At any stage, the function will not add a higher-order term if the model does not also include all lower-order terms that are subsets of the higher-order term. For example, the function will not try to add the term $X1 : X2^2$ unless both $X1$ and $X2^2$ are already in the model. Similarly, the function will not remove lower-order terms that are subsets of higher-order terms that remain in the model. For example, the function will not try to remove $X1$ or $X2^2$ if $X1 : X2^2$ remains in the model.

The default value of 'Criterion' for a generalized linear model is 'Deviance'. `stepwiselm` and `step` of `GeneralizedLinearModel` follow a similar procedure for adding or removing terms.

You can specify other criteria by using the 'Criterion' name-value pair argument. For example, you can specify the change in the value of the Akaike information criterion, Bayesian information criterion, R-squared, or adjusted R-squared as the criterion to add or remove terms.

Depending on the terms included in the initial model, and the order in which the function adds and removes terms, the function might build different models from the same set of potential terms. The function terminates when no single step improves the model. However, a different initial model or a different sequence of steps does not guarantee a better fit. In this sense, stepwise models are locally optimal, but might not be globally optimal.

- `stepwiselm` treats a categorical predictor as follows:
 - A model with a categorical predictor that has L levels (categories) includes $L - 1$ indicator variables. The model uses the first category as a reference level, so it does not include the indicator variable for the reference level. If the data type of the categorical predictor is `categorical`, then you can check the order of categories by using `categories` and reorder the categories by using `reordercats` to customize the reference level.
 - `stepwiselm` treats the group of $L - 1$ indicator variables as a single variable. If you want to treat the indicator variables as distinct predictor variables, create indicator variables manually by using `dummyvar`. Then use the indicator variables, except the one corresponding to the reference level of the categorical variable, when you fit a model. For the categorical predictor X , if you specify all columns of `dummyvar(X)` and an intercept term as predictors, then the design matrix becomes rank deficient.
 - Interaction terms between a continuous predictor and a categorical predictor with L levels consist of the element-wise product of the $L - 1$ indicator variables with the continuous predictor.
 - Interaction terms between two categorical predictors with L and M levels consist of the $(L - 1)*(M - 1)$ indicator variables to include all possible combinations of the two categorical predictor levels.
 - You cannot specify higher-order terms for a categorical predictor because the square of an indicator is equal to itself.

Therefore, if `stepwiselm` adds or removes a categorical predictor, the function actually adds or removes the group of indicator variables in one step. Similarly, if `stepwiselm` adds or removes an interaction term with a categorical predictor, the function actually adds or removes the group of interaction terms including the categorical predictor.

- `stepwiselm` considers `NaN`, `' '` (empty character vector), `""` (empty string), `<missing>`, and `<undefined>` values in `tbl`, `X`, and `Y` to be missing values. `stepwiselm` does not use observations with missing values in the fit. The `ObservationInfo` property of a fitted model indicates whether or not `stepwiselm` uses each observation in the fit.

Alternative Functionality

- You can construct a model using `fitlm`, and then manually adjust the model using `step`, `addTerms`, or `removeTerms`.

Introduced in R2013b

stepwisefit

Stepwise regression

Syntax

```
b = stepwisefit(X,y)
[b,se,pval,inmodel,stats,nextstep,history] = stepwisefit(...)
[...] = stepwisefit(X,y,param1,val1,param2,val2,...)
```

Description

`b = stepwisefit(X,y)` uses a stepwise method to perform a multilinear regression of the response values in the n -by-1 vector y on the p predictive terms in the n -by- p matrix X . Distinct predictive terms should appear in different columns of X .

b is a p -by-1 vector of estimated coefficients for all of the terms in X . The `stepwisefit` function calculates the coefficient estimate values in b as follows:

- If a term is not in the final model, then the corresponding coefficient estimate in b results from adding only that term to the predictors in the final model.
- If a term is in the final model, then the coefficient estimate in b for that term is a result of the final model, that is `stepwise` does not consider the terms it excluded from the model while computing these values.

Note `stepwisefit` automatically includes a constant term in all models. Do not enter a column of 1s directly into X .

`stepwisefit` treats NaN values in either X or y as missing values, and ignores them.

`[b,se,pval,inmodel,stats,nextstep,history] = stepwisefit(...)` returns the following additional information:

- `se` — A vector of standard errors for b

- `pval` — A vector of p -values for testing whether elements of `b` are 0
- `inmodel` — A logical vector, with length equal to the number of columns in `X`, specifying which terms are in the final model
- `stats` — A structure of additional statistics with the following fields. All statistics pertain to the final model except where noted.
 - `source` — The character vector `'stepwisefit'`
 - `dfe` — Degrees of freedom for error
 - `df0` — Degrees of freedom for the regression
 - `SStotal` — Total sum of squares of the response
 - `SSresid` — Sum of squares of the residuals
 - `fstat` — F -statistic for testing the final model vs. no model (mean only)
 - `pval` — p value of the F -statistic
 - `rmse` — Root mean square error
 - `xr` — Residuals for predictors not in the final model, after removing the part of them explained by predictors in the model
 - `yr` — Residuals for the response using predictors in the final model
 - `B` — Coefficients for terms in final model, with values for a term not in the model set to the value that would be obtained by adding that term to the model
 - `SE` — Standard errors for coefficient estimates
 - `TSTAT` — t statistics for coefficient estimates
 - `PVAL` — p -values for coefficient estimates
 - `intercept` — Estimated intercept
 - `wasnan` — Indicates which rows in the data contained NaN values
- `nextstep` — The recommended next step—either the index of the next term to move in or out of the model, or 0 if no further steps are recommended
- `history` — Structure containing information on steps taken, with the following fields:
 - `B` — Matrix of regression coefficients, where each column is one step, and each row is one coefficient.
 - `rmse` — Root mean square errors for the model at each step.
 - `df0` — Degrees of freedom for the regression at each step.
 - `in` — Logical array indicating which predictors are in the model at each step, where each row is one step, and each column is one predictor.

[...] = `stepwisefit(X,y,param1,val1,param2,val2,...)` specifies one or more of the name/value pairs described in the following table.

Parameter	Value
'inmodel'	A logical vector specifying terms to include in the initial fit. The default is to specify no terms.
'penter'	The maximum p value for a term to be added. The default is 0.05.
'premove'	The minimum p value for a term to be removed. The default is the maximum of the value of 'penter' and 0.10.
'display'	'on' displays information about each step in the command window. This is the default. 'off' omits the display.
'maxiter'	The maximum number of steps in the regression. The default is Inf.
'keep'	A logical vector specifying terms to keep in their initial state. The default is to specify no terms.
'scale'	'on' centers and scales each column of X (computes z-scores) before fitting. 'off' does not scale the terms. This is the default.

Examples

Load the data in `hald.mat`, which contains observations of the heat of reaction of various cement mixtures:

```
load hald
whos
  Name           Size      Bytes   Class   Attributes
  Description    22x58    2552    char
  hald           13x5     520     double
  heat          13x1     104     double
  ingredients    13x4     416     double
```

The response (`heat`) depends on the quantities of the four predictors (the columns of `ingredients`).

Use `stepwisefit` to carry out the stepwise regression algorithm, beginning with no terms in the model and using entrance/exit tolerances of 0.05/0.10 on the p -values:

```
stepwisefit(ingredients,heat,...
            'penter',0.05,'premove',0.10);
Initial columns included: none
Step 1, added column 4, p=0.000576232
Step 2, added column 1, p=1.10528e-006
Final columns included: 1 4
   'Coeff'      'Std.Err.'    'Status'    'P'
   [ 1.4400]    [ 0.1384]    'In'        [1.1053e-006]
   [ 0.4161]    [ 0.1856]    'Out'       [ 0.0517]
   [-0.4100]    [ 0.1992]    'Out'       [ 0.0697]
   [-0.6140]    [ 0.0486]    'In'        [1.8149e-007]
```

`stepwisefit` automatically includes an intercept term in the model, so you do not add it explicitly to `ingredients` as you would for `regress`. For terms not in the model, coefficient estimates and their standard errors are those that result by adding the corresponding term to the final model.

The `inmodel` parameter is used to specify terms in an initial model:

```
initialModel = ...
               [false true false false]; % Force in 2nd term
stepwisefit(ingredients,heat,...
            'inmodel',initialModel,...
            'penter',.05,'premove',0.10);
Initial columns included: 2
Step 1, added column 1, p=2.69221e-007
Final columns included: 1 2
   'Coeff'      'Std.Err.'    'Status'    'P'
   [ 1.4683]    [ 0.1213]    'In'        [2.6922e-007]
   [ 0.6623]    [ 0.0459]    'In'        [5.0290e-008]
   [ 0.2500]    [ 0.1847]    'Out'       [ 0.2089]
   [-0.2365]    [ 0.1733]    'Out'       [ 0.2054]
```

The preceding two models, built from different initial models, use different subsets of the predictive terms. Terms 2 and 4, swapped in the two models, are highly correlated:

```
term2 = ingredients(:,2);
term4 = ingredients(:,4);
R = corrcoef(term2,term4)
R =
    1.0000    -0.9730
   -0.9730    1.0000
```

To compare the models, use the `stats` output of `stepwisefit`:

```
[betahat1,se1,pval1,inmodel1,stats1] = ...
    stepwisefit(ingredients,heat,...
        'penter',.05,'premove',0.10,...
        'display','off');
[betahat2,se2,pval2,inmodel2,stats2] = ...
    stepwisefit(ingredients,heat,...
        'inmodel',initialModel,...
        'penter',.05,'premove',0.10,...
        'display','off');

RMSE1 = stats1.rmse
RMSE1 =
    2.7343
RMSE2 = stats2.rmse
RMSE2 =
    2.4063
```

The second model has a lower Root Mean Square Error (RMSE).

Algorithms

Stepwise regression is a systematic method for adding and removing terms from a multilinear model based on their statistical significance in a regression. The method begins with an initial model and then compares the explanatory power of incrementally larger and smaller models. At each step, the p value of an F -statistic is computed to test models with and without a potential term. If a term is not currently in the model, the null hypothesis is that the term would have a zero coefficient if added to the model. If there is sufficient evidence to reject the null hypothesis, the term is added to the model. Conversely, if a term is currently in the model, the null hypothesis is that the term has a zero coefficient. If there is insufficient evidence to reject the null hypothesis, the term is removed from the model. The method proceeds as follows:

- 1 Fit the initial model.
- 2 If any terms not in the model have p -values less than an entrance tolerance (that is, if it is unlikely that they would have zero coefficient if added to the model), add the one with the smallest p value and repeat this step; otherwise, go to step 3.
- 3 If any terms in the model have p -values greater than an exit tolerance (that is, if it is unlikely that the hypothesis of a zero coefficient can be rejected), remove the one with the largest p value and go to step 2; otherwise, end.

Depending on the terms included in the initial model and the order in which terms are moved in and out, the method may build different models from the same set of potential terms. The method terminates when no single step improves the model. There is no guarantee, however, that a different initial model or a different sequence of steps will not lead to a better fit. In this sense, stepwise models are locally optimal, but may not be globally optimal.

Introduced before R2006a

subsasgn

Class: dataset

Subscripted assignment to dataset array

Note The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB® `table` data type instead. See MATLAB `table` documentation for more information.

Description

$A = \text{subsasgn}(A, S, B)$ is called for the syntax $A(i, j)=B$, $A\{i, j\}=B$, or $A.\text{var}=B$ when A is a dataset array. S is a structure array with the fields:

<code>type</code>	'()', '{}', or '.' specifying the subscript type.
<code>subs</code>	Cell array or character vector containing the actual subscripts.

$A(i, j) = B$ assigns the contents of the dataset array B to a subset of the observations and variables in the dataset array A . i and j are one of the following types:

- positive integers
- vectors of positive integers
- observation/variable names
- cell arrays containing one or more observation/variable names
- logical vectors

The assignment does not use observation names, variable names, or any other properties of B to modify properties of A ; however properties of A are extended with default values if the assignment expands the number of observations or variables in A . Elements of B are assigned into A by position, not by matching names.

$A\{i, j\} = B$ assigns the value B into an element of the dataset array A . i and J are positive integers, or logical vectors. Cell indexing cannot assign into multiple dataset

elements, that is, the subscripts `i` and `j` must each refer to only a single observation or variable. `B` is cast to the type of the target variable if necessary. If the dataset element already exists, `A{i, j}` may also be followed by further subscripting as supported by the variable.

For dataset variables that are cell arrays, assignments such as `A{1, 'CellVar'} = B` assign into the contents of the target dataset element in the same way that `{}`-indexing of an ordinary cell array does.

For dataset variables that are n-D arrays, i.e., each observation is a matrix or array, an assignment such as `A{1, 'ArrayVar'} = B` assigns into the second and following dimensions of the target dataset element, i.e., the assignment adds a leading singleton dimension to `B` to account for the observation dimension of the dataset variable.

`A.var = B` or `A.(varname) = B` assigns `B` to a dataset variable. `var` is a variable name literal, or `varname` is a character variable containing a variable name. If the dataset variable already exists, the assignment completely replaces that variable. To assign into an element of the variable, `A.var` or `A.(varname)` may be followed by further subscripting as supported by the variable. In particular, `A.var(obsnames, ...)` = `B` and `A.var{obsnames, ...} = B` (when supported by `var`) provide assignment into a dataset variable using observation names.

`A.properties.propertyname = P` assigns to a dataset property. `propertyname` is one of the following:

- 'ObsNames'
- 'VarNames'
- 'Description'
- 'Units'
- 'DimNames'
- 'UserData'
- 'VarDescription'

To assign into an element of the property, `A.properties.propertyname` may also be followed by further subscripting as supported by the property.

You cannot assign multiple values into dataset variables or properties using assignments such as `[A.CellVar{1:2}] = B`, `[A.StructVar(1:2).field] = B`, or `[A.Properties.ObsNames{1:2}] = B`. Use multiple assignments of the form `A.CellVar{1} = B` instead.

Similarly, if a dataset variable is a cell array with multiple columns or is an n-D cell array, then the contents of that variable for a single observation consists of multiple cells, and you cannot assign to all of them using the syntax `A{1, 'CellVar'} = B`. Use multiple assignments of the form `[A.CellVar{1,1}] = B` instead.

See Also

`dataset` | `set` | `subsref`

subsref

Class: dataset

Subscripted reference for dataset array

Note The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB® `table` data type instead. See MATLAB `table` documentation for more information.

Syntax

`B = subsref(A,S)`

Description

`B = subsref(A,S)` is called for the syntax `A(i,j)`, `A{i,j}`, or `A.var` when `A` is a dataset array. `S` is a structure array with the fields:

<code>type</code>	Character vector containing <code>'()'</code> , <code>'{}'</code> , or <code>','</code> specifying the subscript type.
<code>subs</code>	Cell array or character vector containing the actual subscripts.

`B = A(i,j)` returns a dataset array that contains a subset of the observations and variables in the dataset array `A`. `i` and `j` are one of the following types:

- positive integers
- vectors of positive integers
- observation/variable names
- cell arrays containing one or more observation/variable names
- logical vectors

`B` contains the same property values as `A`, subsetted for observations or variables where appropriate.

`B = A{i, j}` returns an element of a dataset variable. `i` and `j` are positive integers, or logical vectors. Cell indexing cannot return multiple dataset elements, that is, the subscripts `i` and `j` must each refer to only a single observation or variable. `A{i, j}` may also be followed by further subscripting as supported by the variable.

For dataset variables that are cell arrays, expressions such as `A{1, 'CellVar'}` return the contents of the referenced dataset element in the same way that `{}`-indexing on an ordinary cell array does. If the dataset variable is a single column of cells, the contents of a single cell is returned. If the dataset variable has multiple columns or is n-D, multiple outputs containing the contents of multiple cells are returned.

For dataset variables that are n-D arrays, i.e., each observation is a matrix or an array, expressions such as `A{1, 'ArrayVar'}` return `A.ArrayVar(1, :, ...)` with the leading singleton dimension squeezed out.

`B = A.var` or `A.(varname)` returns a dataset variable. `var` is a variable name literal, or `varname` is a character variable containing a variable name. `A.var` or `A.(varname)` may also be followed by further subscripting as supported by the variable. In particular, `A.var(obsnames, ...)` and `A.var{obsnames, ...}` (when supported by `var`) provide subscripting into a dataset variable using observation names.

`P = A.Properties.propertyname` returns a dataset property. `propertyname` is one of the following:

- `'ObsNames'`
- `'VarNames'`
- `'Description'`
- `'Units'`
- `'DimNames'`
- `'UserData'`
- `'VarDescription'`

`A.properties.propertyname` may also be followed by further subscripting as supported by the property.

Limitations

Subscripting expressions such as `A.CellVar{1:2}`, `A.StructVar(1:2).field`, or `A.Properties.ObsNames{1:2}` are valid, but result in `subsref` returning multiple

outputs in the form of a comma-separated list. If you explicitly assign to output arguments on the left-hand side of an assignment, for example, `[cellval1, cellval2] = A.CellVar{1:2}`, those variables will receive the corresponding values. However, if there are no output arguments, only the first output in the comma-separated list is returned.

Similarly, if a dataset variable is a cell array with multiple columns or is an n-D cell array, then subscripting expressions such as `A{1, 'CellVar'}` result in `subsref` returning the contents of multiple cells. You should explicitly assign to output arguments on the left-hand side of an assignment, for example, `[cellval1, cellval2] = A{1, 'CellVar'}`.

`dataset` | `set` | `subsasgn`

summary

Class: dataset

Print summary of dataset array

Note The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB® `table` data type instead. See MATLAB `table` documentation for more information.

Syntax

```
summary(A)  
s = summary(A)
```

Description

`summary(A)` prints a summary of a dataset array and the variables that it contains.

`s = summary(A)` returns a scalar structure `s` that contains a summary of the dataset `A` and the variables that `A` contains. For more information on the fields in `s`, see `Outputs`.

Summary information depends on the type of the variables in the data set:

- For numerical variables, `summary` computes a five-number summary of the data, giving the minimum, the first quartile, the median, the third quartile, and the maximum.
- For logical variables, `summary` counts the number of `true`s and `false`s in the data.
- For categorical variables, `summary` counts the number of data at each level.

Output Arguments

The following list describes the fields in the structure `s`:

- **Description** — A character array containing the dataset description.
- **Variables** — A structure array with one element for each dataset variable in A. Each element has the following fields:
 - **Name** — A character vector containing the name of the variable.
 - **Description** — A character vector containing the variable's description.
 - **Units** — A character vector containing the variable's units.
 - **Size** — A numeric vector containing the size of the variable.
 - **Class** — A character vector containing the class of the variable.
 - **Data** — A scalar structure containing the following fields.

For numeric variables:

- **Probabilities** — A numeric vector containing the probabilities [0.0 .25 .50 .75 1.0] and NaN (if any are present in the corresponding dataset variable).
- **Quantiles** — A numeric vector containing the values that correspond to 'Probabilities' for the corresponding dataset variable, and a count of NaNs (if any are present).

For logical variables:

- **Values** — The logical vector [true false].
- **Counts** — A numeric vector of counts for each logical value.

For categorical variables:

- **Levels** — A cell array containing the labels for each level of the corresponding dataset variable.
- **Counts** — A numeric vector of counts for each level.

'Data' is empty if variable is not numeric, categorical, or logical. If a dataset variable has more than one column, then the corresponding 'Quantiles' or 'Counts' field is a matrix or an array.

Examples

Summarize Fisher's iris data:

```

load fisheriris
species = nominal(species);
data = dataset(species,meas);
summary(data)
species: [150x1 nominal]
    setosa    versicolor    virginica
        50         50         50
meas: [150x4 double]
    min      4.3000      2      1      0.1000
    1st Q    5.1000      2.8000    1.6000    0.3000
    median   5.8000      3      4.3500    1.3000
    3rd Q    6.4000      3.3000    5.1000    1.8000
    max      7.9000      4.4000    6.9000    2.5000

```

Summarize the data in hospital.mat:

```

load hospital
summary(hospital)

```

Dataset array created from the data file hospital.dat.

The first column of the file ("id") is used for observation names. Other columns ("sex" and "smoke") have been converted from their original coded values into categorical and logical variables. Two sets of columns ("sys" and "dia", "trial1" through "trial4") have been combined into single variables with multivariate observations. Column headers have been replaced with more descriptive variable names. Units have been added where appropriate.

```

LastName: [100x1 cell array of character vectors]

```

```

Sex: [100x1 nominal]
    Female    Male
        53      47

```

```

Age: [100x1 double, Units = Yrs]
    min      1st Q      median      3rd Q      max
    25       32       39       44       50

```

```

Weight: [100x1 double, Units = Lbs]
    min      1st Q      median      3rd Q      max
    111     130.5000    142.5000    180.5000    202

```

```

Smoker: [100x1 logical]

```

```
    true    false
     34     66
```

BloodPressure: [100x2 double, Units = mm Hg]

Systolic/Diastolic

```
min           109           68
1st Q         117.5000       77.5000
median        122           81.5000
3rd Q         127.5000       89
max           138           99
```

Trials: [100x1 cell, Units = Counts]

From zero to four measurement trials performed

struct2dataset

Convert structure array to dataset array

Note The dataset data type might be removed in a future release. To work with heterogeneous data, use the MATLAB® table data type instead. See MATLAB table documentation for more information.

Syntax

```
ds = struct2dataset(S)
ds = struct2dataset(S,Name,Value)
```

Description

`ds = struct2dataset(S)` converts a structure array to a dataset array.

`ds = struct2dataset(S,Name,Value)` performs the conversion using additional options specified by one or more `Name,Value` pair arguments.

Examples

Convert Scalar Structure Array to Dataset Array

Convert a scalar structure array to a dataset array using the default options.

Create a structure array to convert.

```
S.Name = {'CLARK';'BROWN';'MARTIN'};
S.Gender = {'M';'F';'M'};
S.SystolicBP = [124;122;130];
S.DiastolicBP = [93;80;92];
S
```

```
S = struct with fields:
    Name: {3x1 cell}
    Gender: {3x1 cell}
    SystolicBP: [3x1 double]
    DiastolicBP: [3x1 double]
```

The scalar structure array has four fields, each with three rows.

Convert the structure array to a dataset array.

```
ds = struct2dataset(S)
```

```
ds =
    Name          Gender    SystolicBP    DiastolicBP
    'CLARK'       'M'         124           93
    'BROWN'       'F'         122           80
    'MARTIN'      'M'         130           92
```

The structure field names in `S` become the variable names in the output dataset array. The size of `ds` is 3-by-4.

Convert Nonscalar Structure Array to Dataset Array

Convert a nonscalar structure array to a dataset array, using one of the structure fields for observation names.

Create a nonscalar structure array to convert.

```
S(1,1).Name = 'CLARK';
S(1,1).Gender = 'M';
S(1,1).SystolicBP = 124;
S(1,1).DiastolicBP = 93;

S(2,1).Name = 'BROWN';
S(2,1).Gender = 'F';
S(2,1).SystolicBP = 122;
S(2,1).DiastolicBP = 80;

S(3,1).Name = 'MARTIN';
S(3,1).Gender = 'M';
```

```
S(3,1).SystolicBP = 130;
S(3,1).DiastolicBP = 92;
```

```
S
```

```
S = 3x1 struct array with fields:
    Name
    Gender
    SystolicBP
    DiastolicBP
```

This is a 3-by-1 structure array with 4 fields.

Convert the structure array to a dataset array, using the Name field for observation names.

```
ds = struct2dataset(S, 'ReadObsNames', 'Name')
```

```
ds =
      Gender    SystolicBP    DiastolicBP
    CLARK      'M'          124           93
    BROWN      'F'          122           80
    MARTIN      'M'          130           92
```

The size of `ds` is 3-by-3 because the structure field `Name` is used for observation names, and not as a dataset array variable.

```
ds.Properties.DimNames
```

```
ans = 1x2 cell array
    {'Name'}    {'Variables'}
```

```
ds.Properties.ObsNames
```

```
ans = 3x1 cell array
    {'CLARK' }
    {'BROWN' }
    {'MARTIN' }
```

Input Arguments

S — Input structure array

structure array

Input structure array to convert to a dataset array, specified as a scalar structure array with N fields, each with M rows, or a nonscalar M -by-1 structure array with N fields.

Data Types: `struct`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'ReadObsNames', 'myField'` specifies that the structure field, `myField`, contains observation names.

ReadObsNames — Name of structure field containing observation names for dataset array

`false` (default) | character vector | string scalar

Name of structure field containing observation names for the output dataset array, specified as the comma-separated pair consisting of `'ReadObsNames'` and a character vector or string scalar containing a field name from the input structure array, `S`. When you specify a field name, `struct2dataset` uses that field to create observation names, and sets `ds.Properties.DimNames` equal to `{ReadObsNames, 'Variables'}`.

For example, to specify that observation names are in the structure field, `Names`, use

Example: `'ReadObsNames', 'Names'`

By default, or if `ReadObsNames` is equal to `false`, `struct2dataset` does not create observation names unless you specify names using the name-value pair argument `ObsNames`.

ObsNames — Observation names for dataset array

string array | cell array of character vectors

Observation names for the output dataset array, specified as the comma-separated pair consisting of `'ObsNames'` and a string array or cell array of character vectors containing

observation names. The names do not need to be valid MATLAB identifiers, but they must be unique.

AsScalar — Indicator for how to treat scalar structure

false | true

Indicator for how to treat a scalar input structure array, specified as the comma-separated pair consisting of 'AsScalar' and either `true` or `false`. The default value is `true` if `S` is a scalar structure array, and `false` otherwise.

By default, `struct2dataset` converts a scalar structure array with N fields, each with M rows, into an M -by- N dataset array.

If instead you set `AsScalar` equal to `false` for a scalar input structure array, then `struct2dataset` converts `S` to a dataset array with N observations.

Output Arguments

ds — Output dataset array

dataset array

Output dataset array, returned by default with M observations and N variables.

- If `S` is a scalar structure array with N fields, each with M rows, then `ds` is an M -by- N dataset array.
- If `S` is a nonscalar M -by-1 structure array with N fields, then `ds` is an M -by- N dataset array.
- If `S` is a scalar structure array with N fields, each with M rows, and `AsScalar` is set equal to `false`, then `ds` is a dataset array with N observations.

Introduced in R2012b

surfht

Interactive contour plot

Syntax

```
surfht(z)  
surfht(x,y,z)
```

Description

`surfht(z)` creates an interactive contour plot of the data in matrix `z`. `surfht` treats the values in `z` as the height above the plane.

`surfht(x,y,z)` creates an interactive contour plot of the data in matrix `z`, using the `x`-axis values contained in `x` and the `y`-axis values contained in `y`.

Examples

Create an Interactive Contour Plot

This example shows how to use `surfht` to create an interactive contour plot.

Create a grid of the (x,y) domain from $(-2,-2)$ to $(2,2)$ using `meshgrid`.

```
[x,y] = meshgrid(-2:0.2:2,-2:0.2:2);
```

Evaluate the function $z(x,y) = x \times \exp(-x^2 - y^2)$ over this domain.

```
z = x.*exp(-x.^2 - y.^2);
```

Open an interactive contour plot. Since `meshgrid` creates a grid of the `x` and `y` values, open the plot using the first row of `x` and the first column of `y`.

```
surfht(x(1,:),y(:,1),z)
```

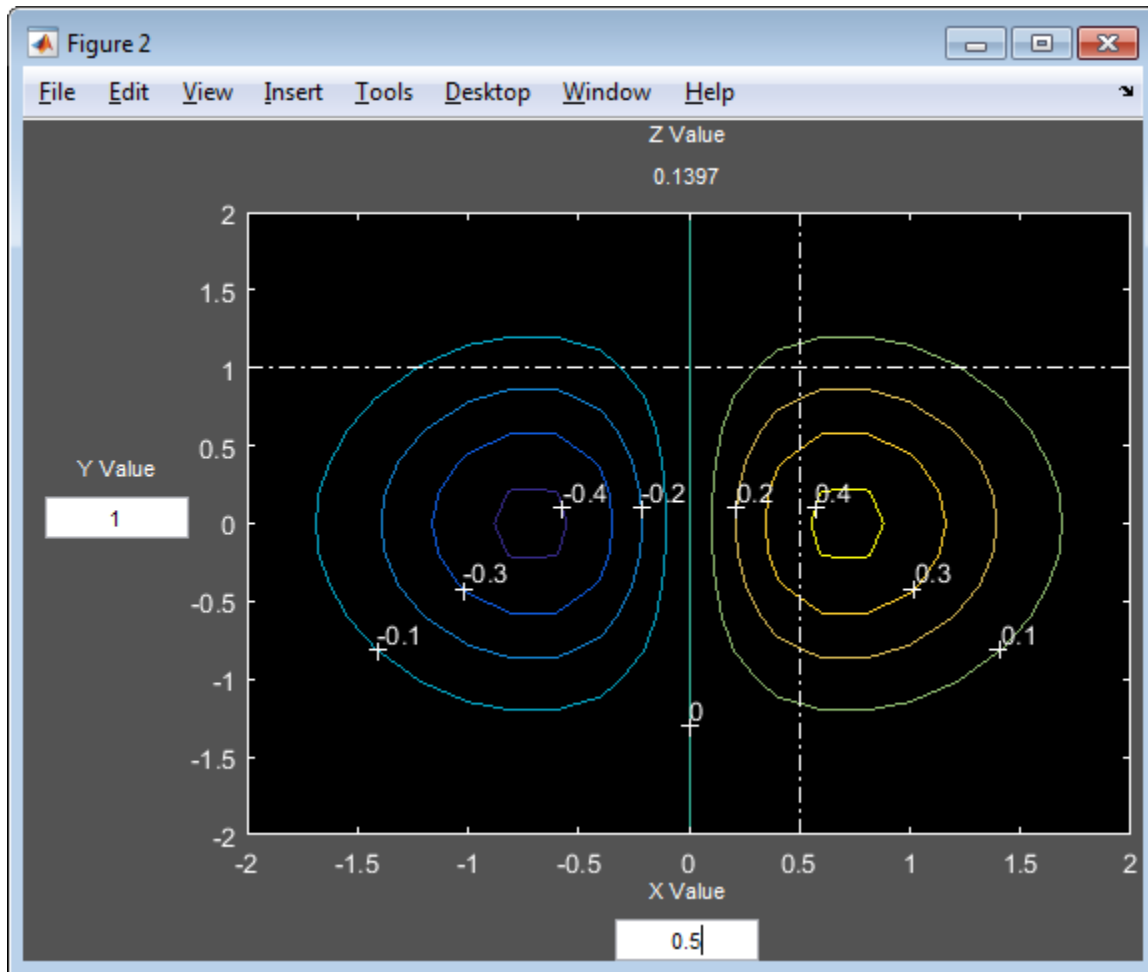

The figure shows a contour plot of the z values along the specified x- and y-axes.

Click the plot to evaluate z at the (x,y) coordinates indicated by the intersecting white lines.

For example, at $x = 0.71041$ and $y = 0.025723$, the value of z is 0.41827 .

Alternatively, enter values in the fields labeled X Value and Y Value to evaluate z at the specified coordinates. For example, evaluate z at $x = 0.5$ and $y = 1$.

The value of z is 0.1397.

Input Arguments

z — z-axis values for contour plot

numeric matrix

z-axis values for contour plot, specified as a numeric matrix.

surfht treats the values in `z` as the height above the plane. By default, the `x`-axis values of the plot are the column indices of `z`, and the `y`-axis values of the plot are the row indices of `z`. To change the `x`- and `y`-axis values, specify `x` and `y`, respectively.

Data Types: `single` | `double`

x — x-axis values for contour plot

column indices of `z` (default) | numeric vector

`x`-axis values for contour plot, specified as a numeric vector. The length of `x` must match the number of columns in `z`.

Data Types: `single` | `double`

y — y-axis values for contour plot

row indices of `z` (default) | numeric vector

`y`-axis values for contour plot, specified as a numeric vector. The length of `y` must match the number of rows in `z`.

Data Types: `single` | `double`

Tips

- The intersection of the vertical and horizontal reference lines on the interactive plot defines the current `x` value and `y` value.
- Drag the dotted white reference lines to watch the interpolated `z` value (at the top of the plot) update simultaneously.
- Alternatively, obtain a specific interpolated `z` value by typing the `x` value and `y` value into editable text fields on the `x`-axis and `y`-axis, respectively.

Introduced before R2006a

table2dataset

Convert table to dataset array

Note The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB® `table` data type instead. See MATLAB `table` documentation for more information.

Syntax

```
ds = table2dataset(t)
```

Description

`ds = table2dataset(t)` converts a table to a dataset array.

Examples

Convert a Table to a Dataset Array

Load the sample data, which contains nutritional information for 77 cereals.

```
load cereal;
```

Create a table containing the calorie, protein, fat, and name data for the first five cereals. Label the variables.

```
Calories = Calories(1:5);  
Protein = Protein(1:5);  
Fat = Fat(1:5);  
Name = Name(1:5);
```

```
cereal = table(Calories,Protein,Fat,'RowNames',Name)
```

```
cereal=5×3 table
```

```
          Calories      Protein      Fat
```

100% Bran	70	4	1
100% Natural Bran	120	3	5
All-Bran	70	4	1
All-Bran with Extra Fiber	50	4	0
Almond Delight	110	2	2

Convert the table to a dataset array.

```
ds = table2dataset(cereal)
```

```
ds =
      Calories  Protein  Fat
100% Bran      70       4    1
100% Natural Bran 120       3    5
All-Bran       70       4    1
All-Bran with Extra Fiber 50       4    0
Almond Delight 110       2    2
```

Input Arguments

t — Input table

table

Input table to convert to a dataset array, specified as a table. Each variable in **t** becomes a variable in the output dataset array **ds**.

Data Types: table

Output Arguments

ds — Output dataset array

dataset array

Output dataset array, returned as a dataset array containing the variables from the input table **t**.

tabulate

Frequency table

Syntax

```
tbl = tabulate(x)
tabulate(x)
```

Description

`tbl = tabulate(x)` creates a frequency table of data in vector `x`. Information in `tbl` is arranged as follows:

- 1st column — The unique values of `x`
- 2nd column — The number of instances of each value
- 3rd column — The percentage of each value

If `x` is a numeric array, `tbl` is a numeric matrix. If the elements of `x` are positive integers, `tbl` includes 0 counts for integers between 1 and `max(x)` that do not appear in `x`.

If `x` is a categorical variable, character array, string array or cell array of character vectors, `tbl` is a cell array.

`tabulate(x)` with no output arguments displays the table in the command window.

Examples

```
tabulate([1 2 4 4 3 4])
```

Value	Count	Percent
1	1	16.67%
2	1	16.67%
3	1	16.67%
4	3	50.00%

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. For more information, see “Tall Arrays” (MATLAB).

Introduced before R2006a

tblread

Read tabular data from file

Syntax

```
[data,varnames,casenames] = tblread  
[data,varnames,casenames] = tblread(filename)  
[data,varnames,casenames] = tblread(filename,delimiter)
```

Description

[*data,varnames,casenames*] = `tblread` displays the File Open dialog box for interactive selection of a tabular data file. The file format has variable names in the first row, case names in the first column and data starting in the (2, 2) position. Outputs are:

- **data** — Numeric matrix with a value for each variable-case pair
- **varnames** — Character matrix containing the variable names in the first row of the file
- **casenames** — Character matrix containing the names of each case in the first column of the file

[*data,varnames,casenames*] = `tblread(filename)` allows command line specification of the name of a file in the current folder, or the complete path name of any file, using the character vector or string scalar *filename*.

[*data,varnames,casenames*] = `tblread(filename,delimiter)` reads from the file using *delimiter* as the delimiting character. Accepted values for *delimiter* are:

- ' ' or 'space'
- '\t' or 'tab'
- ',' or 'comma'
- ';' or 'semi'
- '|' or 'bar'

The default value of *delimiter* is 'space'.

Examples

```
[data,varnames,casenames] = tblread('sat.dat')
data =
  470  530
  520  480

varnames =
Male
Female

casenames =
Verbal
Quantitative
```

[caseread](#) | [readtable](#) | [tblwrite](#) | [tdfread](#)

Introduced before R2006a

tblwrite

Write tabular data to file

Syntax

```
tblwrite(data,varnames,casenames)
tblwrite(data,varnames,casenames,filename)
tblwrite(data,varnames,casenames,filename,delimiter)
```

Description

`tblwrite(data,varnames,casenames)` displays the **File Open** dialog box for interactive specification of the tabular data output file. The file format has variable names in the first row, case names in the first column and `data` starting in the (2,2) position.

`varnames` is a character matrix or string array containing the variable names. `casenames` is a character matrix or string array containing the names of each case in the first column. `data` is a character matrix or string array with a value for each variable-case pair.

`tblwrite(data,varnames,casenames,filename)` specifies a file in the current folder, or the complete path name of any file in the character vector or string scalar `filename`.

`tblwrite(data,varnames,casenames,filename,delimiter)` writes to the file using `delimiter` as the delimiting character. The following table lists the accepted values for `delimiter` and their equivalent names.

Value	Name
' '	'space'
'\t'	'tab'
','	'comma'
';'	'semi'

Value	Name
' '	'bar'

The default value of *delimiter* is 'space'.

Examples

Continuing the example from `tblread`:

```
tblwrite(data, varnames, casenames, 'sattest.dat')
type sattest.dat
```

	Male	Female
Verbal	470	530
Quantitative	520	480

Introduced before R2006a

tcdf

Student's t cumulative distribution function

Syntax

```
p = tcdf(x,nu)
p = tcdf(x,nu,'upper')
```

Description

`p = tcdf(x,nu)` returns the cumulative distribution function (cdf) of the Student's t distribution at each of the values in `x` using the corresponding degrees of freedom in `nu`. `x` and `nu` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other inputs.

`p = tcdf(x,nu,'upper')` returns the complement of the Student's t cdf at each value in `x`, using an algorithm that more accurately computes the extreme upper tail probabilities.

Examples

Compute Student's t cdf

```
mu = 1;      % Population mean
sigma = 2;   % Population standard deviation
n = 100;     % Sample size

rng default % For reproducibility
x = normrnd(mu,sigma,n,1); % Random sample from population

xbar = mean(x); % Sample mean
s = std(x);     % Sample standard deviation
t = (xbar - mu)/(s/sqrt(n))
```

```
t = 1.0589
p = 1-tcdf(t,n-1) % Probability of larger t-statistic
p = 0.1461
```

This probability is the same as the p value returned by a t test of the null hypothesis that the sample comes from a normal population with mean μ

```
[h,ptest] = ttest(x,mu,0.05,'right')
h = 0
ptest = 0.1461
```

Definitions

Student's t cdf

The cumulative distribution function (cdf) of Student's t distribution is

$$p = F(x) \Big|_{\nu} = \int_{-\infty}^x \frac{\Gamma\left(\frac{\nu+1}{2}\right)}{\Gamma\left(\frac{\nu}{2}\right)} \frac{1}{\sqrt{\nu\pi}} \frac{1}{\left(1 + \frac{t^2}{\nu}\right)^{\frac{\nu+1}{2}}} dt$$

where ν is the degrees of freedom and $\Gamma(\cdot)$ is the Gamma function. The result p is the probability that a single observation from the t distribution with ν degrees of freedom will fall in the interval $[-\infty, x]$.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU arrays. For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

“Student's t Distribution” on page B-173

Introduced before R2006a

tdfread

Read tab-delimited file

Syntax

```
tdfread  
tdfread(filename)  
tdfread(filename,delimiter)  
s = tdfread(filename,...)
```

Description

tdfread displays the **File Open** dialog box for interactive selection of a data file, then reads data from the file. The file should have variable names separated by tabs in the first row, and data values separated by tabs in the remaining rows. tdfread creates variables in the workspace, one for each column of the file. The variable names are taken from the first row of the file. If a column of the file contains only numeric data in the second and following rows, tdfread creates a double variable. Otherwise, tdfread creates a char variable. After all values are imported, tdfread displays information about the imported values using the format of the tdfread command.

tdfread(*filename*) allows command line specification of the name of a file in the current folder, or the complete path name of any file, using *filename*.

tdfread(*filename,delimiter*) indicates that the character specified by *delimiter* separates columns in the file. Accepted values for *delimiter* are:

- ' ' or 'space'
- '\t' or 'tab'
- ',' or 'comma'
- ';' or 'semi'
- '|' or 'bar'

The default delimiter is 'tab'.

`s = tdfread(filename, ...)` returns a scalar structure `s` whose fields each contain a variable.

Examples

The following displays the contents of the file `sat2.dat`:

```
type sat2.dat

Test,Gender,Score
Verbal,Male,470
Verbal,Female,530
Quantitative,Male,520
Quantitative,Female,480
```

The following creates the variables `Gender`, `Score`, and `Test` from the file `sat2.dat` and displays the contents of the MATLAB workspace:

```
tdfread('sat2.dat','')

Name      Size      Bytes      Class      Attributes
Gender    4x6        48         char
Score     4x1        32         double
Test      4x12       96         char
```

Introduced before R2006a

ClassificationDiscriminant.template

Class: ClassificationDiscriminant

(Not Recommended) Discriminant analysis classifier template for ensemble

Note `ClassificationDiscriminant.template` is not recommended. Use `templateDiscriminant` instead.

Syntax

```
t = ClassificationDiscriminant.template()  
t = ClassificationDiscriminant.template(Name, Value)
```

Description

`t = ClassificationDiscriminant.template()` returns a learner template suitable to use in the `fitcensemble` function.

`t = ClassificationDiscriminant.template(Name, Value)` creates a template with additional options specified by one or more `Name, Value` pair arguments.

Input Arguments

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name, Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Delta — Linear coefficient threshold

0 (default) | nonnegative scalar value

Linear coefficient threshold, specified as the comma-separated pair consisting of 'Delta' and a nonnegative scalar value. If a coefficient of $Md\ell$ has magnitude smaller than Delta, $Md\ell$ sets this coefficient to 0, and you can eliminate the corresponding predictor from the model. Set Delta to a higher value to eliminate more predictors.

Delta must be 0 for quadratic discriminant models.

Data Types: single | double

DiscrimType – Discriminant type

'linear' (default) | 'quadratic' | 'diaglinear' | 'diagquadratic' |
'pseudolinear' | 'pseudoquadratic'

Discriminant type, specified as the comma-separated pair consisting of 'DiscrimType' and a character vector in this table.

Value	Description	Predictor Covariance Treatment
'linear'	Regularized linear discriminant analysis (LDA)	<ul style="list-style-type: none"> All classes have the same covariance matrix. $\widehat{\Sigma}_\gamma = (1 - \gamma)\widehat{\Sigma} + \gamma \text{diag}(\widehat{\Sigma})$. <p>$\widehat{\Sigma}$ is the empirical, pooled covariance matrix and γ is the amount of regularization.</p>
'diaglinear'	LDA	All classes have the same, diagonal covariance matrix.
'pseudolinear'	LDA	All classes have the same covariance matrix. The software inverts the covariance matrix using the pseudo inverse.
'quadratic'	Quadratic discriminant analysis (QDA)	The covariance matrices can vary among classes.

Value	Description	Predictor Covariance Treatment
'diagquadratic'	QDA	The covariance matrices are diagonal and can vary among classes.
'pseudoquadratic'	QDA	The covariance matrices can vary among classes. The software inverts the covariance matrix using the pseudo inverse.

Note To use regularization, you must specify `'linear'`. To specify the amount of regularization, use the `Gamma` name-value pair argument.

