computed after omitting rows with any missing values in Y

`[nlogL,COVB] = mvregresslike(...)` also returns an estimated covariance matrix `COVB` of the parameter estimates b .

`[nlogL,COVB] = mvregresslike(...,type,format)` specifies the type and format of `COVB`.

type is either:

- 'hessian' — To use the Hessian or observed information. This method takes into account the increased uncertainties due to missing data. This is the default.
- 'fisher' — To use the Fisher or expected information. This method uses the complete data expected information, and does not include uncertainty due to missing data.

format is either:

- 'beta' — To compute COVB for **b** only. This is the default.
- 'full' — To compute COVB for both **b** and **SIGMA**.

Introduced in R2007a

mvnrnd

Multivariate normal random numbers

Syntax

```
R = mvnrnd(mu,sigma,n)
R = mvnrnd(mu,sigma)
```

Description

`R = mvnrnd(mu,sigma,n)` returns a matrix `R` of `n` random vectors chosen from the same multivariate normal distribution, with mean vector `mu` and covariance matrix `sigma`. For more information, see “Multivariate Normal Distribution” on page 32-4387.

`R = mvnrnd(mu,sigma)` returns an m -by- d matrix `R` of random vectors sampled from m separate d -dimensional multivariate normal distributions, with means and covariances specified by `mu` and `sigma`, respectively. Each row of `R` is a single multivariate normal random vector.

Examples

Generate Multivariate Normal Random Numbers

Generate random numbers from the same multivariate normal distribution.

Define `mu` and `sigma`, and generate 100 random numbers.

```
mu = [2 3];
sigma = [1 1.5; 1.5 3];
rng('default') % For reproducibility
R = mvnrnd(mu,sigma,100);
```

Plot the random numbers.

```
plot(R(:,1),R(:,2),'+')
```

Sample from Different Multivariate Normal Distributions

Randomly sample from five different three-dimensional normal distributions.

Specify the means `mu` and the covariances `sigma` of the distributions. Let all the distributions share the same covariance matrix, but vary the mean vectors.

```
firstDim = (1:5)';  
mu = repmat(firstDim,1,3)
```

```
mu = 5×3
```

```
1    1    1
2    2    2
3    3    3
4    4    4
5    5    5
```

```
sigma = eye(3)
```

```
sigma = 3×3
```

```
1    0    0
0    1    0
0    0    1
```

Randomly sample once from each of the five distributions.

```
rng('default') % For reproducibility
```

```
R = mvnrnd(mu,sigma)
```

```
R = 5×3
```

```
1.5377    -0.3077    -0.3499
3.8339     1.5664     5.0349
0.7412     3.3426     3.7254
4.8622     7.5784     3.9369
5.3188     7.7694     5.7147
```

Plot the results.

```
scatter3(R(:,1),R(:,2),R(:,3))
```

Input Arguments

mu — Means of multivariate normal distributions

numeric vector | numeric matrix

Means of multivariate normal distributions, specified as a 1-by- d numeric vector or an m -by- d numeric matrix.

- If **mu** is a vector, then `mvnrnd` replicates the vector to match the trailing dimension of **sigma**.

- If `mu` is a matrix, then each row of `mu` is the mean vector of a single multivariate normal distribution.

Data Types: `single` | `double`

sigma — Covariances of multivariate normal distributions

symmetric, positive semi-definite matrix | numeric array

Covariances of multivariate normal distributions, specified as a d -by- d symmetric, positive semi-definite matrix or a d -by- d -by- m numeric array.

- If `sigma` is a matrix, then `mvnrnd` replicates the matrix to match the number of rows in `mu`.
- If `sigma` is an array, then each page of `sigma`, `sigma(:, :, i)`, is the covariance matrix of a single multivariate normal distribution and, therefore, is a symmetric, positive semi-definite matrix.

If the covariance matrices are diagonal, containing variances along the diagonal and zero covariances off it, then you can also specify `sigma` as a 1-by- d vector or a 1-by- d -by- m array containing just the diagonal entries.

Data Types: `single` | `double`

n — Number of multivariate random numbers

positive scalar integer

Number of multivariate random numbers, specified as a positive scalar integer. `n` specifies the number of rows in `R`.

Data Types: `single` | `double`

Output Arguments

R — Multivariate normal random numbers

numeric matrix

Multivariate normal random numbers, returned as one of the following:

- m -by- d numeric matrix, where m and d are the dimensions specified by `mu` and `sigma`
- n -by- d numeric matrix, where `n` is the specified input argument and d is the dimension specified by `mu` and `sigma`

If `mu` is a matrix and `sigma` is an array, then `mvnrnd` computes `R(i, :)` using `mu(i, :)` and `sigma(:, :, i)`.

Definitions

Multivariate Normal Distribution

The multivariate normal distribution is a generalization of the univariate normal distribution to two or more variables. It has two parameters, a mean vector μ and a covariance matrix Σ , that are analogous to the mean and variance parameters of a univariate normal distribution. The diagonal elements of Σ contain the variances for each variable, and the off-diagonal elements of Σ contain the covariances between variables.

The probability density function (pdf) of the d -dimensional multivariate normal distribution is

$$y = f(x, \mu, \Sigma) = \frac{1}{\sqrt{|\Sigma|(2\pi)^d}} \exp\left(-\frac{1}{2}(x-\mu)' \Sigma^{-1}(x-\mu)\right)$$

where x and μ are 1-by- d vectors and Σ is a d -by- d symmetric, positive definite matrix. Only `mvnrnd` allows positive semi-definite Σ matrices, which can be singular. The pdf cannot have the same form when Σ is singular.

The multivariate normal cumulative distribution function (cdf) evaluated at x is the probability that a random vector v , distributed as multivariate normal, lies within the semi-infinite rectangle with upper limits defined by x :

$$\Pr\{v(1) \leq x(1), v(2) \leq x(2), \dots, v(d) \leq x(d)\}.$$

Although the multivariate normal cdf does not have a closed form, `mvncdf` can compute cdf values numerically.

Tips

- `mvnrnd` requires the matrix `sigma` to be symmetric. If `sigma` has only minor asymmetry, you can use `(sigma + sigma')/2` instead to resolve the asymmetry.

- In the one-dimensional case, `sigma` is the variance, not the standard deviation. For example, `mvnrnd(0,4)` is the same as `normrnd(0,2)`, where 4 is the variance and 2 is the standard deviation.

mvtcdf

Multivariate t cumulative distribution function

Syntax

```
y = mvtcdf(X,C,DF)
y = mvtcdf(xl,xu,C,DF)
[y,err] = mvtcdf(...)
[...] = mvntdf(...,options)
```

Description

`y = mvtcdf(X,C,DF)` returns the cumulative probability of the multivariate t distribution with correlation parameters C and degrees of freedom DF , evaluated at each row of X . Rows of the n -by- d matrix X correspond to observations or points, and columns correspond to variables or coordinates. y is an n -by-1 vector.

C is a symmetric, positive definite, d -by- d matrix, typically a correlation matrix. If its diagonal elements are not 1, `mvtcdf` scales C to correlation form. `mvtcdf` does not rescale X . DF is a scalar, or a vector with n elements.

The multivariate t cumulative probability at X is defined as the probability that a random vector T , distributed as multivariate t , will fall within the semi-infinite rectangle with upper limits defined by X , i.e., $\Pr\{T(1) \leq X(1), T(2) \leq X(2), \dots, T(d) \leq X(d)\}$.

`y = mvtcdf(xl,xu,C,DF)` returns the multivariate t cumulative probability evaluated over the rectangle with lower and upper limits defined by x_l and x_u , respectively.

`[y,err] = mvtcdf(...)` returns an estimate of the error in y . For bivariate and trivariate distributions, `mvtcdf` uses adaptive quadrature on a transformation of the t density, based on methods developed by Genz, as described in the references. The default absolute error tolerance for these cases is $1e-8$. For four or more dimensions, `mvtcdf` uses a quasi-Monte Carlo integration algorithm based on methods developed by Genz and Bretz, as described in the references. The default absolute error tolerance for these cases is $1e-4$.

[...] = `mvntdf(...,options)` specifies control parameters for the numerical integration used to compute `y`. This argument can be created by a call to `statset`.

Choices of `statset` parameters are:

- `'TolFun'` — Maximum absolute error tolerance. Default is $1e-8$ when $d < 4$, or $1e-4$ when $d \geq 4$.
- `'MaxFunEvals'` — Maximum number of integrand evaluations allowed when $d \geq 4$. Default is $1e7$. `'MaxFunEvals'` is ignored when $d < 4$.
- `'Display'` — Level of display output. Choices are `'off'` (the default), `'iter'`, and `'final'`. `'Display'` is ignored when $d < 4$.

Examples

Compute the Multivariate t Distribution cdf

Compute the cdf of a multivariate t distribution with correlation parameters $C = [1 \ .4; \ .4 \ 1]$ and 2 degrees of freedom.

```
C = [1 .4; .4 1];
df = 2;
[X1,X2] = meshgrid(linspace(-2,2,25)',linspace(-2,2,25)');
X = [X1(:) X2(:)];
p = mvtcdf(X,C,df);
```

Plot the cdf.

```
figure;
surf(X1,X2,reshape(p,25,25));
```

mvtpdf

Multivariate t probability density function

Syntax

```
y = mvtpdf(X,C,df)
```

Description

`y = mvtpdf(X,C,df)` returns the probability density of the multivariate t distribution with correlation parameters `C` and degrees of freedom `df`, evaluated at each row of `X`. Rows of the n -by- d matrix `X` correspond to observations or points, and columns correspond to variables or coordinates. `C` is a symmetric, positive definite, d -by- d matrix, typically a correlation matrix. If its diagonal elements are not 1, `mvtpdf` scales `C` to correlation form. `mvtcdf` does not rescale `X`. `df` is a scalar, or a vector with n elements. `y` is an n -by-1 vector.

Examples

Compute the Multivariate t Distribution pdf

Compute the pdf of a multivariate t distribution with correlation parameters `C = [1 .4; .4 1]` and 2 degrees of freedom.

```
[X1,X2] = meshgrid(linspace(-2,2,25)',linspace(-2,2,25)');  
X = [X1(:) X2(:)];  
C = [1 .4; .4 1];  
df = 2;  
p = mvtpdf(X,C,df);
```

Plot the pdf.

```
figure;  
surf(X1,X2,reshape(p,25,25))
```

mvtrnd

Multivariate t random numbers

Syntax

```
R = mvtrnd(C,df,cases)
R = mvtrnd(C,df)
```

Description

`R = mvtrnd(C,df,cases)` returns a matrix of random numbers chosen from the multivariate t distribution, where C is a correlation matrix. `df` is the degrees of freedom and is either a scalar or is a vector with `cases` elements. If p is the number of columns in C , then the output R has `cases` rows and p columns.

Let \mathbf{t} represent a row of R . Then the distribution of \mathbf{t} is that of a vector having a multivariate normal distribution with mean 0, variance 1, and covariance matrix C , divided by an independent chi-square random value having `df` degrees of freedom. The rows of R are independent.

C must be a square, symmetric and positive definite matrix. If its diagonal elements are not all 1 (that is, if C is a covariance matrix rather than a correlation matrix), `mvtrnd` rescales C to transform it to a correlation matrix before generating the random numbers.

`R = mvtrnd(C,df)` returns a single random number from the multivariate t distribution.

Examples

Generate Multivariate t Distribution Random Numbers

Generate random numbers from a multivariate t distribution with correlation parameters `SIGMA = [1 0.8;0.8 1]` and 3 degrees of freedom.

```
rng default; % For reproducibility
SIGMA = [1 0.8;0.8 1];
R = mvtrnd(SIGMA,3,100);
```

Plot the random numbers.

```
figure;
plot(R(:,1),R(:,2),'+')
```

Introduced before R2006a

NumObservations property

Class: cvpartition

Number of observations (including observations with missing group values)

Description

Number of observations (including observations with missing group values).

nancov

Covariance ignoring NaN values

Syntax

```
Y = nancov(X)
Y = nancov(X1,X2)
Y = nancov(...,1)
Y = nancov(...,'pairwise')
```

Description

$Y = \text{nancov}(X)$ is the covariance cov of X , computed after removing observations with NaN values.

For vectors x , $\text{nancov}(x)$ is the sample variance of the remaining elements, once NaN values are removed. For matrices X , $\text{nancov}(X)$ is the sample covariance of the remaining observations, once observations (rows) containing any NaN values are removed.

$Y = \text{nancov}(X1,X2)$, where $X1$ and $X2$ are matrices with the same number of elements, is equivalent to $\text{nancov}(X)$, where $X = [X1(:) X2(:)]$.

`nancov` removes the mean from each variable (column for matrix X) before calculating Y . If n is the number of remaining observations after removing observations with NaN values, `nancov` normalizes Y by either $n - 1$ or n , depending on whether $n > 1$ or $n = 1$, respectively. To specify normalization by n , use $Y = \text{nancov}(\dots,1)$.

$Y = \text{nancov}(\dots, 'pairwise')$ computes $Y(i,j)$ using rows with no NaN values in columns i or j . The result Y may not be a positive definite matrix.

Examples

Generate random data for two variables (columns) with random missing values:

```
X = rand(10,2);
p = randperm(numel(X));
X(p(1:5)) = NaN
X =
    0.8147    0.1576
      NaN      NaN
    0.1270    0.9572
    0.9134      NaN
    0.6324      NaN
    0.0975    0.1419
    0.2785    0.4218
    0.5469    0.9157
    0.9575    0.7922
    0.9649      NaN
```

Establish a correlation between a third variable and the other two variables:

```
X(:,3) = sum(X,2)
X =
    0.8147    0.1576    0.9723
      NaN      NaN      NaN
    0.1270    0.9572    1.0842
    0.9134      NaN      NaN
    0.6324      NaN      NaN
    0.0975    0.1419    0.2394
    0.2785    0.4218    0.7003
    0.5469    0.9157    1.4626
    0.9575    0.7922    1.7497
    0.9649      NaN      NaN
```

Compute the covariance matrix for the three variables after removing observations (rows) with NaN values:

```
Y = nancov(X)
Y =
    0.1311    0.0096    0.1407
    0.0096    0.1388    0.1483
    0.1407    0.1483    0.2890
```

Alternative Functionality

Instead of using `nancov`, you can use the MATLAB function `cov` with the input argument `nanflag`. For example, instead of `nancov(X)`, use `cov(X, 'omitrows')`, and instead of `nancov(X, 'pairwise')`, use `cov(X, 'partialrows')`.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- If the input is variable-size and is `[]` at run time, the generated code returns `[]` not `NaN`.

For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “General Code Generation Workflow” on page 31-5.

`NaN` | `cov` | `nanvar` | `var`

Introduced before R2006a

nanmax

Maximum, ignoring NaN values

Syntax

```
y = nanmax(X)
y = nanmax(X, [], dim)
[y, indices] = nanmax( ___ )

y = nanmax(X, [], 'all')
y = nanmax(X, [], vecdim)

Y = nanmax(X1, X2)
```

Description

`y = nanmax(X)` is the maximum `max` of `X`, computed after removing NaN values.

For vectors `x`, `nanmax(x)` is the maximum of the remaining elements, once NaN values are removed. For matrices `X`, `nanmax(X)` is a row vector of column maxima, once NaN values are removed. For multidimensional arrays `X`, `nanmax` operates along the first nonsingleton dimension.

`y = nanmax(X, [], dim)` operates along the dimension `dim` of `X`.

`[y, indices] = nanmax(___)` also returns the row indices of the maximum values for each column in the vector `indices`.

`y = nanmax(X, [], 'all')` returns the maximum of all elements of `X`, computed after removing NaN values.

`y = nanmax(X, [], vecdim)` returns the maximum over the dimensions specified in the vector `vecdim`, computed after removing NaN values. Each element of `vecdim` represents a dimension of the input array `X`. The output `y` has length 1 in the specified operating dimensions. The other dimension lengths are the same for `X` and `y`. For example, if `X` is a 2-by-3-by-4 array, then `nanmax(X, [], [1 2])` returns a 1-by-1-by-4 array. Each element of the output array is the maximum of the elements on the corresponding page of `X`.

`Y = nanmax(X1,X2)` returns an array `Y` the same size as `X1` and `X2` with `Y(i,j) = nanmax(X1(i,j),X2(i,j))`. Scalar inputs are expanded to an array of the same size as the other input.

Examples

Maximum of Matrix Data

Find the column maximum values and their indices for matrix data with missing values.

```
X = magic(3);
X([1 6:9]) = NaN
```

```
X = 3×3
```

```
NaN    1    NaN
  3     5    NaN
  4    NaN    NaN
```

```
[y,indices] = nanmax(X)
```

```
y = 1×3
```

```
  4     5    NaN
```

```
indices = 1×3
```

```
  3     2     1
```

Maximum of All Values

Find the maximum of all the values in an array, ignoring missing values.

Create a 2-by-5-by-3 array `X` with some missing values.

```
X = reshape(1:30,[2 5 3]);
X([10:12 25]) = NaN
```

```
X =  
X(:, :, 1) =  
  
     1     3     5     7     9  
     2     4     6     8    NaN
```

```
X(:, :, 2) =  
  
    NaN    13    15    17    19  
    NaN    14    16    18    20
```

```
X(:, :, 3) =  
  
    21    23    NaN    27    29  
    22    24    26    28    30
```

Find the maximum of the elements of X.

```
y = nanmax(X, [], 'all')
```

```
y = 30
```

Alternative Functionality

Instead of using `nanmax`, you can use the MATLAB function `max` with the input argument `nanflag` specified as the value `'omitnan'`.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The 'all' and vecdim input arguments are not supported.
- The dim input argument must be a compile-time constant.
- If you do not specify the dim input argument, the working (or operating) dimension can be different in the generated code. As a result, run-time errors can occur. For more details, see “Automatic dimension restriction” (MATLAB Coder).

For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “General Code Generation Workflow” on page 31-5.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Usage notes and limitations:

- The 'all' and vecdim input arguments are not supported.

For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

NaN | max | nanmin

Introduced before R2006a

nanmean

Mean, ignoring NaN values

Syntax

```
y = nanmean(X)
y = nanmean(X, 'all')
y = nanmean(X, dim)
y = nanmean(X, vecdim)
```

Description

`y = nanmean(X)` returns the mean of the elements of `X`, computed after removing all NaN values.

- If `X` is a vector, then `nanmean(X)` is the mean of all the non-NaN elements of `X`.
- If `X` is a matrix, then `nanmean(X)` is a row vector of column means, computed after removing NaN values.
- If `X` is a multidimensional array, then `nanmean` operates along the first nonsingleton dimension of `X`. The size of this dimension becomes 1 while the sizes of all other dimensions remain the same. `nanmean` removes all NaN values.

For information on how `nanmean` treats arrays of all NaN values, see “Tips” on page 32-4412.

`y = nanmean(X, 'all')` returns the mean of all elements of `X`, computed after removing NaN values.

`y = nanmean(X, dim)` returns the mean along the operating dimension `dim` of `X`, computed after removing NaN values.

`y = nanmean(X, vecdim)` returns the mean over the dimensions specified in the vector `vecdim`. The function computes the means after removing NaN values. For example, if `X` is a matrix, then `nanmean(X, [1 2])` is the mean of all non-NaN elements of `X` because every element of a matrix is contained in the array slice defined by dimensions 1 and 2.

Examples

Mean of Matrix Data

Find the column means for matrix data with missing values.

```
X = magic(3);
X([1 6:9]) = NaN
```

```
X = 3×3
```

```
NaN    1    NaN
  3     5    NaN
  4    NaN    NaN
```

```
y = nanmean(X)
```

```
y = 1×3
```

```
3.5000    3.0000    NaN
```

Mean of All Values

Find the mean of all the values in an array, ignoring missing values.

Create a 2-by-5-by-3 array X with some missing values.

```
X = reshape(1:30,[2 5 3]);
X([10:12 25]) = NaN
```

```
X =
X(:,:,1) =
```

```
  1    3    5    7    9
  2    4    6    8    NaN
```

```
X(:,:,2) =
```

```
NaN    13    15    17    19
NaN    14    16    18    20
```

```
X(:, :, 3) =
```

```
21    23    NaN    27    29
22    24    26    28    30
```

Find the mean of the elements of X.

```
y = nanmean(X, 'all')
```

```
y = 15.6538
```

Mean Along Scalar Dimension

Find the row means for matrix data with missing values by specifying to compute the means along the second dimension.

```
X = magic(3);
X([1 6:9]) = NaN
```

```
X = 3×3
```

```
NaN     1     NaN
3       5     NaN
4     NaN     NaN
```

```
y = nanmean(X, 2)
```

```
y = 3×1
```

```
1
4
4
```

Mean Along Vector Dimension

Find the mean of a multidimensional array over multiple dimensions.

Create a 2-by-5-by-3 array X with some missing values.

```
X = reshape(1:30,[2 5 3]);  
X([10:12 25]) = NaN
```

```
X =  
X(:,:,1) =
```

```
     1     3     5     7     9  
     2     4     6     8    NaN
```

```
X(:,:,2) =
```

```
    NaN    13    15    17    19  
    NaN    14    16    18    20
```

```
X(:,:,3) =
```

```
    21    23    NaN    27    29  
    22    24    26    28    30
```

Find the mean of each page of X by specifying dimensions 1 and 2 as the operating dimensions.

```
ypage = nanmean(X,[1 2])
```

```
ypage =  
ypage(:,:,1) =
```

```
     5
```

```
ypage(:,:,2) =
```

```
    16.5000
```

```
ypage(:,:,3) =
```

```
25.5556
```

For example, `ypage(1,1,1)` is the mean of the non-NaN elements in `X(:, :, 1)`.

Find the mean of the elements in each `X(i, :, :)` slice by specifying dimensions 2 and 3 as the operating dimensions.

```
yrow = nanmean(X,[2 3])
```

```
yrow = 2×1
```

```
14.5385  
16.7692
```

For example, `yrow(2)` is the mean of the non-NaN elements in `X(2, :, :)`.

Input Arguments

X — Input data

scalar | vector | matrix | multidimensional array

Input data, specified as a scalar, vector, matrix, or multidimensional array.

If `X` is an empty array, then `nanmean(X)` is NaN. For more details, see “Tips” on page 32-4412.

Data Types: `single` | `double`

dim — Dimension to operate along

positive integer scalar

Dimension to operate along, specified as a positive integer scalar. If you do not specify a value, then the default value is the first array dimension whose size does not equal 1.

`dim` indicates the dimension whose length reduces to 1. `size(y, dim)` is 1 while the sizes of all other dimensions remain the same.

Consider a two-dimensional array `X`:

- If `dim` is equal to 1, then `nanmean(X, 1)` returns a row vector containing the mean for each column.
- If `dim` is equal to 2, then `nanmean(X, 2)` returns a column vector containing the mean for each row.

If `dim` is greater than `ndims(X)` or if `size(X, dim)` is 1, then `nanmean` returns `X`.

Data Types: `single` | `double`

vecdim — Vector of dimensions

positive integer vector

Vector of dimensions, specified as a positive integer vector. Each element of `vecdim` represents a dimension of the input array `X`. The output `y` has length 1 in the specified operating dimensions. The other dimension lengths are the same for `X` and `y`.

For example, if `X` is a 2-by-3-by-3 array, then `nanmean(X, [1 2])` returns a 1-by-1-by-3 array. Each element of the output is the mean of the elements on the corresponding page of `X`.

Data Types: `single` | `double`

Output Arguments

y — Mean values

scalar | vector | matrix | multidimensional array

Mean values, returned as a scalar, vector, matrix, or multidimensional array.

Tips

- When `nanmean` computes the mean of an array of all NaN values, the array is empty once the NaN values are removed and, therefore, the sum of the remaining elements is 0. Because the mean calculation involves division by 0, the mean value is NaN. The output NaN is not a mean of NaN values.

Alternative Functionality

Instead of using `nanmean`, you can use the MATLAB function `mean` with the input argument `nanflag` specified as the value `'omitnan'`.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The `'all'` and `vecdim` input arguments are not supported.
- The `dim` input argument must be a compile-time constant.
- If you do not specify the `dim` input argument, the working (or operating) dimension can be different in the generated code. As a result, run-time errors can occur. For more details, see “Automatic dimension restriction” (MATLAB Coder).

For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “General Code Generation Workflow” on page 31-5.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Usage notes and limitations:

- The 'all' and vecdim input arguments are not supported.

For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

NaN | mean | nanmedian

Introduced before R2006a

nanmedian

Median, ignoring NaN values

Syntax

```
y = nanmedian(X)
y = nanmedian(X, 'all')
y = nanmedian(X, dim)
y = nanmedian(X, vecdim)
```

Description

`y = nanmedian(X)` is the median of `X`, computed after removing NaN values.

For vectors `x`, `nanmedian(x)` is the median of the remaining elements, once NaN values are removed. For matrices `X`, `nanmedian(X)` is a row vector of column medians, once NaN values are removed. For multidimensional arrays `X`, `nanmedian` operates along the first nonsingleton dimension.

`y = nanmedian(X, 'all')` returns the median of all elements of `X`, computed after removing NaN values.

`y = nanmedian(X, dim)` takes the median along the operating dimension `dim` of `X`.

`y = nanmedian(X, vecdim)` returns the median over the dimensions specified in the vector `vecdim`, computed after removing NaN values. Each element of `vecdim` represents a dimension of the input array `X`. The output `y` has length 1 in the specified operating dimensions. The other dimension lengths are the same for `X` and `y`. For example, if `X` is a 2-by-3-by-4 array, then `nanmedian(X, [1 2])` returns a 1-by-1-by-4 array. Each element of the output array is the median of the elements on the corresponding page of `X`.

Examples

Median of Matrix Data

Find the column medians for matrix data with missing values.

```
X = magic(3);
X([1 6:9]) = NaN
```

```
X = 3×3
```

```
NaN     1     NaN
     3     5     NaN
     4    NaN     NaN
```

```
y = nanmedian(X)
```

```
y = 1×3
```

```
    3.5000    3.0000         NaN
```

Median Along Vector Dimension

Find the median of a multidimensional array over multiple dimensions.

Create a 3-by-5-by-2 array X with some missing values.

```
X = reshape(1:30,[3 5 2]);
X([10:12 25]) = NaN
```

```
X =
X(:,:,1) =
```

```
     1     4     7     NaN    13
     2     5     8     NaN    14
     3     6     9     NaN    15
```

```
X(:,:,2) =
```

```
    16    19    22     NaN    28
    17    20    23     26    29
```

```
18    21    24    27    30
```

Find the median of each page of X by specifying dimensions 1 and 2 as the operating dimensions.

```
ypage = nanmedian(X,[1 2])
```

```
ypage =  
ypage(:,:,1) =
```

```
6.5000
```

```
ypage(:,:,2) =
```

```
22.5000
```

For example, `ypage(1,1,1)` is the median of the non-NaN elements in $X(:, :, 1)$.

Find the median of the elements in each $X(:, i, :)$ slice by specifying dimensions 1 and 3 as the operating dimensions.

```
ycol = nanmedian(X,[1 3])
```

```
ycol = 1×5
```

```
9.5000    12.5000    15.5000    26.5000    21.5000
```

For example, `ycol(4)` is the median of the non-NaN elements in $X(:, 4, :)$.

Alternative Functionality

Instead of using `nanmedian`, you can use the MATLAB function `median` with the input argument `nanflag` specified as the value `'omitnan'`.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The 'all' and `vecdim` input arguments are not supported.
- The `dim` input argument must be a compile-time constant.
- If you do not specify the `dim` input argument, the working (or operating) dimension can be different in the generated code. As a result, run-time errors can occur. For more details, see “Automatic dimension restriction” (MATLAB Coder).

For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “General Code Generation Workflow” on page 31-5.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Usage notes and limitations:

- The 'all' and `vecdim` input arguments are not supported.

For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

nanmin

Minimum, ignoring NaN values

Syntax

```
y = nanmin(X)
y = nanmin(X,[],dim)
[y,indices] = nanmin( ___ )

y = nanmin(X,[],'all')
y = nanmin(X,[],vecdim)

Y = nanmin(X1,X2)
```

Description

`y = nanmin(X)` is the minimum `min` of `X`, computed after removing NaN values.

For vectors `x`, `nanmin(x)` is the minimum of the remaining elements, once NaN values are removed. For matrices `X`, `nanmin(X)` is a row vector of column minima, once NaN values are removed. For multidimensional arrays `X`, `nanmin` operates along the first nonsingleton dimension.

`y = nanmin(X,[],dim)` operates along the dimension `dim` of `X`.

`[y,indices] = nanmin(___)` also returns the row indices of the minimum values for each column in the vector `indices`.

`y = nanmin(X,[],'all')` returns the minimum of all elements of `X`, computed after removing NaN values.

`y = nanmin(X,[],vecdim)` returns the minimum over the dimensions specified in the vector `vecdim`, computed after removing NaN values. Each element of `vecdim` represents a dimension of the input array `X`. The output `y` has length 1 in the specified operating dimensions. The other dimension lengths are the same for `X` and `y`. For example, if `X` is a 2-by-3-by-4 array, then `nanmin(X,[],[1 2])` returns a 1-by-1-by-4 array. Each element of the output array is the minimum of the elements on the corresponding page of `X`.

`Y = nanmin(X1,X2)` returns an array `Y` the same size as `X1` and `X2` with `Y(i,j) = nanmin(X1(i,j),X2(i,j))`. Scalar inputs are expanded to an array of the same size as the other input.

Examples

Minimum of Matrix Data

Find the column minimum values and their indices for matrix data with missing values.

```
X = magic(3);
X([1 6:9]) = NaN
```

```
X = 3×3
```

```
NaN     1     NaN
     3     5     NaN
     4     NaN    NaN
```

```
[y,indices] = nanmin(X)
```

```
y = 1×3
```

```
     3     1     NaN
```

```
indices = 1×3
```

```
     2     1     1
```

Minimum of All Values

Find the minimum of all the values in an array, ignoring missing values.

Create a 2-by-5-by-3 array `X` with some missing values.

```
X = reshape(1:30,[2 5 3]);
X([10:12 25]) = NaN
```

```
X =  
X(:, :, 1) =  
  
     1     3     5     7     9  
     2     4     6     8    NaN
```

```
X(:, :, 2) =  
  
    NaN    13    15    17    19  
    NaN    14    16    18    20
```

```
X(:, :, 3) =  
  
    21    23    NaN    27    29  
    22    24    26    28    30
```

Find the minimum of the elements of X.

```
y = nanmin(X, [], 'all')
```

```
y = 1
```

Alternative Functionality

Instead of using `nanmin`, you can use the MATLAB function `min` with the input argument `nanflag` specified as the value `'omitnan'`.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The 'all' and vecdim input arguments are not supported.
- The dim input argument must be a compile-time constant.
- If you do not specify the dim input argument, the working (or operating) dimension can be different in the generated code. As a result, run-time errors can occur. For more details, see “Automatic dimension restriction” (MATLAB Coder).

For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “General Code Generation Workflow” on page 31-5.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Usage notes and limitations:

- The 'all' and vecdim input arguments are not supported.

For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

NaN | min | nanmax

Introduced before R2006a

nanstd

Standard deviation, ignoring NaN values

Syntax

```
y = nanstd(X)
y = nanstd(X, flag)
y = nanstd(X, flag, 'all')
y = nanstd(X, flag, dim)
y = nanstd(X, flag, vecdim)
```

Description

`y = nanstd(X)` is the standard deviation `std` of `X`, computed after removing all NaN values.

- If `X` is a vector, then `nanstd(X)` is the sample standard deviation of all the non-NaN elements of `X`.
- If `X` is a matrix, then `nanstd(X)` is a row vector of column sample standard deviations, computed after removing NaN values.
- If `X` is a multidimensional array, then `nanstd` operates along the first nonsingleton dimension of `X`. The size of this dimension becomes 1 while the sizes of all other dimensions remain the same. `nanstd` removes all NaN values.
- By default, `nanstd` normalizes `y` by $n - 1$, where n is the number of remaining observations after removing observations with NaN values.

`y = nanstd(X, flag)` returns the standard deviation of `X` based on the normalization specified by `flag`. The `flag` is 0 (default) or 1 to specify normalization by $n - 1$ or n , respectively, where n is the number of remaining observations after removing observations with NaN values.

`y = nanstd(X, flag, 'all')` returns the standard deviation of all elements of `X`, computed after removing NaN values.

`y = nanstd(X, flag, dim)` returns the standard deviation along the operating dimension `dim` of `X`, computed after removing NaN values.

`y = nanstd(X, flag, vecdim)` returns the standard deviation over the dimensions specified in the vector `vecdim`. The function computes the standard deviations after removing NaN values. For example, if `X` is a matrix, then `nanstd(X, 0, [1 2])` is the sample standard deviation of all non-NaN elements of `X` because every element of a matrix is contained in the array slice defined by dimensions 1 and 2.

Examples

Standard Deviation of Matrix Data

Find the column standard deviations for matrix data with missing values.

```
X = magic(3);
X([1 6:9]) = NaN
```

```
X = 3×3
```

```
NaN     1     NaN
  3     5     NaN
  4     NaN    NaN
```

```
y = nanstd(X)
```

```
y = 1×3
```

```
0.7071     2.8284     NaN
```

Standard Deviation for Population vs. Sample

Load the `carsmall` data set.

```
load carsmall
```

Compute the population and sample standard deviations for the Horsepower data. The `nanstd` function ignores the missing value in Horsepower.

```
y1 = nanstd(Horsepower,1) % Population formula
```

```
y1 = 45.2963
```

```
y2 = nanstd(Horsepower,0) % Sample formula
```

```
y2 = 45.5268
```

Standard Deviation of All Values

Find the standard deviation of all the values in an array, ignoring missing values.

Create a 3-by-4-by-2 array `X` with some missing values.

```
X = reshape(1:24,[3 4 2]);
```

```
X([8:10 18]) = NaN
```

```
X =
```

```
X(:,:,1) =
```

1	4	7	NaN
2	5	NaN	11
3	6	NaN	12

```
X(:,:,2) =
```

13	16	19	22
14	17	20	23
15	NaN	21	24

Find the sample standard deviation of the elements of `X`.

```
y = nanstd(X,0,'all')
```

```
y = 7.5385
```

Standard Deviation Along Scalar Dimension

Find the row standard deviations for matrix data with missing values. Specify to compute the sample standard deviations along the second dimension.

```
X = magic(3);
X([1 6:9]) = NaN
```

```
X = 3×3
```

```
NaN    1    NaN
 3     5    NaN
 4    NaN    NaN
```

```
y = nanstd(X,0,2)
```

```
y = 3×1
```

```
    0
1.4142
    0
```

Standard Deviation Along Vector Dimension

Find the standard deviation of a multidimensional array over multiple dimensions.

Create a 3-by-4-by-2 array X with some missing values.

```
X = reshape(1:24,[3 4 2]);
X([8:10 18]) = NaN
```

```
X =
X(:,:,1) =
```

```
 1     4     7    NaN
 2     5    NaN    11
 3     6    NaN    12
```

```
X(:,:,2) =
```

```
13    16    19    22
14    17    20    23
15    NaN    21    24
```

Find the sample standard deviation of each page of `X` by specifying dimensions 1 and 2 as the operating dimensions.

```
ypage = nanstd(X,0,[1 2])
```

```
ypage =
ypage(:,:,1) =
```

```
3.8079
```

```
ypage(:,:,2) =
```

```
3.7779
```

For example, `ypage(1,1,2)` is the sample standard deviation of the non-`NaN` elements in `X(:,:,2)`.

Find the sample standard deviation of the elements in each `X(i, :, :)` slice by specifying dimensions 2 and 3 as the operating dimensions.

```
yrow = nanstd(X,0,[2 3])
```

```
yrow = 3×1
```

```
7.9102
7.6904
8.2158
```

For example, `yrow(3)` is the sample standard deviation of the non-`NaN` elements in `X(3, :, :)`.

Input Arguments

X — Input data

scalar | vector | matrix | multidimensional array

Input data, specified as a scalar, vector, matrix, or multidimensional array.

Data Types: `single` | `double`

flag — Indicator for normalization

0 (default) | 1

Indicator for the normalization used to compute the standard deviation, specified as 0 or 1.

- If `flag` is 0 (default), then `nanstd` returns the sample standard deviation on page 32-4428 of *X*. `nanstd(X,0)` is the same as `nanstd(X)`.
- If `flag` is 1, then `nanstd` returns the population standard deviation on page 32-4429 of *X*.

Data Types: `single` | `double`

dim — Dimension to operate along

positive integer scalar

Dimension to operate along, specified as a positive integer scalar. If you do not specify a value, then the default value is the first array dimension whose size does not equal 1.

`dim` indicates the dimension whose length reduces to 1. `size(y,dim)` is 1 while the sizes of all other dimensions remain the same.

Consider a two-dimensional array *X*:

- If `dim` is equal to 1, then `nanstd(X,0,1)` returns a row vector containing the sample standard deviation for each column.
- If `dim` is equal to 2, then `nanstd(X,0,2)` returns a column vector containing the sample standard deviation for each row.

If `dim` is greater than `ndims(X)` or if `size(X,dim)` is 1, then `nanstd` returns an array of zeros with the same dimensions and missing values as *X*.

Data Types: `single` | `double`

vecdim — Vector of dimensions

positive integer vector

Vector of dimensions, specified as a positive integer vector. Each element of `vecdim` represents a dimension of the input array `X`. The output `y` has length 1 in the specified operating dimensions. The other dimension lengths are the same for `X` and `y`.

For example, if `X` is a 2-by-3-by-3 array, then `nanstd(X,0,[1 2])` returns a 1-by-1-by-3 array. Each element of the output array is the sample standard deviation of the elements on the corresponding page of `X`.

Data Types: `single` | `double`

Output Arguments

y — Standard deviation values

scalar | vector | matrix | multidimensional array

Standard deviation values, returned as a scalar, vector, matrix, or multidimensional array.

Definitions

Sample Standard Deviation

The *sample standard deviation* S is given by

$$S = \sqrt{\frac{\sum_{i=1}^n (x_i - \bar{X})^2}{n-1}}$$

S is the square root of an unbiased estimator of the variance of the population from which X is drawn, as long as X consists of independent, identically distributed samples. \bar{X} is the sample mean.

Notice that the denominator in this variance formula is $n - 1$.

Population Standard Deviation

If the data is the entire population of values, then you can use the *population standard deviation*,

$$\sigma = \sqrt{\frac{\sum_{i=1}^n (x_i - \mu)^2}{n}}.$$

If X is a random sample from a population, then the mean μ is estimated by the sample mean, and σ is the biased maximum likelihood estimator of the population standard deviation.

Notice that the denominator in this variance formula is n .

Alternative Functionality

Instead of using `nanstd`, you can use the MATLAB function `std` with the input argument `nanflag` specified as the value `'omitnan'`.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The `'all'` and `vecdim` input arguments are not supported.
- The `dim` input argument must be a compile-time constant.

- If you do not specify the `dim` input argument, the working (or operating) dimension can be different in the generated code. As a result, run-time errors can occur. For more details, see “Automatic dimension restriction” (MATLAB Coder).

For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “General Code Generation Workflow” on page 31-5.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Usage notes and limitations:

- The 'all' and `vecdim` input arguments are not supported.

For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

NaN | `nanmean` | `nanvar` | `std`

Introduced before R2006a

nansum

Sum, ignoring NaN values

Syntax

```
y = nansum(X)
y = nansum(X, 'all')
y = nansum(X, dim)
y = nansum(X, vecdim)
```

Description

`y = nansum(X)` returns the sum of the elements of `X`, computed after removing all NaN values.

- If `X` is a vector, then `nansum(X)` is the sum of all the non-NaN elements of `X`.
- If `X` is a matrix, then `nansum(X)` is a row vector of column sums, computed after removing NaN values.
- If `X` is a multidimensional array, then `nansum` operates along the first nonsingleton dimension of `X`. The size of this dimension becomes 1 while the sizes of all other dimensions remain the same. `nansum` removes all NaN values.

For information on how `nansum` treats arrays of all NaN values, see “Tips” on page 32-4437.

`y = nansum(X, 'all')` returns the sum of all elements of `X`, computed after removing NaN values.

`y = nansum(X, dim)` returns the sum along the operating dimension `dim` of `X`, computed after removing NaN values.

`y = nansum(X, vecdim)` returns the sum over the dimensions specified in the vector `vecdim`. The function computes the sums after removing NaN values. For example, if `X` is a matrix, then `nansum(X, [1 2])` is the sum of all non-NaN elements of `X` because every element of a matrix is contained in the array slice defined by dimensions 1 and 2.

Examples

Sum of Matrix Data

Find the column sums for matrix data with missing values.

```
X = magic(3);  
X([1 6:9]) = NaN
```

```
X = 3×3
```

```
NaN    1    NaN  
 3     5    NaN  
 4    NaN    NaN
```

```
y = nansum(X)
```

```
y = 1×3
```

```
 7     6     0
```

Sum of All Values

Find the sum of all the values in an array, ignoring missing values.

Create a 2-by-4-by-3 array X with some missing values.

```
X = reshape(1:24,[2 4 3]);  
X([5:6 20]) = NaN
```

```
X =  
X(:,:,1) =
```

```
 1     3    NaN    7  
 2     4    NaN    8
```

```
X(:,:,2) =
```

```

     9    11    13    15
    10    12    14    16

```

```
X(:, :, 3) =
```

```

    17    19    21    23
    18   NaN    22    24

```

Find the sum of the elements of X.

```
y = nansum(X, 'all')
```

```
y = 269
```

Sum Along Scalar Dimension

Find the row sums for matrix data with missing values by specifying to compute the sums along the second dimension.

```
X = magic(3);
X([1 6:9]) = NaN
```

```
X = 3×3
```

```

   NaN     1   NaN
     3     5   NaN
     4   NaN   NaN

```

```
y = nansum(X, 2)
```

```
y = 3×1
```

```

     1
     8
     4

```

Sum Along Vector Dimension

Find the sum of a multidimensional array over multiple dimensions.

Create a 2-by-4-by-3 array X with some missing values.

```
X = reshape(1:24,[2 4 3]);  
X([5:6 20]) = NaN
```

```
X =  
X(:,:,1) =
```

```
     1     3  NaN     7  
     2     4  NaN     8
```

```
X(:,:,2) =
```

```
     9    11    13    15  
    10    12    14    16
```

```
X(:,:,3) =
```

```
    17    19    21    23  
    18  NaN    22    24
```

Find the sum of each page of X by specifying dimensions 1 and 2 as the operating dimensions.

```
ypage = nansum(X,[1 2])
```

```
ypage =  
ypage(:,:,1) =
```

```
    25
```

```
ypage(:,:,2) =
```

```
   100
```

```
ypage(:,:,3) =
```

144

For example, `ypage(1,1,1)` is the sum of the non-NaN elements in `X(:, :, 1)`.

Find the sum of the elements in each `X(i, :, :)` slice by specifying dimensions 2 and 3 as the operating dimensions.

```
yrow = nansum(X,[2 3])
```

```
yrow = 2×1
```

```
139
```

```
130
```

For example, `yrow(2)` is the sum of the non-NaN elements in `X(2, :, :)`.

Input Arguments

X — Input data

scalar | vector | matrix | multidimensional array

Input data, specified as a scalar, vector, matrix, or multidimensional array.

If `X` is an empty array, then `nansum(X)` is 0.

Data Types: `single` | `double`

dim — Dimension to operate along

positive integer scalar

Dimension to operate along, specified as a positive integer scalar. If you do not specify a value, then the default value is the first array dimension whose size does not equal 1.

`dim` indicates the dimension whose length reduces to 1. `size(y, dim)` is 1 while the sizes of all other dimensions remain the same.

Consider a two-dimensional array `X`:

- If `dim` is equal to 1, then `nansum(X,1)` returns a row vector containing the sum for each column.
- If `dim` is equal to 2, then `nansum(X,2)` returns a column vector containing the sum for each row.

If `dim` is greater than `ndims(X)` or if `size(X,dim)` is 1, then `nansum` returns `X`, with 0 values in the place of any missing values.

Data Types: `single` | `double`

vecdim — Vector of dimensions

positive integer vector

Vector of dimensions, specified as a positive integer vector. Each element of `vecdim` represents a dimension of the input array `X`. The output `y` has length 1 in the specified operating dimensions. The other dimension lengths are the same for `X` and `y`.

For example, if `X` is a 2-by-3-by-3 array, then `nansum(X,[1 2])` returns a 1-by-1-by-3 array. Each element of the output array is the sum of the elements on the corresponding page of `X`.

Data Types: `single` | `double`

Output Arguments

y — Sum values

scalar | vector | matrix | multidimensional array

Sum values, returned as a scalar, vector, matrix, or multidimensional array.

Tips

- When `nansum` computes the sum of an array of all NaN values, the array is empty once the NaN values are removed and, therefore, the sum of the remaining elements is 0. The output 0 is not a sum of NaN values.

Alternative Functionality

Instead of using `nansum`, you can use the MATLAB function `sum` with the input argument `nanflag` specified as the value `'omitnan'`.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The `'all'` and `vecdim` input arguments are not supported.
- The `dim` input argument must be a compile-time constant.
- If you do not specify the `dim` input argument, the working (or operating) dimension can be different in the generated code. As a result, run-time errors can occur. For more details, see “Automatic dimension restriction” (MATLAB Coder).

For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “General Code Generation Workflow” on page 31-5.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Usage notes and limitations:

- The 'all' and vecdim input arguments are not supported.

For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

NaN | sum

Introduced before R2006a

nanvar

Variance, ignoring NaN values

Syntax

```
y = nanvar(X)
y = nanvar(X,w)
y = nanvar(X,w,'all')
y = nanvar(X,w,dim)
y = nanvar(X,w,vecdim)
```

Description

`y = nanvar(X)` is the variance `var` of `X`, computed after removing NaN values.

For vectors `x`, `nanvar(x)` is the sample variance of the remaining elements, once NaN values are removed. For matrices `X`, `nanvar(X)` is a row vector of column sample variances, once NaN values are removed. For multidimensional arrays `X`, `nanvar` operates along the first nonsingleton dimension.

`nanvar` removes the mean from each variable (column for matrix `X`) before calculating `y`. If n is the number of remaining observations after removing observations with NaN values, `nanvar` normalizes `y` by either $n - 1$ or n , depending on whether $n > 1$ or $n = 1$, respectively.

`y = nanvar(X,w)` computes the variance of `X` according to the weighting scheme `w`. When `w` is `0` (default), `X` is normalized by $n - 1$, where n is the number of non-NaN observations. When `w` is `1`, `w` is normalized by the number of non-NaN observations. Otherwise, `w` can be a weight vector containing nonnegative elements. The length of `w` must equal the length of the dimension over which `nanvar` operates. Elements of `X` corresponding to NaN values of `w` are ignored.

`y = nanvar(X,w,'all')` returns the variance over all elements of `X` when `w = 0` or `w = 1`. The `nanvar` function computes the variance after removing NaN values.

`y = nanvar(X,w,dim)` returns the variance along the operating dimension `dim` of `X`.

`y = nanvar(X,w,vecdim)` returns the variance over the dimensions specified in the vector `vecdim`, computed after removing NaN values. Each element of `vecdim` represents a dimension of the input array `X`. The output `y` has length 1 in the specified operating dimensions. The other dimension lengths are the same for `X` and `y`. For example, if `X` is a 2-by-3-by-4 array, then `nanvar(X,[1],[1 2])` returns a 1-by-1-by-4 array. Each element of the output array is the variance of the elements on the corresponding page of `X`. This syntax is supported when `w = 0` or `w = 1`.

Examples

Variance of Matrix Data

Find the column variances for matrix data with missing values.

```
X = magic(3);  
X([1 6:9]) = NaN
```

```
X = 3×3
```

```
NaN     1     NaN  
 3       5     NaN  
 4     NaN     NaN
```

```
y = nanvar(X)
```

```
y = 1×3
```

```
0.5000    8.0000    NaN
```

Variance Along Vector Dimension

Find the variance of a multidimensional array over multiple dimensions.

Create a 3-by-4-by-2 array `X` with some missing values.

```
X = reshape(1:24,[3 4 2]);  
X([8:10 18]) = NaN
```

```
X =
X(:,:,1) =

     1     4     7  NaN
     2     5  NaN    11
     3     6  NaN    12
```

```
X(:,:,2) =

    13    16    19    22
    14    17    20    23
    15   NaN    21    24
```

Find the sample variance of each page of X by specifying dimensions 1 and 2 as the operating dimensions.

```
ypage = nanvar(X,0,[1 2])
```

```
ypage =
ypage(:,:,1) =

    14.5000
```

```
ypage(:,:,2) =

    14.2727
```

For example, `ypage(1,1,2)` is the sample variance of the non-NaN elements in `X(:,:,2)`.

Find the sample variance of the elements in each `X(:,i,:)` slice by specifying dimensions 1 and 3 as the operating dimensions.

```
ycol = nanvar(X,0,[1 3])
```

```
ycol = 1x4

    44.0000    40.3000    42.9167    40.3000
```

For example, `ycol(4)` is the sample variance of the non-NaN elements in `X(:,4,:)`.

Alternative Functionality

Instead of using `nanvar`, you can use the MATLAB function `var` with the input argument `nanflag` specified as the value `'omitnan'`.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The `'all'` and `vecdim` input arguments are not supported.
- The `dim` input argument must be a compile-time constant.
- If you do not specify the `dim` input argument, the working (or operating) dimension can be different in the generated code. As a result, run-time errors can occur. For more details, see “Automatic dimension restriction” (MATLAB Coder).

For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “General Code Generation Workflow” on page 31-5.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Usage notes and limitations:

- The `'all'` and `vecdim` input arguments are not supported.

For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

Introduced before R2006a

nbincdf

Negative binomial cumulative distribution function

Syntax

```
y = nbincdf(x,R,p)
y = nbincdf(x,R,p, 'upper')
```

Description

`y = nbincdf(x,R,p)` computes the negative binomial cdf at each of the values in `x` using the corresponding number of successes, `R` and probability of success in a single trial, `p`. `x`, `R`, and `p` can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of `y`. A scalar input for `x`, `R`, or `p` is expanded to a constant array with the same dimensions as the other inputs.

`y = nbincdf(x,R,p, 'upper')` returns the complement of the negative binomial cdf at each value in `x`, using an algorithm that more accurately computes the extreme upper tail probabilities.

The negative binomial cdf is

$$y = F(x \mid r, p) = \sum_{i=0}^x \binom{r+i-1}{i} p^r q^i I_{(0,1,\dots)}(i)$$

The simplest motivation for the negative binomial is the case of successive random trials, each having a constant probability `p` of success. The number of *extra* trials you must perform in order to observe a given number `R` of successes has a negative binomial distribution. However, consistent with a more general interpretation of the negative binomial, `nbincdf` allows `R` to be any positive value, including nonintegers. When `R` is noninteger, the binomial coefficient in the definition of the cdf is replaced by the equivalent expression

$$\frac{\Gamma(r+i)}{\Gamma(r)\Gamma(i+1)}$$

Examples

Compute Negative Binomial Distribution CDF

```
x = (0:15);  
p = nbincdf(x,3,0.5);  
stairs(x,p)
```

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Topics

“Negative Binomial Distribution” on page B-122

Introduced before R2006a

nbinfit

Negative binomial parameter estimates

Syntax

```
parmhat = nbinfit(data)
[parmhat,parmci] = nbinfit(data,alpha)
[...] = nbinfit(data,alpha,options)
```

Description

`parmhat = nbinfit(data)` returns the maximum likelihood estimates (MLEs) of the parameters of the negative binomial distribution given the data in the vector `data`.

`[parmhat,parmci] = nbinfit(data,alpha)` returns MLEs and $100(1-\alpha)$ percent confidence intervals. By default, `alpha = 0.05`, which corresponds to 95% confidence intervals.

`[...] = nbinfit(data,alpha,options)` accepts a structure, `options`, that specifies control parameters for the iterative algorithm the function uses to compute maximum likelihood estimates. The negative binomial fit function accepts an `options` structure which you can create using the function `statset`. Enter `statset('nbinfit')` to see the names and default values of the parameters that `nbinfit` accepts in the `options` structure. See the reference page for `statset` for more information about these options.

Note The variance of a negative binomial distribution is greater than its mean. If the sample variance of the data in `data` is less than its sample mean, `nbinfit` cannot compute MLEs. You should use the `poissfit` function instead.

Topics

“Negative Binomial Distribution” on page B-122

Introduced before R2006a

nbininv

Negative binomial inverse cumulative distribution function

Syntax

```
X = nbininv(Y,R,P)
```

Description

`X = nbininv(Y,R,P)` returns the inverse of the negative binomial cdf with corresponding number of successes, `R` and probability of success in a single trial, `P`. Since the binomial distribution is discrete, `nbininv` returns the least integer `X` such that the negative binomial cdf evaluated at `X` equals or exceeds `Y`. `Y`, `R`, and `P` can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of `X`. A scalar input for `Y`, `R`, or `P` is expanded to a constant array with the same dimensions as the other inputs.

The simplest motivation for the negative binomial is the case of successive random trials, each having a constant probability `P` of success. The number of *extra* trials you must perform in order to observe a given number `R` of successes has a negative binomial distribution. However, consistent with a more general interpretation of the negative binomial, `nbininv` allows `R` to be any positive value, including nonintegers.

Examples

How many times would you need to flip a fair coin to have a 99% probability of having observed 10 heads?

```
flips = nbininv(0.99,10,0.5) + 10  
flips =  
    33
```

Note that you have to flip at least 10 times to get 10 heads. That is why the second term on the right side of the equals sign is a 10.

Introduced before R2006a

nbinpdf

Negative binomial probability density function

Syntax

`Y = nbinpdf(X,R,P)`

Description

`Y = nbinpdf(X,R,P)` returns the negative binomial pdf at each of the values in `X` using the corresponding number of successes, `R` and probability of success in a single trial, `P`. `X`, `R`, and `P` can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of `Y`. A scalar input for `X`, `R`, or `P` is expanded to a constant array with the same dimensions as the other inputs. Note that the density function is zero unless the values in `X` are integers.

The negative binomial pdf is

$$y = f(x | r, p) = \binom{r+x-1}{x} p^r q^x I_{(0,1,\dots)}(x)$$

The simplest motivation for the negative binomial is the case of successive random trials, each having a constant probability `P` of success. The number of *extra* trials you must perform in order to observe a given number `R` of successes has a negative binomial distribution. However, consistent with a more general interpretation of the negative binomial, `nbinpdf` allows `R` to be any positive value, including nonintegers. When `R` is noninteger, the binomial coefficient in the definition of the pdf is replaced by the equivalent expression

$$\frac{\Gamma(r+x)}{\Gamma(r)\Gamma(x+1)}$$

Examples

Compute the Negative Binomial Distribution pdf

Compute the pdf of a negative binomial distribution with parameters $R = 3$ and $p = 0.5$.

```
x = (0:10);  
y = nbinpdf(x,3,0.5);
```

Plot the pdf.

```
figure;  
plot(x,y,'+')  
xlim([-0.5,10.5])
```

nbinrnd

Negative binomial random numbers

Syntax

```
RND = nbinrnd(R,P)
RND = nbinrnd(R,P,m,n,...)
RND = nbinrnd(R,P,[m,n,...])
```

Description

`RND = nbinrnd(R,P)` is a matrix of random numbers chosen from a negative binomial distribution with corresponding number of successes, `R` and probability of success in a single trial, `P`. `R` and `P` can be vectors, matrices, or multidimensional arrays that have the same size, which is also the size of `RND`. A scalar input for `R` or `P` is expanded to a constant array with the same dimensions as the other input.

`RND = nbinrnd(R,P,m,n,...)` or `RND = nbinrnd(R,P,[m,n,...])` generates an `m`-by-`n`-by-... array. The `R`, `P` parameters can each be scalars or arrays of the same size as `R`.

The simplest motivation for the negative binomial is the case of successive random trials, each having a constant probability `P` of success. The number of *extra* trials you must perform in order to observe a given number `R` of successes has a negative binomial distribution. However, consistent with a more general interpretation of the negative binomial, `nbinrnd` allows `R` to be any positive value, including nonintegers.

Examples

Suppose you want to simulate a process that has a defect probability of 0.01. How many units might Quality Assurance inspect before finding three defective items?

```
r = nbinrnd(3,0.01,1,6)+3
r =
    496    142    420    396    851    178
```

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

The generated code can return a different sequence of numbers than MATLAB if either of the following is true:

- The output is nonscalar.
- An input parameter is invalid for the distribution.

For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “General Code Generation Workflow” on page 31-5.

nbinstat

Negative binomial mean and variance

Syntax

```
[M,V] = nbinstat(R,P)
```

Description

`[M,V] = nbinstat(R,P)` returns the mean of and variance for the negative binomial distribution with corresponding number of successes, R and probability of success in a single trial, P . R and P can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of M and V . A scalar input for R or P is expanded to a constant array with the same dimensions as the other input.

The mean of the negative binomial distribution with parameters r and p is rq / p , where $q = 1 - p$. The variance is rq / p^2 .

The simplest motivation for the negative binomial is the case of successive random trials, each having a constant probability P of success. The number of *extra* trials you must perform in order to observe a given number R of successes has a negative binomial distribution. However, consistent with a more general interpretation of the negative binomial, `nbinstat` allows R to be any positive value, including nonintegers.

Examples

```
p = 0.1:0.2:0.9;  
r = 1:5;  
[R,P] = meshgrid(r,p);  
[M,V] = nbinstat(R,P)  
M =

FeatureSelectionNCAClassification class

Feature selection for classification using neighborhood component analysis (NCA)

Description

`FeatureSelectionNCAClassification` object contains the data, fitting information, feature weights, and other parameters of a neighborhood component analysis (NCA) model. `fscnca` learns the feature weights using a diagonal adaptation of NCA and returns an instance of a `FeatureSelectionNCAClassification` object. The function achieves feature selection by regularizing the feature weights.

Construction

Create a `FeatureSelectionNCAClassification` object using `fscnca`.

Properties

NumObservations — Number of observations in the training data

scalar

Number of observations in the training data (X and Y) after removing NaN or Inf values, stored as a scalar.

Data Types: `double`

ModelParameters — Model parameters

structure

Model parameters used for training the model, stored as a structure.

You can access the fields of `ModelParameters` using dot notation.

For example, for a `FeatureSelectionNCAClassification` object named `mdl`, you can access the `LossFunction` value using `mdl.ModelParameters.LossFunction`.

Data Types: struct

Lambda — Regularization parameter

scalar

Regularization parameter used for training this model, stored as a scalar. For n observations, the best Lambda value that minimizes the generalization error of the NCA model is expected to be a multiple of $1/n$.

Data Types: double

FitMethod — Name of fitting method

'exact' | 'none' | 'average'

Name of the fitting method used to fit this model, stored as one of the following:

- 'exact' — Perform fitting using all of the data.
- 'none' — No fitting. Use this option to evaluate the generalization error of the NCA model using the initial feature weights supplied in the call to `fscnca`.
- 'average' — Divide the data into partitions (subsets), fit each partition using the `exact` method, and return the average of the feature weights. You can specify the number of partitions using the `NumPartitions` name-value pair argument.

Solver — Name of the solver used to fit this model

'lbfgs' | 'sgd' | 'minibatch-lbfgs'

Name of the solver used to fit this model, stored as one of the following:

- 'lbfgs' — Limited memory Broyden-Fletcher-Goldfarb-Shanno (LBFGS) algorithm
- 'sgd' — Stochastic gradient descent (SGD) algorithm
- 'minibatch-lbfgs' — stochastic gradient descent with LBFGS algorithm applied to mini-batches

GradientTolerance — Relative convergence tolerance on gradient norm

positive scalar

Relative convergence tolerance on the gradient norm for the 'lbfgs' and 'minibatch-lbfgs' solvers, stored as a positive scalar value.

Data Types: double

IterationLimit — Maximum number of iterations for optimization

positive integer

Maximum number of iterations for optimization, stored as a positive integer value.

Data Types: double

PassLimit — Maximum number of passes

positive integer

Maximum number of passes for 'sgd' and 'minibatch-lbfgs' solvers. Every pass processes all of the observations in the data.

Data Types: double

InitialLearningRate — Initial learning rate

positive real scalar

Initial learning rate for the 'sgd' and 'minibatch-lbfgs' solvers, stored as a positive real scalar. The learning rate decays over iterations starting at the value specified for InitialLearningRate.

Use the NumTuningIterations and TuningSubsetSize name-value pair arguments to control the automatic tuning of initial learning rate in the call to fscnca.

Data Types: double

Verbose — Verbosity level indicator

nonnegative integer

Verbosity level indicator, stored as a nonnegative integer. Possible values are:

- 0 — No convergence summary
- 1 — Convergence summary, including norm of gradient and objective function value
- >1 — More convergence information, depending on the fitting algorithm. When you use the 'minibatch-lbfgs' solver and verbosity level > 1, the convergence information includes the iteration log from intermediate minibatch LBFGS fits.

Data Types: double

InitialFeatureWeights — Initial feature weights p -by-1 vector of positive real scalars

Initial feature weights, stored as a p -by-1 vector of positive real scalars, where p is the number of predictors in X .

Data Types: double

FeatureWeights — Feature weights

p -by-1 vector of real scalars

Feature weights, stored as a p -by-1 vector of real scalars, where p is the number of predictors in X .

If `FitMethod` is 'average', then `FeatureWeights` is a p -by- m matrix. m is the number of partitions specified via the 'NumPartitions' name-value pair argument in the call to `fscnca`.

The absolute value of `FeatureWeights(k)` is a measure of the importance of predictor k . A `FeatureWeights(k)` value that is close to 0 indicates that predictor k does not influence the response in Y .

Data Types: double

FitInfo — Fit information

structure

Fit information, stored as a structure with the following fields.

Field Name	Meaning
Iteration	Iteration index
Objective	Regularized objective function for minimization
UnregularizedObjective	Unregularized objective function for minimization
Gradient	Gradient of regularized objective function for minimization

- For classification, `UnregularizedObjective` represents the negative of the leave-one-out accuracy of the NCA classifier on the training data.
- For regression, `UnregularizedObjective` represents the leave-one-out loss between the true response and the predicted response when using the NCA regression model.

- For the 'lbfgs' solver, Gradient is the final gradient. For the 'sgd' and 'minibatch-lbfgs' solvers, Gradient is the final mini-batch gradient.
- If FitMethod is 'average', then FitInfo is an m -by-1 structure array, where m is the number of partitions specified via the 'NumPartitions' name-value pair argument.

You can access the fields of FitInfo using dot notation. For example, for a FeatureSelectionNCAClassificationobject named mdl, you can access the Objective field using `mdl.FitInfo.Objective`.

Data Types: struct

Mu — Predictor means

p -by-1 vector | []

Predictor means, stored as a p -by-1 vector for standardized training data. In this case, the `predict` method centers predictor matrix X by subtracting the respective element of Mu from every column.

If data is not standardized during training, then Mu is empty.

Data Types: double

Sigma — Predictor standard deviations

p -by-1 vector | []

Predictor standard deviations, stored as a p -by-1 vector for standardized training data. In this case, the `predict` method scales predictor matrix X by dividing every column by the respective element of Sigma after centering the data using Mu.

If data is not standardized during training, then Sigma is empty.

Data Types: double

X — Predictor values

n -by- p matrix

Predictor values used to train this model, stored as an n -by- p matrix. n is the number of observations and p is the number of predictor variables in the training data.

Data Types: double

Y — Response values

numeric vector of size n

Response values used to train this model, stored as a numeric vector of size n , where n is the number of observations.

Data Types: double

W — Observation weights

numeric vector of size n

Observation weights used to train this model, stored as a numeric vector of size n . The sum of observation weights is n .

Data Types: double

Methods

- loss Evaluate accuracy of learned feature weights on test data
- predict Predict responses using neighborhood component analysis (NCA) classifier
- refit Refit neighborhood component analysis (NCA) model for classification

Examples

Explore FeatureSelectionNCAClassification Object

Load the sample data.

```
load ionosphere
```

The data set has 34 continuous predictors. The response variable is the radar returns, labeled as b (bad) or g (good).

Fit a neighborhood component analysis (NCA) model for classification to detect the relevant features.

```
mdl = fscnca(X,Y);
```

The returned NCA model, `mdl`, is a `FeatureSelectionNCAClassification` object. This object stores information about the training data, model, and optimization. You can access the object properties, such as the feature weights, using dot notation.

Plot the feature weights.

```
figure()
plot mdl.FeatureWeights, 'ro'
xlabel('Feature Index')
ylabel('Feature Weight')
grid on
```

The weights of the irrelevant features are zero. The 'Verbose', 1 option in the call to `fscna` displays the optimization information on the command line. You can also visualize the optimization process by plotting the objective function versus the iteration number.

```
figure
plot mdl.FitInfo.Iteration, mdl.FitInfo.Objective, 'ro-')
```

```
grid on
xlabel('Iteration Number')
ylabel('Objective')
```

The `ModelParameters` property is a struct that contains more information about the model. You can access the fields of this property using dot notation. For example, see if the data was standardized or not.

```
mdl.ModelParameters.Standardize
```

```
ans = logical
      0
```

0 means that the data was not standardized before fitting the NCA model. You can standardize the predictors when they are on very different scales using the 'Standardize', 1 name-value pair argument in the call to `fscnca` .

FeatureSelectionNCARegression class

Feature selection for regression using neighborhood component analysis (NCA)

Description

`FeatureSelectionNCARegression` contains the data, fitting information, feature weights, and other model parameters of a neighborhood component analysis (NCA) model. `fsrnca` learns the feature weights using a diagonal adaptation of NCA and returns an instance of `FeatureSelectionNCARegression` object. The function achieves feature selection by regularizing the feature weights.

Construction

Create a `FeatureSelectionNCARegression` object using `fsrnca`.

Properties

NumObservations — Number of observations in the training data

scalar

Number of observations in the training data (X and Y) after removing NaN or Inf values, stored as a scalar.

Data Types: `double`

ModelParameters — Model parameters

structure

Model parameters used for training the model, stored as a structure.

You can access the fields of `ModelParameters` using dot notation.

For example, for a `FeatureSelectionNCARegression` object named `mdl`, you can access the `LossFunction` value using `mdl.ModelParameters.LossFunction`.

Data Types: `struct`

Lambda — Regularization parameter

scalar

Regularization parameter used for training this model, stored as a scalar. For n observations, the best `Lambda` value that minimizes the generalization error of the NCA model is expected to be a multiple of $1/n$.

Data Types: `double`

FitMethod — Name of the fitting method used to fit this model

`'exact' | 'none' | 'average'`

Name of the fitting method used to fit this model, stored as one of the following:

- `'exact'` — Perform fitting using all of the data.
- `'none'` — No fitting. Use this option to evaluate the generalization error of the NCA model using the initial feature weights supplied in the call to `fsrnca`.
- `'average'` — The software divides the data into partitions (subsets), fits each partition using the `exact` method, and returns the average of the feature weights. You can specify the number of partitions using the `NumPartitions` name-value pair argument.

Solver — Name of the solver used to fit this model

`'lbfgs' | 'sgd' | 'minibatch-lbfgs'`

Name of the solver used to fit this model, stored as one of the following:

- `'lbfgs'` — Limited memory Broyden-Fletcher-Goldfarb-Shanno (LBFGS) algorithm
- `'sgd'` — Stochastic gradient descent (SGD) algorithm
- `'minibatch-lbfgs'` — stochastic gradient descent with LBFGS algorithm applied to mini-batches

GradientTolerance — Relative convergence tolerance on gradient norm

positive scalar

Relative convergence tolerance on the gradient norm for the `'lbfgs'` and `'minibatch-lbfgs'` solvers, stored as a positive scalar value.

Data Types: `double`

IterationLimit — Maximum number of iterations for optimization

positive integer

Maximum number of iterations for optimization, stored as a positive integer value.

Data Types: double

PassLimit — Maximum number of passes

positive integer

Maximum number of passes for 'sgd' and 'minibatch-lbfgs' solvers. Every pass processes all of the observations in the data.

Data Types: double

InitialLearningRate — Initial learning rate

positive real scalar

Initial learning rate for 'sgd' and 'minibatch-lbfgs' solvers. The learning rate decays over iterations starting at the value specified for `InitialLearningRate`.

Use the `NumTuningIterations` and `TuningSubsetSize` to control the automatic tuning of initial learning rate in the call to `fsrnca`.

Data Types: double

Verbose — Verbosity level indicator

nonnegative integer

Verbosity level indicator, stored as a nonnegative integer. Possible values are:

- 0 — No convergence summary
- 1 — Convergence summary, including norm of gradient and objective function value
- >1 — More convergence information, depending on the fitting algorithm. When you use the 'minibatch-lbfgs' solver and verbosity level > 1, the convergence information includes the iteration log from intermediate minibatch LBFGS fits.

Data Types: double

InitialFeatureWeights — Initial feature weights p -by-1 vector of positive real scalars

Initial feature weights, stored as a p -by-1 vector of positive real scalars, where p is the number of predictors in X .

Data Types: double

FeatureWeights — Feature weights

p -by-1 vector of real scalar values

Feature weights, stored as a p -by-1 vector of real scalar values, where p is the number of predictors in X .

For 'FitMethod' equal to 'average', FeatureWeights is a p -by- m matrix, where m is the number of partitions specified via the 'NumPartitions' name-value pair argument in the call to `fsrcna`.

The absolute value of FeatureWeights(k) is a measure of the importance of predictor k . If FeatureWeights(k) is close to 0, then this indicates that predictor k does not influence the response in Y .

Data Types: double

FitInfo — Fit information

structure

Fit information, stored as a structure with the following fields.

Field Name	Meaning
Iteration	Iteration index
Objective	Regularized objective function for minimization
UnregularizedObjective	Unregularized objective function for minimization
Gradient	Gradient of regularized objective function for minimization

- For classification, UnregularizedObjective represents the negative of the leave-one-out accuracy of the NCA classifier on the training data.
- For regression, UnregularizedObjective represents the leave-one-out loss between the true response and the predicted response when using the NCA regression model.
- For the 'lbfgs' solver, Gradient is the final gradient. For the 'sgd' and 'minibatch-lbfgs' solvers, Gradient is the final mini-batch gradient.

- If `FitMethod` is 'average', then `FitInfo` is an m -by-1 structure array, where m is the number of partitions specified via the 'NumPartitions' name-value pair argument.

You can access the fields of `FitInfo` using dot notation. For example, for a `FeatureSelectionNCARegression` object named `mdl`, you can access the `Objective` field using `mdl.FitInfo.Objective`.

Data Types: `struct`

Mu — Predictor means

p -by-1 vector | []

Predictor means, stored as a p -by-1 vector for standardized training data. In this case, the `predict` method centers predictor matrix X by subtracting the respective element of `Mu` from every column.

If data is not standardized during training, then `Mu` is empty.

Data Types: `double`

Sigma — Predictor standard deviations

p -by-1 vector | []

Predictor standard deviations, stored as a p -by-1 vector for standardized training data. In this case, the `predict` method scales predictor matrix X by dividing every column by the respective element of `Sigma` after centering the data using `Mu`.

If data is not standardized during training, then `Sigma` is empty.

Data Types: `double`

X — Predictor values

n -by- p matrix

Predictor values used to train this model, stored as an n -by- p matrix. n is the number of observations and p is the number of predictor variables in the training data.

Data Types: `double`

Y — Response values

numeric vector of size n

Response values used to train this model, stored as a numeric vector of size n , where n is the number of observations.

Data Types: double

W — Observation weights

numeric vector of size n

Observation weights used to train this model, stored as a numeric vector of size n . The sum of observation weights is n .

Data Types: double

Methods

- `loss` Evaluate accuracy of learned feature weights on test data
- `predict` Predict responses using neighborhood component analysis (NCA) regression model
- `refit` Refit neighborhood component analysis (NCA) model for regression

Examples

Explore FeatureSelectionNCARegression Object

Load the sample data.

```
load imports-85
```

The first 15 columns contain the continuous predictor variables, whereas the 16th column contains the response variable, which is the price of a car. Define the variables for the neighborhood component analysis model.

```
Predictors = X(:,1:15);  
Y = X(:,16);
```

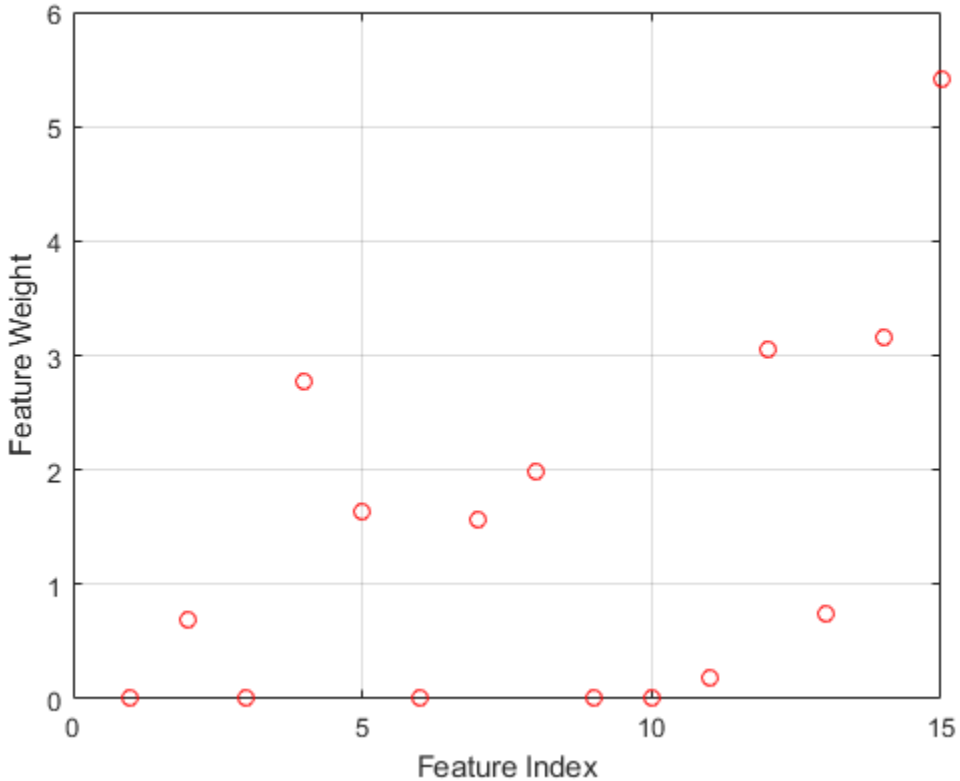

Fit a neighborhood component analysis (NCA) model for regression to detect the relevant features.

```
mdl = fsrnca(Predictors,Y);
```

The returned NCA model, `mdl`, is a `FeatureSelectionNCARegression` object. This object stores information about the training data, model, and optimization. You can access the object properties, such as the feature weights, using dot notation.

Plot the feature weights.

```
figure()  
plot(mdl.FeatureWeights, 'ro')  
xlabel('Feature Index')  
ylabel('Feature Weight')  
grid on
```

The weights of the irrelevant features are zero. The 'Verbose', 1 option in the call to `fsrcna` displays the optimization information on the command line. You can also visualize the optimization process by plotting the objective function versus the iteration number.

```
figure()
plot mdl.FitInfo.Iteration, mdl.FitInfo.Objective, 'ro-'
grid on
xlabel('Iteration Number')
ylabel('Objective')
```

The `ModelParameters` property is a struct that contains more information about the model. You can access the fields of this property using dot notation. For example, see if the data was standardized or not.

```
mdl.ModelParameters.Standardize
```

```
ans = logical  
     0
```

0 means that the data was not standardized before fitting the NCA model. You can standardize the predictors when they are on very different scales using the 'Standardize', 1 name-value pair argument in the call to `fsrnca`.

ncfcdf

Noncentral F cumulative distribution function

Syntax

```
p = ncfcdf(x, nu1, nu2, delta)
p = ncfcdf(x, nu1, nu2, delta, 'upper')
```

Description

`p = ncfcdf(x, nu1, nu2, delta)` computes the noncentral F cdf at each value in x using the corresponding numerator degrees of freedom in `nu1`, denominator degrees of freedom in `nu2`, and positive noncentrality parameters in `delta`. `nu1`, `nu2`, and `delta` can be vectors, matrices, or multidimensional arrays that have the same size, which is also the size of `p`. A scalar input for `x`, `nu1`, `nu2`, or `delta` is expanded to a constant array with the same dimensions as the other inputs.

`p = ncfcdf(x, nu1, nu2, delta, 'upper')` returns the complement of the noncentral F cdf at each value in x , using an algorithm that more accurately computes the extreme upper tail probabilities.

The noncentral F cdf is

$$F(x \mid \nu_1, \nu_2, \delta) = \sum_{j=0}^{\infty} \left(\frac{\left(\frac{1}{2}\delta\right)^j}{j!} e^{-\frac{\delta}{2}} \right) I\left(\frac{\nu_1 \cdot x}{\nu_2 + \nu_1 \cdot x} \mid \frac{\nu_1}{2} + j, \frac{\nu_2}{2}\right)$$

where $I(x|a,b)$ is the incomplete beta function with parameters a and b .

Examples

Compute Noncentral F Distribution cdf

Compare the noncentral F cdf with $\delta = 10$ to the F cdf with the same number of numerator and denominator degrees of freedom (5 and 20 respectively).

```
x = (0.01:0.1:10.01)';  
p1 = ncfcdf(x,5,20,10);  
p = fcdf(x,5,20);  
plot(x,p, '- ',x,p1, '-')
```

Topics

“Noncentral F Distribution” on page B-130

Introduced before R2006a

ncfinv

Noncentral F inverse cumulative distribution function

Syntax

```
X = ncfinv(P,NU1,NU2,DELTA)
```

Description

`X = ncfinv(P,NU1,NU2,DELTA)` returns the inverse of the noncentral F cdf with numerator degrees of freedom `NU1`, denominator degrees of freedom `NU2`, and positive noncentrality parameter `DELTA` for the corresponding probabilities in `P`. `P`, `NU1`, `NU2`, and `DELTA` can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of `X`. A scalar input for `P`, `NU1`, `NU2`, or `DELTA` is expanded to a constant array with the same dimensions as the other inputs.

Examples

One hypothesis test for comparing two sample variances is to take their ratio and compare it to an F distribution. If the numerator and denominator degrees of freedom are 5 and 20 respectively, then you reject the hypothesis that the first variance is equal to the second variance if their ratio is less than that computed below.

```
critical = finv(0.95,5,20)
critical =
    2.7109
```

Suppose the truth is that the first variance is twice as big as the second variance. How likely is it that you would detect this difference?

```
prob = 1 - nfcdf(critical,5,20,2)
prob =
    0.1297
```

If the true ratio of variances is 2, what is the typical (median) value you would expect for the F statistic?

```
ncfinv(0.5,5,20,2)
ans =
    1.2786
```

Topics

“Noncentral F Distribution” on page B-130

Introduced before R2006a

ncfpdf

Noncentral F probability density function

Syntax

```
Y = ncfpdf(X, NU1, NU2, DELTA)
```

Description

`Y = ncfpdf(X, NU1, NU2, DELTA)` computes the noncentral F pdf at each of the values in X using the corresponding numerator degrees of freedom in $NU1$, denominator degrees of freedom in $NU2$, and positive noncentrality parameters in $DELTA$. X , $NU1$, $NU2$, and $DELTA$ can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of Y . A scalar input for $NU1$, $NU2$, or $DELTA$ is expanded to a constant array with the same dimensions as the other inputs.

The F distribution is a special case of the noncentral F where $\delta = 0$. As δ increases, the distribution flattens like the plot in the example.

Examples

Compute Noncentral F Distribution pdf

Compute the pdf of a noncentral F distribution with degrees of freedom $NU1 = 5$ and $NU2 = 20$, and noncentrality parameter $DELTA = 10$. For comparison, also compute the pdf of an F distribution with the same degrees of freedom.

```
x = (0.01:0.1:10.01)';  
p1 = ncfpdf(x,5,20,10);  
p = fpdf(x,5,20);
```

Plot the pdf of the noncentral F distribution and the pdf of the F distribution on the same figure.

```
figure;  
plot(x,p1,'b-','LineWidth',2)  
hold on  
plot(x,p,'g--','LineWidth',2)  
legend('Noncentral F','F distribution')
```

ncfrnd

Noncentral F random numbers

Syntax

```
R = ncfrnd(NU1,NU2,DELTA)
R = ncfrnd(NU1,NU2,DELTA,m,n,...)
R = ncfrnd(NU1,NU2,DELTA,[m,n,...])
```

Description

`R = ncfrnd(NU1,NU2,DELTA)` returns a matrix of random numbers chosen from the noncentral F distribution with corresponding numerator degrees of freedom in `NU1`, denominator degrees of freedom in `NU2`, and positive noncentrality parameters in `DELTA`. `NU1`, `NU2`, and `DELTA` can be vectors, matrices, or multidimensional arrays that have the same size, which is also the size of `R`. A scalar input for `NU1`, `NU2`, or `DELTA` is expanded to a constant matrix with the same dimensions as the other inputs.

`R = ncfrnd(NU1,NU2,DELTA,m,n,...)` or `R = ncfrnd(NU1,NU2,DELTA,[m,n,...])` generates an `m`-by-`n`-by-... array. The `NU1`, `NU2`, `DELTA` parameters can each be scalars or arrays of the same size as `R`.

Examples

Compute six random numbers from a noncentral F distribution with 10 numerator degrees of freedom, 100 denominator degrees of freedom and a noncentrality parameter, δ , of 4.0. Compare this to the F distribution with the same degrees of freedom.

```
r = ncfrnd(10,100,4,1,6)
r =
  2.5995  0.8824  0.8220  1.4485  1.4415  1.4864

r1 = frnd(10,100,1,6)
r1 =
  0.9826  0.5911  1.0967  0.9681  2.0096  0.6598
```

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

The generated code can return a different sequence of numbers than MATLAB if either of the following is true:

- The output is nonscalar.
- An input parameter is invalid for the distribution.

For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “General Code Generation Workflow” on page 31-5.

ncfstat

Noncentral F mean and variance

Syntax

```
[M,V] = ncfstat(NU1,NU2,DELTA)
```

Description

`[M,V] = ncfstat(NU1,NU2,DELTA)` returns the mean of and variance for the noncentral F pdf with corresponding numerator degrees of freedom in `NU1`, denominator degrees of freedom in `NU2`, and positive noncentrality parameters in `DELTA`. `NU1`, `NU2`, and `DELTA` can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of `M` and `V`. A scalar input for `NU1`, `NU2`, or `DELTA` is expanded to a constant array with the same dimensions as the other input.

The mean of the noncentral F distribution with parameters ν_1 , ν_2 , and δ is

$$\frac{\nu_2(\delta + \nu_1)}{\nu_1(\nu_2 - 2)}$$

where $\nu_2 > 2$.

The variance is

$$2\left(\frac{\nu_2}{\nu_1}\right)^2 \left[\frac{(\delta + \nu_1)^2 + (2\delta + \nu_1)(\nu_2 - 2)}{(\nu_2 - 2)^2(\nu_2 - 4)} \right]$$

where $\nu_2 > 4$.

Examples

```
[m,v]= ncfstat(10,100,4)  
m =
```

1.4286
v =
0.4252

nctcdf

Noncentral t cumulative distribution function

Syntax

```
p = nctcdf(x,nu,delta)
p = nctcdf(x,nu,delta,'upper')
```

Description

`p = nctcdf(x,nu,delta)` computes the noncentral t cdf at each value in `x` using the corresponding degrees of freedom in `nu` and noncentrality parameters in `delta`. `x`, `nu`, and `delta` can be vectors, matrices, or multidimensional arrays that have the same size, which is also the size of `p`. A scalar input for `x`, `nu`, or `delta` is expanded to a constant array with the same dimensions as the other inputs.

`p = nctcdf(x,nu,delta,'upper')` returns the complement of the noncentral t cdf at each value in `x`, using an algorithm that more accurately computes the extreme upper tail probabilities.

Examples

Compute Noncentral t Distribution cdf

Compare the noncentral t cdf with `DELTA = 1` to the t cdf with the same number of degrees of freedom (10).

```
x = (-5:0.1:5)';
p1 = nctcdf(x,10,1);
p = tcdf(x,10);
plot(x,p,'-',x,p1,':')
```

nctpdf

Noncentral t probability density function

Syntax

```
Y = nctpdf(X,V,DELTA)
```

Description

`Y = nctpdf(X,V,DELTA)` computes the noncentral t pdf at each of the values in X using the corresponding degrees of freedom in V and noncentrality parameters in $DELTA$.

Vector or matrix inputs for X , V , and $DELTA$ must have the same size, which is also the size of Y . A scalar input for X , V , or $DELTA$ is expanded to a constant matrix with the same dimensions as the other inputs.

Examples

Compute Noncentral t Distribution pdf

Compute the pdf of a noncentral t distribution with degrees of freedom $V = 10$ and noncentrality parameter $DELTA = 1$. For comparison, also compute the pdf of a t distribution with the same degrees of freedom.

```
x = (-5:0.1:5)';  
nct = nctpdf(x,10,1);  
t = tpdf(x,10);
```

Plot the pdf of the noncentral t distribution and the pdf of the t distribution on the same figure.

Noncentral t random numbers

Syntax

```
R = nctrnd(V,DELTA)
R = nctrnd(V,DELTA,m,n,...)
R = nctrnd(V,DELTA,[m,n,...])
```

Description

`R = nctrnd(V,DELTA)` returns a matrix of random numbers chosen from the noncentral T distribution using the corresponding degrees of freedom in `V` and noncentrality parameters in `DELTA`. `V` and `DELTA` can be vectors, matrices, or multidimensional arrays. A scalar input for `V` or `DELTA` is expanded to a constant array with the same dimensions as the other input.

`R = nctrnd(V,DELTA,m,n,...)` or `R = nctrnd(V,DELTA,[m,n,...])` generates an `m-by-n-by-...` array. The `V`, `DELTA` parameters can each be scalars or arrays of the same size as `R`.

Examples

```
nctrnd(10,1,5,1)
ans =
    1.6576
    1.0617
    1.4491
    0.2930
    3.6297

nctstat

Noncentral t mean and variance

Syntax

```
[M,V] = nctstat(NU,DELTA)
```

Description

`[M,V] = nctstat(NU,DELTA)` returns the mean of and variance for the noncentral t pdf with NU degrees of freedom and noncentrality parameter $DELTA$. NU and $DELTA$ can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of M and V . A scalar input for NU or $DELTA$ is expanded to a constant array with the same dimensions as the other input.

The mean of the noncentral t distribution with parameters ν and δ is

$$\frac{\delta(\nu/2)^{1/2}\Gamma((\nu-1)/2)}{\Gamma(\nu/2)}$$

where $\nu > 1$.

The variance is

$$\frac{\nu}{(\nu-2)}(1+\delta^2) - \frac{\nu}{2}\delta^2\left[\frac{\Gamma((\nu-1)/2)}{\Gamma(\nu/2)}\right]^2$$

where $\nu > 2$.

Examples

```
[m,v] = nctstat(10,1)
```

```
m =  
1.0837
```

v =
1.3255

ncx2cdf

Noncentral chi-square cumulative distribution function

Syntax

```
p = ncx2cdf(x,v,delta)
p = ncx2cdf(x,v,delta,'upper')
```

Description

`p = ncx2cdf(x,v,delta)` computes the noncentral chi-square cdf at each value in `x` using the corresponding degrees of freedom in `v` and positive noncentrality parameters in `delta`. `x`, `v`, and `delta` can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of `p`. A scalar input for `x`, `v`, or `delta` is expanded to a constant array with the same dimensions as the other inputs.

`p = ncx2cdf(x,v,delta,'upper')` returns the complement of the noncentral chi-square cdf at each value in `x`, using an algorithm that more accurately computes the extreme upper tail probabilities.

Some texts refer to this distribution as the generalized Rayleigh, Rayleigh-Rice, or Rice distribution.

The noncentral chi-square cdf is

$$F(x|v, \delta) = \sum_{j=0}^{\infty} \left(\frac{\left(\frac{1}{2}\delta\right)^j}{j!} e^{-\frac{\delta}{2}} \right) \Pr[\chi_{v+2j}^2 \leq x]$$

Examples

Compute Noncentral Chi-Square cdf

Compare the noncentral chi-square cdf with $\Delta = 2$ to the chi-square cdf with the same number of degrees of freedom (4):

```
x = (0:0.1:10)';  
ncx2 = ncx2cdf(x,4,2);  
chi2 = chi2cdf(x,4);  
  
plot(x,ncx2,'b-','LineWidth',2)  
hold on  
plot(x,chi2,'g--','LineWidth',2)  
legend('ncx2','chi2','Location','NW')
```

ncx2inv

Noncentral chi-square inverse cumulative distribution function

Syntax

```
X = ncx2inv(P,V,DELTA)
```

Description

`X = ncx2inv(P,V,DELTA)` returns the inverse of the noncentral chi-square cdf using the corresponding degrees of freedom in `V` and positive noncentrality parameters in `DELTA`, at the corresponding probabilities in `P`. `P`, `V`, and `DELTA` can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of `X`. A scalar input for `P`, `V`, or `DELTA` is expanded to a constant array with the same dimensions as the other inputs.

Examples

```
ncx2inv([0.01 0.05 0.1],4,2)
ans =
    0.4858    1.1498    1.7066
```

Algorithms

`ncx2inv` uses Newton's method to converge to the solution.

Introduced before R2006a

ncx2pdf

Noncentral chi-square probability density function

Syntax

```
Y = ncx2pdf(X,V,DELTA)
```

Description

`Y = ncx2pdf(X,V,DELTA)` computes the noncentral chi-square pdf at each of the values in `X` using the corresponding degrees of freedom in `V` and positive noncentrality parameters in `DELTA`. Vector or matrix inputs for `X`, `V`, and `DELTA` must have the same size, which is also the size of `Y`. A scalar input for `X`, `V`, or `DELTA` is expanded to a constant array with the same dimensions as the other inputs.

Some texts refer to this distribution as the generalized Rayleigh, Rayleigh-Rice, or Rice distribution.

Examples

Compute Noncentral Chi-Square Distribution pdf

Compute the pdf of a noncentral chi-square distribution with degrees of freedom $V = 4$ and noncentrality parameter $DELTA = 2$. For comparison, also compute the pdf of a chi-square distribution with the same degrees of freedom.

```
x = (0:0.1:10)';  
ncx2 = ncx2pdf(x,4,2);  
chi2 = chi2pdf(x,4);
```

Plot the pdf of the noncentral chi-square distribution on the same figure as the pdf of the chi-square distribution.

```
figure;  
plot(x,ncx2,'b-','LineWidth',2)
```

```
hold on
plot(x,chi2,'g--','LineWidth',2)
legend('ncx2','chi2')
```

ncx2rnd

Noncentral chi-square random numbers

Syntax

```
R = ncx2rnd(V, DELTA)
R = ncx2rnd(V, DELTA, m, n, ...)
R = ncx2rnd(V, DELTA, [m, n, ...])
```

Description

`R = ncx2rnd(V, DELTA)` returns a matrix of random numbers chosen from the noncentral chi-square distribution using the corresponding degrees of freedom in `V` and positive noncentrality parameters in `DELTA`. `V` and `DELTA` can be vectors, matrices, or multidimensional arrays that have the same size, which is also the size of `R`. A scalar input for `V` or `DELTA` is expanded to a constant array with the same dimensions as the other input.

`R = ncx2rnd(V, DELTA, m, n, ...)` or `R = ncx2rnd(V, DELTA, [m, n, ...])` generates an `m`-by-`n`-by-... array. The `V`, `DELTA` parameters can each be scalars or arrays of the same size as `R`.

Examples

```
ncx2rnd(4, 2, 6, 3)
ans =
    6.8552    5.9650   11.2961
    5.2631    4.2640    5.9495
    9.1939    6.7162    3.8315
   10.3100    4.4828    7.1653
    2.1142    1.9826    4.6400
    3.8852    5.3999    0.9282
```

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

The generated code can return a different sequence of numbers than MATLAB if either of the following is true:

- The output is nonscalar.
- An input parameter is invalid for the distribution.

For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “General Code Generation Workflow” on page 31-5.

ncx2stat

Noncentral chi-square mean and variance

Syntax

```
[M,V] = ncx2stat(NU,DELTA)
```

Description

`[M,V] = ncx2stat(NU,DELTA)` returns the mean of and variance for the noncentral chi-square pdf with `NU` degrees of freedom and noncentrality parameter `DELTA`. `NU` and `DELTA` can be vectors, matrices, or multidimensional arrays that all have the same size, which is also the size of `M` and `V`. A scalar input for `NU` or `DELTA` is expanded to a constant array with the same dimensions as the other input.

The mean of the noncentral chi-square distribution with parameters ν and δ is $\nu+\delta$, and the variance is $2(\nu+2\delta)$.

Examples

```
[m,v] = ncx2stat(4,2)
m =
    6
v =
   16
```

ndims

Class: dataset

Number of dimensions of dataset array

Note The dataset data type might be removed in a future release. To work with heterogeneous data, use the MATLAB® table data type instead. See MATLAB table documentation for more information.

Syntax

`n = ndims(A)`

Description

`n = ndims(A)` returns the number of dimensions in the dataset A. The number of dimensions in an array is always 2.

See Also

size

ne

Class: grandstream

Not equal relation for handles

Syntax

`h1 ~= h2`

Description

Handles are equal if they are handles for the same object and are unequal otherwise.

`h1 ~= h2` performs element-wise comparisons between handle arrays `h1` and `h2`. `h1` and `h2` must be of the same dimensions unless one is a scalar. The result is a logical array of the same dimensions, where each element is an element-wise `~=` result.

If one of `h1` or `h2` is scalar, scalar expansion is performed and the result will match the dimensions of the array that is not scalar.

`tf = ne(h1, h2)` stores the result in a logical array of the same dimensions.

See Also

`eq` | `ge` | `gt` | `le` | `lt` | `grandstream`

negloglik

Package: prob

Negative loglikelihood of probability distribution

Syntax

```
nll = negloglik(pd)
```

Description

`nll = negloglik(pd)` returns the value of the negative loglikelihood function for the data used to fit the probability distribution `pd`.