Example: `'DiscrimType','quadratic'`

FillCoeffs — Coeffs property flag

`'on' | 'off'`

`Coeffs` property flag, specified as the comma-separated pair consisting of `'FillCoeffs'` and `'on'` or `'off'`. Setting the flag to `'on'` populates the `Coeffs` property in the classifier object. This can be computationally intensive, especially when cross-validating. The default is `'on'`, unless you specify a cross-validation name-value pair, in which case the flag is set to `'off'` by default.

Example: `'FillCoeffs','off'`

Gamma — Amount of regularization

scalar value in the interval `[0,1]`

Amount of regularization to apply when estimating the covariance matrix of the predictors, specified as the comma-separated pair consisting of `'Gamma'` and a scalar value in the interval `[0,1]`. `Gamma` provides finer control over the covariance matrix structure than `DiscrimType`.

- If you specify `0`, then the software does not use regularization to adjust the covariance matrix. That is, the software estimates and uses the unrestricted, empirical covariance matrix.

- For linear discriminant analysis, if the empirical covariance matrix is singular, then the software automatically applies the minimal regularization required to invert the covariance matrix. You can display the chosen regularization amount by entering `Mdl.Gamma` at the command line.
- For quadratic discriminant analysis, if at least one class has an empirical covariance matrix that is singular, then the software throws an error.
- If you specify a value in the interval (0,1), then you must implement linear discriminant analysis, otherwise the software throws an error. Consequently, the software sets `DiscrimType` to `'linear'`.
- If you specify `1`, then the software uses maximum regularization for covariance matrix estimation. That is, the software restricts the covariance matrix to be diagonal. Alternatively, you can set `DiscrimType` to `'diagLinear'` or `'diagQuadratic'` for diagonal covariance matrices.

Example: `'Gamma',1`

Data Types: `single | double`

SaveMemory — Flag to save covariance matrix

`'off'` (default) | `'on'`

Flag to save covariance matrix, specified as the comma-separated pair consisting of `'SaveMemory'` and either `'on'` or `'off'`. If you specify `'on'`, then `fitcdiscr` does not store the full covariance matrix, but instead stores enough information to compute the matrix. The `predict` method computes the full covariance matrix for prediction, and does not store the matrix. If you specify `'off'`, then `fitcdiscr` computes and stores the full covariance matrix in `Mdl`.

Specify `SaveMemory` as `'on'` when the input matrix contains thousands of predictors.

Example: `'SaveMemory','on'`

Output Arguments

t — Discriminant analysis classification template

classification template object

Discriminant analysis classification template suitable to use in the `fitcensemble` function, returned as a classification template object. In an ensemble, `t` specifies how to create the discriminant analysis classifier.

Examples

Discriminant Analysis Template for Nondefault Options

Create a nondefault discriminant analysis template for use in `fitcensemble`.

Create a template for pseudolinear discriminant analysis.

```
t = ClassificationDiscriminant.template('discrimType','pseudoLinear')
```

```
t =
```

```
Fit template for classification Discriminant.
```

```
DiscrimType: 'pseudoLinear'  
  Gamma: []  
  Delta: []  
FillCoeffs: []  
SaveMemory: []  
  Version: 1  
  Method: 'Discriminant'  
  Type: 'classification'
```

You can use `t` for ensemble learning.

See Also

`ClassificationDiscriminant` | `fitcensemble` | `templateDiscriminant`

ClassificationKNN.template

(Not Recommended) *k*-nearest neighbor classifier template for ensemble

Note `ClassificationKNN.template` is not recommended. Use `templateKNN` instead.

Syntax

```
t = ClassificationKNN.template()  
t = ClassificationKNN.template(Name,Value)
```

Description

`t = ClassificationKNN.template()` returns a learner template suitable to use in the `fitcensemble` function.

`t = ClassificationKNN.template(Name,Value)` creates a template with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

BreakTies — Tie-breaking algorithm

'smallest' (default) | 'nearest' | 'random'

Tie-breaking algorithm used by the `predict` method if multiple classes have the same smallest cost, specified as the comma-separated pair consisting of `'BreakTies'` and one of the following:

- 'smallest' — Use the smallest index among tied groups.
- 'nearest' — Use the class with the nearest neighbor among tied groups.
- 'random' — Use a random tiebreaker among tied groups.

By default, ties occur when multiple classes have the same number of nearest points among the K nearest neighbors.

Example: 'BreakTies', 'nearest'

BucketSize — Maximum data points in node

50 (default) | positive integer value

Maximum number of data points in the leaf node of the *kd*-tree, specified as the comma-separated pair consisting of 'BucketSize' and a positive integer value. This argument is meaningful only when *NSMethod* is 'kdtree'.

Example: 'BucketSize', 40

Data Types: single | double

Cov — Covariance matrix

nancov(X) (default) | positive definite matrix of scalar values

Covariance matrix, specified as the comma-separated pair consisting of 'Cov' and a positive definite matrix of scalar values representing the covariance matrix when computing the Mahalanobis distance. This argument is only valid when 'Distance' is 'mahalanobis'.

You cannot simultaneously specify 'Standardize' and either of 'Scale' or 'Cov'.

Data Types: single | double

Distance — Distance metric

'cityblock' | 'chebychev' | 'correlation' | 'cosine' | 'euclidean' |
'hamming' | function handle | ...

Distance metric, specified as the comma-separated pair consisting of 'Distance' and a valid distance metric name or function handle. The allowable distance metric names depend on your choice of a neighbor-searcher method (see *NSMethod*).

NSMethod	Distance Metric Names
exhaustive	Any distance metric of ExhaustiveSearcher

NSMethod	Distance Metric Names
kdtree	'cityblock', 'chebychev', 'euclidean', or 'minkowski'

This table includes valid distance metrics of ExhaustiveSearcher.

Distance Metric Names	Description
'cityblock'	City block distance.
'chebychev'	Chebychev distance (maximum coordinate difference).
'correlation'	One minus the sample linear correlation between observations (treated as sequences of values).
'cosine'	One minus the cosine of the included angle between observations (treated as vectors).
'euclidean'	Euclidean distance.
'hamming'	Hamming distance, percentage of coordinates that differ.
'jaccard'	One minus the Jaccard coefficient, the percentage of nonzero coordinates that differ.
'mahalanobis'	Mahalanobis distance, computed using a positive definite covariance matrix C . The default value of C is the sample covariance matrix of X , as computed by <code>nancov(X)</code> . To specify a different value for C , use the 'Cov' name-value pair argument.
'minkowski'	Minkowski distance. The default exponent is 2. To specify a different exponent, use the 'Exponent' name-value pair argument.
'seuclidean'	Standardized Euclidean distance. Each coordinate difference between X and a query point is scaled, meaning divided by a scale value S . The default value of S is the standard deviation computed from X , $S = \text{nanstd}(X)$. To specify another value for S , use the <code>Scale</code> name-value pair argument.
'spearman'	One minus the sample Spearman's rank correlation between observations (treated as sequences of values).

Distance Metric Names	Description
@ <i>distfun</i>	<p>Distance function handle. <i>distfun</i> has the form</p> <pre>function D2 = distfun(ZI,ZJ) % calculation of distance ...</pre> <p>where</p> <ul style="list-style-type: none"> • ZI is a 1-by-N vector containing one row of X or Y. • ZJ is an M2-by-N matrix containing multiple rows of X or Y. • D2 is an M2-by-1 vector of distances, and D2(k) is the distance between observations ZI and ZJ(k, :).

If you specify `CategoricalPredictors` as 'all', then the default distance metric is 'hamming'. Otherwise, the default distance metric is 'euclidean'.

For definitions, see “Distance Metrics” on page 18-16.

Example: 'Distance', 'minkowski'

Data Types: char | function_handle

DistanceWeight — Distance weighting function

'equal' (default) | 'inverse' | 'squaredinverse' | function handle

Distance weighting function, specified as the comma-separated pair consisting of 'DistanceWeight' and either a function handle or one of the values in this table.

Value	Description
'equal'	No weighting
'inverse'	Weight is 1/distance
'squaredinverse'	Weight is 1/distance ²
@ <i>fcn</i>	<i>fcn</i> is a function that accepts a matrix of nonnegative distances, and returns a matrix the same size containing nonnegative distance weights. For example, 'squaredinverse' is equivalent to @(d)d.^(-2).

Example: 'DistanceWeight', 'inverse'

Data Types: char | function_handle

Exponent — Minkowski distance exponent

2 (default) | positive scalar value

Minkowski distance exponent, specified as the comma-separated pair consisting of 'Exponent' and a positive scalar value. This argument is only valid when 'Distance' is 'minkowski'.

Example: 'Exponent',3

Data Types: single | double

IncludeTies — Tie inclusion flag

false (default) | true

Tie inclusion flag, specified as the comma-separated pair consisting of 'IncludeTies' and a logical value indicating whether `predict` includes all the neighbors whose distance values are equal to the Kth smallest distance. If `IncludeTies` is true, `predict` includes all these neighbors. Otherwise, `predict` uses exactly K neighbors.

Example: 'IncludeTies',true

Data Types: logical

NSMethod — Nearest neighbor search method

'kdtree' | 'exhaustive'

Nearest neighbor search method, specified as the comma-separated pair consisting of 'NSMethod' and 'kdtree' or 'exhaustive'.

- 'kdtree' — Creates and uses a *kd*-tree to find nearest neighbors. 'kdtree' is valid when the distance metric is one of the following:
 - 'euclidean'
 - 'cityblock'
 - 'minkowski'
 - 'chebychev'
- 'exhaustive' — Uses the exhaustive search algorithm. When predicting the class of a new point `xnew`, the software computes the distance values from all points in `X` to `xnew` to find nearest neighbors.

The default is 'kdtree' when X has 10 or fewer columns, X is not sparse, and the distance metric is a 'kdtree' type; otherwise, 'exhaustive'.

Example: 'NSMethod', 'exhaustive'

NumNeighbors — Number of nearest neighbors to find

1 (default) | positive integer value

Number of nearest neighbors in X to find for classifying each point when predicting, specified as the comma-separated pair consisting of 'NumNeighbors' and a positive integer value.

Example: 'NumNeighbors', 3

Data Types: single | double

Scale — Distance scale

nanstd(X) (default) | vector of nonnegative scalar values

Distance scale, specified as the comma-separated pair consisting of 'Scale' and a vector containing nonnegative scalar values with length equal to the number of columns in X . Each coordinate difference between X and a query point is scaled by the corresponding element of `Scale`. This argument is only valid when 'Distance' is 'seuclidean'.

You cannot simultaneously specify 'Standardize' and either of 'Scale' or 'Cov'.

Data Types: single | double

Output Arguments

t — Classification template

classification template object

K -nearest neighbor classification template suitable to use in the `fitcensemble` function. In an ensemble, `t` specifies how to create the KNN classifier.

Examples

KNN template for nondefault options

Create a nondefault k -nearest neighbor template for use in `fitcensemble`.

Create a template for 5-nearest neighbor search.

```
t = ClassificationKNN.template('NumNeighbors',5)
```

```
t =
```

```
Fit template for classification KNN.
```

```
    NumNeighbors: 5
      NSMethod: ''
      Distance: ''
      BucketSize: ''
    IncludeTies: []
  DistanceWeight: []
    BreakTies: []
      Exponent: []
        Cov: []
          Scale: []
StandardizeData: []
      Version: 1
        Method: 'KNN'
          Type: 'classification'
```

You can use `t` for ensemble learning.

ClassificationTree.template

Class: ClassificationTree

(Not Recommended) Create classification template

Note ClassificationTree.template is not recommended. Use templateTree instead.

Syntax

```
t = ClassificationTree.template
t = ClassificationTree.template(Name,Value)
```

Description

t = ClassificationTree.template returns a learner template suitable to use in the fitcensemble function.

t = ClassificationTree.template(Name,Value) creates a template with additional options specified by one or more Name,Value pair arguments. You can specify several name-value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

Input Arguments

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name,Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1,Value1,...,NameN,ValueN.

AlgorithmForCategorical

Algorithm to find the best split on a categorical predictor for data with $K = 3$ or more classes. The available algorithms are:

'Exact'	For a categorical predictor with C categories, consider all $2^{C-1} - 1$ combinations.
'PullLeft'	Start with all C categories on the right branch. Consider moving each category to the left branch as it achieves the minimum impurity for the K classes among the remaining categories. Out of this sequence, choose the split that has the lowest impurity.
'PCA'	Compute a score for each category using the inner product between the first principal component of a weighted covariance matrix (of the centered class probability matrix) and the vector of class probabilities for that category. Sort the scores in ascending order, and consider all $C - 1$ splits.
'OVByClass'	Start with all C categories on the right branch. For each class, order the categories based on their probability for that class. For the first class, consider moving each category to the left branch in order, recording the impurity criterion at each move. Repeat for the remaining classes. Out of this sequence, choose the split that has the minimum impurity.

Default: ClassificationTree selects the optimal subset of algorithms for each split using the known number of classes and levels of a categorical predictor. For two classes, ClassificationTree always performs the exact search.

MaxCat

`ClassificationTree` splits a categorical predictor using the exact search algorithm if the predictor has at most `MaxCat` levels in the split node. Otherwise, `ClassificationTree` finds the best categorical split using one of the inexact algorithms.

Specify `MaxCat` as a numeric nonnegative scalar value. Passing a small value can lead to long computation time and memory overload.

Default: 10

MergeLeaves

Character vector that specifies whether to merge leaves after the tree is grown. Values are 'on' or 'off'.

When 'on', `ClassificationTree` merges leaves that originate from the same parent node, and that give a sum of risk values greater or equal to the risk associated with the parent node. When 'off', `ClassificationTree` does not merge leaves.

Default: 'off'

MinLeaf

Each leaf has at least `MinLeaf` observations per tree leaf. If you supply both `MinParent` and `MinLeaf`, `ClassificationTree` uses the setting that gives larger leaves: $\text{MinParent} = \max(\text{MinParent}, 2 * \text{MinLeaf})$.

Default: Half the number of training observations for boosting, 1 for bagging

MinParent

Each branch node in the tree has at least `MinParent` observations. If you supply both `MinParent` and `MinLeaf`, `ClassificationTree` uses the setting that gives larger leaves: $\text{MinParent} = \max(\text{MinParent}, 2 * \text{MinLeaf})$.

Default: Number of training observations for boosting, 2 for bagging

NVarToSample

Number of predictors to select at random for each split. Can be a positive integer or 'all', which means use all available predictors.

Default: 'all' for boosting, square root of number of predictors for bagging

Prune

When 'on', `ClassificationTree` grows the classification tree and computes the optimal sequence of pruned subtrees. When 'off' `ClassificationTree` grows the tree without pruning.

Default: 'off'

PruneCriterion

Character vector with the pruning criterion, either 'error' or 'impurity'.

Default: 'error'

SplitCriterion

Criterion for choosing a split. One of 'gdi' (Gini's diversity index), 'twoing' for the twoing rule, or 'deviance' for maximum deviance reduction (also known as cross entropy).

Default: 'gdi'

Surrogate

Character vector describing whether to find surrogate decision splits at each branch node. Specify as 'on', 'off', 'all', or a positive scalar value.

- When 'on', `ClassificationTree` finds at most 10 surrogate splits at each branch node.
- When set to a positive integer value, `ClassificationTree` finds at most the specified number of surrogate splits at each branch node.
- When set to 'all', `ClassificationTree` finds all surrogate splits at each branch node. The 'all' setting can use much time and memory.

Use surrogate splits to improve the accuracy of predictions for data with missing values. The setting also enables you to compute measures of predictive association between predictors.

Default: 'off'

Output Arguments

t

Classification tree template suitable to use in the `fitcensemble` function. In an ensemble, `t` specifies how to grow the classification trees.

Examples

Construct a Classification Template with Surrogate Splits

Create a classification template with surrogate splits, and train an ensemble for the Fisher iris model with the template.

Load Fisher's iris data set.

```
load fisheriris
```

Create a decision tree template with surrogate splits and at least 50 observations per tree leaf.

```
t = ClassificationTree.template('surrogate','on','MinLeaf',50)
```

```
t =  
Fit template for classification Tree.
```

```
    SplitCriterion: []  
      MinParent: []  
        MinLeaf: 50  
      MaxSplits: []  
    NVarToSample: []  
      MergeLeaves: []  
        Prune: []  
    PruneCriterion: []  
      QEToler: []  
    NSurrogate: 'on'  
      MaxCat: []  
      AlgCat: []  
    PredictorSelection: []  
      UseChisqTest: []  
      Stream: []
```

```
Reproducible: []  
Version: 2  
Method: 'Tree'  
Type: 'classification'
```

Specify `t` as a weak learner for a classification ensemble.

```
ens = fitcensemble(meas,species,'Method','AdaBoostM2','Learners',t);
```

How well does the ensemble classify the training data? This can be an underestimate of the loss on new data, but is nonetheless interesting.

```
loss = resubLoss(ens)
```

```
loss = 0.0400
```

RegressionTree.template

Class: RegressionTree

(Not Recommended) Create regression template

Note RegressionTree.template is not recommended. Use templateTree instead.

Syntax

```
t = RegressionTree.template
t = RegressionTree.template(Name, Value)
```

Description

t = RegressionTree.template returns a learner template suitable to use in the fitrensemble function.

t = RegressionTree.template(Name, Value) creates a template with additional options specified by one or more Name, Value pair arguments. You can specify several name-value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Input Arguments

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

MergeLeaves

Character vector that specifies whether to merge leaves after the tree is grown. Values are 'on' or 'off'.

When 'on', RegressionTree merges leaves that originate from the same parent node, and that give a sum of risk values greater or equal to the risk associated with the parent node. When 'off', RegressionTree does not merge leaves.

Default: 'off'

MinLeaf

Each leaf has at least MinLeaf observations per tree leaf. If you supply both MinParent and MinLeaf, RegressionTree uses the setting that gives larger leaves: $\text{MinParent} = \max(\text{MinParent}, 2 * \text{MinLeaf})$.

Default: Half the number of training observations for boosting, 5 for bagging

MinParent

Each branch node in the tree has at least MinParent observations. If you supply both MinParent and MinLeaf, RegressionTree uses the setting that gives larger leaves: $\text{MinParent} = \max(\text{MinParent}, 2 * \text{MinLeaf})$.

Default: Number of training observations for boosting, 10 for bagging

NVarToSample

Number of predictors to select at random for each split. Can be a positive integer or 'all', which means use all available predictors.

Default: 'all' for boosting, one third of the number of predictors for bagging

Prune

When 'on', RegressionTree grows the regression tree and computes the optimal sequence of pruned subtrees. When 'off' RegressionTree grows the tree without pruning.

Default: 'off'

Surrogate

Character vector describing whether to find surrogate decision splits at each branch node. Specify as 'on', 'off', 'all', or a positive scalar value.

- When 'on', `RegressionTree` finds at most 10 surrogate splits at each branch node.
- When set to a positive integer value, `RegressionTree` finds at most the specified number of surrogate splits at each branch node.
- When set to 'all', `RegressionTree` finds all surrogate splits at each branch node. The 'all' setting can use much time and memory.

Use surrogate splits to improve the accuracy of predictions for data with missing values. The setting also enables you to compute measures of predictive association between predictors.

Default: 'off'

Output Arguments

t

Regression tree template suitable to use in the `fitensemble` function. In an ensemble, `t` specifies how to grow the regression trees.

Examples

Create a Regression Template

Create a regression template with surrogate splits, and train an ensemble for the `carsmall` data with the template.

```
load carsmall
t = RegressionTree.template('surrogate','on');
X = [Acceleration Displacement Horsepower Weight];
Y = MPG;
ens = fitensemble(X,Y,'Learners',t);
```

See Also

`RegressionTree` | `fitrensemble` | `fitrtree` | `templateTree`

templateDiscriminant

Discriminant analysis classifier template

Syntax

```
t = templateDiscriminant()  
t = templateDiscriminant(Name,Value)
```

Description

`t = templateDiscriminant()` returns a discriminant analysis learner template suitable for training ensembles or error-correcting output code (ECOC) multiclass models.

If you specify a default template, then the software uses default values for all input arguments during training.

Specify `t` as a learner in `fitcensemble` or `fitcecoc`.

`t = templateDiscriminant(Name,Value)` creates a template with additional options specified by one or more name-value pair arguments.

For example, you can specify the discriminant type or the regularization parameter.

If you display `t` in the Command Window, then all options appear empty (`[]`), except those that you specify using name-value pair arguments. During training, the software uses default values for empty options.

Examples

Create a Discriminant Analysis Template for Ensemble Learning

Create a nondefault discriminant analysis template for use in `fitcensemble`.

Load Fisher's iris data set.

```
load fisheriris
```

Create a template for pseudolinear discriminant analysis.

```
t = templateDiscriminant('DiscrimType', 'pseudoLinear')
```

```
t =
```

```
Fit template for classification Discriminant.
```

```
DiscrimType: 'pseudoLinear'
  Gamma: []
  Delta: []
  FillCoeffs: []
  SaveMemory: []
  Version: 1
  Method: 'Discriminant'
  Type: 'classification'
```

All properties of the template object are empty except for `DiscrimType`, `Method`, and `Type`. When trained on, the software fills in the empty properties with their respective default values.

Specify `t` as a weak learner for a classification ensemble.

```
Mdl = fitensemble(meas, species, 'Method', 'Subspace', 'Learners', t);
```

Display the in-sample (resubstitution) misclassification error.

```
L = resubLoss(Mdl)
```

```
L = 0.0400
```

Input Arguments

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes.

You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example: `'DiscrimType', 'pseudoLinear', 'SaveMemory', 'on'` specifies a template for pseudolinear discriminant analysis that does not store the full covariance matrix.

Delta — Linear coefficient threshold

θ (default) | nonnegative scalar value

Linear coefficient threshold, specified as the comma-separated pair consisting of `'Delta'` and a nonnegative scalar value. If a coefficient of `Mdl` has magnitude smaller than `Delta`, `Mdl` sets this coefficient to θ , and you can eliminate the corresponding predictor from the model. Set `Delta` to a higher value to eliminate more predictors.

`Delta` must be θ for quadratic discriminant models.

Data Types: `single` | `double`

DiscrimType — Discriminant type

`'linear'` (default) | `'quadratic'` | `'diaglinear'` | `'diagquadratic'` | `'pseudoLinear'` | `'pseudoquadratic'`

Discriminant type, specified as the comma-separated pair consisting of `'DiscrimType'` and a character vector or string scalar in this table.

Value	Description	Predictor Covariance Treatment
<code>'linear'</code>	Regularized linear discriminant analysis (LDA)	<ul style="list-style-type: none"> All classes have the same covariance matrix. $\widehat{\Sigma}_\gamma = (1 - \gamma)\widehat{\Sigma} + \gamma\text{diag}(\widehat{\Sigma})$. <p>$\widehat{\Sigma}$ is the empirical, pooled covariance matrix and γ is the amount of regularization.</p>
<code>'diaglinear'</code>	LDA	All classes have the same, diagonal covariance matrix.

Value	Description	Predictor Covariance Treatment
'pseudolinear'	LDA	All classes have the same covariance matrix. The software inverts the covariance matrix using the pseudo inverse.
'quadratic'	Quadratic discriminant analysis (QDA)	The covariance matrices can vary among classes.
'diagquadratic'	QDA	The covariance matrices are diagonal and can vary among classes.
'pseudoquadratic'	QDA	The covariance matrices can vary among classes. The software inverts the covariance matrix using the pseudo inverse.

Note To use regularization, you must specify 'linear'. To specify the amount of regularization, use the Gamma name-value pair argument.

Example: 'DiscrimType', 'quadratic'

FillCoeffs — Coeffs property flag

'on' | 'off'

Coeffs property flag, specified as the comma-separated pair consisting of 'FillCoeffs' and 'on' or 'off'. Setting the flag to 'on' populates the Coeffs property in the classifier object. This can be computationally intensive, especially when cross-validating. The default is 'on', unless you specify a cross-validation name-value pair, in which case the flag is set to 'off' by default.

Example: 'FillCoeffs', 'off'

Gamma — Amount of regularization

scalar value in the interval [0,1]

Amount of regularization to apply when estimating the covariance matrix of the predictors, specified as the comma-separated pair consisting of 'Gamma' and a scalar value in the interval [0,1]. Gamma provides finer control over the covariance matrix structure than `DiscrimType`.

- If you specify 0, then the software does not use regularization to adjust the covariance matrix. That is, the software estimates and uses the unrestricted, empirical covariance matrix.
 - For linear discriminant analysis, if the empirical covariance matrix is singular, then the software automatically applies the minimal regularization required to invert the covariance matrix. You can display the chosen regularization amount by entering `Mdl.Gamma` at the command line.
 - For quadratic discriminant analysis, if at least one class has an empirical covariance matrix that is singular, then the software throws an error.
- If you specify a value in the interval (0,1), then you must implement linear discriminant analysis, otherwise the software throws an error. Consequently, the software sets `DiscrimType` to 'linear'.
- If you specify 1, then the software uses maximum regularization for covariance matrix estimation. That is, the software restricts the covariance matrix to be diagonal. Alternatively, you can set `DiscrimType` to 'diagLinear' or 'diagQuadratic' for diagonal covariance matrices.

Example: 'Gamma',1

Data Types: single | double

SaveMemory — Flag to save covariance matrix

'off' (default) | 'on'

Flag to save covariance matrix, specified as the comma-separated pair consisting of 'SaveMemory' and either 'on' or 'off'. If you specify 'on', then `fitcdiscr` does not store the full covariance matrix, but instead stores enough information to compute the matrix. The `predict` method computes the full covariance matrix for prediction, and does not store the matrix. If you specify 'off', then `fitcdiscr` computes and stores the full covariance matrix in `Mdl`.

Specify `SaveMemory` as 'on' when the input matrix contains thousands of predictors.

Example: 'SaveMemory', 'on'

Output Arguments

t — Discriminant analysis classification template

template object

Discriminant analysis classification template suitable for training ensembles or error-correcting output code (ECOC) multiclass models, returned as a template object. Pass **t** to `fitcensemble` or `fitcecoc` to specify how to create the discriminant analysis classifier for the ensemble or ECOC model, respectively.

If you display **t** to the Command Window, then all unspecified options appear empty (`[]`). However, the software replaces empty options with their corresponding default values during training.

See Also

`ClassificationDiscriminant` | `fitcecoc` | `fitcensemble` | `predict`

Introduced in R2014a

templateECOC

Error-correcting output codes learner template

Syntax

```
t = templateECOC()  
t = templateECOC(Name,Value)
```

Description

`t = templateECOC()` returns an error-correcting output codes (ECOC) classification learner template.

If you specify a default template, then the software uses default values for all input arguments during training.

`t = templateECOC(Name,Value)` returns a template with additional options specified by one or more name-value pair arguments.

For example, you can specify a coding design, whether to fit posterior probabilities, or the types of binary learners.

If you display `t` in the Command Window, then all options appear empty (`[]`), except those that you specify using name-value pair arguments. During training, the software uses default values for empty options.

Examples

Create a Default ECOC Classification Learner Template

Use `templateECOC` to create a default ECOC template.

```
t = templateECOC()
```

```
t =
Fit template for classification ECOC.

    BinaryLearners: ''
           Coding: ''
           FitPosterior: []
           Options: []
    VerbosityLevel: []
           NumConcurrent: []
           Version: 1
           Method: 'ECOC'
           Type: 'classification'
```

All properties of the template object are empty except for `Method` and `Type`. When you pass `t` to `testckfold`, the software fills in the empty properties with their respective default values. For example, the software fills the `BinaryLearners` property with 'SVM'. For details on other default values, see `fitcecoc`.

`t` is a plan for an ECOC learner. When you create it, no computation occurs. You can pass `t` to `testckfold` to specify a plan for an ECOC classification model to statistically compare with another model.

Statistically Compare Performance of Two ECOC Classification Models

One way to select predictors or features is to train two models where one that uses a subset of the predictors that trained the other. Statistically compare the predictive performances of the models. If there is sufficient evidence that model trained on fewer predictors performs better than the model trained using more of the predictors, then you can proceed with a more efficient model.

Load Fisher's iris data set. Plot all 2-dimensional combinations of predictors.

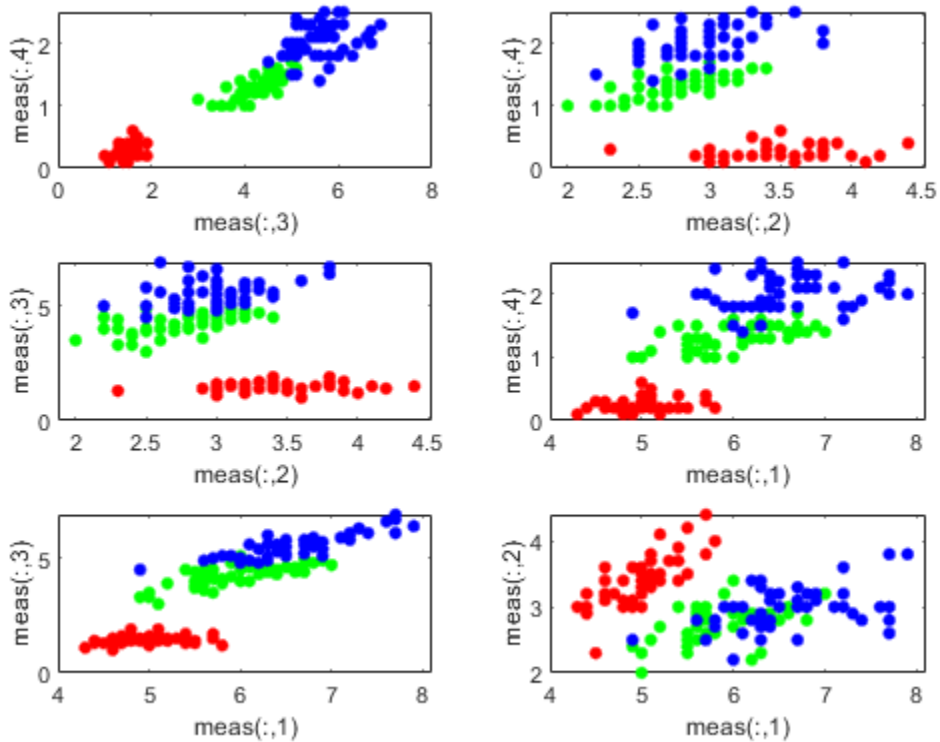

```
load fisheriris
d = size(meas,2); % Number of predictors
pairs = combnk(1:d,2);

figure;
for j = 1:size(pairs,1);
    subplot(3,2,j);
    gscatter(meas(:,pairs(j,1)),meas(:,pairs(j,2)),species);
```

```

xlabel(sprintf('meas(:,%d)',pairs(j,1)));
ylabel(sprintf('meas(:,%d)',pairs(j,2)));
legend off;
end

```

Based on the scatterplot, `meas(:,3)` and `meas(:,4)` seem like they separate the groups well.

Create an ECOC template. Specify to use a one-versus-all coding design.

```
t = templateECOC('Coding','onevsall');
```

By default, the ECOC model uses linear SVM binary learners. You can choose other, supported algorithms by specifying them using the 'Learners' name-value pair argument.

Test whether an ECOC model that is just trained using predictors 3 and 4 performs at most as well as an ECOC model that is trained using all predictors. Rejecting this null hypothesis means that the ECOC model trained using predictors 3 and 4 performs better than the ECOC model trained using all predictors. Suppose C_1 represents the classification error of the ECOC model trained using predictors 3 and 4 and C_2 represents the classification error of the ECOC model trained using all predictors, then the test is:

$$H_0: C_1 \geq C_2$$

$$H_1: C_1 < C_2$$

By default, `testckfold` conducts a 5-by-2 k -fold F test, which is not appropriate as a one-tailed test. Specify to conduct a 5-by-2 k -fold t test.

```
rng(1); % For reproducibility
[h,pValue] = testckfold(t,t,meas(:,pairs(1,:)),meas,species,...
    'Alternative','greater','Test','5x2t')
```

```
h = logical
    0
```

```
pValue = 0.8940
```

The `h = 0` indicates that there is not enough evidence to suggest that the model trained using predictors 3 and 4 is more accurate than the model trained using all predictors.

Input Arguments

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example:

'Coding', 'ternarycomplete', 'FitPosterior', true, 'Learners', 'tree' specifies a ternary complete coding design, to transform scores to posterior probabilities, and to grow classification trees for all binary learners.

Coding — Coding design

'onevsone' (default) | 'allpairs' | 'binarycomplete' | 'denserandom' | 'onevsall' | 'ordinal' | 'sparserandom' | 'ternarycomplete' | numeric matrix

Coding design name, specified as the comma-separated pair consisting of 'Coding' and a numeric matrix or a value in this table.

Value	Number of Binary Learners	Description
'allpairs' and 'onevsone'	$K(K - 1)/2$	For each binary learner, one class is positive, another is negative, and the software ignores the rest. This design exhausts all combinations of class pair assignments.
'binarycomplete'	$2^{(K - 1)} - 1$	This design partitions the classes into all binary combinations, and does not ignore any classes. For each binary learner, all class assignments are -1 and 1 with at least one positive and negative class in the assignment.
'denserandom'	Random, but approximately $10 \log_2 K$	For each binary learner, the software randomly assigns classes into positive or negative classes, with at least one of each type. For more details, see “Random Coding Design Matrices” on page 32-1874.

Value	Number of Binary Learners	Description
'onevsall'	K	For each binary learner, one class is positive and the rest are negative. This design exhausts all combinations of positive class assignments.
'ordinal'	$K - 1$	For the first binary learner, the first class is negative, and the rest positive. For the second binary learner, the first two classes are negative, the rest positive, and so on.
'sparsestochastic'	Random, but approximately $15 \log_2 K$	For each binary learner, the software randomly assigns classes as positive or negative with probability 0.25 for each, and ignores classes with probability 0.5. For more details, see "Random Coding Design Matrices" on page 32-1874.
'ternarycomplete'	$(3^K - 2^{(K+1)} + 1)/2$	This design partitions the classes into all ternary combinations. All class assignments are 0, -1, and 1 with at least one positive and one negative class in the assignment.

You can also specify a coding design using a custom coding matrix. The custom coding matrix is a K -by- L matrix. Each row corresponds to a class and each column corresponds to a binary learner. The class order (rows) corresponds to the order in `ClassNames`. Compose the matrix by following these guidelines:

- Every element of the custom coding matrix must be -1, 0, or 1, and the value must correspond to a dichotomous class assignment. This table describes the meaning of `Coding(i, j)`, that is, the class that learner `j` assigns to observations in class `i`.

Value	Dichotomous Class Assignment
-1	Learner <code>j</code> assigns observations in class <code>i</code> to a negative class.
0	Before training, learner <code>j</code> removes observations in class <code>i</code> from the data set.
1	Learner <code>j</code> assigns observations in class <code>i</code> to a positive class.

- Every column must contain at least one -1 or 1.
- For all column indices `i, j` such that `i ≠ j`, `Coding(:, i)` cannot equal `Coding(:, j)` and `Coding(:, i)` cannot equal `-Coding(:, j)`.
- All rows of the custom coding matrix must be different.

For more details on the form of custom coding design matrices, see “Custom Coding Design Matrices” on page 32-1872.

Example: `'Coding', 'ternarycomplete'`

Data Types: `char | string | double | single | int16 | int32 | int64 | int8`

FitPosterior — Flag indicating whether to transform scores to posterior probabilities

`false` or 0 (default) | `true` or 1

Flag indicating whether to transform scores to posterior probabilities, specified as the comma-separated pair consisting of `'FitPosterior'` and a `true` (1) or `false` (0).

If `FitPosterior` is `true`, then the software transforms binary-learner classification scores to posterior probabilities. You can obtain posterior probabilities by using `kfoldPredict`, `predict`, or `resubPredict`.

`fitcecoc` does not support fitting posterior probabilities if:

- The ensemble method is `AdaBoostM2`, `LPBoost`, `RUSBoost`, `RobustBoost`, or `TotalBoost`.

- The binary learners (**Learners**) are linear or kernel classification models that implement SVM. To obtain posterior probabilities for linear or kernel classification models, implement logistic regression instead.

Example: `'FitPosterior', true`

Data Types: `logical`

Learners – Binary learner templates

`'svm'` (default) | `'discriminant'` | `'kernel'` | `'knn'` | `'linear'` | `'naivebayes'` | `'tree'` | template object | cell vector of template objects

Binary learner templates, specified as the comma-separated pair consisting of `'Learners'` and a character vector, string scalar, template object, or cell vector of template objects. Specifically, you can specify binary classifiers such as SVM, and the ensembles that use `GentleBoost`, `LogitBoost`, and `RobustBoost`, to solve multiclass problems. However, `fitcecoc` also supports multiclass models as binary classifiers.

- If `Learners` is a character vector or string scalar, then the software trains each binary learner using the default values of the specified algorithm. This table summarizes the available algorithms.

Value	Description
<code>'discriminant'</code>	Discriminant analysis. For default options, see <code>templateDiscriminant</code> .
<code>'kernel'</code>	Kernel classification model. For default options, see <code>templateKernel</code> .
<code>'knn'</code>	k -nearest neighbors. For default options, see <code>templateKNN</code> .
<code>'linear'</code>	Linear classification model. For default options, see <code>templateLinear</code> .
<code>'naivebayes'</code>	Naive Bayes. For default options, see <code>templateNaiveBayes</code> .
<code>'svm'</code>	SVM. For default options, see <code>templateSVM</code> .
<code>'tree'</code>	Classification trees. For default options, see <code>templateTree</code> .

- If `Learners` is a template object, then each binary learner trains according to the stored options. You can create a template object using:

- `templateDiscriminant`, for discriminant analysis.
- `templateEnsemble`, for ensemble learning. You must at least specify the learning method (`Method`), the number of learners (`NLearn`), and the type of learner (`Learners`). You cannot use the `AdaBoostM2` ensemble method for binary learning.
- `templateKernel`, for kernel classification.
- `templateKNN`, for k -nearest neighbors.
- `templateLinear`, for linear classification.
- `templateNaiveBayes`, for naive Bayes.
- `templateSVM`, for SVM.
- `templateTree`, for classification trees.
- If `Learners` is a cell vector of template objects, then:
 - Cell j corresponds to binary learner j (in other words, column j of the coding design matrix), and the cell vector must have length L . L is the number of columns in the coding design matrix. For details, see `Coding`.
 - To use one of the built-in loss functions for prediction, then all binary learners must return a score in the same range. For example, you cannot include default SVM binary learners with default naive Bayes binary learners. The former returns a score in the range $(-\infty, \infty)$, and the latter returns a posterior probability as a score. Otherwise, you must provide a custom loss as a function handle to functions such as `predict` and `loss`.
 - You cannot specify linear classification model learner templates with any other template.
 - Similarly, you cannot specify kernel classification model learner templates with any other template.

By default, the software trains learners using default SVM templates.

Example: `'Learners', 'tree'`

Output Arguments

t — ECOC classification template

template object

ECOC classification template, returned as a template object. Pass `t` to `testckfold` to specify how to create an ECOC classifier whose predictive performance you want to compare with another classifier.

If you display `t` to the Command Window, then all, unspecified options appear empty (`[]`). However, the software replaces empty options with their corresponding default values during training.

`ClassificationECOC` | `designecoc` | `fitcecoc` | `predict` |
`templateDiscriminant` | `templateEnsemble` | `templateKNN` | `templateSVM` |
`templateTree` | `testckfold`

Introduced in R2015a

templateEnsemble

Ensemble learning template

Syntax

```
t = templateEnsemble(Method, NLearn, Learners)
t = templateEnsemble(Method, NLearn, Learners, Name, Value)
```

Description

`t = templateEnsemble(Method, NLearn, Learners)` returns an ensemble learning template that specifies to use the ensemble aggregation method `Method`, `NLearn` learning cycles, and weak learners `Learners`.

All other options of the template (`t`) specific to ensemble learning appear empty, but the software uses their corresponding default values during training.

`t = templateEnsemble(Method, NLearn, Learners, Name, Value)` returns an ensemble template with additional options specified by one or more name-value pair arguments.

For example, you can specify the number of predictors in each random subspace learner, learning rate for shrinkage, or the target classification error for `RobustBoost`.

If you display `t` in the Command Window, then all options appear empty (`[]`), except those options that you specify using name-value pair arguments. During training, the software uses default values for empty options.

Examples

Create an Ensemble Learning Template

Use `templateEnsemble` to specify an ensemble learning template. You must specify the ensemble method, the number of learning cycles, and the type of weak learners. For this

example, specify the AdaBoostM1 method, 100 learners, and classification tree weak learners.

```
t = templateEnsemble('AdaBoostM1',100,'tree')
```

```
t =
```

```
Fit template for classification AdaBoostM1.
```

```

      Type: 'classification'
      Method: 'AdaBoostM1'
LearnerTemplates: 'Tree'
      NLearn: 100
      LearnRate: []

```

All properties of the template object are empty except for `Method`, `Type`, `LearnerTemplates`, and `NLearn`. When trained on, the software fills in the empty properties with their respective default values. For example, the software fills the `LearnRate` property with 1.

`t` is a plan for an ensemble learner, and no computation takes place when you specify it. You can pass `t` to `fitcecoc` to specify ensemble binary learners for ECOC multiclass learning.

Create an Ensemble Template for ECOC Multiclass Learning

Create an ensemble template for use in `fitcecoc`.

Load the arrhythmia data set.

```
load arrhythmia
tabulate(categorical(Y));
```

Value	Count	Percent
1	245	54.20%
2	44	9.73%
3	15	3.32%
4	15	3.32%
5	13	2.88%
6	25	5.53%
7	3	0.66%
8	2	0.44%

9	9	1.99%
10	50	11.06%
14	4	0.88%
15	5	1.11%
16	22	4.87%

```
rng(1); % For reproducibility
```

Some classes have small relative frequencies in the data.

Create a template for a AdaBoostM1 ensemble of classification trees, and specify to use 100 learners and a shrinkage of 0.1. By default, boosting grows stumps (i.e., one node having a set of leaves). Since there are classes with small frequencies, the trees must be leafy enough to be sensitive to the minority classes. Specify the minimum number of leaf node observations to 3.

```
tTree = templateTree('MinLeafSize',20);  
t = templateEnsemble('AdaBoostM1',100,tTree,'LearnRate',0.1);
```

All properties of the template objects are empty except for Method and Type, and the corresponding properties of the name-value pair argument values in the function calls. When you pass t to the training function, the software fills in the empty properties with their respective default values.