Examples

Negative Log Likelihood for a Fitted Distribution

Load the sample data.

```
load carsmall
```

Create a Weibull distribution object by fitting it to the mile per gallon (MPG) data.

```
pd = fitdist(MPG, 'Weibull')
```

```
pd =  
  WeibullDistribution
```

```
  Weibull distribution  
  A = 26.5079    [24.8333, 28.2954]  
  B = 3.27193   [2.79441, 3.83104]
```

Compute the negative log likelihood for the fitted Weibull distribution.

```
wll = negloglik(pd)
```

```
wll = 327.4942
```

Negative Loglikelihood for a Kernel Distribution

Load the sample data. Fit a kernel distribution to the miles per gallon (MPG) data.

```
load carsmall;  
pd = fitdist(MPG, 'Kernel')
```

```
pd =  
  KernelDistribution  
  
  Kernel = normal  
  Bandwidth = 4.11428  
  Support = unbounded
```

Compute the negative loglikelihood.

```
nll = negloglik(pd)
```

```
nll = 327.3139
```

Input Arguments

pd — Probability distribution

probability distribution object

Probability distribution, specified as a probability distribution object created using one of the following.

Function or App	Description
<code>fitdist</code>	Fit a probability distribution object to sample data.
Distribution Fitter	Fit a probability distribution to sample data using the interactive Distribution Fitter app and export the fitted object to the workspace.

Output Arguments

nll — Negative loglikelihood

numeric value

Negative loglikelihood value for the data used to fit the distribution, returned as a numeric value.

net

Generate quasirandom point set

Syntax

```
X = net(p,n)
```

Description

`X = net(p,n)` returns the first n points from the point set p , which is either a `haltonset` or `sobolset` object. X is an n -by- d matrix, where d is the number of dimensions of the points in p .

The object p encapsulates properties of a specified quasirandom sequence. Values of the point set are generated whenever you access p using `net` or parenthesis indexing. Values are not stored within p .

Examples

Create Halton Point Set

Generate a three-dimensional Halton point set, skip the first 1000 values, and then retain every 101st point.

```
p = haltonset(3, 'Skip', 1e3, 'Leap', 1e2)
```

```
p =  
Halton point set in 3 dimensions (89180190640991 points)
```

Properties:

```
    Skip : 1000  
    Leap : 100  
    ScrambleMethod : none
```

Apply reverse-radix scrambling by using `scramble`.

```
p = scramble(p, 'RR2')  
  
p =  
Halton point set in 3 dimensions (89180190640991 points)  
  
Properties:  
      Skip : 1000  
      Leap : 100  
      ScrambleMethod : RR2
```

Generate the first four points by using `net`.

```
X0 = net(p,4)  
  
X0 = 4×3  
  
    0.0928    0.6950    0.0029  
    0.6958    0.2958    0.8269  
    0.3013    0.6497    0.4141  
    0.9087    0.7883    0.2166
```

Generate every third point, up to the eleventh point, by using parenthesis indexing.

```
X = p(1:3:11,:)   
  
X = 4×3  
  
    0.0928    0.6950    0.0029  
    0.9087    0.7883    0.2166  
    0.3843    0.9840    0.9878  
    0.6831    0.7357    0.7923
```

Input Arguments

p — Point set

haltonset object | sobolset object

Point set, specified as either a `haltonset` or `sobolset` object.

Example: `haltonset(4)`

n — Number of points to return

positive integer scalar

Number of points to return from the point set, specified as a positive integer scalar. `n` must be between 1 and `length(p)`, the number of points in `p`.

`net` always returns the first `n` points in `p`. To select a different set of `n` points from the quasirandom sequence, you can change `p` by using its `Leap` and `Skip` properties or the `scramble` object function. Alternatively, you can access points in `p` by using parenthesis indexing rather than the `net` object function.

Example: `1024`

Data Types: `single` | `double`

`haltonset` | `grandstream` | `reduceDimensions` | `scramble` | `sobolset`

Introduced in R2008a

nLinearCoeffs

Number of nonzero linear coefficients

Syntax

```
ncoeffs = nLinearCoeffs(obj)
ncoeffs = nLinearCoeffs(obj,delta)
```

Description

`ncoeffs = nLinearCoeffs(obj)` returns the number of nonzero linear coefficients in the linear discriminant model `obj`.

`ncoeffs = nLinearCoeffs(obj,delta)` returns the number of nonzero linear coefficients for threshold parameter `delta`.

Input Arguments

obj

Discriminant analysis classifier, produced using `fitcdiscr`.

delta

Scalar or vector value of the Delta parameter. See “Gamma and Delta” on page 32-4522.

Output Arguments

ncoeffs

Nonnegative integer, the number of nonzero coefficients in the discriminant analysis model `obj`.

If you call `nLinearCoeffs` with a `delta` argument, `ncoeffs` is the number of nonzero linear coefficients for threshold parameter `delta`. If `delta` is a vector, `ncoeffs` is a vector with the same number of elements.

If `obj` is a quadratic discriminant model, `ncoeffs` is the number of predictors in `obj`.

Examples

Find the Number of Nonzero Coefficients in a Discriminant Analysis Classifier

Find the number of nonzero coefficients in a discriminant analysis classifier for various `Delta` values.

Create a discriminant analysis classifier from the `fishseriris` data.

```
load fisheriris
obj = fitcdiscr(meas,species);
```

Find the number of nonzero coefficients in `obj`.

```
ncoeffs = nLinearCoeffs(obj)
```

```
ncoeffs = 4
```

Find the number of nonzero coefficients for `delta = 1, 2, 4, and 8`.

```
delta = [1 2 4 8];
ncoeffs = nLinearCoeffs(obj,delta)
```

```
ncoeffs = 4×1
```

```
4
4
3
0
```

The `DeltaPredictor` property gives the values of `delta` where the number of nonzero coefficients changes.

```
ncoeffs2 = nLinearCoeffs(obj,obj.DeltaPredictor)
```

```
ncoeffs2 = 4x1
```

```
4  
3  
1  
2
```

Definitions

Gamma and Delta

Regularization is the process of finding a small set of predictors that yield an effective predictive model. For linear discriminant analysis, there are two parameters, γ and δ , that control regularization as follows. `cvshrink` helps you select appropriate values of the parameters.

Let Σ represent the covariance matrix of the data X , and let \widehat{X} be the centered data (the data X minus the mean by class). Define

$$D = \text{diag}(\widehat{X}^T * \widehat{X}).$$

The regularized covariance matrix $\widetilde{\Sigma}$ is

$$\widetilde{\Sigma} = (1 - \gamma)\Sigma + \gamma D.$$

Whenever $\gamma \geq \text{MinGamma}$, $\widetilde{\Sigma}$ is nonsingular.

Let μ_k be the mean vector for those elements of X in class k , and let μ_0 be the global mean vector (the mean of the rows of X). Let C be the correlation matrix of the data X , and let \widetilde{C} be the regularized correlation matrix:

$$\widetilde{C} = (1 - \gamma)C + \gamma I,$$

where I is the identity matrix.

The linear term in the regularized discriminant analysis classifier for a data point x is

$$(x - \mu_0)^T \tilde{\Sigma}^{-1} (\mu_k - \mu_0) = [(x - \mu_0)^T D^{-1/2}] [\tilde{C}^{-1} D^{-1/2} (\mu_k - \mu_0)].$$

The parameter δ enters into this equation as a threshold on the final term in square brackets. Each component of the vector $[\tilde{C}^{-1} D^{-1/2} (\mu_k - \mu_0)]$ is set to zero if it is smaller in magnitude than the threshold δ . Therefore, for class k , if component j is thresholded to zero, component j of x does not enter into the evaluation of the posterior probability.

The `DeltaPredictor` property is a vector related to this threshold. When $\delta \geq \text{DeltaPredictor}(i)$, all classes k have

$$|\tilde{C}^{-1} D^{-1/2} (\mu_k - \mu_0)| \leq \delta.$$

Therefore, when $\delta \geq \text{DeltaPredictor}(i)$, the regularized classifier does not use predictor i .

nlinfit

Nonlinear regression

Syntax

```
beta = nlinfit(X,Y,modelfun,beta0)
beta = nlinfit(X,Y,modelfun,beta0,options)
beta = nlinfit( ___,Name,Value)
[beta,R,J,CovB,MSE,ErrorModelInfo] = nlinfit( ___ )
```

Description

`beta = nlinfit(X,Y,modelfun,beta0)` returns a vector of estimated coefficients for the nonlinear regression of the responses in `Y` on the predictors in `X` using the model specified by `modelfun`. The coefficients are estimated using iterative least squares estimation, with initial values specified by `beta0`.

`beta = nlinfit(X,Y,modelfun,beta0,options)` fits the nonlinear regression using the algorithm control parameters in the structure `options`. You can return any of the output arguments in the previous syntaxes.

`beta = nlinfit(___,Name,Value)` uses additional options specified by one or more name-value pair arguments. For example, you can specify observation weights or a nonconstant error model. You can use any of the input arguments in the previous syntaxes.

`[beta,R,J,CovB,MSE,ErrorModelInfo] = nlinfit(___)` additionally returns the residuals, `R`, the Jacobian of `modelfun`, `J`, the estimated variance-covariance matrix for the estimated coefficients, `CovB`, an estimate of the variance of the error term, `MSE`, and a structure containing details about the error model, `ErrorModelInfo`.

Examples

Nonlinear Regression Model Using Default Options

Load sample data.

```
S = load('reaction');  
X = S.reactants;  
y = S.rate;  
beta0 = S.beta;
```

Fit the Hougen-Watson model to the rate data using the initial values in beta0.

```
beta = nlinfit(X,y,@hougen,beta0)
```

```
beta = 5×1  
  
    1.2526  
    0.0628  
    0.0400  
    0.1124  
    1.1914
```

Nonlinear Regression Using Robust Options

Generate sample data from the nonlinear regression model $y = b_1 + b_2 \cdot \exp\{-b_3x\} + \epsilon$, where b_1 , b_2 , and b_3 are coefficients, and the error term is normally distributed with mean 0 and standard deviation 0.1.

```
modelfun = @(b,x)(b(1)+b(2)*exp(-b(3)*x));
```

```
rng('default') % for reproducibility  
b = [1;3;2];  
x = exprnd(2,100,1);  
y = modelfun(b,x) + normrnd(0,0.1,100,1);
```

Set robust fitting options.

```
opts = statset('nlinfit');  
opts.RobustWgtFun = 'bisquare';
```

Fit the nonlinear model using the robust fitting options.

```
beta0 = [2;2;2];
beta = nlinfit(x,y,modelfun,beta0,opts)

beta = 3×1

    1.0041
    3.0997
    2.1483
```

Nonlinear Regression Using Observation Weights

Load sample data.

```
S = load('reaction');
X = S.reactants;
y = S.rate;
beta0 = S.beta;
```

Specify a vector of known observation weights.

```
W = [8 2 1 6 12 9 12 10 10 12 2 10 8]';
```

Fit the Hougen-Watson model to the rate data using the specified observation weights.

```
[beta,R,J,CovB] = nlinfit(X,y,@hougen,beta0,'Weights',W);
beta

Nonlinear Regression Using Weights Function Handle

Load sample data.

```

S = load('reaction');
X = S.reactants;
y = S.rate;
beta0 = S.beta;

```

Specify a function handle for observation weights. The function accepts the model fitted values as input, and returns a vector of weights.

```

a = 1; b = 1;
weights = @(yhat) 1./((a + b*abs(yhat)).^2);

```

Fit the Hougen-Watson model to the rate data using the specified observation weights function.

```

    ScheffeSimPred: 6
    WeightFunction: 0
    FixedWeights: 0
```

RobustWeightFunction: 0

Input Arguments

X — Predictor variables

matrix

Predictor variables for the nonlinear regression function, specified as a matrix. Typically, X is a design matrix of predictor (independent variable) values, with one row for each value in Y, and one column for each predictor. However, X can be any array that `modelfun` can accept.

Data Types: `single` | `double`

Y — Response values

vector

Response values (dependent variable) for fitting the nonlinear regression function, specified as a vector with the same number of rows as X.

Data Types: `single` | `double`

modelfun — Nonlinear regression model function

function handle

Nonlinear regression model function, specified as a function handle. `modelfun` must accept two input arguments, a coefficient vector and an array X—in that order—and return a vector of fitted response values.

For example, to specify the `hougen` nonlinear regression function, use the function handle `@hougen`.

Data Types: `function_handle`

beta0 — Initial coefficient values

vector

Initial coefficient values for the least squares estimation algorithm, specified as a vector.

Note Poor starting values can lead to a solution with large residual error.

Data Types: `single` | `double`

options — Estimation algorithm options

structure created using `statset`

Estimation algorithm options, specified as a structure you create using `statset`. The following `statset` parameters are applicable to `nlinfit`.

DerivStep — Relative difference for finite difference gradient

$\text{eps}^{(1/3)}$ (default) | positive scalar value | vector

Relative difference for the finite difference gradient calculation, specified as a positive scalar value, or a vector the same size as `beta`. Use a vector to specify a different relative difference for each coefficient.

Display — Level of output display

'off' (default) | 'iter' | 'final'

Level of output display during estimation, specified as one of 'off', 'iter', or 'final'. If you specify 'iter', output is displayed at each iteration. If you specify 'final', output is displayed after the final iteration.

FunValCheck — Indicator for whether to check for invalid values

'on' (default) | 'off'

Indicator for whether to check for invalid values such as NaN or Inf from the objective function, specified as 'on' or 'off'.

MaxIter — Maximum number of iterations

100 (default) | positive integer

Maximum number of iterations for the estimation algorithm, specified as a positive integer. Iterations continue until estimates are within the convergence tolerance, or the maximum number of iterations specified by `MaxIter` is reached.

RobustWgtFun — Weight function

character vector | string scalar | function handle | []

Weight function for robust fitting, specified as a valid character vector, string scalar, or function handle.

Note `RobustWgtFun` must have value [] when you use observation weights, `W`.

The following table describes the possible character vectors and string scalars. Let r denote normalized residuals and w denote robust weights. The indicator function $I[x]$ is equal to 1 if the expression x is true, and 0 otherwise.

Weight Function	Equation	Default Tuning Constant
' ' (default)	No robust fitting	—
'andrews'	$w = I[r < \pi] \times \sin(r)/r$	1.339
'bisquare'	$w = I[r < 1] \times (1 - r^2)^2$	4.685
'cauchy'	$w = 1/(1 + r^2)$	2.385
'fair'	$w = 1/(1 + r)$	1.400
'huber'	$w = 1/\max(1, r)$	1.345
'logistic'	$w = \tanh(r)/r$	1.205
'talwar'	$w = I[r < 1]$	2.795
'welsch'	$w = \exp\{-r^2\}$	2.985

You can alternatively specify a function handle that accepts a vector of normalized residuals as input, and returns a vector of robust weights as output. If you use a function handle, you must provide a Tune constant.

Tune — Tuning constant

positive scalar value

Tuning constant for robust fitting, specified as a positive scalar value. The tuning constant is used to normalize residuals before applying a robust weight function. The default tuning constant depends on the function specified by `RobustWgtFun`.

If you use a function handle to specify `RobustWgtFun`, then you must specify a value for `Tune`.

TolFun — Termination tolerance on residual sum of squares

1e-8 (default) | positive scalar value

Termination tolerance for the residual sum of squares, specified as a positive scalar value. Iterations continue until estimates are within the convergence tolerance, or the maximum number of iterations specified by `MaxIter` is reached.

ToLX — Termination tolerance on estimated coefficients`1e-8 (default) | positive scalar value`

Termination tolerance on the estimated coefficients, `beta`, specified as a positive scalar value. Iterations continue until estimates are within the convergence tolerance, or the maximum number of iterations specified by `MaxIter` is reached.

Robust — Indicator for robust fitting`'off' (default) | 'on'`

Indicator for robust fitting, specified as `'off'` or `'on'`.

Note `Robust` will be removed in a future software release. Use `RobustWgtFun` for robust fitting.

WgtFun — Weight function for robust fitting`character vector | string scalar | function handle`

Weight function for robust fitting, specified as a character vector or string scalar indicating a weight function, or a function handle. `WgtFun` is valid only when `Robust` has value `'on'`.

Note `WgtFun` will be removed in a future software release. Use `RobustWgtFun` instead.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example: `'ErrorModel', 'proportional', 'ErrorParameters', 0.5` specifies a proportional error model, with initial value 0.5 for the error parameter estimation

ErrorModel — Form of error term`'constant' (default) | 'proportional' | 'combined'`

Form of the error term, specified as the comma-separated pair consisting of `'ErrorModel'` and `'constant'`, `'proportional'`, or `'combined'` indicating the

error model. Each model defines the error using a standard mean-zero and unit-variance variable e in combination with independent components: the function value f , and one or two parameters a and b .

'constant' (default)	$y = f + ae$
'proportional'	$y = f + bfe$
'combined'	$y = f + (a + b f)e$

The only allowed error model when using `Weights` is 'constant'.

Note `options.RobustWgtFun` must have value `[]` when using an error model other than 'constant'.

ErrorParameters — Initial estimates for error model parameters

1 or [1, 1] (default) | scalar value | two-element vector

Initial estimates for the error model parameters in the chosen `ErrorModel`, specified as the comma-separated pair consisting of 'ErrorParameters' and a scalar value or two-element vector.

Error Model	Parameters	Default Values
'constant'	a	1
'proportional'	b	1
'combined'	a, b	[1, 1]

For example, if 'ErrorModel' has the value 'combined', you can specify the starting value 1 for a and the starting value 2 for b as follows.

Example: 'ErrorParameters', [1, 2]

You can only use the 'constant' error model when using `Weights`.

Note `options.RobustWgtFun` must have value `[]` when using an error model other than 'constant'.

Data Types: double | single

Weights — Observation weights

vector | function handle

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a vector of real positive weights or a function handle. You can use observation weights to down-weight the observations that you want to have less influence on the fitted model.

- If **W** is a vector, then it must be the same size as **Y**.
- If **W** is a function handle, then it must accept a vector of predicted response values as input, and return a vector of real positive weights as output.

Note `options.RobustWgtFun` must have value `[]` when you use observation weights.

Data Types: double | single | function_handle

Output Arguments

beta — Estimated regression coefficients

vector

Estimated regression coefficients, returned as a vector. The number of elements in **beta** equals the number of elements in `beta0`.

Let $f(X_i, \mathbf{b})$ denote the nonlinear function specified by `modelfun`, where \mathbf{x}_i are the predictors for observation i , $i = 1, \dots, N$, and \mathbf{b} are the regression coefficients. The vector of coefficients returned in **beta** minimizes the weighted least squares equation,

$$\sum_{i=1}^N w_i [y_i - f(\mathbf{x}_i, \mathbf{b})]^2.$$

For unweighted nonlinear regression, all of the weight terms are equal to 1.

R — Residuals

vector

Residuals for the fitted model, returned as a vector.

- If you specify observation weights using the name-value pair argument `Weights`, then **R** contains weighted residuals on page 32-4536.

- If you specify an error model other than 'constant' using the name-value pair argument `ErrorModel`, then you can no longer interpret `R` as model fit residuals.

J — Jacobian

matrix

Jacobian of the nonlinear regression model, `modelfun`, returned as an N -by- p matrix, where N is the number of observations and p is the number of estimated coefficients.

- If you specify observation weights using the name-value pair argument `Weights`, then `J` is the weighted model function Jacobian on page 32-4536.
- If you specify an error model other than 'constant' using the name-value pair argument `ErrorModel`, then you can no longer interpret `J` as the model function Jacobian.

CovB — Estimated variance-covariance matrix

matrix

Estimated variance-covariance matrix for the fitted coefficients, `beta`, returned as a p -by- p matrix, where p is the number of estimated coefficients. If the model Jacobian, `J`, has full column rank, then $\text{CovB} = \text{inv}(J' * J) * \text{MSE}$, where `MSE` is the mean squared error.

MSE — Mean squared error

scalar value

Mean squared error (MSE) of the fitted model, returned as a scalar value. MSE is an estimate of the variance of the error term. If the model Jacobian, `J`, has full column rank, then $\text{MSE} = (R' * R) / (N - p)$, where N is the number of observations, and p is the number of estimated coefficients.

ErrorModelInfo — Information about error model fit

structure

Information about the error model fit, returned as a structure with the following fields:

<code>ErrorModel</code>	Chosen error model
<code>ErrorParameters</code>	Estimated error parameters
<code>ErrorVariance</code>	Function handle that accepts an N -by- p matrix, <code>X</code> , and returns an N -by-1 vector of error variances using the estimated error model

MSE	Mean squared error
ScheffeSimPred	Scheffé parameter for simultaneous prediction intervals when using the estimated error model
WeightFunction	Logical with value <code>true</code> if you used a custom weight function previously in <code>nlinfit</code>
FixedWeights	Logical with value <code>true</code> if you used fixed weights previously in <code>nlinfit</code>
RobustWeightFunction	Logical with value <code>true</code> if you used robust fitting previously in <code>nlinfit</code>

Definitions

Weighted Residuals

A weighted residual is a residual multiplied by the square root of the corresponding observation weight.

Given estimated regression coefficients, \mathbf{b} , the residual for observation i is

$$r_i = y_i - f(\mathbf{x}_i, \mathbf{b}),$$

where y_i is the observed response and $f(\mathbf{x}_i, \mathbf{b})$ is the fitted response at predictors \mathbf{x}_i .

When you fit a weighted nonlinear regression with weights w_i , $i = 1, \dots, N$, `nlinfit` returns the weighted residuals,

$$r_i^* = \sqrt{w_i}(y_i - f(\mathbf{x}_i, \mathbf{b})).$$

Weighted Model Function Jacobian

The weighted model function Jacobian is the nonlinear model Jacobian multiplied by the square root of the observation weight matrix.

Given estimated regression coefficients, \mathbf{b} , the estimated model Jacobian, \mathbf{J} , for the nonlinear function $f(\mathbf{x}_i, \mathbf{b})$ has elements

$$\mathbf{J}_{ij} = \frac{\partial f(\mathbf{x}_i, \mathbf{b})}{\partial b_j},$$

where b_j is the j th element of \mathbf{b} .

When you fit a weighted nonlinear regression with diagonal weights matrix \mathbf{W} , `nlinfit` returns the weighted Jacobian matrix,

$$\mathbf{J}^* = \mathbf{W}^{1/2} \mathbf{J}.$$

Tips

- To produce error estimates on predictions, use the optional output arguments `R`, `J`, `CovB`, or `MSE` as inputs to `nlpredci`.
- To produce error estimates on the estimated coefficients, `beta`, use the optional output arguments `R`, `J`, `CovB`, or `MSE` as inputs to `nlparci`.
- If you use the robust fitting option, `RobustWgtFun`, you must use `CovB`—and might need `MSE`—as inputs to `nlpredci` or `nlparci` to ensure that the confidence intervals take the robust fit properly into account.

Algorithms

- `nlinfit` treats NaN values in `Y` or `modelfun(beta0,X)` as missing data, and ignores the corresponding observations.
- For nonrobust estimation, `nlinfit` uses the Levenberg-Marquardt nonlinear least squares algorithm [1].
- For robust estimation, `nlinfit` uses an iterative reweighted least squares algorithm ([2], [3]). At each iteration, the robust weights are recalculated based on each observation's residual from the previous iteration. These weights downweight outliers, so that their influence on the fit is decreased. Iterations continue until the weights converge.
- When you specify a function handle for observation weights, the weights depend on the fitted model. In this case, `nlinfit` uses an iterative generalized least squares algorithm to fit the nonlinear regression model.

Topics

"Nonlinear Regression" on page 13-2

Introduced before R2006a

nlintool

Interactive nonlinear regression

Syntax

```
nlintool(X,y,fun,beta0)
nlintool(X,y,fun,beta0,alpha)
nlintool(X,y,fun,beta0,alpha,'xname','yname')
```

Description

`nlintool(X,y,fun,beta0)` is a graphical user interface to the `nlinfit` function, and uses the same input arguments. The interface displays plots of the fitted response against each predictor, with the other predictors held fixed. The fixed values are in the text boxes below each predictor axis. Change the fixed values by typing in a new value or by dragging the vertical lines in the plots to new positions. When you change the value of a predictor, all plots update to display the model at the new point in predictor space. Dashed red curves show 95% simultaneous confidence bands for the function.

`nlintool(X,y,fun,beta0,alpha)` shows $100(1-\alpha)\%$ confidence bands. These are simultaneous confidence bounds for the function value. Using the **Bounds** menu you can switch between simultaneous and non-simultaneous bounds, and between bounds on the function and bounds for predicting a new observation.

`nlintool(X,y,fun,beta0,alpha,'xname','yname')` labels the plots using the character matrix or string array `'xname'` for the predictors and the character vector or string scalar `'yname'` for the response.

Examples

The data in `reaction.mat` are partial pressures of three chemical reactants and the corresponding reaction rates. The function `hougen` implements the nonlinear Hougen-Watson model for reaction rates. The following fits the model to the data:

```
load reaction
nlintool(reactants,rate,@hougen,beta,0.01,xn,yn)
```

Introduced before R2006a

nlmefit

Nonlinear mixed-effects estimation

Syntax

```
beta = nlmefit(X,y,group,V,fun,beta0)
[beta,PSI] = nlmefit(X,y,group,V,fun,beta0)
[beta,PSI,stats] = nlmefit(X,y,group,V,fun,beta0)
[beta,PSI,stats,B] = nlmefit(X,y,group,V,fun,beta0)
[beta,PSI,stats,B] = nlmefit(X,y,group,V,fun,beta0,'Name',value)
```

Description

`beta = nlmefit(X,y,group,V,fun,beta0)` fits a nonlinear mixed-effects regression model and returns estimates of the fixed effects in `beta`. By default, `nlmefit` fits a model in which each parameter is the sum of a fixed and a random effect, and the random effects are uncorrelated (their covariance matrix is diagonal).

`X` is an n -by- h matrix of n observations on h predictors.

`y` is an n -by-1 vector of responses.

`group` is a grouping variable indicating m groups in the observations. `group` is a categorical variable, a numeric vector, a character matrix with rows for group names, a string array, or a cell array of character vectors. For more information on grouping variables, see “Grouping Variables” on page 2-57.

`V` is an m -by- g matrix or cell array of g group-specific predictors. These are predictors that take the same value for all observations in a group. The rows of `V` are assigned to groups using `grp2idx`, according to the order specified by `grp2idx(group)`. Use a cell array for `V` if group predictors vary in size across groups. Use `[]` for `V` if there are no group-specific predictors.

`fun` is a handle to a function that accepts predictor values and model parameters and returns fitted values. `fun` has the form

```
yfit = modelfun(PHI,XFUN,VFUN)
```

The arguments are:

- `PHI` — A 1-by- p vector of model parameters.
 - `XFUN` — A k -by- h array of predictors, where:
 - $k = 1$ if `XFUN` is a single row of `X`.
 - $k = n_i$ if `XFUN` contains the rows of `X` for a single group of size n_i .
 - $k = n$ if `XFUN` contains all rows of `X`.
 - `VFUN` — Group-specific predictors given by one of:
 - A 1-by- g vector corresponding to a single group and a single row of `V`.
 - An n -by- g array, where the j th row is `V(I,:)` if the j th observation is in group `I`.
- If `V` is empty, `nlmefit` calls `modelfun` with only two inputs.
- `yfit` — A k -by-1 vector of fitted values

When either `PHI` or `VFUN` contains a single row, it corresponds to all rows in the other two input arguments.

Note If `modelfun` can compute `yfit` for more than one vector of model parameters per call, use the 'Vectorization' parameter (described later) for improved performance.

`beta0` is a q -by-1 vector with initial estimates for q fixed effects. By default, q is the number of model parameters p .

`nlmefit` fits the model by maximizing an approximation to the marginal likelihood with random effects integrated out, assuming that:

- Random effects are multivariate normally distributed and independent between groups.
- Observation errors are independent, identically normally distributed, and independent of the random effects.

`[beta,PSI] = nlmefit(X,y,group,V,fun,beta0)` also returns `PSI`, an r -by- r estimated covariance matrix for the random effects. By default, r is equal to the number of model parameters p .

`[beta,PSI,stats] = nlmefit(X,y,group,V,fun,beta0)` also returns `stats`, a structure with fields:

- `dfe` — The error degrees of freedom for the model
- `logl` — The maximized loglikelihood for the fitted model
- `rmse` — The square root of the estimated error variance (computed on the log scale for the exponential error model)
- `errorparam` — The estimated parameters of the error variance model
- `aic` — The Akaike information criterion, calculated as $\text{aic} = -2 * \log l + 2 * \text{numParam}$, where `numParam` is the number of fitting parameters, including the degree of freedom for covariance matrix of the random effects, the number of fixed effects and the number of parameters of the error model, and `logl` is a field in the `stats` structure
- `bic` — The Bayesian information criterion, calculated as $\text{bic} = -2 * \log l + \log(M) * \text{numParam}$
 - `M` is the number of groups.
 - `numParam` and `logl` are defined as in `aic`.

Note that some literature suggests that the computation of `bic` should be , $\text{bic} = -2 * \log l + \log(N) * \text{numParam}$, where `N` is the number of observations.

- `covb` — The estimated covariance matrix of the parameter estimates
- `sebeta` — The standard errors for `beta`
- `ires` — The population residuals (`y-y_population`), where `y_population` is the individual predicted values
- `pres` — The population residuals (`y-y_population`), where `y_population` is the population predicted values
- `iwres` — The individual weighted residuals
- `pwres` — The population weighted residuals
- `cwres` — The conditional weighted residuals

`[beta,PSI,stats,B] = nlmefit(X,y,group,V,fun,beta0)` also returns `B`, an r -by- m matrix of estimated random effects for the m groups. By default, r is equal to the number of model parameters p .

`[beta,PSI,stats,B] = nlmefit(X,y,group,V,fun,beta0,'Name',value)` specifies one or more optional parameter name/value pairs. Specify *Name* inside single quotes.

Use the following parameters to fit a model different from the default. (The default model is obtained by setting both `FEConstDesign` and `REConstDesign` to `eye(p)`, or by

setting both FEParamsSelect and REParamsSelect to 1:p.) Use at most one parameter with an 'FE' prefix and one parameter with an 'RE' prefix. The nlmeFit function requires you to specify at least one fixed effect and one random effect.

Parameter	Value
FEParamsSelect	A vector specifying which elements of the parameter vector PHI include a fixed effect, given as a numeric vector of indices from 1 to p or as a 1-by-p logical vector. If q is the specified number of elements, then the model includes q fixed effects.
FEConstDesign	A p -by- q design matrix ADESIGN, where ADESIGN*beta are the fixed components of the p elements of PHI.
FEGroupDesign	A p -by- q -by- m array specifying a different p -by- q fixed-effects design matrix for each of the m groups.
FEObsDesign	A p -by- q -by- n array specifying a different p -by- q fixed-effects design matrix for each of the n observations.
REParamsSelect	A vector specifying which elements of the parameter vector PHI include a random effect, given as a numeric vector of indices from 1 to p or as a 1-by-p logical vector. The model includes r random effects, where r is the specified number of elements.
REConstDesign	A p -by- r design matrix BDESIGN, where BDESIGN*B are the random components of the p elements of PHI.
REGroupDesign	A p -by- r -by- m array specifying a different p -by- r random-effects design matrix for each of m groups.
REObsDesign	A p -by- r -by- n array specifying a different p -by- r random-effects design matrix for each of n observations.

Use the following parameters to control the iterative algorithm for maximizing the likelihood:

Parameter	Value
RefineBeta0	Determines whether <code>nlmefit</code> makes an initial refinement of <code>beta0</code> by first fitting <code>modelfun</code> without random effects and replacing <code>beta0</code> with <code>beta</code> . Choices are 'on' and 'off'. The default value is 'on'.
ErrorModel	<p>A character vector or string scalar specifying the form of the error term. Default is 'constant'. Each model defines the error using a standard normal (Gaussian) variable e, the function value f, and one or two parameters a and b. Choices are:</p> <ul style="list-style-type: none"> • 'constant': $y = f + a*e$ • 'proportional': $y = f + b*f*e$ • 'combined': $y = f + (a+b*f)*e$ • 'exponential': $y = f*\exp(a*e)$, or equivalently $\log(y) = \log(f) + a*e$ <p>If this parameter is given, the output <code>stats.errorparam</code> field has the value</p> <ul style="list-style-type: none"> • a for 'constant' and 'exponential' • b for 'proportional' • $[a\ b]$ for 'combined'
ApproximationType	<p>The method used to approximate the likelihood of the model. Choices are:</p> <ul style="list-style-type: none"> • 'LME' — Use the likelihood for the linear mixed-effects model at the current conditional estimates of <code>beta</code> and <code>B</code>. This is the default. • 'RELME' — Use the restricted likelihood for the linear mixed-effects model at the current conditional estimates of <code>beta</code> and <code>B</code>. • 'FO' — First-order Laplacian approximation without random effects. • 'FOCE' — First-order Laplacian approximation at the conditional estimates of <code>B</code>.

Parameter	Value
Vectorization	<p>Indicates acceptable sizes for the PHI, XFUN, and VFUN input arguments to <code>model fun</code>. Choices are:</p> <ul style="list-style-type: none"> • 'SinglePhi' — <code>model fun</code> can only accept a single set of model parameters at a time, so PHI must be a single row vector in each call. <code>nlmefit</code> calls <code>model fun</code> in a loop, if necessary, with a single PHI vector and with XFUN containing rows for a single observation or group at a time. VFUN may be a single row that applies to all rows of XFUN, or a matrix with rows corresponding to rows in XFUN. This is the default. • 'SingleGroup' — <code>model fun</code> can only accept inputs corresponding to a single group in the data, so XFUN must contain rows of X from a single group in each call. Depending on the model, PHI is a single row that applies to the entire group or a matrix with one row for each observation. VFUN is a single row. • 'Full' — <code>model fun</code> can accept inputs for multiple parameter vectors and multiple groups in the data. Either PHI or VFUN may be a single row that applies to all rows of XFUN or a matrix with rows corresponding to rows in XFUN. This option can improve performance by reducing the number of calls to <code>model fun</code>, but may require <code>model fun</code> to perform singleton expansion on PHI or V.
CovParameterization	<p>Specifies the parameterization used internally for the scaled covariance matrix. Choices are 'chol' for the Cholesky factorization or 'logm' the matrix logarithm. The default is 'logm'.</p>

Parameter	Value
CovPattern	<p>Specifies an r-by-r logical or numeric matrix P that defines the pattern of the random-effects covariance matrix Ψ. <code>nlmefit</code> estimates the variances along the diagonal of Ψ and the covariances specified by nonzeros in the off-diagonal elements of P. Covariances corresponding to zero off-diagonal elements in P are constrained to be zero. If P does not specify a row-column permutation of a block diagonal matrix, <code>nlmefit</code> adds nonzero elements to P as needed. The default value of P is <code>eye(r)</code>, corresponding to uncorrelated random effects.</p> <p>Alternatively, P may be a 1-by-r vector containing values in $1:r$, with equal values specifying groups of random effects. In this case, <code>nlmefit</code> estimates covariances only within groups, and constrains covariances across groups to be zero.</p>
ParamTransform	<p>A vector of p-values specifying a transformation function $f()$ for each of the P parameters: $XB = ADESIGN*BETA + BDESIGN*PHI = f(XB)$. Each element of the vector must be one of the following integer codes specifying the transformation for the corresponding value of PHI:</p> <ul style="list-style-type: none"> • 0: $PHI = XB$ (default for all parameters) • 1: $\log(PHI) = XB$ • 2: $\text{probit}(PHI) = XB$ • 3: $\text{logit}(PHI) = XB$

Parameter	Value
Options	<p>A structure of the form returned by <code>statset.nlmefit</code> uses the following <code>statset</code> parameters:</p> <ul style="list-style-type: none"> • 'DerivStep' — Relative difference used in finite difference gradient calculation. May be a scalar, or a vector whose length is the number of model parameters p. The default is $\text{eps}^{(1/3)}$. • 'Display' — Level of iterative display during estimation. Choices are: <ul style="list-style-type: none"> • 'off' (default) — Displays no information • 'final' — Displays information after the final iteration • 'iter' — Displays information at each iteration • 'FunValCheck' — Check for invalid values, such as NaN or Inf, from <code>modelfun</code>. Choices are 'on' and 'off'. The default is 'on'. • 'MaxIter' — Maximum number of iterations allowed. The default is 200. • 'OutputFcn' — Function handle specified using @, a cell array with function handles or an empty array (default). The solver calls all output functions after each iteration. • 'TolFun' — Termination tolerance on the loglikelihood function. The default is $1\text{e-}4$. • 'TolX' — Termination tolerance on the estimated fixed and random effects. The default is $1\text{e-}4$.
OptimFun	<p>Specifies the optimization function used in maximizing the likelihood. Choices are 'fminsearch' to use <code>fminsearch</code> or 'fminunc' to use <code>fminunc</code>. The default is 'fminsearch'. You can specify 'fminunc' only if Optimization Toolbox software is installed.</p>

Examples

Nonlinear Mixed-Effects Model

Enter and display data on the growth of five orange trees.

```
CIRC = [30 58 87 115 120 142 145;  
        33 69 111 156 172 203 203;  
        30 51 75 108 115 139 140;  
        32 62 112 167 179 209 214;  
        30 49 81 125 142 174 177];  
time = [118 484 664 1004 1231 1372 1582];  
  
h = plot(time,CIRC','o','LineWidth',2);  
xlabel('Time (days)')  
ylabel('Circumference (mm)')  
title('{\bf Orange Tree Growth}')  
legend([repmat('Tree ',5,1),num2str((1:5)')],...  
        'Location','NW')  
grid on  
hold on
```

Use an anonymous function to specify a logistic growth model.

```
model = @(PHI,t)(PHI(:,1))./(1+exp(-(t-PHI(:,2))./PHI(:,3))));
```

Fit the model using `nlmefit` with default settings (that is, assuming each parameter is the sum of a fixed and a random effect, with no correlation among the random effects):

```
TIME = repmat(time,5,1);
NUMS = repmat((1:5)',size(time));

beta0 = [100 100 100];
[beta1,PSI1,stats1] = nlmefit(TIME(:),CIRC(:),NUMS(:),...
    [],model,beta0)
```

```

beta1 = 3×1

    bic: 272.7479
    covb: [3x3 double]
    sebeta: [15.2270 33.1573 26.8230]
    ires: [35x1 double]
    pres: [35x1 double]
    iwres: [35x1 double]
    pwres: [35x1 double]
    cwres: [35x1 double]
```

```
b2 = 2x5
```

```
-28.5262    31.6066   -36.5078    39.0748   -5.6474
  9.9981    -0.7623     6.0046    -9.4579   -5.7824
```

The loglikelihood `logl` is unaffected, and both the Akaike and Bayesian information criteria (`aic` and `bic`) are reduced, supporting the decision to drop the second random effect from the model.

Use the estimated fixed effects in `beta2` and the estimated random effects for each tree in `b2` to plot the model through the data.

```
PHI = repmat(beta2,1,5) + ...           % Fixed effects
      [b2(1,:);zeros(1,5);b2(2,:)];     % Random effects

tplot = 0:0.1:1600;
for I = 1:5
    fitted_model=@(t)(PHI(1,I))./(1+exp(-(t-PHI(2,I))./ ...
        PHI(3,I)));
    plot(tplot,fitted_model(tplot),'Color',h(I).Color, ...
        'LineWidth',2)
end
```

Introduced in R2008b

nlmefitsa

Fit nonlinear mixed-effects model with stochastic EM algorithm

Syntax

```
[BETA,PSI,STATS,B] = nlmefitsa(X,Y,GROUP,V,MODELFUN,BETA0)  
[BETA,PSI,STATS,B] =  
nlmefitsa(X,Y,GROUP,V,MODELFUN,BETA0,'Name',Value)
```

Description

[BETA,PSI,STATS,B] = nlmefitsa(X,Y,GROUP,V,MODELFUN,BETA0) fits a nonlinear mixed-effects regression model and returns estimates of the fixed effects in BETA. By default, nlmefitsa fits a model where each model parameter is the sum of a corresponding fixed and random effect, and the covariance matrix of the random effects is diagonal, i.e., uncorrelated random effects.

The BETA, PSI, and other values this function returns are the result of a random (Monte Carlo) simulation designed to converge to the maximum likelihood estimates of the parameters. Because the results are random, it is advisable to examine the plot of simulation to results to be sure that the simulation has converged. It may also be helpful to run the function multiple times, using multiple starting values, or use the 'Replicates' parameter to perform multiple simulations.

[BETA,PSI,STATS,B] = nlmefitsa(X,Y,GROUP,V,MODELFUN,BETA0,'Name',Value) accepts one or more comma-separated parameter name/value pairs. Specify *Name* inside single quotes.

Input Arguments

Definitions:

In the following list of arguments, the following variable definitions apply:

- n — number of observations
- h — number of predictor variables
- m — number of groups
- g — number of group-specific predictor variables
- p — number of parameters
- f — number of fixed effects

X

An n -by- h matrix of n observations on h predictor variables.

Y

An n -by-1 vector of responses.

GROUP

A grouping variable indicating to which of m groups each observation belongs. **GROUP** can be a categorical variable, a numeric vector, a character matrix with rows for group names, a string array, or a cell array of character vectors.

V

An m -by- g matrix of g group-specific predictor variables for each of the m groups in the data. These are predictor values that take on the same value for all observations in a group. Rows of **V** are ordered according to `GRP2IDX(GROUP)`. Use an m -by- g cell array for **V** if any of the group-specific predictor values vary in size across groups. Specify `[]` for **V** if there are no group predictors.

MODELFUN

A handle to a function that accepts predictor values and model parameters, and returns fitted values. **MODELFUN** has the form `YFIT = MODELFUN(PHI, XFUN, VFUN)` with input arguments

- **PHI** — A 1-by- p vector of model parameters.
- **XFUN** — An l -by- h array of predictor variables where
 - l is 1 if **XFUN** is a single row of **X**
 - l is n_i if **XFUN** contains the rows of **X** for a single group of size n_i

- l is n if XFUN contains all rows of X .
- VFUN — Either
 - A 1-by- g vector of group-specific predictors for a single group, corresponding to a single row of V
 - An n -by- g matrix, where the k -th row of VFUN is $V(i,:)$ if the k -th observation is in group i .

If V is empty, `nlmefitsa` calls `MODELFUN` with only two inputs.

`MODELFUN` returns an l -by-1 vector of fitted values `YFIT`. When either `PHI` or `VFUN` contains a single row, that one row corresponds to all rows in the other two input arguments. For improved performance, use the '`Vectorization`' parameter name/value pair (described below) if `MODELFUN` can compute `YFIT` for more than one vector of model parameters in one call.

BETA0

An f -by-1 vector with initial estimates for the f fixed effects. By default, f is equal to the number of model parameters p . `BETA0` can also be an f -by-REPS matrix, and the estimation is repeated REPS times using each column of `BETA0` as a set of starting values.

Name-Value Pair Arguments

By default, `nlmefitsa` fits a model where each model parameter is the sum of a corresponding fixed and random effect. Use the following parameter name/value pairs to fit a model with a different number of or dependence on fixed or random effects. Use at most one parameter name with an '`FE`' prefix and one parameter name with an '`RE`' prefix. Note that some choices change the way `nlmefitsa` calls `MODELFUN`, as described further below.

FEParamsSelect

A vector specifying which elements of the model parameter vector `PHI` include a fixed effect, as a numeric vector with elements in $1:p$, or as a 1-by- p logical vector. The model will include f fixed effects, where f is the specified number of elements.

FEConstDesign

A p -by- f design matrix `ADESIGN`, where `ADESIGN*BETA` are the fixed components of the p elements of `PHI`.

FEGroupDesign

A p -by- f -by- m array specifying a different p -by- f fixed effects design matrix for each of the m groups.

REParamsSelect

A vector specifying which elements of the model parameter vector PHI include a random effect, as a numeric vector with elements in $1:p$, or as a 1-by- p logical vector. The model will include r random effects, where r is the specified number of elements.

REConstDesign

A p -by- r design matrix BDESIGN, where BDESIGN*B are the random components of the p elements of PHI. This matrix must consist of 0s and 1s, with at most one 1 per row.

The default model is equivalent to setting both FEConstDesign and REConstDesign to `eye(p)`, or to setting both FEParamsSelect and REParamsSelect to $1:p$.

Additional optional parameter name/value pairs control the iterative algorithm used to maximize the likelihood:

CovPattern

Specifies an r -by- r logical or numeric matrix PAT that defines the pattern of the random effects covariance matrix PSI. `nlmefitsa` computes estimates for the variances along the diagonal of PSI as well as covariances that correspond to non-zeroes in the off-diagonal of PAT. `nlmefitsa` constrains the remaining covariances, i.e., those corresponding to off-diagonal zeroes in PAT, to be zero. PAT must be a row-column permutation of a block diagonal matrix, and `nlmefitsa` adds non-zero elements to PAT as needed to produce such a pattern. The default value of PAT is `eye(r)`, corresponding to uncorrelated random effects.

Alternatively, specify PAT as a 1-by- r vector containing values in $1:r$. In this case, elements of PAT with equal values define groups of random effects, `nlmefitsa` estimates covariances only within groups, and constrains covariances across groups to be zero.

Cov0

Initial value for the covariance matrix PSI. Must be an r -by- r positive definite matrix. If empty, the default value depends on the values of BETA0.

ComputeStdErrors

true to compute standard errors for the coefficient estimates and store them in the output STATS structure, or false (default) to omit this computation.

ErrorModel

A character vector or string scalar specifying the form of the error term. Default is 'constant'. Each model defines the error using a standard normal (Gaussian) variable e , the function value f , and one or two parameters a and b . Choices are

- 'constant' — $y = f + a*e$
- 'proportional' — $y = f + b*f*e$
- 'combined' — $y = f + (a+b*f)*e$
- 'exponential' — $y = f*\exp(a*e)$, or equivalently $\log(y) = \log(f) + a*e$

If this parameter is given, the output STATS.errorparam field has the value

- a for 'constant' and 'exponential'
- b for 'proportional'
- $[a\ b]$ for 'combined'

ErrorParameters

A scalar or two-element vector specifying starting values for parameters of the error model. This specifies the a , b , or $[a\ b]$ values depending on the ErrorModel parameter.

LogLikMethod

Specifies the method for approximating the loglikelihood. Choices are:

- 'is' — Importance sampling
- 'gq' — Gaussian quadrature
- 'lin' — Linearization
- 'none' — Omit the loglikelihood approximation (default)

NBurnIn

Number of initial burn-in iterations during which the parameter estimates are not recomputed. Default is 5.

NChains

Number c of "chains" simulated. Default is 1. Setting $c > 1$ causes c simulated coefficient vectors to be computed for each group during each iteration. Default depends on the data, and is chosen to provide about 100 groups across all chains.

NIterations

Number of iterations. This can be a scalar or a three-element vector. Controls how many iterations are performed for each of three phases of the algorithm:

- 1 simulated annealing
- 2 full step size
- 3 reduced step size

Default is [150 150 100]. A scalar is distributed across the three phases in the same proportions as the default.

NMCMCIterations

Number of Markov Chain Monte Carlo (MCMC) iterations. This can be a scalar or a three-element vector. Controls how many of three different types of MCMC updates are performed during each phase of the main iteration:

- 1 full multivariate update
- 2 single coordinate update
- 3 multiple coordinate update

Default is [2 2 2]. A scalar value is treated as a three-element vector with all elements equal to the scalar.

OptimFun

Either 'fminsearch' or 'fminunc', specifying the optimization function to be used during the estimation process. Default is 'fminsearch'. Use of 'fminunc' requires Optimization Toolbox.

Options

A structure created by a call to `statset`. `nlmefitsa` uses the following `statset` parameters:

- 'DerivStep' — Relative difference used in finite difference gradient calculation. May be a scalar, or a vector whose length is the number of model parameters p . The default is $\text{eps}^{(1/3)}$.
- Display — Level of display during estimation.
 - 'off' (default) — Displays no information
 - 'final' — Displays information after the final iteration of the estimation algorithm
 - 'iter' — Displays information at each iteration
- FunValCheck
 - 'on' (sdefault) — Check for invalid values (such as NaN or Inf) from MODELFUN
 - 'off' — Skip this check
- OutputFcn — Function handle specified using @, a cell array with function handles or an empty array. `nlmefitsa` calls all output functions after each iteration. See `nlmefitoutputfcn.m` (the default output function for `nlmefitsa`) for an example of an output function.

ParamTransform

A vector of p -values specifying a transformation function $f()$ for each of the p parameters:

```
XB = ADESIGN*BETA + BDESIGN*B
PHI = f(XB)
```

Each element of the vector must be one of the following integer codes specifying the transformation for the corresponding value of PHI:

- 0: $\text{PHI} = \text{XB}$ (default for all parameters)
- 1: $\log(\text{PHI}) = \text{XB}$
- 2: $\text{probit}(\text{PHI}) = \text{XB}$
- 3: $\text{logit}(\text{PHI}) = \text{XB}$

Replicates

Number REPS of estimations to perform starting from the starting values in the vector BETA0. If BETA0 is a matrix, REPS must match the number of columns in BETA0. Default is the number of columns in BETA0.

Vectorization

Determines the possible sizes of the PHI, XFUN, and VFUN input arguments to MODELFUN. Possible values are:

- 'SinglePhi' — MODELFUN is a function (such as an ODE solver) that can only compute YFIT for a single set of model parameters at a time, i.e., PHI must be a single row vector in each call. `nlmefitsa` calls MODELFUN in a loop if necessary using a single PHI vector and with XFUN containing rows for a single observation or group at a time. VFUN may be a single row that applies to all rows of XFUN, or a matrix with rows corresponding to rows in XFUN.
- 'SingleGroup' — MODELFUN can only accept inputs corresponding to a single group in the data, i.e., XFUN must contain rows of X from a single group in each call. Depending on the model, PHI is a single row that applies to the entire group, or a matrix with one row for each observation. VFUN is a single row.
- 'Full' — MODELFUN can accept inputs for multiple parameter vectors and multiple groups in the data. Either PHI or VFUN may be a single row that applies to all rows of XFUN, or a matrix with rows corresponding to rows in XFUN. Using this option can improve performance by reducing the number of calls to MODELFUN, but may require MODELFUN to perform singleton expansion on PHI or V.

The default for 'Vectorization' is 'SinglePhi'. In all cases, if V is empty, `nlmefitsa` calls MODELFUN with only two inputs.

Output Arguments

BETA

Estimates of the fixed effects

PSI

An r -by- r estimated covariance matrix for the random effects. By default, r is equal to the number of model parameters p .

STATS

A structure with the following fields:

- `logl` — The maximized loglikelihood for the fitted model; empty if the `LogLikMethod` parameter has its default value of 'none'
- `rmse` — The square root of the estimated error variance (computed on the log scale for the exponential error model)
- `errorparam` — The estimated parameters of the error variance model
- `aic` — The Akaike information criterion (empty if `logl` is empty), calculated as $aic = -2 * \logl + 2 * numParam$, where
 - `logl` is the maximized loglikelihood.
 - `numParam` is the number of fitting parameters, including the degree of freedom for covariance matrix of the random effects, the number of fixed effects and the number of parameters of the error model.
- `bic` — The Bayesian information criterion (empty if `logl` is empty), calculated as $bic = -2 * \logl + \log(M) * numParam$
 - `M` is the number of groups.
 - `logl` and `numParam` are defined as in `aic`.

Note that some literature suggests that the computation of `bic` should be , $bic = -2 * \logl + \log(N) * numParam$, where `N` is the number of observations. To adjust the value of the output you can redefine `bic` as follows: $bic = bic - \text{numel}(\text{unique}(\text{group})) + \text{numel}(Y)$

- `sebeta` — The standard errors for BETA (empty if the `ComputeStdErrors` parameter has its default value of false)
- `covb` — The estimated covariance of the parameter estimates (empty if `ComputeStdErrors` is false)
- `dfe` — The error degrees of freedom
- `pres` — The population residuals ($y - y_{\text{population}}$), where `y_population` is the population predicted values
- `ires` — The population residuals ($y - y_{\text{population}}$), where `y_population` is the individual predicted values
- `pwres` — The population weighted residuals
- `cwres` — The conditional weighted residuals
- `iwres` — The individual weighted residuals

Examples

Nonlinear Mixed-Effects Model with Stochastic EM Algorithm

Load the sample data.

```
load indomethacin
```

Fit a model to data on concentrations of the drug indomethacin in the bloodstream of six subjects over eight hours.

```
model = @(phi,t)(phi(:,1).*exp(-phi(:,2).*t)+phi(:,3).*exp(-phi(:,4).*t));  
phi0 = [1 1 1 1];  
xform = [0 1 0 1]; % log transform for 2nd and 4th parameters  
[beta,PSI,stats,br] = nlmefitsa(time,concentration,...  
    subject,[],model,phi0,'ParamTransform',xform)
```

```
beta =
```

```
    0.8563  
   -0.7950  
    2.7744  
    1.0772
```

```
PSI =
```

```

-0.0010	-0.0198	0.0137	-0.0757	0.0478	-0.0076

Plot the data along with an overall population fit

```
clf
phi = [beta(1), exp(beta(2)), beta(3), exp(beta(4))];
h = gscatter(time,concentration,subject);
xlabel('Time (hours)')
ylabel('Concentration (mcg/ml)')
title('{\bf Indomethacin Elimination}')
xx = linspace(0,8);
line(xx,model(phi,xx),'linewidth',2,'color','k')
```

Plot individual curves based on random-effect estimates.

```
for j=1:6
    phir = [beta(1)+br(1,j), exp(beta(2)+br(2,j)), ...
            beta(3)+br(3,j), exp(beta(4)+br(4,j))];
    line(xx,model(phir,xx),'color',get(h(j),'color'))
end
```

Algorithms

In order to estimate the parameters of a nonlinear mixed effects model, we would like to choose the parameter values that maximize a likelihood function. These values are called the maximum likelihood estimates. The likelihood function can be written in the form

$$p(y|\beta, \sigma^2, \Sigma) = \int p(y|\beta, b, \sigma^2)p(b|\Sigma)db$$

where

- y is the response data

- β is the vector of population coefficients
- σ^2 is the residual variance
- Σ is the covariance matrix for the random effects
- b is the set of unobserved random effects

Each $p()$ function on the right-hand-side is a normal (Gaussian) likelihood function that may depend on covariates.

Since the integral does not have a closed form, it is difficult to find parameters that maximize it. Delyon, Lavielle, and Moulines [1] proposed to find the maximum likelihood estimates using an Expectation-Maximization (EM) algorithm in which the E step is replaced by a stochastic procedure. They called their algorithm SAEM, for Stochastic Approximation EM. They demonstrated that this algorithm has desirable theoretical properties, including convergence under practical conditions and convergence to a local maximum of the likelihood function. Their proposal involves three steps:

- 1 Simulation: Generate simulated values of the random effects b from the posterior density $p(b|\Sigma)$ given the current parameter estimates.
- 2 Stochastic approximation: Update the expected value of the loglikelihood function by taking its value from the previous step, and moving part way toward the average value of the loglikelihood calculated from the simulated random effects.
- 3 Maximization step: Choose new parameter estimates to maximize the loglikelihood function given the simulated values of the random effects.

“Mixed-Effects Models” on page 13-22

“Grouping Variables” on page 2-57

Introduced in R2010a

nlparci

Nonlinear regression parameter confidence intervals

Syntax

```
ci = nlparci(beta, resid, 'covar', sigma)
ci = nlparci(beta, resid, 'jacobian', J)
ci = nlparci(..., 'alpha', alpha)
```

Description

`ci = nlparci(beta, resid, 'covar', sigma)` returns the 95% confidence intervals `ci` for the nonlinear least squares parameter estimates `beta`. Before calling `nlparci`, use `nlinfit` to fit a nonlinear regression model and get the coefficient estimates `beta`, residuals `resid`, and estimated coefficient covariance matrix `sigma`.

`ci = nlparci(beta, resid, 'jacobian', J)` is an alternative syntax that also computes 95% confidence intervals. `J` is the Jacobian computed by `nlinfit`. If the 'robust' option is used with `nlinfit`, use the 'covar' input rather than the 'jacobian' input so that the required `sigma` parameter takes the robust fitting into account.

`ci = nlparci(..., 'alpha', alpha)` returns $100(1-\alpha)\%$ confidence intervals.

`nlparci` treats NaNs in `resid` or `J` as missing values, and ignores the corresponding observations.

The confidence interval calculation is valid for systems where the length of `resid` exceeds the length of `beta` and `J` has full column rank. When `J` is ill-conditioned, confidence intervals may be inaccurate.

Examples

Fit to exponential decay

Suppose you have data, and want to fit a model of the form

$$y_i = a_1 + a_2 \exp(-a_3 x_i) + \varepsilon_i.$$

Here the a_i are the parameters you want to estimate, x_i are the data points, the y_i are the responses, and the ε_i are noise terms.

- 1 Write a function handle that represents the model:

```
mdl = @(a,x)(a(1) + a(2)*exp(-a(3)*x));
```

- 2 Generate synthetic data with parameters $\mathbf{a} = [1;3;2]$, with the x data points distributed exponentially with parameter 2, and normally distributed noise with standard deviation 0.1:

```
rng(9845,'twister') % for reproducibility
a = [1;3;2];
x = exprnd(2,100,1);
epsn = normrnd(0,0.1,100,1);
y = mdl(a,x) + epsn;
```

- 3 Fit the model to data starting from the arbitrary guess $\mathbf{a0} = [2;2;2]$:

```
a0 = [2;2;2];
[ahat,r,J,cov,mse] = nlinfit(x,y,mdl,a0);
ahat
```

```
ahat =
    1.0153
    3.0229
    2.1070
```

- 4 Check whether $[1;3;2]$ is in a 95% confidence interval using the Jacobian argument in `nlparci`:

```
ci = nlparci(ahat,r,'Jacobian',J)
```

```
ci =
    0.9869    1.0438
    2.9401    3.1058
    1.9963    2.2177
```

- 5 You can obtain the same result using the covariance argument:

```
ci = nlparci(ahat,r,'covar',cov)
```

```
ci =  
  0.9869    1.0438  
  2.9401    3.1058  
  1.9963    2.2177
```

See Also

`nlinfit` | `nlpredci`

Introduced before R2006a

nlpredci

Nonlinear regression prediction confidence intervals

Syntax

```
[Ypred,delta] = nlpredci(modelfun,X,beta,R,'Covar',CovB)
[Ypred,delta] = nlpredci(modelfun,X,beta,R,'Covar',CovB,Name,Value)

[Ypred,delta] = nlpredci(modelfun,X,beta,R,'Jacobian',J)
[Ypred,delta] = nlpredci(modelfun,X,beta,R,'Jacobian',J,Name,Value)
```

Description

`[Ypred,delta] = nlpredci(modelfun,X,beta,R,'Covar',CovB)` returns predictions, `Ypred`, and 95% confidence interval half-widths, `delta`, for the nonlinear regression model `modelfun` at input values `X`. Before calling `nlpredci`, use `nlinfit` to fit `modelfun` and get the estimated coefficients, `beta`, residuals, `R`, and variance-covariance matrix, `CovB`.

`[Ypred,delta] = nlpredci(modelfun,X,beta,R,'Covar',CovB,Name,Value)` uses additional options specified by one or more name-value pair arguments.

`[Ypred,delta] = nlpredci(modelfun,X,beta,R,'Jacobian',J)` returns predictions, `Ypred`, and 95% confidence interval half-widths, `delta`, for the nonlinear regression model `modelfun` at input values `X`. Before calling `nlpredci`, use `nlinfit` to fit `modelfun` and get the estimated coefficients, `beta`, residuals, `R`, and Jacobian, `J`.

If you use a robust option with `nlinfit`, then you should use the `Covar` syntax rather than the `Jacobian` syntax. The variance-covariance matrix, `CovB`, is required to properly take the robust fitting into account.

`[Ypred,delta] = nlpredci(modelfun,X,beta,R,'Jacobian',J,Name,Value)` uses additional options specified by one or more name-value pair arguments.

Examples

Confidence Interval for Nonlinear Regression Curve

Load sample data.

```
S = load('reaction');  
X = S.reactants;  
y = S.rate;  
beta0 = S.beta;
```

Fit the Hougen-Watson model to the rate data using the initial values in beta0.

```
[beta,R,J] = nlinfit(X,y,@hougen,beta0);
```

Obtain the predicted response and 95% confidence interval half-width for the value of the curve at average reactant levels.

```
[ypred,delta] = nlpredci(@hougen,mean(X),beta,R,'Jacobian',J)
```

```
ypred = 5.4622
```

```
delta = 0.1921
```

Compute the 95% confidence interval for the value of the curve.

```
[ypred-delta,ypred+delta]
```

```
ans = 1×2
```

```
5.2702    5.6543
```

Prediction Interval for New Observation

Load sample data.

```
S = load('reaction');  
X = S.reactants;  
y = S.rate;  
beta0 = S.beta;
```

Fit the Hougen-Watson model to the rate data using the initial values in `beta0`.

```
[beta,R,J] = nlinfit(X,y,@hougen,beta0);
```

Obtain the predicted response and 95% prediction interval half-width for a new observation with reactant levels [100,100,100].

```
[ypred,delta] = nlpredci(@hougen,[100,100,100],beta,R,'Jacobian',J,...  
                        'PredOpt','observation')
```

```
ypred = 1.8346
```

```
delta = 0.5101
```

Compute the 95% prediction interval for the new observation.

```
[ypred-delta,ypred+delta]
```

```
ans = 1×2
```

```
    1.3245    2.3447
```

Simultaneous Confidence Intervals for Robust Fit Curve

Generate sample data from the nonlinear regression model $y = b_1 + b_2 \cdot \exp\{b_3x\} + \epsilon$, where b_1 , b_2 , and b_3 are coefficients, and the error term is normally distributed with mean 0 and standard deviation 0.5.

```
modelfun = @(b,x)(b(1)+b(2)*exp(-b(3)*x));
```

```
rng('default') % for reproducibility
```

```
b = [1;3;2];
```

```
x = exprnd(2,100,1);
```

```
y = modelfun(b,x) + normrnd(0,0.5,100,1);
```

Fit the nonlinear model using robust fitting options.

```
opts = statset('nlinfit');
```

```
opts.RobustWgtFun = 'bisquare';
```

```
beta0 = [2;2;2];
```

```
[beta,R,J,CovB,MSE] = nlinfit(x,y,modelfun,beta0,opts);
```

Plot the fitted regression model and simultaneous 95% confidence bounds.

```
xrange = min(x):.01:max(x);  
[ypred,delta] = nlpredci(modelfun,xrange,beta,R,'Covar',CovB,...  
    'MSE',MSE,'SimOpt','on');  
lower = ypred - delta;  
upper = ypred + delta;  
  
figure()  
plot(x,y,'ko') % observed data  
hold on  
plot(xrange,ypred,'k','LineWidth',2)  
plot(xrange,[lower;upper],'r--','LineWidth',1.5)
```

Confidence Interval Using Observation Weights

Load sample data.

```
S = load('reaction');  
X = S.reactants;  
y = S.rate;  
beta0 = S.beta;
```

Specify a function handle for observation weights, then fit the Hougen-Watson model to the rate data using the specified observation weights function.

```
a = 1; b = 1;  
weights = @(yhat) 1./((a + b*abs(yhat)).^2);  
[beta,R,J,CovB] = nlinfit(X,y,@hougen,beta0,'Weights',weights);
```

Compute the 95% prediction interval for a new observation with reactant levels [100,100,100] using the observation weight function.

```
[ypred,delta] = nlpredci(@hougen,[100,100,100],beta,R,'Jacobian',J,...  
    'PredOpt','observation','Weights',weights);  
[ypred-delta,ypred+delta]
```

```
ans = 1×2
```

```
    1.5264    2.1033
```

Confidence Interval Using Nonconstant Error Model

Load sample data.

```
S = load('reaction');  
X = S.reactants;  
y = S.rate;  
beta0 = S.beta;
```

Fit the Hougen-Watson model to the rate data using the combined error variance model.

```
[beta,R,J,CovB,MSE,S] = nlinfit(X,y,@hougen,beta0,'ErrorModel','combined');
```

Compute the 95% prediction interval for a new observation with reactant levels [100,100,100] using the fitted error variance model.

```
[ypred,delta] = nlpredci(@hougen,[100,100,100],beta,R,'Jacobian',J,...
    'PredOpt','observation','ErrorModelInfo',S);
[ypred-delta,ypred+delta]
```

```
ans = 1×2
```

```
    1.3245    2.3447
```

Input Arguments

modelfun — Nonlinear regression model function

function handle

Nonlinear regression model function, specified as a function handle. `modelfun` must accept two input arguments, a coefficient vector and an array `X`—in that order—and return a vector of fitted response values.

For example, to specify the `hougen` nonlinear regression function, use the function handle `@hougen`.

Data Types: `function_handle`

X — Input values for predictions

matrix

Input values for predictions, specified as a matrix. `nlpredci` makes a prediction for the covariates in each row of `X`. There should be a column in `X` for each coefficient in the model.

Data Types: `single` | `double`

beta — Estimated regression coefficients

vector returned by `nlinfit`

Estimated regression coefficients, specified as the vector of fitted coefficients returned by a previous call to `nlinfit`.

Data Types: `single` | `double`

R — Residuals

vector returned by `nlinfit`

Residuals for the fitted model `fun`, specified as the vector of residuals returned by a previous call to `nlinfit`.

CovB — Estimated variance-covariance matrix

matrix returned by `nlinfit`

Estimated variance-covariance matrix for the fitted coefficients, `beta`, specified as the variance-covariance matrix returned by a previous call to `nlinfit`.

J — Estimated Jacobian

matrix returned by `nlinfit`

Estimated Jacobian of the nonlinear regression model, `modelfun`, specified as the Jacobian matrix returned by a previous call to `nlinfit`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'Alpha', 0.1, 'PredOpt', 'observation'` specifies 90% prediction intervals for new observations.

Alpha — Significance level

`0.05` (default) | scalar value in the range (0,1)

Significance level for the confidence interval, specified as the comma-separated pair consisting of `'Alpha'` and a scalar value in the range (0,1). If `Alpha` has value α , then `nlpredci` returns intervals with $100 \times (1 - \alpha)\%$ confidence level.

The default confidence level is 95% ($\alpha = 0.05$).

Example: `'Alpha', 0.1`

Data Types: `single` | `double`

ErrorModelInfo — Information about error model fit

structure returned by `nlinfit`

Information about the error model fit, specified as the comma-separated pair consisting of 'ErrorModelInfo' and a structure returned by a previous call to `nlinfit`.

`ErrorModelInfo` only has an effect on the returned prediction interval when `PredOpt` has the value 'observation'. If you do not use `ErrorModelInfo`, then `nlpredci` assumes the error variance model is 'constant'.

The error model structure returned by `nlinfit` has the following fields:

<code>ErrorModel</code>	Chosen error model
<code>ErrorParameters</code>	Estimated error parameters
<code>ErrorVariance</code>	Function handle that accepts an N -by- p matrix, X , and returns an N -by-1 vector of error variances using the estimated error model
<code>MSE</code>	Mean squared error
<code>ScheffeSimPred</code>	Scheffé parameter for simultaneous prediction intervals when using the estimated error model
<code>WeightFunction</code>	Logical with value <code>true</code> if you used a custom weight function previously in <code>nlinfit</code>
<code>FixedWeights</code>	Logical with value <code>true</code> if you used fixed weights previously in <code>nlinfit</code>
<code>RobustWeightFunction</code>	Logical with value <code>true</code> if you used robust fitting previously in <code>nlinfit</code>

MSE — Mean squared error

MSE returned by `nlinfit`

Mean squared error (MSE) for the fitted nonlinear regression model, specified as the comma-separated pair consisting of 'MSE' and the MSE value returned by a previous call to `nlinfit`.

If you use a robust option with `nlinfit`, then you must specify the MSE when predicting new observations to properly take the robust fitting into account. If you do not specify the MSE, then `nlpredci` computes the MSE from the residuals, R , and does not take the robust fitting into account.

For example, if `mse` is the MSE value returned by `nlinfit`, then you can specify 'MSE',`mse`.

Data Types: `single` | `double`

PredOpt — Prediction interval to compute`'curve' (default) | 'observation'`

Prediction interval to compute, specified as the comma-separated pair consisting of 'PredOpt' and either 'curve' or 'observation'.

- If you specify the value 'curve', then `nlpredci` returns confidence intervals for the estimated curve (function value) at the observations X .
- If you specify the value 'observation', then `nlpredci` returns prediction intervals for new observations at X .

If you specify 'observation' after using a robust option with `nlinfit`, then you must also specify a value for MSE to provide the robust estimate of the mean squared error.

Example: 'PredOpt', 'observation'

SimOpt — Indicator for specifying simultaneous bounds`'off' (default) | 'on'`

Indicator for specifying simultaneous bounds, specified as the comma-separated pair consisting of 'SimOpt' and either 'off' or 'on'. Use the value 'off' to compute nonsimultaneous bounds, and 'on' for simultaneous bounds.

Weights — Observation weights`vector | function handle`

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a vector of positive scalar values or a function handle. The default is no weights.

- If you specify a vector of weights, then it must have the same number of elements as the number of observations (rows) in X .
- If you specify a function handle for the weights, then it must accept a vector of predicted response values as input, and return a vector of real positive weights as output.

Given weights, W , `nlpredci` estimates the error variance at observation i by $mse \cdot (1/W(i))$, where `mse` is the mean squared error value specified using `MSE`.

Example: 'Weights', @WFun

Data Types: double | single | function_handle

Output Arguments

Ypred — Predicted responses

vector

Predicted responses, returned as a vector with the same number of rows as \mathbf{X} .

delta — Confidence interval half-widths

vector

Confidence interval half-widths, returned as a vector with the same number of rows as \mathbf{X} . By default, `delta` contains the half-widths for nonsimultaneous 95% confidence intervals for `model fun` at the observations in \mathbf{X} . You can compute the lower and upper bounds of the confidence intervals as $\mathbf{Ypred} - \mathbf{delta}$ and $\mathbf{Ypred} + \mathbf{delta}$, respectively.

If 'PredOpt' has value 'observation', then `delta` contains the half-widths for prediction intervals of new observations at the values in \mathbf{X} .

Definitions

Confidence Intervals for Estimable Predictions

When the estimated model Jacobian is not of full rank, then it might not be possible to construct sensible confidence intervals at all prediction points. In this case, `nlpredci` still tries to construct confidence intervals for any estimable prediction points.

For example, suppose you fit the linear function $f(\mathbf{x}_i, \beta) = \beta_1 x_{i1} + \beta_2 x_{i2} + \beta_3 x_{i3}$ at the points in the design matrix

$$\mathbf{X} = \begin{pmatrix} 1 & 1 & 0 \\ 1 & 1 & 0 \\ 1 & 1 & 0 \\ 1 & 0 & 1 \\ 1 & 0 & 1 \\ 1 & 0 & 1 \end{pmatrix}.$$

The estimated Jacobian at the values in \mathbf{X} is the design matrix itself, $\mathbf{J} = \mathbf{X}$. Thus, the Jacobian is not of full rank:

```
rng('default') % For reproducibility
y = randn(6,1);

linfun = @(b,x) x*b;
beta0 = [1;1;1];
X = [repmat([1 1 0],3,1); repmat([1 0 1],3,1)];

[beta,R,J] = nlinfit(X,y,linfun,beta0);
```

```
Warning: The Jacobian at the solution is ill-conditioned, and
some model parameters may not be estimated well (they are not
identifiable). Use caution in making predictions.
> In nlinfit at 283
```

In this example, `nlpredci` can only compute prediction intervals at points that satisfy the linear relationship

$$x_{i1} = x_{i2} + x_{i3}.$$

If you try to compute confidence intervals for predictions at nonidentifiable points, `nlpredci` returns NaN for the corresponding interval half-widths:

```
xpred = [1 1 1;0 1 -1;2 1 1];
[ypred,delta] = nlpredci(linfun,xpred,beta,R,'Jacobian',J)

ypred =

    -0.0035
     0.0798
    -0.0047

delta =

     NaN
     3.8102
     3.8102
```

Here, the first element of `delta` is NaN because the first row in `xpred` does not satisfy the required linear dependence, and is therefore not an estimable contrast.

Tips

- To compute confidence intervals for complex parameters or data, you need to split the problem into its real and imaginary parts. When calling `nlinfit`:
 - 1 Define your parameter vector `beta` as the concatenation of the real and imaginary parts of the original parameter vector.
 - 2 Concatenate the real and imaginary parts of the response vector `Y` as a single vector.
 - 3 Modify your model function `modelfun` to accept `X` and the purely real parameter vector, and return a concatenation of the real and imaginary parts of the fitted values.

With the problem formulated this way, `nlinfit` computes real estimates, and confidence intervals are feasible.

Algorithms

- `nlpredci` treats NaN values in the residuals, `R`, or the Jacobian, `J`, as missing values, and ignores the corresponding observations.
- If the Jacobian, `J`, does not have full column rank, then some of the model parameters might be nonidentifiable. In this case, `nlpredci` tries to construct confidence intervals for estimable predictions on page 32-4583, and returns NaN for those that are not.

NonLinearModel | `nlinfit` | `nlparci`

Introduced before R2006a

nnmf

Nonnegative matrix factorization

Syntax

```
[W,H] = nnmf(A,k)
[W,H] = nnmf(A,k,param1,val1,param2,val2,...)
[W,H,D] = nnmf(...)
```

Description

`[W,H] = nnmf(A,k)` factors the nonnegative n -by- m matrix A into nonnegative factors W (n -by- k) and H (k -by- m). The factorization is not exact; $W*H$ is a lower-rank approximation to A . The factors W and H are chosen to minimize the root-mean-squared residual D between A and $W*H$:

$$D = \text{norm}(A-W*H, 'fro')/\text{sqrt}(N*M)$$

The factorization uses an iterative method starting with random initial values for W and H . Because the root-mean-squared residual D may have local minima, repeated factorizations may yield different W and H . Sometimes the algorithm converges to a solution of lower rank than k , which may indicate that the result is not optimal.

W and H are normalized so that the rows of H have unit length. The columns of W are ordered by decreasing length.

`[W,H] = nnmf(A,k,param1,val1,param2,val2,...)` specifies optional parameter name/value pairs from the following table.

Parameter	Value
'algorithm'	<p>Either 'als' (the default) to use an alternating least-squares algorithm, or 'mult' to use a multiplicative update algorithm.</p> <p>In general, the 'als' algorithm converges faster and more consistently. The 'mult' algorithm is more sensitive to initial values, which makes it a good choice when using 'replicates' to find W and H from multiple random starting values.</p>
'w0'	An n -by- k matrix to be used as the initial value for W.
'h0'	A k -by- m matrix to be used as the initial value for H.

Parameter	Value
'options'	<p>An options structure as created by the <code>statset</code> function. <code>nnmf</code> uses the following fields of the options structure:</p> <ul style="list-style-type: none"> • <code>Display</code> — Level of display. Choices: <ul style="list-style-type: none"> • <code>'off'</code> (default) — No display • <code>'final'</code> — Display final result • <code>'iter'</code> — Iterative display of intermediate results • <code>MaxIter</code> — Maximum number of iterations. Default is <code>100</code>. Unlike in optimization settings, reaching <code>MaxIter</code> iterations is treated as convergence. • <code>TolFun</code> — Termination tolerance on change in size of the residual. Default is <code>1e-4</code>. • <code>TolX</code> — Termination tolerance on relative change in the elements of <code>W</code> and <code>H</code>. Default is <code>1e-4</code>. • <code>UseParallel</code> — Set to <code>true</code> to compute in parallel. Default is <code>false</code>. • <code>UseSubstreams</code> — Set to <code>true</code> to compute in parallel in a reproducible fashion. Default is <code>false</code>. To compute reproducibly, set <code>Streams</code> to a type allowing substreams: <code>'mlfg6331_64'</code> or <code>'mrg32k3a'</code>. • <code>Streams</code> — A <code>RandStream</code> object or cell array of such objects. If you do not specify <code>Streams</code>, <code>nnmf</code> uses the default stream or streams. If you choose to specify <code>Streams</code>, use a single object except in the case <ul style="list-style-type: none"> • <code>UseParallel</code> is <code>true</code> • <code>UseSubstreams</code> is <code>false</code> <p>In that case, use a cell array the same size as the <code>Parallel</code> pool.</p> <p>To compute in parallel, you need <code>Parallel Computing Toolbox</code>.</p>

Parameter	Value
'replicates'	The number of times to repeat the factorization, using new random starting values for W and H, except at the first replication if 'w0' and 'h0' are given. This is most beneficial with the 'mult' algorithm. The default is 1.

[W,H,D] = nnmf(...) also returns D, the root mean square residual.

Examples

Nonnegative Rank-Two Approximation and Biplot

Load the sample data.

```
load fisheriris
```

Compute a nonnegative rank-two approximation of the measurements of the four variables in Fisher's iris data.

```
rng(1) % For reproducibility
[W,H] = nnmf(meas,2);
H
```

```
H = 2×4
```

```
    0.6945    0.2856    0.6220    0.2218
    0.8020    0.5683    0.1834    0.0149
```

The first and third variables in `meas` (sepal length and petal length, with coefficients 0.6945 and 0.6220, respectively) provide relatively strong weights to the first column of `W`. The first and second variables in `meas` (sepal length and sepal width, with coefficients 0.8020 and 0.5683) provide relatively strong weights to the second column of `W`.

Create a biplot of the data and the variables in `meas` in the column space of `W`.

```
biplot(H', 'scores', W, 'varlabels', {'sl', 'sw', 'pl', 'pw'});
axis([0 1.1 0 1.1])
xlabel('Column 1')
ylabel('Column 2')
```

Change Algorithm

Starting from a random array X with rank 20, try a few iterations at several replicates using the multiplicative algorithm:

```
X = rand(100,20)*rand(20,50);
opt = statset('MaxIter',5,'Display','final');
[W0,H0] = nnmf(X,5,'replicates',10,...
               'options',opt,...
               'algorithm','mult');
```

rep	iteration	rms resid	delta x
1	5	0.560887	0.0245182
2	5	0.66418	0.0364471
3	5	0.609125	0.0358355
4	5	0.608894	0.0415491
5	5	0.619291	0.0455135
6	5	0.621549	0.0299965
7	5	0.640549	0.0438758
8	5	0.673015	0.0366856
9	5	0.606835	0.0318931
10	5	0.633526	0.0319591

Final root mean square residual = 0.560887

Continue with more iterations from the best of these results using alternating least squares:

```
opt = statset('Maxiter',1000,'Display','final');  
[W,H] = nnmf(X,5,'w0',W0,'h0',H0,...  
            'options',opt,...  
            'algorithm','als');
```

rep	iteration	rms resid	delta x
1	24	0.257336	0.00271859

Final root mean square residual = 0.257336

Extended Capabilities

Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the 'UseParallel' option to true.

Set the 'UseParallel' field of the options structure to true using `statset` and specify the 'Options' name-value pair argument in the call to this function.

For example: `'Options',statset('UseParallel',true)`

For more information, see the 'Options' name-value pair argument.

For more general information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

Introduced in R2008a

nominal

Arrays for nominal data

Note The `nominal` and `ordinal` array data types might be removed in a future release. To represent ordered and unordered discrete, nonnumeric data, use the “Categorical Arrays” (MATLAB) data type instead.

Description

Nominal data are discrete, nonnumeric values that do not have a natural ordering. `nominal` array objects provide efficient storage and convenient manipulation of such data, while also maintaining meaningful labels for the values.

You can manipulate `nominal` arrays like ordinary numeric arrays, by subscripting, concatenating, and reshaping. Use `nominal` arrays as grouping variables when the elements indicate the group to which an observation belongs.

Creation

Syntax

```
B = nominal(X)
B = nominal(X,labels)
B = nominal(X,labels,levels)

B = nominal(X,labels,[],edges)
```

Description

`B = nominal(X)` creates a nominal array `B` from the array `X`. `nominal` creates the levels of `B` from the sorted unique values in `X`, and creates default labels for the levels.

`B = nominal(X,labels)` labels the levels in `B` according to `labels`.

`B = nominal(X, labels, levels)` creates a nominal array with possible levels defined by `levels`.

`B = nominal(X, labels, [], edges)` creates a nominal array by binning the numeric array `X` with bin edges given by the numeric vector `edges`.

Input Arguments

X — Input array

numeric | logical | character | string | categorical | cell array of character vectors

Input array to convert to `nominal`, specified as a numeric, logical, character, string, or categorical array, or a cell array of character vectors. The levels of the resulting `nominal` array correspond to the sorted unique values in `X`.

labels — Labels for discrete levels

character array | string array | cell array of character vectors

Labels for the discrete levels, specified as a character array, string array, or cell array of character vectors. By default, `nominal` assigns labels to the levels in `B` in order of the sorted unique values in `X`.

You can include duplicate labels in `labels` to merge multiple values in `X` into a single level in `B`.

Data Types: `char` | `string` | `cell`

levels — Possible nominal levels

vector

Possible nominal levels for the output `nominal` array, specified as a vector whose values can be compared to those in `X` using the equality operator. `nominal` assigns labels to each level from the corresponding elements of `labels`. If `X` contains any values not present in `levels`, the levels of the corresponding elements of `B` are undefined.

edges — Bin edges

numeric vector

Bin edges used to create the nominal array by binning a numeric array, specified as a numeric vector. The uppermost bin includes values equal to the rightmost edge. `nominal` assigns labels to each level in the resulting nominal array from the corresponding

elements of `labels`. When you specify the `edges` input argument, it must have one more element than `labels`.

Output Arguments

B — Nominal array

nominal array object

Nominal array, returned as a `nominal` array object.

By default, an element of `B` is undefined if the corresponding element of `X` is `NaN` (when `X` is numeric), an empty character vector (when `X` is a character), an empty or missing string (when `X` is a string), or undefined (when `X` is categorical). `nominal` treats such elements as undefined or missing and does not include entries for them among the possible levels. To create an explicit level for such elements instead of treating them as undefined, use the `levels` input argument and include `NaN`, the empty character vector, the empty or missing string, or an undefined element.

Properties

labels — Level labels

cell array of character vectors

This property is read-only.

Level labels, specified as a cell array of character vectors. Access labels using `getlabels`.

Data Types: `cell`

undeflabel — Label for undefined levels

'<undefined>' (default)

This property is read-only.

Label for undefined levels, specified as '<undefined>'. You can find undefined elements in categorical arrays by using `isundefined`.

Object Functions

addlevels	Add levels to nominal or ordinal arrays
droplevels	Drop levels from a nominal or ordinal array
getlabels	Access nominal or ordinal array labels
getlevels	Access nominal or ordinal array levels
islevel	Determine if levels are in nominal or ordinal array
levelcounts	Element counts by level of a nominal or ordinal array
mergelevels	Merge levels of nominal or ordinal arrays
reorderlevels	Reorder levels of nominal or ordinal arrays
setlabels	Assign labels to levels of nominal or ordinal arrays

The following is a partial list of the many other MATLAB array functions you can use with nominal arrays. For a complete list, see “Other MATLAB Functions Supporting Nominal and Ordinal Arrays” on page 2-3.

double	Double-precision arrays
histogram	Histogram plot
isequal	Determine array equality
isundefined	Find undefined elements in categorical array
pie	Pie chart
summary	Print summary of table, timetable, or categorical array
times	Element-wise multiplication

Examples

Create and Label Nominal Arrays

Create nominal arrays from a cell array of character vectors and from integer data. Provide explicit labels.

Create a nominal array from a cell array of character vectors with values 'r', 'g', and 'b'. Label these levels 'red', 'green', and 'blue', respectively. `nominal` assigns the labels according to the sorted (alphabetical) order of the elements in X.

```
X = {'r' 'b' 'g'; 'g' 'r' 'b'; 'b' 'r' 'g'}
```

```
X = 3x3 cell array
    {'r'}    {'b'}    {'g'}
    {'g'}    {'r'}    {'b'}
```

```
{'b'} {'r'} {'g'}
```

```
labels = {'blue','green','red'};  
B = nominal(X,labels)
```

```
B = 3x3 nominal array  
    red      blue      green  
    green    red       blue  
    blue     red       green
```

Create a nominal array from integer data with values 1 to 4, merging odd and even values into two nominal levels with the labels 'odd' and 'even'. Merge the values by duplicating the labels.

```
X = randi([1 4],5,2)
```

```
X = 5x2
```

```
    4     1  
    4     2  
    1     3  
    4     4  
    3     4
```

```
labels = {'odd','even','odd','even'};  
B = nominal(X,labels)
```

```
B = 5x2 nominal array  
    even    odd  
    even    even  
    odd     odd  
    even    even  
    odd     even
```

Create and Manipulate Nominal Arrays

Create a nominal array from data in a cell array.

```
X = {'r','b','g';'g','r','b';'b','r','g'};
labels = {'blue','green','red'};
colors = nominal(X,labels)
```

```
colors = 3x3 nominal array
      red      blue      green
      green    red      blue
      blue     red      green
```

Identify the elements in `colors` that are members of the level 'red'. A value of 1 in the resulting array indicates that the corresponding element of `colors` is a member of 'red'.

```
colors == 'red'
ans = 3x3 logical array
```

```
 1  0  0
 0  1  0
 0  1  0
```

Identify the elements in `colors` that are members of either the level 'red' or 'blue'.

```
ismember(colors,{'red','blue'})
```

```
ans = 3x3 logical array
```

```
 1  1  0
 0  1  1
 1  1  0
```

Merge the elements of the 'red' and 'blue' levels into a new level labeled 'purple'.

```
colors = mergelevels(colors,{'red','blue'},'purple')
```

```
colors = 3x3 nominal array
      purple    purple    green
      green     purple    purple
      purple    purple    green
```

Display the levels of `colors`.

```
getlevels(colors)
```

```
ans = 1x2 nominal array  
    purple      green
```

Summarize the number of elements in each level. By default, `summary` returns counts for each column of the input array.

```
summary(colors)
```

```
    purple      2      3      1  
    green       1      0      2
```

Create a pie chart for the data in `colors`.

```
pie(colors)
```

Introduced in R2007a

notify

Class: grandstream

Notify listeners of event

Syntax

```
notify(h, 'eventname')  
notify(h, 'eventname', data)
```

Description

`notify(h, 'eventname')` notifies listeners added to the event named `eventname` on handle object array `h` that the event is taking place. `h` is the array of handles to objects triggering the event, and `eventname` must be a character vector.

`notify(h, 'eventname', data)` provides a way of encapsulating information about an event which can then be accessed by each registered listener. `data` must belong to the `event.eventdata` class.

See Also

[addlistener](#) | [event.EventData](#) | [events](#) | [grandstream](#)

NonLinearModel class

Nonlinear regression model class

Description

An object comprising training data, model description, diagnostic information, and fitted coefficients for a nonlinear regression. Predict model responses with the `predict` or `feval` methods.

Construction

Create a `NonLinearModel` object using `fitnlm`.

Properties

CoefficientCovariance — Covariance matrix of coefficient estimates

numeric matrix

This property is read-only.

Covariance matrix of coefficient estimates, specified as a p -by- p matrix of numeric values. p is the number of coefficients in the fitted model.

For details, see “Coefficient Standard Errors and Confidence Intervals” on page 11-73.

Data Types: `single` | `double`

CoefficientNames — Coefficient names

cell array of character vectors

This property is read-only.

Coefficient names, specified as a cell array of character vectors, each containing the name of the corresponding term.

Data Types: cell

Coefficients — Coefficient values

table

This property is read-only.

Coefficient values, specified as a table. `Coefficients` contains one row for each coefficient and these columns:

- `Estimate` — Estimated coefficient value
- `SE` — Standard error of the estimate
- `tStat` — t -statistic for a test that the coefficient is zero
- `pValue` — p -value for the t -statistic

Use `anova` (only for a linear regression model) or `coefTest` to perform other tests on the coefficients. Use `coefCI` to find the confidence intervals of the coefficient estimates.

To obtain any of these columns as a vector, index into the property using dot notation. For example, obtain the estimated coefficient vector in the model `mdl`:

```
beta = mdl.Coefficients.Estimate
```

Data Types: table

Diagnostics — Diagnostic information

table

This property is read-only.

Diagnostic information for the model, specified as a table. Diagnostics can help identify outliers and influential observations. `Diagnostics` contains the following fields.

Field	Meaning	Utility
Leverage	Diagonal elements of <code>HatMatrix</code>	Leverage indicates to what extent the predicted value for an observation is determined by the observed value for that observation. A value close to 1 indicates that the prediction is largely determined by that observation, with little contribution from the other observations. A value close to 0 indicates the fit is largely determined by the other observations. For a model with P coefficients and N observations, the average value of <code>Leverage</code> is P/N . An observation with <code>Leverage</code> larger than $2 * P/N$ can be regarded as having high leverage.
<code>CooksDistance</code>	Cook's measure of scaled change in fitted values	<code>CooksDistance</code> is a measure of scaled change in fitted values. An observation with <code>CooksDistance</code> larger than three times the mean Cook's distance can be an outlier.
<code>HatMatrix</code>	Projection matrix to compute fitted from observed responses	<code>HatMatrix</code> is an N -by- N matrix such that $\text{Fitted} = \text{HatMatrix} * Y$, where Y is the response vector and <code>Fitted</code> is the vector of fitted response values.

Data Types: `table`

DFE — Degrees of freedom for error

positive integer

This property is read-only.

Degrees of freedom for the error (residuals), equal to the number of observations minus the number of estimated coefficients, specified as a positive integer.

Data Types: `double`

Fitted — Fitted response values based on input data

numeric vector

This property is read-only.

Fitted (predicted) values based on the input data, specified as a numeric vector. `fitnlm` attempts to make `Fitted` as close as possible to the response data.

Data Types: `single` | `double`

Formula — Model information

`NonLinearFormula` object

This property is read-only.

Model information, specified as a `NonLinearFormula` object.

Display the formula of the fitted model `mdl` by using dot notation.

`mdl.Formula`

Iterative — Information about fitting process

structure

This property is read-only.

Information about the fitting process, specified as a structure with the following fields:

- `InitialCoefs` — Initial coefficient values (the β_0 vector)
- `IterOpts` — Options included in the `Options` name-value pair argument for `fitnlm`.

Data Types: `struct`

LogLikelihood — Log likelihood

numeric value

This property is read-only.

Log likelihood of the model distribution at the response values, specified as a numeric value. The mean is fitted from the model, and other parameters are estimated as part of the model fit.

Data Types: `single` | `double`

ModelCriterion — Criterion for model comparison

structure

This property is read-only.

Criterion for model comparison, specified as a structure with these fields:

- **AIC** — Akaike information criterion. $AIC = -2 \cdot \log L + 2 \cdot m$, where $\log L$ is the loglikelihood and m is the number of estimated parameters.
- **AICc** — Akaike information criterion corrected for the sample size. $AICc = AIC + (2 \cdot m \cdot (m + 1)) / (n - m - 1)$, where n is the number of observations.
- **BIC** — Bayesian information criterion. $BIC = -2 \cdot \log L + m \cdot \log(n)$.
- **CAIC** — Consistent Akaike information criterion. $CAIC = -2 \cdot \log L + m \cdot (\log(n) + 1)$.

Information criteria are model selection tools that you can use to compare multiple models fit to the same data. These criteria are likelihood-based measures of model fit that include a penalty for complexity (specifically, the number of parameters). Different information criteria are distinguished by the form of the penalty.

When you compare multiple models, the model with the lowest information criterion value is the best-fitting model. The best-fitting model can vary depending on the criterion used for model comparison.

To obtain any of the criterion values as a scalar, index into the property using dot notation. For example, obtain the AIC value `aic` in the model `mdl`:

```
aic = mdl.ModelCriterion.AIC
```

Data Types: `struct`

MSE — Mean squared error

numeric value

This property is read-only.

Mean squared error, specified as a numeric value. The mean squared error is an estimate of the variance of the error term in the model.

Data Types: `single` | `double`

NumCoefficients — Number of model coefficients

positive integer

This property is read-only.

Number of coefficients in the fitted model, specified as a positive integer.

`NumCoefficients` is the same as `NumEstimatedCoefficients` for `NonLinearModel` objects. `NumEstimatedCoefficients` is equal to the degrees of freedom for regression.

Data Types: double

NumEstimatedCoefficients — Number of estimated coefficients

positive integer

This property is read-only.

Number of estimated coefficients in the fitted model, specified as a positive integer. `NumEstimatedCoefficients` is the same as `NumCoefficients` for `NonLinearModel` objects. `NumEstimatedCoefficients` is equal to the degrees of freedom for regression.

Data Types: double

NumPredictors — Number of predictor variables

positive integer

This property is read-only.

Number of predictor variables used to fit the model, specified as a positive integer.

Data Types: double

NumVariables — Number of variables

positive integer

This property is read-only.

Number of variables in the input data, specified as a positive integer. `NumVariables` is the number of variables in the original table or dataset, or the total number of columns in the predictor matrix and response vector.

`NumVariables` also includes any variables that are not used to fit the model as predictors or as the response.

Data Types: double

ObservationInfo — Observation information

table

This property is read-only.

Observation information, specified as an n -by-4 table, where n is equal to the number of rows of input data. The `ObservationInfo` contains the columns described in this table.

Column	Description
Weights	Observation weight, specified as a numeric value. The default value is 1.
Excluded	Indicator of excluded observation, specified as a logical value. The value is <code>true</code> if you exclude the observation from the fit by using the 'Exclude' name-value pair argument.
Missing	Indicator of missing observation, specified as a logical value. The value is <code>true</code> if the observation is missing.
Subset	Indicator of whether or not a fitting function uses the observation, specified as a logical value. The value is <code>true</code> if the observation is not excluded or missing, meaning that fitting function uses the observation.

To obtain any of these columns as a vector, index into the property using dot notation. For example, obtain the weight vector `w` of the model `mdl`:

```
w = mdl.ObservationInfo.Weights
```

Data Types: `table`

ObservationNames — Observation names

cell array of character vectors

This property is read-only.

Observation names, specified as a cell array of character vectors containing the names of the observations used in the fit.