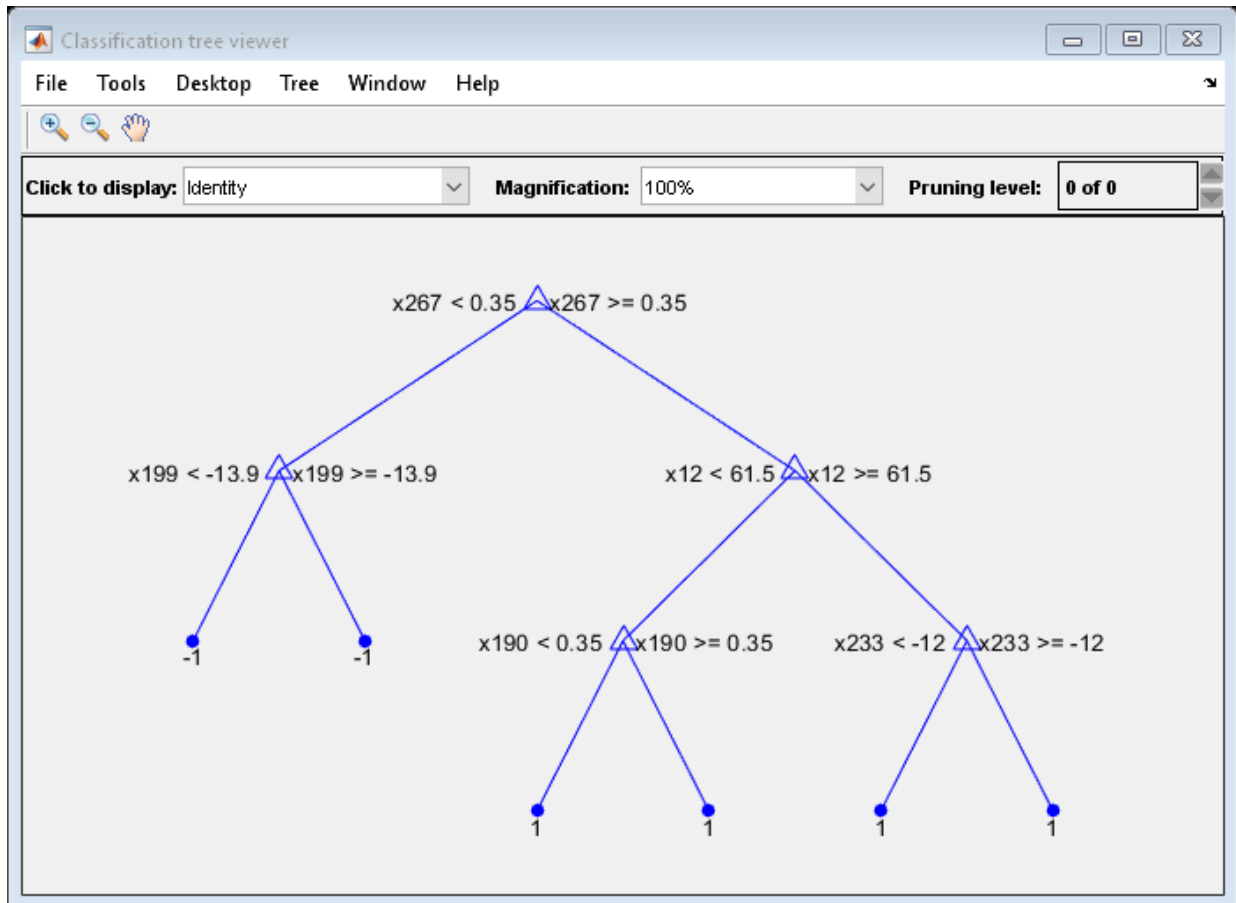

Specify t as a binary learner for an ECOC multiclass model. Train using the default one-versus-one coding design.

```
Mdl = fitcecoc(X,Y,'Learners',t);
```

- Mdl is a ClassificationECOC multiclass model.
- Mdl.BinaryLearners is a 78-by-1 cell array of CompactClassificationEnsemble models.
- Mdl.BinaryLearners{j}.Trained is a 100-by-1 cell array of CompactClassificationTree models, for j = 1,...,78.

You can verify that one of the binary learners contains a weak learner that isn't a stump by using view.

```
view(Mdl.BinaryLearners{1}.Trained{1}, 'Mode', 'graph')
```

Display the in-sample (resubstitution) misclassification error.

```
L = resubLoss(Mdl, 'LossFun', 'classiferror')
```

```
L = 0.0597
```

Speed Up Training ECOC Classifiers Using Binning and Parallel Computing

Train a one-versus-all ECOC classifier using a GentleBoost ensemble of decision trees with surrogate splits. To speed up training, bin numeric predictors and use parallel

computing. Binning is valid only when `fitcecoc` uses a tree learner. After training, estimate the classification error using 10-fold cross-validation. Note that parallel computing requires Parallel Computing Toolbox™.

Load Sample Data

Load and inspect the `arrhythmia` data set.

```
load arrhythmia
[n,p] = size(X)

n = 452

p = 279

isLabels = unique(Y);
nLabels = numel(isLabels)

nLabels = 13

tabulate(categorical(Y))
```

Value	Count	Percent
1	245	54.20%
2	44	9.73%
3	15	3.32%
4	15	3.32%
5	13	2.88%
6	25	5.53%
7	3	0.66%
8	2	0.44%
9	9	1.99%
10	50	11.06%
14	4	0.88%
15	5	1.11%
16	22	4.87%

The data set contains 279 predictors, and the sample size of 452 is relatively small. Of the 16 distinct labels, only 13 are represented in the response (Y). Each label describes various degrees of arrhythmia, and 54.20% of the observations are in class 1.

Train One-Versus-All ECOC Classifier

Create an ensemble template. You must specify at least three arguments: a method, a number of learners, and the type of learner. For this example, specify `'GentleBoost'`

for the method, 100 for the number of learners, and a decision tree template that uses surrogate splits because there are missing observations.

```
tTree = templateTree('surrogate','on');
tEnsemble = templateEnsemble('GentleBoost',100,tTree);
```

tEnsemble is a template object. Most of its properties are empty, but the software fills them with their default values during training.

Train a one-versus-all ECOC classifier using the ensembles of decision trees as binary learners. To speed up training, use binning and parallel computing.

- Binning ('NumBins',50) — When you have a large training data set, you can speed up training (a potential decrease in accuracy) by using the 'NumBins' name-value pair argument. This argument is valid only when fitcecoc uses a tree learner. If you specify the 'NumBins' value, then the software bins every numeric predictor into a specified number of equiprobable bins, and then grows trees on the bin indices instead of the original data. You can try 'NumBins',50 first, and then change the 'NumBins' value depending on the accuracy and training speed.
- Parallel computing ('Options',statset('UseParallel',true)) — With a Parallel Computing Toolbox license, you can speed up the computation by using parallel computing, which sends each binary learner to a worker in the pool. The number of workers depends on your system configuration. When you use decision trees for binary learners, fitcecoc parallelizes training using Intel® Threading Building Blocks (TBB) for dual-core systems and above. Therefore, specifying the 'UseParallel' option is not helpful on a single computer. Use this option on a cluster.

Additionally, specify that the prior probabilities are $1/K$, where $K = 13$ is the number of distinct classes.

```
options = statset('UseParallel',true);
Mdl = fitcecoc(X,Y,'Coding','onevsall','Learners',tEnsemble,...
    'Prior','uniform','NumBins',50,'Options',options);
```

```
Starting parallel pool (parpool) using the 'local' profile ...
Connected to the parallel pool (number of workers: 6).
```

Mdl is a ClassificationECOC model.

Cross-Validation

Cross-validate the ECOC classifier using 10-fold cross-validation.

```
CVMdl = crossval(Mdl,'Options',options);
```

Warning: One or more folds do not contain points from all the groups.

CVMdl is a `ClassificationPartitionedECOC` model. The warning indicates that some classes are not represented while the software trains at least one fold. Therefore, those folds cannot predict labels for the missing classes. You can inspect the results of a fold using cell indexing and dot notation. For example, access the results of the first fold by entering `CVMdl.Trained{1}`.

Use the cross-validated ECOC classifier to predict validation-fold labels. You can compute the confusion matrix by using `confusionchart`. Move and resize the chart by changing the inner position property to ensure that the percentages appear in the row summary.

```
oofLabel = kfoldPredict(CVMdl,'Options',options);  
ConfMat = confusionchart(Y,oofLabel,'RowSummary','total-normalized');  
ConfMat.InnerPosition = [0.10 0.12 0.85 0.85];
```

1	212	13			1	2				8				9	46.9%	7.3%
2	19	20		1		1				1		1	1		4.4%	5.3%
3		1	14												3.1%	0.2%
4	3	1		10	1										2.2%	1.1%
5	7				3					2				1	0.7%	2.2%
6	1	1				22								1	4.9%	0.7%
7	2		1													0.7%
8	2															0.4%
9									9						2.0%	
10	15				2	1				27				5	6.0%	5.1%
14	3													1		0.9%
15	1	1	1	1	1											1.1%
16	14	2	1			2	1					1	1			4.9%
	1	2	3	4	5	6	7	8	9	10	14	15	16			
	Predicted Class															

Reproduce Binned Data

Reproduce binned predictor data by using the BinEdges property of the trained model and the discretize function.

```
X = Mdl.X; % Predictor data
Xbinned = zeros(size(X));
edges = Mdl.BinEdges;
% Find indices of binned predictors.
idxNumeric = find(~cellfun(@isempty,edges));
if iscolumn(idxNumeric)
    idxNumeric = idxNumeric';
end
for j = idxNumeric
```

```
x = X(:,j);  
% Convert x to array if x is a table.  
if istable(x)  
    x = table2array(x);  
end  
% Group x into bins by using the discretize function.  
xbinned = discretize(x,[-inf; edges{j}; inf]);  
Xbinned(:,j) = xbinned;  
end
```

Xbinned contains the bin indices, ranging from 1 to the number of bins, for numeric predictors. Xbinned values are 0 for categorical predictors. If X contains NaNs, then the corresponding Xbinned values are NaNs.

Input Arguments

Method — Ensemble aggregation method

```
'AdaBoostM1' | 'LogitBoost' | 'GentleBoost' | 'RUSBoost' | 'Subspace' |  
'Bag' | 'AdaBoostM2' | 'LSBoost' | ...
```

Ensemble aggregation method, specified as one of the method names in this list.

- For classification with two classes:
 - 'AdaBoostM1'
 - 'LogitBoost'
 - 'GentleBoost'
 - 'RobustBoost' (requires Optimization Toolbox)
 - 'LPBoost' (requires Optimization Toolbox)
 - 'TotalBoost' (requires Optimization Toolbox)
 - 'RUSBoost'
 - 'Subspace'
 - 'Bag'
- For classification with three or more classes:
 - 'AdaBoostM2'
 - 'LPBoost' (requires Optimization Toolbox)

- 'TotalBoost' (requires Optimization Toolbox)
- 'RUSBoost'
- 'Subspace'
- 'Bag'
- For regression:
 - 'LSBoost'
 - 'Bag'

If you specify 'Method', 'Bag', then specify the problem type using the `Type` name-value pair argument, because you can specify 'Bag' for classification and regression problems.

For details about ensemble aggregation algorithms and examples, see “Ensemble Algorithms” on page 18-50 and “Choose an Applicable Ensemble Aggregation Method” on page 18-42.

NLearn — Number of ensemble learning cycles

positive integer | 'AllPredictorCombinations'

Number of ensemble learning cycles, specified as a positive integer or 'AllPredictorCombinations'.

- If you specify a positive integer, then, at every learning cycle, the software trains one weak learner for every template object in `Learners`. Consequently, the software trains `NLearn* numel(Learners)` learners.
- If you specify 'AllPredictorCombinations', then set `Method` to 'Subspace' and specify one learner only in `Learners`. With these settings, the software trains learners for all possible combinations of predictors taken `NPredToSample` at a time. Consequently, the software trains `nchoosek(size(X,2), NPredToSample)` learners.

For more details, see “Tips” on page 32-6708.

Data Types: single | double | char | string

Learners — Weak learners to use in ensemble

weak-learner name | weak-learner template object | cell vector of weak-learner template objects

Weak learners to use in the ensemble, specified as a weak-learner name, weak-learner template object, or cell array of weak-learner template objects.

Weak Learner	Weak-Learner Name	Template Object Creation Function	Method Settings
Discriminant analysis	'Discriminant'	templateDiscriminant	Recommended for 'Subspace'
k nearest neighbors	'KNN'	templateKNN	For 'Subspace' only
Decision tree	'Tree'	templateTree	All methods except 'Subspace'

For more details, see NLearn and “Tips” on page 32-6708.

Example: For an ensemble composed of two types of classification trees, supply `{t1 t2}`, where `t1` and `t2` are classification tree templates.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example: `'LearningRate', 0.05, 'NPrint', 5` specifies to use 0.05 as the learning rate and to display a message to the command line every time it trains 5 learners.

General Ensemble Options

NPrint — Printout frequency

'off' (default) | positive integer

Printout frequency, specified as the comma-separated pair consisting of `'NPrint'` and a positive integer or `'off'`.

To track the number of *weak learners* or *folds* that the software trained so far, specify a positive integer. That is, if you specify the positive integer m and:

- Do not specify any cross-validation option of the fitting function (for example, `CrossVal`), then the software displays a message to the command line every time it completes training m weak learners.
- A cross-validation option, then the software displays a message to the command line every time it finishes training m folds.

If you specify 'off', then the software does not display a message when it completes training weak learners.

Tip When training an ensemble of many weak learners on a large data set, specify a positive integer for `NPrint`.

Example: 'NPrint',5

Data Types: single | double | char | string

Type — Supervised learning type

'classification' | 'regression'

Supervised learning type, specified as the comma-separated pair consisting of 'Type' and 'classification' or 'regression'.

- If Method is 'bag', then the supervised learning type is ambiguous. Therefore, specify Type when bagging.
- Otherwise, the value of Method determines the supervised learning type.

Example: 'Type','classification'

Sampling Options for Boosting Methods and Bagging

FResample — Fraction of training set to resample

1 (default) | positive scalar in (0,1]

Fraction of the training set to resample for every weak learner, specified as the comma-separated pair consisting of 'FResample' and a positive scalar in (0,1].

To use 'FResample', specify 'bag' for Method or set Resample to 'on'.

Example: 'FResample',0.75

Data Types: single | double

Replace — Flag indicating to sample with replacement

'on' (default) | 'off'

Flag indicating sampling with replacement, specified as the comma-separated pair consisting of 'Replace' and 'off' or 'on'.

- For 'on', the software samples the training observations with replacement.
- For 'off', the software samples the training observations without replacement. If you set `Resample` to 'on', then the software samples training observations assuming uniform weights. If you also specify a boosting method, then the software boosts by reweighting observations.

Unless you set `Method` to 'bag' or set `Resample` to 'on', `Replace` has no effect.

Example: 'Replace', 'off'

Resample — Flag indicating to resample

'off' | 'on'

Flag indicating to resample, specified as the comma-separated pair consisting of 'Resample' and 'off' or 'on'.

- If `Method` is a boosting method, then:
 - 'Resample', 'on' specifies to sample training observations using updated weights as the multinomial sampling probabilities.
 - 'Resample', 'off' (default) specifies to reweight observations at every learning iteration.
- If `Method` is 'bag', then 'Resample' must be 'on'. The software resamples a fraction of the training observations (see `FResample`) with or without replacement (see `Replace`).

If you specify to resample using `Resample`, then it is good practice to resample to entire data set. That is, use the default setting of 1 for `FResample`.

AdaBoostM1, AdaBoostM2, LogitBoost, GentleBoost, and LSBoost Method Options

LearnRate — Learning rate for shrinkage

1 (default) | numeric scalar in (0,1]

Learning rate for shrinkage, specified as the comma-separated pair consisting of a numeric scalar in the interval (0,1].

To train an ensemble using shrinkage, set `LearnRate` to a value less than 1, for example, 0.1 is a popular choice. Training an ensemble using shrinkage requires more learning iterations, but often achieves better accuracy.

Example: 'LearnRate', 0.1

Data Types: `single` | `double`

RUSBoost Method Options

LearnRate — Learning rate for shrinkage

1 (default) | numeric scalar in (0,1]

Learning rate for shrinkage, specified as the comma-separated pair consisting of a numeric scalar in the interval (0,1].

To train an ensemble using shrinkage, set `LearnRate` to a value less than 1, for example, 0.1 is a popular choice. Training an ensemble using shrinkage requires more learning iterations, but often achieves better accuracy.

Example: `'LearnRate', 0.1`

Data Types: `single` | `double`

RatioToSmallest — Sampling proportion with respect to lowest-represented class

positive numeric scalar | numeric vector of positive values

Sampling proportion with respect to the lowest-represented class, specified as the comma-separated pair consisting of `'RatioToSmallest'` and a numeric scalar or numeric vector of positive values with length equal to the number of distinct classes in the training data.

Suppose that there are K classes in the training data and the lowest-represented class has m observations in the training data.

- If you specify the positive numeric scalar s , then the software samples $s*m$ observations from each class, that is, it uses the same sampling proportion for each class. For more details, see “Algorithms” on page 32-6709.
- If you specify the numeric vector $[s_1, s_2, \dots, s_K]$, then the software samples s_i*m observations from class i , $i = 1, \dots, K$. The elements of `RatioToSmallest` correspond to the order of the class names specified using the `ClassNames` name-value pair argument of the fitting function (see “Tips” on page 32-6708).

The default value is `ones(K, 1)`, which specifies to sample m observations from each class.

Example: `'RatioToSmallest', [2, 1]`

Data Types: `single` | `double`

LPBoost and TotalBoost Method Options**MarginPrecision — Margin precision to control convergence speed**

0.1 (default) | numeric scalar in [0,1]

Margin precision to control convergence speed, specified as the comma-separated pair consisting of 'MarginPrecision' and a numeric scalar in the interval [0,1]. MarginPrecision affects the number of boosting iterations required for convergence.

Tip To train an ensemble using many learners, specify a small value for MarginPrecision. For training using a few learners, specify a large value.

Example: 'MarginPrecision',0.5

Data Types: single | double

RobustBoost Method Options**RobustErrorGoal — Target classification error**

0.1 (default) | nonnegative numeric scalar

Target classification error, specified as the comma-separated pair consisting of 'RobustErrorGoal' and a nonnegative numeric scalar. The upper bound on possible values depends on the values of RobustMarginSigma and RobustMaxMargin. However, the upper bound cannot exceed 1.

Tip For a particular training set, usually there is an optimal range for RobustErrorGoal. If you set it too low or too high, then the software can produce a model with poor classification accuracy. Try cross-validating to search for the appropriate value.

Example: 'RobustErrorGoal',0.05

Data Types: single | double

RobustMarginSigma — Classification margin distribution spread

0.1 (default) | positive numeric scalar

Classification margin distribution spread over the training data, specified as the comma-separated pair consisting of 'RobustMarginSigma' and a positive numeric scalar.

Before specifying `RobustMarginSigma`, consult the literature on `RobustBoost`, for example, [19].

Example: `'RobustMarginSigma',0.5`

Data Types: `single` | `double`

RobustMaxMargin — Maximal classification margin

0 (default) | nonnegative numeric scalar

Maximal classification margin in the training data, specified as the comma-separated pair consisting of `'RobustMaxMargin'` and a nonnegative numeric scalar. The software minimizes the number of observations in the training data having classification margins below `RobustMaxMargin`.

Example: `'RobustMaxMargin',1`

Data Types: `single` | `double`

Random Subspace Method Options

NPredToSample — Number of predictors to sample

1 (default) | positive integer

Number of predictors to sample for each random subspace learner, specified as the comma-separated pair consisting of `'NPredToSample'` and a positive integer in the interval $1, \dots, p$, where p is the number of predictor variables (`size(X,2)` or `size(Tbl,2)`).

Data Types: `single` | `double`

Output Arguments

t — Classification template for ensemble learning

classification template object

Classification template for ensemble learning, returned as a template object. You can pass `t` to, for example, `fitcecoc` to specify how to create the ensemble learning classifier for the ECOC model.

If you display `t` in the Command Window, then all, unspecified options appear empty (`[]`). However, the software replaces empty options with their corresponding default values during training.

Tips

- NLearn can vary from a few dozen to a few thousand. Usually, an ensemble with good predictive power requires from a few hundred to a few thousand weak learners. However, you do not have to train an ensemble for that many cycles at once. You can start by growing a few dozen learners, inspect the ensemble performance and then, if necessary, train more weak learners using `resume` for classification problems, or `resume` for regression problems.
- Ensemble performance depends on the ensemble setting and the setting of the weak learners. That is, if you specify weak learners with default parameters, then the ensemble can perform. Therefore, like ensemble settings, it is good practice to adjust the parameters of the weak learners using templates, and to choose values that minimize generalization error.
- If you specify to resample using `Resample`, then it is good practice to resample to entire data set. That is, use the default setting of 1 for `FResample`.
- In classification problems (that is, `Type` is `'classification'`):
 - If the ensemble aggregation method (`Method`) is `'bag'` and:
 - The misclassification cost is highly imbalanced, then, for in-bag samples, the software oversamples unique observations from the class that has a large penalty.
 - The class prior probabilities are highly skewed, the software oversamples unique observations from the class that has a large prior probability.

For smaller sample sizes, these combinations can result in a very low relative frequency of out-of-bag observations from the class that has a large penalty or prior probability. Consequently, the estimated out-of-bag error is highly variable and it might be difficult to interpret. To avoid large estimated out-of-bag error variances, particularly for small sample sizes, set a more balanced misclassification cost matrix using the `Cost` name-value pair argument of the fitting function, or a less skewed prior probability vector using `Prior` name-value pair argument of the fitting function.

- Because the order of some input and output arguments correspond to the distinct classes in the training data, it is good practice to specify the class order using the `ClassNames` name-value pair argument of the fitting function.
 - To quickly determine the class order, remove all observations from the training data that are unclassified (that is, have a missing label), obtain and display an

array of all the distinct classes, and then specify the array for `ClassNames`. For example, suppose the response variable (`Y`) is a cell array of labels. This code specifies the class order in the variable `classNames`.

```
Ycat = categorical(Y);
classNames = categories(Ycat)
```

`categorical` assigns `<undefined>` to unclassified observations and `categories` excludes `<undefined>` from its output. Therefore, if you use this code for cell arrays of labels or similar code for categorical arrays, then you do not have to remove observations with missing labels to obtain a list of the distinct classes.

- To specify that order should be from lowest-represented label to most-represented, then quickly determine the class order (as in the previous bullet), but arrange the classes in the list by frequency before passing the list to `ClassNames`. Following from the previous example, this code specifies the class order from lowest- to most-represented in `classNamesLH`.

```
Ycat = categorical(Y);
classNames = categories(Ycat);
freq = countcats(Ycat);
[~,idx] = sort(freq);
classNamesLH = classNames(idx);
```

Algorithms

- For details of ensemble aggregation algorithms, see “Ensemble Algorithms” on page 18-50.
- If you specify `Method` to be a boosting algorithm and `Learners` to be decision trees, then the software grows stumps by default. A decision stump is one root node connected to two terminal, leaf nodes. You can adjust tree depth by specifying the `MaxNumSplits`, `MinLeafSize`, and `MinParentSize` name-value pair arguments using `templateTree`.
- The software generates in-bag samples by oversampling classes with large misclassification costs and undersampling classes with small misclassification costs. Consequently, out-of-bag samples have fewer observations from classes with large misclassification costs and more observations from classes with small misclassification costs. If you train a classification ensemble using a small data set and a highly skewed cost matrix, then the number of out-of-bag observations per class might be very low.

Therefore, the estimated out-of-bag error might have a large variance and might be difficult to interpret. The same phenomenon can occur for classes with large prior probabilities.

- For the RUSBoost ensemble aggregation method (`Method`), the name-value pair argument `RatioToSmallest` specifies the sampling proportion for each class with respect to the lowest-represented class. For example, suppose that there are 2 classes in the training data, *A* and *B*. *A* have 100 observations and *B* have 10 observations. Also, suppose that the lowest-represented class has *m* observations in the training data.
 - If you set `'RatioToSmallest', 2`, then $s*m = 2*10 = 20$. Consequently, the software trains every learner using 20 observations from class *A* and 20 observations from class *B*. If you set `'RatioToSmallest', [2 2]`, then you will obtain the same result.
 - If you set `'RatioToSmallest', [2, 1]`, then $s1*m = 2*10 = 20$ and $s2*m = 1*10 = 10$. Consequently, the software trains every learner using 20 observations from class *A* and 10 observations from class *B*.
- For ensembles of decision trees, and for dual-core systems and above, `fitensemble` and `fitrensemble` parallelize training using Intel Threading Building Blocks (TBB). For details on Intel TBB, see <https://software.intel.com/en-us/intel-tbb>.

“Framework for Ensemble Learning” on page 18-40

Introduced in R2014b

templateKernel

Kernel model template

`templateKernel` creates a template suitable for fitting a Gaussian kernel classification model for nonlinear classification.

The template specifies the binary learner model, number of dimensions of expanded space, kernel scale, box constraint, and regularization strength, among other parameters. After creating the template, train the model by passing the template and data to `fitcecoc`.

Syntax

```
t = templateKernel()  
t = templateKernel(Name,Value)
```

Description

`t = templateKernel()` returns a kernel model template.

If you create a default template, then the software uses default values for all input arguments during training.

`t = templateKernel(Name,Value)` returns a template with additional options specified by one or more name-value pair arguments. For example, you can implement logistic regression or specify the number of dimensions of the expanded space.

If you display `t` in the Command Window, then some properties of `t` appear empty (`[]`). During training, the software uses default values for the empty properties.

Examples

Create Default Kernel Model Template

Create a default kernel model template and use it to train an error-correcting output codes (ECOC) multiclass model.

Load Fisher's iris data set.

```
load fisheriris
```

Create a default kernel model template.

```
t = templateKernel()
```

```
t =
```

```
Fit template for classification Kernel.
```

```
    BetaTolerance: []
    BlockSize: []
    BoxConstraint: []
    Epsilon: []
    NumExpansionDimensions: []
    GradientTolerance: []
    HessianHistorySize: []
    IterationLimit: []
    KernelScale: []
    Lambda: []
    Learner: 'svm'
    LossFunction: []
    Stream: []
    VerbosityLevel: []
    Version: 1
    Method: 'Kernel'
    Type: 'classification'
```

During training, the software fills in the empty properties with their respective default values.

Specify `t` as a binary learner for an ECOC multiclass model.

```
Mdl = fitcecoc(meas,species,'Learners',t)
```

```
Mdl =
```

```
classreg.learning.classif.CompactClassificationECOC
    ResponseName: 'Y'
```

```

    ClassNames: {'setosa' 'versicolor' 'virginica'}
    ScoreTransform: 'none'
    BinaryLearners: {3x1 cell}
    CodingMatrix: [3x3 double]

```

Properties, Methods

Mdl is a CompactClassificationECOC multiclass classifier.

Specify Kernel Model Template Options

Create a kernel model template with additional options to implement logistic regression with a kernel scale parameter selected by a heuristic procedure.

```
t = templateKernel('Learner','logistic','KernelScale','auto')
```

```
t =
Fit template for classification Kernel.
```

```

```

Input Arguments

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example:

`'Learner', 'logistic', 'NumExpansionDimensions', 2^15, 'KernelScale', 'auto'` specifies to implement logistic regression after mapping the predictor data to the 2^{15} dimensional space using feature expansion with a kernel scale parameter selected by a heuristic procedure.

Kernel Classification Options

Learner — Linear classification model type

`'svm'` (default) | `'logistic'`

Linear classification model type, specified as the comma-separated pair consisting of `'Learner'` and `'svm'` or `'logistic'`.

In the following table, $f(x) = T(x)\beta + b$.

- x is an observation (row vector) from p predictor variables.
- $T(\cdot)$ is a transformation of an observation (row vector) for feature expansion. $T(x)$ maps x in \mathbb{R}^p to a high-dimensional space (\mathbb{R}^m).
- β is a vector of m coefficients.
- b is the scalar bias.

Value	Algorithm	Response Range	Loss Function
<code>'svm'</code>	Support vector machine	$y \in \{-1, 1\}$; 1 for the positive class and -1 otherwise	Hinge: $\ell[y, f(x)] = \max[0, 1 - yf(x)]$
<code>'logistic'</code>	Logistic regression	Same as <code>'svm'</code>	Deviance (logistic): $\ell[y, f(x)] = \log\{1 + \exp[-yf(x)]\}$

Example: 'Learner', 'logistic'

NumExpansionDimensions — Number of dimensions of expanded space

'auto' (default) | positive integer

Number of dimensions of the expanded space, specified as the comma-separated pair consisting of 'NumExpansionDimensions' and 'auto' or a positive integer. For 'auto', the `templateKernel` function selects the number of dimensions using $2.^{\text{ceil}(\min(\log_2(p)+5, 15))}$, where p is the number of predictors.

For details, see “Random Feature Expansion” on page 32-6719.

Example: 'NumExpansionDimensions', 2^15

Data Types: char | string | single | double

KernelScale — Kernel scale parameter

1 (default) | 'auto' | positive scalar

Kernel scale parameter, specified as the comma-separated pair consisting of 'KernelScale' and 'auto' or a positive scalar. The software obtains a random basis for random feature expansion by using the kernel scale parameter. For details, see “Random Feature Expansion” on page 32-6719.

If you specify 'auto', then the software selects an appropriate kernel scale parameter using a heuristic procedure. This heuristic procedure uses subsampling, so estimates can vary from one call to another. Therefore, to reproduce results, set a random number seed by using `rng` before training.

Example: 'KernelScale', 'auto'

Data Types: char | string | single | double

BoxConstraint — Box constraint

1 (default) | positive scalar

Box constraint, specified as the comma-separated pair consisting of 'BoxConstraint' and a positive scalar.

This argument is valid only when 'Learner' is 'svm' (default) and you do not specify a value for the regularization term strength 'Lambda'. You can specify either 'BoxConstraint' or 'Lambda' because the box constraint (C) and the regularization term strength (λ) are related by $C = 1/(\lambda n)$, where n is the number of observations.

Example: 'BoxConstraint',100

Data Types: single | double

Lambda — Regularization term strength

'auto' (default) | nonnegative scalar

Regularization term strength, specified as the comma-separated pair consisting of 'Lambda' and 'auto' or a nonnegative scalar.

For 'auto', the value of 'Lambda' is $1/n$, where n is the number of observations.

You can specify either 'BoxConstraint' or 'Lambda' because the box constraint (C) and the regularization term strength (λ) are related by $C = 1/(\lambda n)$.

Example: 'Lambda',0.01

Data Types: char | string | single | double

Convergence Controls

BetaTolerance — Relative tolerance on linear coefficients and bias term

1e-5 (default) | nonnegative scalar

Relative tolerance on the linear coefficients and the bias term (intercept), specified as the comma-separated pair consisting of 'BetaTolerance' and a nonnegative scalar.

Let $B_t = [\beta_t' \ b_t]$, that is, the vector of the coefficients and the bias term at optimization iteration t . If $\left\| \frac{B_t - B_{t-1}}{B_t} \right\|_2 < \text{BetaTolerance}$, then optimization terminates.

If you also specify GradientTolerance, then optimization terminates when the software satisfies either stopping criterion.

Example: 'BetaTolerance',1e-6

Data Types: single | double

GradientTolerance — Absolute gradient tolerance

1e-6 (default) | nonnegative scalar

Absolute gradient tolerance, specified as the comma-separated pair consisting of 'GradientTolerance' and a nonnegative scalar.

Let $\nabla \mathcal{L}_t$ be the gradient vector of the objective function with respect to the coefficients and bias term at optimization iteration t . If $\|\nabla \mathcal{L}_t\|_\infty = \max|\nabla \mathcal{L}_t| < \text{GradientTolerance}$, then optimization terminates.

If you also specify `BetaTolerance`, then optimization terminates when the software satisfies either stopping criterion.

Example: `'GradientTolerance', 1e-5`

Data Types: `single` | `double`

IterationLimit — Maximum number of optimization iterations

positive integer

Maximum number of optimization iterations, specified as the comma-separated pair consisting of `'IterationLimit'` and a positive integer.

The default value is 1000 if the transformed data fits in memory, as specified by the `BlockSize` name-value pair argument. Otherwise, the default value is 100.

Example: `'IterationLimit', 500`

Data Types: `single` | `double`

Other Kernel Classification Options

BlockSize — Maximum amount of allocated memory

$4e^3$ (4GB) (default) | positive scalar

Maximum amount of allocated memory (in megabytes), specified as the comma-separated pair consisting of `'BlockSize'` and a positive scalar.

If `templateKernel` requires more memory than the value of `'BlockSize'` to hold the transformed predictor data, then the software uses a block-wise strategy. For details about the block-wise strategy, see “Algorithms” on page 32-7430.

Example: `'BlockSize', 1e4`

Data Types: `single` | `double`

RandomStream — Random number stream

global stream (default) | random stream object

Random number stream for reproducibility of data transformation, specified as the comma-separated pair consisting of 'RandomStream' and a random stream object. For details, see “Random Feature Expansion” on page 32-6719.

Use 'RandomStream' to reproduce the random basis functions that `templateKernel` uses to transform the predictor data to a high-dimensional space. For details, see “Managing the Global Stream” (MATLAB) and “Creating and Controlling a Random Number Stream” (MATLAB).

Example: 'RandomStream',RandStream('mlfg6331_64')

HessianHistorySize — Size of history buffer for Hessian approximation

15 (default) | positive integer

Size of the history buffer for Hessian approximation, specified as the comma-separated pair consisting of 'HessianHistorySize' and a positive integer. At each iteration, `templateKernel` composes the Hessian approximation by using statistics from the latest `HessianHistorySize` iterations.

Example: 'HessianHistorySize',10

Data Types: single | double

Verbose — Verbosity level

0 (default) | 1

Verbosity level, specified as the comma-separated pair consisting of 'Verbose' and either 0 or 1. `Verbose` controls the display of diagnostic information at the command line.

Value	Description
0	<code>templateKernel</code> does not display diagnostic information.
1	<code>templateKernel</code> displays the value of the objective function, gradient magnitude, and other diagnostic information.

Example: 'Verbose',1

Data Types: single | double

Output Arguments

t — Kernel model template

template object

Kernel model template, returned as a template object. To train a kernel classification model for multiclass problems, pass **t** to `fitcecoc`.

If you display **t** in the Command Window, then some properties appear empty (`[]`). The software replaces the empty properties with their corresponding default values during training.

Definitions

Random Feature Expansion

Random feature expansion, such as Random Kitchen Sinks[1] and Fastfood[2], is a scheme to approximate Gaussian kernels of the kernel classification algorithm to use for big data in a computationally efficient way. Random feature expansion is more practical for big data applications that have large training sets, but can also be applied to smaller data sets that fit in memory.

The kernel classification algorithm searches for an optimal hyperplane that separates the data into two classes after mapping features into a high-dimensional space. Nonlinear features that are not linearly separable in a low-dimensional space can be separable in the expanded high-dimensional space. All the calculations for hyperplane classification use only dot products. You can obtain a nonlinear classification model by replacing the dot product $x_1 x_2'$ with the nonlinear kernel function $G(x_1, x_2) = \langle \varphi(x_1), \varphi(x_2) \rangle$, where x_i is the i th observation (row vector) and $\varphi(x_i)$ is a transformation that maps x_i to a high-dimensional space (called the “kernel trick”). However, evaluating $G(x_1, x_2)$ (Gram matrix) for each pair of observations is computationally expensive for a large data set (large n).

The random feature expansion scheme finds a random transformation so that its dot product approximates the Gaussian kernel. That is,

$$G(x_1, x_2) = \langle \varphi(x_1), \varphi(x_2) \rangle \approx T(x_1)T(x_2)',$$

where $T(x)$ maps x in \mathbb{R}^p to a high-dimensional space (\mathbb{R}^m). The Random Kitchen Sink scheme uses the random transformation

$$T(x) = m^{-1/2} \exp(iZx'),$$

where $Z \in \mathbb{R}^{m \times p}$ is a sample drawn from $N(0, \sigma^{-2})$ and σ^2 is a kernel scale. This scheme requires $O(mp)$ computation and storage. The Fastfood scheme introduces another random basis V instead of Z using Hadamard matrices combined with Gaussian scaling matrices. This random basis reduces the computation cost to $O(m \log p)$ and reduces storage to $O(m)$.

The `templateKernel` function uses the Fastfood scheme for random feature expansion and uses linear classification to train a Gaussian kernel classification model. Unlike solvers in the `templateSVM` function, which require computation of the n -by- n Gram matrix, the solver in `templateKernel` only needs to form a matrix of size n -by- m , with m typically much less than n for big data.

Box Constraint

A box constraint is a parameter that controls the maximum penalty imposed on margin-violating observations, and aids in preventing overfitting (regularization). Increasing the box constraint can lead to longer training times.

The box constraint (C) and the regularization term strength (λ) are related by $C = 1/(\lambda n)$, where n is the number of observations.

Algorithms

`templateKernel` minimizes the regularized objective function using a Limited-memory Broyden-Fletcher-Goldfarb-Shanno (LBFGS) solver with ridge (L_2) regularization. To find the type of LBFGS solver used for training, type `FitInfo.Solver` in the Command Window.

- 'LBFGS-fast' — LBFGS solver.
- 'LBFGS-blockwise' — LBFGS solver with a block-wise strategy. If `templateKernel` requires more memory than the value of `BlockSize` to hold the transformed predictor data, then it uses a block-wise strategy.
- 'LBFGS-tall' — LBFGS solver with a block-wise strategy for tall arrays.

When `templateKernel` uses a block-wise strategy, `templateKernel` implements LBFGS by distributing the calculation of the loss and gradient among different parts of

the data at each iteration. Also, `templateKernel` refines the initial estimates of the linear coefficients and the bias term by fitting the model locally to parts of the data and combining the coefficients by averaging. If you specify `'Verbose', 1`, then `templateKernel` displays diagnostic information for each data pass and stores the information in the `History` field of `FitInfo`.

When `templateKernel` does not use a block-wise strategy, the initial estimates are zeros. If you specify `'Verbose', 1`, then `templateKernel` displays diagnostic information for each iteration and stores the information in the `History` field of `FitInfo`.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

Usage notes and limitations when you train a model by passing a kernel model template and tall arrays to `fitcecoc`:

- The default values for these name-value pair arguments are different when you work with tall arrays.
 - `'Verbose'` — Default value is 1.

- 'BetaTolerance' — Default value is relaxed to $1e-3$.
- 'GradientTolerance' — Default value is relaxed to $1e-5$.
- 'IterationLimit' — Default value is relaxed to 20.
- If 'KernelScale' is 'auto', then `templateKernel` uses the random stream controlled by `tallrng` for subsampling. For reproducibility, you must set a random number seed for both the global stream and the random stream controlled by `tallrng`.
- If 'Lambda' is 'auto', then `templateKernel` might take an extra pass through the data to calculate the number of observations.
- `templateKernel` uses a block-wise strategy. For details, see “Algorithms” on page 32-6720.

For more information, see “Tall Arrays” (MATLAB).

Introduced in R2018b

templateKNN

k-nearest neighbor classifier template

Syntax

```
t = templateKNN()  
t = templateKNN(Name,Value)
```

Description

`t = templateKNN()` returns a *k*-nearest neighbor (KNN) learner template suitable for training ensembles or error-correcting output code (ECOC) multiclass models.

If you specify a default template, then the software uses default values for all input arguments during training.

Specify `t` as a learner in `fitcensemble` or `fitcecoc`.

`t = templateKNN(Name,Value)` creates a template with additional options specified by one or more name-value pair arguments.

For example, you can specify the nearest neighbor search method, the number of nearest neighbors to find, or the distance metric.

If you display `t` in the Command Window, then all options appear empty (`[]`), except those that you specify using name-value pair arguments. During training, the software uses default values for empty options.

Examples

Create a *k*-Nearest Neighbor Template for Ensemble

Create a nondefault *k*-nearest neighbor template for use in `fitcensemble`.

Load Fisher's iris data set.

```
load fisheriris
```

Create a template for a 5-nearest neighbor search, and specify to standardize the predictors.

```
t = templateKNN('NumNeighbors',5,'Standardize',1)
```

```
t =  
Fit template for classification KNN.
```

```
    NumNeighbors: 5  
      NSMethod: ''  
      Distance: ''  
    BucketSize: ''  
    IncludeTies: []  
DistanceWeight: []  
    BreakTies: []  
    Exponent: []  
        Cov: []  
        Scale: []  
StandardizeData: 1  
    Version: 1  
    Method: 'KNN'  
    Type: 'classification'
```

All properties of the template object are empty except for `NumNeighbors`, `Method`, `StandardizeData`, and `Type`. When you specify `t` as a learner, the software fills in the empty properties with their respective default values.

Specify `t` as a weak learner for a classification ensemble.

```
Mdl = fitensemble(meas,species,'Method','Subspace','Learners',t);
```

Display the in-sample (resubstitution) misclassification error.

```
L = resubLoss(Mdl)
```

```
L = 0.0600
```

Create a *k*-Nearest Neighbor Template for ECOC Multiclass Learning

Create a nondefault *k*-nearest neighbor template for use in `fitcecoc`.

Load Fisher's iris data set.

```
load fisheriris
```

Create a template for a 5-nearest neighbor search, and specify to standardize the predictors.

```
t = templateKNN('NumNeighbors',5,'Standardize',1)
```

```
t =  
Fit template for classification KNN.
```

```
    NumNeighbors: 5  
      NSMethod: ''  
      Distance: ''  
    BucketSize: ''  
    IncludeTies: []  
  DistanceWeight: []  
    BreakTies: []  
      Exponent: []  
          Cov: []  
          Scale: []  
StandardizeData: 1  
      Version: 1  
      Method: 'KNN'  
      Type: 'classification'
```

All properties of the template object are empty except for `NumNeighbors`, `Method`, `StandardizeData`, and `Type`. When you specify `t` as a learner, the software fills in the empty properties with their respective default values.

Specify `t` as a binary learner for an ECOC multiclass model.

```
Mdl = fitcecoc(meas,species,'Learners',t);
```

By default, the software trains `Mdl` using the one-versus-one coding design.

Display the in-sample (resubstitution) misclassification error.

```
L = resubLoss(Mdl,'LossFun','classiferror')
```

`L = 0.0467`

Input Arguments

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'NumNeighbors', 4, 'Distance', 'minkowski'` specifies a 4-nearest neighbor classifier template using the Minkowski distance measure.

BreakTies — Tie-breaking algorithm

`'smallest' (default) | 'nearest' | 'random'`

Tie-breaking algorithm used by the `predict` method if multiple classes have the same smallest cost, specified as the comma-separated pair consisting of `'BreakTies'` and one of the following:

- `'smallest'` — Use the smallest index among tied groups.
- `'nearest'` — Use the class with the nearest neighbor among tied groups.
- `'random'` — Use a random tiebreaker among tied groups.

By default, ties occur when multiple classes have the same number of nearest points among the `K` nearest neighbors.

Example: `'BreakTies', 'nearest'`

BucketSize — Maximum data points in node

`50 (default) | positive integer value`

Maximum number of data points in the leaf node of the `kd`-tree, specified as the comma-separated pair consisting of `'BucketSize'` and a positive integer value. This argument is meaningful only when `NSMethod` is `'kdtree'`.

Example: `'BucketSize', 40`

Data Types: `single` | `double`

Cov — Covariance matrix

nancov(X) (default) | positive definite matrix of scalar values

Covariance matrix, specified as the comma-separated pair consisting of 'Cov' and a positive definite matrix of scalar values representing the covariance matrix when computing the Mahalanobis distance. This argument is only valid when 'Distance' is 'mahalanobis'.

You cannot simultaneously specify 'Standardize' and either of 'Scale' or 'Cov'.

Data Types: single | double

Distance — Distance metric

'cityblock' | 'chebychev' | 'correlation' | 'cosine' | 'euclidean' |
'hamming' | function handle | ...

Distance metric, specified as the comma-separated pair consisting of 'Distance' and a valid distance metric name or function handle. The allowable distance metric names depend on your choice of a neighbor-searcher method (see NSMethod).

NSMethod	Distance Metric Names
exhaustive	Any distance metric of ExhaustiveSearcher
kdtree	'cityblock', 'chebychev', 'euclidean', or 'minkowski'

This table includes valid distance metrics of ExhaustiveSearcher.

Distance Metric Names	Description
'cityblock'	City block distance.
'chebychev'	Chebychev distance (maximum coordinate difference).
'correlation'	One minus the sample linear correlation between observations (treated as sequences of values).
'cosine'	One minus the cosine of the included angle between observations (treated as vectors).
'euclidean'	Euclidean distance.
'hamming'	Hamming distance, percentage of coordinates that differ.
'jaccard'	One minus the Jaccard coefficient, the percentage of nonzero coordinates that differ.