- If the fit is based on a table or dataset containing observation names, `ObservationNames` uses those names.
- Otherwise, `ObservationNames` is an empty cell array.

Data Types: `cell`

PredictorNames — Names of predictors used to fit model

cell array of character vectors

This property is read-only.

Names of predictors used to fit the model, specified as a cell array of character vectors.

Data Types: cell

Residuals — Residuals for fitted model

table

This property is read-only.

Residuals for the fitted model, specified as a table that contains one row for each observation and the columns described in this table.

Column	Description
Raw	Observed minus fitted values
Pearson	Raw residuals divided by the root mean squared error (RMSE)
Standardized	Raw residuals divided by their estimated standard deviation
Studentized	Raw residual divided by an independent estimate of the residual standard deviation. The residual for observation i is divided by an estimate of the error standard deviation based on all observations except observation i .

Use `plotResiduals` to create a plot of the residuals. For details, see “Residuals” on page 11-104.

Rows not used in the fit because of missing values (in `ObservationInfo.Missing`) or excluded values (in `ObservationInfo.Excluded`) contain NaN values.

To obtain any of these columns as a vector, index into the property using dot notation. For example, obtain the raw residual vector `r` in the model `mdl`:

```
r = mdl.Residuals.Raw
```

Data Types: table

ResponseName — Response variable name

character vector

This property is read-only.

Response variable name, specified as a character vector.

Data Types: char

RMSE — Root mean squared error

numeric value

This property is read-only.

Root mean squared error, specified as a numeric value. The root mean squared error is an estimate of the standard deviation of the error term in the model.

Data Types: `single` | `double`

Robust — Robust fit information

structure

This property is read-only.

Robust fit information, specified as a structure with the following fields:

Field	Description
<code>WgtFun</code>	Robust weighting function, such as 'bisquare' (see <code>robustfit</code>)
<code>Tune</code>	Value specified for tuning parameter (can be <code>[]</code>)
<code>Weights</code>	Vector of weights used in final iteration of robust fit

This structure is empty unless `fitnlm` constructed the model using robust regression.

Data Types: `struct`

Rsquared — R-squared value for model

structure

This property is read-only.

R-squared value for the model, specified as a structure with two fields:

- **Ordinary** — Ordinary (unadjusted) R-squared
- **Adjusted** — R-squared adjusted for the number of coefficients

The R-squared value is the proportion of the total sum of squares explained by the model. The ordinary R-squared value relates to the `SSR` and `SST` properties:

$$\text{Rsquared} = \text{SSR}/\text{SST} = 1 - \text{SSE}/\text{SST},$$

where `SST` is the total sum of squares, `SSE` is the sum of squared errors, and `SSR` is the regression sum of squares.

For details, see “Coefficient of Determination (R-Squared)” on page 11-77.

To obtain either of these values as a scalar, index into the property using dot notation. For example, obtain the adjusted R-squared value in the model `mdl`:

```
r2 = mdl.Rsquared.Adjusted
```

Data Types: `struct`

SSE — Sum of squared errors

numeric value

This property is read-only.

Sum of squared errors (residuals), specified as a numeric value.

The Pythagorean theorem implies

$$SST = SSE + SSR,$$

where *SST* is the total sum of squares, *SSE* is the sum of squared errors, and *SSR* is the regression sum of squares.

Data Types: `single` | `double`

SSR — Regression sum of squares

numeric value

This property is read-only.

Regression sum of squares, specified as a numeric value. The regression sum of squares is equal to the sum of squared deviations of the fitted values from their mean.

The Pythagorean theorem implies

$$SST = SSE + SSR,$$

where *SST* is the total sum of squares, *SSE* is the sum of squared errors, and *SSR* is the regression sum of squares.

Data Types: `single` | `double`

SST — Total sum of squares

numeric value

This property is read-only.

Total sum of squares, specified as a numeric value. The total sum of squares is equal to the sum of squared deviations of the response vector y from the mean (\bar{y}).

The Pythagorean theorem implies

$$SST = SSE + SSR,$$

where SST is the total sum of squares, SSE is the sum of squared errors, and SSR is the regression sum of squares.

Data Types: `single` | `double`

VariableInfo — Information about variables

table

This property is read-only.

Information about variables contained in `Variables`, specified as a table with one row for each variable and the columns described in this table.

Column	Description
<code>Class</code>	Variable class, specified as a cell array of character vectors, such as <code>'double'</code> and <code>'categorical'</code>
<code>Range</code>	Variable range, specified as a cell array of vectors <ul style="list-style-type: none"> • Continuous variable — Two-element vector $[min, max]$, the minimum and maximum values • Categorical variable — Vector of distinct variable values
<code>InModel</code>	Indicator of which variables are in the fitted model, specified as a logical vector. The value is <code>true</code> if the model includes the variable.
<code>IsCategorical</code>	Indicator of categorical variables, specified as a logical vector. The value is <code>true</code> if the variable is categorical.

`VariableInfo` also includes any variables that are not used to fit the model as predictors or as the response.

Data Types: `table`

VariableNames — Names of variables

cell array of character vectors

This property is read-only.

Names of variables, specified as a cell array of character vectors.

- If the fit is based on a table or dataset, this property provides the names of the variables in the table or dataset.
- If the fit is based on a predictor matrix and response vector, `VariableNames` contains the values specified by the 'VarNames' name-value pair argument of the fitting method. The default value of 'VarNames' is {'x1', 'x2', ..., 'xn', 'y'}.

`VariableNames` also includes any variables that are not used to fit the model as predictors or as the response.

Data Types: `cell`

Variables – Input data

`table`

This property is read-only.

Input data, specified as a table. `Variables` contains both predictor and response values. If the fit is based on a table or dataset array, `Variables` contains all the data from the table or dataset array. Otherwise, `Variables` is a table created from the input data matrix X and response the vector y .

`Variables` also includes any variables that are not used to fit the model as predictors or as the response.

Data Types: `table`

Methods

<code>coefCI</code>	Confidence intervals of coefficient estimates of nonlinear regression model
<code>coefTest</code>	Linear hypothesis test on nonlinear regression model coefficients
<code>disp</code>	Display nonlinear regression model
<code>feval</code>	Evaluate nonlinear regression model prediction
<code>fit</code>	(Not Recommended) Fit nonlinear regression model
<code>plotDiagnostics</code>	Plot diagnostics of nonlinear regression model
<code>plotResiduals</code>	Plot residuals of nonlinear regression model
<code>plotSlice</code>	Plot of slices through fitted nonlinear regression surface
<code>predict</code>	Predict response of nonlinear regression model
<code>random</code>	Simulate responses for nonlinear regression model

Copy Semantics

Value. To learn how value classes affect copy operations, see [Copying Objects \(MATLAB\)](#).

Examples

Fit a Nonlinear Regression Model

Fit a nonlinear regression model for auto mileage based on the `carbig` data. Predict the mileage of an average car.

Load the sample data. Create a matrix `X` containing the measurements for the horsepower (`Horsepower`) and weight (`Weight`) of each car. Create a vector `y` containing the response values in miles per gallon (`MPG`).

```
load carbig
X = [Horsepower,Weight];
y = MPG;
```

Fit a nonlinear regression model.

```

modelfun = @(b,x)b(1) + b(2)*x(:,1).^b(3) + ...
            b(4)*x(:,2).^b(5);
beta0 = [-50 500 -1 500 -1];
mdl = fitnlm(X,y,modelfun,beta0)

```

```

mdl =
Nonlinear regression model:
    y ~ b1 + b2*x1^b3 + b4*x2^b5

```

Estimated Coefficients:				
	Estimate	SE	tStat	pValue
b1	-49.383	119.97	-0.41164	0.68083
b2	376.43	567.05	0.66384	0.50719
b3	-0.78193	0.47168	-1.6578	0.098177
b4	422.37	776.02	0.54428	0.58656
b5	-0.24127	0.48325	-0.49926	0.61788

```

Number of observations: 392, Error degrees of freedom: 387
Root Mean Squared Error: 3.96
R-Squared: 0.745, Adjusted R-Squared 0.743
F-statistic vs. constant model: 283, p-value = 1.79e-113

```

Find the predicted mileage of an average auto. Since the sample data contains some missing (NaN) observations, compute the mean using `nanmean`.

```
Xnew = nanmean(X)
```

```
Xnew = 1×2
103 ×
```

```
    0.1051    2.9794
```

```
MPGnew = predict(mdl,Xnew)
```

```
MPGnew = 21.8073
```

Definitions

Hat Matrix

The hat matrix H is defined in terms of the data matrix X and the Jacobian matrix J :

$$J_{i,j} = \left. \frac{\partial f}{\partial \beta_j} \right|_{x_i, \beta}$$

Here f is the nonlinear model function, and β is the vector of model coefficients.

The Hat Matrix H is

$$H = J(J^T J)^{-1} J^T.$$

The diagonal elements H_{ii} satisfy

$$0 \leq h_{ii} \leq 1$$

$$\sum_{i=1}^n h_{ii} = p,$$

where n is the number of observations (rows of X), and p is the number of coefficients in the regression model.

Leverage

Leverage is a measure of the effect of a particular observation on the regression predictions due to the position of that observation in the space of the inputs.

The leverage of observation i is the value of the i th diagonal term h_{ii} of the hat matrix H . The hat matrix H is defined in terms of the data matrix X :

$$H = X(X^T X)^{-1} X^T.$$

The hat matrix is also known as the *projection matrix* because it projects the vector of observations y onto the vector of predictions \hat{y} , thus putting the "hat" on y .

Because the sum of the leverage values is p (the number of coefficients in the regression model), an observation i can be considered an outlier if its leverage substantially exceeds p/n , where n is the number of observations.

For more details, see "Hat Matrix and Leverage" on page 11-99.

Cook's Distance

The Cook's distance D_i of observation i is

$$D_i = \frac{\sum_{j=1}^n (\hat{y}_j - \hat{y}_{j(i)})^2}{p \text{MSE}},$$

where

- \hat{y}_j is the j th fitted response value.
- $\hat{y}_{j(i)}$ is the j th fitted response value, where the fit does not include observation i .
- MSE is the mean squared error.
- p is the number of coefficients in the regression model.

Cook's distance is algebraically equivalent to the following expression:

$$D_i = \frac{r_i^2}{p \text{MSE}} \left(\frac{h_{ii}}{(1 - h_{ii})^2} \right),$$

where e_i is the i th residual.

"Nonlinear Regression" on page 13-2

normcdf

Normal cumulative distribution function

Syntax

```
p = normcdf(x)
p = normcdf(x,mu)
p = normcdf(x,mu,sigma)

[p,pLo,pUp] = normcdf(x,mu,sigma,pCov)
[p,pLo,pUp] = normcdf(x,mu,sigma,pCov,alpha)

___ = normcdf( ___, 'upper' )
```

Description

`p = normcdf(x)` returns the cumulative distribution function (cdf) of the standard normal distribution, evaluated at the values in `x`.

`p = normcdf(x,mu)` returns the cdf of the normal distribution with mean `mu` and unit standard deviation, evaluated at the values in `x`.

`p = normcdf(x,mu,sigma)` returns the cdf of the normal distribution with mean `mu` and standard deviation `sigma`, evaluated at the values in `x`.

`[p,pLo,pUp] = normcdf(x,mu,sigma,pCov)` also returns the 95% confidence bounds `[pLo,pUp]` of `p` when `mu` and `sigma` are estimates. `pCov` is the covariance matrix of the estimated parameters.

`[p,pLo,pUp] = normcdf(x,mu,sigma,pCov,alpha)` specifies the confidence level for the confidence interval `[pLo,pUp]` to be $100(1-\alpha)\%$.

`___ = normcdf(___, 'upper')` returns the complement of the cdf, evaluated at the values in `x`, using an algorithm that more accurately computes the extreme upper-tail probabilities. 'upper' can follow any of the input arguments in the previous syntaxes.

Examples

Standard Normal Distribution cdf

Compute the probability that an observation from a standard normal distribution falls on the interval $[-1 \ 1]$.

```
p = normcdf([-1 1]);
p(2)-p(1)

ans = 0.6827
```

About 68% of the observations from a normal distribution fall within one standard deviation of the mean 0.

Normal Distribution cdf

Compute the cdf values evaluated at the values in x for the normal distribution with mean μ and standard deviation σ .

```
x = [-2, -1, 0, 1, 2];
mu = 2;
sigma = 1;
p = normcdf(x, mu, sigma)

p = 1x5

    0.0000    0.0013    0.0228    0.1587    0.5000
```

Compute the cdf values evaluated at zero for various normal distributions with different mean parameters.

```
mu = [-2, -1, 0, 1, 2];
sigma = 1;
p = normcdf(0, mu, sigma)

p = 1x5

    0.9772    0.8413    0.5000    0.1587    0.0228
```

Confidence Interval of Normal cdf Value

Find the maximum likelihood estimates (MLEs) of the normal distribution parameters, and then find the confidence interval of the corresponding cdf value.

Generate 1000 normal random numbers from the normal distribution with mean 5 and standard deviation 2.

```
rng('default') % For reproducibility
n = 1000; % Number of samples
x = normrnd(5,2,n,1);
```

Find the MLEs for the distribution parameters (mean and standard deviation) by using `mle`.

```
phat = mle(x)

phat = 1×2

    4.9347    1.9969
```

```
muHat = phat(1);
sigmaHat = phat(2);
```

Estimate the covariance of the distribution parameters by using `normlike`. The function `normlike` returns an approximation to the asymptotic covariance matrix if you pass the MLEs and the samples used to estimate the MLEs.

```
[~,pCov] = normlike([muHat,sigmaHat],x)

pCov = 2×2

    0.0040    -0.0000
   -0.0000    0.0020
```

Find the cdf value at zero and its 95% confidence interval.

```
[p,pLo,pUp] = normcdf(0,muHat,sigmaHat,pCov)

p = 0.0067
```

```
pLo = 0.0047
```

```
pUp = 0.0095
```

`p` is the cdf value using the normal distribution with the parameters `muHat` and `sigmaHat`. The interval `[pLo, pUp]` is the 95% confidence interval of the cdf evaluated at 0, considering the uncertainty of `muHat` and `sigmaHat` using `pCov`. The 95% confidence interval means the probability that `[pLo, pUp]` contains the true cdf value is 0.95.

Complementary cdf (Tail Distribution)

Determine the probability that an observation from a standard normal distribution will fall on the interval `[10, Inf]`.

```
p1 = 1 - normcdf(10)
```

```
p1 = 0
```

`normcdf(10)` is nearly 1, so `p1` becomes 0. Specify `'upper'` so that `normcdf` computes the extreme upper-tail probabilities more accurately.

```
p2 = normcdf(10, 'upper')
```

```
p2 = 7.6199e-24
```

You can also use `'upper'` to compute a right-tailed *p*-value.

Test for Normal Distribution Using Function Handle

Use the probability distribution function `normcdf` as a function handle in the chi-square goodness-of-fit test (`chi2gof`).

Test the null hypothesis that the sample data in the input vector `x` comes from a normal distribution with parameters μ and σ equal to the mean (`mean`) and standard deviation (`std`) of the sample data, respectively.

```
rng('default') % For reproducibility
x = normrnd(50,5,100,1);
h = chi2gof(x, 'cdf', {@normcdf, mean(x), std(x)})
```

```
h = 0
```

The returned result $h = 0$ indicates that `chi2gof` does not reject the null hypothesis at the default 5% significance level.

Input Arguments

x — Values at which to evaluate cdf

scalar value | array of scalar values

Values at which to evaluate the cdf, specified as a scalar value or an array of scalar values.

If you specify `pCov` to compute the confidence interval $[pLo, pUp]$, then `x` must be a scalar value.

To evaluate the cdf at multiple values, specify `x` using an array. To evaluate the cdfs of multiple distributions, specify `mu` and `sigma` using arrays. If one or more of the input arguments `x`, `mu`, and `sigma` are arrays, then the array sizes must be the same. In this case, `normcdf` expands each scalar input into a constant array of the same size as the array inputs. Each element in `p` is the cdf value of the distribution specified by the corresponding elements in `mu` and `sigma`, evaluated at the corresponding element in `x`.

Example: `[-1,0,3,4]`

Data Types: `single` | `double`

mu — Mean

0 (default) | scalar value | array of scalar values

Mean of the normal distribution, specified as a scalar value or an array of scalar values.

If you specify `pCov` to compute the confidence interval $[pLo, pUp]$, then `mu` must be a scalar value.

To evaluate the cdf at multiple values, specify `x` using an array. To evaluate the cdfs of multiple distributions, specify `mu` and `sigma` using arrays. If one or more of the input arguments `x`, `mu`, and `sigma` are arrays, then the array sizes must be the same. In this case, `normcdf` expands each scalar input into a constant array of the same size as the array inputs. Each element in `p` is the cdf value of the distribution specified by the corresponding elements in `mu` and `sigma`, evaluated at the corresponding element in `x`.

Example: `[0 1 2; 0 1 2]`

Data Types: `single` | `double`

sigma — Standard deviation

1 (default) | nonnegative scalar value | array of nonnegative scalar values

Standard deviation of the normal distribution, specified as a nonnegative scalar value or an array of nonnegative scalar values.

If `sigma` is zero, then the output `p` is either 0 or 1. `p` is 0 if `x` is smaller than `mu`, or 1 otherwise.

If you specify `pCov` to compute the confidence interval [`pLo`, `pUp`], then `sigma` must be a scalar value.

To evaluate the cdf at multiple values, specify `x` using an array. To evaluate the cdfs of multiple distributions, specify `mu` and `sigma` using arrays. If one or more of the input arguments `x`, `mu`, and `sigma` are arrays, then the array sizes must be the same. In this case, `normcdf` expands each scalar input into a constant array of the same size as the array inputs. Each element in `p` is the cdf value of the distribution specified by the corresponding elements in `mu` and `sigma`, evaluated at the corresponding element in `x`.

Example: `[1 1 1; 2 2 2]`

Data Types: `single` | `double`

pCov — Covariance of estimates

2-by-2 numeric matrix

Covariance of the estimates `mu` and `sigma`, specified as a 2-by-2 matrix.

If you specify `pCov` to compute the confidence interval [`pLo`, `pUp`], then `x`, `mu`, and `sigma` must be scalar values.

You can estimate `mu` and `sigma` by using `mle`, and estimate the covariance of `mu` and `sigma` by using `normlike`. For an example, see “Confidence Interval of Normal cdf Value” on page 32-4622.

Data Types: `single` | `double`

alpha — Significance level

0.05 (default) | scalar in the range (0,1)

Significance level for the confidence interval, specified as a scalar in the range (0,1). The confidence level is $100(1-\alpha)\%$, where α is the probability that the confidence interval does not contain the true value.

Example: 0.01

Data Types: `single` | `double`

Output Arguments

p — cdf values

scalar value | array of scalar values

cdf values, evaluated at the values in `x`, returned as a scalar value or an array of scalar values. `p` is the same size as `x`, `mu`, and `sigma` after any necessary scalar expansion. Each element in `p` is the cdf value of the distribution specified by the corresponding elements in `mu` and `sigma`, evaluated at the corresponding element in `x`.

pLo — Lower confidence bound for p

scalar value | array of scalar values

Lower confidence bound for `p`, returned as a scalar value or an array of scalar values. `pLo` has the same size as `p`.

pUp — Upper confidence bound for p

scalar value | array of scalar values

Upper confidence bound for `p`, returned as a scalar value or an array of scalar values. `pUp` has the same size as `p`.

Definitions

Normal Distribution

The normal distribution is a two-parameter family of curves. The first parameter, μ , is the mean. The second parameter, σ , is the standard deviation.

The standard normal distribution has zero mean and unit standard deviation.

The normal cumulative distribution function (cdf) is

$$p = F(x) \Big|_{\mu, \sigma} = \frac{1}{\sigma\sqrt{2\pi}} \int_{-\infty}^x e^{-\frac{(t-\mu)^2}{2\sigma^2}} dt, \quad \text{for } x \in \mathbb{R}.$$

p is the probability that a single observation from a normal distribution with parameters μ and σ falls in the interval $(-\infty, x]$.

Algorithms

- The `normcdf` function uses the complementary error function `erfc`. The relationship between `normcdf` and `erfc` is

$$\text{normcdf}(x) = \frac{1}{2} \text{erfc}\left(-\frac{x}{\sqrt{2}}\right).$$

The complementary error function `erfc(x)` is defined as

$$\text{erfc}(x) = 1 - \text{erf}(x) = \frac{2}{\sqrt{\pi}} \int_x^{\infty} e^{-t^2} dt.$$

- The `normcdf` function computes confidence bounds for p by using the delta method. `normcdf(x, mu, sigma)` is equivalent to `normcdf((x-mu)/sigma, 0, 1)`. Therefore, the `normcdf` function estimates the variance of $(x-\mu)/\sigma$ using the covariance matrix of μ and σ by the delta method, and finds the confidence bounds of $(x-\mu)/\sigma$ using the estimates of this variance. Then, the function transforms the bounds to the scale of p . The computed bounds give approximately the desired confidence level when you estimate μ , σ , and $pCov$ from large samples.

Alternative Functionality

- `normcdf` is a function specific to normal distribution. Statistics and Machine Learning Toolbox also offers the generic function `cdf`, which supports various probability distributions. To use `cdf`, create a `NormalDistribution` probability distribution object and pass the object as an input argument or specify the probability distribution name and its parameters. Note that the distribution-specific function `normcdf` is faster than the generic function `cdf`.
- Use the **Probability Distribution Function** app to create an interactive plot of the cumulative distribution function (cdf) or probability density function (pdf) for a probability distribution.

Introduced before R2006a

normfit

Normal parameter estimates

Syntax

```
[muHat,sigmaHat] = normfit(x)
```

```
[muHat,sigmaHat,muCI,sigmaCI] = normfit(x)
```

```
[muHat,sigmaHat,muCI,sigmaCI] = normfit(x,alpha)
```

```
[ ___ ] = normfit(x,alpha,censoring)
```

```
[ ___ ] = normfit(x,alpha,censoring,freq)
```

```
[ ___ ] = normfit(x,alpha,censoring,freq,options)
```

Description

[muHat,sigmaHat] = normfit(x) returns estimates of normal distribution parameters (the mean muHat and standard deviation sigmaHat), given the sample data in x. muHat is the sample mean, and sigmaHat is the square root of the unbiased estimator of the variance.

[muHat,sigmaHat,muCI,sigmaCI] = normfit(x) also returns 95% confidence intervals for the parameter estimates on the mean and standard deviation in the arrays muCI and sigmaCI, respectively.

[muHat,sigmaHat,muCI,sigmaCI] = normfit(x,alpha) specifies the confidence level for the confidence intervals to be 100(1-alpha)%.

[___] = normfit(x,alpha,censoring) specifies whether each value in x is right-censored or not. Use the logical vector censoring in which 1 indicates observations that are right-censored and 0 indicates observations that are fully observed. With censoring, muHat and sigmaHat are the maximum likelihood estimates (MLEs).

[___] = normfit(x,alpha,censoring,freq) specifies the frequency or weights of observations.

[___] = normfit(x,alpha,censoring,freq,options) specifies optimization options for the iterative algorithm normfit to use to compute MLEs with censoring. Create options by using the function statset.

You can pass in [] for alpha, censoring, and freq to use their default values.

Examples

Estimate Parameters and Confidence Intervals

Generate 1000 normal random numbers from the normal distribution with mean 3 and standard deviation 5.

```
rng('default') % For reproducibility
x = normrnd(3,5,[1000,1]);
```

Find the parameter estimates and the 99% confidence intervals.

```
[muHat,sigmaHat,muCI,sigmaCI] = normfit(x,0.01)
```

```
muHat = 2.8368
```

```
sigmaHat = 4.9948
```

```
muCI = 2×1
```

```
    2.4292
    3.2445
```

```
sigmaCI = 2×1
```

```
    4.7218
    5.2989
```

muHat is the sample mean, and sigmaHat is the square root of the unbiased estimator of the variance. muCI and sigmaCI contain the 99% confidence intervals of the mean and standard deviation parameters, respectively. The first row is the lower bound, and the second row is the upper bound.

Change Algorithm Options

Find the MLEs of a data set with censoring by using `normfit`. Use `statset` to specify the iterative algorithm options that `normfit` uses to compute MLEs for censored data, and then find the MLEs again.

Load the sample data.

```
load lightbulb
```

The first column of the data contains the lifetime (in hours) of two types of bulbs. The second column contains the binary variable indicating whether the bulb is fluorescent or incandescent. 1 indicates that the bulb is fluorescent, and 0 indicates that the bulb is incandescent. The third column contains the censorship information, where 0 indicates the bulb is observed until failure, and 1 indicates the item (bulb) is censored.

Find the indices for fluorescent bulbs.

```
idx = find(lightbulb(:,2) == 0);
```

Assume that the lifetime follows the normal distribution, and find the MLEs of the normal distribution parameters. The second input argument of `normfit` specifies the confidence level. Pass in `[]` to use its default value 0.05. The third input argument specifies the censorship information.

```
ensoring = lightbulb(idx,3) == 1;  
[muHat1,sigmaHat1] = normfit(lightbulb(idx,1),[],ensoring)
```

```
muHat1 = 9.4966e+03
```

```
sigmaHat1 = 3.0640e+03
```

Display the default algorithm parameters that `normfit` uses to estimate the normal distribution parameters.

```
statset('normfit')
```

```
ans = struct with fields:  
    Display: 'off'  
    MaxFunEvals: 200  
    MaxIter: 100  
    TolBnd: 1.0000e-06
```

```
TolFun: 1.0000e-08
TolTypeFun: []
    TolX: 1.0000e-08
    TolTypeX: []
    GradObj: []
    Jacobian: []
    DerivStep: []
    FunValCheck: []
    Robust: []
    RobustWgtFun: []
    WgtFun: []
    Tune: []
    UseParallel: []
    UseSubstreams: []
    Streams: {}
    OutputFcn: []
```

Save the options using a different name. Change how the results are displayed (`Display`) and the termination tolerance for the objective function (`TolFun`).

```
options = statset('normfit');
options.Display = 'final';
options.TolFun = 1e-10;
```

Alternatively, you can specify algorithm parameters by using the name-value pair arguments of the function `statset`.

```
options = statset('Display','final','TolFun',1e-10);
```

Find the MLEs with the new algorithm parameters.

```
[muHat2,sigmaHat2] = normfit(lightbulb(idx,1),[],censoring,[],options)
```

```
Successful convergence: Norm of gradient less than OPTIONS.TolFun
```

```
muHat2 = 9.4966e+03
```

```
sigmaHat2 = 3.0640e+03
```

`normfit` displays a report on the final iteration.

Convert Unbiased Estimator to MLE

The function `normfit` finds the sample mean and the square root of the unbiased estimator of the variance with no censoring. The sample mean is equal to the MLE of the mean parameter, but the square root of the unbiased estimator of the variance is not equal to the MLE of the standard deviation parameter.

Find the normal distribution parameters by using `normfit`, convert them into MLEs, and then compare the negative log likelihoods of the estimates by using `normlike`.

Generate 100 normal random numbers from the standard normal distribution.

```
rng('default') % For reproducibility
n = 100;
x = normrnd(0,1,[n,1]);
```

Find the sample mean and the square root of the unbiased estimator of the variance.

```
[muHat,sigmaHat] = normfit(x)

muHat = 0.1231
sigmaHat = 1.1624
```

Convert the square root of the unbiased estimator of the variance into the MLE of the standard deviation parameter.

```
sigmaHat_MLE = sqrt((n-1)/n)*sigmaHat
sigmaHat_MLE = 1.1566
```

The difference between `sigmaHat` and `sigmaHat_MLE` is negligible for large n .

Alternatively, you can find the MLEs by using the function `mle`.

```
phat = mle(x)

phat = 1×2

    0.1231    1.1566
```

`phat(1)` and `phat(2)` are the MLEs of the mean and the standard deviation parameter, respectively.

Confirm that the log likelihood of the MLEs (`muHat` and `sigmaHat_MLE`) is greater than the log likelihood of the unbiased estimators (`muHat` and `sigmaHat`) by using the `normlike` function.

```
logL = -normlike([muHat,sigmaHat],x)
logL = -156.4424
logL_MLE = -normlike([muHat,sigmaHat_MLE],x)
logL_MLE = -156.4399
```

Input Arguments

x — Sample data

vector

Sample data, specified as a vector.

Data Types: `single` | `double`

alpha — Significance level

0.05 (default) | scalar in the range (0,1)

Significance level for the confidence intervals, specified as a scalar in the range (0,1). The confidence level is $100(1-\alpha)\%$, where `alpha` is the probability that the confidence intervals do not contain the true value.

Example: `0.01`

Data Types: `single` | `double`

censoring — Indicator for censoring

array of 0s (default) | logical vector

Indicator for the censoring of each value in `x`, specified as a logical vector of the same size as `x`. Use 1 for observations that are right-censored and 0 for observations that are fully observed.

The default is an array of 0s, meaning that all observations are fully observed.

Data Types: `logical`

freq — Frequency or weights of observations

array of 1s (default) | nonnegative vector

Frequency or weights of observations, specified as a nonnegative vector that is the same size as `x`. The `freq` input argument typically contains nonnegative integer counts for the corresponding elements in `x`, but can contain any nonnegative values.

To obtain the weighted MLEs for a data set with censoring, specify weights of observations, normalized to the number of observations in `x`.

The default is an array of 1s, meaning one observation per element of `x`.

Data Types: `single` | `double`

options — Optimization options`statset('normfit')` (default) | structure

Optimization options, specified as a structure. `options` determines the control parameters for the iterative algorithm that `normfit` uses to compute MLEs for censored data.

Create `options` by using the function `statset` or by creating a structure array containing the fields and values described in this table.

Field Name	Value	Default Value
<code>Display</code>	Amount of information displayed by the algorithm. <ul style="list-style-type: none"> <code>'off'</code> — Displays no information. <code>'final'</code> — Displays the final output. 	<code>'off'</code>
<code>MaxFunEvals</code>	Maximum number of objective function evaluations allowed, specified as a positive integer.	200
<code>MaxIter</code>	Maximum number of iterations allowed, specified as a positive integer.	100

Field Name	Value	Default Value
TolBnd	Lower bound of the standard deviation parameter estimate, specified as a positive scalar. The bounds for the mean and standard deviation parameter estimates are $[-Inf, Inf]$ and $[TolBnd, Inf]$, respectively.	1e-6
TolFun	Termination tolerance for the objective function value, specified as a positive scalar.	1e-8
TolX	Termination tolerance for the parameters, specified as a positive scalar.	1e-8

You can also enter `statset('normfit')` in the Command Window to see the names and default values of the fields that `normfit` accepts in the `options` structure.

Example: `statset('Display','final','MaxIter',1000)` specifies to display the final information of the iterative algorithm results, and change the maximum number of iterations allowed to 1000.

Data Types: `struct`

Output Arguments

muHat — Estimate of mean

scalar

Estimate of the mean parameter of the normal distribution, returned as a scalar.

- With no censoring, `muHat` is the sample mean.
- With censoring, `muHat` is the MLE. To compute the weighted MLE, specify the weights of observations by using `freq`.

sigmaHat — Estimate of standard deviation

scalar

Estimate of the standard deviation parameter of the normal distribution, returned as a scalar.

- With no censoring, `sigmaHat` is the square root of the unbiased estimator of the variance. To compute the MLE with no censoring, use the `mle` function.
- With censoring, `sigmaHat` is the MLE. To compute the weighted MLE, specify the weights of observations by using `freq`.

muCI — Confidence interval for mean

2-by-1 column vector

Confidence interval for the mean parameter of the normal distribution, returned as a 2-by-1 column vector containing the lower and upper bounds of the $100(1-\alpha)\%$ confidence interval.

The first and second rows correspond to the lower and upper bounds of the confidence intervals, respectively.

sigmaCI — Confidence interval for standard deviation

2-by-1 column vector

Confidence interval for the standard deviation parameter of the normal distribution, returned as a 2-by-1 column vector containing the lower and upper bounds of the $100(1-\alpha)\%$ confidence interval.

The first and second rows correspond to the lower and upper bounds of the confidence intervals, respectively.

Algorithms

To compute the confidence intervals, `normfit` uses the exact method for uncensored data and the Wald method for censored data. The exact method provides exact coverage for uncensored samples based on t and chi-square distributions.

Alternative Functionality

`normfit` is a function specific to normal distribution. Statistics and Machine Learning Toolbox also offers the generic functions `mle`, `fitdist`, and `paramci` and the **Distribution Fitter** app, which support various probability distributions.

- `mle` returns MLEs and the confidence intervals of MLEs for the parameters of various probability distributions. You can specify the probability distribution name or a custom probability density function.
- Create a `NormalDistribution` probability distribution object by fitting the distribution to data using the `fitdist` function or the **Distribution Fitter** app. The object properties `mu` and `sigma` store the parameter estimates. To obtain the confidence intervals for the parameter estimates, pass the object to `paramci`.

Topics

“Normal Distribution” on page B-136

Introduced before R2006a

norminv

Normal inverse cumulative distribution function

Syntax

```
x = norminv(p)
x = norminv(p,mu)
x = norminv(p,mu,sigma)
```

```
[x,xLo,xUp] = norminv(p,mu,sigma,pCov)
[x,xLo,xUp] = norminv(p,mu,sigma,pCov,alpha)
```

Description

`x = norminv(p)` returns the inverse of the standard normal cumulative distribution function (cdf), evaluated at the probability values in `p`.

`x = norminv(p,mu)` returns the inverse of the normal cdf with mean `mu` and the unit standard deviation, evaluated at the probability values in `p`.

`x = norminv(p,mu,sigma)` returns the inverse of the normal cdf with mean `mu` and standard deviation `sigma`, evaluated at the probability values in `p`.

`[x,xLo,xUp] = norminv(p,mu,sigma,pCov)` also returns the 95% confidence bounds `[xLo,xUp]` of `x` when `mu` and `sigma` are estimates. `pCov` is the covariance matrix of the estimated parameters.

`[x,xLo,xUp] = norminv(p,mu,sigma,pCov,alpha)` specifies the confidence level for the confidence interval `[xLo,xUp]` to be $100(1-\alpha)\%$.

Examples

Inverse of Standard Normal cdf

Find an interval that contains 95% of the values from a standard normal distribution.

```
x = norminv([0.025 0.975])
```

```
x = 1×2
```

```
-1.9600    1.9600
```

Note that the interval `x` is not the only such interval, but it is the shortest. Find another interval.

```
x1 = norminv([0.01 0.96])
```

```
x1 = 1×2
```

```
-2.3263    1.7507
```

The interval `x1` also contains 95% of the probability, but it is longer than `x`.

Inverse of Normal Distribution cdf

Compute the inverse of cdf values evaluated at the probability values in `p` for the normal distribution with mean `mu` and standard deviation `sigma`.

```
p = 0:0.25:1;
```

```
mu = 2;
```

```
sigma = 1;
```

```
x = norminv(p,mu,sigma)
```

```
x = 1×5
```

```
-Inf    1.3255    2.0000    2.6745    Inf
```

Compute the inverse of cdf values evaluated at 0.5 for various normal distributions with different mean parameters.

```
mu = [-2,-1,0,1,2];
sigma = 1;
x = norminv(0.5,mu,sigma)

x = 1×5
    -2    -1     0     1     2
```

Confidence Interval of Inverse Normal cdf Value

Find the maximum likelihood estimates (MLEs) of the normal distribution parameters, and then find the confidence interval of the corresponding inverse cdf value.

Generate 1000 normal random numbers from the normal distribution with mean 5 and standard deviation 2.

```
rng('default') % For reproducibility
n = 1000; % Number of samples
x = normrnd(5,2,[n,1]);
```

Find the MLEs for the distribution parameters (mean and standard deviation) by using `mle`.

```
phat = mle(x)

phat = 1×2
    4.9347    1.9969
```

```
muHat = phat(1);
sigmaHat = phat(2);
```

Estimate the covariance of the distribution parameters by using `normlike`. The function `normlike` returns an approximation to the asymptotic covariance matrix if you pass the MLEs and the samples used to estimate the MLEs.

```
[~,pCov] = normlike([muHat,sigmaHat],x)

pCov = 2×2
```

```

0.0040    -0.0000
-0.0000    0.0020

```

Find the inverse cdf value at 0.5 and its 99% confidence interval.

```
[x,xLo,xUp] = norminv(0.5,muHat,sigmaHat,pCov,0.01)
```

```
x = 4.9347
```

```
xLo = 4.7721
```

```
xUp = 5.0974
```

`x` is the inverse cdf value using the normal distribution with the parameters `muHat` and `sigmaHat`. The interval `[xLo,xUp]` is the 99% confidence interval of the inverse cdf value evaluated at 0.5, considering the uncertainty of `muHat` and `sigmaHat` using `pCov`. The 99% confidence interval means the probability that `[xLo,xUp]` contains the true inverse cdf value is 0.99.

Input Arguments

p — Probability values at which to evaluate inverse of cdf

scalar value in `[0,1]` | array of scalar values

Probability values at which to evaluate the inverse of the cdf (icdf), specified as a scalar value or an array of scalar values, where each element is in the range `[0,1]`.

If you specify `pCov` to compute the confidence interval `[xLo,xUp]`, then `p` must be a scalar value.

To evaluate the icdf at multiple values, specify `p` using an array. To evaluate the icdfs of multiple distributions, specify `mu` and `sigma` using arrays. If one or more of the input arguments `p`, `mu`, and `sigma` are arrays, then the array sizes must be the same. In this case, `norminv` expands each scalar input into a constant array of the same size as the array inputs. Each element in `x` is the icdf value of the distribution specified by the corresponding elements in `mu` and `sigma`, evaluated at the corresponding element in `p`.

Example: `[0.1,0.5,0.9]`

Data Types: `single` | `double`

mu — Mean

0 (default) | scalar value | array of scalar values

Mean of the normal distribution, specified as a scalar value or an array of scalar values.

If you specify `pCov` to compute the confidence interval `[xLo, xUp]`, then `mu` must be a scalar value.

To evaluate the `icdf` at multiple values, specify `p` using an array. To evaluate the `icdfs` of multiple distributions, specify `mu` and `sigma` using arrays. If one or more of the input arguments `p`, `mu`, and `sigma` are arrays, then the array sizes must be the same. In this case, `norminv` expands each scalar input into a constant array of the same size as the array inputs. Each element in `x` is the `icdf` value of the distribution specified by the corresponding elements in `mu` and `sigma`, evaluated at the corresponding element in `p`.

Example: `[0 1 2; 0 1 2]`

Data Types: `single` | `double`

sigma — Standard deviation

1 (default) | positive scalar value | array of positive scalar values

Standard deviation of the normal distribution, specified as a positive scalar value or an array of positive scalar values.

If you specify `pCov` to compute the confidence interval `[xLo, xUp]`, then `sigma` must be a scalar value.

To evaluate the `icdf` at multiple values, specify `p` using an array. To evaluate the `icdfs` of multiple distributions, specify `mu` and `sigma` using arrays. If one or more of the input arguments `p`, `mu`, and `sigma` are arrays, then the array sizes must be the same. In this case, `norminv` expands each scalar input into a constant array of the same size as the array inputs. Each element in `x` is the `icdf` value of the distribution specified by the corresponding elements in `mu` and `sigma`, evaluated at the corresponding element in `p`.

Example: `[1 1 1; 2 2 2]`

Data Types: `single` | `double`

pCov — Covariance of estimates

2-by-2 numeric matrix

Covariance of the estimates `mu` and `sigma`, specified as a 2-by-2 matrix.

If you specify `pCov` to compute the confidence interval `[xLo, xUp]`, then `p`, `mu`, and `sigma` must be scalar values.

You can estimate `mu` and `sigma` by using `mle`, and estimate the covariance of `mu` and `sigma` by using `normlike`. For an example, see “Confidence Interval of Inverse Normal cdf Value” on page 32-4642.

Data Types: `single` | `double`

alpha — Significance level

0.05 (default) | scalar in the range (0,1)

Significance level for the confidence interval, specified as a scalar in the range (0,1). The confidence level is $100(1-\text{alpha})\%$, where `alpha` is the probability that the confidence interval does not contain the true value.

Example: `0.01`

Data Types: `single` | `double`

Output Arguments

x — icdf values

scalar value | array of scalar values

icdf values, evaluated at the probability values in `p`, returned as a scalar value or an array of scalar values. `x` is the same size as `p`, `mu`, and `sigma` after any necessary scalar expansion. Each element in `x` is the icdf value of the distribution specified by the corresponding elements in `mu` and `sigma`, evaluated at the corresponding element in `p`.

xLo — Lower confidence bound for x

scalar value | array of scalar values

Lower confidence bound for `x`, returned as a scalar value or an array of scalar values. `xLo` has the same size as `x`.

xUp — Upper confidence bound for x

scalar value | array of scalar values

Upper confidence bound for `x`, returned as a scalar value or an array of scalar values. `xUp` has the same size as `x`.

Definitions

Normal Distribution

The normal distribution is a two-parameter family of curves. The first parameter, μ , is the mean. The second parameter, σ , is the standard deviation.

The standard normal distribution has zero mean and unit standard deviation.

The normal inverse function is defined in terms of the normal cdf as

$$x = F^{-1}(p | \mu, \sigma) = \{x: F(x | \mu, \sigma) = p\},$$

where

$$p = F(x | \mu, \sigma) = \frac{1}{\sigma\sqrt{2\pi}} \int_{-\infty}^x e^{-\frac{(t-\mu)^2}{2\sigma^2}} dt.$$

The result x is the solution of the integral equation where you supply the desired probability p .

Algorithms

- The `norminv` function uses the inverse complementary error function `erfcinv`. The relationship between `norminv` and `erfcinv` is

$$\text{norminv}(p) = -\sqrt{2} \text{erfcinv}(2p)$$

The inverse complementary error function `erfcinv(x)` is defined as `erfcinv(erfc(x))=x`, and the complementary error function `erfc(x)` is defined as

$$\text{erfc}(x) = 1 - \text{erf}(x) = \frac{2}{\sqrt{\pi}} \int_x^{\infty} e^{-t^2} dt.$$

- The `norminv` function computes confidence bounds for x by using the delta method. `norminv(p, mu, sigma)` is equivalent to `mu + sigma*norminv(p, 0, 1)`. Therefore, the `norminv` function estimates the variance of `mu + sigma*norminv(p, 0, 1)` using the covariance matrix of `mu` and `sigma` by the delta method, and finds the confidence bounds using the estimates of this variance. The computed bounds give

approximately the desired confidence level when you estimate μ , σ , and $pCov$ from large samples.

Alternative Functionality

- `norminv` is a function specific to normal distribution. Statistics and Machine Learning Toolbox also offers the generic function `icdf`, which supports various probability distributions. To use `icdf`, create a `NormalDistribution` probability distribution object and pass the object as an input argument or specify the probability distribution name and its parameters. Note that the distribution-specific function `norminv` is faster than the generic function `icdf`.

NormalDistribution | erfcinv | icdf | normcdf | normfit | normlike | normspec

Topics

“Normal Distribution” on page B-136

Introduced before R2006a

normlike

Normal negative loglikelihood

Syntax

```
nlogL = normlike(params,x)
nlogL = normlike(params,x,censoring)
nlogL = normlike(params,x,censoring,freq)
```

```
[nlogL,aVar] = normlike( ___ )
```

Description

`nlogL = normlike(params,x)` returns the normal negative loglikelihood of the distribution parameters (`params`) given the sample data (`x`). `params(1)` and `params(2)` correspond to the mean and standard deviation of the normal distribution, respectively.

`nlogL = normlike(params,x,censoring)` specifies whether each value in `x` is right-censored or not. Use the logical vector `censoring` in which 1 indicates observations that are right-censored and 0 indicates observations that are fully observed.

`nlogL = normlike(params,x,censoring,freq)` specifies the frequency or weights of observations. To specify `freq` without specifying `censoring`, you can pass `[]` for `censoring`.

`[nlogL,aVar] = normlike(___)` also returns the inverse of the Fisher information matrix `aVar`, using any of the input argument combinations in the previous syntaxes. If values in `params` are the maximum likelihood estimates (MLEs) of the parameters, `aVar` is an approximation to the asymptotic covariance matrix.

Examples

Negative Loglikelihood of MLEs

Find the MLEs of a data set with censoring by using `normfit`, and then find the negative loglikelihood of the MLEs by using `normlike`.

Load the sample data.

```
load lightbulb
```

The first column of the data contains the lifetime (in hours) of two types of bulbs. The second column contains the binary variable indicating whether the bulb is fluorescent or incandescent. 1 indicates that the bulb is fluorescent, and 0 indicates that the bulb is incandescent. The third column contains the censorship information, where 0 indicates the bulb is observed until failure, and 1 indicates the item (bulb) is censored.

Find the indices for fluorescent bulbs.

```
idx = find(lightbulb(:,2) == 0);
```

Find the MLEs of the normal distribution parameters. The second input argument of `normfit` specifies the confidence level. Pass in `[]` to use its default value 0.05. The third input argument specifies the censorship information.

```
ensoring = lightbulb(idx,3) == 1;  
[muHat,sigmaHat] = normfit(lightbulb(idx,1),[],ensoring)
```

```
muHat = 9.4966e+03
```

```
sigmaHat = 3.0640e+03
```

Find the negative loglikelihood of the MLEs.

```
nlogL = normlike([muHat,sigmaHat],lightbulb(idx,1),ensoring)
```

```
nlogL = 376.2305
```

Convert Unbiased Estimator to MLE

The function `normfit` finds the sample mean and the square root of the unbiased estimator of the variance with no censoring. The sample mean is equal to the MLE of the mean parameter, but the square root of the unbiased estimator of the variance is not equal to the MLE of the standard deviation parameter.

Find the normal distribution parameters by using `normfit`, convert them into MLEs, and then compare the negative log likelihoods of the estimates by using `normlike`.

Generate 100 normal random numbers from the standard normal distribution.

```
rng('default') % For reproducibility
n = 100;
x = normrnd(0,1,[n,1]);
```

Find the sample mean and the square root of the unbiased estimator of the variance.

```
[muHat,sigmaHat] = normfit(x)
muHat = 0.1231
sigmaHat = 1.1624
```

Convert the square root of the unbiased estimator of the variance into the MLE of the standard deviation parameter.

```
sigmaHat_MLE = sqrt((n-1)/n)*sigmaHat
sigmaHat_MLE = 1.1566
```

The difference between `sigmaHat` and `sigmaHat_MLE` is negligible for large n .

Alternatively, you can find the MLEs by using the function `mle`.

```
phat = mle(x)
phat = 1×2
    0.1231    1.1566
```

`phat(1)` and `phat(2)` are the MLEs of the mean and the standard deviation parameter, respectively.

Confirm that the log likelihood of the MLEs (`muHat` and `sigmaHat_MLE`) is greater than the log likelihood of the unbiased estimators (`muHat` and `sigmaHat`) by using the `normlike` function.

```
logL = -normlike([muHat,sigmaHat],x)
logL = -156.4424
```

```
logL_MLE = -normlike([muHat,sigmaHat_MLE],x)
logL_MLE = -156.4399
```

Confidence Interval of Inverse Normal cdf Value

Find the maximum likelihood estimates (MLEs) of the normal distribution parameters, and then find the confidence interval of the corresponding inverse cdf value.