Distance Metric Names	Description
'mahalanobis'	Mahalanobis distance, computed using a positive definite covariance matrix <i>C</i> . The default value of <i>C</i> is the sample covariance matrix of <i>X</i> , as computed by <code>nancov(X)</code> . To specify a different value for <i>C</i> , use the 'Cov' name-value pair argument.
'minkowski'	Minkowski distance. The default exponent is 2. To specify a different exponent, use the 'Exponent' name-value pair argument.
'seuclidean'	Standardized Euclidean distance. Each coordinate difference between <i>X</i> and a query point is scaled, meaning divided by a scale value <i>S</i> . The default value of <i>S</i> is the standard deviation computed from <i>X</i> , <code>S = nanstd(X)</code> . To specify another value for <i>S</i> , use the <code>Scale</code> name-value pair argument.
'spearman'	One minus the sample Spearman's rank correlation between observations (treated as sequences of values).
@ <i>distfun</i>	Distance function handle. <i>distfun</i> has the form <pre>function D2 = distfun(ZI,ZJ) % calculation of distance ...</pre> <p>where</p> <ul style="list-style-type: none"> • <i>ZI</i> is a 1-by-<i>N</i> vector containing one row of <i>X</i> or <i>Y</i>. • <i>ZJ</i> is an <i>M2</i>-by-<i>N</i> matrix containing multiple rows of <i>X</i> or <i>Y</i>. • <i>D2</i> is an <i>M2</i>-by-1 vector of distances, and <i>D2</i>(<i>k</i>) is the distance between observations <i>ZI</i> and <i>ZJ</i>(<i>k</i>, :).

If you specify `CategoricalPredictors` as 'all', then the default distance metric is 'hamming'. Otherwise, the default distance metric is 'euclidean'.

For definitions, see “Distance Metrics” on page 18-16.

Example: 'Distance', 'minkowski'

Data Types: char | string | function_handle

DistanceWeight — Distance weighting function

'equal' (default) | 'inverse' | 'squaredinverse' | function handle

Distance weighting function, specified as the comma-separated pair consisting of 'DistanceWeight' and either a function handle or one of the values in this table.

Value	Description
'equal'	No weighting
'inverse'	Weight is 1/distance
'squaredinverse'	Weight is 1/distance ²
@ <i>fcn</i>	<i>fcn</i> is a function that accepts a matrix of nonnegative distances, and returns a matrix the same size containing nonnegative distance weights. For example, 'squaredinverse' is equivalent to @(d)d.^(-2).

Example: 'DistanceWeight','inverse'

Data Types: char | string | function_handle

Exponent — Minkowski distance exponent

2 (default) | positive scalar value

Minkowski distance exponent, specified as the comma-separated pair consisting of 'Exponent' and a positive scalar value. This argument is only valid when 'Distance' is 'minkowski'.

Example: 'Exponent',3

Data Types: single | double

IncludeTies — Tie inclusion flag

false (default) | true

Tie inclusion flag, specified as the comma-separated pair consisting of 'IncludeTies' and a logical value indicating whether `predict` includes all the neighbors whose distance values are equal to the Kth smallest distance. If `IncludeTies` is true, `predict` includes all these neighbors. Otherwise, `predict` uses exactly K neighbors.

Example: 'IncludeTies',true

Data Types: logical

NSMethod — Nearest neighbor search method`'kdtree' | 'exhaustive'`

Nearest neighbor search method, specified as the comma-separated pair consisting of 'NSMethod' and 'kdtree' or 'exhaustive'.

- 'kdtree' — Creates and uses a *kd*-tree to find nearest neighbors. 'kdtree' is valid when the distance metric is one of the following:
 - 'euclidean'
 - 'cityblock'
 - 'minkowski'
 - 'chebychev'
- 'exhaustive' — Uses the exhaustive search algorithm. When predicting the class of a new point *xnew*, the software computes the distance values from all points in *X* to *xnew* to find nearest neighbors.

The default is 'kdtree' when *X* has 10 or fewer columns, *X* is not sparse, and the distance metric is a 'kdtree' type; otherwise, 'exhaustive'.

Example: 'NSMethod', 'exhaustive'

NumNeighbors — Number of nearest neighbors to find`1 (default) | positive integer value`

Number of nearest neighbors in *X* to find for classifying each point when predicting, specified as the comma-separated pair consisting of 'NumNeighbors' and a positive integer value.

Example: 'NumNeighbors', 3

Data Types: single | double

Scale — Distance scale`nanstd(X) (default) | vector of nonnegative scalar values`

Distance scale, specified as the comma-separated pair consisting of 'Scale' and a vector containing nonnegative scalar values with length equal to the number of columns in *X*. Each coordinate difference between *X* and a query point is scaled by the corresponding element of *Scale*. This argument is only valid when 'Distance' is 'seuclidean'.

You cannot simultaneously specify 'Standardize' and either of 'Scale' or 'Cov'.

Data Types: `single` | `double`

Standardize — Flag to standardize predictors

`false` (default) | `true`

Flag to standardize the predictors, specified as the comma-separated pair consisting of 'Standardize' and `true` (1) or `false` (0).

If you set 'Standardize', `true`, then the software centers and scales each column of the predictor data (X) by the column mean and standard deviation, respectively.

The software does not standardize categorical predictors, and throws an error if all predictors are categorical.

You cannot simultaneously specify 'Standardize', 1 and either of 'Scale' or 'Cov'.

It is good practice to standardize the predictor data.

Example: 'Standardize', `true`

Data Types: `logical`

Output Arguments

t — kNN classification template

template object

kNN classification template suitable for training ensembles or error-correcting output code (ECOC) multiclass models, returned as a template object. Pass `t` to `fitcensemble` or `fitcecoc` to specify how to create the KNN classifier for the ensemble or ECOC model, respectively.

If you display `t` to the Command Window, then all, unspecified options appear empty (`[]`). However, the software replaces empty options with their corresponding default values during training.

See Also

`ClassificationKNN` | `ExhaustiveSearcher` | `fitcecoc` | `fitcensemble`

Topics

“Random Subspace Classification” on page 18-139

Introduced in R2014a

templateLinear

Linear classification learner template

`templateLinear` creates a template suitable for fitting a linear classification model to high-dimensional data for multiclass problems.

The template specifies the binary learner model, regularization type and strength, and solver, among other things. After creating the template, train the model by passing the template and data to `fitcecoc`.

Syntax

```
t = templateLinear()  
t = templateLinear(Name,Value)
```

Description

`t = templateLinear()` returns a linear classification learner template.

If you specify a default template, then the software uses default values for all input arguments during training.

`t = templateLinear(Name,Value)` returns a template with additional options specified by one or more name-value pair arguments. For example, you can specify to implement logistic regression, specify the regularization type or strength, or specify the solver to use for objective-function minimization.

If you display `t` in the Command Window, then all options appear empty (`[]`) except options that you specify using name-value pair arguments. During training, the software uses default values for empty options.

Examples

Train Multiclass Linear Classification Model

Train an ECOC model composed of multiple binary, linear classification models.

Load the NLP data set.

```
load nlpdata
```

X is a sparse matrix of predictor data, and Y is a categorical vector of class labels. There are more than two classes in the data.

Create a default linear-classification-model template.

```
t = templateLinear();
```

To adjust the default values, see the “Name-Value Pair Arguments” on page 32-6735 on `templateLinear` page.

Train an ECOC model composed of multiple binary, linear classification models that can identify the product given the frequency distribution of words on a documentation web page. For faster training time, transpose the predictor data, and specify that observations correspond to columns.

```
X = X';  
rng(1); % For reproducibility  
Mdl = fitcecoc(X,Y,'Learners',t,'ObservationsIn','columns')
```

```
Mdl =  
  classreg.learning.classif.CompactClassificationECOC  
    ResponseName: 'Y'  
    ClassNames: [1x13 categorical]  
    ScoreTransform: 'none'  
    BinaryLearners: {78x1 cell}  
    CodingMatrix: [13x78 double]
```

Properties, Methods

Alternatively, you can train an ECOC model composed of default linear classification models using `'Learners','Linear'`.

To conserve memory, `fitcecoc` returns trained ECOC models composed of linear classification learners in `CompactClassificationECOC` model objects.

Input Arguments

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'Learner', 'logistic', 'Regularization', 'lasso', 'CrossVal', 'on'` specifies to implement logistic regression with a lasso penalty, and to implement 10-fold cross-validation.

Linear Classification Options

Lambda — Regularization term strength

`'auto'` (default) | nonnegative scalar | vector of nonnegative values

Regularization term strength, specified as the comma-separated pair consisting of `'Lambda'` and `'auto'`, a nonnegative scalar, or a vector of nonnegative values.

- For `'auto'`, $\text{Lambda} = 1/n$.
 - If you specify a cross-validation, name-value pair argument (e.g., `CrossVal`), then n is the number of in-fold observations.
 - Otherwise, n is the training sample size.
- For a vector of nonnegative values, the software sequentially optimizes the objective function for each distinct value in `Lambda` in ascending order.
 - If `Solver` is `'sgd'` or `'asgd'` and `Regularization` is `'lasso'`, then the software does not use the previous coefficient estimates as a warm start on page 32-2002 for the next optimization iteration. Otherwise, the software uses warm starts.
 - If `Regularization` is `'lasso'`, then any coefficient estimate of 0 retains its value when the software optimizes using subsequent values in `Lambda`.

Returns coefficient estimates for all optimization iterations.

Example: `'Lambda', 10.^(-(10:-2:2))`

Data Types: char | string | double | single

Learner — Linear classification model type

'svm' (default) | 'logistic'

Linear classification model type, specified as the comma-separated pair consisting of 'Learner' and 'svm' or 'logistic'.

In this table, $f(x) = x\beta + b$.

- β is a vector of p coefficients.
- x is an observation from p predictor variables.
- b is the scalar bias.

Value	Algorithm	Response Range	Loss Function
'svm'	Support vector machine	$y \in \{-1,1\}$; 1 for the positive class and -1 otherwise	Hinge: $\ell[y, f(x)] = \max\{0, 1 - yf(x)\}$
'logistic'	Logistic regression	Same as 'svm'	Deviance (logistic): $\ell[y, f(x)] = \log\{1 + \exp[-yf(x)]\}$

Example: 'Learner', 'logistic'

Regularization — Complexity penalty type

'lasso' | 'ridge'

Complexity penalty type, specified as the comma-separated pair consisting of 'Regularization' and 'lasso' or 'ridge'.

The software composes the objective function for minimization from the sum of the average loss function (see Learner) and the regularization term in this table.

Value	Description
'lasso'	Lasso (L1) penalty: $\lambda \sum_{j=1}^p \beta_j $
'ridge'	Ridge (L2) penalty: $\frac{\lambda}{2} \sum_{j=1}^p \beta_j^2$

To specify the regularization term strength, which is λ in the expressions, use `Lambda`.

The software excludes the bias term (β_0) from the regularization penalty.

If `Solver` is `'sparsa'`, then the default value of `Regularization` is `'lasso'`. Otherwise, the default is `'ridge'`.

Tip

- For predictor variable selection, specify `'lasso'`.
 - For optimization accuracy, specify `'ridge'`.
-

Example: `'Regularization','lasso'`

Solver — Objective function minimization technique

`'sgd' | 'asgd' | 'dual' | 'bfgs' | 'lbfgs' | 'sparsa'` | string array | cell array of character vectors

Objective function minimization technique, specified as the comma-separated pair consisting of `'Solver'` and a character vector or string scalar, a string array, or a cell array of character vectors with values from this table.

Value	Description	Restrictions
<code>'sgd'</code>	Stochastic gradient descent (SGD) [5][3]	
<code>'asgd'</code>	Average stochastic gradient descent (ASGD) [8]	
<code>'dual'</code>	Dual SGD for SVM [2][7]	Regularization must be <code>'ridge'</code> and <code>Learner</code> must be <code>'svm'</code> .
<code>'bfgs'</code>	Broyden-Fletcher-Goldfarb-Shanno quasi-Newton algorithm (BFGS) [4]	Inefficient if X is very high-dimensional.
<code>'lbfgs'</code>	Limited-memory BFGS (LBFGS) [4]	Regularization must be <code>'ridge'</code> .

Value	Description	Restrictions
'sparsa'	Sparse Reconstruction by Separable Approximation (SpaRSA) [6]	Regularization must be 'lasso'.

If you specify:

- A ridge penalty (see `Regularization`) and the predictor data set contains 100 or fewer predictor variables, then the default solver is `'bfgs'`.
- An SVM model (see `Learner`), a ridge penalty, and the predictor data set contains more than 100 predictor variables, then the default solver is `'dual'`.
- A lasso penalty and the predictor data set contains 100 or fewer predictor variables, then the default solver is `'sparsa'`.

Otherwise, the default solver is `'sgd'`.

For more details on which solver to choose, see “Tips” on page 32-6748.

Example: `'Solver', {'sgd', 'lbfgs'}`

Beta — Initial linear coefficient estimates

`zeros(p, 1)` (default) | numeric vector | numeric matrix

Initial linear coefficient estimates (β), specified as the comma-separated pair consisting of `'Beta'` and a p -dimensional numeric vector or a p -by- L numeric matrix. p is the number of predictor variables in X and L is the number of regularization-strength values (for more details, see `Lambda`).

- If you specify a p -dimensional vector, then the software optimizes the objective function L times using this process.
 - 1 The software optimizes using `Beta` as the initial value and the minimum value of `Lambda` as the regularization strength.
 - 2 The software optimizes again using the resulting estimate from the previous optimization as a warm start on page 32-2002, and the next smallest value in `Lambda` as the regularization strength.
 - 3 The software implements step 2 until it exhausts all values in `Lambda`.
- If you specify a p -by- L matrix, then the software optimizes the objective function L times. At iteration j , the software uses `Beta(:, j)` as the initial value and, after it sorts `Lambda` in ascending order, uses `Lambda(j)` as the regularization strength.

If you set 'Solver', 'dual', then the software ignores Beta.

Data Types: single | double

Bias — Initial intercept estimate

numeric scalar | numeric vector

Initial intercept estimate (b), specified as the comma-separated pair consisting of 'Bias' and a numeric scalar or an L -dimensional numeric vector. L is the number of regularization-strength values (for more details, see Lambda).

- If you specify a scalar, then the software optimizes the objective function L times using this process.
 - 1 The software optimizes using Bias as the initial value and the minimum value of Lambda as the regularization strength.
 - 2 The uses the resulting estimate as a warm start to the next optimization iteration, and uses the next smallest value in Lambda as the regularization strength.
 - 3 The software implements step 2 until it exhausts all values in Lambda.
- If you specify an L -dimensional vector, then the software optimizes the objective function L times. At iteration j , the software uses Bias(j) as the initial value and, after it sorts Lambda in ascending order, uses Lambda(j) as the regularization strength.
- By default:
 - If Learner is 'logistic', then let g_j be 1 if $Y(j)$ is the positive class, and -1 otherwise. Bias is the weighted average of the g for training or, for cross-validation, in-fold observations.
 - If Learner is 'svm', then Bias is 0.

Data Types: single | double

FitBias — Linear model intercept inclusion flag

true (default) | false

Linear model intercept inclusion flag, specified as the comma-separated pair consisting of 'FitBias' and true or false.

Value	Description
true	The software includes the bias term b in the linear model, and then estimates it.
false	The software sets $b = 0$ during estimation.

Example: 'FitBias', false

Data Types: logical

PostFitBias — Flag to fit linear model intercept after optimization

false (default) | true

Flag to fit the linear model intercept after optimization, specified as the comma-separated pair consisting of 'PostFitBias' and true or false.

Value	Description
false	The software estimates the bias term b and the coefficients β during optimization.
true	To estimate b , the software: <ol style="list-style-type: none"> 1 Estimates β and b using the model 2 Estimates classification scores 3 Refits b by placing the threshold on the classification scores that attains maximum accuracy

If you specify true, then FitBias must be true.

Example: 'PostFitBias', true

Data Types: logical

Verbose — Verbosity level

0 (default) | 1

Verbosity level, specified as the comma-separated pair consisting of 'Verbose' and either 0 or 1. Verbose controls the display of diagnostic information at the command line.

Value	Description
0	templateLinear does not display diagnostic information.
1	templateLinear periodically displays the value of the objective function, gradient magnitude, and other diagnostic information.

Example: 'Verbose',1

Data Types: single | double

SGD and ASGD Solver Options

BatchSize — Mini-batch size

positive integer

Mini-batch size, specified as the comma-separated pair consisting of 'BatchSize' and a positive integer. At each iteration, the software estimates the gradient using BatchSize observations from the training data.

- If the predictor data is a numeric matrix, then the default value is 10.
- If the predictor data is a sparse matrix, then the default value is $\max([10, \text{ceil}(\sqrt{\text{ff}})])$, where $\text{ff} = \text{numel}(X)/\text{nnz}(X)$, that is, the fullness factor of X .

Example: 'BatchSize',100

Data Types: single | double

LearnRate — Learning rate

positive scalar

Learning rate, specified as the comma-separated pair consisting of 'LearnRate' and a positive scalar. LearnRate specifies how many steps to take per iteration. At each iteration, the gradient specifies the direction and magnitude of each step.

- If Regularization is 'ridge', then LearnRate specifies the initial learning rate γ_0 . The software determines the learning rate for iteration t , γ_t , using

$$\gamma_t = \frac{\gamma_0}{(1 + \lambda \gamma_0 t)^c}.$$

- λ is the value of Lambda.

- If Solver is 'sgd', then $c = 1$.
- If Solver is 'asgd', then c is 0.75 [7].
- If Regularization is 'lasso', then, for all iterations, LearnRate is constant.

By default, LearnRate is $1/\sqrt{1+\max(\sum(X.^2, \text{obsDim}))}$, where obsDim is 1 if the observations compose the columns of the predictor data X, and 2 otherwise.

Example: 'LearnRate', 0.01

Data Types: single | double

OptimizeLearnRate — Flag to decrease learning rate

true (default) | false

Flag to decrease the learning rate when the software detects divergence (that is, overstepping the minimum), specified as the comma-separated pair consisting of 'OptimizeLearnRate' and true or false.

If OptimizeLearnRate is 'true', then:

- 1 For the few optimization iterations, the software starts optimization using LearnRate as the learning rate.
- 2 If the value of the objective function increases, then the software restarts and uses half of the current value of the learning rate.
- 3 The software iterates step 2 until the objective function decreases.

Example: 'OptimizeLearnRate', true

Data Types: logical

TruncationPeriod — Number of mini-batches between lasso truncation runs

10 (default) | positive integer

Number of mini-batches between lasso truncation runs, specified as the comma-separated pair consisting of 'TruncationPeriod' and a positive integer.

After a truncation run, the software applies a soft threshold to the linear coefficients. That is, after processing $k = \text{TruncationPeriod}$ mini-batches, the software truncates the estimated coefficient j using

$$\widehat{\beta}_j^* = \begin{cases} \widehat{\beta}_j - u_t & \text{if } \widehat{\beta}_j > u_t, \\ 0 & \text{if } |\widehat{\beta}_j| \leq u_t, \\ \widehat{\beta}_j + u_t & \text{if } \widehat{\beta}_j < -u_t. \end{cases}$$

- For SGD, $\widehat{\beta}_j$ is the estimate of coefficient j after processing k mini-batches. $u_t = k\gamma_t\lambda$. γ_t is the learning rate at iteration t . λ is the value of Lambda.
- For ASGD, $\widehat{\beta}_j$ is the averaged estimate coefficient j after processing k mini-batches, $u_t = k\lambda$.

If Regularization is 'ridge', then the software ignores TruncationPeriod.

Example: 'TruncationPeriod',100

Data Types: single | double

SGD and ASGD Convergence Controls

BatchLimit — Maximal number of batches

positive integer

Maximal number of batches to process, specified as the comma-separated pair consisting of 'BatchLimit' and a positive integer. When the software processes BatchLimit batches, it terminates optimization.

- By default:
 - The software passes through the data PassLimit times.
 - If you specify multiple solvers, and use (A)SGD to get an initial approximation for the next solver, then the default value is $\text{ceil}(1e6/\text{BatchSize})$. BatchSize is the value of the 'BatchSize' name-value pair argument.
- If you specify 'BatchLimit' and 'PassLimit', then the software chooses the argument that results in processing the fewest observations.
- If you specify 'BatchLimit' but not 'PassLimit', then the software processes enough batches to complete up to one entire pass through the data.

Example: 'BatchLimit',100

Data Types: single | double

BetaTolerance — Relative tolerance on linear coefficients and bias term

1e-4 (default) | nonnegative scalar

Relative tolerance on the linear coefficients and the bias term (intercept), specified as the comma-separated pair consisting of 'BetaTolerance' and a nonnegative scalar.

Let $B_t = [\beta_t' \ b_t]$, that is, the vector of the coefficients and the bias term at optimization iteration t . If $\left\| \frac{B_t - B_{t-1}}{B_t} \right\|_2 < \text{BetaTolerance}$, then optimization terminates.

If the software converges for the last solver specified in `Solver`, then optimization terminates. Otherwise, the software uses the next solver specified in `Solver`.

Example: 'BetaTolerance', 1e-6

Data Types: single | double

NumCheckConvergence — Number of batches to process before next convergence check

positive integer

Number of batches to process before next convergence check, specified as the comma-separated pair consisting of 'NumCheckConvergence' and a positive integer.

To specify the batch size, see `BatchSize`.

The software checks for convergence about 10 times per pass through the entire data set by default.

Example: 'NumCheckConvergence', 100

Data Types: single | double

PassLimit — Maximal number of passes

1 (default) | positive integer

Maximal number of passes through the data, specified as the comma-separated pair consisting of 'PassLimit' and a positive integer.

The software processes all observations when it completes one pass through the data.

When the software passes through the data `PassLimit` times, it terminates optimization.

If you specify 'BatchLimit' and PassLimit, then the software chooses the argument that results in processing the fewest observations.

Example: 'PassLimit',5

Data Types: single | double

Dual SGD Convergence Controls

BetaTolerance — Relative tolerance on linear coefficients and bias term

1e-4 (default) | nonnegative scalar

Relative tolerance on the linear coefficients and the bias term (intercept), specified as the comma-separated pair consisting of 'BetaTolerance' and a nonnegative scalar.

Let $B_t = [\beta_t' \ b_t]$, that is, the vector of the coefficients and the bias term at optimization iteration t . If $\left\| \frac{B_t - B_{t-1}}{B_t} \right\|_2 < \text{BetaTolerance}$, then optimization terminates.

If you also specify DeltaGradientTolerance, then optimization terminates when the software satisfies either stopping criterion.

If the software converges for the last solver specified in Solver, then optimization terminates. Otherwise, the software uses the next solver specified in Solver.

Example: 'BetaTolerance',1e-6

Data Types: single | double

DeltaGradientTolerance — Gradient-difference tolerance

1 (default) | nonnegative scalar

Gradient-difference tolerance between upper and lower pool Karush-Kuhn-Tucker (KKT) complementarity conditions on page 32-2088 violators, specified as the comma-separated pair consisting of 'DeltaGradientTolerance' and a nonnegative scalar.

- If the magnitude of the KKT violators is less than DeltaGradientTolerance, then the software terminates optimization.
- If the software converges for the last solver specified in Solver, then optimization terminates. Otherwise, the software uses the next solver specified in Solver.

Example: 'DeltaGapTolerance',1e-2

Data Types: double | single

NumCheckConvergence — Number of passes through entire data set to process before next convergence check

5 (default) | positive integer

Number of passes through entire data set to process before next convergence check, specified as the comma-separated pair consisting of 'NumCheckConvergence' and a positive integer.

Example: 'NumCheckConvergence', 100

Data Types: single | double

PassLimit — Maximal number of passes

10 (default) | positive integer

Maximal number of passes through the data, specified as the comma-separated pair consisting of 'PassLimit' and a positive integer.

When the software completes one pass through the data, it has processed all observations.

When the software passes through the data PassLimit times, it terminates optimization.

Example: 'PassLimit', 5

Data Types: single | double

BFGS, LBFGS, and SpARSA Convergence Controls**BetaTolerance — Relative tolerance on linear coefficients and bias term**

1e-4 (default) | nonnegative scalar

Relative tolerance on the linear coefficients and the bias term (intercept), specified as the comma-separated pair consisting of 'BetaTolerance' and a nonnegative scalar.

Let $B_t = [\beta_t' \ b_t]$, that is, the vector of the coefficients and the bias term at optimization

iteration t . If $\left\| \frac{B_t - B_{t-1}}{B_t} \right\|_2 < \text{BetaTolerance}$, then optimization terminates.

If you also specify GradientTolerance, then optimization terminates when the software satisfies either stopping criterion.

If the software converges for the last solver specified in Solver, then optimization terminates. Otherwise, the software uses the next solver specified in Solver.

Example: 'BetaTolerance',1e-6

Data Types: single | double

GradientTolerance — Absolute gradient tolerance

1e-6 (default) | nonnegative scalar

Absolute gradient tolerance, specified as the comma-separated pair consisting of 'GradientTolerance' and a nonnegative scalar.

Let $\nabla \mathcal{L}_t$ be the gradient vector of the objective function with respect to the coefficients and bias term at optimization iteration t . If $\|\nabla \mathcal{L}_t\|_\infty = \max|\nabla \mathcal{L}_t| < \text{GradientTolerance}$, then optimization terminates.

If you also specify `BetaTolerance`, then optimization terminates when the software satisfies either stopping criterion.

If the software converges for the last solver specified in the software, then optimization terminates. Otherwise, the software uses the next solver specified in `Solver`.

Example: 'GradientTolerance',1e-5

Data Types: single | double

HessianHistorySize — Size of history buffer for Hessian approximation

15 (default) | positive integer

Size of history buffer for Hessian approximation, specified as the comma-separated pair consisting of 'HessianHistorySize' and a positive integer. That is, at each iteration, the software composes the Hessian using statistics from the latest `HessianHistorySize` iterations.

The software does not support 'HessianHistorySize' for `SpaRSA`.

Example: 'HessianHistorySize',10

Data Types: single | double

IterationLimit — Maximal number of optimization iterations

1000 (default) | positive integer

Maximal number of optimization iterations, specified as the comma-separated pair consisting of 'IterationLimit' and a positive integer. `IterationLimit` applies to these values of `Solver`: 'bfgs', 'lbfgs', and 'sparsa'.

Example: 'IterationLimit',500

Data Types: single | double

Output Arguments

t — Linear classification model learner template

template object

Linear classification model learner template, returned as a template object. To train a linear classification model using high-dimensional data for multiclass problems, pass **t** to `fitcecoc`.

If you display **t** to the Command Window, then all, unspecified options appear empty (`[]`). However, the software replaces empty options with their corresponding default values during training.

Definitions

Warm Start

A warm start is initial estimates of the beta coefficients and bias term supplied to an optimization routine for quicker convergence.

Tips

- It is a best practice to orient your predictor matrix so that observations correspond to columns and to specify 'ObservationsIn', 'columns'. As a result, you can experience a significant reduction in optimization-execution time.
- For better optimization accuracy if the predictor data is high-dimensional and Regularization is 'ridge', set any of these combinations for Solver:
 - 'sgd'
 - 'asgd'
 - 'dual' if Learner is 'svm'

- {'sgd', 'lbfgs'}
- {'asgd', 'lbfgs'}
- {'dual', 'lbfgs'} if Learner is 'svm'

Other combinations can result in poor optimization accuracy.

- For better optimization accuracy if the predictor data is moderate- through low-dimensional and Regularization is 'ridge', set Solver to 'bfgs'.
- If Regularization is 'lasso', set any of these combinations for Solver:
 - 'sgd'
 - 'asgd'
 - 'sparsa'
 - {'sgd', 'sparsa'}
 - {'asgd', 'sparsa'}
- When choosing between SGD and ASGD, consider that:
 - SGD takes less time per iteration, but requires more iterations to converge.
 - ASGD requires fewer iterations to converge, but takes more time per iteration.
- If the predictor data has few observations, but many predictor variables, then:
 - Specify 'PostFitBias', true.
 - For SGD or ASGD solvers, set PassLimit to a positive integer that is greater than 1, for example, 5 or 10. This setting often results in better accuracy.
- For SGD and ASGD solvers, BatchSize affects the rate of convergence.
 - If BatchSize is too small, then the software achieves the minimum in many iterations, but computes the gradient per iteration quickly.
 - If BatchSize is too large, then the software achieves the minimum in fewer iterations, but computes the gradient per iteration slowly.
- Large learning rate (see LearnRate) speed-up convergence to the minimum, but can lead to divergence (that is, over-stepping the minimum). Small learning rates ensure convergence to the minimum, but can lead to slow termination.
- If Regularization is 'lasso', then experiment with various values of TruncationPeriod. For example, set TruncationPeriod to 1, 10, and then 100.
- For efficiency, the software does not standardize predictor data. To standardize the predictor data (X), enter

```
X = bsxfun(@rdivide,bsxfun(@minus,X,mean(X,2)),std(X,0,2));
```

The code requires that you orient the predictors and observations as the rows and columns of X , respectively. Also, for memory-usage economy, the code replaces the original predictor data the standardized data.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

Usage notes and limitations when you train a model by passing a linear model template and tall arrays to `fitcecoc`:

- The default values for these name-value pair arguments are different when you work with tall arrays.
 - 'Lambda' — Can be 'auto' (default) or a scalar
 - 'Regularization' — Supports only 'ridge'
 - 'Solver' — Supports only 'lbfgs'
 - 'FitBias' — Supports only true
 - 'Verbose' — Default value is 1
 - 'BetaTolerance' — Default value is relaxed to $1e-3$
 - 'GradientTolerance' — Default value is relaxed to $1e-3$
 - 'IterationLimit' — Default value is relaxed to 20
- When `fitcecoc` uses a `templateLinear` object with tall arrays, the only available solver is LBFGS. The software implements LBFGS by distributing the calculation of the loss and gradient among different parts of the tall array at each iteration. If you do not specify initial values for `Beta` and `Bias`, the software refines the initial estimates of the parameters by fitting the model locally to parts of the data and combining the coefficients by averaging.

For more information, see “Tall Arrays” (MATLAB).

Introduced in R2016a

templateNaiveBayes

Naive Bayes classifier template

Syntax

```
t = templateNaiveBayes()  
t = templateNaiveBayes(Name,Value)
```

Description

`t = templateNaiveBayes()` returns a naive Bayes on page 32-6758 template suitable for training error-correcting output code (ECOC) multiclass models.

If you specify a default template, then the software uses default values for all input arguments during training.

Specify `t` as a learner in `fitcecoc`.

`t = templateNaiveBayes(Name,Value)` returns a template with additional options specified by one or more name-value pair arguments. All properties of `t` are empty, except those you specify using `Name,Value` pair arguments.

For example, you can specify distributions for the predictors.

If you display `t` in the Command Window, then all options appear empty (`[]`), except those that you specify using name-value pair arguments. During training, the software uses default values for empty options.

Examples

Create a Default Naive Bayes Template

Use `templateNaiveBayes` to specify a default naive Bayes template.

```
t = templateNaiveBayes()

t =
Fit template for classification NaiveBayes.

    DistributionNames: [1x0 double]
           Kernel: []
          Support: []
           Width: []
          Version: 1
          Method: 'NaiveBayes'
           Type: 'classification'
```

All properties of the template object are empty except for `Method` and `Type`. When you pass `t` to the training function, the software fills in the empty properties with their respective default values. For example, the software fills the `DistributionNames` property with a 1-by- `D` cell array of character vectors with 'normal' in each cell, where `D` is the number of predictors. For details on other default values, see `fitcnb`.

`t` is a plan for a naive Bayes learner, and no computation occurs when you specify it. You can pass `t` to `fitcecoc` to specify naive Bayes binary learners for ECOC multiclass learning.

Create a Naive Bayes Template for ECOC Multiclass Learning

Create a nondefault naive Bayes template for use in `fitcecoc`.

Load Fisher's iris data set.

```
load fisheriris
```

Create a template for naive Bayes binary classifiers, and specify kernel distributions for all predictors.

```
t = templateNaiveBayes('DistributionNames','kernel')

t =
Fit template for classification NaiveBayes.

    DistributionNames: 'kernel'
           Kernel: []
```

```
Support: []
Width: []
Version: 1
Method: 'NaiveBayes'
Type: 'classification'
```

All properties of the template object are empty except for `DistributionNames`, `Method`, and `Type`. When you pass `t` to the training function, the software fills in the empty properties with their respective default values.

Specify `t` as a binary learner for an ECOC multiclass model.

```
Mdl = fitcecoc(meas,species,'Learners',t);
```

By default, the software trains `Mdl` using the one-versus-one coding design.

Display the in-sample (resubstitution) misclassification error.

```
L = resubLoss(Mdl,'LossFun','classiferror')
```

```
L = 0.0333
```

Input Arguments

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'DistributionNames','mn'` specifies to treat all predictors as token counts for a multinomial model.

DistributionNames — Data distributions

'kernel' | 'mn' | 'mvmn' | 'normal' | string array | cell array of character vectors

Data distributions `fitcnb` uses to model the data, specified as the comma-separated pair consisting of `'DistributionNames'` and a character vector or string scalar, a string array, or a cell array of character vectors with values from this table.

Value	Description
'kernel'	Kernel smoothing density estimate.
'mn'	Multinomial distribution. If you specify mn, then all features are components of a multinomial distribution. Therefore, you cannot include 'mn' as an element of a string array or a cell array of character vectors. For details, see “Algorithms” on page 32-2044.
'mvmn'	Multivariate multinomial distribution. For details, see “Algorithms” on page 32-2044.
'normal'	Normal (Gaussian) distribution.

If you specify a character vector or string scalar, then the software models all the features using that distribution. If you specify a 1-by- P string array or cell array of character vectors, then the software models feature j using the distribution in element j of the array.

By default, the software sets all predictors specified as categorical predictors (using the `CategoricalPredictors` name-value pair argument) to 'mvmn'. Otherwise, the default distribution is 'normal'.

You must specify that at least one predictor has distribution 'kernel' to additionally specify `Kernel`, `Support`, or `Width`.

Example: 'DistributionNames', 'mn'

Example: 'DistributionNames', {'kernel', 'normal', 'kernel'}

Kernel — Kernel smoother type

'normal' (default) | 'box' | 'epanechnikov' | 'triangle' | string array | cell array of character vectors

Kernel smoother type, specified as the comma-separated pair consisting of 'Kernel' and a character vector or string scalar, a string array, or a cell array of character vectors.

This table summarizes the available options for setting the kernel smoothing density region. Let $I\{u\}$ denote the indicator function.

Value	Kernel	Formula
'box'	Box (uniform)	$f(x) = 0.5I\{ x \leq 1\}$
'epanechnikov'	Epanechnikov	$f(x) = 0.75(1 - x^2)I\{ x \leq 1\}$
'normal'	Gaussian	$f(x) = \frac{1}{\sqrt{2\pi}}\exp(-0.5x^2)$
'triangle'	Triangular	$f(x) = (1 - x)I\{ x \leq 1\}$

If you specify a 1-by- P string array or cell array, with each element of the array containing any value in the table, then the software trains the classifier using the kernel smoother type in element j for feature j in X . The software ignores elements of `Kernel` not corresponding to a predictor whose distribution is `'kernel'`.

You must specify that at least one predictor has distribution `'kernel'` to additionally specify `Kernel`, `Support`, or `Width`.

Example: `'Kernel', {'epanechnikov', 'normal'}`

Support — Kernel smoothing density support

`'unbounded'` (default) | `'positive'` | string array | cell array | numeric row vector

Kernel smoothing density support, specified as the comma-separated pair consisting of `'Support'` and `'positive'`, `'unbounded'`, a string array, a cell array, or a numeric row vector. The software applies the kernel smoothing density to the specified region.

This table summarizes the available options for setting the kernel smoothing density region.

Value	Description
1-by-2 numeric row vector	For example, <code>[L,U]</code> , where <code>L</code> and <code>U</code> are the finite lower and upper bounds, respectively, for the density support.
'positive'	The density support is all positive real values.
'unbounded'	The density support is all real values.

If you specify a 1-by- P string array or cell array, with each element in the string array containing any text value in the table and each element in the cell array containing any value in the table, then the software trains the classifier using the kernel support in

element j for feature j in X . The software ignores elements of `Kernel` not corresponding to a predictor whose distribution is `'kernel'`.

You must specify that at least one predictor has distribution `'kernel'` to additionally specify `Kernel`, `Support`, or `Width`.

Example: `'KSSupport',{[-10,20],'unbounded'}`

Data Types: `char | string | cell | double`

Width — Kernel smoothing window width

`matrix of numeric values | numeric column vector | numeric row vector | scalar`

Kernel smoothing window width, specified as the comma-separated pair consisting of `'Width'` and a matrix of numeric values, numeric column vector, numeric row vector, or scalar.

Suppose there are K class levels and P predictors. This table summarizes the available options for setting the kernel smoothing window width.

Value	Description
K -by- P matrix of numeric values	Element (k,j) specifies the width for predictor j in class k .
K -by-1 numeric column vector	Element k specifies the width for all predictors in class k .
1-by- P numeric row vector	Element j specifies the width in all class levels for predictor j .
scalar	Specifies the bandwidth for all features in all classes.

By default, the software selects a default width automatically for each combination of predictor and class by using a value that is optimal for a Gaussian distribution. If you specify `Width` and it contains `NaNs`, then the software selects widths for the elements containing `NaNs`.

You must specify that at least one predictor has distribution `'kernel'` to additionally specify `Kernel`, `Support`, or `Width`.

Example: `'Width',[NaN NaN]`

Data Types: `double | struct`

Output Arguments

t — Naive Bayes classification template

template object

Naive Bayes classification template suitable for training error-correcting output code (ECOC) multiclass models, returned as a template object. Pass **t** to `fitcecoc` to specify how to create the naive Bayes classifier for the ECOC model.

If you display **t** to the Command Window, then all, unspecified options appear empty (`[]`). However, the software replaces empty options with their corresponding default values during training.

Definitions

Naive Bayes

Naive Bayes is a classification algorithm that applies density estimation to the data.

The algorithm leverages Bayes theorem, and (naively) assumes that the predictors are conditionally independent, given the class. Though the assumption is usually violated in practice, naive Bayes classifiers tend to yield posterior distributions that are robust to biased class density estimates, particularly where the posterior is 0.5 (the decision boundary) [1].

Naive Bayes classifiers assign observations to the most probable class (in other words, the maximum a posteriori decision rule). Explicitly, the algorithm:

- 1 Estimates the densities of the predictors within each class.
- 2 Models posterior probabilities according to Bayes rule. That is, for all $k = 1, \dots, K$,

$$\hat{P}(Y = k | X_1, \dots, X_P) = \frac{\pi(Y = k) \prod_{j=1}^P P(X_j | Y = k)}{\sum_{k=1}^K \pi(Y = k) \prod_{j=1}^P P(X_j | Y = k)},$$

where:

- Y is the random variable corresponding to the class index of an observation.
 - X_1, \dots, X_P are the random predictors of an observation.
 - $\pi(Y = k)$ is the prior probability that a class index is k .
- 3 Classifies an observation by estimating the posterior probability for each class, and then assigns the observation to the class yielding the maximum posterior probability.

If the predictors compose a multinomial distribution, then the posterior probability $\widehat{P}(Y = k | X_1, \dots, X_P) \propto \pi(Y = k)P_{mn}(X_1, \dots, X_P | Y = k)$, where $P_{mn}(X_1, \dots, X_P | Y = k)$ is the probability mass function of a multinomial distribution.

Algorithms

- If you specify 'DistributionNames', 'mn' when training Mdl using fitcnb, then the software fits a multinomial distribution using the bag-of-tokens model on page 32-2043. The software stores the probability that token j appears in class k in the property DistributionParameters{ k, j }. Using additive smoothing [2], the estimated probability is

$$P(\text{token } j \mid \text{class } k) = \frac{1 + c_{j|k}}{P + c_k},$$

where:

- $c_{j|k} = n_k \frac{\sum_{i: y_i \in \text{class } k} x_{ij} w_i}{\sum_{i: y_i \in \text{class } k} w_i}$; which is the weighted number of occurrences of token j in class k .
 - n_k is the number of observations in class k .
 - w_i is the weight for observation i . The software normalizes weights within a class such that they sum to the prior probability for that class.
 - $c_k = \sum_{j=1}^P c_{j|k}$; which is the total weighted number of occurrences of all tokens in class k .
- If you specify 'DistributionNames', 'mvmn' when training Mdl using fitcnb, then:

- 1 For each predictor, the software collects a list of the unique levels, stores the sorted list in `CategoricalLevels`, and considers each level a bin. Each predictor/class combination is a separate, independent multinomial random variable.
- 2 For predictor j in class k , the software counts instances of each categorical level using the list stored in `CategoricalLevels{j}`.
- 3 The software stores the probability that predictor j , in class k , has level L in the property `DistributionParameters{k, j}`, for all levels in `CategoricalLevels{j}`. Using additive smoothing [2], the estimated probability is

$$P(\text{predictor } j = L \mid \text{class } k) = \frac{1 + m_{j|k}(L)}{m_j + m_k},$$

where:

- $m_{j|k}(L) = n_k \frac{\sum_{i: y_i \in \text{class } k} I\{x_{ij} = L\} w_i}{\sum_{i: y_i \in \text{class } k} w_i}$; which is the weighted number of observations for which predictor j equals L in class k .
- n_k is the number of observations in class k .
- $I\{x_{ij} = L\} = 1$ if $x_{ij} = L$, 0 otherwise.
- w_i is the weight for observation i . The software normalizes weights within a class such that they sum to the prior probability for that class.
- m_j is the number of distinct levels in predictor j .
- m_k is the weighted number of observations in class k .

`ClassificationECOC` | `ClassificationNaiveBayes` | `fitcecoc` | `fitcnb`

Introduced in R2014b

templateSVM

Support vector machine template

Syntax

```
t = templateSVM()  
t = templateSVM(Name, Value)
```

Description

`t = templateSVM()` returns a support vector machine (SVM) learner template suitable for training error-correcting output code (ECOC) multiclass models.

If you specify a default template, then the software uses default values for all input arguments during training.

Specify `t` as a binary learner, or one in a set of binary learners, in `fitcecoc` to train an ECOC multiclass classifier.

`t = templateSVM(Name, Value)` returns a template with additional options specified by one or more name-value pair arguments.

For example, you can specify the box constraint, the kernel function, or whether to standardize the predictors.

If you display `t` in the Command Window, then all options appear empty (`[]`), except those that you specify using name-value pair arguments. During training, the software uses default values for empty options.

Examples

Create a Default Support Vector Machine Template

Use `templateSVM` to specify a default SVM template.

```

t = templateSVM()

t =
Fit template for classification SVM.

        Alpha: [0x1 double]
    BoxConstraint: []
        CacheSize: []
    CachingMethod: ''
        ClipAlphas: []

        Solver: ''
    StandardizeData: []
    SaveSupportVectors: []
    VerbosityLevel: []
        Version: 2
        Method: 'SVM'
        Type: 'classification'

```

All properties of the template object are empty except for `Method` and `Type`. When you pass `t` to the training function, the software fills in the empty properties with their respective default values. For example, the software fills the `KernelFunction` property with `'linear'`. For details on other default values, see `fitcsvm`.

`t` is a plan for an SVM learner, and no computation occurs when you specify it. You can pass `t` to `fitcecoc` to specify SVM binary learners for ECOC multiclass learning. However, by default, `fitcecoc` uses default SVM binary learners.

Create an SVM Template for ECOC Multiclass Learning

Create a nondefault SVM template for use in `fitcecoc`.

Load Fisher's iris data set.

```
load fisheriris
```

Create a template for SVM binary classifiers, and specify to use a Gaussian kernel function.

```
t = templateSVM('KernelFunction','gaussian')
```

```
t =
```

```
Fit template for classification SVM.
```

```
          Alpha: [0x1 double]
      BoxConstraint: []
          CacheSize: []
      CachingMethod: ''
          ClipAlphas: []
DeltaGradientTolerance: []
          Epsilon: []
          GapTolerance: []
          KKTolerance: []
      IterationLimit: []
      KernelFunction: 'gaussian'
          KernelScale: []
          KernelOffset: []
KernelPolynomialOrder: []
          NumPrint: []
              Nu: []
      OutlierFraction: []
RemoveDuplicates: []
      ShrinkagePeriod: []
          Solver: ''
      StandardizeData: []
SaveSupportVectors: []
      VerbosityLevel: []
          Version: 2
          Method: 'SVM'
          Type: 'classification'
```

All properties of the template object are empty except for `DistributionNames`, `Method`, and `Type`. When trained on, the software fills in the empty properties with their respective default values.

Specify `t` as a binary learner for an ECOC multiclass model.

```
Mdl = fitcecoc(meas,species,'Learners',t);
```

`Mdl` is a `ClassificationECOC` multiclass classifier. By default, the software trains `Mdl` using the one-versus-one coding design.

Display the in-sample (resubstitution) misclassification error.

```
L = resubLoss(Mdl,'LossFun','classiferror')
```

```
L = 0.0200
```

Retain and Discard Support Vectors of SVM Binary Learners

When you train an ECOC model with linear SVM binary learners, `fitcecoc` empties the `Alpha`, `SupportVectorLabels`, and `SupportVectors` properties of the binary learners by default. You can choose instead to retain the support vectors and related values, and then discard them from the model later.

Load Fisher's iris data set.

```
load fisheriris
rng(1); % For reproducibility
```

Train an ECOC model using the entire data set. Specify retaining the support vectors by passing in the appropriate SVM template.

```
t = templateSVM('SaveSupportVectors',true);
MdlSV = fitcecoc(meas,species,'Learners',t);
```

`MdlSV` is a trained `ClassificationECOC` model with linear SVM binary learners. By default, `fitcecoc` implements a one-versus-one coding design, which requires three binary learners for three-class learning.

Access the estimated α (alpha) values using dot notation.

```
alpha = cell(3,1);
alpha{1} = MdLSV.BinaryLearners{1}.Alpha;
alpha{2} = MdLSV.BinaryLearners{2}.Alpha;
alpha{3} = MdLSV.BinaryLearners{3}.Alpha;
alpha
```

```
alpha = 3x1 cell array
    { 3x1 double}
    { 3x1 double}
    {23x1 double}
```

`alpha` is a 3-by-1 cell array that stores the estimated values of α .

Discard the support vectors and related values from the ECOC model.

```
Mdl = discardSupportVectors(MdLSV);
```

`Mdl` is similar to `MdLSV`, except that the `Alpha`, `SupportVectorLabels`, and `SupportVectors` properties of all the linear SVM binary learners are empty (`[]`).

```
areAllEmpty = @(x)isempty([x.Alpha x.SupportVectors x.SupportVectorLabels]);
cellfun(areAllEmpty,Mdl.BinaryLearners)
```

```
ans = 3x1 logical array
```

```
1
1
1
```

Compare the sizes of the two ECOC models.

```
vars = whos('Mdl','MdLSV');
100*(1 - vars(1).bytes/vars(2).bytes)
```

```
ans = 4.8583
```

`Mdl` is about 5% smaller than `MdLSV`.

Reduce your memory usage by compacting `Mdl` and then clearing `Mdl` and `MdLSV` from the workspace.

```
CompactMdl = compact(Mdl);
clear Mdl MdLSV;
```

Predict the label for a random row of the training data using the more efficient SVM model.

```
idx = randsample(size(meas,1),1)

idx = 63

predictedLabel = predict(CompactMdl,meas(idx,:))

predictedLabel = 1x1 cell array
    {'versicolor'}

trueLabel = species(idx)

trueLabel = 1x1 cell array
    {'versicolor'}
```

Input Arguments

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example:

```
'BoxConstraint',0.1,'KernelFunction','gaussian','Standardize',1
```

specifies a box constraint of 0.1, to use the Gaussian (RBF) kernel, and to standardize the predictors.

BoxConstraint — Box constraint

1 (default) | positive scalar

Box constraint on page 32-2087, specified as the comma-separated pair consisting of `'BoxConstraint'` and a positive scalar.

For one-class learning, the software always sets the box constraint to 1.

For more details on the relationships and algorithmic behavior of `BoxConstraint`, `Cost`, `Prior`, `Standardize`, and `Weights`, see “Algorithms” on page 32-2092.

Example: `'BoxConstraint', 100`

Data Types: `double` | `single`

CacheSize — Cache size

`1000` (default) | `'maximal'` | positive scalar

Cache size, specified as the comma-separated pair consisting of `'CacheSize'` and `'maximal'` or a positive scalar.

If `CacheSize` is `'maximal'`, then the software reserves enough memory to hold the entire n -by- n Gram matrix on page 32-2088.

If `CacheSize` is a positive scalar, then the software reserves `CacheSize` megabytes of memory for training the model.

Example: `'CacheSize', 'maximal'`

Data Types: `double` | `single` | `char` | `string`

ClipAlphas — Flag to clip alpha coefficients

`true` (default) | `false`

Flag to clip alpha coefficients, specified as the comma-separated pair consisting of `'ClipAlphas'` and either `true` or `false`.

Suppose that the alpha coefficient for observation j is α_j and the box constraint of observation j is C_j , $j = 1, \dots, n$, where n is the training sample size.

Value	Description
<code>true</code>	At each iteration, if α_j is near 0 or near C_j , then MATLAB sets α_j to 0 or to C_j , respectively.
<code>false</code>	MATLAB does not change the alpha coefficients during optimization.

MATLAB stores the final values of α in the `Alpha` property of the trained SVM model object.

`ClipAlphas` can affect SMO and ISDA convergence.

Example: `'ClipAlphas', false`

Data Types: logical

DeltaGradientTolerance — Tolerance for gradient difference

nonnegative scalar

Tolerance for the gradient difference between upper and lower violators obtained by Sequential Minimal Optimization (SMO) or Iterative Single Data Algorithm (ISDA), specified as the comma-separated pair consisting of 'DeltaGradientTolerance' and a nonnegative scalar.

If `DeltaGradientTolerance` is 0, then the software does not use the tolerance for the gradient difference to check for optimization convergence.

The default values are:

- 1e-3 if the solver is SMO (for example, you set 'Solver', 'SMO')
- 0 if the solver is ISDA (for example, you set 'Solver', 'ISDA')

Example: 'DeltaGradientTolerance', 1e-2

Data Types: double | single

GapTolerance — Feasibility gap tolerance

0 (default) | nonnegative scalar

Feasibility gap tolerance obtained by SMO or ISDA, specified as the comma-separated pair consisting of 'GapTolerance' and a nonnegative scalar.

If `GapTolerance` is 0, then the software does not use the feasibility gap tolerance to check for optimization convergence.

Example: 'GapTolerance', 1e-2

Data Types: double | single

IterationLimit — Maximal number of numerical optimization iterations

1e6 (default) | positive integer

Maximal number of numerical optimization iterations, specified as the comma-separated pair consisting of 'IterationLimit' and a positive integer.

The software returns a trained model regardless of whether the optimization routine successfully converges. `Mdl.ConvergenceInfo` contains convergence information.

Example: 'IterationLimit', 1e8

Data Types: double | single

KernelFunction — Kernel function

'linear' (default) | 'gaussian' | 'rbf' | 'polynomial' | function name

Kernel function used to compute the elements of the Gram matrix on page 32-2088, specified as the comma-separated pair consisting of 'KernelFunction' and a kernel function name. Suppose $G(x_j, x_k)$ is element (j, k) of the Gram matrix, where x_j and x_k are p -dimensional vectors representing observations j and k in X . This table describes supported kernel function names and their functional forms.

Kernel Function Name	Description	Formula
'gaussian' or 'rbf'	Gaussian or Radial Basis Function (RBF) kernel, default for one-class learning	$G(x_j, x_k) = \exp(-\ x_j - x_k\ ^2)$
'linear'	Linear kernel, default for two-class learning	$G(x_j, x_k) = x_j'x_k$
'polynomial'	Polynomial kernel. Use 'PolynomialOrder', q to specify a polynomial kernel of order q .	$G(x_j, x_k) = (1 + x_j'x_k)^q$

You can set your own kernel function, for example, `kernel`, by setting 'KernelFunction', 'kernel'. The value `kernel` must have this form.

```
function G = kernel(U,V)
```

where:

- U is an m -by- p matrix. Columns correspond to predictor variables, and rows correspond to observations.
- V is an n -by- p matrix. Columns correspond to predictor variables, and rows correspond to observations.
- G is an m -by- n Gram matrix on page 32-2088 of the rows of U and V .

`kernel.m` must be on the MATLAB path.

It is a good practice to avoid using generic names for kernel functions. For example, call a sigmoid kernel function 'mysigmoid' rather than 'sigmoid'.

Example: 'KernelFunction', 'gaussian'

Data Types: char | string

KernelOffset — Kernel offset parameter

nonnegative scalar

Kernel offset parameter, specified as the comma-separated pair consisting of 'KernelOffset' and a nonnegative scalar.

The software adds KernelOffset to each element of the Gram matrix.

The defaults are:

- 0 if the solver is SMO (that is, you set 'Solver', 'SMO')
- 0.1 if the solver is ISDA (that is, you set 'Solver', 'ISDA')

Example: 'KernelOffset', 0

Data Types: double | single

KernelScale — Kernel scale parameter

1 (default) | 'auto' | positive scalar

Kernel scale parameter, specified as the comma-separated pair consisting of 'KernelScale' and 'auto' or a positive scalar. The software divides all elements of the predictor matrix X by the value of KernelScale. Then, the software applies the appropriate kernel norm to compute the Gram matrix.

- If you specify 'auto', then the software selects an appropriate scale factor using a heuristic procedure. This heuristic procedure uses subsampling, so estimates can vary from one call to another. Therefore, to reproduce results, set a random number seed using rng before training.
- If you specify KernelScale and your own kernel function, for example, 'KernelFunction', 'kernel', then the software throws an error. You must apply scaling within kernel.

Example: 'KernelScale', 'auto'

Data Types: double | single | char | string

KKTTolerance — Karush-Kuhn-Tucker complementarity conditions violation tolerance

nonnegative scalar

Karush-Kuhn-Tucker (KKT) complementarity conditions on page 32-2088 violation tolerance, specified as the comma-separated pair consisting of 'KKTTolerance' and a nonnegative scalar.

If KKTTolerance is 0, then the software does not use the KKT complementarity conditions violation tolerance to check for optimization convergence.

The default values are:

- 0 if the solver is SMO (for example, you set 'Solver', 'SMO')
- 1e-3 if the solver is ISDA (for example, you set 'Solver', 'ISDA')

Example: 'KKTTolerance', 1e-2

Data Types: double | single

NumPrint — Number of iterations between optimization diagnostic message output

1000 (default) | nonnegative integer

Number of iterations between optimization diagnostic message output, specified as the comma-separated pair consisting of 'NumPrint' and a nonnegative integer.

If you specify 'Verbose', 1 and 'NumPrint', numprint, then the software displays all optimization diagnostic messages from SMO and ISDA every numprint iterations in the Command Window.

Example: 'NumPrint', 500

Data Types: double | single

OutlierFraction — Expected proportion of outliers in training data

0 (default) | numeric scalar in the interval [0,1)

Expected proportion of outliers in the training data, specified as the comma-separated pair consisting of 'OutlierFraction' and a numeric scalar in the interval [0,1).

Suppose that you set 'OutlierFraction', outlierfraction, where outlierfraction is a value greater than 0.

- For two-class learning, the software implements robust learning. In other words, the software attempts to remove $100 \times \text{outlierfraction}\%$ of the observations when the optimization algorithm converges. The removed observations correspond to gradients that are large in magnitude.
- For one-class learning, the software finds an appropriate bias term such that `outlierfraction` of the observations in the training set have negative scores.

Example: `'OutlierFraction',0.01`

Data Types: `double | single`

PolynomialOrder — Polynomial kernel function order

3 (default) | positive integer

Polynomial kernel function order, specified as the comma-separated pair consisting of `'PolynomialOrder'` and a positive integer.

If you set `'PolynomialOrder'` and `KernelFunction` is not `'polynomial'`, then the software throws an error.

Example: `'PolynomialOrder',2`

Data Types: `double | single`

SaveSupportVectors — Store support vectors, their labels, and the estimated α coefficients

`true | false`

Store support vectors, their labels, and the estimated α coefficients as properties of the resulting model, specified as the comma-separated pair consisting of `'SaveSupportVectors'` and `true` or `false`.

If `SaveSupportVectors` is `true`, the resulting model stores the support vectors in the `SupportVectors` property, their labels in the `SupportVectorLabels` property, and the estimated α coefficients in the `Alpha` property of the compact, SVM learners.

If `SaveSupportVectors` is `false` and `KernelFunction` is `'linear'`, the resulting model does not store the support vectors and the related estimates.

To reduce memory consumption by compact SVM models, specify `SaveSupportVectors`.

For linear, SVM binary learners in an ECOC model, the default value is `false`. Otherwise, the default value is `true`.

Example: 'SaveSupportVectors', true

Data Types: logical

ShrinkagePeriod — Number of iterations between reductions of active set

0 (default) | nonnegative integer

Number of iterations between reductions of the active set, specified as the comma-separated pair consisting of 'ShrinkagePeriod' and a nonnegative integer.

If you set 'ShrinkagePeriod', 0, then the software does not shrink the active set.

Example: 'ShrinkagePeriod', 1000

Data Types: double | single

Solver — Optimization routine

'ISDA' | 'L1QP' | 'SMO'

Optimization routine, specified as the comma-separated pair consisting of 'Solver' and a value in this table.

Value	Description
'ISDA'	Iterative Single Data Algorithm (see [30])
'L1QP'	Uses <code>quadprog</code> to implement $L1$ soft-margin minimization by quadratic programming. This option requires an Optimization Toolbox license. For more details, see “Quadratic Programming Definition” (Optimization Toolbox).
'SMO'	Sequential Minimal Optimization (see [17])

The default value is 'ISDA' for two-class learning or if you set 'OutlierFraction' to a positive value, and 'SMO' otherwise.

Example: 'Solver', 'ISDA'

Standardize — Flag to standardize predictor data

false (default) | true

Flag to standardize the predictor data, specified as the comma-separated pair consisting of 'Standardize' and true (1) or false (0).

If you set 'Standardize', true:

- The software centers and scales each column of the predictor data (X) by the weighted column mean and standard deviation, respectively (for details on weighted standardizing, see “Algorithms” on page 32-2092). MATLAB does not standardize the data contained in the dummy variable columns generated for categorical predictors.
- The software trains the classifier using the standardized predictor matrix, but stores the unstandardized data in the classifier property X.

Example: 'Standardize',true

Data Types: logical

Verbose — Verbosity level

0 (default) | 1 | 2

Verbosity level, specified as the comma-separated pair consisting of 'Verbose' and 0, 1, or 2. The value of `Verbose` controls the amount of optimization information that the software displays in the Command Window and saves the information as a structure to `Mdl.ConvergenceInfo.History`.

This table summarizes the available verbosity level options.

Value	Description
0	The software does not display or save convergence information.
1	The software displays diagnostic messages and saves convergence criteria every <code>numprint</code> iterations, where <code>numprint</code> is the value of the name-value pair argument 'NumPrint'.
2	The software displays diagnostic messages and saves convergence criteria at every iteration.

Example: 'Verbose',1

Data Types: double | single

Output Arguments

t — SVM classification template

template object

SVM classification template suitable for training error-correcting output code (ECOC) multiclass models, returned as a template object. Pass `t` to `fitcecoc` to specify how to create the SVM classifier for the ECOC model.

If you display `t` to the Command Window, then all, unspecified options appear empty (`[]`). However, the software replaces empty options with their corresponding default values during training.

Tip

By default and for efficiency, `fitcecoc` empties the `Alpha`, `SupportVectorLabels`, and `SupportVectors` properties for all linear SVM binary learners. `fitcecoc` lists `Beta`, rather than `Alpha`, in the model display.

To store `Alpha`, `SupportVectorLabels`, and `SupportVectors`, pass a linear SVM template that specifies storing support vectors to `fitcecoc`. For example, enter:

```
t = templateSVM('SaveSupportVectors',true)
Mdl = fitcecoc(X,Y,'Learners',t);
```

You can remove the support vectors and related values by passing the resulting `ClassificationECOC` model to `discardSupportVectors`.

Introduced in R2014b

templateTree

Create decision tree template

Syntax

```
t = templateTree
t = templateTree(Name, Value)
```

Description

`t = templateTree` returns a default decision tree learner template suitable for training an ensemble (boosted and bagged decision trees) or error-correcting output code (ECOC) multiclass model. Specify `t` as a learner using:

- `fitcensemble` for classification ensembles
- `fitrensemble` for regression ensembles
- `fitcecoc` for ECOC model classification

If you specify a default decision tree template, then the software uses default values for all input arguments during training. It is good practice to specify the type of decision tree, e.g., for a classification tree template, specify `'Type', 'classification'`. If you specify the type of decision tree and display `t` in the Command Window, then all options except `Type` appear empty (`[]`).

`t = templateTree(Name, Value)` creates a template with additional options specified by one or more name-value pair arguments.

For example, you can specify the algorithm used to find the best split on a categorical predictor, the split criterion, or the number of predictors selected for each split.

If you display `t` in the Command Window, then all options appear empty (`[]`), except those that you specify using name-value pair arguments. During training, the software uses default values for empty options.

Examples

Create a Classification Template with Surrogate Splits

Create a decision tree template with surrogate splits, and use the template to train an ensemble using sample data.

Load Fisher's iris data set.

```
load fisheriris
```

Create a decision tree template of tree stumps with surrogate splits.

```
t = templateTree('Surrogate', 'on', 'MaxNumSplits', 1)
```

```
t =
Fit template for Tree.
    Surrogate: 'on'
    MaxNumSplits: 1
```

Options for the template object are empty except for `Surrogate` and `MaxNumSplits`. When you pass `t` to the training function, the software fills in the empty options with their respective default values.

Specify `t` as a weak learner for a classification ensemble.

```
Mdl = fitensemble(meas, species, 'Method', 'AdaBoostM2', 'Learners', t)
```

```
Mdl =
classreg.learning.classif.ClassificationEnsemble
    ResponseName: 'Y'
    CategoricalPredictors: []
        ClassNames: {'setosa' 'versicolor' 'virginica'}
        ScoreTransform: 'none'
    NumObservations: 150
    NumTrained: 100
        Method: 'AdaBoostM2'
        LearnerNames: {'Tree'}
    ReasonForTermination: 'Terminated normally after completing the requested number of iterations'
        FitInfo: [100x1 double]
    FitInfoDescription: {2x1 cell}
```

Properties, Methods

Display the in-sample (resubstitution) misclassification error.

```
L = resubLoss(Mdl)
```

```
L = 0.0333
```

Optimize Regression Ensemble Using Cross-Validation

One way to create an ensemble of boosted regression trees that has satisfactory predictive performance is to tune the decision tree complexity level using cross-validation. While searching for an optimal complexity level, tune the learning rate to minimize the number of learning cycles as well.

This example manually finds optimal parameters by using the cross-validation option (the 'Kfold' name-value pair argument) and the `kfoldLoss` function. Alternatively, you can use the 'OptimizeHyperparameters' name-value pair argument to optimize hyperparameters automatically. See “Optimize Regression Ensemble” on page 32-2563.

Load the `carsmall` data set. Choose the number of cylinders, volume displaced by the cylinders, horsepower, and weight as predictors of fuel economy.

```
load carsmall
Tbl = table(Cylinders,Displacement,Horsepower,Weight,MPG);
```

The default values of the tree depth controllers for boosting regression trees are:

- 10 for `MaxNumSplits`.
- 5 for `MinLeafSize`
- 10 for `MinParentSize`

To search for the optimal tree-complexity level:

- 1 Cross-validate a set of ensembles. Exponentially increase the tree-complexity level for subsequent ensembles from decision stump (one split) to at most $n - 1$ splits. n is the sample size. Also, vary the learning rate for each ensemble between 0.1 to 1.

- 2 Estimate the cross-validated mean-squared error (MSE) for each ensemble.
- 3 For tree-complexity level j , $j = 1 \dots J$, compare the cumulative, cross-validated MSE of the ensembles by plotting them against number of learning cycles. Plot separate curves for each learning rate on the same figure.
- 4 Choose the curve that achieves the minimal MSE, and note the corresponding learning cycle and learning rate.

Cross-validate a deep regression tree and a stump. Because the data contain missing values, use surrogate splits. These regression trees serve as benchmarks.

```
rng(1) % For reproducibility
MdlDeep = fitrtree(Tbl,'MPG','CrossVal','on','MergeLeaves','off', ...
    'MinParentSize',1,'Surrogate','on');
MdlStump = fitrtree(Tbl,'MPG','MaxNumSplits',1,'CrossVal','on', ...
    'Surrogate','on');
```

Cross-validate an ensemble of 150 boosted regression trees using 5-fold cross-validation. Using a tree template:

- Vary the maximum number of splits using the values in the sequence $\{2^0, 2^1, \dots, 2^m\}$. m is such that 2^m is no greater than $n - 1$.
- Turn on surrogate splits.

For each variant, adjust the learning rate using each value in the set $\{0.1, 0.25, 0.5, 1\}$.

```
n = size(Tbl,1);
m = floor(log2(n - 1));
learnRate = [0.1 0.25 0.5 1];
numLR = numel(learnRate);
maxNumSplits = 2.^(0:m);
numMNS = numel(maxNumSplits);
numTrees = 150;
Mdl = cell(numMNS,numLR);

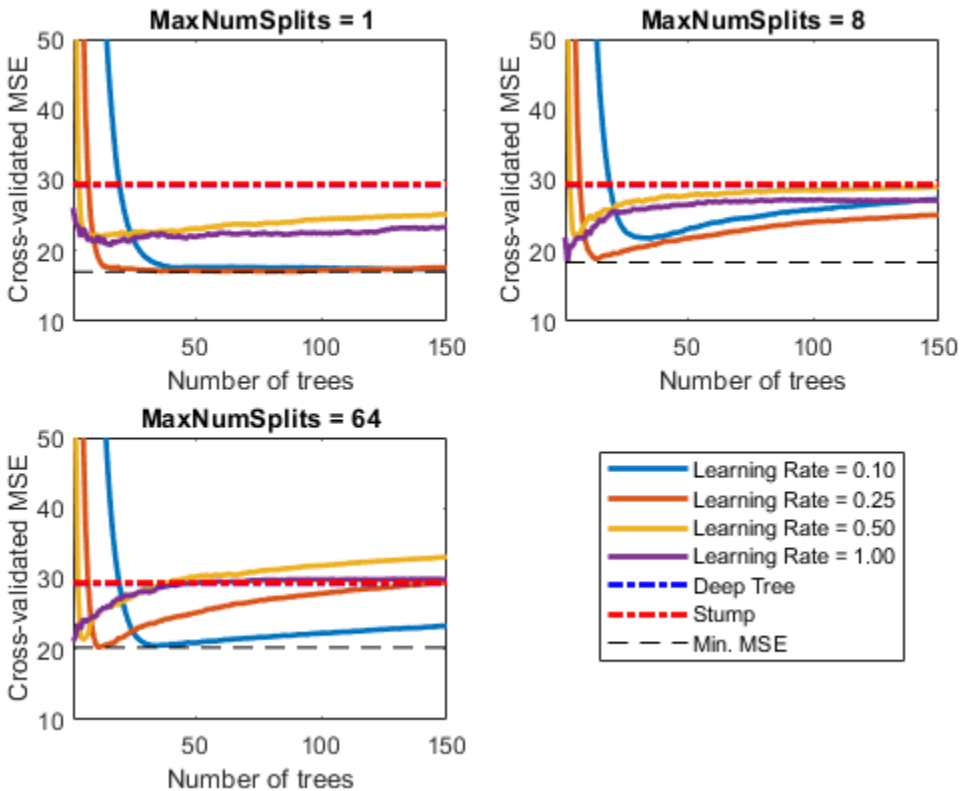

for k = 1:numLR
    for j = 1:numMNS
        t = templateTree('MaxNumSplits',maxNumSplits(j),'Surrogate','on');
        Mdl{j,k} = fitrensemble(Tbl,'MPG','NumLearningCycles',numTrees, ...
            'Learners',t,'KFold',5,'LearnRate',learnRate(k));
    end
end
```

Estimate the cumulative, cross-validated MSE of each ensemble.

```
kflAll = @(x)kfoldLoss(x, 'Mode', 'cumulative');
errorCell = cellfun(kflAll, Mdl, 'Uniform', false);
error = reshape(cell2mat(errorCell), [numTrees numel(maxNumSplits) numel(learnRate)]);
errorDeep = kfoldLoss(MdlDeep);
errorStump = kfoldLoss(MdlStump);
```

Plot how the cross-validated MSE behaves as the number of trees in the ensemble increases. Plot the curves with respect to learning rate on the same plot, and plot separate plots for varying tree-complexity levels. Choose a subset of tree complexity levels to plot.

```
mnsPlot = [1 round(numel(maxNumSplits)/2) numel(maxNumSplits)];
figure;
for k = 1:3
    subplot(2,2,k)
        plot(squeeze(error(:,mnsPlot(k),:)), 'LineWidth', 2)
        axis tight
        hold on
        h = gca;
        plot(h.XLim, [errorDeep errorDeep], '-.b', 'LineWidth', 2)
        plot(h.XLim, [errorStump errorStump], '-.r', 'LineWidth', 2)
        plot(h.XLim, min(min(error(:,mnsPlot(k),:))).*[1 1], '--k')
        h.YLim = [10 50];
        xlabel('Number of trees')
        ylabel('Cross-validated MSE')
        title(sprintf('MaxNumSplits = %0.3g', maxNumSplits(mnsPlot(k))))
        hold off
end
hL = legend([cellstr(num2str(learnRate), 'Learning Rate = %0.2f'); ...
            'Deep Tree'; 'Stump'; 'Min. MSE']);
hL.Position(1) = 0.6;
```

Each curve contains a minimum cross-validated MSE occurring at the optimal number of trees in the ensemble.

Identify the maximum number of splits, number of trees, and learning rate that yields the lowest MSE overall.

```
[minErr,minErrIdxLin] = min(error(:));
[idxNumTrees,idxMNS,idxLR] = ind2sub(size(error),minErrIdxLin);
fprintf('\nMin. MSE = %0.5f',minErr)
```

```
Min. MSE = 17.01148
```

```
fprintf('\nOptimal Parameter Values:\nNum. Trees = %d',idxNumTrees);
```

```
Optimal Parameter Values:  
Num. Trees = 38
```

```
fprintf('\nMaxNumSplits = %d\nLearning Rate = %0.2f\n',...  
        maxNumSplits(idxMNS),learnRate(idxLR))
```

```
MaxNumSplits = 4  
Learning Rate = 0.10
```

Create a predictive ensemble based on the optimal hyperparameters and the entire training set.

```
tFinal = templateTree('MaxNumSplits',maxNumSplits(idxMNS),'Surrogate','on');  
MdlFinal = fitrensemble(Tbl,'MPG','NumLearningCycles',idxNumTrees, ...  
    'Learners',tFinal,'LearnRate',learnRate(idxLR))
```

```
MdlFinal =  
classreg.learning.regr.RegressionEnsemble  
    PredictorNames: {'Cylinders' 'Displacement' 'Horsepower' 'Weight'}  
    ResponseName: 'MPG'  
    CategoricalPredictors: []  
    ResponseTransform: 'none'  
    NumObservations: 94  
    NumTrained: 38  
    Method: 'LSBoost'  
    LearnerNames: {'Tree'}  
    ReasonForTermination: 'Terminated normally after completing the requested number of  
    FitInfo: [38x1 double]  
    FitInfoDescription: {2x1 cell}  
    Regularization: []
```

Properties, Methods

`MdlFinal` is a `RegressionEnsemble`. To predict the fuel economy of a car given its number of cylinders, volume displaced by the cylinders, horsepower, and weight, you can pass the predictor data and `MdlFinal` to `predict`.

Instead of searching optimal values manually by using the cross-validation option ('`KFold`') and the `kfoldLoss` function, you can use the 'OptimizeHyperparameters' name-value pair argument. When you specify 'OptimizeHyperparameters', the software finds optimal parameters automatically using Bayesian optimization. The optimal values obtained by using

'OptimizeHyperparameters' can be different from those obtained using manual search.

```
t = templateTree('Surrogate','on');
mdl = fitensemble(Tbl,'MPG','Learners',t, ...
    'OptimizeHyperparameters',{ 'NumLearningCycles','LearnRate','MaxNumSplits'})
```

Properties, Methods

Unbiased Estimates of Predictor Importance Using Parallel Computing

Load the `carsmall` data set. Consider a model that predicts the mean fuel economy of a car given its acceleration, number of cylinders, engine displacement, horsepower, manufacturer, model year, and weight. Consider `Cylinders`, `Mfg`, and `Model_Year` as categorical variables.

```
load carsmall
Cylinders = categorical(Cylinders);
Mfg = categorical(cellstr(Mfg));
Model_Year = categorical(Model_Year);
X = table(Acceleration,Cylinders,Displacement,Horsepower,Mfg,...
          Model_Year,Weight,MPG);
```

Display the number of categories represented in the categorical variables.

```
numCylinders = numel(categories(Cylinders))

numCylinders = 3

numMfg = numel(categories(Mfg))

numMfg = 28

numModelYear = numel(categories(Model_Year))

numModelYear = 3
```

Because there are 3 categories only in `Cylinders` and `Model_Year`, the standard CART, predictor-splitting algorithm prefers splitting a continuous predictor over these two variables.

Train a random forest of 500 regression trees using the entire data set. To grow unbiased trees, specify usage of the curvature test for splitting predictors. Because there are missing values in the data, specify usage of surrogate splits. To reproduce random predictor selections, set the seed of the random number generator by using `rng` and specify `'Reproducible',true`.

```
rng('default'); % For reproducibility
t = templateTree('PredictorSelection','curvature','Surrogate','on', ...
                'Reproducible',true); % For reproducibility of random predictor selections
Mdl = fitrensemble(X,'MPG','Method','bag','NumLearningCycles',500, ...
                  'Learners',t);
```

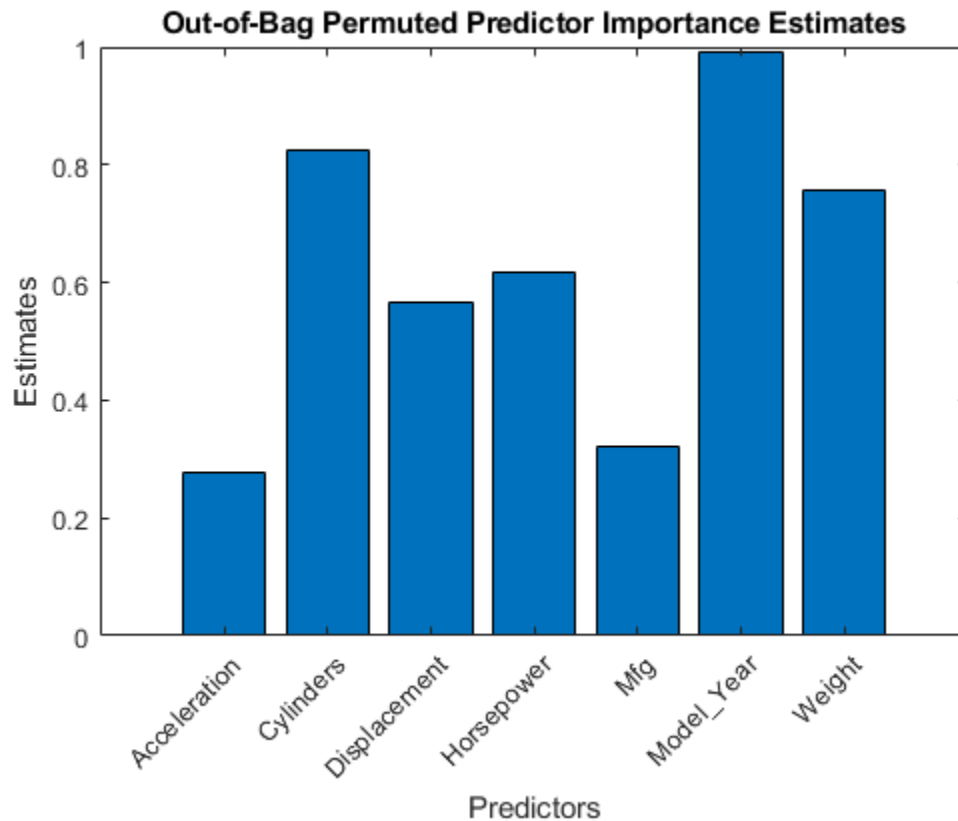

Estimate predictor importance measures by permuting out-of-bag observations. Perform calculations in parallel.

```
options = statset('UseParallel',true);
imp = oobPermutedPredictorImportance(Mdl,'Options',options);
```

```
Starting parallel pool (parpool) using the 'local' profile ...
Connected to the parallel pool (number of workers: 6).
```

Compare the estimates using a bar graph.

```
figure;  
bar(imp);  
title('Out-of-Bag Permuted Predictor Importance Estimates');  
ylabel('Estimates');  
xlabel('Predictors');  
h = gca;  
h.XTickLabel = Mdl.PredictorNames;  
h.XTickLabelRotation = 45;  
h.TickLabelInterpreter = 'none';
```

In this case, `Model_Year` is the most important predictor, followed by `Cylinders`. Compare these results to the results in “Estimate Importance of Predictors” on page 32-4735.

Create an Ensemble Template for ECOC Multiclass Learning

Create an ensemble template for use in `fitcecoc`.

Load the arrhythmia data set.

```
load arrhythmia
tabulate(categorical(Y));
```

Value	Count	Percent
1	245	54.20%
2	44	9.73%
3	15	3.32%
4	15	3.32%
5	13	2.88%
6	25	5.53%
7	3	0.66%
8	2	0.44%
9	9	1.99%
10	50	11.06%
14	4	0.88%
15	5	1.11%
16	22	4.87%

```
rng(1); % For reproducibility
```

Some classes have small relative frequencies in the data.

Create a template for a `AdaBoostM1` ensemble of classification trees, and specify to use 100 learners and a shrinkage of 0.1. By default, boosting grows stumps (i.e., one node having a set of leaves). Since there are classes with small frequencies, the trees must be leafy enough to be sensitive to the minority classes. Specify the minimum number of leaf node observations to 3.

```
tTree = templateTree('MinLeafSize',20);
t = templateEnsemble('AdaBoostM1',100,tTree,'LearnRate',0.1);
```

All properties of the template objects are empty except for `Method` and `Type`, and the corresponding properties of the name-value pair argument values in the function calls.

When you pass `t` to the training function, the software fills in the empty properties with their respective default values.

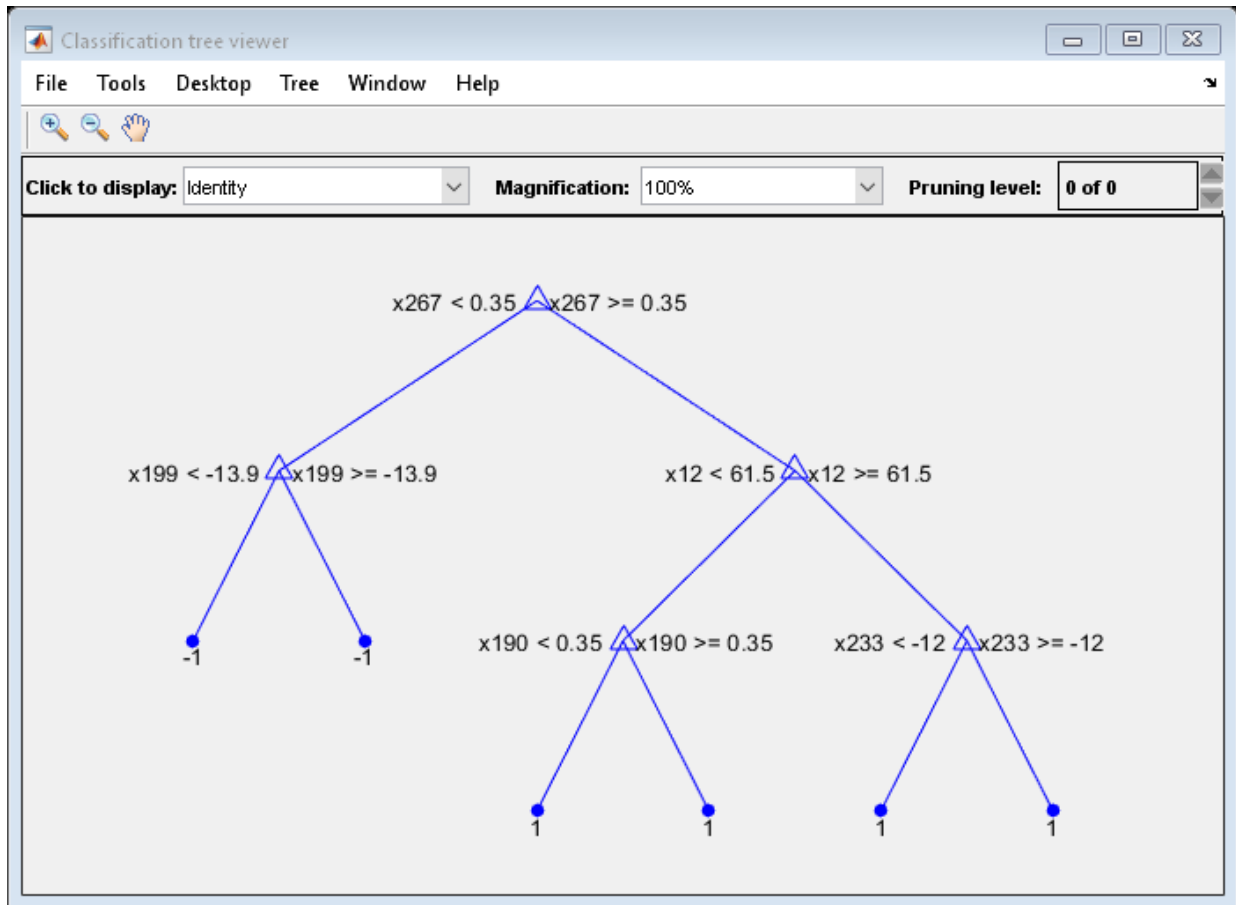

Specify `t` as a binary learner for an ECOC multiclass model. Train using the default one-versus-one coding design.

```
Mdl = fitcecoc(X,Y,'Learners',t);
```

- `Mdl` is a `ClassificationECOC` multiclass model.
- `Mdl.BinaryLearners` is a 78-by-1 cell array of `CompactClassificationEnsemble` models.
- `Mdl.BinaryLearners{j}.Trained` is a 100-by-1 cell array of `CompactClassificationTree` models, for $j = 1, \dots, 78$.

You can verify that one of the binary learners contains a weak learner that isn't a stump by using `view`.

```
view(Mdl.BinaryLearners{1}.Trained{1}, 'Mode', 'graph')
```

Display the in-sample (resubstitution) misclassification error.

```
L = resubLoss(Mdl, 'LossFun', 'classiferror')
```

```
L = 0.0597
```

Input Arguments

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Surrogate','on','NumVariablesToSample','all'` specifies a template with surrogate splits, and uses all available predictors at each split.

For Classification Trees and Regression Trees

MaxNumSplits — Maximal number of decision splits

positive integer

Maximal number of decision splits (or branch nodes) per tree, specified as the comma-separated pair consisting of `'MaxNumSplits'` and a positive integer. `templateTree` splits `MaxNumSplits` or fewer branch nodes. For more details on splitting behavior, see “Algorithms” on page 32-6801.

For bagged decision trees and decision tree binary learners in ECOC models, the default is $n - 1$, where n is the number of observations in the training sample. For boosted decision trees, the default is 10.

Example: `'MaxNumSplits',5`

Data Types: `single` | `double`

MergeLeaves — Leaf merge flag

`'off'` | `'on'`

Leaf merge flag, specified as the comma-separated pair consisting of `'MergeLeaves'` and either `'on'` or `'off'`.

When `'on'`, the decision tree merges leaves that originate from the same parent node, and that provide a sum of risk values greater or equal to the risk associated with the parent node. When `'off'`, the decision tree does not merge leaves.

For boosted and bagged decision trees, the defaults are `'off'`. For decision tree binary learners in ECOC models, the default is `'on'`.

Example: 'MergeLeaves', 'on'

MinLeafSize — Minimum observations per leaf

positive integer value

Minimum observations per leaf, specified as the comma-separated pair consisting of 'MinLeafSize' and a positive integer value. Each leaf has at least MinLeafSize observations per tree leaf. If you supply both MinParentSize and MinLeafSize, the decision tree uses the setting that gives larger leaves: $\text{MinParentSize} = \max(\text{MinParentSize}, 2 * \text{MinLeafSize})$.

For boosted and bagged decision trees, the defaults are 1 for classification and 5 for regression. For decision tree binary learners in ECOG models, the default is 1.

Example: 'MinLeafSize', 2

MinParentSize — Minimum observations per branch node

positive integer value

Minimum observations per branch node, specified as the comma-separated pair consisting of 'MinParentSize' and a positive integer value. Each branch node in the tree has at least MinParentSize observations. If you supply both MinParentSize and MinLeafSize, the decision tree uses the setting that gives larger leaves: $\text{MinParentSize} = \max(\text{MinParentSize}, 2 * \text{MinLeafSize})$.

For boosted and bagged decision trees, the defaults are 2 for classification and 10 for regression. For decision tree binary learners in ECOG models, the default is 10.

Example: 'MinParentSize', 4

NumVariablesToSample — Number of predictors to select at random for each split

positive integer value | 'all'

Number of predictors to select at random for each split, specified as the comma-separated pair consisting of 'NumVariablesToSample' and a positive integer value. Alternatively, you can specify 'all' to use all available predictors.

If the training data includes many predictors and you want to analyze predictor importance, then specify 'NumVariablesToSample' as 'all'. Otherwise, the software might not select some predictors, underestimating their importance.

To reproduce the random selections, you must set the seed of the random number generator by using `rng` and specify `'Reproducible', true`.

For boosted decision trees and decision tree binary learners in ECOC models, the default is `'all'`. The default for bagged decision trees is the square root of the number of predictors for classification, or one third of the number of predictors for regression.

Example: `'NumVariablesToSample', 3`

Data Types: `single` | `double` | `char` | `string`

PredictorSelection — Algorithm used to select the best split predictor

`'allsplits'` (default) | `'curvature'` | `'interaction-curvature'`

Algorithm used to select the best split predictor at each node, specified as the comma-separated pair consisting of `'PredictorSelection'` and a value in this table.