Generate 1000 normal random numbers from the normal distribution with mean 5 and standard deviation 2.

```
rng('default') % For reproducibility
n = 1000; % Number of samples
x = normrnd(5,2,[n,1]);
```

Find the MLEs for the distribution parameters (mean and standard deviation) by using `mle`.

```
phat = mle(x)

phat = 1×2

    4.9347    1.9969
```

```
muHat = phat(1);
sigmaHat = phat(2);
```

Estimate the covariance of the distribution parameters by using `normlike`. The function `normlike` returns an approximation to the asymptotic covariance matrix if you pass the MLEs and the samples used to estimate the MLEs.

```
[~,pCov] = normlike([muHat,sigmaHat],x)

pCov = 2×2

    0.0040    -0.0000
   -0.0000    0.0020
```

Find the inverse cdf value at 0.5 and its 99% confidence interval.

```
[x,xLo,xUp] = norminv(0.5,muHat,sigmaHat,pCov,0.01)
```

```
x = 4.9347
```

```
xLo = 4.7721
```

```
xUp = 5.0974
```

x is the inverse cdf value using the normal distribution with the parameters μHat and σHat . The interval $[xLo, xUp]$ is the 99% confidence interval of the inverse cdf value evaluated at 0.5, considering the uncertainty of μHat and σHat using $p\text{Cov}$. The 99% confidence interval means the probability that $[xLo, xUp]$ contains the true inverse cdf value is 0.99.

Input Arguments

params — Normal distribution parameters

vector of two numeric values

Normal distribution parameters consisting of the mean and standard deviation, specified as a vector of two numeric values. `params(1)` and `params(2)` correspond to the mean and standard deviation of the normal distribution, respectively. `params(2)` must be positive.

Example: `[0,1]`

Data Types: `single` | `double`

x — Sample data

vector

Sample data, specified as a vector.

Data Types: `single` | `double`

censoring — Indicator for censoring

array of 0s (default) | logical vector

Indicator for the censoring of each value in x , specified as a logical vector of the same size as x . Use 1 for observations that are right-censored and 0 for observations that are fully observed.

The default is an array of 0s, meaning that all observations are fully observed.

Data Types: `logical`

freq — Frequency or weights of observations

array of 1s (default) | nonnegative vector

Frequency or weights of observations, specified as a nonnegative vector that is the same size as `x`. The `freq` input argument typically contains nonnegative integer counts for the corresponding elements in `x`, but can contain any nonnegative values.

To obtain the weighted negative loglikelihood for a data set with censoring, specify weights of observations, normalized to the number of observations in `x`.

The default is an array of 1s, meaning one observation per element of `x`.

Data Types: `single` | `double`

Output Arguments

nlogL — Negative loglikelihood

numeric scalar

Negative loglikelihood value of the distribution parameters (`params`) given the sample data (`x`), returned as a numeric scalar.

aVar — Inverse of Fisher information matrix

numeric matrix

Inverse of the Fisher information matrix, returned as a 2-by-2 numeric matrix. `aVar` is based on the observed Fisher information given the observed data (`x`), not the expected information.

If values in `params` are the MLEs of the parameters, `aVar` is an approximation to the asymptotic variance-covariance matrix (also known as the asymptotic covariance matrix). To find the MLEs, use `mle`.

Alternative Functionality

normlike is a function specific to normal distribution. Statistics and Machine Learning Toolbox also offers the generic functions `mlecov`, `fitdist`, `negloglik`, and `proflk` and the **Distribution Fitter** app, which support various probability distributions.

- `mlecov` returns the asymptotic covariance matrix of the MLEs of the parameters for a distribution specified by a custom probability density function. For example, `mlecov(params,x,'pdf',@normpdf)` returns the asymptotic covariance matrix of the MLEs for the normal distribution.
- Create a `NormalDistribution` probability distribution object by fitting the distribution to data using the `fitdist` function or the **Distribution Fitter** app. The object property `ParameterCovariance` stores the covariance matrix of the parameter estimates. To obtain the negative loglikelihood of the parameter estimates and the profile of the likelihood function, pass the object to `negloglik` and `proflk`, respectively.

normpdf

Normal probability density function

Syntax

```
y = normpdf(x)
y = normpdf(x,mu)
y = normpdf(x,mu,sigma)
```

Description

`y = normpdf(x)` returns the probability density function (pdf) of the standard normal distribution, evaluated at the values in `x`.

`y = normpdf(x,mu)` returns the pdf of the normal distribution with mean `mu` and the unit standard deviation, evaluated at the values in `x`.

`y = normpdf(x,mu,sigma)` returns the pdf of the normal distribution with mean `mu` and standard deviation `sigma`, evaluated at the values in `x`.

Examples

Standard Normal Distribution pdf

Compute the pdf values for the standard normal distribution at the values in `x`.

```
x = [-2,-1,0,1,2];
y = normpdf(x)
```

```
y = 1×5
```

```
    0.0540    0.2420    0.3989    0.2420    0.0540
```

Normal Distribution pdf

Compute the pdf values evaluated at the values in `x` for the normal distribution with mean `mu` and standard deviation `sigma`.

```
x = [-2, -1, 0, 1, 2];  
mu = 2;  
sigma = 1;  
y = normpdf(x, mu, sigma)
```

```
y = 1×5
```

```
    0.0001    0.0044    0.0540    0.2420    0.3989
```

Compute the pdf values evaluated at zero for various normal distributions with different mean parameters.

```
mu = [-2, -1, 0, 1, 2];  
sigma = 1;  
y = normpdf(0, mu, sigma)
```

```
y = 1×5
```

```
    0.0540    0.2420    0.3989    0.2420    0.0540
```

Input Arguments

x — Values at which to evaluate pdf

scalar value | array of scalar values

Values at which to evaluate the pdf, specified as a scalar value or an array of scalar values.

To evaluate the pdf at multiple values, specify `x` using an array. To evaluate the pdfs of multiple distributions, specify `mu` and `sigma` using arrays. If one or more of the input arguments `x`, `mu`, and `sigma` are arrays, then the array sizes must be the same. In this case, `normpdf` expands each scalar input into a constant array of the same size as the

array inputs. Each element in **y** is the pdf value of the distribution specified by the corresponding elements in **mu** and **sigma**, evaluated at the corresponding element in **x**.

Example: [-1,0,3,4]

Data Types: single | double

mu — Mean

0 (default) | scalar value | array of scalar values

Mean of the normal distribution, specified as a scalar value or an array of scalar values.

To evaluate the pdf at multiple values, specify **x** using an array. To evaluate the pdfs of multiple distributions, specify **mu** and **sigma** using arrays. If one or more of the input arguments **x**, **mu**, and **sigma** are arrays, then the array sizes must be the same. In this case, **normpdf** expands each scalar input into a constant array of the same size as the array inputs. Each element in **y** is the pdf value of the distribution specified by the corresponding elements in **mu** and **sigma**, evaluated at the corresponding element in **x**.

Example: [0 1 2; 0 1 2]

Data Types: single | double

sigma — Standard deviation

1 (default) | positive scalar value | array of positive scalar values

Standard deviation of the normal distribution, specified as a positive scalar value or an array of positive scalar values.

To evaluate the pdf at multiple values, specify **x** using an array. To evaluate the pdfs of multiple distributions, specify **mu** and **sigma** using arrays. If one or more of the input arguments **x**, **mu**, and **sigma** are arrays, then the array sizes must be the same. In this case, **normpdf** expands each scalar input into a constant array of the same size as the array inputs. Each element in **y** is the pdf value of the distribution specified by the corresponding elements in **mu** and **sigma**, evaluated at the corresponding element in **x**.

Example: [1 1 1; 2 2 2]

Data Types: single | double

Output Arguments

y — pdf values

scalar value | array of scalar values

pdf values, evaluated at the values in `x`, returned as a scalar value or an array of scalar values. `y` is the same size as `x`, `mu`, and `sigma` after any necessary scalar expansion. Each element in `y` is the pdf value of the distribution specified by the corresponding elements in `mu` and `sigma`, evaluated at the corresponding element in `x`.

Definitions

Normal Distribution

The normal distribution is a two-parameter family of curves. The first parameter, μ , is the mean. The second parameter, σ , is the standard deviation.

The standard normal distribution has zero mean and unit standard deviation.

The normal probability density function (pdf) is

$$y = f(x) \Big| \mu, \sigma = \frac{1}{\sigma\sqrt{2\pi}} e^{-\frac{(x-\mu)^2}{2\sigma^2}}, \quad \text{for } x \in \mathbb{R}.$$

The *likelihood function* is the pdf viewed as a function of the parameters. The maximum likelihood estimates (MLEs) are the parameter estimates that maximize the likelihood function for fixed values of `x`.

Alternative Functionality

- `normpdf` is a function specific to normal distribution. Statistics and Machine Learning Toolbox also offers the generic function `pdf`, which supports various probability distributions. To use `pdf`, create a `NormalDistribution` probability distribution object and pass the object as an input argument or specify the probability distribution name and its parameters. Note that the distribution-specific function `normpdf` is faster than the generic function `pdf`.

- Use the **Probability Distribution Function** app to create an interactive plot of the cumulative distribution function (cdf) or probability density function (pdf) for a probability distribution.

Introduced before R2006a

normplot

Normal probability plot

Syntax

```
normplot(x)  
normplot(ax,x)  
h = normplot( ___ )
```

Description

`normplot(x)` creates a normal probability plot comparing the distribution of the data in `x` to the normal distribution.

`normplot` plots each data point in `x` using plus sign ('+') markers and draws two reference lines that represent the theoretical distribution. A solid reference line connects the first and third quartiles of the data, and a dashed reference line extends the solid line to the ends of the data. If the sample data has a normal distribution, then the data points appear along the reference line. A distribution other than normal introduces curvature in the data plot.

`normplot(ax,x)` adds a normal probability plot into the axes specified by `ax`.

`h = normplot(___)` returns graphics handles corresponding to the plotted lines, using any of the previous syntaxes.

Examples

Generate a Normal Probability Plot

Generate random sample data from a normal distribution with $\mu = 10$ and $\sigma = 1$.

```
rng default; % For reproducibility  
x = normrnd(10,1,25,1);
```

Create a normal probability plot of the sample data.

```
figure;  
normplot(x)
```

The plot indicates that the data follows a normal distribution.

Assess Normality Using a Normal Probability Plot

Generate 50 random numbers from each of four different distributions: A standard normal distribution; a Student's-t distribution with five degrees of freedom (a "fat-tailed"

distribution); a set of Pearson random numbers with mu equal to 0, sigma equal to 1, skewness equal to 0.5, and kurtosis equal to 3 (a "right-skewed" distribution); and a set of Pearson random numbers with mu equal to 0, sigma equal to 1, skewness equal to -0.5, and kurtosis equal to 3 (a "left-skewed" distribution).

```
rng(11) % For reproducibility
x1 = normrnd(0,1,[50,1]);
x2 = trnd(5,[50,1]);
x3 = pearsrnd(0,1,0.5,3,[50,1]);
x4 = pearsrnd(0,1,-0.5,3,[50,1]);
```

Plot four histograms on the same figure for a visual comparison of the pdf of each distribution.

```
figure
subplot(2,2,1)
histogram(x1,10)
title('Normal')
axis([-4,4,0,15])

subplot(2,2,2)
histogram(x2,10)
title('Fat Tails')
axis([-4,4,0,15])

subplot(2,2,3)
histogram(x3,10)
title('Right-Skewed')
axis([-4,4,0,15])

subplot(2,2,4)
histogram(x4,10)
title('Left-Skewed')
axis([-4,4,0,15])
```

The histograms show how each sample differs from the normal distribution.

Create a normal probability plot for each sample.

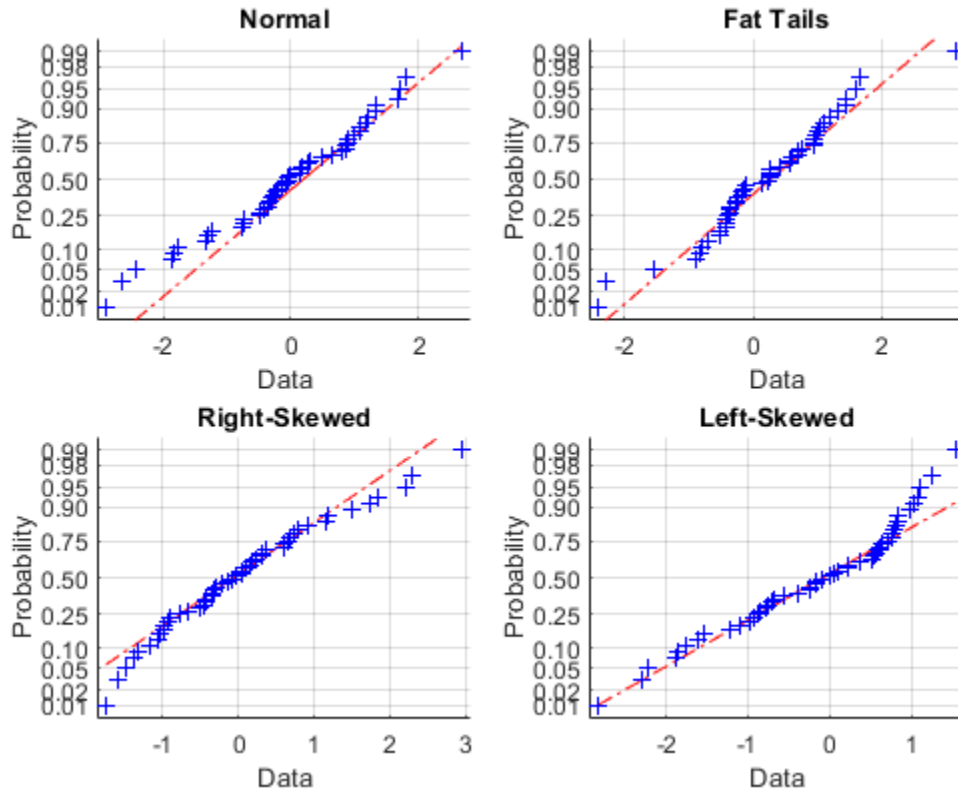

```
figure
subplot(2,2,1)
normplot(x1)
title('Normal')

subplot(2,2,2)
normplot(x2)
title('Fat Tails')

subplot(2,2,3)
```

```
normplot(x3)
title('Right-Skewed')
```

```
subplot(2,2,4)
normplot(x4)
title('Left-Skewed')
```

Adjust Normal Probability Plot Line Properties

Create a 50-by-2 matrix containing 50 random numbers from each of two different distributions: A standard normal distribution in column 1, and a set of Pearson random

numbers with mu equal to 0, sigma equal to 1, skewness equal to 0.5, and kurtosis equal to 3 (a "right-skewed" distribution) in column 2.

```
rng default % For reproducibility
x = [normrnd(0,1,[50,1]) pearsrnd(0,1,0.5,3,[50,1])];
```

Create a normal probability plot for both samples on the same figure. Return the plot line graphic handles.

```
figure
h = normplot(x)

h =
    6x1 Line array:

    Line
    Line
    Line
    Line
    Line
    Line
```

```
legend({'Normal', 'Right-Skewed'}, 'Location', 'southeast')
```

The handles `h(1)` and `h(2)` correspond to the data points for the normal and skewed distributions, respectively. The handles `h(3)` and `h(4)` correspond to the second and third quartile line fit to the sample data. The handles `h(5)` and `h(6)` correspond to the extrapolated line that extends to the minimum and maximum of each set of sample data.

To illustrate, increase the line width of the second and third quartile line for the normally distributed data sample (represented by `h(3)`) to 2.

```
h(3).LineWidth = 2;
h(4).LineWidth = 2;
```

Input Arguments

x — Sample data

numeric vector | numeric matrix

Sample data, specified as a numeric vector or numeric matrix. `normplot` displays each value in `x` using the symbol '+'. If `x` is a matrix, then `normplot` displays a separate line for each column of `x`.

Data Types: `single` | `double`

ax — Target axes

Axes object | UIAxes object

Target axes, specified as an Axes object or a UIAxes object. `normplot` adds an additional plot into the axes specified by `ax`. For details, see Axes Properties and UIAxes Properties.

Use `gca` to return the current axes for the current figure.

Output Arguments

h — Graphics handles for line objects

vector of Line graphics handles

Graphics handles for line objects, returned as a vector of Line graphics handles. Graphics handles are unique identifiers that you can use to query and modify the properties of a specific line on the plot. For each column of `x`, `normplot` returns three handles:

- The line representing the data points. `normplot` represents each data point in `x` using plus sign ('+') markers.
- The line joining the first and third quartiles of each column of `x`, represented as a solid line.
- The extrapolation of the quartile line, extended to the minimum and maximum values of `x`, represented as a dashed line.

To view and set properties of line objects, use dot notation. For information on using dot notation, see “Access Property Values” (MATLAB). For information on the Line properties that you can set, see Primitive Line.

Algorithms

`normplot` matches the quantiles of sample data to the quantiles of a normal distribution. The sample data is sorted and plotted on the x-axis. The y-axis represents the quantiles of the normal distribution, converted into probability values. Therefore, the y-axis scaling is not linear.

Where the x-axis value is the i th sorted value from a sample of size N , the y-axis value is the midpoint between evaluation points of the empirical cumulative distribution function of the data. The midpoint is equal to $\frac{(i - 0.5)}{N}$.

`normplot` superimposes a reference line to assess the linearity of the plot. The line goes through the first and third quartiles of the data.

Alternative Functionality

You can use the `probplot` function to create a probability plot. The `probplot` function enables you to indicate censored data and specify the distribution for a probability plot.

“Normal Distribution” on page B-136

Introduced before R2006a

normrnd

Normal random numbers

Syntax

```
r = normrnd(mu,sigma)
r = normrnd(mu,sigma,sz1,...,szN)
r = normrnd(mu,sigma,[sz1,...,szN])
```

Description

`r = normrnd(mu,sigma)` generates a random number from the normal distribution with mean parameter `mu` and standard deviation parameter `sigma`.

`r = normrnd(mu,sigma,sz1,...,szN)` or `r = normrnd(mu,sigma,[sz1,...,szN])` generates a `sz1`-by-...-by-`szN` array of normal random numbers.

Examples

Generate Normal Random Number

Generate a single random value from the standard normal distribution.

```
rng('default') % For reproducibility
r = normrnd(0,1)
```

```
r = 0.5377
```

Reset Random Number Generator

Save the current state of the random number generator. Then create a 1-by-5 vector of normal random numbers from the normal distribution with mean 3 and standard deviation 10.

```
s = rng;  
r = normrnd(3,10,[1,5])  
  
r = 1×5  
    8.3767    21.3389   -19.5885    11.6217     6.1877
```

Restore the state of the random number generator to `s`, and then create a new 1-by-5 vector of random numbers. The values are the same as before.

```
rng(s);  
r1 = normrnd(3,10,[1,5])  
  
r1 = 1×5  
    8.3767    21.3389   -19.5885    11.6217     6.1877
```

Clone Size from Existing Array

Create a matrix of normally distributed random numbers with the same size as an existing array.

```
A = [3 2; -2 1];  
sz = size(A);  
R = normrnd(0,1,sz)  
  
R = 2×2  
    0.5377   -2.2588  
    1.8339    0.8622
```

You can combine the previous two lines of code into a single line.

```
R = normrnd(1,0,size(A));
```

Input Arguments

mu — Mean

scalar value | array of scalar values

Mean of the normal distribution, specified as a scalar value or an array of scalar values.

To generate random numbers from multiple distributions, specify `mu` and `sigma` using arrays. If both `mu` and `sigma` are arrays, then the array sizes must be the same. If either `mu` or `sigma` is a scalar, then `normrnd` expands the scalar argument into a constant array of the same size as the other argument. Each element in `r` is the random number generated from the distribution specified by the corresponding elements in `mu` and `sigma`.

Example: `[0 1 2; 0 1 2]`

Data Types: `single` | `double`

sigma — Standard deviation

nonnegative scalar value | array of nonnegative scalar values

Standard deviation of the normal distribution, specified as a nonnegative scalar value or an array of nonnegative scalar values.

If `sigma` is zero, then the output `r` is always equal to `mu`.

To generate random numbers from multiple distributions, specify `mu` and `sigma` using arrays. If both `mu` and `sigma` are arrays, then the array sizes must be the same. If either `mu` or `sigma` is a scalar, then `normrnd` expands the scalar argument into a constant array of the same size as the other argument. Each element in `r` is the random number generated from the distribution specified by the corresponding elements in `mu` and `sigma`.

Example: `[1 1 1; 2 2 2]`

Data Types: `single` | `double`

sz1, ..., szN — Size of each dimension

integers | row vector of integers

Size of each dimension, specified as integers or a row vector of integers. For example, specifying `5, 3, 2` or `[5, 3, 2]` generates a 5-by-3-by-2 array of random numbers from the probability distribution.

If either `mu` or `sigma` is an array, then the specified dimensions `sz1, . . . , szN` must match the common dimensions of `mu` and `sigma` after any necessary scalar expansion. The default values of `sz1, . . . , szN` are the common dimensions.

- If you specify a single value `sz1`, then `r` is a square matrix of size `sz1`.
- If the size of any dimension is 0 or negative, then `r` is an empty array.
- Beyond the second dimension, `normrnd` ignores trailing dimensions with a size of 1. For example, `normrnd(3,1,1,1)` produces a 3-by-1 vector of random numbers.

Data Types: `single` | `double`

Output Arguments

r — Normal random numbers

scalar value | array of scalar values

Normal random numbers, returned as a scalar value or an array of scalar values with the dimensions specified by `sz1, . . . , szN`. Each element in `r` is the random number generated from the distribution specified by the corresponding elements in `mu` and `sigma`.

Alternative Functionality

- `normrnd` is a function specific to normal distribution. Statistics and Machine Learning Toolbox also offers the generic function `random`, which supports various probability distributions. To use `random`, create a `NormalDistribution` probability distribution object and pass the object as an input argument or specify the probability distribution name and its parameters. Note that the distribution-specific function `normrnd` is faster than the generic function `random`.
- Use `randn` to generate random numbers from the standard normal distribution.
- To generate random numbers interactively, use `randtool`, a random number generation user interface.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

The generated code can return a different sequence of numbers than MATLAB if either of the following is true:

- The output is nonscalar.
- An input parameter is invalid for the distribution.

For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “General Code Generation Workflow” on page 31-5.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU arrays. For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

Introduced before R2006a

normspec

Normal density plot shading between specifications

Syntax

```
p = normspec(specs)
p = normspec(specs,mu,sigma)
p = normspec(specs,mu,sigma,region)
[p,h] = normspec( ___ )
```

Description

`p = normspec(specs)` plots the standard normal density, shading the portion inside the specification limits given by the two-element vector `specs`, and returns the probability `p` of the shaded area. If `spec` has no lower limit, then set `specs(1)` to `-Inf`; if `spec` has no upper limit, then set `specs(2)` to `Inf`.

`p = normspec(specs,mu,sigma)` uses a normal density with parameters `mu` and `sigma`.

`p = normspec(specs,mu,sigma,region)` specifies the shading region as either 'inside' or 'outside' the specification limits. The default is 'inside'.

`[p,h] = normspec(___)` also returns a column vector of chart line objects using any of the input arguments in the previous syntaxes. Use `h` to modify properties of a specific chart line after you create it. For a list of properties, see [Line](#).

Examples

Create Standard Normal Density Plot Shading Inside of Limits

Create a standard normal density plot, shading the portion inside the specification limits `[-1,1]`.

```
p = normspec([-1,1])
```

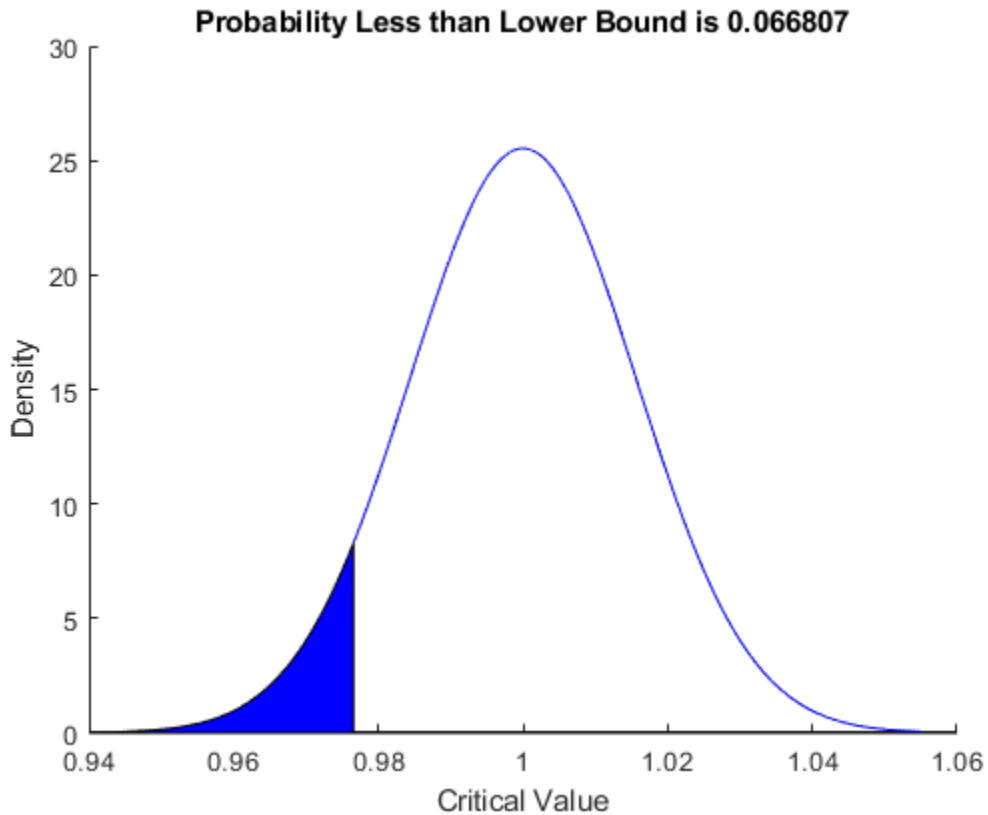

```
p = 0.6827
```

Create Normal Density Plot Shading Outside of Limits

Create a normal density plot, shading the portion outside the specification limits.

For example, consider a production process that fills cans of paint. The average amount of paint in any can is 1 gallon, but variability in the process produces a standard deviation of 2 ounces (2/128 gallons). Create a normal density plot, shading the portion corresponding to the probability that the cans will be filled under specification by 3 or more ounces.

```
p = normspec([1-3/128,Inf],1,2/128,'outside')
```

```
p = 0.0668
```

Input Arguments

specs — Specification limits

two-element numeric vector

Specification limits, specified as a two-element numeric vector. Set `specs(1)` to `-Inf` if there is no lower limit; set `specs(2)` to `Inf` if there is no upper limit.

Data Types: `single` | `double`

mu — Mean

0 (default) | scalar value

Mean of the normal distribution, specified as a scalar value.

Data Types: `single` | `double`

sigma — Standard deviation

1 (default) | positive scalar value

Standard deviation of the normal distribution, specified as a positive scalar value.

Data Types: `single` | `double`

region — Shading region

'inside' (default) | 'outside'

Shading region, specified as either 'inside' or 'outside'. The function `normspec` shades the region either 'inside' or 'outside' the specification limits.

Output Arguments

p — Probability of shaded area

nonnegative scalar value

Probability of the shaded area, returned as a nonnegative scalar value.

h — One or more chart line objects

scalar | vector

One or more chart line objects, returned as a scalar or vector. These objects are unique identifiers that you use to query and modify properties of a specific chart line. For a list of properties, see [Chart Line](#).

Introduced before R2006a

normstat

Normal mean and variance

Syntax

```
[m,v] = normstat(mu,sigma)
```

Description

`[m,v] = normstat(mu,sigma)` returns the mean and variance of the normal distribution with mean μ and standard deviation σ .

The mean of the normal distribution with parameters μ and σ is μ , and the variance is σ^2 .

Examples

Compute Mean and Variance

Compute the mean and variance of the normal distribution with parameters μ and σ .

```
mu = 1;  
sigma = 1:5;  
[m,v] = normstat(mu,sigma)
```

```
m = 1×5
```

```
    1    1    1    1    1
```

```
v = 1×5
```

```
    1    4    9   16   25
```

Input Arguments

mu — Mean

scalar value | array of scalar values

Mean of the normal distribution, specified as a scalar value or an array of scalar values.

To compute the means and variances of multiple distributions, specify distribution parameters using an array of scalar values. If both `mu` and `sigma` are arrays, then the array sizes must be the same. If either `mu` or `sigma` is a scalar, then `normstat` expands the scalar argument into a constant array of the same size as the other argument. Each element in `m` and `v` is the mean and variance of the distribution specified by the corresponding elements in `mu` and `sigma`.

Example: `[0 1 2; 0 1 2]`

Data Types: `single` | `double`

sigma — Standard deviation

positive scalar value | array of positive scalar values

Standard deviation of the normal distribution, specified as a positive scalar value or an array of positive scalar values.

To compute the means and variances of multiple distributions, specify distribution parameters using an array of scalar values. If both `mu` and `sigma` are arrays, then the array sizes must be the same. If either `mu` or `sigma` is a scalar, then `normstat` expands the scalar argument into a constant array of the same size as the other argument. Each element in `m` and `v` is the mean and variance of the distribution specified by the corresponding elements in `mu` and `sigma`.

Example: `[1 1 1; 2 2 2]`

Data Types: `single` | `double`

Output Arguments

m — Mean

scalar value | array of scalar values

Mean of the normal distribution, returned as a scalar value or an array of scalar values. `m` is the same size as `mu` and `sigma` after any necessary scalar expansion. Each element in `m`

is the mean of the normal distribution specified by the corresponding elements in `mu` and `sigma`.

v — Variance

scalar value | array of scalar values

Variance of the normal distribution, returned as a scalar value or an array of scalar values. `v` is the same size as `mu` and `sigma` after any necessary scalar expansion. Each element in `v` is the variance of the normal distribution specified by the corresponding elements in `mu` and `sigma`.

Alternative Functionality

- `normstat` is a function specific to normal distribution. Statistics and Machine Learning Toolbox also offers generic functions to compute summary statistics, including mean (`mean`), median (`median`), interquartile range (`iqr`), variance (`var`), and standard deviation (`std`). These generic functions support various probability distributions. To use these functions, create a `NormalDistribution` probability distribution object and pass the object as an input argument.

nsegments

Number of segments in piecewise distribution

Syntax

```
n = nsegments(pd)
```

Description

`n = nsegments(pd)` returns the number of segments in the piecewise distribution object `pd`.

Examples

Number of Segments in `paretotails` Object

Generate a sample data set and fit a piecewise distribution with a Pareto tail to the data by using `paretotails`. Find the number of segments in the fitted distribution by using the object function `nsegments`.

Generate a sample data set containing 10% outliers in the right tail.

```
rng('default'); % For reproducibility
right_tail = exprnd(5,100,1);
center = randn(900,1);
x = [center;right_tail];
```

Create a `paretotails` object by fitting a piecewise distribution to `x`. Specify the boundaries of the tails using the lower and upper tail cumulative probabilities. Pass in 0 and 0.9 so that a fitted object does not contain a lower tail segment, and consists of the empirical distribution for the lower 90% of the data set and a generalized Pareto distribution (GPD) for the upper 10% of the data set.

```
pd = paretotails(x,0,0.9)
```

```
pd =  
Piecewise distribution with 2 segments  
  -Inf < x < 1.73931 (0 < p < 0.9): interpolated empirical cdf  
  1.73931 < x < Inf (0.9 < p < 1): upper tail, GPD(0.643752,1.62246)
```

Return the number of segments in `pd` by using the `nsegments` function.

```
n = nsegments(pd)
```

```
n = 2
```

You can also get the number of segments by using the `NumSegments` property. Access the `NumSegments` property by using dot notation.

```
pd.NumSegments
```

```
ans = 2
```

Input Arguments

pd — Piecewise distribution with Pareto tails

`paretotails` object

Piecewise distribution with Pareto tails, specified as a `paretotails` object.

numel

Class: dataset

Number of elements in dataset array

Note The dataset data type might be removed in a future release. To work with heterogeneous data, use the MATLAB® table data type instead. See MATLAB table documentation for more information.

Syntax

```
n = numel(A)
n = numel(A, varargin)
```

Description

`n = numel(A)` returns 1. To find the number of elements, `n`, in the dataset array `A`, use `prod(size(A))` or `numel(A, ':', ':')`.

`n = numel(A, varargin)` returns the number of subscripted elements, `n`, in `A(index1, index2, ..., indexn)`, where `varargin` is a string array or cell array whose elements are `index1, index2, ... indexn`.

See Also

`length` | `size`

NumTestSets property

Class: cvpartition

Number of test sets

Description

Value is the number of folds in partitions of type 'kfold' and 'leaveout'.

Value is 1 in partitions of type 'holdout' and 'resubstitution'.

ObsNames property

Class: dataset

Cell array of nonempty, distinct character vectors giving names of observations in data set

Note The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB® `table` data type instead. See MATLAB `table` documentation for more information.

Description

A cell array of nonempty, distinct character vectors giving the names of the observations in the data set. This property may be empty, but if not empty, the number of character vectors must equal the number of observations.

optimalleaforder

Optimal leaf ordering for hierarchical clustering

Syntax

```
leafOrder = optimalleaforder(tree,D)  
leafOrder = optimalleaforder(tree,D,Name,Value)
```

Description

`leafOrder = optimalleaforder(tree,D)` returns an optimal leaf ordering for the hierarchical binary cluster tree, `tree`, using the distances, `D`. An optimal leaf ordering of a binary tree maximizes the sum of the similarities between adjacent leaves by flipping tree branches without dividing the clusters.

`leafOrder = optimalleaforder(tree,D,Name,Value)` returns the optimal leaf ordering using one or more name-value pair arguments.

Examples

Plot Dendrogram With Optimal Leaf Order

Create a hierarchical binary cluster tree using `linkage`. Then, compare the dendrogram plot with the default ordering to a dendrogram with an optimal leaf ordering.

Generate sample data.

```
rng('default') % For reproducibility  
X = rand(10,2);
```

Create a distance vector and a hierarchical binary clustering tree. Use the distances and clustering tree to determine an optimal leaf order.

```
D = pdist(X);  
tree = linkage(D, 'average');  
leafOrder = optimalleaforder(tree,D);
```

Plot the dendrogram with the default ordering and the dendrogram with the optimal leaf ordering.

```
figure()  
subplot(2,1,1)  
dendrogram(tree)  
title('Default Leaf Order')  
  
subplot(2,1,2)  
dendrogram(tree, 'reorder', leafOrder)  
title('Optimal Leaf Order')
```

The order of the leaves in the bottom figure corresponds to the elements in `leafOrder`.

```
leafOrder
```

```
leafOrder = 1x10
```

```
1 4 9 10 2 5 8 3 7 6
```

Optimal Leaf Order Using Inverse Distance Similarity

Generate sample data.

```
rng('default') % For reproducibility
X = rand(10,2);
```

Create a distance vector and a hierarchical binary clustering tree.

```
D = pdist(X);
tree = linkage(D,'average');
```

Use the inverse distance similarity transformation to determine an optimal leaf order.

```
leafOrder = optimalleaforder(tree,D,'Transformation','inverse')
```

```
leafOrder = 1×10
```

```
    1     4     9    10     2     5     8     3     7     6
```

Input Arguments

tree — Hierarchical binary cluster tree

matrix returned by `linkage`

Hierarchical binary cluster tree, specified as an $(M - 1)$ -by-3 matrix that you generate using `linkage`, where M is the number of leaves.

D — Distances

matrix | vector

Distances for determining similarities between leaves, specified as a matrix or vector of distances. For example, you can generate distances using `pdist`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'Criteria','group','Transformation','inverse'` specifies that the sum of similarities be maximized between every leaf and all other leaves in adjacent clusters, using an inverse similarity transformation.

Criteria — Optimization criterion`'adjacent' (default) | 'group'`

Optimization criterion for determining an optimal leaf ordering, specified as the comma-separated pair consisting of `'criteria'` and one of these values:

<code>'adjacent'</code>	Maximize the sum of similarities between adjacent leaves.
<code>'group'</code>	Maximize the sum of similarities between every leaf and all other leaves in the adjacent clusters at the same level of the dendrogram.

Example: `'Criteria', 'group'`

Transformation — Method for transforming distances to similarities`'linear' (default) | 'inverse' | function handle`

Method for transforming distances to similarities, specified as the comma-separated pair consisting of `'Transformation'` and one of `'linear'`, `'inverse'`, or a function handle.

Let d_{ij} and Sim_{ij} denote the distance and similarity between leaves i and j , respectively. The included similarity transformations are:

<code>'linear'</code>	$Sim_{ij} = \max_{i,j} (d_{i,j}) - d_{ij}$
<code>'inverse'</code>	$Sim_{ij} = 1/d_{ij}$

To use a custom transformation function, specify a handle to a function that accepts a matrix of distances, D , and returns a matrix of similarities, S . The function should be monotonic decreasing in the range of distance values. S must have the same size as D , with $S(i, j)$ being the similarity computed based on $D(i, j)$.

Example: `'Transformation', @myTransform`

Output Arguments

leafOrder — Optimal leaf order

vector

Optimal leaf order, returned as a length- M vector, where M is the number of leaves. `leafOrder` is a permutation of the vector `1:M`, giving an optimal leaf ordering based on the specified distances and similarity transformation.

References

- [1] Bar-Joseph, Z., Gifford, D.K., and Jaakkola, T.S. (2001). Fast optimal leaf ordering for hierarchical clustering. *Bioinformatics* 17, Suppl 1:S22-9. PMID: 11472989.

dendrogram | linkage | pdist

Introduced in R2012b

oobEdge

Out-of-bag classification edge

Syntax

```
edge = oobEdge(ens)
edge = oobEdge(ens,Name,Value)
```

Description

`edge = oobEdge(ens)` returns out-of-bag classification edge for `ens`.

`edge = oobEdge(ens,Name,Value)` computes classification edge with additional options specified by one or more `Name,Value` pair arguments. You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Input Arguments

ens

A classification bagged ensemble, constructed with `fitcensemble`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

learners

Indices of weak learners in the ensemble ranging from 1 to `ens.NumTrained`. `oobEdge` uses only these learners for calculating loss.

Default: `1:NumTrained`

mode

Character vector or string scalar representing the meaning of the output L:

- 'ensemble' — L is a scalar value, the loss for the entire ensemble.
- 'individual' — L is a vector with one element per trained learner.
- 'cumulative' — L is a vector in which element J is obtained by using learners 1:J from the input list of learners.

Default: 'ensemble'

Output Arguments

edge

Classification edge, a weighted average of the classification margin.

Examples

Estimate Out-of-Bag Edge

Load Fisher's iris data set.

```
load fisheriris
```

Train an ensemble of 100 bagged classification trees using the entire data set.

```
Mdl = fitensemble(meas,species,'Method','Bag');
```

Estimate the out-of-bag edge.

```
edge = oobEdge(Mdl)
```

```
edge = 0.8873
```

Definitions

Edge

The edge is the weighted mean value of the classification margin. The weights are the class probabilities in `ens.Prior`.

Margin

The classification margin is the difference between the classification score for the true class and maximal classification score for the false classes. Margin is a column vector with the same number of rows as in the matrix `ens.X`.

Out of Bag

Bagging, which stands for “bootstrap aggregation”, is a type of ensemble learning. To bag a weak learner such as a decision tree on a dataset, `fitcensemble` generates many bootstrap replicas of the dataset and grows decision trees on these replicas. `fitcensemble` obtains each bootstrap replica by randomly selecting `N` observations out of `N` with replacement, where `N` is the dataset size. To find the predicted response of a trained ensemble, `predict` take an average over predictions from individual trees.

Drawing `N` out of `N` observations with replacement omits on average 37% ($1/e$) of observations for each decision tree. These are “out-of-bag” observations. For each observation, `oobLoss` estimates the out-of-bag prediction by averaging over predictions from all trees in the ensemble for which this observation is out of bag. It then compares the computed prediction against the true response for this observation. It calculates the out-of-bag error by comparing the out-of-bag predicted responses against the true responses for all observations used for training. This out-of-bag average is an unbiased estimator of the true ensemble error.

See Also

`oobLoss` | `oobMargin` | `oobPredict`

oobError

Class: TreeBagger

Out-of-bag error

Syntax

```
err = oobError(B)
err = oobError(B, 'param1', val1, 'param2', val2, ...)
```

Description

`err = oobError(B)` computes the misclassification probability (for classification trees) or mean squared error (for regression trees) for out-of-bag observations in the training data, using the trained bagger `B`. `err` is a vector of length `NTrees`, where `NTrees` is the number of trees in the ensemble.

`err = oobError(B, 'param1', val1, 'param2', val2, ...)` specifies optional parameter name/value pairs:

<code>'Mode'</code>	Character vector or string scalar indicating how <code>oobError</code> computes errors. If set to <code>'cumulative'</code> (default), the method computes cumulative errors and <code>err</code> is a vector of length <code>NTrees</code> , where the first element gives error from <code>trees(1)</code> , second element gives error from <code>trees(1:2)</code> etc., up to <code>trees(1:NTrees)</code> . If set to <code>'individual'</code> , <code>err</code> is a vector of length <code>NTrees</code> , where each element is an error from each tree in the ensemble. If set to <code>'ensemble'</code> , <code>err</code> is a scalar showing the cumulative error for the entire ensemble.
---------------------	--

'Trees'	Vector of indices indicating what trees to include in this calculation. By default, this argument is set to 'all' and the method uses all trees. If 'Trees' is a numeric vector, the method returns a vector of length NTrees for 'cumulative' and 'individual' modes, where NTrees is the number of elements in the input vector, and a scalar for 'ensemble' mode. For example, in the 'cumulative' mode, the first element gives error from <code>trees(1)</code> , the second element gives error from <code>trees(1:2)</code> etc.
'TreeWeights'	Vector of tree weights. This vector must have the same length as the 'Trees' vector. <code>oobError</code> uses these weights to combine output from the specified trees by taking a weighted average instead of the simple nonweighted majority vote. You cannot use this argument in the 'individual' mode.

Algorithms

`oobError` estimates the weighted ensemble error for out-of-bag observations. That is, `oobError` applies error to the training data stored in the input `TreeBagger` model `B`, and selects the out-of-bag observations for each tree to compose the ensemble error.

- `B.X` and `B.Y` are the training data predictors and responses, respectively.
- `B.OOBIndices` specifies which observations are out-of-bag for each tree in the ensemble.
- `B.W` specifies the observation weights.
- Optionally:
 - Using the 'Mode' name-value pair argument, you can specify to return the individual, weighted ensemble error for each tree, or the entire, weighted ensemble error. By default, `oobError` returns the cumulative, weighted ensemble error.
 - Using the 'Trees' name-value pair argument, you can choose which trees to use in the ensemble error calculations.
 - Using the 'TreeWeights' name-value pair argument, you can attribute each tree with a weight.

`oobError` applies the algorithms described below. For more details, see `error` and `predict`.

For regression problems, `oobError` returns the weighted MSE.

- 1 `oobError` predicts responses for all out-of-bag observations.
- 2 The MSE estimate depends on the value of 'Mode'.
 - If you specify 'Mode', 'Individual', then `oobError` sets any in bag observations within a selected tree to the weighted sample average of the observed, training data responses. Then, `oobError` computes the weighted MSE for each selected tree.
 - If you specify 'Mode', 'Cumulative', then `oobError` returns a vector of cumulative, weighted MSEs, where MSE_t is the cumulative, weighted MSE for selected tree t . To compute MSE_t , for each observation that is out of bag for at least one tree through tree t , `oobError` computes the cumulative, weighted mean of the predicted responses through tree t . `oobError` sets observations that are in bag for all selected trees through tree t to the weighted sample average of the observed, training data responses. Then, `oobError` computes MSE_t .
 - If you specify 'Mode', 'Ensemble', then, for each observation that is out of bag for at least one tree, `oobError` computes the weighted mean over all selected trees. `oobError` sets observations that are in bag for all selected trees to the weighted sample average of the observed, training data responses. Then, `oobError` computes the weighted MSE, which is the same as the final, cumulative, weighted MSE.

In classification problems, `oobError` returns the weighted misclassification rate.

- 1 `oobError` predicts classes for all out-of-bag observations.
- 2 The weighted misclassification rate estimate depends on the value of 'Mode'.
 - If you specify 'Mode', 'Individual', then `oobError` sets any in bag observations within a selected tree to the predicted, weighted, most popular class over all training responses. If there are multiple most popular classes, `error` considers the one listed first in the `ClassNames` property of the `TreeBagger` model the most popular. Then, `oobError` computes the weighted misclassification rate for each selected tree.
 - If you specify 'Mode', 'Cumulative', then `oobError` returns a vector of cumulative, weighted misclassification rates, where e_t^* is the cumulative, weighted misclassification rate for selected tree t . To compute e_t^* , for each observation that is out of bag for at least one tree through tree t , `oobError` finds the predicted, cumulative, weighted most popular class through tree t . `oobError` sets observations that are in bag for all selected trees through tree t to the

weighted, most popular class over all training responses. If there are multiple most popular classes, `error` considers the one listed first in the `ClassNames` property of the `TreeBagger` model the most popular. Then, `oobError` computes e_t^* .

- If you specify `'Mode'`, `'Ensemble'`, then, for each observation that is out of bag for at least one tree, `oobError` computes the weighted, most popular class over all selected trees. `oobError` sets observations that are in bag for all selected trees through tree t to the predicted, weighted, most popular class over all training responses. If there are multiple most popular classes, `error` considers the one listed first in the `ClassNames` property of the `TreeBagger` model the most popular. Then, `oobError` computes the weighted misclassification rate, which is the same as the final, cumulative, weighted misclassification rate.

oobLoss

Out-of-bag classification error

Syntax

```
L = oobloss(ens)
L = oobloss(ens,Name,Value)
```

Description

`L = oobloss(ens)` returns the classification error for `ens` computed for out-of-bag data.

`L = oobloss(ens,Name,Value)` computes error with additional options specified by one or more `Name,Value` pair arguments. You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Input Arguments

ens

A classification bagged ensemble, constructed with `fitcensemble`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Learners

Indices of weak learners in the ensemble ranging from 1 to `NumTrained`. `oobLoss` uses only these learners for calculating loss.

Default: 1:NumTrained

lossfun

Loss function, specified as the comma-separated pair consisting of 'LossFun' and a built-in, loss-function name or function handle.

- The following table lists the available loss functions. Specify one using its corresponding character vector or string scalar.

Value	Description
'binodeviance'	Binomial deviance
'classiferror'	Classification error
'exponential'	Exponential
'hinge'	Hinge
'logit'	Logistic
'mincost'	Minimal expected misclassification cost (for classification scores that are posterior probabilities)
'quadratic'	Quadratic

'mincost' is appropriate for classification scores that are posterior probabilities. Bagged ensembles return posterior probabilities as classification scores by default.

- Specify your own function using function handle notation.