Value	Description
<code>'allsplits'</code>	Standard CART — Selects the split predictor that maximizes the split-criterion gain over all possible splits of all predictors [1].
<code>'curvature'</code>	Curvature test — Selects the split predictor that minimizes the p -value of chi-square tests of independence between each predictor and the response [3][4]. Training speed is similar to standard CART.
<code>'interaction-curvature'</code>	Interaction test — Chooses the split predictor that minimizes the p -value of chi-square tests of independence between each predictor and the response, and that minimizes the p -value of a chi-square test of independence between each pair of predictors and response [3]. Training speed can be slower than standard CART.

For `'curvature'` and `'interaction-curvature'`, if all tests yield p -values greater than 0.05, then MATLAB stops splitting nodes.

Tip

- The curvature and interaction tests are not recommended for boosting decision trees. To train an ensemble of boosted trees that has greater accuracy, use standard CART instead.

- Standard CART tends to select split predictors containing many distinct values, e.g., continuous variables, over those containing few distinct values, e.g., categorical variables [4]. If the predictor data set is heterogeneous, or if there are predictors that have relatively fewer distinct values than other variables, then consider specifying the curvature or interaction test.
 - If there are predictors that have relatively fewer distinct values than other predictors, for example, if the predictor data set is heterogeneous.
 - If an analysis of predictor importance is your goal. For more on predictor importance estimation, see `oobPermutedPredictorImportance` for classification problems, and `oobPermutedPredictorImportance` for regression problems.
 - Trees grown using standard CART are not sensitive to predictor variable interactions. Also, such trees are less likely to identify important variables in the presence of many irrelevant predictors than the application of the interaction test. Therefore, to account for predictor interactions and identify importance variables in the presence of many irrelevant variables, specify the interaction test [3].
 - Prediction speed is unaffected by the value of `'PredictorSelection'`.
-

For details on how `templateTree` selects split predictors, see “Node Splitting Rules” on page 32-2177 (classification), “Node Splitting Rules” on page 32-2681 (regression), and “Choose Split Predictor Selection Technique” on page 19-19.

Example: `'PredictorSelection', 'curvature'`

Prune — Flag to estimate optimal sequence of pruned subtrees

`'off' | 'on'`

Flag to estimate the optimal sequence of pruned subtrees, specified as the comma-separated pair consisting of `'Prune'` and `'on'` or `'off'`.

If `Prune` is `'on'`, then the software trains the classification tree learners without pruning them, but estimates the optimal sequence of pruned subtrees for each learner in the ensemble or decision tree binary learner in ECOC models. Otherwise, the software trains the classification tree learners without estimating the optimal sequence of pruned subtrees.

For boosted and bagged decision trees, the default is `'off'`.

For decision tree binary learners in ECOC models, the default is `'on'`.

Example: 'Prune', 'on'

PruneCriterion — Pruning criterion

'error' | 'impurity' | 'mse'

Pruning criterion, specified as the comma-separated pair consisting of 'PruneCriterion' and a pruning criterion valid for the tree type.

- For classification trees, you can specify 'error' (default) or 'impurity'. If you specify 'impurity', then `templateTree` uses the impurity measure specified by the 'SplitCriterion' name-value pair argument.
- For regression trees, you can specify only 'mse' (default).

Example: 'PruneCriterion', 'impurity'

Reproducible — Flag to enforce reproducibility

false (logical 0) (default) | true (logical 1)

Flag to enforce reproducibility over repeated runs of training a model, specified as the comma-separated pair consisting of 'Reproducible' and either false or true.

If 'NumVariablesToSample' is not 'all', then the software selects predictors at random for each split. To reproduce the random selections, you must specify 'Reproducible', true and set the seed of the random number generator by using `rng`. Note that setting 'Reproducible' to true can slow down training.

Example: 'Reproducible', true

Data Types: logical

SplitCriterion — Split criterion

'gdi' | 'twoing' | 'deviance' | 'mse'

Split criterion, specified as the comma-separated pair consisting of 'SplitCriterion' and a split criterion valid for the tree type.

- For classification trees:
 - 'gdi' for Gini's diversity index (default)
 - 'twoing' for the twoing rule
 - 'deviance' for maximum deviance reduction (also known as cross entropy)
- For regression trees:

- 'mse' for mean squared error (default)

Example: 'SplitCriterion', 'deviance'

Surrogate — Surrogate decision splits

'off' (default) | 'on' | 'all' | positive integer value

Surrogate decision splits flag, specified as the comma-separated pair consisting of 'Surrogate' and one of 'off', 'on', 'all', or a positive integer value.

- When 'off', the decision tree does not find surrogate splits at the branch nodes.
- When 'on', the decision tree finds at most 10 surrogate splits at each branch node.
- When set to 'all', the decision tree finds all surrogate splits at each branch node. The 'all' setting can consume considerable time and memory.
- When set to a positive integer value, the decision tree finds at most the specified number of surrogate splits at each branch node.

Use surrogate splits to improve the accuracy of predictions for data with missing values. This setting also lets you compute measures of predictive association between predictors.

Example: 'Surrogate', 'on'

Data Types: single | double | char | string

For Classification Trees Only

AlgorithmForCategorical — Algorithm for best categorical predictor split

'Exact' | 'PullLeft' | 'PCA' | 'OVAbyClass'

Algorithm to find the best split on a categorical predictor for data with C categories for data and $K \geq 3$ classes, specified as the comma-separated pair consisting of 'AlgorithmForCategorical' and one of the following.

Value	Description
'Exact'	Consider all $2^{C-1} - 1$ combinations.

Value	Description
'PullLeft'	Start with all C categories on the right branch. Consider moving each category to the left branch as it achieves the minimum impurity for the K classes among the remaining categories. From this sequence, choose the split that has the lowest impurity.
'PCA'	Compute a score for each category using the inner product between the first principal component of a weighted covariance matrix (of the centered class probability matrix) and the vector of class probabilities for that category. Sort the scores in ascending order, and consider all $C - 1$ splits.
'OVAbyClass'	Start with all C categories on the right branch. For each class, order the categories based on their probability for that class. For the first class, consider moving each category to the left branch in order, recording the impurity criterion at each move. Repeat for the remaining classes. From this sequence, choose the split that has the minimum impurity.

The software selects the optimal subset of algorithms for each split using the known number of classes and levels of a categorical predictor. For two classes, it always performs the exact search. Use the 'AlgorithmForCategorical' name-value pair argument to specify a particular algorithm.

For more details, see “Splitting Categorical Predictors in Classification Trees” on page 19-31.

Example: 'AlgorithmForCategorical', 'PCA'

MaxNumCategories — Maximum category levels in split node

10 (default) | nonnegative scalar value

Maximum category levels in the split node, specified as the comma-separated pair consisting of 'MaxNumCategories' and a nonnegative scalar value. A classification tree splits a categorical predictor using the exact search algorithm if the predictor has at most MaxNumCategories levels in the split node. Otherwise, it finds the best categorical split using one of the inexact algorithms. Note that passing a small value can increase computation time and memory overload.

Example: 'MaxNumCategories',8

For Regression Trees Only

QuadraticErrorTolerance — Quadratic error tolerance

1e-6 (default) | positive scalar value

Quadratic error tolerance per node, specified as the comma-separated pair consisting of 'QuadraticErrorTolerance' and a positive scalar value. A regression tree stops splitting nodes when the weighted mean squared error per node drops below QuadraticErrorTolerance* ε , where ε is the weighted mean squared error of all n responses computed before growing the decision tree.

$$\varepsilon = \sum_{i=1}^n w_i (y_i - \bar{y})^2.$$

w_i is the weight of observation i , given that the weights of all the observations sum to one

($\sum_{i=1}^n w_i = 1$), and

$$\bar{y} = \sum_{i=1}^n w_i y_i$$

is the weighted average of all the responses.

Example: 'QuadraticErrorTolerance',1e-4

Output Arguments

t — Decision tree template for classification or regression

template object

Decision tree template for classification or regression suitable for training an ensemble (boosted and bagged decision trees) or error-correcting output code (ECOC) multiclass

model, returned as a template object. Pass `t` to `fitcensemble`, or `fitrensemble`, or `fitcecoc` to specify how to create the decision tree for the classification ensemble, regression ensemble, or ECOC model, respectively.

If you display `t` in the Command Window, then all unspecified options appear empty (`[]`). However, the software replaces empty options with their corresponding default values during training.

Algorithms

- To accommodate `MaxNumSplits`, the software splits all nodes in the current layer, and then counts the number of branch nodes. A layer is the set of nodes that are equidistant from the root node. If the number of branch nodes exceeds `MaxNumSplits`, then the software follows this procedure.
 - 1 Determine how many branch nodes in the current layer need to be unsplit so that there would be at most `MaxNumSplits` branch nodes.
 - 2 Sort the branch nodes by their impurity gains.
 - 3 Unsplit the desired number of least successful branches.
 - 4 Return the decision tree grown so far.

This procedure aims at producing maximally balanced trees.

- The software splits branch nodes layer by layer until at least one of these events occurs.
 - There are `MaxNumSplits + 1` branch nodes.
 - A proposed split causes the number of observations in at least one branch node to be fewer than `MinParentSize`.
 - A proposed split causes the number of observations in at least one leaf node to be fewer than `MinLeafSize`.
 - The algorithm cannot find a good split within a layer (i.e., the pruning criterion (see `PruneCriterion`), does not improve for all proposed splits in a layer). A special case of this event is when all nodes are pure (i.e., all observations in the node have the same class).
 - For values `'curvature'` or `'interaction-curvature'` of `PredictorSelection`, all tests yield p -values greater than 0.05.

`MaxNumSplits` and `MinLeafSize` do not affect splitting at their default values. Therefore, if you set `'MaxNumSplits'`, then splitting might stop due to the value of `MinParentSize` before `MaxNumSplits` splits occur.

- For details on selecting split predictors and node-splitting algorithms when growing decision trees, see “Algorithms” on page 32-2177 for classification trees and “Algorithms” on page 32-2681 for regression trees.

Introduced in R2014a

test

Class: cvpartition

Test indices for cross-validation

Syntax

```
idx = test(c)
idx = test(c,i)
```

Description

`idx = test(c)` returns the logical vector `idx` of test indices for an object `c` of the `cvpartition` on page 32-1237 class of type 'holdout' or 'resubstitution'.

If `c.Type` is 'holdout', `idx` specifies the observations in the test set.

If `c.Type` is 'resubstitution', `idx` specifies all observations.

`idx = test(c,i)` returns the logical vector `idx` of test indices for repetition `i` of an object `c` of the `cvpartition` on page 32-1237 class of type 'kfold' or 'leaveout'.

If `c.Type` is 'kfold', `idx` specifies the observations in the test set in fold `i`.

If `c.Type` is 'leaveout', `idx` specifies the observation left out at repetition `i`.

Examples

Identify the test indices in the first fold of a partition of 10 observations for 3-fold cross-validation:

```
c = cvpartition(10,'kfold',3)
c =
K-fold cross validation partition
      N: 10
```

```
    NumTestSets: 3
      TrainSize: 7 6 7
      TestSize:  3 4 3

test(c,1)
ans =
     1
     1
     0
     0
     0
     0
     0
     0
     1
     0
```

testcholdout

Compare predictive accuracies of two classification models

`testcholdout` statistically assesses the accuracies of two classification models. The function first compares their predicted labels against the true labels, and then it detects whether the difference between the misclassification rates is statistically significant.

You can assess whether the accuracies of the classification models are different, or whether one classification model performs better than another. `testcholdout` can conduct several McNemar test on page 32-6819 variations, including the asymptotic test, the exact-conditional test, and the mid- p -value test. For cost-sensitive assessment on page 32-6816, available tests include a chi-square test (requires an Optimization Toolbox license) and a likelihood ratio test.

Syntax

```
h = testcholdout(YHat1,YHat2,Y)
h = testcholdout(YHat1,YHat2,Y,Name,Value)
[h,p,e1,e2] = testcholdout( ___ )
```

Description

`h = testcholdout(YHat1,YHat2,Y)` returns the test decision, by conducting the mid- p -value McNemar test on page 32-6819, from testing the null hypothesis that the predicted class labels `YHat1` and `YHat2` have equal accuracy for predicting the true class labels `Y`. The alternative hypothesis is that the labels have unequal accuracy.

`h = 1` indicates to reject the null hypothesis at the 5% significance level. `h = 0` indicates to not reject the null hypothesis at 5% level.

`h = testcholdout(YHat1,YHat2,Y,Name,Value)` returns the result of the hypothesis test with additional options specified by one or more `Name,Value` pair arguments. For example, you can specify the type of alternative hypothesis, specify the type of test, or supply a cost matrix.

`[h,p,e1,e2] = testcholdout(___)` returns the p -value for the hypothesis test (p) and the respective classification loss on page 32-6821 of each set of predicted class labels ($e1$ and $e2$) using any of the input arguments in the previous syntaxes.

Examples

Compare Accuracies of Two Different Classification Models

Train two classification models using different algorithms. Conduct a statistical test comparing the misclassification rates of the two models on a held-out set.

Load the `ionosphere` data set.

```
load ionosphere
```

Create a partition that evenly splits the data into training and testing sets.

```
rng(1); % For reproducibility
CVP = cvpartition(Y,'holdout',0.5);
idxTrain = training(CVP); % Training-set indices
idxTest = test(CVP); % Test-set indices
```

CVP is a cross-validation partition object that specifies the training and test sets.

Train an SVM model and an ensemble of 100 bagged classification trees. For the SVM model, specify to use the radial basis function kernel and a heuristic procedure to determine the kernel scale.

```
MdlSVM = fitsvm(X(idxTrain,:),Y(idxTrain),'Standardize',true,...
    'KernelFunction','RBF','KernelScale','auto');
t = templateTree('Reproducible',true); % For reproducibility of random predictor selection
MdlBag = fitcensemble(X(idxTrain,:),Y(idxTrain),'Method','Bag','Learners',t);
```

MdlSVM is a trained `ClassificationSVM` model. MdlBag is a trained `ClassificationBaggedEnsemble` model.

Label the test-set observations using the trained models.

```
YhatSVM = predict(MdlSVM,X(idxTest,:));
YhatBag = predict(MdlBag,X(idxTest,:));
```

YhatSVM and YhatBag are vectors containing the predicted class labels of the respective models.

Test whether the two models have equal predictive accuracies.

```
h = testcholdout(YhatSVM,YhatBag,Y(idxTest))

h = logical
    0
```

$h = 0$ indicates to not reject the null hypothesis that the two models have equal predictive accuracies.

Assess Whether One Classification Model Classifies Better Than Another

Train two classification models using the same algorithm, but adjust a hyperparameter to make the algorithm more complex. Conduct a statistical test to assess whether the simpler model has better accuracy in held-out data than the more complex model.

Load the ionosphere data set.

```
load ionosphere;
```

Create a partition that evenly splits the data into training and testing sets.

```
rng(1); % For reproducibility
CVP = cvpartition(Y,'holdout',0.5);
idxTrain = training(CVP); % Training-set indices
idxTest = test(CVP); % Test-set indices
```

CVP is a cross-validation partition object that specifies the training and test sets.

Train two SVM models: one that uses a linear kernel (the default for binary classification) and one that uses the radial basis function kernel. Use the default kernel scale of 1.

```
MdlLinear = fitcsvm(X(idxTrain,:),Y(idxTrain),'Standardize',true);
MdlRBF = fitcsvm(X(idxTrain,:),Y(idxTrain),'Standardize',true,...
    'KernelFunction','RBF');
```

MdlLinear and MdlRBF are trained ClassificationSVM models.

Label the test-set observations using the trained models.

```
YhatLinear = predict(MdlLinear,X(idxTest,:));
YhatRBF = predict(MdlRBF,X(idxTest,:));
```

YhatLinear and YhatRBF are vectors containing the predicted class labels of the respective models.

Test the null hypothesis that the simpler model (MdlLinear) is at most as accurate as the more complex model (MdlRBF). Because the test-set size is large, conduct the asymptotic McNemar test, and compare the results with the mid- p -value test (the cost-insensitive testing default). Request to return p -values and misclassification rates.

```
Asymp = zeros(4,1); % Preallocation
MidP = zeros(4,1);

[Asymp(1),Asymp(2),Asymp(3),Asymp(4)] = testcholdout(YhatLinear,YhatRBF,Y(idxTest),...
    'Alternative','greater','Test','asymptotic');
[MidP(1),MidP(2),MidP(3),MidP(4)] = testcholdout(YhatLinear,YhatRBF,Y(idxTest),...
    'Alternative','greater');
table(Asymp,MidP,'RowNames',{'h' 'p' 'e1' 'e2'})

ans=4x2 table
           Asymp           MidP
           -----           -----
h                1                1
p       7.2801e-09       2.7649e-10
e1         0.13714         0.13714
e2         0.33143         0.33143
```

The p -value is close to zero for both tests, which indicates strong evidence to reject the null hypothesis that the simpler model is less accurate than the more complex model. No matter what test you specify, `testcholdout` returns the same type of misclassification measure for both models.

Conduct Cost-Sensitive Comparison of Two Classification Models

For data sets with imbalanced class representations, or if the false-positive and false-negative costs are imbalanced, you can statistically compare the predictive performance of two classification models by including a cost matrix in the analysis.

Load the arrhythmia data set. Determine the class representations in the data.

```
load arrhythmia;
Y = categorical(Y);
tabulate(Y);
```

Value	Count	Percent
1	245	54.20%
2	44	9.73%
3	15	3.32%
4	15	3.32%
5	13	2.88%
6	25	5.53%
7	3	0.66%
8	2	0.44%
9	9	1.99%
10	50	11.06%
14	4	0.88%
15	5	1.11%
16	22	4.87%

There are 16 classes, however some are not represented in the data set (for example, class 13). Most observations are classified as not having arrhythmia (class 1). The data set is highly discrete with imbalanced classes.

Combine all observations with arrhythmia (classes 2 through 15) into one class. Remove those observations with unknown arrhythmia status (class 16) from the data set.

```
idx = (Y ~= '16');
Y = Y(idx);
X = X(idx,:);
Y(Y ~= '1') = 'WithArrhythmia';
Y(Y == '1') = 'NoArrhythmia';
Y = removecats(Y);
```

Create a partition that evenly splits the data into training and test sets.

```
rng(1); % For reproducibility
CVP = cvpartition(Y,'holdout',0.5);
idxTrain = training(CVP); % Training-set indices
idxTest = test(CVP); % Test-set indices
```

CVP is a cross-validation partition object that specifies the training and test sets.

Create a cost matrix such that misclassifying a patient with arrhythmia into the "no arrhythmia" class is five times worse than misclassifying a patient without arrhythmia

into the arrhythmia class. Classifying correctly incurs no cost. The rows indicate the true class and the columns indicate predicted class. When you conduct a cost-sensitive analysis, a good practice is to specify the order of the classes.

```
Cost = [0 1;5 0];  
ClassNames = {'NoArrhythmia', 'WithArrhythmia'};
```

Train two boosting ensembles of 50 classification trees, one that uses AdaBoostM1 and another that uses LogitBoost. Because there are missing values in the data set, specify to use surrogate splits. Train the models using the cost matrix.

```
t = templateTree('Surrogate', 'on');  
numTrees = 50;  
MdlAda = fitcensemble(X(idxTrain,:), Y(idxTrain), 'Method', 'AdaBoostM1', ...  
    'NumLearningCycles', numTrees, 'Learners', t, ...  
    'Cost', Cost, 'ClassNames', ClassNames);  
MdlLogit = fitcensemble(X(idxTrain,:), Y(idxTrain), 'Method', 'LogitBoost', ...  
    'NumLearningCycles', numTrees, 'Learners', t, ...  
    'Cost', Cost, 'ClassNames', ClassNames);
```

MdlAda and MdlLogit are trained ClassificationEnsemble models.

Label the test-set observations using the trained models.

```
YhatAda = predict(MdlAda, X(idxTest, :));  
YhatLogit = predict(MdlLogit, X(idxTest, :));
```

YhatLinear and YhatRBF are vectors containing the predicted class labels of the respective models.

Test whether the AdaBoostM1 ensemble (MdlAda) and the LogitBoost ensemble (MdlLogit) have equal predictive accuracy. Supply the cost matrix. Conduct the asymptotic, likelihood ratio, cost-sensitive test (the default when you pass in a cost matrix). Request to return p -values and misclassification costs.

```
[h, p, e1, e2] = testcholdout(YhatAda, YhatLogit, Y(idxTest), 'Cost', Cost)
```

```
h = logical  
    0
```

```
p = 0.4488
```

```
e1 = 0.5302
```

$e_2 = 0.4698$

$h = 0$ indicates to not reject the null hypothesis that the two models have equal predictive accuracies.

Input Arguments

YHat1 — Predicted class labels

categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Predicted class labels of the first classification model, specified as a categorical, character, or string array, logical or numeric vector, or cell array of character vectors.

If YHat1 is a character array, then each element must correspond to one row of the array.

YHat1, YHat2, and Y must have equal lengths.

It is a best practice for YHat1, YHat2, and Y to share the same data type.

Data Types: categorical | char | string | logical | single | double | cell

YHat2 — Predicted class labels

categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Predicted class labels of the second classification model, specified as a categorical, character, or string array, logical or numeric vector, or cell array of character vectors.

If YHat2 is a character array, then each element must correspond to one row of the array.

YHat1, YHat2, and Y must have equal lengths.

It is a best practice for YHat1, YHat2, and Y to share the same data type.

Data Types: categorical | char | string | logical | single | double | cell

Y — True class labels

categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

True class labels, specified as a categorical, character, or string array, logical or numeric vector, or cell array of character vectors.

If `Y` is a character array, then each element must correspond to one row of the array.

`YHat1`, `YHat2`, and `Y` must have equal lengths.

It is a best practice for `YHat1`, `YHat2`, and `Y` to share the same data type.

Data Types: `categorical` | `char` | `string` | `logical` | `single` | `double` | `cell`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'Alternative', 'greater', 'Test', 'asymptotic', 'Cost', [0 2; 1 0]` specifies to test whether the first set of first predicted class labels is more accurate than the second set, to conduct the asymptotic McNemar test, and to penalize misclassifying observations with the true label `ClassNames{1}` twice as much as for misclassifying observations with the true label `ClassNames{2}`.

Alpha — Hypothesis test significance level

`0.05` (default) | scalar value in the interval $(0,1)$

Hypothesis test significance level, specified as the comma-separated pair consisting of `'Alpha'` and a scalar value in the interval $(0,1)$.

Example: `'Alpha', 0.1`

Data Types: `single` | `double`

Alternative — Alternative hypothesis to assess

`'unequal'` (default) | `'greater'` | `'less'`

Alternative hypothesis to assess, specified as the comma-separated pair consisting of `'Alternative'` and one of the values listed in the table.

Value	Alternative hypothesis
<code>'unequal'</code> (default)	For predicting <code>Y</code> , <code>YHat1</code> and <code>YHat2</code> have unequal accuracies.

Value	Alternative hypothesis
'greater'	For predicting Y, YHat1 is more accurate than YHat2.
'less'	For predicting Y, YHat1 is less accurate than YHat2.

Example: 'Alternative', 'greater'

ClassNames — Class names

categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Class names, specified as the comma-separated pair consisting of 'ClassNames' and a categorical, character, or string array, logical or numeric vector, or cell array of character vectors. You must set ClassNames using the data type of Y.

If ClassNames is a character array, then each element must correspond to one row of the array.

Use ClassNames to:

- Specify the order of any input argument dimension that corresponds to class order. For example, use ClassNames to specify the order of the dimensions of Cost.
- Select a subset of classes for testing. For example, suppose that the set of all distinct class names in Y is {'a', 'b', 'c'}. To train and test models using observations from classes 'a' and 'c' only, specify 'ClassNames', {'a', 'c'}.

The default is the set of all distinct class names in Y.

Example: 'ClassNames', {'b', 'g'}

Data Types: single | double | logical | char | string | cell | categorical

Cost — Misclassification cost

square matrix | structure array

Misclassification cost, specified as the comma-separated pair consisting of 'Cost' and a square matrix or structure array.

- If you specify the square matrix Cost, then $Cost(i, j)$ is the cost of classifying a point into class j if its true class is i. That is, the rows correspond to the true class and the columns correspond to the predicted class. To specify the class order for the corresponding rows and columns of Cost, additionally specify the ClassNames name-value pair argument.

- If you specify the structure `S`, then `S` must have two fields:
 - `S.ClassNames`, which contains the class names as a variable of the same data type as `Y`. You can use this field to specify the order of the classes.
 - `S.ClassificationCosts`, which contains the cost matrix, with rows and columns ordered as in `S.ClassNames`.

If you specify `Cost`, then `testcholdout` cannot conduct one-sided, exact, or mid- p tests. You must also specify `'Alternative'`, `'unequal'`, `'Test'`, `'asymptotic'`. For cost-sensitive testing options, see the `CostTest` name-value pair argument.

A best practice is to supply the same cost matrix used to train the classification models.

The default is $\text{Cost}(i, j) = 1$ if $i \neq j$, and $\text{Cost}(i, j) = 0$ if $i = j$.

Example: `'Cost', [0 1 2 ; 1 0 2; 2 2 0]`

Data Types: `single` | `double` | `struct`

CostTest — Cost-sensitive test type

`'likelihood'` (default) | `'chisquare'`

Cost-sensitive test type, specified as the comma-separated pair consisting of `'CostTest'` and `'chisquare'` or `'likelihood'`. Unless you specify a cost matrix using the `Cost` name-value pair argument, `testcholdout` ignores `CostTest`.

This table summarizes the available options for cost-sensitive testing.

Value	Asymptotic test type	Requirements
<code>'chisquare'</code>	Chi-square test	Optimization Toolbox license to implement <code>quadprog</code>
<code>'likelihood'</code>	Likelihood ratio test	None

For more details, see “Cost-Sensitive Testing” on page 32-6816.

Example: `'CostTest', 'chisquare'`

Test — Test to conduct

`'asymptotic'` | `'exact'` | `'midp'`

Test to conduct, specified as the comma-separated pair consisting of `'Test'` and `'asymptotic'`, `'exact'`, and `'midp'`. This table summarizes the available options for cost-insensitive testing.

Value	Description
'asymptotic'	Asymptotic McNemar test
'exact'	Exact-conditional McNemar test
'midp' (default)	Mid- p -value McNemar test

For more details, see “McNemar Tests” on page 32-6819.

For cost-sensitive testing, `Test` must be 'asymptotic'. When you specify the `Cost` name-value pair argument, and choose a cost-sensitive test using the `CostTest` name-value pair argument, 'asymptotic' is the default.

Example: 'Test', 'asymptotic'

Note NaNs, <undefined> values, empty character vectors (' '), empty strings (""), and <missing> values indicate missing data values. testcholdout:

- Treats missing values in `YHat1` and `YHat2` as misclassified observations.
 - Removes missing values in `Y` and the corresponding values of `YHat1` and `YHat2`
-

Output Arguments

h — Hypothesis test result

1 | 0

Hypothesis test result, returned as a logical value.

`h = 1` indicates the rejection of the null hypothesis at the `Alpha` significance level.

`h = 0` indicates failure to reject the null hypothesis at the `Alpha` significance level.

Data Types: `logical`

p — p -value

scalar in the interval [0,1]

p -value of the test, returned as a scalar in the interval [0,1]. p is the probability that a random test statistic is at least as extreme as the observed test statistic, given that the null hypothesis is true.

`testcholdout` estimates p using the distribution of the test statistic, which varies with the type of test. For details on test statistics derived from the available variants of the McNemar test, see “McNemar Tests” on page 32-6819. For details on test statistics derived from cost-sensitive tests, see “Cost-Sensitive Testing” on page 32-6816.

e1 — Classification loss

scalar

Classification loss on page 32-6821 that summarizes the accuracy of the first set of class labels (\hat{Y}_1) predicting the true class labels (Y), returned as a scalar.

For cost-insensitive testing, **e1** is the misclassification rate. That is, **e1** is the proportion of misclassified observations, which is a scalar in the interval $[0,1]$.

For cost-sensitive testing, **e1** is the misclassification cost. That is, **e1** is the weighted average of the misclassification costs, in which the weights are the respective estimated proportions of misclassified observations.

e2 — Classification loss

scalar

Classification loss on page 32-6821 that summarizes the accuracy of the second set of class labels (\hat{Y}_2) predicting the true class labels (Y), returned as a scalar.

For cost-insensitive testing, **e2** is the misclassification rate. That is, **e2** is the proportion of misclassified observations, which is a scalar in the interval $[0,1]$.

For cost-sensitive testing, **e2** is the misclassification cost. That is, **e2** is the weighted average of the costs of misclassification, in which the weights are the respective estimated proportions of misclassified observations.

Definitions

Cost-Sensitive Testing

Conduct cost-sensitive testing when the cost of misclassification is imbalanced. By conducting a cost-sensitive analysis, you can account for the cost imbalance when you train the classification models and when you statistically compare them.

If the cost of misclassification is imbalanced, then the misclassification rate tends to be a poorly performing classification loss. Use misclassification cost instead to compare classification models.

Misclassification costs are often imbalanced in applications. For example, consider classifying subjects based on a set of predictors into two categories: healthy and sick. Misclassifying a sick subject as healthy poses a danger to the subject's life. However, misclassifying a healthy subject as sick typically causes some inconvenience, but does not pose significant danger. In this situation, you assign misclassification costs such that misclassifying a sick subject as healthy is more costly than misclassifying a healthy subject as sick.

The definitions that follow summarize the cost-sensitive tests. In the definitions:

- n_{ijk} and $\hat{\pi}_{ijk}$ are the number and estimated proportion of test-sample observations with the following characteristics. k is the true class, i is the label assigned by the first classification model, and j is the label assigned by the second classification model. The unknown true value of $\hat{\pi}_{ijk}$ is π_{ijk} . The test-set sample size is $\sum_{i,j,k} n_{ijk} = n_{test}$.

Additionally, $\sum_{i,j,k} \pi_{ijk} = \sum_{i,j,k} \hat{\pi}_{ijk} = 1$.

- c_{ij} is the relative cost of assigning label j to an observation with true class i . $c_{ii} = 0$, $c_{ij} \geq 0$, and, for at least one (i,j) pair, $c_{ij} > 0$.
- All subscripts take on integer values from 1 through K , which is the number of classes.
- The expected difference in the misclassification costs of the two classification models is

$$\delta = \sum_{i=1}^K \sum_{j=1}^K \sum_{k=1}^K (c_{ki} - c_{kj}) \pi_{ijk}.$$

- The hypothesis test is

$$H_0: \delta = 0$$

$$H_1: \delta \neq 0$$

The available cost-sensitive tests are appropriate for two-tailed testing.

Available asymptotic tests that address imbalanced costs are a chi-square test and a likelihood ratio test.

- Chi-square test — The chi-square test statistic is based on the Pearson and Neyman chi-square test statistics, but with a Laplace correction factor to account for any $n_{ijk} = 0$. The test statistic is

$$t_{\chi^2}^* = \sum_i \sum_{j \neq k} \frac{\left(n_{ijk} + 1 - (n_{test} + K^3) \widehat{\pi}_{ijk}^{(1)} \right)^2}{n_{ijk} + 1}.$$

If $1 - F_{\chi^2}(t_{\chi^2}^*; 2; 1) < \alpha$, then reject H_0 .

- $\widehat{\pi}_{ijk}^{(1)}$ are estimated by minimizing $t_{\chi^2}^*$ under the constraint that $\delta = 0$.
- $F_{\chi^2}(x; 1)$ is the χ^2 cdf with one degree of freedom evaluated at x .
- Likelihood ratio test — The likelihood ratio test is based on N_{ijk} , which are binomial random variables with sample size n_{test} and success probability π_{ijk} . The random variables represent the random number of observations with: true class k , label i assigned by the first classification model, and label j assigned by the second classification model. Jointly, the distribution of the random variables is multinomial.

The test statistic is

$$t_{LRT}^* = 2 \log \left[\frac{P\left(\bigcap_{i,j,k} N_{ijk} = n_{ijk}; n_{test}, \widehat{\pi}_{ijk} = \widehat{\pi}_{ijk}^{(2)} \right)}{P\left(\bigcap_{i,j,k} N_{ijk} = n_{ijk}; n_{test}, \widehat{\pi}_{ijk} = \widehat{\pi}_{ijk}^{(3)} \right)} \right].$$

If $1 - F_{\chi^2}(t_{LRT}^*; 1) < \alpha$, then reject H_0 .

- $\widehat{\pi}_{ijk}^{(2)} = \frac{n_{ijk}}{n_{test}}$ is the unrestricted MLE of π_{ijk} .
- $\widehat{\pi}_{ijk}^{(3)} = \frac{n_{ijk}}{n_{test} + \lambda(c_{ki} - c_{kj})}$ is the MLE under the null hypothesis that $\delta = 0$. λ is the solution to

$$\sum_{i,j,k} \frac{n_{ijk}(c_{ki} - c_{kj})}{n_{test} + \lambda(c_{ki} - c_{kj})} = 0.$$

- $F_{\chi^2}(x; 1)$ is the χ^2 cdf with one degree of freedom evaluated at x .

McNemar Tests

McNemar Tests are hypothesis tests that compare two population proportions while addressing the issues resulting from two dependent, matched-pair samples.

One way to compare the predictive accuracies of two classification models is:

- 1 Partition the data into training and test sets.
- 2 Train both classification models using the training set.
- 3 Predict class labels using the test set.
- 4 Summarize the results in a two-by-two table similar to this figure.

		Model 2		
		Correct	Incorrect	
Model 1	Correct	n_{11}	n_{12}	$n_{1\bullet}$
	Incorrect	n_{21}	n_{22}	$n_{2\bullet}$
		$n_{\bullet 1}$	$n_{\bullet 2}$	n_{test}

n_{ii} are the number of concordant pairs, that is, the number of observations that both models classify the same way (correctly or incorrectly). n_{ij} , $i \neq j$, are the number of discordant pairs, that is, the number of observations that models classify differently (correctly or incorrectly).

The misclassification rates for Models 1 and 2 are $\hat{\pi}_{2\bullet} = n_{2\bullet}/n$ and $\hat{\pi}_{\bullet 2} = n_{\bullet 2}/n$, respectively. A two-sided test for comparing the accuracy of the two models is

$$H_0: \pi_{\bullet 2} = \pi_{2\bullet}$$

$$H_1: \pi_{\bullet 2} \neq \pi_{2\bullet}$$

The null hypothesis suggests that the population exhibits marginal homogeneity, which reduces the null hypothesis to $H_0: \pi_{12} = \pi_{21}$. Also, under the null hypothesis, $N_{12} \sim \text{Binomial}(n_{12} + n_{21}, 0.5)$ [1].

These facts are the basis for the available McNemar test variants: the asymptotic, exact-conditional, and mid-p-value McNemar tests. The definitions that follow summarize the available variants.

- Asymptotic — The asymptotic McNemar test statistics and rejection regions (for significance level α) are:

- For one-sided tests, the test statistic is

$$t_{d1}^* = \frac{n_{12} - n_{21}}{\sqrt{n_{12} + n_{21}}}.$$

If $1 - \Phi(|t_1^*|) < \alpha$, where Φ is the standard Gaussian cdf, then reject H_0 .

- For two-sided tests, the test statistic is

$$t_{d2}^* = \frac{(n_{12} - n_{21})^2}{n_{12} + n_{21}}.$$

If $1 - F_{\chi^2}(t_2^*; m) < \alpha$, where $F_{\chi^2}(x; m)$ is the χ_m^2 cdf evaluated at x , then reject H_0 .

The asymptotic test requires large-sample theory, specifically, the Gaussian approximation to the binomial distribution.

- The total number of discordant pairs, $n_d = n_{12} + n_{21}$, must be greater than 10 ([1], Ch. 10.1.4).
- In general, asymptotic tests do not guarantee nominal coverage. The observed probability of falsely rejecting the null hypothesis can exceed α , as suggested in simulation studies in [18]. However, the asymptotic McNemar test performs well in terms of statistical power.
- Exact-Conditional — The exact-conditional McNemar test statistics and rejection regions (for significance level α) are ([36], [38]):
 - For one-sided tests, the test statistic is

$$t_1^* = n_{12}.$$

If $F_{\text{Bin}}(t_1^*; n_d, 0.5) < \alpha$, where $F_{\text{Bin}}(x; n, p)$ is the binomial cdf with sample size n and success probability p evaluated at x , then reject H_0 .

- For two-sided tests, the test statistic is

$$t_2^* = \min(n_{12}, n_{21}).$$

If $F_{\text{Bin}}(t_2^*; n_d, 0.5) < \alpha/2$, then reject H_0 .

The exact-conditional test always attains nominal coverage. Simulation studies in [18] suggest that the test is conservative, and then show that the test lacks statistical power compared to other variants. For small or highly discrete test samples, consider using the mid- p -value test ([1], Ch. 3.6.3).

- Mid- p -value test — The mid- p -value McNemar test statistics and rejection regions (for significance level α) are ([32]):
 - For one-sided tests, the test statistic is

$$t_1^* = n_{12}.$$

If $F_{\text{Bin}}(t_1^* - 1; n_{12} + n_{21}, 0.5) + 0.5f_{\text{Bin}}(t_1^*; n_{12} + n_{21}, 0.5) < \alpha$, where $F_{\text{Bin}}(x; n, p)$ and $f_{\text{Bin}}(x; n, p)$ are the binomial cdf and pdf, respectively, with sample size n and success probability p evaluated at x , then reject H_0 .

- For two-sided tests, the test statistic is

$$t_2^* = \min(n_{12}, n_{21}).$$

If $F_{\text{Bin}}(t_2^* - 1; n_{12} + n_{21} - 1, 0.5) + 0.5f_{\text{Bin}}(t_2^*; n_{12} + n_{21}, 0.5) < \alpha/2$, then reject H_0 .

The mid- p -value test addresses the over-conservative behavior of the exact-conditional test. The simulation studies in [18] demonstrate that this test attains nominal coverage, and has good statistical power.

Classification Loss

Classification losses indicate the accuracy of a classification model or set of predicted labels. Two classification losses are the misclassification rate and cost.

`testcholdout` returns the classification losses (see `e1` and `e2`) under the alternative hypothesis (that is, the unrestricted classification losses). n_{ijk} is the number of test-sample

observations with: true class k , label i assigned by the first classification model, and label j assigned by the second classification model. The corresponding estimated proportion is

$\hat{\pi}_{ijk} = \frac{n_{ijk}}{n_{test}}$. The test-set sample size is $\sum_{i,j,k} n_{ijk} = n_{test}$. The indices are taken from 1 through K , the number of classes.

- The misclassification rate, or classification error, is a scalar in the interval $[0,1]$ representing the proportion of misclassified observations. That is, the misclassification rate for the first classification model is

$$e_1 = \sum_{j=1}^K \sum_{k=1}^K \sum_{i \neq k} \hat{\pi}_{ijk}.$$

For the misclassification rate of the second classification model (e_2), switch the indices i and j in the formula.

Classification accuracy decreases as the misclassification rate increases to 1.

- The misclassification cost is a nonnegative scalar that is a measure of classification quality relative to the values of the specified cost matrix. Its interpretation depends on the specified costs of misclassification. The misclassification cost is the weighted average of the costs of misclassification (specified in a cost matrix, C) in which the weights are the respective estimated proportions of misclassified observations. The misclassification cost for the first classification model is

$$e_1 = \sum_{j=1}^K \sum_{k=1}^K \sum_{i \neq k} \hat{\pi}_{ijk} c_{ki},$$

where c_{kj} is the cost of classifying an observation into class j if its true class is k . For the misclassification cost of the second classification model (e_2), switch the indices i and j in the formula.

In general, for a fixed cost matrix, classification accuracy decreases as the misclassification cost increases.

Tips

- It is a good practice to obtain predicted class labels by passing any trained classification model and new predictor data to the `predict` method. For example, for predicted labels from an SVM model, see `predict`.

- Cost-sensitive tests perform numerical optimization, which requires additional computational resources. The likelihood ratio test conducts numerical optimization indirectly by finding the root of a Lagrange multiplier in an interval. For some data sets, if the root lies close to the boundaries of the interval, then the method can fail. Therefore, if you have an Optimization Toolbox license, consider conducting the cost-sensitive chi-square test instead. For more details, see `CostTest` and “Cost-Sensitive Testing” on page 32-6816.

Introduced in R2015a

testckfold

Compare accuracies of two classification models by repeated cross validation

`testckfold` statistically assesses the accuracies of two classification models by repeatedly cross validating the two models, determining the differences in the classification loss, and then formulating the test statistic by combining the classification loss differences. This type of test is particularly appropriate when sample size is limited.

You can assess whether the accuracies of the classification models are different, or whether one classification model performs better than another. Available tests include a 5-by-2 paired *t* test, a 5-by-2 paired *F* test, and a 10-by-10 repeated cross-validation *t* test. For more details, see “Repeated Cross-Validation Tests” on page 32-6846. To speed up computations, `testckfold` supports parallel computing (requires a Parallel Computing Toolbox license).

Syntax

```
h = testckfold(C1,C2,X1,X2)
h = testckfold(C1,C2,X1,X2,Y)
h = testckfold( ___,Name,Value)
[h,p,e1,e2] = testckfold( ___ )
```

Description

`h = testckfold(C1,C2,X1,X2)` returns the test decision that results from conducting a 5-by-2 paired *F* cross-validation test. The null hypothesis is the classification models `C1` and `C2` have equal accuracy in predicting the true class labels using the predictor and response data in the tables `X1` and `X2`. `h = 1` indicates to reject the null hypothesis at the 5% significance level.

`testckfold` conducts the cross-validation test by applying `C1` and `C2` to all predictor variables in `X1` and `X2`, respectively. The true class labels in `X1` and `X2` must be the same. The response variable names in `X1`, `X2`, `C1.ResponseName`, and `C2.ResponseName` must be the same.

For examples of ways to compare models, see “Tips” on page 32-6850.

`h = testckfold(C1,C2,X1,X2,Y)` applies the full classification model or classification templates `C1` and `C2` to all predictor variables in the tables or matrices of data `X1` and `X2`, respectively. `Y` is the table variable name corresponding to the true class labels, or an array of true class labels.

`h = testckfold(____, Name, Value)` uses any of the input arguments in the previous syntaxes and additional options specified by one or more `Name, Value` pair arguments. For example, you can specify the type of alternative hypothesis, the type of test, or the use of parallel computing.

`[h,p,e1,e2] = testckfold(____)` also returns the p -value for the hypothesis test (`p`) and the respective classification losses on page 32-6848 for each cross-validation run and fold (`e1` and `e2`).

Examples

Compare Classification Tree Predictor-Selection Algorithms

At each node, `fitctree` chooses the best predictor to split using an exhaustive search by default. Alternatively, you can choose to split the predictor that shows the most evidence of dependence with the response by conducting curvature tests. This example statistically compares classification trees grown via exhaustive search for the best splits and grown by conducting curvature tests with interaction.

Load the `census1994` data set.

```
load census1994.mat
rng(1) % For reproducibility
```

Grow a default classification tree using the training set, `adultdata`, which is a table. The response-variable name is `'salary'`.

```
C1 = fitctree(adultdata,'salary')
```

```
C1 =
  ClassificationTree
    PredictorNames: {1x14 cell}
    ResponseName: 'salary'
    CategoricalPredictors: [2 4 6 7 8 9 10 14]
    ClassNames: [<=50K >50K]
```

```
ScoreTransform: 'none'  
NumObservations: 32561
```

Properties, Methods

C1 is a full `ClassificationTree` model. Its `ResponseName` property is `'salary'`. C1 uses an exhaustive search to find the best predictor to split on based on maximal splitting gain.