Suppose that n be the number of observations in X and K be the number of distinct classes (`numel(ens.ClassNames)`, `ens` is the input model). Your function must have this signature

```
lossvalue = lossfun(C,S,W,Cost)
```

where:

- The output argument `lossvalue` is a scalar.
- You choose the function name (`lossfun`).
- `C` is an n -by- K logical matrix with rows indicating which class the corresponding observation belongs. The column order corresponds to the class order in `ens.ClassNames`.

Construct C by setting $C(p, q) = 1$ if observation p is in class q , for each row. Set all other elements of row p to 0 .

- S is an n -by- K numeric matrix of classification scores. The column order corresponds to the class order in `ens.ClassNames`. S is a matrix of classification scores, similar to the output of `predict`.
- W is an n -by-1 numeric vector of observation weights. If you pass W , the software normalizes them to sum to 1.
- $Cost$ is a K -by- K numeric matrix of misclassification costs. For example, $Cost = ones(K) - eye(K)$ specifies a cost of 0 for correct classification, and 1 for misclassification.

Specify your function using `'LossFun', @lossfun`.

For more details on loss functions, see “Classification Loss” on page 32-4709.

Default: `'classiferror'`

mode

Character vector or string scalar representing the meaning of the output L :

- `'ensemble'` — L is a scalar value, the loss for the entire ensemble.
- `'individual'` — L is a vector with one element per trained learner.
- `'cumulative'` — L is a vector in which element J is obtained by using learners $1:J$ from the input list of learners.

Default: `'ensemble'`

Output Arguments

L

Classification loss on page 32-4709 of the out-of-bag observations, a scalar. L can be a vector, or can represent a different quantity, depending on the name-value settings.

Examples

Estimate Out-Of-Bag Error

Load Fisher's iris data set.

```
load fisheriris
```

Grow a bag of 100 classification trees.

```
ens = fitcensemble(meas,species,'Method','Bag');
```

Estimate the out-of-bag classification error.

```
L = oobLoss(ens)
```

```
L = 0.0400
```

Definitions

Out of Bag

Bagging, which stands for “bootstrap aggregation”, is a type of ensemble learning. To bag a weak learner such as a decision tree on a dataset, `fitcensemble` generates many bootstrap replicas of the dataset and grows decision trees on these replicas.

`fitcensemble` obtains each bootstrap replica by randomly selecting N observations out of N with replacement, where N is the dataset size. To find the predicted response of a trained ensemble, `predict` take an average over predictions from individual trees.

Drawing N out of N observations with replacement omits on average 37% ($1/e$) of observations for each decision tree. These are "out-of-bag" observations. For each observation, `oobLoss` estimates the out-of-bag prediction by averaging over predictions from all trees in the ensemble for which this observation is out of bag. It then compares the computed prediction against the true response for this observation. It calculates the out-of-bag error by comparing the out-of-bag predicted responses against the true responses for all observations used for training. This out-of-bag average is an unbiased estimator of the true ensemble error.

Classification Loss

Classification loss functions measure the predictive inaccuracy of classification models. When you compare the same type of loss among many models, a lower loss indicates a better predictive model.

Consider the following scenario.

- L is the weighted average classification loss.
- n is the sample size.
- For binary classification:
 - y_j is the observed class label. The software codes it as -1 or 1, indicating the negative or positive class, respectively.
 - $f(X_j)$ is the raw classification score for observation (row) j of the predictor data X .
 - $m_j = y_j f(X_j)$ is the classification score for classifying observation j into the class corresponding to y_j . Positive values of m_j indicate correct classification and do not contribute much to the average loss. Negative values of m_j indicate incorrect classification and contribute significantly to the average loss.
- For algorithms that support multiclass classification (that is, $K \geq 3$):
 - y_j^* is a vector of $K - 1$ zeros, with 1 in the position corresponding to the true, observed class y_j . For example, if the true class of the second observation is the third class and $K = 4$, then $y_2^* = [0 \ 0 \ 1 \ 0]$. The order of the classes corresponds to the order in the `ClassNames` property of the input model.
 - $f(X_j)$ is the length K vector of class scores for observation j of the predictor data X . The order of the scores corresponds to the order of the classes in the `ClassNames` property of the input model.
 - $m_j = y_j^* f(X_j)$. Therefore, m_j is the scalar classification score that the model predicts for the true, observed class.
- The weight for observation j is w_j . The software normalizes the observation weights so that they sum to the corresponding prior class probability. The software also normalizes the prior probabilities so they sum to 1. Therefore,

$$\sum_{j=1}^n w_j = 1.$$

Given this scenario, the following table describes the supported loss functions that you can specify by using the 'LossFun' name-value pair argument.

Loss Function	Value of LossFun	Equation
Binomial deviance	'binodeviance'	$L = \sum_{j=1}^n w_j \log\{1 + \exp[-2m_j]\}.$
Exponential loss	'exponential'	$L = \sum_{j=1}^n w_j \exp(-m_j).$
Classification error	'classiferror'	$L = \sum_{j=1}^n w_j I\{\hat{y}_j \neq y_j\}.$ <p>It is the weighted fraction of misclassified observations where \hat{y}_j is the class label corresponding to the class with the maximal posterior probability. $I\{x\}$ is the indicator function.</p>
Hinge loss	'hinge'	$L = \sum_{j=1}^n w_j \max\{0, 1 - m_j\}.$
Logit loss	'logit'	$L = \sum_{j=1}^n w_j \log(1 + \exp(-m_j)).$

Loss Function	Value of LossFun	Equation
Minimal cost	'mincost'	<p>Minimal cost. The software computes the weighted minimal cost using this procedure for observations $j = 1, \dots, n$.</p> <ol style="list-style-type: none"> 1 Estimate the 1-by-K vector of expected classification costs for observation j: $v_j = f(X_j)'C.$ <p>$f(X_j)$ is the column vector of class posterior probabilities for binary and multiclass classification. C is the cost matrix that the input model stores in the <code>Cost</code> property.</p> 2 For observation j, predict the class label corresponding to the minimum expected classification cost: $\hat{y}_j = \min_{j=1, \dots, K} (v_j).$ 3 Using C, identify the cost incurred (c_j) for making the prediction. <p>The weighted, average, minimum cost loss is</p> $L = \sum_{j=1}^n w_j c_j.$
Quadratic loss	'quadratic'	$L = \sum_{j=1}^n w_j (1 - m_j)^2.$

This figure compares the loss functions (except 'mincost') for one observation over m . Some functions are normalized to pass through [0,1].

oobLoss

Out-of-bag regression error

Syntax

```
L = oobLoss(ens)
L = oobLoss(ens,Name,Value)
```

Description

`L = oobLoss(ens)` returns the mean squared error for `ens` computed for out-of-bag data.

`L = oobLoss(ens,Name,Value)` computes error with additional options specified by one or more `Name,Value` pair arguments. You can specify several name-value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Input Arguments

ens

A regression bagged ensemble, constructed with `fitrensemble`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Learners

Indices of weak learners in the ensemble ranging from 1 to `NumTrained`. `oobLoss` uses only these learners for calculating loss.

Default: 1:NumTrained

lossfun

Function handle for loss function, or 'mse', meaning mean squared error. If you pass a function handle fun, oobLoss calls it as

```
FUN(Y,Yfit,W)
```

where Y, Yfit, and W are numeric vectors of the same length. Y is the observed response, Yfit is the predicted response, and W is the observation weights.

Default: 'mse'

mode

Character vector or string scalar representing the meaning of the output L:

- 'ensemble' — L is a scalar value, the loss for the entire ensemble.
- 'individual' — L is a vector with one element per trained learner.
- 'cumulative' — L is a vector in which element J is obtained by using learners 1:J from the input list of learners.

Default: 'ensemble'

Output Arguments

L

Mean squared error of the out-of-bag observations, a scalar. L can be a vector, or can represent a different quantity, depending on the name-value settings.

Examples

Find Out-of-Bag Regression Error

Compute the out-of-bag error for the carsmall data.

Load the carsmall data set and select engine displacement, horsepower, and vehicle weight as predictors.

```
load carsmall
X = [Displacement Horsepower Weight];
```

Train an ensemble of bagged regression trees.

```
ens = fitensemble(X,MPG,'Method','Bag');
```

Find the out-of-bag error.

```
L = oobLoss(ens)
```

```
L = 19.2825
```

oobMargin

Out-of-bag classification margins

Syntax

```
margin = oobMargin(ens)
margin = oobMargin(ens,Name,Value)
```

Description

`margin = oobMargin(ens)` returns out-of-bag classification margins.

`margin = oobMargin(ens,Name,Value)` calculates margins with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

ens

A classification bagged ensemble, constructed with `fitcensemble`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Learners

Indices of weak learners in the ensemble ranging from 1 to `ens.NumTrained`. `oobEdge` uses only these learners for calculating loss.

Default: `1:NumTrained`

Output Arguments

margin

A numeric column vector of length `size(ens.X,1)`.

Examples

Find Out-of-Bag Classification Margins

Find the out-of-bag margins for a bagged ensemble from the Fisher iris data.

Load the sample data set.

```
load fisheriris
```

Train an ensemble of bagged classification trees.

```
ens = fitensemble(meas,species,'Method','Bag');
```

Find the number of out-of-bag margins that are equal to 1.

```
margin = oobMargin(ens);  
sum(margin == 1)
```

```
ans = 117
```

Drawing N out of N observations with replacement omits on average 37% ($1/e$) of observations for each decision tree. These are "out-of-bag" observations. For each observation, `oobLoss` estimates the out-of-bag prediction by averaging over predictions from all trees in the ensemble for which this observation is out of bag. It then compares the computed prediction against the true response for this observation. It calculates the out-of-bag error by comparing the out-of-bag predicted responses against the true responses for all observations used for training. This out-of-bag average is an unbiased estimator of the true ensemble error.

Margin

The classification margin is the difference between the classification score for the true class and maximal classification score for the false classes. `Margin` is a column vector with the same number of rows as in the matrix `ens.X`.

`margin` | `oobEdge` | `oobLoss` | `oobPredict`

oobMargin

Class: TreeBagger

Out-of-bag margins

Syntax

```
mar = oobMargin(B)
mar = oobMargin(B, 'param1', val1, 'param2', val2, ...)
```

Description

`mar = oobMargin(B)` computes an `Nobs-by-NTrees` matrix of classification margins for out-of-bag observations in the training data, using the trained bagger `B`.

`mar = oobMargin(B, 'param1', val1, 'param2', val2, ...)` specifies optional parameter name/value pairs:

<code>'Mode'</code>	Character vector or string scalar indicating how <code>oobMargin</code> computes errors. If set to <code>'cumulative'</code> (default), the method computes cumulative margins and <code>mar</code> is an <code>Nobs-by-NTrees</code> matrix, where the first column gives margins from <code>trees(1)</code> , second column gives margins from <code>trees(1:2)</code> etc., up to <code>trees(1:NTrees)</code> . If set to <code>'individual'</code> , <code>mar</code> is an <code>Nobs-by-NTrees</code> matrix, where each column gives margins from each tree in the ensemble. If set to <code>'ensemble'</code> , <code>mar</code> is a single column of length <code>Nobs</code> showing the cumulative margins for the entire ensemble.
---------------------	--

- 'Trees' Vector of indices indicating what trees to include in this calculation. By default, this argument is set to 'all' and the method uses all trees. If 'Trees' is a numeric vector, the method returns an Nobs-by-NTrees matrix for 'cumulative' and 'individual' modes, where NTrees is the number of elements in the input vector, and a single column for 'ensemble' mode. For example, in the 'cumulative' mode, the first column gives margins from `trees(1)`, the second column gives margins from `trees(1:2)` etc.
- 'TreeWeights' Vector of tree weights. This vector must have the same length as the 'Trees' vector. `oobMargin` uses these weights to combine output from the specified trees by taking a weighted average instead of the simple nonweighted majority vote. You cannot use this argument in the 'individual' mode.

See Also

`CompactTreeBagger.margin`

oobMeanMargin

Class: TreeBagger

Out-of-bag mean margins

Syntax

```
mar = oobMeanMargin(B)
mar = oobMeanMargin(B, 'param1', val1, 'param2', val2, ...)
```

Description

`mar = oobMeanMargin(B)` computes average classification margins for out-of-bag observations in the training data, using the trained bagger `B`. `oobMeanMargin` averages the margins over all out-of-bag observations. `mar` is a row-vector of length `NTrees`, where `NTrees` is the number of trees in the ensemble.

`mar = oobMeanMargin(B, 'param1', val1, 'param2', val2, ...)` specifies optional parameter name/value pairs:

<code>'Mode'</code>	Character vector or string scalar indicating how <code>oobMeanMargin</code> computes errors. If set to <code>'cumulative'</code> (default), is a vector of length <code>NTrees</code> where the first element gives mean margin from <code>trees(1)</code> , second column gives mean margins from <code>trees(1:2)</code> etc., up to <code>trees(1:NTrees)</code> . If set to <code>'individual'</code> , <code>mar</code> is a vector of length <code>NTrees</code> , where each element is a mean margin from each tree in the ensemble. If set to <code>'ensemble'</code> , <code>mar</code> is a scalar showing the cumulative mean margin for the entire ensemble.
---------------------	---

- 'Trees' Vector of indices indicating what trees to include in this calculation. By default, this argument is set to 'all' and the method uses all trees. If 'Trees' is a numeric vector, the method returns a vector of length `NTrees` for 'cumulative' and 'individual' modes, where `NTrees` is the number of elements in the input vector, and a scalar for 'ensemble' mode. For example, in the 'cumulative' mode, the first element gives mean margin from `trees(1)`, the second element gives mean margin from `trees(1:2)` etc.
- 'TreeWeights' Vector of tree weights. This vector must have the same length as the 'Trees' vector. `oobMeanMargin` uses these weights to combine output from the specified trees by taking a weighted average instead of the simple nonweighted majority vote. You cannot use this argument in the 'individual' mode.

See Also

`CompactTreeBagger.meanMargin`

oobPermutedPredictorImportance

Predictor importance estimates by permutation of out-of-bag predictor observations for random forest of classification trees

Syntax

```
Imp = oobPermutedPredictorImportance(Mdl)
Imp = oobPermutedPredictorImportance(Mdl, Name, Value)
```

Description

`Imp = oobPermutedPredictorImportance(Mdl)` returns a vector of out-of-bag, predictor importance estimates by permutation on page 32-4731 using the random forest of classification trees `Mdl`. `Mdl` must be a `ClassificationBaggedEnsemble` model object.

`Imp = oobPermutedPredictorImportance(Mdl, Name, Value)` uses additional options specified by one or more `Name, Value` pair arguments. For example, you can speed up computation using parallel computing or indicate which trees to use in the predictor importance estimation.

Input Arguments

Mdl — Random forest of classification trees

`ClassificationBaggedEnsemble` model object

Random forest of classification trees, specified as a `ClassificationBaggedEnsemble` model object created by `fitcensemble`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes.

You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Learners — Indices of learners to use in predictor importance estimation

`1:Mdl.NumTrained` (default) | numeric vector of positive integers

Indices of learners to use in predictor importance estimation, specified as the comma-separated pair consisting of 'Learners' and a numeric vector of positive integers. Values must be at most `Mdl.NumTrained`. When `oobPermutedPredictorImportance` estimates the predictor importance, it includes the learners in `Mdl.Trained(learners)` only, where `learners` is the value of 'Learners'.

Example: 'Learners', [1:2:Mdl.NumTrained]

Options — Parallel computing options

`[]` (default) | structure array returned by `statset`

Parallel computing options, specified as the comma-separated pair consisting of 'Options' and a structure array returned by `statset`. 'Options' requires a Parallel Computing Toolbox license.

`oobPermutedPredictorImportance` uses the 'UseParallel' field only. `statset('UseParallel', true)` invokes a pool of workers.

Example: 'Options', `statset('UseParallel', true)`

Output Arguments

Imp — Out-of-bag, predictor importance estimates by permutation

numeric vector

Out-of-bag, predictor importance estimates by permutation on page 32-4731, returned as a 1-by- p numeric vector. p is the number of predictor variables in the training data (`size(Mdl.X, 2)`). `Imp(j)` is the predictor importance of the predictor `Mdl.PredictorNames(j)`.

Examples

Estimate Importance of Predictors

Load the census1994 data set. Consider a model that predicts a person's salary category given their age, working class, education level, marital status, race, sex, capital gain and loss, and number of working hours per week.

```
load census1994
X = adultdata(:,{'age', 'workClass', 'education_num', 'marital_status', 'race', ...
    'sex', 'capital_gain', 'capital_loss', 'hours_per_week', 'salary'});
```

You can train a random forest of 50 classification trees using the entire data set.

```
Mdl = fitcensemble(X, 'salary', 'Method', 'Bag', 'NumLearningCycles', 50);
```

`fitcensemble` uses a default template tree object `templateTree()` as a weak learner when 'Method' is 'Bag'. In this example, for reproducibility, specify 'Reproducible', true when you create a tree template object, and then use the object as a weak learner.

```
rng('default') % For reproducibility
t = templateTree('Reproducible', true); % For reproducibility of random predictor selection
Mdl = fitcensemble(X, 'salary', 'Method', 'Bag', 'NumLearningCycles', 50, 'Learners', t);
```

Mdl is a `ClassificationBaggedEnsemble` model.

Estimate predictor importance measures by permuting out-of-bag observations. Compare the estimates using a bar graph.

```
imp = oobPermutedPredictorImportance(Mdl);

figure;
bar(imp);
title('Out-of-Bag Permuted Predictor Importance Estimates');
ylabel('Estimates');
xlabel('Predictors');
h = gca;
h.XTickLabel = Mdl.PredictorNames;
h.XTickLabelRotation = 45;
h.TickLabelInterpreter = 'none';
```

`imp` is a 1-by-9 vector of predictor importance estimates. Larger values indicate predictors that have a greater influence on predictions. In this case, `marital_status` is the most important predictor, followed by `capital_gain`.

Unbiased Estimates of Predictor Importance Using Parallel Computing

Load the `census1994` data set. Consider a model that predicts a person's salary category given their age, working class, education level, marital status, race, sex, capital gain and loss, and number of working hours per week.

```
load census1994
X = adultdata(:,{'age','workClass','education_num','marital_status','race', ...
               'sex','capital_gain','capital_loss','hours_per_week','salary'});
```

Display the number of categories represented in the categorical variables using `summary`.

```
summary(X)
```

>50K       7841

```

Because there are few categories represented in the categorical variables compared to levels in the continuous variables, the standard CART, predictor-splitting algorithm prefers splitting a continuous predictor over the categorical variables.

Train a random forest of 50 classification trees using the entire data set. To grow unbiased trees, specify usage of the curvature test for splitting predictors. Because there are missing values in the data, specify usage of surrogate splits. To reproduce random predictor selections, set the seed of the random number generator by using `rng` and specify `'Reproducible',true`.

```

rng('default') % For reproducibility
t = templateTree('PredictorSelection','curvature','Surrogate','on', ...
    'Reproducible',true); % For reproducibility of random predictor selections
Mdl = fitensemble(X,'salary','Method','bag','NumLearningCycles',50, ...
    'Learners',t);

```

Estimate predictor importance measures by permuting out-of-bag observations. Perform calculations in parallel.

```

options = statset('UseParallel',true);
imp = oobPermutedPredictorImportance(Mdl,'Options',options);

```

```

Starting parallel pool (parpool) using the 'local' profile ...
Connected to the parallel pool (number of workers: 6).

```

Compare the estimates using a bar graph.

```

figure
bar(imp)
title('Out-of-Bag Permuted Predictor Importance Estimates')
ylabel('Estimates')
xlabel('Predictors')
h = gca;

```

```
h.XTickLabel = Mdl.PredictorNames;  
h.XTickLabelRotation = 45;  
h.TickLabelInterpreter = 'none';
```

In this case, `capital_gain` is the most important predictor, followed by `marital_status`. Compare these results to the results in “Estimate Importance of Predictors” on page 32-4724.

Definitions

Out-of-Bag, Predictor Importance Estimates by Permutation

Out-of-bag, predictor importance estimates by permutation measure how influential the predictor variables in the model are at predicting the response. The influence of a predictor increases with the value of this measure.

If a predictor is influential in prediction, then permuting its values should affect the model error. If a predictor is not influential, then permuting its values should have little to no effect on the model error.

The following process describes the estimation of out-of-bag predictor importance values by permutation. Suppose that R is a random forest of T learners and p is the number of predictors in the training data.

- 1 For tree t , $t = 1, \dots, T$:
 - a Identify the out-of-bag observations and the indices of the predictor variables that were split to grow tree t , $s_t \subseteq \{1, \dots, p\}$.
 - b Estimate the out-of-bag error ε_t .
 - c For each predictor variable x_j , $j \in s_t$:
 - i Randomly permute the observations of x_j .
 - ii Estimate the model error, ε_{tj} , using the out-of-bag observations containing the permuted values of x_j .
 - iii Take the difference $d_{tj} = \varepsilon_{tj} - \varepsilon_t$. Predictor variables not split when growing tree t are attributed a difference of 0.
- 2 For each predictor variable in the training data, compute the mean, \bar{d}_j , and standard deviation, σ_j , of the differences over the learners, $j = 1, \dots, p$.
- 3 The out-of-bag predictor importance by permutation for x_j is \bar{d}_j/σ_j .

Tips

When growing a random forest using `fitcensemble`:

- Standard CART tends to select split predictors containing many distinct values, e.g., continuous variables, over those containing few distinct values, e.g., categorical variables [3]. If the predictor data set is heterogeneous, or if there are predictors that have relatively fewer distinct values than other variables, then consider specifying the curvature or interaction test.
- Trees grown using standard CART are not sensitive to predictor variable interactions. Also, such trees are less likely to identify important variables in the presence of many irrelevant predictors than the application of the interaction test. Therefore, to account for predictor interactions and identify importance variables in the presence of many irrelevant variables, specify the interaction test [2].
- If the training data includes many predictors and you want to analyze predictor importance, then specify 'NumVariablesToSample' of the `templateTree` function as 'all' for the tree learners of the ensemble. Otherwise, the software might not select some predictors, underestimating their importance.

For more details, see `templateTree` and “Choose Split Predictor Selection Technique” on page 19-19.

Introduced in R2016b

oobPermutedPredictorImportance

Predictor importance estimates by permutation of out-of-bag predictor observations for random forest of regression trees

Syntax

```
Imp = oobPermutedPredictorImportance(Mdl)
Imp = oobPermutedPredictorImportance(Mdl, Name, Value)
```

Description

`Imp = oobPermutedPredictorImportance(Mdl)` returns a vector of out-of-bag, predictor importance estimates by permutation on page 32-4740 using the random forest of regression trees `Mdl`. `Mdl` must be a `RegressionBaggedEnsemble` model object.

`Imp = oobPermutedPredictorImportance(Mdl, Name, Value)` uses additional options specified by one or more `Name, Value` pair arguments. For example, you can speed up computation using parallel computing or indicate which trees to use in the predictor importance estimation.

Input Arguments

Mdl — Random forest of regression trees

`RegressionBaggedEnsemble` model object

Random forest of regression trees, specified as a `RegressionBaggedEnsemble` model object created by `fitrensemble`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Learners — Indices of learners to use in predictor importance estimation

1:Mdl.NumTrained (default) | numeric vector of positive integers

Indices of learners to use in predictor importance estimation, specified as the comma-separated pair consisting of 'Learners' and a numeric vector of positive integers. Values must be at most Mdl.NumTrained. When oobPermutedPredictorImportance estimates the predictor importance, it includes the learners in Mdl.Trained(*learners*) only, where *learners* is the value of 'Learners'.

Example: 'Learners',[1:2:Mdl.NumTrained]

Options — Parallel computing options

[] (default) | structure array returned by `statset`

Parallel computing options, specified as the comma-separated pair consisting of 'Options' and a structure array returned by `statset`. 'Options' requires a Parallel Computing Toolbox license.

`oobPermutedPredictorImportance` uses the 'UseParallel' field only. `statset('UseParallel',true)` invokes a pool of workers.

Example: 'Options',`statset('UseParallel',true)`

Output Arguments

Imp — Out-of-bag, predictor importance estimates by permutation

numeric vector

Out-of-bag, predictor importance estimates by permutation on page 32-4740, returned as a 1-by-*p* numeric vector. *p* is the number of predictor variables in the training data (`size(Mdl.X,2)`). `Imp(j)` is the predictor importance of the predictor `Mdl.PredictorNames(j)`.

Examples

Estimate Importance of Predictors

Load the `carsmall` data set. Consider a model that predicts the mean fuel economy of a car given its acceleration, number of cylinders, engine displacement, horsepower,

manufacturer, model year, and weight. Consider `Cylinders`, `Mfg`, and `Model_Year` as categorical variables.

```
load carsmall
Cylinders = categorical(Cylinders);
Mfg = categorical(cellstr(Mfg));
Model_Year = categorical(Model_Year);
X = table(Acceleration,Cylinders,Displacement,Horsepower,Mfg,...
         Model_Year,Weight,MPG);
```

You can train a random forest of 500 regression trees using the entire data set.

```
Mdl = fitrensemble(X,'MPG','Method','Bag','NumLearningCycles',500);
```

`fitrensemble` uses a default template tree object `templateTree()` as a weak learner when 'Method' is 'Bag'. In this example, for reproducibility, specify 'Reproducible', true when you create a tree template object, and then use the object as a weak learner.

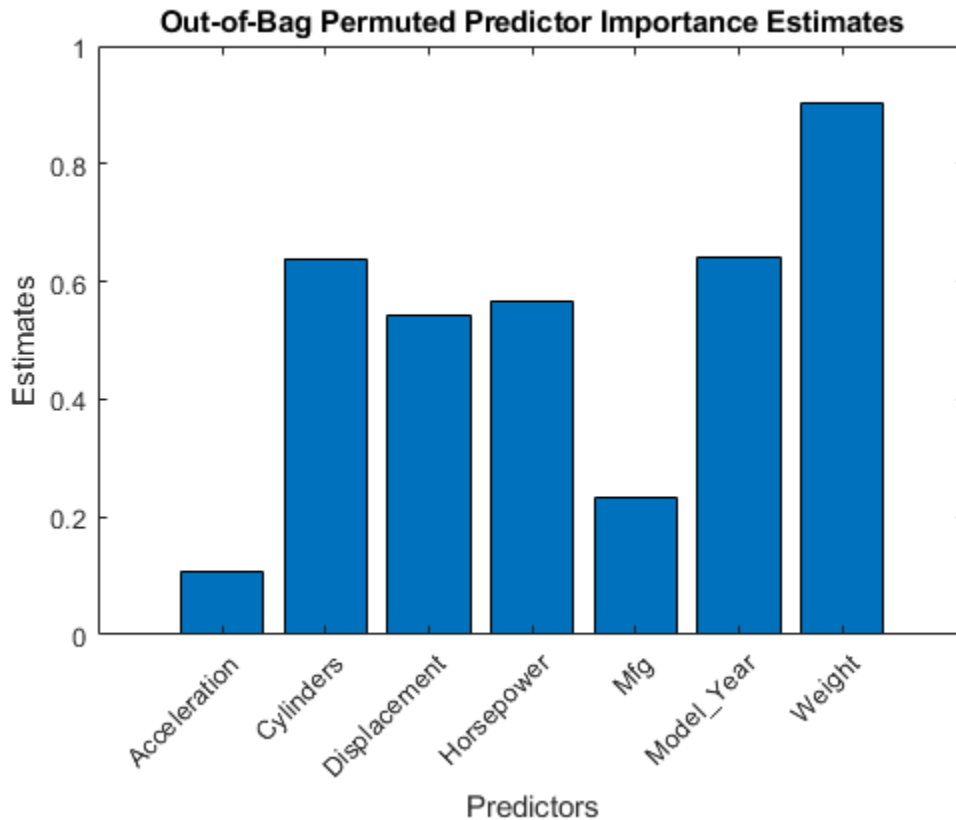

```
rng('default') % For reproducibility
t = templateTree('Reproducible',true); % For reproducibility of random predictor selection
Mdl = fitrensemble(X,'MPG','Method','Bag','NumLearningCycles',50,'Learners',t);
```

`Mdl` is a `RegressionBaggedEnsemble` model.

Estimate predictor importance measures by permuting out-of-bag observations. Compare the estimates using a bar graph.

```
imp = oobPermutedPredictorImportance(Mdl);

figure;
bar(imp);
title('Out-of-Bag Permuted Predictor Importance Estimates');
ylabel('Estimates');
xlabel('Predictors');
h = gca;
h.XTickLabel = Mdl.PredictorNames;
h.XTickLabelRotation = 45;
h.TickLabelInterpreter = 'none';
```

`imp` is a 1-by-7 vector of predictor importance estimates. Larger values indicate predictors that have a greater influence on predictions. In this case, `Weight` is the most important predictor, followed by `Model_Year`.

Unbiased Estimates of Predictor Importance Using Parallel Computing

Load the `carsmall` data set. Consider a model that predicts the mean fuel economy of a car given its acceleration, number of cylinders, engine displacement, horsepower, manufacturer, model year, and weight. Consider `Cylinders`, `Mfg`, and `Model_Year` as categorical variables.

```
load carsmall
Cylinders = categorical(Cylinders);
Mfg = categorical(cellstr(Mfg));
Model_Year = categorical(Model_Year);
X = table(Acceleration,Cylinders,Displacement,Horsepower,Mfg,...
         Model_Year,Weight,MPG);
```

Display the number of categories represented in the categorical variables.

```
numCylinders = numel(categories(Cylinders))

numCylinders = 3

numMfg = numel(categories(Mfg))

numMfg = 28

numModelYear = numel(categories(Model_Year))

numModelYear = 3
```

Because there are 3 categories only in `Cylinders` and `Model_Year`, the standard CART, predictor-splitting algorithm prefers splitting a continuous predictor over these two variables.

Train a random forest of 500 regression trees using the entire data set. To grow unbiased trees, specify usage of the curvature test for splitting predictors. Because there are missing values in the data, specify usage of surrogate splits. To reproduce random predictor selections, set the seed of the random number generator by using `rng` and specify `'Reproducible',true`.

```
rng('default'); % For reproducibility
t = templateTree('PredictorSelection','curvature','Surrogate','on', ...
               'Reproducible',true); % For reproducibility of random predictor selections
Mdl = fitrensemble(X,'MPG','Method','bag','NumLearningCycles',500, ...
                 'Learners',t);
```

Estimate predictor importance measures by permuting out-of-bag observations. Perform calculations in parallel.

```
options = statset('UseParallel',true);
imp = oobPermutedPredictorImportance(Mdl,'Options',options);
```

```
Starting parallel pool (parpool) using the 'local' profile ...
Connected to the parallel pool (number of workers: 6).
```

Compare the estimates using a bar graph.

```
figure;  
bar(imp);  
title('Out-of-Bag Permuted Predictor Importance Estimates');  
ylabel('Estimates');  
xlabel('Predictors');  
h = gca;  
h.XTickLabel = Mdl.PredictorNames;  
h.XTickLabelRotation = 45;  
h.TickLabelInterpreter = 'none';
```

In this case, `Model_Year` is the most important predictor, followed by `Cylinders`. Compare these results to the results in “Estimate Importance of Predictors” on page 32-4735.

Definitions

Out-of-Bag, Predictor Importance Estimates by Permutation

Out-of-bag, predictor importance estimates by permutation measure how influential the predictor variables in the model are at predicting the response. The influence of a predictor increases with the value of this measure.

If a predictor is influential in prediction, then permuting its values should affect the model error. If a predictor is not influential, then permuting its values should have little to no effect on the model error.

The following process describes the estimation of out-of-bag predictor importance values by permutation. Suppose that R is a random forest of T learners and p is the number of predictors in the training data.

- 1 For tree t , $t = 1, \dots, T$:
 - a Identify the out-of-bag observations and the indices of the predictor variables that were split to grow tree t , $s_t \subseteq \{1, \dots, p\}$.
 - b Estimate the out-of-bag error ε_t .
 - c For each predictor variable x_j , $j \in s_t$:
 - i Randomly permute the observations of x_j .
 - ii Estimate the model error, ε_{tj} , using the out-of-bag observations containing the permuted values of x_j .
 - iii Take the difference $d_{tj} = \varepsilon_{tj} - \varepsilon_t$. Predictor variables not split when growing tree t are attributed a difference of 0.
- 2 For each predictor variable in the training data, compute the mean, \bar{d}_j , and standard deviation, σ_j , of the differences over the learners, $j = 1, \dots, p$.
- 3 The out-of-bag predictor importance by permutation for x_j is \bar{d}_j / σ_j .

Tips

When growing a random forest using `fitrensemble`:

- Standard CART tends to select split predictors containing many distinct values, e.g., continuous variables, over those containing few distinct values, e.g., categorical variables [3]. If the predictor data set is heterogeneous, or if there are predictors that have relatively fewer distinct values than other variables, then consider specifying the curvature or interaction test.
- Trees grown using standard CART are not sensitive to predictor variable interactions. Also, such trees are less likely to identify important variables in the presence of many irrelevant predictors than the application of the interaction test. Therefore, to account for predictor interactions and identify importance variables in the presence of many irrelevant variables, specify the interaction test [2].
- If the training data includes many predictors and you want to analyze predictor importance, then specify `'NumVariablesToSample'` of the `templateTree` function as `'all'` for the tree learners of the ensemble. Otherwise, the software might not select some predictors, underestimating their importance.

For more details, see `templateTree` and “Choose Split Predictor Selection Technique” on page 19-19.

oobPredict

Predict out-of-bag response of ensemble

Syntax

```
[label,score] = oobPredict(ens)
[label,score] = oobPredict(ens,Name,Value)
```

Description

[label,score] = oobPredict(ens) returns class labels and scores for ens for out-of-bag data.

[label,score] = oobPredict(ens,Name,Value) computes labels and scores with additional options specified by one or more Name,Value pair arguments.

Input Arguments

ens

A classification bagged ensemble, constructed with fitcensemble.

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

learners

Indices of weak learners in the ensemble ranging from 1 to ens.NumTrained. oobEdge uses only these learners for calculating loss.

Default: 1:NumTrained

Output Arguments

label

Classification labels of the same data type as the training data `Y`. (The software treats string arrays as cell arrays of character vectors.) There are `N` elements or rows, where `N` is the number of training observations. The label is the class with the highest score. In case of a tie, the label is earliest in `ens.ClassNames`.

score

An `N`-by-`K` numeric matrix for `N` observations and `K` classes. A high score indicates that an observation is likely to come from this class. Scores are in the range 0 to 1.

Examples

Find Out-of-Bag Response of Classification Ensemble

Find the out-of-bag predictions and scores for the Fisher iris data. Find the scores with notable uncertainty in the resulting classifications.

Load the sample data set.

```
load fisheriris
```

Train an ensemble of bagged classification trees.

```
ens = fitcensemble(meas,species,'Method','Bag');
```

Find the out-of-bag predictions and scores.

```
[label,score] = oobPredict(ens);
```

Find the scores in the range (0.2, 0.8). These scores have notable uncertainty in the resulting classifications.

```
unsure = ((score > .2) & (score < .8));  
sum(sum(unsure)) % Number of uncertain predictions
```

```
ans = 20
```

Definitions

Out of Bag

Bagging, which stands for “bootstrap aggregation”, is a type of ensemble learning. To bag a weak learner such as a decision tree on a dataset, `fitensemble` generates many bootstrap replicas of the dataset and grows decision trees on these replicas.

`fitensemble` obtains each bootstrap replica by randomly selecting N observations out of N with replacement, where N is the dataset size. To find the predicted response of a trained ensemble, `predict` takes an average over predictions from individual trees.

Drawing N out of N observations with replacement omits on average 37% ($1/e$) of observations for each decision tree. These are "out-of-bag" observations. For each observation, `oobLoss` estimates the out-of-bag prediction by averaging over predictions from all trees in the ensemble for which this observation is out of bag. It then compares the computed prediction against the true response for this observation. It calculates the out-of-bag error by comparing the out-of-bag predicted responses against the true responses for all observations used for training. This out-of-bag average is an unbiased estimator of the true ensemble error.

Score (ensemble)

For ensembles, a classification score represents the confidence of a classification into a class. The higher the score, the higher the confidence.

Different ensemble algorithms have different definitions for their scores. Furthermore, the range of scores depends on ensemble type. For example:

- `AdaBoostM1` scores range from $-\infty$ to ∞ .
- Bag scores range from 0 to 1.

oobPredict

Predict out-of-bag response of ensemble

Syntax

```
Yfit = oobPredict(ens)
Yfit = oobPredict(ens,Name,Value)
```

Description

`Yfit = oobPredict(ens)` returns the predicted responses for the out-of-bag data in `ens`.

`Yfit = oobPredict(ens,Name,Value)` predicts responses with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

ens

A regression bagged ensemble, constructed with `fitrensemble`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

learners

Indices of weak learners in the ensemble ranging from 1 to `NumTrained`. `oobLoss` uses only these learners for calculating loss.

Default: `1:NumTrained`

Output Arguments

Yfit

A vector of predicted responses for out-of-bag data. Yfit has `size(ens.X,1)` elements.

You can find the indices of out-of-bag observations for weak learner L with the command

```
~ens.UseObsForLearner(:,L)
```

Examples

Find Out-of-Bag Response of Regression Ensemble

Compute the out-of-bag predictions for the `carsmall` data set. Display the first three terms of the fit.

Load the `carsmall` data set and select displacement, horsepower, and vehicle weight as predictors.

```
load carsmall
X = [Displacement Horsepower Weight];
```

Train an ensemble of bagged regression trees.

```
ens = fitensemble(X,MPG,'Method','Bag');
```

Find the out-of-bag predictions, and display the first three terms of the fit.

```
Yfit = oobPredict(ens);
Yfit(1:3) % First three terms
```

```
ans = 3×1
```

```
16.1500
15.6942
15.9584
```

`oobLoss` | `predict`

oobPredict

Class: TreeBagger

Ensemble predictions for out-of-bag observations

Syntax

```
Y = oobPredict(B)
Y = oobPredict(B,Name,Value)
[Y,stdevs] = oobPredict(____)
[Y,scores] = oobPredict(____)
[Y,scores,stdevs] = oobPredict(____)
```

Description

`Y = oobPredict(B)` computes predicted responses using the trained bagger `B` for out-of-bag observations in the training data. The output has one prediction for each observation in the training data. The returned `Y` is a cell array of character vectors for classification and a numeric array for regression.

`Y = oobPredict(B,Name,Value)` specifies additional options using one or both name-value pair arguments:

- `'Trees'` — Array of tree indices to use for computation of responses. The default is `'all'`.
- `'TreeWeights'` — Array of `NTrees` weights for weighting votes from the specified trees, where `NTrees` is the number of trees in the ensemble.

For regression, `[Y,stdevs] = oobPredict(____)` also returns standard deviations of the computed responses over the ensemble of the grown trees using any of the input argument combinations in previous syntaxes.

For classification, `[Y,scores] = oobPredict(____)` also returns scores for all classes. `scores` is a matrix with one row per observation and one column per class. For each out-of-bag observation and each class, the score generated by each tree is the probability of

the observation originating from the class, computed as the fraction of observations of the class in a tree leaf. `oobPredict` averages these scores over all trees in the ensemble.

`[Y, scores, stdevs] = oobPredict(___)` also returns standard deviations of the computed scores for classification. `stdevs` is a matrix with one row per observation and one column per class, with standard deviations taken over the ensemble of the grown trees.

Algorithms

`oobPredict` and `predict` similarly predict classes and responses.

- In regression problems:
 - For each observation that is out of bag for at least one tree, `oobPredict` composes the weighted mean by selecting responses of trees in which the observation is out of bag. For this computation, the `'TreeWeights'` name-value pair argument specifies the weights.
 - For each observation that is in bag for all trees, the predicted response is the weighted mean of all of the training responses. For this computation, the `W` property of the `TreeBagger` model (i.e., the observation weights) specify the weights.
- In classification problems:
 - For each observation that is out of bag for at least one tree, `oobPredict` composes the weighted mean of the class posterior probabilities by selecting the trees in which the observation is out of bag. Consequently, the predicted class is the class corresponding to the largest weighted mean. For this computation, the `'TreeWeights'` name-value pair argument specifies the weights.
 - For each observation that is in bag for all trees, the predicted class is the weighted, most popular class over all training responses. For this computation, the `W` property of the `TreeBagger` model (i.e., the observation weights) specify the weights. If there are multiple most popular classes, `oobPredict` considers the one listed first in the `ClassNames` property of the `TreeBagger` model the most popular.

oobQuantileError

Class: TreeBagger

Out-of-bag quantile loss of bag of regression trees

Syntax

```
err = quantileError(Mdl)
err = quantileError(Mdl,Name,Value)
```

Description

`err = quantileError(Mdl)` returns half of the out-of-bag on page 32-4757 mean absolute deviation (MAD) from comparing the true responses in `Mdl.Y` to the predicted, out-of-bag medians at `Mdl.X`, the predictor data, and using the bag of regression trees `Mdl`. `Mdl` must be a `TreeBagger` model object.

`err = quantileError(Mdl,Name,Value)` uses additional options specified by one or more `Name,Value` pair arguments. For example, specify quantile probabilities, the error type, or which trees to include in the quantile-regression-error estimation.

Input Arguments

Mdl — Bag of regression trees

`TreeBagger` model object (default)

Bag of regression trees, specified as a `TreeBagger` model object created by `TreeBagger`.

- The value of `Mdl.Method` must be `regression`.
- When you train `Mdl` using `TreeBagger`, you must specify the name-value pair `'OOBPrediction','on'`. Consequently, `TreeBagger` saves required out-of-bag observation index matrix in `Mdl.OOBIndices`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Mode — Ensemble error type

'ensemble' (default) | 'cumulative' | 'individual'

Ensemble error type, specified as the comma-separated pair consisting of 'Mode' and a value in this table. Suppose τ is the value of `Quantile`.

Value	Description
'cumulative'	<code>err</code> is a <code>Mdl.NumTrees</code> -by- <code>numel(τ)</code> numeric matrix of cumulative quantile regression errors. <code>err(j,k)</code> is the $\tau(k)$ quantile regression error using the learners in <code>Mdl.Trees(1:j)</code> only.
'ensemble'	<code>err</code> is a 1-by- <code>numel(τ)</code> numeric vector of cumulative quantile regression errors for the entire ensemble. <code>err(k)</code> is the $\tau(k)$ ensemble quantile regression error.
'individual'	<code>err</code> is a <code>Mdl.NumTrees</code> -by- <code>numel(τ)</code> numeric matrix of quantile regression errors from individual learners. <code>err(j,k)</code> is the $\tau(k)$ quantile regression error using the learner in <code>Mdl.Trees(j)</code> only.

For 'cumulative' and 'individual', if you choose to include fewer trees in quantile estimation using `Trees`, then this action affects the number of rows in `err` and corresponding row indices.

Example: 'Mode', 'cumulative'

Quantile — Quantile probability

0.5 (default) | numeric vector containing values in [0,1]

Quantile probability, specified as the comma-separated pair consisting of 'Quantile' and a numeric vector containing values in the interval [0,1]. For each observation (row) in `Mdl.X`, `oobQuantileError` estimates corresponding quantiles for all probabilities in `Quantile`.

Example: 'Quantile', [0 0.25 0.5 0.75 1]

Data Types: single | double

Trees — Indices of trees to use in response estimation

'all' (default) | numeric vector of positive integers

Indices of trees to use in response estimation, specified as the comma-separated pair consisting of 'Trees' and 'all' or a numeric vector of positive integers. Indices correspond to the cells of `Mdl.Trees`; each cell therein contains a tree in the ensemble. The maximum value of `Trees` must be less than or equal to the number of trees in the ensemble (`Mdl.NumTrees`).

For 'all', `oobQuantileError` uses all trees in the ensemble (that is, the indices `1:Mdl.NumTrees`).

Values other than the default can affect the number of rows in `err`.

Example: 'Trees', [1 10 Mdl.NumTrees]

Data Types: char | string | single | double

TreeWeights — Weights to attribute to responses from individual trees

ones(Mdl.NumTrees, 1) (default) | numeric vector of nonnegative values

Weights to attribute to responses from individual trees, specified as the comma-separated pair consisting of 'TreeWeights' and a numeric vector of `numel(trees)` nonnegative values. `trees` is the value of `Trees`.

If you specify 'Mode', 'individual', then `oobQuantileError` ignores `TreeWeights`.

Data Types: single | double

Output Arguments

err — Half of out-of-bag quantile regression error

numeric scalar | numeric matrix

Half of the out-of-bag quantile regression error on page 32-4758, returned as a numeric scalar or T -by-`numel(tau)` matrix. `tau` is the value of `Quantile`.

T depends on the values of `Mode`, `Trees`, and `Quantile`. Suppose that you specify 'Quantile', `tau` and 'Trees', `trees`.

- For 'Mode', 'cumulative', `err` is a `numel(trees)`-by-`numel(tau)` numeric matrix. `err(j,k)` is the $\tau(k)$ cumulative, out-of-bag quantile regression error using the learners in `Mdl.Trees(trees(1:j))`.
- For 'Mode', 'ensemble', `err` is a 1-by-`numel(tau)` numeric vector. `err(k)` is the $\tau(k)$ cumulative, out-of-bag quantile regression error using the learners in `Mdl.Trees(trees)`.
- For 'Mode', 'individual', `err` is a `numel(trees)`-by-`numel(tau)` numeric matrix. `err(j,k)` is the $\tau(k)$ out-of-bag quantile regression error using the learner in `Mdl.Trees(trees(j))`.

Examples

Estimate Out-of-Bag Quantile Regression Error

Load the `carsmall` data set. Consider a model that predicts the fuel economy of a car given its engine displacement, weight, and number of cylinders. Consider `Cylinders` a categorical variable.

```
load carsmall
Cylinders = categorical(Cylinders);
X = table(Displacement,Weight,Cylinders,MPG);
```

Train an ensemble of bagged regression trees using the entire data set. Specify 100 weak learners and save the out-of-bag indices.

```
rng(1); % For reproducibility
Mdl = TreeBagger(100,X,'MPG','Method','regression','OOBPrediction','on');
```

`Mdl` is a `TreeBagger` ensemble.

Perform quantile regression, and out-of-bag estimate the MAD of the entire ensemble using the predicted conditional medians.

```
oobErr = oobQuantileError(Mdl)
```

```
oobErr = 1.5321
```

`oobErr` is an unbiased estimate of the quantile regression error for the entire ensemble.

Find Appropriate Ensemble Size Using Out-of-Bag Quantile Regression Error

Load the `carsmall` data set. Consider a model that predicts the fuel economy of a car given its engine displacement, weight, and number of cylinders.

```
load carsmall
X = table(Displacement,Weight,Cylinders,MPG);
```

Train an ensemble of bagged regression trees using the entire data set. Specify 250 weak learners and save the out-of-bag indices.

```
rng('default'); % For reproducibility
Mdl = TreeBagger(250,X,'MPG','Method','regression',...
    'OOBPrediction','on');
```

Estimate the cumulative, out-of-bag, 0.25, 0.5, and 0.75 quantile regression errors.

```
err = oobQuantileError(Mdl,'Quantile',[0.25 0.5 0.75],'Mode','cumulative');
```

`err` is a 250-by-3 matrix of cumulative, out-of-bag, quantile regression errors. Columns correspond to quantile probabilities and rows correspond to trees in the ensemble. The errors are cumulative, so they incorporate aggregated predictions from previous trees.

Plot the cumulative, out-of-bag, quantile errors on the same plot.