Grow another classification tree using the same data set, but specify to find the best predictor to split using the curvature test with interaction.

```
C2 = fitctree(adultdata, 'salary', 'PredictorSelection', 'interaction-curvature')
```

```
C2 =  
ClassificationTree  
    PredictorNames: {1x14 cell}  
    ResponseName: 'salary'  
    CategoricalPredictors: [2 4 6 7 8 9 10 14]  
    ClassNames: [<=50K >50K]  
    ScoreTransform: 'none'  
    NumObservations: 32561
```

Properties, Methods

C2 also is a full `ClassificationTree` model with `ResponseName` equal to `'salary'`.

Conduct a 5-by-2 paired F test to compare the accuracies of the two models using the training set. Because the response-variable names in the data sets and the `ResponseName` properties are all equal, and the response data in both sets are equal, you can omit supplying the response data.

```
h = testckfold(C1,C2,adultdata,adultdata)
```

```
h = logical  
    0
```

$h = 0$ indicates to not reject the null hypothesis that C1 and C2 have the same accuracies at 5% level.

Compare Accuracies of Two Different Classification Models

Conduct a statistical test comparing the misclassification rates of the two models using a 5-by-2 paired F test.

Load Fisher's iris data set.

```
load fisheriris;
```

Create a naive Bayes template and a classification tree template using default options.

```
C1 = templateNaiveBayes;  
C2 = templateTree;
```

C1 and C2 are template objects corresponding to the naive Bayes and classification tree algorithms, respectively.

Test whether the two models have equal predictive accuracies. Use the same predictor data for each model. `testckfold` conducts a 5-by-2, two-sided, paired F test by default.

```
rng(1); % For reproducibility  
h = testckfold(C1,C2,meas,meas,species)
```

```
h = logical  
    0
```

`h = 0` indicates to not reject the null hypothesis that the two models have equal predictive accuracies.

Compare Classification Accuracies of Simple and Complex Models

Conduct a statistical test to assess whether a simpler model has better accuracy than a more complex model using a 10-by-10 repeated cross-validation t test.

Load Fisher's iris data set. Create a cost matrix that penalizes misclassifying a setosa iris twice as much as misclassifying a virginica iris as a versicolor.

```
load fisheriris;
tabulate(species)
```

Value	Count	Percent
setosa	50	33.33%
versicolor	50	33.33%
virginica	50	33.33%

```
Cost = [0 2 2; 2 0 1; 2 1 0];
ClassNames = {'setosa' 'versicolor' 'virginica'};...
% Specifies the order of the rows and columns in Cost
```

The empirical distribution of the classes is uniform, and the classification cost is slightly imbalanced.

Create two ECOC templates: one that uses linear SVM binary learners and one that uses SVM binary learners equipped with the RBF kernel.

```
tSVMLinear = templateSVM('Standardize',true); % Linear SVM by default
tSVMRBF = templateSVM('KernelFunction','RBF','Standardize',true);
C1 = templateECOC('Learners',tSVMLinear);
C2 = templateECOC('Learners',tSVMRBF);
```

C1 and C2 are ECOC template objects. C1 is prepared for linear SVM. C2 is prepared for SVM with an RBF kernel training.

Test the null hypothesis that the simpler model (C1) is at most as accurate as the more complex model (C2) in terms of classification costs. Conduct the 10-by-10 repeated cross-validation test. Request to return p -values and misclassification costs.

```
rng(1); % For reproducibility
[h,p,e1,e2] = testckfold(C1,C2,meas,meas,species,...
    'Alternative','greater','Test','10x10t','Cost',Cost,...
    'ClassNames',ClassNames)
```

```
h = logical
    0
```

```
p = 0.1077
```

```
e1 = 10x10
```

0	0	0	0.0667	0	0.0667	0.1333	0	0.1333
0.0667	0.0667	0	0	0	0	0.0667	0	0.0667

0	0	0	0	0	0.0667	0.0667	0.0667	0.0667
0.0667	0.0667	0	0.0667	0	0.0667	0	0	0.0667
0.0667	0.0667	0.0667	0	0.0667	0.0667	0	0	0.0667
0	0	0.1333	0	0	0.0667	0	0	0.0667
0.0667	0.0667	0	0	0.0667	0	0	0.0667	0.0667
0.0667	0	0.0667	0.0667	0	0.1333	0	0.0667	0.0667
0	0.0667	0.1333	0.0667	0.0667	0	0	0	0.0667
0	0.0667	0.0667	0.0667	0.0667	0	0	0.0667	0.0667

$e2 = 10 \times 10$

0	0	0	0.1333	0	0.0667	0.1333	0	0.0667
0.0667	0.0667	0	0.1333	0	0	0	0.1333	0.0667
0.1333	0.1333	0	0	0	0.0667	0	0.0667	0.0667
0	0.1333	0	0.0667	0.1333	0.1333	0	0	0.0667
0.0667	0.0667	0.0667	0	0.0667	0.1333	0.1333	0	0.0667
0.0667	0	0.0667	0.0667	0	0.0667	0.1333	0	0.0667
0.2000	0.0667	0	0	0.0667	0	0	0.1333	0.0667
0.2000	0	0	0.1333	0	0.1333	0	0.0667	0.0667
0	0.0667	0.0667	0.0667	0.1333	0	0.2000	0	0.0667
0.0667	0.0667	0	0.0667	0.1333	0	0	0.0667	0.0667

The p -value is slightly greater than 0.10, which indicates to retain the null hypothesis that the simpler model is at most as accurate as the more complex model. This result is consistent for any significance level (α) that is at most 0.10.

$e1$ and $e2$ are 10-by-10 matrices containing misclassification costs. Row r corresponds to run r of the repeated cross validation. Column k corresponds to test-set fold k within a particular cross-validation run. For example, element (2,4) of $e2$ is 0.1333. This value means that in cross-validation run 2, when the test set is fold 4, the estimated test-set misclassification cost is 0.1333.

Select Features Using Statistical Accuracy Comparison

Reduce classification model complexity by selecting a subset of predictor variables (features) from a larger set. Then, statistically compare the accuracy between the two models.

Load the ionosphere data set.

```
load ionosphere;
```

Train an ensemble of 100 boosted classification trees using AdaBoostM1 and the entire set of predictors. Inspect the importance measure for each predictor.

```
t = templateTree('MaxNumSplits',1); % Weak-learner template tree object
C = fitcensemble(X,Y,'Method','AdaBoostM1','Learners',t);
predImp = predictorImportance(C);

figure;
bar(predImp);
h = gca;
h.XTick = 1:2:h.XLim(2);
title('Predictor Importances');
xlabel('Predictor');
ylabel('Importance measure');
```

Identify the top five predictors in terms of their importance.

```
[~,idxSort] = sort(predImp, 'descend');
idx5 = idxSort(1:5);
```

Test whether the two models have equal predictive accuracies. Specify the reduced data set and then the full predictor data. Use parallel computing to speed up computations.

```
s = RandStream('mlfg6331_64');
Options = statset('UseParallel',true,'Streams',s,'UseSubstreams',true);
```

```
[h,p,e1,e2] = testckfold(C,C,X(:,idx5),X,Y,'Options',Options)
```

```
Starting parallel pool (parpool) using the 'local' profile ...
Connected to the parallel pool (number of workers: 12).
```

```
h = logical
  0

p = 0.4161

e1 = 5×2

    0.0686    0.0795
    0.0800    0.0625
    0.0914    0.0568
    0.0400    0.0739
    0.0914    0.0966

e2 = 5×2

    0.0914    0.0625
    0.1257    0.0682
    0.0971    0.0625
    0.0800    0.0909
    0.0914    0.1193
```

`testckfold` treats trained classification models as templates, and so it ignores all fitted parameters in `C`. That is, `testckfold` cross validates `C` using only the specified options and the predictor data to estimate the out-of-fold classification losses.

`h = 0` indicates to not reject the null hypothesis that the two models have equal predictive accuracies. This result favors the simpler ensemble.

Input Arguments

C1 — Classification model template or trained classification model

classification model template object | trained classification model object

Classification model template or trained classification model, specified as any classification model template object or trained classification model object described in these tables.

Template Type	Returned By
Classification tree	templateTree
Discriminant analysis	templateDiscriminant
Ensemble (boosting, bagging, and random subspace)	templateEnsemble
Error-correcting output codes (ECOC), multiclass classification model	templateECOC
kNN	templateKNN
Naive Bayes	templateNaiveBayes
Support Vector Machine (SVM)	templateSVM

Trained Model Type	Model Object	Returned By
Classification tree	ClassificationTree	fitctree
Discriminant analysis	ClassificationDiscriminant	fitcdiscr
Ensemble of bagged classification models	ClassificationBaggedEnsemble	fitcensemble
Ensemble of classification models	ClassificationEnsemble	fitcensemble
ECOC model	ClassificationECOC	fitcecoc
kNN	ClassificationKNN	fitcknn
Naive Bayes	ClassificationNaiveBayes	fitcnb
SVM	ClassificationSVM	fitcsvm

For efficiency, supply a classification model template object instead of a trained classification model object.

C2 – Classification model template or trained model

classification model template object | trained classification model object

Classification model template or trained classification model, specified as any classification model template object or trained classification model object described in these tables.

Template Type	Returned By
Classification tree	templateTree
Discriminant analysis	templateDiscriminant
Ensemble (boosting, bagging, and random subspace)	templateEnsemble
Error-correcting output codes (ECOC), multiclass classification model	templateECOC
kNN	templateKNN
Naive Bayes	templateNaiveBayes
Support Vector Machine (SVM)	templateSVM

Trained Model Type	Model Object	Returned By
Classification tree	ClassificationTree	fitctree
Discriminant analysis	ClassificationDiscriminant	fitcdiscr
Ensemble of bagged classification models	ClassificationBaggedEnsemble	fitcensemble
Ensemble of classification models	ClassificationEnsemble	fitcensemble
ECOC model	ClassificationECOC	fitcecoc
kNN	ClassificationKNN	fitcknn
Naive Bayes	ClassificationNaiveBayes	fitcnb
SVM	ClassificationSVM	fitcsvm

For efficiency, supply a classification model template object instead of a trained classification model object.

X1 — Data used to apply to first full classification model or template

numeric matrix | table

Data used to apply to the first full classification model or template, C1, specified as a numeric matrix or table.

Each row of X1 corresponds to one observation, and each column corresponds to one variable. `testckfold` does not support multi-column variables and cell arrays other than cell arrays of character vectors.

X1 and X2 must be of the same data type, and X1, X2, Y must have the same number of observations.

If you specify Y as an array, then `testckfold` treats all columns of X1 as separate predictor variables.

Data Types: `double` | `single` | `table`

X2 — Data used to apply to second full classification model or template

`numeric matrix` | `table`

Data used to apply to the second full classification model or template, C2, specified as a numeric matrix or table.

Each row of X2 corresponds to one observation, and each column corresponds to one variable. `testckfold` does not support multi-column variables and cell arrays other than cell arrays of character vectors.

X1 and X2 must be of the same data type, and X1, X2, Y must have the same number of observations.

If you specify Y as an array, then `testckfold` treats all columns of X2 as separate predictor variables.

Data Types: `double` | `single` | `table`

Y — True class labels

`categorical array` | `character array` | `string array` | `logical vector` | `numeric vector` | `cell array of character vectors` | `character vector` | `string scalar`

True class labels, specified as a categorical, character, or string array, a logical or numeric vector, a cell array of character vectors, or a character vector or string scalar.

- For a character vector or string scalar, X1 and X2 must be tables, their response variables must have the same name and values, and Y must be the common variable name. For example, if `X1.Labels` and `X2.Labels` are the response variables, then Y is `'Labels'` and `X1.Labels` and `X2.Labels` must be equivalent.
- For all other supported data types, Y is an array of true class labels.
 - If Y is a character array, then each element must correspond to one row of the array.
 - X1, X2, Y must have the same number of observations (rows).

- If both of these statements are true, then you can omit supplying `Y`.
 - `X1` and `X2` are tables containing the same response variable (values and name).
 - `C1` and `C2` are full classification models containing `ResponseName` properties specifying the response variable names in `X1` and `X2`.

Consequently, `testckfold` uses the common response variable in the tables. For example, if the response variables in the tables are `X1.Labels` and `X2.Labels`, and the values of `C1.ResponseName` and `C2.ResponseName` are `'Labels'`, then you do not have to supply `Y`.

Data Types: `categorical` | `char` | `string` | `logical` | `single` | `double` | `cell`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example:

```
'Alternative', 'greater', 'Test', '10x10t', 'Options', statsset('UseParallel', true) specifies to test whether the first set of first predicted class labels is more accurate than the second set, to conduct the 10-by-10 t test, and to use parallel computing for cross validation.
```

Alpha — Hypothesis test significance level

`0.05` (default) | scalar value in the interval (0,1)

Hypothesis test significance level, specified as the comma-separated pair consisting of `'Alpha'` and a scalar value in the interval (0,1).

Example: `'Alpha', 0.1`

Data Types: `single` | `double`

Alternative — Alternative hypothesis to assess

`'unequal'` (default) | `'greater'` | `'less'`

Alternative hypothesis to assess, specified as the comma-separated pair consisting of `'Alternative'` and one of the values listed in the table.

Value	Alternative Hypothesis Description	Supported Tests
'unequal' (default)	For predicting Y, the set of predictions resulting from C1 applied to X1 and C2 applied to X2 have unequal accuracies.	'5x2F', '5x2t', and '10x10t'
'greater'	For predicting Y, the set of predictions resulting from C1 applied to X1 is more accurate than C2 applied to X2.	'5x2t' and '10x10t'
'less'	For predicting Y, the set of predictions resulting from C1 applied to X1 is less accurate than C2 applied to X2.	'5x2t' and '10x10t'

For details on supported tests, see [Test](#).

Example: 'Alternative', 'greater'

X1CategoricalPredictors – Flag identifying categorical predictors

[] (default) | logical vector | numeric vector | 'all'

Flag identifying categorical predictors in the first test-set predictor data (X1), specified as the comma-separated pair consisting of 'X1CategoricalPredictors' and one of the following:

- A numeric vector with indices from 1 through p, where p is the number of columns of X1.
- A logical vector of length p, where a true entry means that the corresponding column of X1 is a categorical variable.
- 'all', meaning all predictors are categorical.

Specification of X1CategoricalPredictors is appropriate if:

- At least one predictor is categorical and C1 is a classification tree, an ensemble of classification trees, an ECOC model, or a naive Bayes classification model.
- All predictors are categorical and C1 is a kNN classification model.

If you specify X1CategoricalPredictors for any other case, then testckfold throws an error. For example, the function cannot train SVM learners using categorical predictors.

The default is `[]`, which indicates that there are no categorical predictors.

Example: `'X1CategoricalPredictors', 'all'`

Data Types: `single` | `double` | `logical` | `char` | `string`

X2CategoricalPredictors — Flag identifying categorical predictors

`[]` (default) | `logical vector` | `numeric vector` | `'all'`

Flag identifying categorical predictors in the second test-set predictor data (X2), specified as the comma-separated pair consisting of `'X2CategoricalPredictors'` and one of the following:

- A numeric vector with indices from 1 through `p`, where `p` is the number of columns of X2.
- A logical vector of length `p`, where a `true` entry means that the corresponding column of X2 is a categorical variable.
- `'all'`, meaning all predictors are categorical.

Specification of `X2CategoricalPredictors` is appropriate if:

- At least one predictor is categorical and C2 is a classification tree, an ensemble of classification trees, an ECOC model, or a naive Bayes classification model.
- All predictors are categorical and C2 is a `kNN` classification model.

If you specify `X2CategoricalPredictors` for any other case, then `testckfold` throws an error. For example, the function cannot train SVM learners using categorical predictors.

The default is `[]`, which indicates that there are no categorical predictors.

Example: `'X2CategoricalPredictors', 'all'`

Data Types: `single` | `double` | `logical` | `char` | `string`

ClassNames — Class names

`categorical array` | `character array` | `string array` | `logical vector` | `numeric vector` | `cell array of character vectors`

Class names, specified as the comma-separated pair consisting of `'ClassNames'` and a categorical, character, or string array, logical or numeric vector, or cell array of character vectors. You must set `ClassNames` using the data type of `Y`.

If `ClassNames` is a character array, then each element must correspond to one row of the array.

Use `ClassNames` to:

- Specify the order of any input argument dimension that corresponds to class order. For example, use `ClassNames` to specify the order of the dimensions of `Cost`.
- Select a subset of classes for testing. For example, suppose that the set of all distinct class names in `Y` is `{'a', 'b', 'c'}`. To train and test models using observations from classes 'a' and 'c' only, specify '`ClassNames`', `{'a', 'c'}`.

The default is the set of all distinct class names in `Y`.

Example: '`ClassNames`', `{'b', 'g'}`

Data Types: `single` | `double` | `logical` | `char` | `string` | `cell` | `categorical`

Cost — Classification cost

`square matrix` | `structure array`

Classification cost, specified as the comma-separated pair consisting of '`Cost`' and a square matrix or structure array.

- If you specify the square matrix `Cost`, then `Cost(i, j)` is the cost of classifying a point into class `j` if its true class is `i`. That is, the rows correspond to the true class and the columns correspond to the predicted class. To specify the class order for the corresponding rows and columns of `Cost`, additionally specify the `ClassNames` name-value pair argument.
- If you specify the structure `S`, then `S` must have two fields:
 - `S.ClassNames`, which contains the class names as a variable of the same data type as `Y`. You can use this field to specify the order of the classes.
 - `S.ClassificationCosts`, which contains the cost matrix, with rows and columns ordered as in `S.ClassNames`

For cost-sensitive testing use, `testcholdout`.

It is a best practice to supply the same cost matrix used to train the classification models.

The default is `Cost(i, j) = 1` if `i ~= j`, and `Cost(i, j) = 0` if `i = j`.

Example: '`Cost`', `[0 1 2 ; 1 0 2; 2 2 0]`

Data Types: `double` | `single` | `struct`

LossFun — Loss function

'`classiferror`' (default) | '`binodeviance`' | '`exponential`' | '`hinge`' | function handle

Loss function, specified as the comma-separated pair consisting of 'LossFun' and 'classiferror', 'binodeviance', 'exponential', 'hinge', or a function handle.

- The following table lists the available loss functions.

Value	Loss Function
'binodeviance'	Binomial deviance
'classiferror'	Classification error
'exponential'	Exponential loss
'hinge'	Hinge loss

- Specify your own function using function handle notation.

Suppose that $n = \text{size}(X, 1)$ is the sample size and there are K unique classes. Your function must have the signature `lossvalue = lossfun(C,S,W,Cost)`, where:

- The output argument `lossvalue` is a scalar.
- `lossfun` is the name of your function.
- `C` is an n -by- K logical matrix with rows indicating which class the corresponding observation belongs to. The column order corresponds to the class order in the `ClassNames` name-value pair argument.

Construct `C` by setting $C(p, q) = 1$ if observation p is in class q , for each row. Set all other elements of row p to 0 .

- `S` is an n -by- K numeric matrix of classification scores. The column order corresponds to the class order in the `ClassNames` name-value pair argument. `S` is a matrix of classification scores.
- `W` is an n -by-1 numeric vector of observation weights. If you pass `W`, the software normalizes the weights to sum to 1.
- `Cost` is a K -by- K numeric matrix of classification costs. For example, `Cost = ones(K) - eye(K)` specifies a cost of 0 for correct classification and a cost of 1 for misclassification.

Specify your function using 'LossFun', @*lossfun*.

Options — Parallel computing options

[] (default) | structure array returned by `statset`

Parallel computing options, specified as the comma-separated pair consisting of 'Options' and a structure array returned by `statset`. These options require Parallel Computing Toolbox. `testckfold` uses 'Streams', 'UseParallel', and 'UseSubstreams' fields.

This table summarizes the available options.

Option	Description
'Streams'	<p>A <code>RandStream</code> object or cell array of such objects. If you do not specify <code>Streams</code>, the software uses the default stream or streams. If you specify <code>Streams</code>, use a single object except when the following are true:</p> <ul style="list-style-type: none"> You have an open parallel pool. <code>UseParallel</code> is <code>true</code>. <code>UseSubstreams</code> is <code>false</code>. <p>In that case, use a cell array of the same size as the parallel pool. If a parallel pool is not open, then the software tries to open one (depending on your preferences), and <code>Streams</code> must supply a single random number stream.</p>
'UseParallel'	<p>If you have Parallel Computing Toolbox, then you can invoke a pool of workers by setting 'UseParallel', <code>true</code>.</p>
'UseSubstreams'	<p>Set to <code>true</code> to compute in parallel using the stream specified by 'Streams'. Default is <code>false</code>. For example, set <code>Streams</code> to a type allowing substreams, such as 'mlfg6331_64' or 'mrg32k3a'.</p>

Example: 'Options', `statset('UseParallel', true)`

Data Types: struct

Prior — Prior probabilities

'empirical' (default) | 'uniform' | numeric vector | structure

Prior probabilities for each class, specified as the comma-separated pair consisting of 'Prior' and 'empirical', 'uniform', a numeric vector, or a structure.

This table summarizes the available options for setting prior probabilities.

Value	Description
'empirical'	The class prior probabilities are the class relative frequencies in Y .
'uniform'	All class prior probabilities are equal to $1/K$, where K is the number of classes.
numeric vector	Each element is a class prior probability. Specify the order using the <code>ClassNames</code> name-value pair argument. The software normalizes the elements such that they sum to 1.
structure	A structure S with two fields: <ul style="list-style-type: none"> <code>S.ClassNames</code> contains the class names as a variable of the same type as Y. <code>S.ClassProbs</code> contains a vector of corresponding prior probabilities. The software normalizes the elements such that they sum to 1.

Example: 'Prior', struct('ClassNames',
{'setosa','versicolor'}), 'ClassProbs', [1,2])

Data Types: char | string | single | double | struct

Test — Test to conduct

'5x2F' (default) | '5x2t' | '10x10t'

Test to conduct, specified as the comma-separated pair consisting of 'Test' and one of the following: '5x2F', '5x2t', '10x10t'.

Value	Description	Supported Alternative Hypothesis
'5x2F' (default)	5-by-2 paired <i>F</i> test. Appropriate for two-sided testing only.	'unequal'
'5x2t'	5-by-2 paired <i>t</i> test	'unequal', 'less', 'greater'
'10x10t'	10-by-10 repeated cross validation <i>t</i> test	'unequal', 'less', 'greater'

For details on the available tests, see “Repeated Cross-Validation Tests” on page 32-6846. For details on supported alternative hypotheses, see `Alternative`.

Example: 'Test', '10x10t'

Verbose — Verbosity level

0 (default) | 1 | 2

Verbosity level, specified as the comma-separated pair consisting of 'Verbose' and 0, 1, or 2. Verbose controls the amount of diagnostic information that the software displays in the Command Window during training of each cross-validation fold.

This table summarizes the available verbosity level options.

Value	Description
0	The software does not display diagnostic information.
1	The software displays diagnostic messages every time it implements a new cross validation run.
2	The software displays diagnostic messages every time it implements a new cross validation run, and every time it trains on a particular fold.

Example: 'Verbose', 1

Data Types: double | single

Weights — Observation weights`ones(size(X,1),1)` (default) | numeric vector

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a numeric vector.

The size of `Weights` must equal the number of rows of `X1`. The software weighs the observations in each row of `X` with the corresponding weight in `Weights`.

The software normalizes `Weights` to sum up to the value of the prior probability in the respective class.

Data Types: `double` | `single`

Notes:

- `testckfold` treats trained classification models as templates. Therefore, it ignores all fitted parameters in the model. That is, `testckfold` cross validates using only the options specified in the model and the predictor data.
- The repeated cross-validation tests depend on the assumption that the test statistics are asymptotically normal under the null hypothesis. Highly imbalanced cost matrices (for example, `Cost = [0 100; 1 0]`) and highly discrete response distributions (that is, most of the observations are in a small number of classes) might violate the asymptotic normality assumption. For cost-sensitive testing, use `testcholdout`.
- NaNs, <undefined> values, empty character vectors (' '), empty strings (""), and <missing> values indicate missing data values.
 - For the treatment of missing values in `X1` and `X2`, see the appropriate classification model training function reference page: `fitctree`, `fitcdiscr`, `fitcensemble`, `fitcecoc`, `fitcknn`, `fitcnb`, or `fitcsvm`.
 - `testckfold` removes missing values in `Y` and the corresponding rows of `X1` and `X2`.

Output Arguments**h — Hypothesis test result**`1` | `0`

Hypothesis test result, returned as a logical value.

$h = 1$ indicates the rejection of the null hypothesis at the Alpha significance level.

$h = 0$ indicates failure to reject the null hypothesis at the Alpha significance level.

Data Types: `logical`

p — p-value

scalar in the interval $[0,1]$

p-value of the test, returned as a scalar in the interval $[0,1]$. p is the probability that a random test statistic is at least as extreme as the observed test statistic, given that the null hypothesis is true.

`testckfold` estimates p using the distribution of the test statistic, which varies with the type of test. For details on test statistics, see “Repeated Cross-Validation Tests” on page 32-6846.

e1 — Classification losses

numeric matrix

Classification losses on page 32-6848, returned as a numeric matrix. The rows of `e1` correspond to the cross-validation run and the columns correspond to the test fold.

`testckfold` applies the first test-set predictor data (X1) to the first classification model (C1) to estimate the first set of class labels.

`e1` summarizes the accuracy of the first set of class labels predicting the true class labels (Y) for each cross-validation run and fold. The meaning of the elements of `e1` depends on the type of classification loss.

e2 — Classification losses

numeric matrix

Classification losses on page 32-6848, returned as a numeric matrix. The rows of `e2` correspond to the cross-validation run and the columns correspond to the test fold.

`testckfold` applies the second test-set predictor data (X2) to the second classification model (C2) to estimate the second set of class labels.

`e2` summarizes the accuracy of the second set of class labels predicting the true class labels (Y) for each cross-validation run and fold. The meaning of the elements of `e2` depends on the type of classification loss.

Definitions

Repeated Cross-Validation Tests

Repeated cross-validation tests form the test statistic for comparing the accuracies of two classification models by combining the classification loss differences resulting from repeatedly cross validating the data. Repeated cross-validation tests are useful when sample size is limited.

To conduct an R -by- K test:

- 1 Randomly divide (stratified by class) the predictor data sets and true class labels into K sets, R times. Each division is called a run and each set within a run is called a fold. Each run contains the complete, but divided, data sets.
- 2 For runs $r = 1$ through R , repeat these steps for $k = 1$ through K :
 - a Reserve fold k as a test set, and train the two classification models using their respective predictor data sets on the remaining $K - 1$ folds.
 - b Predict class labels using the trained models and their respective fold k predictor data sets.
 - c Estimate the classification loss by comparing the two sets of estimated labels to the true labels. Denote e_{crk} as the classification loss when the test set is fold k in run r of classification model c .
 - d Compute the difference between the classification losses of the two models:

$$\widehat{\delta}_{rk} = e_{1rk} - e_{2rk}.$$

At the end of a run, there are K classification losses per classification model.

- 3 Combine the results of step 2. For each $r = 1$ through R :
 - Estimate the within-fold averages of the differences and their average:

$$\bar{\delta}_r = \frac{1}{K} \sum_{k=1}^K \widehat{\delta}_{kr}.$$

- Estimate the overall average of the differences: $\bar{\delta} = \frac{1}{KR} \sum_{r=1}^R \sum_{k=1}^K \widehat{\delta}_{rk}.$

- Estimate the within-fold variances of the differences: $s_r^2 = \frac{1}{K} \sum_{k=1}^K (\widehat{\delta}_{rk} - \bar{\delta}_r)^2$.
- Estimate the average of the within-fold differences: $\bar{s}^2 = \frac{1}{R} \sum_{r=1}^R s_r^2$.
- Estimate the overall sample variance of the differences:

$$S^2 = \frac{1}{KR-1} \sum_{r=1}^R \sum_{k=1}^K (\widehat{\delta}_{rk} - \bar{\delta})^2.$$

Compute the test statistic. All supported tests described here assume that, under H_0 , the estimated differences are independent and approximately normally distributed, with mean 0 and a finite, common standard deviation. However, these tests violate the independence assumption, and so the test-statistic distributions are approximate.

- For $R = 2$, the test is a paired test. The two supported tests are a paired t and F test.
 - The test statistic for the paired t test is

$$t_{paired}^* = \frac{\widehat{\delta}_{11}}{\sqrt{\bar{s}^2}}.$$

t_{paired}^* has a t -distribution with R degrees of freedom under the null hypothesis.

To reduce the effects of correlation between the estimated differences, the quantity $\widehat{\delta}_{11}$ occupies the numerator rather than $\bar{\delta}$.

5-by-2 paired t tests can be slightly conservative [4].

- The test statistic for the paired F test is

$$F_{paired}^* = \frac{\frac{1}{RK} \sum_{r=1}^R \sum_{k=1}^K (\widehat{\delta}_{rk})^2}{\bar{s}^2}.$$

F_{paired}^* has an F distribution with RK and R degrees of freedom.

A 5-by-2 paired F test has comparable power to the 5-by-2 t test, but is more conservative [1].

- For $R > 2$, the test is a repeated cross-validation test. The test statistic is

$$t_{CV}^* = \frac{\bar{\delta}}{S/\sqrt{\nu + 1}}.$$

t_{CV}^* has a t distribution with ν degrees of freedom. If the differences were truly independent, then $\nu = RK - 1$. In this case, the degrees of freedom parameter must be optimized.

For a 10-by-10 repeated cross-validation t test, the optimal degrees of freedom between 8 and 11 ([2] and [3]). `testckfold` uses $\nu = 10$.

The advantage of repeated cross validation tests over paired tests is that the results are more repeatable [3]. The disadvantage is that they require high computational resources.

Classification Loss

Classification losses indicate the accuracy of a classification model or set of predicted labels. In general, for a fixed cost matrix, classification accuracy decreases as classification loss increases.

`testckfold` returns the classification losses (see `e1` and `e2`) under the alternative hypothesis (that is, the unrestricted classification losses). In the definitions that follow:

- The classification losses focus on the first classification model. The classification losses for the second model are similar.
- n_{test} is the test-set sample size.
- $I(x)$ is the indicator function. If x is a true statement, then $I(x) = 1$. Otherwise, $I(x) = 0$.
- \hat{p}_{1j} is the predicted class assignment of classification model 1 for observation j .
- y_j is the true class label of observation j .
- Binomial deviance has the form

$$e_1 = \frac{\sum_{j=1}^{n_{test}} w_j \log(1 + \exp(-2y_j f(X_j)))}{\sum_{j=1}^{n_{test}} w_j}$$

where:

- $y_j = 1$ for the positive class and -1 for the negative class.
- $f(X_j)$ is the classification score.

The binomial deviance has connections to the maximization of the binomial likelihood function. For details on binomial deviance, see [5].

- Exponential loss is similar to binomial deviance and has the form

$$e_1 = \frac{\sum_{j=1}^{n_{test}} w_j \exp(-y_j f(X_j))}{\sum_{j=1}^{n_{test}} w_j}.$$

y_j and $f(X_j)$ take the same forms here as in the binomial deviance formula.

- Hinge loss has the form

$$e_1 = \frac{\sum_{j=1}^n w_j \max\{0, 1 - y_j f(X_j)\}}{\sum_{j=1}^n w_j},$$

y_j and $f(X_j)$ take the same forms here as in the binomial deviance formula.

Hinge loss linearly penalizes for misclassified observations and is related to the SVM objective function used for optimization. For more details on hinge loss, see [5].

- Misclassification rate, or classification error, is a scalar in the interval $[0,1]$ representing the proportion of misclassified observations. That is, the misclassification rate for the first classification model is

$$e_1 = \frac{\sum_{j=1}^{n_{test}} w_j I(\hat{p}_{1j} \neq y_j)}{\sum_{j=1}^{n_{test}} w_j}.$$

Tips

- Examples of ways to compare models include:
 - Compare the accuracies of a simple classification model and a more complex model by passing the same set of predictor data.
 - Compare the accuracies of two different models using two different sets of predictors.
 - Perform various types of feature selection. For example, you can compare the accuracy of a model trained using a set of predictors to the accuracy of one trained on a subset or different set of predictors. You can arbitrarily choose the set of predictors, or use a feature selection technique like PCA or sequential feature selection (see `pca` and `sequentialfs`).
- If both of these statements are true, then you can omit supplying `Y`.
 - `X1` and `X2` are tables containing the response variable and use the same response variable name.
 - `C1` and `C2` are full classification models containing equal `ResponseName` properties (e.g. `strcmp(C1.ResponseName, C2.ResponseName) = 1`).

Consequently, `testckfold` uses the common response variable in the tables.

- One way to perform cost-insensitive feature selection is:
 - 1 Create a classification model template that characterizes the first classification model (`C1`).
 - 2 Create a classification model template that characterizes the second classification model (`C2`).
 - 3 Specify two predictor data sets. For example, specify `X1` as the full predictor set and `X2` as a reduced set.
 - 4 Enter `testckfold(C1,C2,X1,X2,Y,'Alternative','less')`. If `testckfold` returns 1, then there is enough evidence to suggest that the classification model that uses fewer predictors performs better than the model that uses the full predictor set.

Alternatively, you can assess whether there is a significant difference between the accuracies of the two models. To perform this assessment, remove the `'Alternative','less'` specification in step 4. `testckfold` conducts a two-sided test, and `h = 0` indicates that there is not enough evidence to suggest a difference in the accuracy of the two models.

- The tests are appropriate for the misclassification rate classification loss on page 32-6848, but you can specify other loss functions (see `LossFun`). The key assumptions are that the estimated classification losses are independent and normally distributed with mean 0 and finite common variance under the two-sided null hypothesis. Classification losses other than the misclassification rate can violate this assumption.
- Highly discrete data, imbalanced classes, and highly imbalanced cost matrices can violate the normality assumption of classification loss differences.

Algorithms

If you specify to conduct the 10-by-10 repeated cross-validation t test using 'Test', '10x10t', then `testckfold` uses 10 degrees of freedom for the t distribution to find the critical region and estimate the p -value. For more details, see [2] and [3].

Alternatives

Use `testcholdout`:

- For test sets with larger sample sizes
- To implement variants of the McNemar test to compare two classification model accuracies
- For cost-sensitive testing using a chi-square or likelihood ratio test. The chi-square test uses `quadprog`, which requires an Optimization Toolbox license.

Extended Capabilities

Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the 'UseParallel' option to true.

Set the 'UseParallel' field of the options structure to true using `statset` and specify the 'Options' name-value pair argument in the call to this function.

For example: `'Options',statset('UseParallel',true)`

For more information, see the 'Options' name-value pair argument.

For more general information about parallel computing, see "Run MATLAB Functions with Automatic Parallel Support" (Parallel Computing Toolbox).

Topics

"Hypothesis Tests"

Introduced in R2015a

TestSize property

Class: cvpartition

Size of each test set

Description

Value is a vector in partitions of type 'kfold' and 'leaveout'.

Value is a scalar in partitions of type 'holdout' and 'resubstitution'.

tiedrank

Rank adjusted for ties

Syntax

```
[R,TIEADJ] = tiedrank(X)
[R,TIEADJ] = tiedrank(X,1)
[R,TIEADJ] = tiedrank(X,0,1)
```

Description

`[R,TIEADJ] = tiedrank(X)` computes the ranks of the values in the vector `X`. If any `X` values are tied, `tiedrank` computes their average rank. The return value `TIEADJ` is an adjustment for ties required by the nonparametric tests `signrank` and `ranksum`, and for the computation of Spearman's rank correlation.

`[R,TIEADJ] = tiedrank(X,1)` computes the ranks of the values in the vector `X`. `TIEADJ` is a vector of three adjustments for ties required in the computation of Kendall's tau. `tiedrank(X,0)` is the same as `tiedrank(X)`.

`[R,TIEADJ] = tiedrank(X,0,1)` computes the ranks from each end, so that the smallest and largest values get rank 1, the next smallest and largest get rank 2, etc. These ranks are used in the Ansari-Bradley test.

Examples

Counting from smallest to largest, the two 20 values are 2nd and 3rd, so they both get rank 2.5 (average of 2 and 3):

```
tiedrank([10 20 30 40 20])
ans =
    1.0000    2.5000    4.0000    5.0000    2.5000
```

Algorithms

tiedrank treats NaNs in X as missing values and ignores them. The rank of NaNs in the output argument R is NaN.

tinvs

Student's t inverse cumulative distribution function

Syntax

`x = tinvs(p,nu)`

Description

`x = tinvs(p,nu)` returns the inverse of Student's t cdf using the degrees of freedom in `nu` for the corresponding probabilities in `p`. `p` and `nu` can be vectors, matrices, or multidimensional arrays that are the same size. A scalar input is expanded to a constant array with the same dimensions as the other inputs. The values in `p` must lie on the interval $[0\ 1]$.

The t inverse function in terms of the t cdf is

$$x = F^{-1}(p|\nu) = \{x: F(x|\nu) = p\}$$

where

$$p = F(x|\nu) = \int_{-\infty}^x \frac{\Gamma\left(\frac{\nu+1}{2}\right)}{\Gamma\left(\frac{\nu}{2}\right)} \frac{1}{\sqrt{\nu\pi}} \frac{1}{\left(1 + \frac{t^2}{\nu}\right)^{\frac{\nu+1}{2}}} dt$$

The result, x , is the solution of the cdf integral with parameter ν , where you supply the desired probability p .

Examples

Compute Student's *t* icdf

What is the 99th percentile of the Student's *t* distribution for one to six degrees of freedom?

```
percentile = tinv(0.99,1:6)
```

```
percentile = 1×6
```

```
    31.8205    6.9646    4.5407    3.7469    3.3649    3.1427
```

Extended Capabilities

Topics

“Student's *t* Distribution” on page B-173

Introduced before R2006a

tpdf

Student's t probability density function

Syntax

```
y = tpdf(x,nu)
```

Description

`y = tpdf(x,nu)` returns the probability density function (pdf) of the Student's t distribution at each of the values in `x` using the corresponding degrees of freedom in `nu`. `x` and `nu` can be vectors, matrices, or multidimensional arrays that have the same size. A scalar input is expanded to a constant array with the same dimensions as the other inputs.

Examples

Compute Student's t pdf

The mode of the Student's t distribution is at $x = 0$. This example shows that the value of the function at the mode is an increasing function of the degrees of freedom.

```
tpdf(0,1:6)
```

```
ans = 1×6
```

```
    0.3183    0.3536    0.3676    0.3750    0.3796    0.3827
```

The t distribution converges to the standard normal distribution as the degrees of freedom approaches infinity. How good is the approximation for ν equal to 30?

```
difference = tpdf(-2.5:2.5,30)-normpdf(-2.5:2.5)
```

```
difference = 1×6
```

0.0035 -0.0006 -0.0042 -0.0042 -0.0006 0.0035

Definitions

Student's t pdf

The probability density function (pdf) of the Student's t distribution is

$$y = f(x) \Big|_{\nu} = \frac{\Gamma\left(\frac{\nu+1}{2}\right)}{\Gamma\left(\frac{\nu}{2}\right)} \frac{1}{\sqrt{\nu\pi}} \frac{1}{\left(1 + \frac{x^2}{\nu}\right)^{\frac{\nu+1}{2}}}$$

where ν is the degrees of freedom and $\Gamma(\cdot)$ is the Gamma function. The result y is the probability of observing a particular value of x from a Student's t distribution with ν degrees of freedom.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Introduced before R2006a

training

Class: cvpartition

Training indices for cross-validation

Syntax

```
idx = training(c)
idx = training(c,i)
```

Description

`idx = training(c)` returns the logical vector `idx` of training indices for an object `c` of the `cvpartition` on page 32-1237 class of type 'holdout' or 'resubstitution'.

If `c.Type` is 'holdout', `idx` specifies the observations in the training set.

If `c.Type` is 'resubstitution', `idx` specifies all observations.

`idx = training(c,i)` returns the logical vector `idx` of training indices for repetition `i` of an object `c` of the `cvpartition` on page 32-1237 class of type 'kfold' or 'leaveout'.

If `c.Type` is 'kfold', `idx` specifies the observations in the training set in fold `i`.

If `c.Type` is 'leaveout', `idx` specifies the observations left in at repetition `i`.

Examples

Identify the training indices in the first fold of a partition of 10 observations for 3-fold cross-validation:

```
c = cvpartition(10,'kfold',3)
c =
K-fold cross validation partition
```

```
      N: 10
NumTestSets: 3
  TrainSize: 7 6 7
   TestSize: 3 4 3

training(c,1)
ans =
  0
  0
  1
  1
  1
  1
  1
  1
  1
  0
  1
```

type

transform

Transform predictors into extracted features

Syntax

```
z = transform(Mdl,x)
```

Description

`z = transform(Mdl,x)` transforms the data `x` into the features `z` via the model `Mdl`.

Examples

Transform Data to Learned Features

Create a feature transformation model with 100 features from the `caltech101patches` data.

```
rng('default') % For reproducibility
data = load('caltech101patches');
q = 100;
X = data.X;
Mdl = sparsefilt(X,q)
```

Warning: Solver LBFGS was not able to converge to a solution.

```
Mdl =
  SparseFiltering
    ModelParameters: [1x1 struct]
      NumPredictors: 363
    NumLearnedFeatures: 100
      Mu: []
      Sigma: []
    FitInfo: [1x1 struct]
    TransformWeights: [363x100 double]
```

```
InitialTransformWeights: []
```

Properties, Methods

`sparsefilt` issues a warning because it stopped due to reaching the iteration limit, instead of reaching a step-size limit or a gradient-size limit. You can still use the learned features in the returned object by calling the `transform` function.

Transform the first five rows of the input data `X` to the new feature space.

```
y = transform(Mdl,X(1:5,:));
size(y)
```

```
ans = 1×2
```

```
    5    100
```

Input Arguments

Mdl — Feature extraction model

SparseFiltering object | ReconstructionICA object

Feature extraction model, specified as a `SparseFiltering` object or as a `ReconstructionICA` object. Create `Mdl` by using the `sparsefilt` function or the `rica` function.

x — Predictor data

matrix with `p` columns | table of numeric values with `p` columns

Predictor data, specified as a matrix with `p` columns or as a table of numeric values with `p` columns. Here, `p` is the number of predictors in the model, which is `Mdl.NumPredictors`. Each row of the input matrix or table represents one data point to transform.

Data Types: `single` | `double` | `table`

Output Arguments

z — Transformed data

n-by-q matrix

Transformed data, returned as an n-by-q matrix. Here, n is the number of rows in the input data x, and q is the number of features, which is `Mdl.NumLearnedFeatures`.

Algorithms

`transform` converts data to predicted features by using the learned weight matrix `W` to map input predictors to output features.

- For `rica`, input data `X` maps linearly to output features `XW`. See “Reconstruction ICA Algorithm” on page 15-159.
- For `sparsefilt`, input data maps nonlinearly to output features $\hat{F}(X,W)$. See “Sparse Filtering Algorithm” on page 15-157.

Caution The result of `transform` for sparse filtering depends on the number of data points. In particular, the result of applying `transform` to each row of a matrix separately differs from the result of applying `transform` to the entire matrix at once.

TreeBagger class

Bag of decision trees

Description

TreeBagger bags an ensemble of decision trees for either classification or regression. Bagging stands for bootstrap aggregation. Every tree in the ensemble is grown on an independently drawn bootstrap replica of input data. Observations not included in this replica are "out of bag" for this tree.