```
figure;
plot(err);
legend('0.25 quantile error','0.5 quantile error','0.75 quantile error');
ylabel('Out-of-bag quantile error');
xlabel('Tree index');
title('Cumulative, Out-of-Bag, Quantile Regression Error')
```

All quantile error curves appear to level off after training about 50 trees. So, training 50 trees appears to be sufficient to achieve minimal quantile error for the three quantile probabilities.

Definitions

Out-of-Bag

In a bagged ensemble, observations are out-of-bag when they are left out of the training sample for a particular learner. Observations are in-bag when they are used to train a particular learner.

When bagging learners, a practitioner takes a bootstrap sample (that is, a random sample with replacement) of size n for each learner, and then trains the learners using their respective bootstrap samples. Drawing n out of n observations with replacement omits on average about 37% of observations for each learner.

The out-of-bag ensemble error, the ensemble error estimated using out-of-bag observations only, is an unbiased estimator of the true ensemble error.

Quantile Regression Error

The quantile regression error of a model given observed predictor data and responses is the weighted mean absolute deviation (MAD). If the model under-predicts the response, then deviation weights are τ , the quantile probability. If the model over-predicts, then deviation weights are $1 - \tau$.

That is, the τ quantile regression error is

$$L_{\tau} = \tau \frac{\sum_{\{j: y_j \geq \hat{y}_{\tau, j}\}} w_j (y_j - \hat{y}_{\tau, j})}{\sum_{j=1}^n w_j} + (1 - \tau) \frac{\sum_{\{j: y_j < \hat{y}_{\tau, j}\}} w_j (\hat{y}_{\tau, j} - y_j)}{\sum_{j=1}^n w_j}.$$

y_j is true response j , $\hat{y}_{\tau, j}$ is the τ quantile that the model predicts, and w_j is observation weight j .

Tip

The out-of-bag ensemble error estimator is unbiased for the true ensemble error. So, to tune parameters of a random forest, estimate the out-of-bag ensemble error instead of implementing cross-validation.

Introduced in R2016b

oobQuantilePredict

Class: TreeBagger

Quantile predictions for out-of-bag observations from bag of regression trees

Syntax

```
YFit = oobQuantilePredict(Mdl)
YFit = oobQuantilePredict(Mdl,Name,Value)
[YFit,YW] = oobQuantilePredict( ___ )
```

Description

`YFit = oobQuantilePredict(Mdl)` returns a vector of medians of the predicted responses at all out-of-bag on page 32-4769 observations in `Mdl.X`, the predictor data, and using `Mdl`, which is a bag of regression trees. `Mdl` must be a `TreeBagger` model object and `Mdl.OOBIndices` must be nonempty.

`YFit = oobQuantilePredict(Mdl,Name,Value)` uses additional options specified by one or more `Name,Value` pair arguments. For example, specify quantile probabilities or trees to include for quantile estimation.

`[YFit,YW] = oobQuantilePredict(___)` also returns a sparse matrix of response weights on page 32-4770 using any of the previous syntaxes.

Input Arguments

Mdl — Bag of regression trees

`TreeBagger` model object (default)

Bag of regression trees, specified as a `TreeBagger` model object created by `TreeBagger`.

- The value of `Mdl.Method` must be `regression`.

- When you train `Mdl` using `TreeBagger`, you must specify the name-value pair `'OOBPrediction','on'`. Consequently, `TreeBagger` saves required out-of-bag observation index matrix in `Mdl.OOBIndices`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Quantile — Quantile probability

0.5 (default) | numeric vector containing values in [0,1]

Quantile probability, specified as the comma-separated pair consisting of `'Quantile'` and a numeric vector containing values in the interval [0,1]. For each observation (row) in `Mdl.X`, `oobQuantilePredict` estimates corresponding quantiles for all probabilities in `Quantile`.

Example: `'Quantile',[0 0.25 0.5 0.75 1]`

Data Types: `single` | `double`

Trees — Indices of trees to use in response estimation

'all' (default) | numeric vector of positive integers

Indices of trees to use in response estimation, specified as the comma-separated pair consisting of `'Trees'` and `'all'` or a numeric vector of positive integers. Indices correspond to the cells of `Mdl.Trees`; each cell therein contains a tree in the ensemble. The maximum value of `Trees` must be less than or equal to the number of trees in the ensemble (`Mdl.NumTrees`).

For `'all'`, `oobQuantilePredict` uses the indices `1:Mdl.NumTrees`.

Example: `'Trees',[1 10 Mdl.NumTrees]`

Data Types: `char` | `string` | `single` | `double`

TreeWeights — Weights to attribute to responses from individual trees

numeric vector of nonnegative values

Weights to attribute to responses from individual trees, specified as the comma-separated pair consisting of 'TreeWeights' and a numeric vector of `numel(trees)` nonnegative values. `trees` is the value of the `Trees` name-value pair argument.

The default is `ones(size(trees))`.

Data Types: `single` | `double`

Output Arguments

YFit — Estimated quantiles

numeric matrix

Estimated quantiles for out-of-bag observations, returned as an n -by-`numel(tau)` numeric matrix. n is the number of observations in the training data (`numel(Mdl.Y)`) and `tau` is the value of the `Quantile` name-value pair argument. That is, `YFit(j,k)` is the estimated $100 * tau(k)$ percentile of the response distribution given `X(j,:)` and using `Mdl`.

YW — Response weights

sparse matrix

Response weights on page 32-4770, returned as an n -by- n sparse matrix. n is the number of responses in the training data (`numel(Mdl.Y)`). `YW(:,j)` specifies the response weights for the observation in `Mdl.X(j,:)`.

`oobQuantilePredict` predicts quantiles using linear interpolation of the empirical cumulative distribution function (cdf). For a particular observation, you can use its response weights to estimate quantiles using alternative methods, such as approximating the cdf using kernel smoothing on page B-80.

Examples

Predict Out-of-Bag Medians Using Quantile Regression

Load the `carsmall` data set. Consider a model that predicts the fuel economy (in MPG) of a car given its engine displacement.

```
load carsmall
```

Train an ensemble of bagged regression trees using the entire data set. Specify 100 weak learners and save out-of-bag indices.

```
rng(1); % For reproducibility
Mdl = TreeBagger(100,Displacement,MPG,'Method','regression',...
    'OOBPrediction','on');
```

Mdl is a TreeBagger ensemble.

Perform quantile regression to predict the out-of-bag median fuel economy for all training observations.

```
oobMedianMPG = oobQuantilePredict(Mdl);
```

oobMedianMPG is an n-by-1 numeric vector of medians corresponding to the conditional distribution of the response given the sorted observations in Mdl.X. n is the number of observations, size(Mdl.X,1).

Sort the observations in ascending order. Plot the observations and the estimated medians on the same figure. Compare the out-of-bag median and mean responses.

```
[sX,idx] = sort(Mdl.X);
oobMeanMPG = oobPredict(Mdl);

figure;
plot(Displacement,MPG,'k.');
hold on
plot(sX,oobMedianMPG(idx));
plot(sX,oobMeanMPG(idx),'r--');
ylabel('Fuel economy');
xlabel('Engine displacement');
legend('Data','Out-of-bag median','Out-of-bag mean');
hold off;
```

Estimate Out-of-Bag Prediction Intervals Using Percentiles

Load the `carsmall` data set. Consider a model that predicts the fuel economy of a car (in MPG) given its engine displacement.

```
load carsmall
```

Train an ensemble of bagged regression trees using the entire data set. Specify 100 weak learners and save out-of-bag indices.

```
rng(1); % For reproducibility
Mdl = TreeBagger(100,Displacement,MPG,'Method','regression',...
    'OOBPrediction','on');
```

Perform quantile regression to predict the out-of-bag 2.5% and 97.5% percentiles.

```
oobQuantPredInts = oobQuantilePredict(Mdl,'Quantile',[0.025,0.975]);
```

`oobQuantPredInts` is an n -by-2 numeric matrix of prediction intervals corresponding to the out-of-bag observations in `Mdl.X`. n is number of observations, `size(Mdl.X,1)`. The first column contains the 2.5% percentiles and the second column contains the 97.5% percentiles.

Plot the observations and the estimated medians on the same figure. Compare the percentile prediction intervals and the 95% prediction intervals, assuming the conditional distribution of MPG is Gaussian.

```
[oobMeanMPG,oobSTEMeanMPG] = oobPredict(Mdl);
STDNPredInts = oobMeanMPG + [-1 1]*norminv(0.975).*oobSTEMeanMPG;
[sX,idx] = sort(Mdl.X);

figure;
h1 = plot(Displacement,MPG,'k. ');
hold on
h2 = plot(sX,oobQuantPredInts(idx,:), 'b');
h3 = plot(sX,STDNPredInts(idx,:), 'r--');
ylabel('Fuel economy');
xlabel('Engine displacement');
legend([h1,h2(1),h3(1)],{'Data','95% percentile prediction intervals',...
    '95% Gaussian prediction intervals'});
hold off;
```

Estimate Out-of-Bag Conditional Cumulative Distribution Using Quantile Regression

Load the `carsmall` data set. Consider a model that predicts the fuel economy of a car (in MPG) given its engine displacement.

```
load carsmall
```

Train an ensemble of bagged regression trees using the entire data set. Specify 100 weak learners and save the out-of-bag indices.

```
rng(1); % For reproducibility
Mdl = TreeBagger(100,Displacement,MPG,'Method','regression',...
    'OOBPrediction','on');
```

Estimate the out-of-bag response weights.

```
[~,YW] = oobQuantilePredict(Mdl);
```

YW is an n-by-n sparse matrix containing the response weights. n is the number of training observations, numel(Y). The response weights for the observation in Mdl.X(j,:) are in YW(:,j). Response weights are independent of any specified quantile probabilities.

Estimate the out-of-bag, conditional cumulative distribution function (ccdf) of the responses by:

- 1 Sorting the responses in ascending order, and then sorting the response weights using the indices induced by sorting the responses.
- 2 Computing the cumulative sums over each column of the sorted response weights.

```
[sortY,sortIdx] = sort(Mdl.Y);
cpdf = full(YW(sortIdx,:));
ccdf = cumsum(cpdf);
```

ccdf(:,j) is the empirical out-of-bag ccdf of the response, given observation j.

Choose a random sample of four training observations. Plot the training sample and identify the chosen observations.

```
[randX,idx] = datasample(Mdl.X,4);
figure;
plot(Mdl.X,Mdl.Y,'o');
hold on
plot(randX,Mdl.Y(idx),'*','MarkerSize',10);
text(randX-10,Mdl.Y(idx)+1.5,{'obs. 1' 'obs. 2' 'obs. 3' 'obs. 4'});
legend('Training Data','Chosen Observations');
xlabel('Engine displacement')
ylabel('Fuel economy')
hold off
```

Plot the out-of-bag ccdf for the four chosen responses in the same figure.

```
figure;
plot(sortY,ccdf(:,idx));
legend('ccdf given obs. 1','ccdf given obs. 2',...
      'ccdf given obs. 3','ccdf given obs. 4',...
      'Location','SouthEast')
title('Out-of-Bag Conditional Cumulative Distribution Functions')
xlabel('Fuel economy')
ylabel('Empirical CDF')
```

Definitions

Out-of-Bag

In a bagged ensemble, observations are out-of-bag when they are left out of the training sample for a particular learner. Observations are in-bag when they are used to train a particular learner.

When bagging learners, a practitioner takes a bootstrap sample (that is, a random sample with replacement) of size n for each learner, and then trains the learners using their

respective bootstrap samples. Drawing n out of n observations with replacement omits on average about 37% of observations for each learner.

The out-of-bag ensemble error, the ensemble error estimated using out-of-bag observations only, is an unbiased estimator of the true ensemble error.

Quantile Random Forest

Quantile random forest [2] is a quantile-regression method that uses a random forest [1] of regression trees to model the conditional distribution of a response variable, given the value of predictor variables. You can use a fitted model to estimate quantiles in the conditional distribution of the response.

Besides quantile estimation, you can use quantile regression to estimate prediction intervals or detect outliers. For example:

- To estimate 95% quantile prediction intervals, estimate the 0.025 and 0.975 quantiles.
- To detect outliers, estimate the 0.01 and 0.99 quantiles. All observations smaller than the 0.01 quantile and larger than the 0.99 quantile are outliers. All observations that are outside the interval $[L, U]$ can be considered outliers:

$$L = Q_1 - 1.5 * IQR$$

and

$$U = Q_3 + 1.5 * IQR,$$

where:

- Q_1 is the 0.25 quantile.
- Q_3 is the 0.75 quantile.
- $IQR = Q_3 - Q_1$ (the interquartile range).

Response Weights

Response weights are scalars that represent the conditional distribution of the response given a value in the predictor space. The observations in the bootstrap samples and the leaves that the training and test observations share induce response weights.

Given the observation x , the response weight for observation j in the training sample using tree t in the ensemble is

$$w_{tj}(x) = \frac{I\{X_j \in S_t(x)\}}{\sum_{k=1}^{n_{\text{train}}} I\{X_k \in S_t(x)\}},$$

where:

- $I\{h\}$ is the indicator function.
- $S_t(x)$ is the leaf of tree t containing x .
- n_{train} is the number of training observations.

In other words, the response weights of a particular tree form the conditional relative frequency distribution of the response.

The response weights for the entire ensemble are averaged over the trees:

$$w_j^*(x) = \frac{1}{T} \sum_{t=1}^T w_{tj}(x).$$

Algorithms

`oobQuantilePredict` estimates out-of-bag quantiles by applying `quantilePredict` to all observations in the training data (`Mdl.X`). For each observation, the method uses only the trees for which the observation is out-of-bag.

For observations that are in-bag for all trees in the ensemble, `oobQuantilePredict` assigns the sample quantile of the response data. In other words, `oobQuantilePredict` does not use quantile regression for out-of-bag observations. Instead, it assigns `quantile(Mdl.Y, tau)`, where `tau` is the value of the `Quantile` name-value pair argument.

Introduced in R2016b

optimizableVariable

Variable description for bayesopt or other optimizers

Description

Create variables for optimizers.

Creation

Syntax

```
variable = optimizableVariable(Name,Range)  
variable = optimizableVariable(Name,Range,Name,Value)
```

Description

`variable = optimizableVariable(Name,Range)` creates a variable with the specified name and range of values.

`variable = optimizableVariable(Name,Range,Name,Value)` sets properties on page 32-4773 using name-value pair arguments. For example, `optimizableVariable('xvar',[1 1000],'Type','integer')` creates an integer variable from 1 to 1000. You can specify multiple name-value pair arguments. Enclose each property name in quotes.

Properties

Name — Variable name

character vector | string scalar

Variable name, specified as a character vector or string scalar. The name must be unique, meaning different from those of other variables in the optimization.

Note

- There are two names associated with an `optimizableVariable`:
 - The MATLAB workspace variable name
 - The name of the variable in the optimization

For example,

```
xvar = optimizableVariable('spacevar',[1,100]);
```

`xvar` is the MATLAB workspace variable, and `'spacevar'` is the variable in the optimization.

Use these names as follows:

- Use `xvar` as an element in the vector of variables you pass to `bayesopt`. For example,
 - Use `'spacevar'` as the name of the variable in the optimization. For example, in an objective function,

```
results = bayesopt(fun,[xvar,tvar])  
  
function objective = mysvmfun(x,cdata,grp)  
SVMModel = fitcsvm(cdata,grp,'KernelFunction','rbf',...  
    'BoxConstraint',x.spacevar,...  
    'KernelScale',x.tvar);  
objective = kfoldLoss(crossval(SVMModel));
```

Example: `'X1'`

Data Types: `char` | `string`

Range — Variable range

2-element increasing real vector | string array or cell array of names of categorical variables

Variable range, specified as a 2-element finite increasing real vector, or as a string array or cell array of names of categorical variables:

- For real or integer variables, `Range` gives the lower bound and upper bound of that variable.

- For categorical variables, Range gives the possible values.

Example: [-10,1]

Example: {'red','blue','black'}

Data Types: double | string | cell

Type — Variable type

'real' (default) | 'integer' | 'categorical'

Variable type, specified as 'real' (real variable), 'integer' (integer variable), or 'categorical' (categorical variable).

Note The MATLAB data type of both 'real' and 'integer' variables is the standard double-precision floating point number. The data type of 'categorical' variables is categorical. So, for example, to read a value of a categorical variable named 'colorv' in a table of variables named x, use the command `char(x.colorv)`. For an example, see the objective function in “Custom Output Functions” on page 10-22.

Example: 'Type', 'categorical'

Transform — Transform applied to variable

'none' (default) | 'log'

Transform applied to variable, specified as 'none' (no transform) or 'log' (logarithmic transform).

For 'log', the variable must be 'real' or 'integer' and positive. The variable is searched and modeled on a log scale.

Example: 'Transform', 'log'

Optimize — Indication to use variable in optimization

true (default) | false

Indication to use variable in optimization, specified as true (use the variable) or false (do not use the variable).

Example: 'Optimize', false

Data Types: logical

Note You can use dot notation to change the following properties after creation.

- Range of real or integer variables. For example,

```
xvar = optimizableVariable('x',[-10,10]);  
% Modify the range:  
xvar.Range = [1,5];
```

- Type between 'integer' and 'real'. For example,

```
xvar.Type = 'integer';
```

- Transform of real or integer variables between 'log' and 'none'. For example,

```
xvar.Transform = 'log';
```

You can use this flexibility, for example, to tweak an optimization that you want to continue. Update the range or transform using dot notation and then call `resume`.

Object Functions

`bayesopt` Select optimal machine learning hyperparameters using Bayesian optimization

Examples

Variables for Optimization Examples

Real variable from 0 to 1:

```
var1 = optimizableVariable('xvar',[0 1])
```

```
var1 =  
  optimizableVariable with properties:
```

```
    Name: 'xvar'  
   Range: [0 1]  
    Type: 'real'  
 Transform: 'none'  
  Optimize: 1
```

Integer variable from 1 to 1000 on a log scale:

```
var2 = optimizableVariable('ivar',[1 1000],'Type','integer','Transform','log')
```

```
var2 =  
  optimizableVariable with properties:
```

```
    Name: 'ivar'  
    Range: [1 1000]  
    Type: 'integer'  
  Transform: 'log'  
  Optimize: 1
```

Categorical variable of rainbow colors:

```
var3 = optimizableVariable('rvar',{'r' 'o' 'y' 'g' 'b' 'i' 'v'},'Type','categorical')
```

```
var3 =  
  optimizableVariable with properties:
```

```
    Name: 'rvar'  
    Range: {'r' 'o' 'y' 'g' 'b' 'i' 'v'}  
    Type: 'categorical'  
  Transform: 'none'  
  Optimize: 1
```

Introduced in R2016b

ordinal

Arrays for ordinal data

Note The `nominal` and `ordinal` array data types might be removed in a future release. To represent ordered and unordered discrete, nonnumeric data, use the “Categorical Arrays” (MATLAB) data type instead.

Description

Ordinal data are discrete, nonnumeric values that have a natural ordering. `ordinal` array objects provide efficient storage and convenient manipulation of such data, while also maintaining meaningful labels for the values.

You can manipulate `ordinal` arrays like ordinary numeric arrays, by subscripting, concatenating, and reshaping. Use `ordinal` arrays as grouping variables when the elements indicate the group to which an observation belongs.

Creation

Syntax

```
B = ordinal(X)
B = ordinal(X, labels)
B = ordinal(X, labels, levels)

B = ordinal(X, labels, [], edges)
```

Description

`B = ordinal(X)` creates an ordinal array `B` from the array `X`. `ordinal` creates the levels of `B` from the sorted unique values in `X`, and creates default labels for the levels.

`B = ordinal(X, labels)` labels the levels in `B` according to `labels`.

`B = ordinal(X, labels, levels)` creates an ordinal array with possible levels defined by `levels`.

`B = ordinal(X, labels, [], edges)` creates an ordinal array by binning the numeric array `X` with bin edges given by the numeric vector `edges`.

Input Arguments

X — Input array

numeric | logical | character | string | categorical | cell array of character vectors

Input array to convert to `ordinal`, specified as a numeric, logical, character, string, or categorical array, or a cell array of character vectors. The levels of the resulting `ordinal` array correspond to the sorted unique values in `X`.

labels — Labels for discrete levels

character array | string array | cell array of character vectors

Labels for the discrete levels, specified as a character array, string array, or cell array of character vectors. By default, `ordinal` assigns labels to the levels in `B` in order of the sorted unique values in `X`.

You can include duplicate labels in `labels` to merge multiple values in `X` into a single level in `B`.

Data Types: `char` | `string` | `cell`

levels — Possible ordinal levels

vector

Possible ordinal levels for the output `ordinal` array, specified as a vector whose values can be compared to those in `X` using the equality operator. `ordinal` assigns labels to each level from the corresponding elements of `labels`. If `X` contains any values not present in `levels`, the levels of the corresponding elements of `B` are undefined.

edges — Bin edges

numeric vector

Bin edges used to create the ordinal array by binning a numeric array, specified as a numeric vector. The uppermost bin includes values equal to the rightmost edge. `ordinal` assigns labels to each level in the resulting ordinal array from the corresponding

elements of `labels`. When you specify the `edges` input argument, it must have one more element than `labels`.

Output Arguments

B — Ordinal array

`ordinal` array object

Ordinal array, returned as an `ordinal` array object.

By default, an element of `B` is undefined if the corresponding element of `X` is `NaN` (when `X` is numeric), an empty character vector (when `X` is a character), an empty or missing string (when `X` is a string), or undefined (when `X` is categorical). `ordinal` treats such elements as undefined or missing and does not include entries for them among the possible levels. To create an explicit level for such elements instead of treating them as undefined, use the `levels` input argument and include `NaN`, the empty character vector, the empty or missing string, or an undefined element.

Properties

labels — Level labels

cell array of character vectors

This property is read-only.

Level labels, specified as a cell array of character vectors. Access labels using `getlabels`.

Data Types: `cell`

undeflabel — Label for undefined levels

'<undefined>' (default)

This property is read-only.

Label for undefined levels, specified as '<undefined>'. You can find undefined elements in categorical arrays by using `isundefined`.

Object Functions

addlevels	Add levels to nominal or ordinal arrays
droplevels	Drop levels from a nominal or ordinal array
getlabels	Access nominal or ordinal array labels
getlevels	Access nominal or ordinal array levels
islevel	Determine if levels are in nominal or ordinal array
levelcounts	Element counts by level of a nominal or ordinal array
mergelevels	Merge levels of nominal or ordinal arrays
reorderlevels	Reorder levels of nominal or ordinal arrays
setlabels	Assign labels to levels of nominal or ordinal arrays

The following is a partial list of the many other MATLAB array functions you can use with ordinal arrays. For a complete list, see “Other MATLAB Functions Supporting Nominal and Ordinal Arrays” on page 2-3.

double	Double-precision arrays
histogram	Histogram plot
isequal	Determine array equality
isundefined	Find undefined elements in categorical array
pie	Pie chart
summary	Print summary of table, timetable, or categorical array
times	Element-wise multiplication

Examples

Create and Label Ordinal Arrays

Create an ordinal array from integer data, providing explicit labels.

```
quality = ordinal([1 2 3 3 2 1 2 1 3],...
    {'low' 'medium' 'high'})
```

```
quality = 1x9 ordinal array
Columns 1 through 7
```

```
    low    medium    high    high    medium    low    medium
```

```
Columns 8 through 9
```

```
    low    high
```

Show that the first element is less than the second element (low is less than medium).

```
quality(1) < quality(2)
```

```
ans = logical  
     1
```

Create an ordinal array by binning values between 0 and 1 into thirds with labels 'small', 'medium', and 'large'.

```
X = rand(5,2)
```

```
X = 5×2
```

```
    0.8147    0.0975  
    0.9058    0.2785  
    0.1270    0.5469  
    0.9134    0.9575  
    0.6324    0.9649
```

```
A = ordinal(X,{'small' 'medium' 'large'},[],[0 1/3 2/3 1])
```

```
A = 5x2 ordinal array  
    large    small  
    large    small  
    small    medium  
    large    large  
    medium   large
```

Create and Manipulate Ordinal Arrays

Create an ordinal array from integer data.

```
quality = ordinal([1 2 3; 3 2 1; 2 1 3],{'low' 'medium' 'high'})
```

```
quality = 3x3 ordinal array  
    low    medium    high  
    high   medium    low  
    medium low      high
```

Identify the elements in `quality` that are members of a level greater than or equal to 'medium'. A value of 1 in the resulting array indicates that the corresponding element of `quality` is a member of this level.

```
quality >= 'medium'
```

```
ans = 3x3 logical array
```

```

0   1   1
1   1   0
1   0   1
```

Identify the elements in `quality` that are members of either the level 'low' or 'high'.

```
ismember(quality,{'low' 'high'})
```

```
ans = 3x3 logical array
```

```

1   0   1
1   0   1
0   1   1
```

Merge the elements of the 'medium' and 'high' levels into a new level labeled 'ok'.

```
quality = mergelevels(quality,{'medium','high'},'ok')
```

```
quality = 3x3 ordinal array
```

```

low    ok    ok
ok     ok    low
ok     low   ok
```

Display the levels of `quality`.

```
getlevels(quality)
```

```
ans = 1x2 ordinal array
```

```

low    ok
```

Summarize the number of elements in each level. By default, `summary` returns counts for each column of the input array.

```
summary(quality)
```

low	1	1	1
ok	2	2	2

outlierMeasure

Class: CompactTreeBagger

Outlier measure for data

Syntax

```
out = outlierMeasure(B,X)
out = outlierMeasure(B,X,'param1',val1,'param2',val2,...)
```

Description

`out = outlierMeasure(B,X)` computes outlier measures for predictors `X` using trees in the ensemble `B`. The method computes the outlier measure for a given observation by taking an inverse of the average squared proximity between this observation and other observations. `outlierMeasure` then normalizes these outlier measures by subtracting the median of their distribution, taking the absolute value of this difference, and dividing by the median absolute deviation. A high value of the outlier measure indicates that this observation is an outlier.

You can supply the proximity matrix directly by using the `'Data'` parameter.

`out = outlierMeasure(B,X,'param1',val1,'param2',val2,...)` specifies optional parameter name/value pairs:

<code>'Data'</code>	Flag indicating how to treat the <code>X</code> input argument. If set to <code>'predictors'</code> (default), the method assumes <code>X</code> is a matrix of predictors and uses it for computation of the proximity matrix. If set to <code>'proximity'</code> , the method treats <code>X</code> as a proximity matrix returned by the <code>proximity</code> method. If you do not supply the proximity matrix, <code>outlierMeasure</code> computes it internally. If you use the <code>proximity</code> method to compute a proximity matrix, supplying it as input to <code>outlierMeasure</code> reduces computing time.
---------------------	--

'Labels'

Vector of true class labels. True class labels can be a numeric vector, character matrix, string array, or cell array of character vectors. When you supply this parameter, the method performs the outlier calculation for any observations using only other observations from the same class. This parameter must specify one label for each observation (row) in X .

proximity

parallelcoords

Parallel coordinates plot

Syntax

```
parallelcoords(x)  
parallelcoords(x, Name, Value)
```

```
parallelcoords(ax, ___)
```

```
h = parallelcoords(___)
```

Description

`parallelcoords(x)` creates a parallel coordinates plot of the multivariate data in the matrix `x`. Use a parallel coordinates plot to visualize high dimensional data, where each observation is represented by the sequence of its coordinate values plotted against their coordinate indices.

`parallelcoords(x, Name, Value)` creates a parallel coordinates plot with additional options specified by one or more `Name, Value` pair arguments. For example, you can standardize the data in `x` or label the coordinate tick marks along the horizontal axis of the plot.

`parallelcoords(ax, ___)` creates a parallel coordinates plot using the axes specified by the axes graphic object `ax`, using any of the previous syntaxes.

`h = parallelcoords(___)` returns a column vector of handles to the `Line` objects created by `parallelcoords`, with one handle for each row of `x`.

Examples

Parallel Coordinates Plot for Grouped Data

Load the Fisher iris sample data.

```
load fisheriris
```

The data contains four measurements (sepal length, sepal width, petal length, and petal width) from three species of iris flowers. The matrix `meas` contains all four measurements for each of 150 flowers. The cell array `species` contains the species name for each of the 150 flowers.

Create a cell array that contains the name of each measurement variable in the sample data.

```
labels = {'Sepal Length', 'Sepal Width', 'Petal Length', 'Petal Width'};
```

Create a parallel coordinate plot using the measurement data in `meas`. Use a different color for each group as identified in `species`, and label the horizontal axis using the variable names.

```
parallelcoords(meas, 'Group', species, 'Labels', labels)
```

The resulting plot contains one line for each observation (flower). The color of each line indicates the flower species.

Parallel Coordinates Plot with Quantile Values

Load the Fisher iris sample data.

```
load fisheriris
```

The data contains four measurements (sepal length, sepal width, petal length, and petal width) from three species of iris flowers. The matrix `meas` contains all four measurements

for each of 150 flowers. The cell array `species` contains the species name for each of the 150 flowers.

Create a cell array that contains the name of each measurement variable in the sample data.

```
labels = {'Sepal Length', 'Sepal Width', 'Petal Length', 'Petal Width'};
```

Create a parallel coordinates plot using the measurement data in `meas`. Plot only the median, 25 percent, and 75 percent quartile values for each group identified in `species`. Label the horizontal axis using the variable names.

```
parallelcoords(meas, 'group', species, 'labels', labels, ...  
              'quantile', .25)
```

The plot shows the median values for each group as a solid line and the quartile values as dotted lines of the same color. For example, the solid blue line shows the median value measured for each variable on *setosa* irises. The dotted blue line below the solid blue line shows the 25th percentile of measurements for each variable on *setosa* irises. The dotted blue line above the solid blue line shows the 75th percentile of measurements for each variable on *setosa* irises.

Adjust Line Properties in Parallel Coordinates Plot

Load the Fisher iris sample data.

```
load fisheriris
```

The data contains four measurements (sepal length, sepal width, petal length, and petal width) from three species of iris flowers. The matrix `meas` contains all four measurements for each of 150 flowers. The cell array `species` contains the species name for each of the 150 flowers.

Create a cell array that contains the name of each measurement variable in the sample data.

```
labels = {'Sepal Length', 'Sepal Width', 'Petal Length', 'Petal Width'};
```

Create a parallel coordinates plot using the measurement data in `meas`. Plot only the median, 25 percent, and 75 percent quartile values for each group identified in `species`. Label the horizontal axis using the variable names. Set the line width to 2.

```
parallelcoords(meas, 'group', species, 'labels', labels, ...  
              'quantile', .25, 'LineWidth', 2)
```

Specifying 'LineWidth' in this way sets the width of every line in the plot to 2.

Recreate the parallel coordinates plot, but this time, use handles to increase the width of only the line representing the median value for each measurement made on irises in the setosa group.

```
h = parallelcoords(meas, 'group', species, 'labels', labels, ...
                  'quantile', .25)
```

```

h =
  9x1 Line array:

  Line (median)
  Line (lower quantile)
  Line (upper quantile)
  Line (median)
  Line (lower quantile)
  Line (upper quantile)
  Line (median)
  Line (lower quantile)
  Line (upper quantile)

```

The returned column vector `h` contains handles that correspond to each line object created by `parallelcoords`. For example, `h(1)` corresponds to the median line for the first grouping variable (`setosa`).

Use dot notation to increase the width of the line showing the median value for each measurement made on irises in the `setosa` group.

```
h(1).LineWidth = 2;
```

Input Arguments

x — Multivariate input data

numeric matrix

Multivariate input data, specified as an n -by- p matrix of numeric values. n is the number of rows of x , and each row corresponds to an observation in x . p is the number of columns in x , and each column corresponds to a variable in x .

`parallelcoords` treats NaN values in x as missing values and does not plot those coordinate values.

Data Types: `single` | `double`

ax — Axes for plot

axes graphic object

Axes for plot, specified as an axes graphic object. If you do not specify `ax`, then `parallelcoords` creates the plot using the current axis. For more information on creating an axes graphic object, see `axes` and `Axes`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'Group', species, 'Quantile', .25` plots the median, 25 percent, and 75 percent quartile values for the input data, using a different color for each group identified in the variable `species`.

Group — Grouping variable for input data

numeric array | categorical variable | character matrix | string array | cell array

Grouping variable for input data, specified as the comma-separated pair consisting of `'Group'` and a numeric array containing a group index for each observation. Alternatively, the array can be a categorical variable, character matrix, string array, or cell array containing a group name for each observation.

Data Types: `single` | `double` | `categorical` | `char` | `string` | `cell`

Labels — Horizontal axis labels

character array | string array | cell array

Horizontal axis labels, specified as the comma-separated pair consisting of 'Labels' and a character array, string array, or cell array containing the label names.

Example: 'Labels',{'Sepal Width','Sepal Length'}

Data Types: char | string | cell

Quantile — Quantiles of input data to plot

numeric value in the range (0,1)

Quantiles of input data to plot, specified as the comma-separated pair consisting of 'Quantile' and a numeric value in the range (0,1). If you specify a value *alpha* for 'Quantile', then `parallelcoords` plots only the median, *alpha*, and $1 - alpha$ quantiles for each of the variables (columns) in *x*.

The quantile plot option provides a useful summary of the data when *x* contains many observations.

Example: 'Quantile',.25

Data Types: single | double

Standardize — Method to standardize input data

'on' | 'PCA' | 'PCAStd'

Method to standardize input data, specified as the comma-separated pair consisting of 'Standardize' and one of the following.

'on'	Scale each column of <i>x</i> to have a mean equal to 0 and a standard deviation equal to 1 before plotting.
'PCA'	Create plot from the principal component scores of <i>x</i> , in order of decreasing eigenvalues. <code>parallelcoords</code> removes rows of <i>x</i> containing missing values (NaN) for PCA standardization.
'PCAStd'	Create plot using the standardized principal component scores.

Example: 'Standardize','on'

Tips

- You can modify certain aspects of the plot lines by specifying a property name and value for any of the properties listed in Primitive Line. However, this approach applies the modification to all the lines in the plot. To modify only certain plot lines, use the syntax that returns graphics handles and use dot notation to adjust each line property individually. For an illustration, see “Adjust Line Properties in Parallel Coordinates Plot” on page 32-4791.

Output Arguments

h — Graphic handles for line objects

vector of Line graphic handles

Graphic handles for line objects, returned as a vector of Line graphic handles. Graphic handles are unique identifiers that you can use to query and modify the properties of a specific line on the plot. To view and set properties of line objects, use dot notation. For information on using dot notation, see “Access Property Values” (MATLAB). For information on the Line properties that you can set, see Primitive Line.

If you use the 'Quantile' name-value pair argument, then `h` contains one handle for each of the three lines objects created. If you use both the 'Quantile' and the 'Group' name-value pair arguments, then `h` contains three handles for each group.

Alternative Functionality

Alternatively, you can create a `ParallelCoordinatesPlot` object by using the `parallelplot` function.

- Unlike the `parallelcoords` function, `parallelplot` allows you to plot tabular data that includes categorical variables.
- `parallelplot` does not support the plotting of quantiles for numeric data. However, the `ParallelCoordinatesPlot` object contains the `DataNormalization` property, which provides several data normalization methods for coordinates with numeric values.

To control the appearance and behavior of the object, change the `ParallelCoordinatesPlot`.

Introduced before R2006a

paramci

Package: prob

Confidence intervals for probability distribution parameters

Syntax

```
ci = paramci(pd)
ci = paramci(pd,Name,Value)
```

Description

`ci = paramci(pd)` returns the array `ci` containing the lower and upper boundaries of the 95% confidence interval for each parameter in probability distribution `pd`.

`ci = paramci(pd,Name,Value)` returns confidence intervals with additional options specified by one or more name-value pair arguments. For example, you can specify a different percentage for the confidence interval, or compute confidence intervals only for selected parameters.

Examples

Parameter Confidence Intervals

Load the sample data. Create a vector containing the first column of students' exam grade data.

```
load examgrades
x = grades(:,1);
```

Fit a normal distribution object to the data.

```
pd = fitdist(x,'Normal')
```

```
pd =  
    NormalDistribution  
  
    Normal distribution  
        mu = 75.0083    [73.4321, 76.5846]  
        sigma = 8.7202    [7.7391, 9.98843]
```

The intervals next to the parameter estimates are the 95% confidence intervals for the distribution parameters.

You can also obtain these intervals by using the function `paramci`.

```
ci = paramci(pd)  
  
ci = 2×2  
  
    73.4321    7.7391  
    76.5846    9.9884
```

Column 1 of `ci` contains the lower and upper 95% confidence interval boundaries for the `mu` parameter, and column 2 contains the boundaries for the `sigma` parameter.

Change Parameter Confidence Intervals

Load the sample data. Create a vector containing the first column of students' exam grade data.

```
load examgrades  
x = grades(:,1);
```

Fit a normal distribution object to the data.

```
pd = fitdist(x, 'Normal')  
  
pd =  
    NormalDistribution  
  
    Normal distribution  
        mu = 75.0083    [73.4321, 76.5846]  
        sigma = 8.7202    [7.7391, 9.98843]
```

Compute the 99% confidence interval for the distribution parameters.

```
ci = paramci(pd, 'Alpha', .01)
```

```
ci = 2×2
```

```
72.9245    7.4627
77.0922    10.4403
```

Column 1 of `ci` contains the lower and upper 99% confidence interval boundaries for the `mu` parameter, and column 2 contains the boundaries for the `sigma` parameter.

Input Arguments

pd — Probability distribution

probability distribution object

Probability distribution, specified as a probability distribution object created using one of the following.

Function or App	Description
<code>makedist</code>	Create a probability distribution object using specified parameter values.
<code>fitdist</code>	Fit a probability distribution object to sample data.
Distribution Fitter	Fit a probability distribution to sample data using the interactive Distribution Fitter app and export the fitted object to the workspace.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'Alpha', 0.01` specifies a 99% confidence interval.

Alpha — Significance level

0.05 (default) | scalar value in the range (0,1)

Significance level for the confidence interval, specified as the comma-separated pair consisting of 'Alpha' and a scalar value in the range (0,1). The confidence level of `ci` is $100(1-\text{Alpha})\%$. The default value 0.05 corresponds to a 95% confidence interval.

Example: 'Alpha',0.01

Data Types: single | double

Parameter — Parameter list

character vector | string array | cell array of character vectors

Parameter list for which to compute confidence intervals, specified as the comma-separated pair consisting of 'Parameter' and a character vector, string array, or cell array of character vectors containing the parameter names. By default, `paramci` computes confidence intervals for all distribution parameters.

Example: 'Parameter', 'mu'

Data Types: char | string | cell

Type — Computation method

'exact' | 'Wald' | 'lr'

Computation method for the confidence intervals, specified as the comma-separated pair consisting of 'Type' and 'exact', 'Wald', or 'lr'.

'exact' computes the confidence intervals using an exact method, and is available for the following distributions.

Distribution	Computation Method
Binomial	Compute using the Clopper-Pearson method based on exact probability calculations. This method does not provide exact coverage probabilities.
Exponential	Compute using a method based on a chi-square distribution. This method provides exact coverage for complete and Type 2 censored samples.

Distribution	Computation Method
Normal	Computation method based on t and chi-square distributions for uncensored samples provides exact coverage for uncensored samples. For censored samples, <code>paramci</code> uses the Wald method if <code>Type</code> is <code>exact</code> .
Lognormal	Computation method based on t and chi-square distributions for uncensored samples provides exact coverage. For censored samples, <code>paramci</code> uses the Wald method if <code>Type</code> is <code>exact</code> .
Poisson	Computation method based on a chi-square distribution provides exact coverage. For large degrees of freedom, the chi-square is approximated by a normal distribution for numerical efficiency.
Rayleigh	Computation method based on a chi-square distribution provides exact coverage probabilities.

'exact' is the default when it is available. Alternatively, you can specify 'Wald' to compute the confidence intervals using the Wald method, or 'lr' to compute the confidence intervals using the likelihood ratio method.

Example: 'Type', 'Wald'

LogFlag — Boolean flag for log scale

vector

Boolean flag for the log scale, specified as the comma-separated pair consisting of 'LogFlag' and a vector containing Boolean values corresponding to each distribution parameter. The flag specifies which Wald intervals to compute on a log scale. The default values depend on the distribution.

Example: 'LogFlag', [0,1]

Data Types: logical

Output Arguments

ci — Confidence interval

array

Confidence interval, returned as a p -by-2 array containing the lower and upper bounds of the $100(1-\text{Alpha})\%$ confidence interval for each distribution parameter. p is the number of distribution parameters.

If you create `pd` by using `makedist` and specifying the distribution parameters, the lower and upper bounds are equal to the specified parameters.

“Working with Probability Distributions” on page 5-3

“Supported Distributions” on page 5-20

Introduced in R2013a

paretotails

Piecewise distribution with Pareto tails

Description

A `paretotails` object is a piecewise distribution with generalized Pareto distributions (GPDs) in the tails.

A `paretotails` object consists of one or two GPDs in the tails and another distribution in the center. You can specify the distribution type for the center by using the `cdf` argument of `paretotails` when you create an object. Valid values are `'ecdf'`, `'kernel'`, and a function handle.

`paretotails` fits a distribution of type `cdf` to the observations (x) and finds the quantiles corresponding to the lower and upper tail cumulative probabilities (p_l and p_u , respectively). Then, `paretotails` fits two GPDs to the lower $100 \cdot p_l$ percent of the observations and the upper $100 \cdot (1 - p_u)$ percent of the observations, respectively. If x does not have at least two distinct observations in a tail, then `paretotails` does not create the corresponding tail segment.

Use the object functions `boundary`, `segment`, `upperparams`, and `lowerparams` to find distribution characteristics. `lowerparams` and `upperparams` return the parameters of the GPDs in the tails. `boundary` returns the boundary points between piecewise distribution segments, `segment` returns the segment of a piecewise distribution containing input values, and `nsegments` returns the number of segments in an object.

Use the object functions `cdf`, `icdf`, `pdf`, and `random` to evaluate the distribution. These functions are well suited to copula and other Monte Carlo simulations. `pdf` returns the GPD density in the tails and the slope of the cumulative distribution function (`cdf`) in the center. These probability density function (`pdf`) values in the center are generally not good estimates of the underlying density of the original data.

Creation

Create a piecewise distribution object using `paretotails`.

Syntax

```
pd = paretotails(x,pl,pu)
pd = paretotails(x,pl,pu,cdfun)
```

Description

`pd = paretotails(x,pl,pu)` returns the piecewise distribution object `pd`, which consists of the empirical distribution in the center and generalized Pareto distributions in the tails. Specify the boundaries of the tails using the lower and upper tail cumulative probabilities `pl` and `pu`, respectively.

`pd = paretotails(x,pl,pu,cdfun)` specifies the type of center distribution segment using `cdfun`.

Input Arguments

x — Input data

numeric vector

Input data, specified as a numeric vector.

Data Types: double

pl — Lower tail cumulative probability

numeric scalar in the range $[0, 1]$

Lower tail cumulative probability, specified as a numeric scalar in the range $[0, 1]$. The quantile of `pl` is the boundary of the lower tail observations.

If `pl` is 0 or `x` does not have at least two distinct observations in the lower tail, then `paretotails` divides the input data in `x` into two groups, center and upper tail. In this case, the fitted piecewise distribution object `pd` consists of two segments: the empirical distribution in the center and GPD in the upper tail.

Example: 0.1

Data Types: single | double

pu — Upper tail cumulative probability

numeric scalar in the range $[0, 1]$

Upper tail cumulative probability, specified as a numeric scalar in the range $[0, 1]$. The quantile of pu is the boundary of the upper tail observations.

If pu is 1 or x does not have at least two distinct observations in the upper tail, then `paretotails` divides the input data in x into two groups, center and lower tail. In this case, the fitted piecewise distribution object `pd` consists of two segments: the empirical distribution in the center and GPD in the lower tail.

Example: 0.9

Data Types: single | double

cdffun — Type of center distribution segment

'ecdf' (default) | 'kernel' | function handle

Type of center distribution segment, specified as 'ecdf', 'kernel', or a function handle.

Value	Description
'ecdf'	<p>Interpolated empirical cdf.</p> <p><code>paretotails</code> uses values in x as the midpoints in the vertical steps of the empirical cdf, and computes the estimates for the points between the values in x by linear interpolation. For details about how to find the interpolated empirical cdf, see A Piecewise Linear Nonparametric CDF Estimate.</p>
'kernel'	<p>Interpolated kernel smoothing estimate of the cdf.</p> <p><code>paretotails</code> uses the <code>ksdensity</code> function to find cdf estimates for 100 points in the range of x, and uses linear interpolation to compute the estimates for the points between the 100 points.</p> <p>'kernel' is equivalent to specifying a function handle <code>fun = @(x)ksdensity(x,'function','cdf');</code>.</p>

Value	Description
function handle	Interpolated estimates using a specified function. <code>paretotails</code> uses a handle to a function of the form <code>[p,xi] = fun(x)</code> that accepts the input data vector <code>x</code> and returns a vector <code>p</code> of cdf values and a vector <code>xi</code> of evaluation points. Values in <code>xi</code> must be sorted and distinct but do not have to equal the values in <code>x</code> . The <code>paretotails</code> function computes the cdf estimates for the points between the values in <code>xi</code> by linear interpolation.

`paretotails` uses `cdfun` to compute the quantiles corresponding to `pl` and `pu`.

Example: 'kernel'

Properties

NumSegments — Number of segments

3 | 2 | 1

This property is read-only.

Number of segments, including the center segment and tail segments in a `paretail` object, specified as a scalar. `NumSegments` is 3, 2, or 1 if the number of the tail segments in the object is 2, 1, or 0, respectively.

Data Types: double

LowerParameters — Lower tail GPD parameters

numeric vector

This property is read-only.

Lower tail GPD parameters, fit to the lower extreme observations in `x`, specified as a numeric vector. The first value is the shape parameter and the second value is the scale parameter of the GPD.

The location parameter of the lower tail GPD is equal to the quantile of `pl`. Use the boundary function to return the location parameter. For example, run `[p,q] = boundary(pd)`, where `pd` is a `paretotails` object. `q(1)` is the location parameter.

Data Types: single | double

UpperParameters — Upper tail GPD parameters

numeric vector

This property is read-only.

Upper tail GPD parameters, fit to the upper extreme observations in x , specified as a numeric vector. The first value is the shape parameter and the second value is the scale parameter of the GPD.

The location parameter of the upper tail GPD is equal to the quantile of pu . Use the `boundary` function to return the location parameter. For example, run `[p,q] = boundary(pd)`, where `pd` is a `paretotails` object. `q(2)` is the location parameter.

Data Types: `single` | `double`

Object Functions

<code>boundary</code>	Piecewise distribution boundaries
<code>cdf</code>	Cumulative distribution function
<code>icdf</code>	Inverse cumulative distribution function
<code>lowerparams</code>	Lower Pareto tail parameters
<code>nsegments</code>	Number of segments in piecewise distribution
<code>pdf</code>	Probability density function
<code>random</code>	Random numbers
<code>segment</code>	Piecewise distribution segments containing input values