TreeBagger relies on the ClassificationTree and RegressionTree functionality for growing individual trees. In particular, ClassificationTree and RegressionTree accepts the number of features selected at random for each decision split as an optional input argument. That is, TreeBagger implements the random forest algorithm [1].

For regression problems, TreeBagger supports mean and quantile regression (that is, quantile regression forest [2]).

- To predict mean responses or estimate the mean-squared error given data, pass a TreeBagger model and the data to predict or error, respectively. To perform similar operations for out-of-bag observations, use oobPredict or oobError.
- To estimate quantiles of the response distribution or the quantile error given data, pass a TreeBagger model and the data to quantilePredict or quantileError, respectively. To perform similar operations for out-of-bag observations, use oobQuantilePredict or oobError.

Construction

TreeBagger Create bag of decision trees

Methods

<code>append</code>	Append new trees to ensemble
<code>compact</code>	Compact ensemble of decision trees
<code>error</code>	Error (misclassification probability or MSE)
<code>fillprox</code>	Proximity matrix for training data
<code>growTrees</code>	Train additional trees and add to ensemble
<code>margin</code>	Classification margin
<code>mdsprox</code>	Multidimensional scaling of proximity matrix
<code>meanMargin</code>	Mean classification margin
<code>oobError</code>	Out-of-bag error
<code>oobMargin</code>	Out-of-bag margins
<code>oobMeanMargin</code>	Out-of-bag mean margins
<code>oobPredict</code>	Ensemble predictions for out-of-bag observations
<code>oobQuantileError</code>	Out-of-bag quantile loss of bag of regression trees
<code>oobQuantilePredict</code>	Quantile predictions for out-of-bag observations from bag of regression trees
<code>predict</code>	Predict responses using ensemble of bagged decision trees
<code>quantileError</code>	Quantile loss using bag of regression trees
<code>quantilePredict</code>	Predict response quantile using bag of regression trees

Properties

ClassNames

A cell array containing the class names for the response variable `Y`. This property is empty for regression trees.

ComputeOoBPrediction

A logical flag specifying whether out-of-bag predictions for training observations should be computed. The default is `false`.

If this flag is `true`, the following properties are available:

- `OOBIndices`
- `OOBInstanceWeight`

If this flag is true, the following methods can be called:

- `oobError`
- `oobMargin`
- `oobMeanMargin`

ComputeOOBPredictorImportance

A logical flag specifying whether out-of-bag estimates of variable importance should be computed. The default is `false`. If this flag is true, then `ComputeOOBPrediction` is true as well.

If this flag is true, the following properties are available:

- `OOBPermutedPredictorDeltaError`
- `OOBPermutedPredictorDeltaMeanMargin`
- `OOBPermutedPredictorCountRaiseMargin`

Cost

Square matrix, where `Cost(i, j)` is the cost of classifying a point into class `j` if its true class is `i` (i.e., the rows correspond to the true class and the columns correspond to the predicted class). The order of the rows and columns of `Cost` corresponds to the order of the classes in `ClassNames`. The number of rows and columns in `Cost` is the number of unique classes in the response.

This property is:

- read-only
- empty (`[]`) for ensembles of regression trees

DefaultYfit

Default value returned by `predict` and `oobPredict`. The `DefaultYfit` property controls what predicted value is returned when no prediction is possible. For example, when `oobPredict` needs to predict for an observation that is in-bag for all trees in the ensemble.

- For classification, you can set this property to either ' ' or 'MostPopular'. If you choose 'MostPopular' (the default), the property value becomes the name of the most probably class in the training data. If you choose ' ', the in-bag observations are excluded from computation of the out-of-bag error and margin.
- For regression, you can set this property to any numeric scalar. The default value is the mean of the response for the training data. If you set this property to NaN, the in-bag observations are excluded from computation of the out-of-bag error and margin.

DeltaCriterionDecisionSplit

A numeric array of size 1-by-*Nvars* of changes in the split criterion summed over splits on each variable, averaged across the entire ensemble of grown trees.

InBagFraction

Fraction of observations that are randomly selected with replacement for each bootstrap replica. The size of each replica is $Nobs \times InBagFraction$, where *Nobs* is the number of observations in the training set. The default value is 1.

MergeLeaves

A logical flag specifying whether decision tree leaves with the same parent are merged for splits that do not decrease the total risk. The default value is `false`.

Method

Method used by trees. The possible values are 'classification' for classification ensembles, and 'regression' for regression ensembles.

MinLeafSize

Minimum number of observations per tree leaf. By default, `MinLeafSize` is 1 for classification and 5 for regression. For decision tree training, the `MinParent` value is set equal to $2 * MinLeafSize$.

NumTrees

Scalar value equal to the number of decision trees in the ensemble.

NumPredictorSplit

A numeric array of size 1-by-*Nvars*, where every element gives a number of splits on this predictor summed over all trees.

NumPredictorsToSample

Number of predictor or feature variables to select at random for each decision split. By default, `NumPredictorsToSample` is equal to the square root of the total number of variables for classification, and one third of the total number of variables for regression.

OOBIndices

Logical array of size *Nobs*-by-*NumTrees*, where *Nobs* is the number of observations in the training data and *NumTrees* is the number of trees in the ensemble. A `true` value for the (i,j) element indicates that observation *i* is out-of-bag for tree *j*. In other words, observation *i* was not selected for the training data used to grow tree *j*.

OOBInstanceWeight

Numeric array of size *Nobs*-by-1 containing the number of trees used for computing the out-of-bag response for each observation. *Nobs* is the number of observations in the training data used to create the ensemble.

OOBPermutedPredictorCountRaiseMargin

A numeric array of size 1-by-*Nvars* containing a measure of variable importance for each predictor variable (feature). For any variable, the measure is the difference between the number of raised margins and the number of lowered margins if the values of that variable are permuted across the out-of-bag observations. This measure is computed for every tree, then averaged over the entire ensemble and divided by the standard deviation over the entire ensemble. This property is empty for regression trees.

OOBPermutedPredictorDeltaError

A numeric array of size 1-by-*Nvars* containing a measure of importance for each predictor variable (feature). For any variable, the measure is the increase in prediction error if the values of that variable are permuted across the out-of-bag observations. This measure is computed for every tree, then averaged over the entire ensemble and divided by the standard deviation over the entire ensemble.

OOBPermutedPredictorDeltaMeanMargin

A numeric array of size 1-by-*Nvars* containing a measure of importance for each predictor variable (feature). For any variable, the measure is the decrease in the classification margin if the values of that variable are permuted across the out-of-bag observations. This measure is computed for every tree, then averaged over the entire ensemble and divided

by the standard deviation over the entire ensemble. This property is empty for regression trees.

OutlierMeasure

A numeric array of size *Nobs*-by-1, where *Nobs* is the number of observations in the training data, containing outlier measures for each observation.

Prior

Numeric vector of prior probabilities for each class. The order of the elements of `Prior` corresponds to the order of the classes in `ClassNames`.

This property is:

- read-only
- empty ([]) for ensembles of regression trees

Proximity

A numeric matrix of size *Nobs*-by-*Nobs*, where *Nobs* is the number of observations in the training data, containing measures of the proximity between observations. For any two observations, their proximity is defined as the fraction of trees for which these observations land on the same leaf. This is a symmetric matrix with 1s on the diagonal and off-diagonal elements ranging from 0 to 1.

Prune

The `Prune` property is true if decision trees are pruned and false if they are not. Pruning decision trees is not recommended for ensembles. The default value is false.

SampleWithReplacement

A logical flag specifying if data are sampled for each decision tree with replacement. This property is true if `TreeBagger` samples data with replacement and false otherwise. Default value is true.

TreeArguments

Cell array of arguments for `fitctree` or `fitrtree`. These arguments are used by `TreeBagger` when growing new trees for the ensemble.

Trees

A cell array of size *NumTrees*-by-1 containing the trees in the ensemble.

SurrogateAssociation

A matrix of size *Nvars*-by-*Nvars* with predictive measures of variable association, averaged across the entire ensemble of grown trees. If you grew the ensemble setting 'surrogate' to 'on', this matrix for each tree is filled with predictive measures of association averaged over the surrogate splits. If you grew the ensemble setting 'surrogate' to 'off' (default), *SurrogateAssociation* is diagonal.

PredictorNames

A cell array containing the names of the predictor variables (features). *TreeBagger* takes these names from the optional 'names' parameter. The default names are 'x1', 'x2', etc.

W

Numeric vector of weights of length *Nobs*, where *Nobs* is the number of observations (rows) in the training data. *TreeBagger* uses these weights for growing every decision tree in the ensemble. The default *W* is `ones(Nobs, 1)`.

X

A table or numeric matrix of size *Nobs*-by-*Nvars*, where *Nobs* is the number of observations (rows) and *Nvars* is the number of variables (columns) in the training data. If you train the ensemble using a table of predictor values, then *X* is a table. If you train the ensemble using a matrix of predictor values, then *X* is a matrix. This property contains the predictor (or feature) values.

Y

A size *Nobs* array of response data. Elements of *Y* correspond to the rows of *X*. For classification, *Y* is the set of true class labels. Labels can be any grouping variable on page 2-57, that is, a numeric or logical vector, character matrix, string array, cell array of character vectors, or categorical vector. *TreeBagger* converts labels to a cell array of character vectors for classification. For regression, *Y* is a numeric vector.

Examples

Train Ensemble of Bagged Classification Trees

Load Fisher's iris data set.

```
load fisheriris
```

Train an ensemble of bagged classification trees using the entire data set. Specify 50 weak learners. Store which observations are out of bag for each tree.

```
rng(1); % For reproducibility
Mdl = TreeBagger(50,meas,species,'OOBPrediction','On',...
    'Method','classification')

Mdl =
    TreeBagger
Ensemble with 50 bagged decision trees:
    Training X:      [150x4]
    Training Y:      [150x1]
    Method:          classification
    NumPredictors:   4
    NumPredictorsToSample: 2
    MinLeafSize:     1
    InBagFraction:   1
    SampleWithReplacement: 1
    ComputeOOBPrediction: 1
    ComputeOOBPredictorImportance: 0
    Proximity:       []
    ClassNames:      'setosa' 'versicolor' 'virginica'

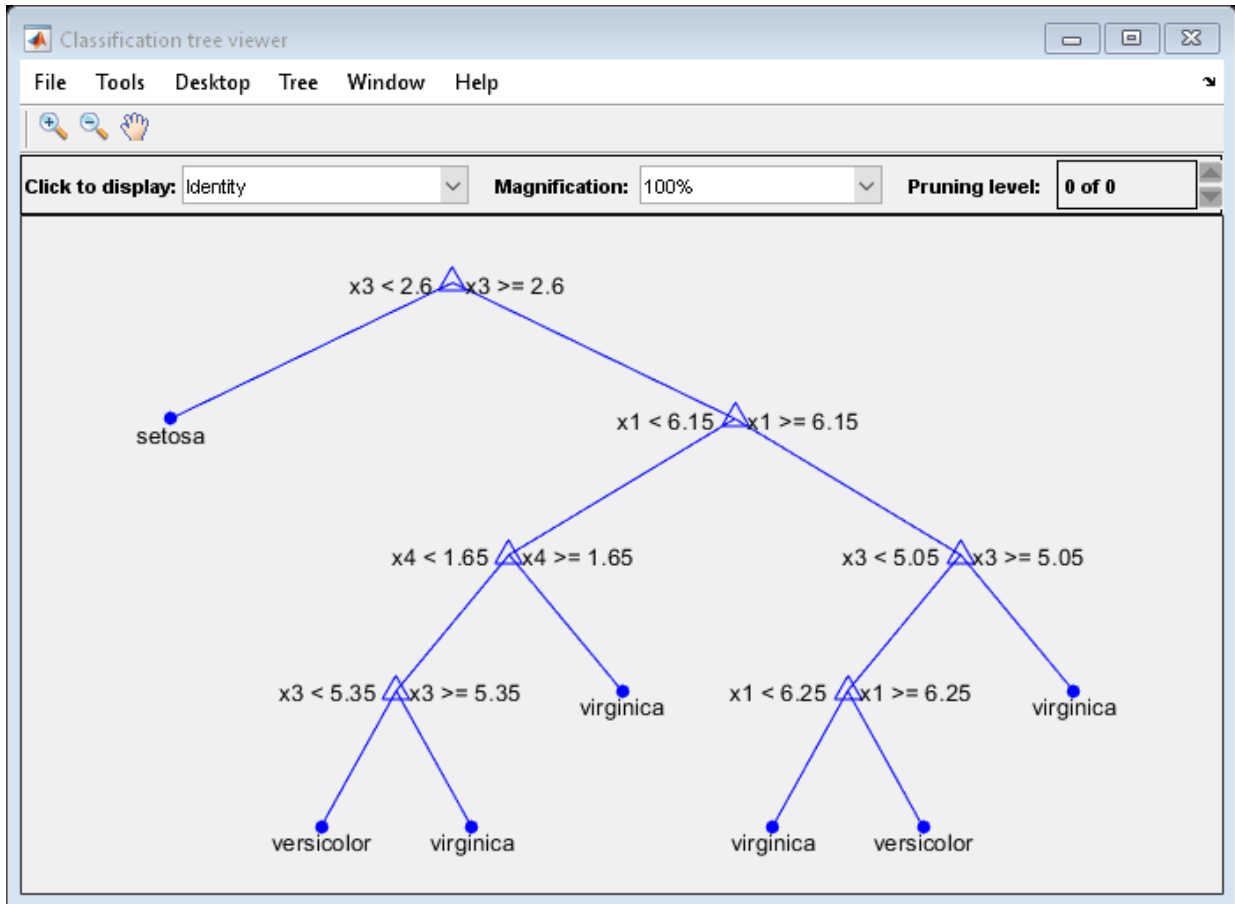

Properties, Methods
```

Mdl is a `TreeBagger` ensemble.

Mdl.Trees stores a 50-by-1 cell vector of the trained classification trees (`CompactClassificationTree` model objects) that compose the ensemble.

Plot a graph of the first trained classification tree.

```
view(Mdl.Trees{1}, 'Mode', 'graph')
```

By default, TreeBagger grows deep trees.

`Mdl.OOBIndices` stores the out-of-bag indices as a matrix of logical values.

Plot the out-of-bag error over the number of grown classification trees.

```
figure;
oobErrorBaggedEnsemble = oobError(Mdl);
plot(oobErrorBaggedEnsemble)
xlabel 'Number of grown trees';
ylabel 'Out-of-bag classification error';
```

The out-of-bag error decreases with the number of grown trees.

To label out-of-bag observations, pass `Mdl` to `oobPredict`.

Train Ensemble of Bagged Regression Trees

Load the `carsmall` data set. Consider a model that predicts the fuel economy of a car given its engine displacement.

```
load carsmall
```

Train an ensemble of bagged regression trees using the entire data set. Specify 100 weak learners.

```
rng(1); % For reproducibility
Mdl = TreeBagger(100,Displacement,MPG,'Method','regression');
```

Mdl is a TreeBagger ensemble.

Using a trained bag of regression trees, you can estimate conditional mean responses or perform quantile regression to predict conditional quantiles.

For ten equally-spaced engine displacements between the minimum and maximum in-sample displacement, predict conditional mean responses and conditional quartiles.

```
predX = linspace(min(Displacement),max(Displacement),10)';
mpgMean = predict(Mdl,predX);
mpgQuartiles = quantilePredict(Mdl,predX,'Quantile',[0.25,0.5,0.75]);
```

Plot the observations, and estimated mean responses and quartiles in the same figure.

```
figure;
plot(Displacement,MPG,'o');
hold on
plot(predX,mpgMean);
plot(predX,mpgQuartiles);
ylabel('Fuel economy');
xlabel('Engine displacement');
legend('Data','Mean Response','First quartile','Median','Third quartile');
```

Unbiased Predictor Importance Estimates

Load the `carsmall` data set. Consider a model that predicts the mean fuel economy of a car given its acceleration, number of cylinders, engine displacement, horsepower, manufacturer, model year, and weight. Consider `Cylinders`, `Mfg`, and `Model_Year` as categorical variables.

```
load carsmall
Cylinders = categorical(Cylinders);
Mfg = categorical(cellstr(Mfg));
Model_Year = categorical(Model_Year);
```

```
X = table(Acceleration,Cylinders,Displacement,Horsepower,Mfg,...
          Model_Year,Weight,MPG);
rng('default'); % For reproducibility
```

Display the number of categories represented in the categorical variables.

```
numCylinders = numel(categories(Cylinders))

numCylinders = 3

numMfg = numel(categories(Mfg))

numMfg = 28

numModelYear = numel(categories(Model_Year))

numModelYear = 3
```

Because there are 3 categories only in `Cylinders` and `Model_Year`, the standard CART, predictor-splitting algorithm prefers splitting a continuous predictor over these two variables.

Train a random forest of 200 regression trees using the entire data set. To grow unbiased trees, specify usage of the curvature test for splitting predictors. Because there are missing values in the data, specify usage of surrogate splits. Store the out-of-bag information for predictor importance estimation.

```
Mdl = TreeBagger(200,X,'MPG','Method','regression','Surrogate','on',...
                'PredictorSelection','curvature','OOBPredictorImportance','on');
```

`TreeBagger` stores predictor importance estimates in the property `OOBPermutedPredictorDeltaError`. Compare the estimates using a bar graph.

```
imp = Mdl.OOBPermutedPredictorDeltaError;

figure;
bar(imp);
title('Curvature Test');
ylabel('Predictor importance estimates');
xlabel('Predictors');
h = gca;
h.XTickLabel = Mdl.PredictorNames;
h.XTickLabelRotation = 45;
h.TickLabelInterpreter = 'none';
```

In this case, `Model_Year` is the most important predictor, followed by `Weight`.

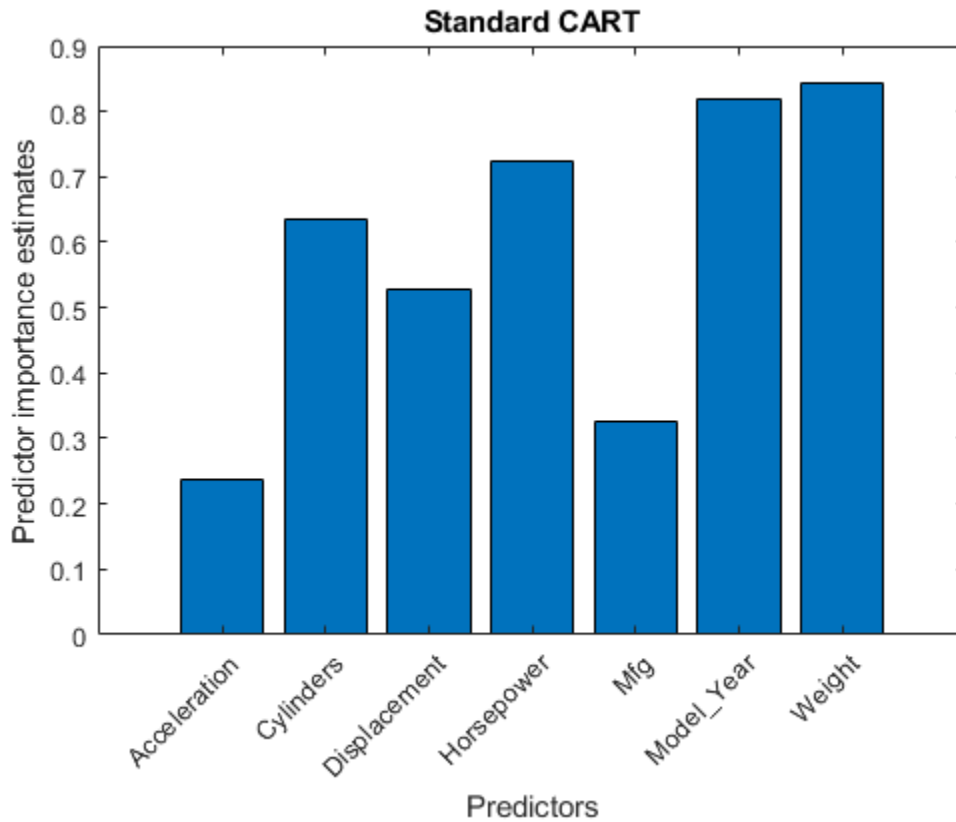

Compare the `imp` to predictor importance estimates computed from a random forest that grows trees using standard CART.

```
MdlCART = TreeBagger(200,X,'MPG','Method','regression','Surrogate','on',...
    'OOBPredictorImportance','on');
```

```
impCART = MdlCART.OOBPermutedPredictorDeltaError;
```

```
figure;
bar(impCART);
title('Standard CART');
ylabel('Predictor importance estimates');
```

```
xlabel('Predictors');  
h = gca;  
h.XTickLabel = Mdl.PredictorNames;  
h.XTickLabelRotation = 45;  
h.TickLabelInterpreter = 'none';
```

In this case, *Weight*, a continuous predictor, is the most important. The next two most importance predictor are *Model_Year* followed closely by *Horsepower*, which is a continuous predictor.

Copy Semantics

Value. To learn how this affects your use of the class, see [Comparing Handle and Value Classes \(MATLAB\)](#) in the MATLAB Object-Oriented Programming documentation.

Tip

For a `TreeBagger` model object `B`, the `Trees` property stores a cell vector of `B.NumTrees` `CompactClassificationTree` or `CompactRegressionTree` model objects. For a textual or graphical display of tree `t` in the cell vector, enter

```
view(B.Trees{t})
```

Alternative Functionality

Statistics and Machine Learning Toolbox offers three objects for bagging and random forest:

- `ClassificationBaggedEnsemble` created by `fitcensemble` for classification
- `RegressionBaggedEnsemble` created by `fitrensemble` for regression
- `TreeBagger` created by `TreeBagger` for classification and regression

For details about the differences between `TreeBagger` and bagged ensembles (`ClassificationBaggedEnsemble` and `RegressionBaggedEnsemble`), see “[Comparison of TreeBagger and Bagged Ensembles](#)” on page 18-56.

TreeBagger

Class: TreeBagger

Create bag of decision trees

Individual decision trees tend to overfit. Bootstrap-aggregated (bagged) decision trees combine the results of many decision trees, which reduces the effects of overfitting and improves generalization. `TreeBagger` grows the decision trees in the ensemble using bootstrap samples of the data. Also, `TreeBagger` selects a random subset of predictors to use at each decision split as in the random forest algorithm [1].

By default, `TreeBagger` bags classification trees. To bag regression trees instead, specify `'Method', 'regression'`.

For regression problems, `TreeBagger` supports mean and quantile regression (that is, quantile regression forest [5]).

Syntax

```
Mdl = TreeBagger(NumTrees, Tbl, ResponseVarName)
```

```
Mdl = TreeBagger(NumTrees, Tbl, formula)
```

```
Mdl = TreeBagger(NumTrees, Tbl, Y)
```

```
B = TreeBagger(NumTrees, X, Y)
```

```
B = TreeBagger(NumTrees, X, Y, Name, Value)
```

Description

`Mdl = TreeBagger(NumTrees, Tbl, ResponseVarName)` returns an ensemble of `NumTrees` bagged classification trees trained using the sample data in the table `Tbl`. `ResponseVarName` is the name of the response variable in `Tbl`.

`Mdl = TreeBagger(NumTrees, Tbl, formula)` returns an ensemble of bagged classification trees trained using the sample data in the table `Tbl`. `formula` is an explanatory model of the response and a subset of predictor variables in `Tbl` used to fit `Mdl`. Specify `Formula` using Wilkinson notation. For more information, see “Wilkinson Notation” on page 11-117.

`Mdl = TreeBagger(NumTrees, Tbl, Y)` returns an ensemble of classification trees using the predictor variables in table `Tbl` and class labels in vector `Y`.

`Y` is an array of response data. Elements of `Y` correspond to the rows of `Tbl`. For classification, `Y` is the set of true class labels. Labels can be any grouping variable on page 2-57, that is, a numeric or logical vector, character matrix, string array, cell array of character vectors, or categorical vector. `TreeBagger` converts labels to a cell array of character vectors. For regression, `Y` is a numeric vector. To grow regression trees, you must specify the name-value pair `'Method', 'regression'`.

`B = TreeBagger(NumTrees, X, Y)` creates an ensemble `B` of `NumTrees` decision trees for predicting response `Y` as a function of predictors in the numeric matrix of training data, `X`. Each row in `X` represents an observation and each column represents a predictor or feature.

`B = TreeBagger(NumTrees, X, Y, Name, Value)` specifies optional parameter name-value pairs:

'InBagFraction'	Fraction of input data to sample with replacement from the input data for growing each new tree. Default value is 1.
-----------------	--

'Cost'	<p>Square matrix C, where $C(i, j)$ is the cost of classifying a point into class j if its true class is i (i.e., the rows correspond to the true class and the columns correspond to the predicted class). The order of the rows and columns of <code>Cost</code> corresponds to the order of the classes in the <code>ClassNames</code> property of the trained <code>TreeBagger</code> model B.</p> <p>Alternatively, <code>cost</code> can be a structure S having two fields:</p> <ul style="list-style-type: none"> • <code>S.ClassNames</code> containing the group names as a categorical variable, character array, string array, or cell array of character vectors • <code>S.ClassificationCosts</code> containing the cost matrix C <p>The default value is $C(i, j) = 1$ if $i \neq j$, and $C(i, j) = 0$ if $i = j$.</p> <p>If <code>Cost</code> is highly skewed, then, for in-bag samples, the software oversamples unique observations from the class that has a large penalty. For smaller sample sizes, this might cause a very low relative frequency of out-of-bag observations from the class that has a large penalty. Therefore, the estimated out-of-bag error is highly variable, and might be difficult to interpret.</p>
'SampleWithReplacement'	<p>'on' to sample with replacement or 'off' to sample without replacement. If you sample without replacement, you need to set <code>'InBagFraction'</code> to a value less than one. Default is 'on'.</p>
'OOBPrediction'	<p>'on' to store info on what observations are out of bag for each tree. This info can be used by <code>oobPrediction</code> to compute the predicted class probabilities for each tree in the ensemble. Default is 'off'.</p>
'OOBPredictorImportance'	<p>'on' to store out-of-bag estimates of feature importance in the ensemble. Default is 'off'. Specifying 'on' also sets the <code>'OOBPrediction'</code> value to 'on'. If an analysis of predictor importance is your goal, then also specify <code>'PredictorSelection'</code>, <code>'curvature'</code> or <code>'PredictorSelection','interaction-curvature'</code>. For more details, see <code>fitctree</code> or <code>fitrtree</code>.</p>

'Method'	Either 'classification' or 'regression'. Regression requires a numeric Y.
'NumPredictorsToSample'	Number of variables to select at random for each decision split. Default is the square root of the number of variables for classification and one third of the number of variables for regression. Valid values are 'all' or a positive integer. Setting this argument to any valid value but 'all' invokes Breiman's random forest algorithm [1].
'NumPrint'	Number of training cycles (grown trees) after which TreeBagger displays a diagnostic message showing training progress. Default is no diagnostic messages.
'MinLeafSize'	Minimum number of observations per tree leaf. Default is 1 for classification and 5 for regression.

'Options'	<p>A structure that specifies options that govern the computation when growing the ensemble of decision trees. One option requests that the computation of decision trees on multiple bootstrap replicates uses multiple processors, if the Parallel Computing Toolbox is available. Two options specify the random number streams to use in selecting bootstrap replicates. You can create this argument with a call to <code>statset</code>. You can retrieve values of the individual fields with a call to <code>statget</code>. Applicable <code>statset</code> parameters are:</p> <ul style="list-style-type: none"> • <code>'UseParallel'</code> — If <code>true</code> and if a <code>parpool</code> of the Parallel Computing Toolbox is open, compute decision trees drawn on separate bootstrap replicates in parallel. If the Parallel Computing Toolbox is not installed, or a <code>parpool</code> is not open, computation occurs in serial mode. Default is <code>false</code>, or serial computation. <p>For dual-core systems and above, <code>TreeBagger</code> parallelizes training using Intel Threading Building Blocks (TBB). Therefore, using the <code>'UseParallel'</code> option is not helpful on a single computer. Use this option on a cluster. For details on Intel TBB, see https://software.intel.com/en-us/intel-tbb.</p> <ul style="list-style-type: none"> • <code>'UseSubstreams'</code> — If <code>true</code> select each bootstrap replicate using a separate Substream of the random number generator (aka Stream). This option is available only with <code>RandStream</code> types that support Substreams: <code>'mlfg6331_64'</code> or <code>'mrg32k3a'</code>. Default is <code>false</code>, do not use a different Substream to compute each bootstrap replicate. • <code>Streams</code> — A <code>RandStream</code> object or cell array of such objects. If you do not specify <code>Streams</code>, <code>TreeBagger</code> uses the default stream or streams. If you choose to specify <code>Streams</code>, use a single object except in the case <ul style="list-style-type: none"> • <code>UseParallel</code> is <code>true</code> • <code>UseSubstreams</code> is <code>false</code> <p>In that case, use a cell array the same size as the <code>Parallel</code> pool.</p>
-----------	--

'Prior'	<p>Prior probabilities for each class. Specify as one of:</p> <ul style="list-style-type: none">• A character vector or string scalar:<ul style="list-style-type: none">• 'Empirical' determines class probabilities from class frequencies in Y. If you pass observation weights, they are used to compute the class probabilities. This is the default.• 'Uniform' sets all class probabilities equal.• A vector (one scalar value for each class). The order of the elements <code>Prior</code> corresponds to the order of the classes in the <code>ClassNames</code> property of the trained <code>TreeBagger</code> model <code>B</code>.• A structure <code>S</code> with two fields:<ul style="list-style-type: none">• <code>S.ClassNames</code> containing the class names as a categorical variable, character array, string array, or cell array of character vectors• <code>S.ClassProbs</code> containing a vector of corresponding probabilities <p>If you set values for both <code>Weights</code> and <code>Prior</code>, the weights are renormalized to add up to the value of the prior probability in the respective class.</p> <p>If <code>Prior</code> is highly skewed, then, for in-bag samples, the software oversamples unique observations from the class that has a large prior probability. For smaller sample sizes, this might cause a very low relative frequency of out-of-bag observations from the class that has a large prior probability. Therefore, the estimated out-of-bag error is highly variable, and might be difficult to interpret.</p>
---------	--

'PredictorNames'	<p>Predictor variable names, specified as the comma-separated pair consisting of 'PredictorNames' and a string array or cell array of unique character vectors. The functionality of 'PredictorNames' depends on the way you supply the training data.</p> <ul style="list-style-type: none">• If you supply X and Y, then you can use 'PredictorNames' to give the predictor variables in X names.<ul style="list-style-type: none">• The order of the names in PredictorNames must correspond to the column order of X. That is, PredictorNames{1} is the name of $X(:,1)$, PredictorNames{2} is the name of $X(:,2)$, and so on. Also, $\text{size}(X,2)$ and $\text{numel}(\text{PredictorNames})$ must be equal.• By default, PredictorNames is {'x1', 'x2', ...}.• If you supply Tbl, then you can use 'PredictorNames' to choose which predictor variables to use in training. That is, <code>TreeBagger</code> uses the predictor variables in PredictorNames and the response only in training.<ul style="list-style-type: none">• PredictorNames must be a subset of $\text{Tbl.Properties.VariableNames}$ and cannot include the name of the response variable.• By default, PredictorNames contains the names of all predictor variables.• It good practice to specify the predictors for training using one of 'PredictorNames' or formula only.
------------------	--

'CategoricalPredictors'	<p>Categorical predictors list, specified as the comma-separated pair consisting of 'CategoricalPredictors' and one of the following.</p> <ul style="list-style-type: none"> • A numeric vector with indices from 1 to p, where p is the number of columns of X. • A logical vector of length p, where a true entry means that the corresponding column of X is a categorical variable. • A string array or cell array of character vectors, where each element in the array is the name of a predictor variable. The names must match entries in PredictorNames values. • A character matrix, where each row of the matrix is a name of a predictor variable. The names must match entries in PredictorNames values. Pad the names with extra blanks so each row of the character matrix has the same length. • 'all', meaning all predictors are categorical.
'ChunkSize'	<p>Chunk size, specified as the comma-separated pair consisting of 'ChunkSize' and a positive integer. The chunk size specifies the number of observations in each chunk of data. The default value is 50000.</p> <hr/> <p>Note This option only applies when using TreeBagger on tall arrays. See “Extended Capabilities” on page 32-0 for more information.</p>

In addition to the optional arguments above, TreeBagger accepts these optional fitctree and fitrtree arguments.

Supported fitctree arguments	Supported fitrtree arguments
AlgorithmForCategorical	MaxNumSplits

Examples

Train Ensemble of Bagged Classification Trees

Load Fisher's iris data set.

```
load fisheriris
```

Train an ensemble of bagged classification trees using the entire data set. Specify 50 weak learners. Store which observations are out of bag for each tree.

```
rng(1); % For reproducibility
Mdl = TreeBagger(50,meas,species,'OOBPrediction','On',...
    'Method','classification')

Mdl =
    TreeBagger
    Ensemble with 50 bagged decision trees:
           Training X:           [150x4]
           Training Y:           [150x1]
           Method:                classification
           NumPredictors:         4
           NumPredictorsToSample: 2
           MinLeafSize:           1
           InBagFraction:         1
           SampleWithReplacement: 1
           ComputeOOBPrediction:  1
           ComputeOOBPredictorImportance: 0
           Proximity:             []
           ClassNames:           'setosa'   'versicolor'   'virginica'

    Properties, Methods
```

Mdl is a TreeBagger ensemble.

Mdl.Trees stores a 50-by-1 cell vector of the trained classification trees (CompactClassificationTree model objects) that compose the ensemble.

Plot a graph of the first trained classification tree.

```
view(Mdl.Trees{1}, 'Mode', 'graph')
```

By default, TreeBagger grows deep trees.

Mdl.OOBIndices stores the out-of-bag indices as a matrix of logical values.

Plot the out-of-bag error over the number of grown classification trees.

```
figure;  
oobErrorBaggedEnsemble = oobError(Mdl);  
plot(oobErrorBaggedEnsemble)  
xlabel 'Number of grown trees';  
ylabel 'Out-of-bag classification error';
```

The out-of-bag error decreases with the number of grown trees.

To label out-of-bag observations, pass `Mdl` to `oobPredict`.

Train Ensemble of Bagged Regression Trees

Load the `carsmall` data set. Consider a model that predicts the fuel economy of a car given its engine displacement.

```
load carsmall
```

Train an ensemble of bagged regression trees using the entire data set. Specify 100 weak learners.

```
rng(1); % For reproducibility
Mdl = TreeBagger(100,Displacement,MPG,'Method','regression');
```

`Mdl` is a `TreeBagger` ensemble.

Using a trained bag of regression trees, you can estimate conditional mean responses or perform quantile regression to predict conditional quantiles.

For ten equally-spaced engine displacements between the minimum and maximum in-sample displacement, predict conditional mean responses and conditional quartiles.

```
predX = linspace(min(Displacement),max(Displacement),10)';
mpgMean = predict(Mdl,predX);
mpgQuartiles = quantilePredict(Mdl,predX,'Quantile',[0.25,0.5,0.75]);
```

Plot the observations, and estimated mean responses and quartiles in the same figure.

```
figure;
plot(Displacement,MPG,'o');
hold on
plot(predX,mpgMean);
plot(predX,mpgQuartiles);
ylabel('Fuel economy');
xlabel('Engine displacement');
legend('Data','Mean Response','First quartile','Median','Third quartile');
```

Unbiased Predictor Importance Estimates

Load the `carsmall` data set. Consider a model that predicts the mean fuel economy of a car given its acceleration, number of cylinders, engine displacement, horsepower, manufacturer, model year, and weight. Consider `Cylinders`, `Mfg`, and `Model_Year` as categorical variables.

```
load carsmall
Cylinders = categorical(Cylinders);
Mfg = categorical(cellstr(Mfg));
Model_Year = categorical(Model_Year);
```

```
X = table(Acceleration,Cylinders,Displacement,Horsepower,Mfg,...
          Model_Year,Weight,MPG);
rng('default'); % For reproducibility
```

Display the number of categories represented in the categorical variables.

```
numCylinders = numel(categories(Cylinders))
```

```
numCylinders = 3
```

```
numMfg = numel(categories(Mfg))
```

```
numMfg = 28
```

```
numModelYear = numel(categories(Model_Year))
```

```
numModelYear = 3
```

Because there are 3 categories only in `Cylinders` and `Model_Year`, the standard CART, predictor-splitting algorithm prefers splitting a continuous predictor over these two variables.

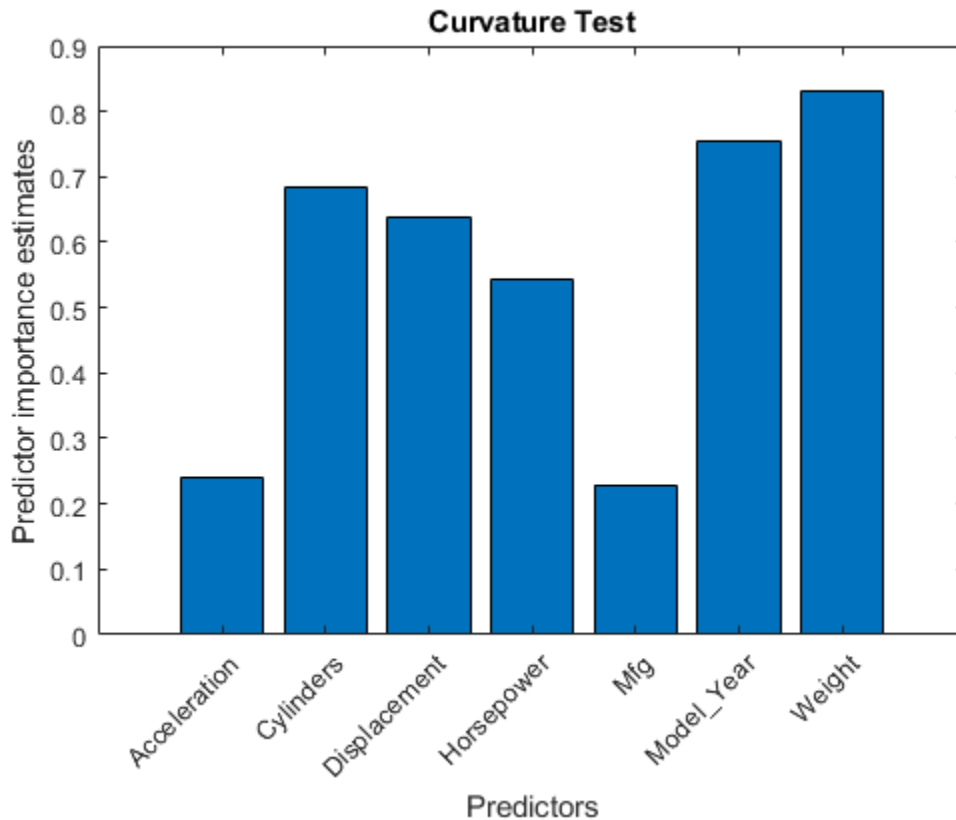

Train a random forest of 200 regression trees using the entire data set. To grow unbiased trees, specify usage of the curvature test for splitting predictors. Because there are missing values in the data, specify usage of surrogate splits. Store the out-of-bag information for predictor importance estimation.

```
Mdl = TreeBagger(200,X,'MPG','Method','regression','Surrogate','on',...
                'PredictorSelection','curvature','OOBPredictorImportance','on');
```

`TreeBagger` stores predictor importance estimates in the property `OOBPermutedPredictorDeltaError`. Compare the estimates using a bar graph.

```
imp = Mdl.OOBPermutedPredictorDeltaError;
```

```
figure;
bar(imp);
title('Curvature Test');
ylabel('Predictor importance estimates');
xlabel('Predictors');
h = gca;
h.XTickLabel = Mdl.PredictorNames;
h.XTickLabelRotation = 45;
h.TickLabelInterpreter = 'none';
```

In this case, `Model_Year` is the most important predictor, followed by `Weight`.

Compare the `imp` to predictor importance estimates computed from a random forest that grows trees using standard CART.

```
MdlCART = TreeBagger(200,X,'MPG','Method','regression','Surrogate','on',...
    'OOBPredictorImportance','on');
```

```
impCART = MdlCART.OOBPermutedPredictorDeltaError;
```

```
figure;
bar(impCART);
title('Standard CART');
ylabel('Predictor importance estimates');
```

```
xlabel('Predictors');  
h = gca;  
h.XTickLabel = Mdl.PredictorNames;  
h.XTickLabelRotation = 45;  
h.TickLabelInterpreter = 'none';
```

In this case, *Weight*, a continuous predictor, is the most important. The next two most importance predictor are *Model_Year* followed closely by *Horsepower*, which is a continuous predictor.

Train Ensemble of Bagged Classification Trees on Tall Array

Train an ensemble of bagged classification trees for observations in a tall array, and find the misclassification probability of each tree in the model for weighted observations. The sample data set `airlinesmall.csv` is a large data set that contains a tabular file of airline flight data.

Create a datastore that references the location of the folder containing the data set. Select a subset of the variables to work with, and treat 'NA' values as missing data so that `datastore` replaces them with NaN values. Create a tall table that contains the data in the datastore.

```
ds = datastore('airlinesmall.csv');
ds.SelectedVariableNames = {'Month', 'DayofMonth', 'DayOfWeek', ...
                           'DepTime', 'ArrDelay', 'Distance', 'DepDelay'};
ds.TreatAsMissing = 'NA';
tt = tall(ds) % Tall table
```

```
Starting parallel pool (parpool) using the 'local' profile ...
Connected to the parallel pool (number of workers: 6).
```

```
tt =
```

```
M×7 tall table
```

Month	DayofMonth	DayOfWeek	DepTime	ArrDelay	Distance	DepDelay
10	21	3	642	8	308	12
10	26	1	1021	8	296	1
10	23	5	2055	21	480	20
10	23	5	1332	13	296	12
10	22	4	629	4	373	-1
10	28	3	1446	59	308	63
10	8	4	928	3	447	-2

When you perform calculations on tall arrays, the default execution environment uses either the local MATLAB session or a local parallel pool (if you have Parallel Computing Toolbox™). You can use the `mapreducer` function to change the execution environment.

Determine the flights that are late by 10 minutes or more by defining a logical variable that is true for a late flight. This variable contains the class labels. A preview of this variable includes the first few rows.

  ClassNames: '0' '1'
```

Properties, Methods

`tMdl` is a `CompactTreeBagger` ensemble with 20 bagged decision trees.

Calculate the misclassification probability of each tree in the model. Attribute a weight contained in the vector `W` to each observation by using the `'Weights'` name-value pair argument.

```
tterr = error(tMdl,X,Y,'Weights',W)
```

```

Find the average misclassification probability for the ensemble of decision trees.

```
avg_terr = mean(terr)

avg_terr = 0.1025
```

Tips

- Avoid large estimated out-of-bag error variances by setting a more balanced misclassification cost matrix or a less skewed prior probability vector.
- The `Trees` property of `B` stores a cell array of `B.NumTrees` `CompactClassificationTree` or `CompactRegressionTree` model objects. For a textual or graphical display of tree `t` in the cell array, enter

```
view(B.Trees{t})
```

- Standard CART tends to select split predictors containing many distinct values, e.g., continuous variables, over those containing few distinct values, e.g., categorical variables [4]. Consider specifying the curvature or interaction test if any of the following are true:
 - If there are predictors that have relatively fewer distinct values than other predictors, for example, if the predictor data set is heterogeneous.

- If an analysis of predictor importance is your goal. `TreeBagger` stores predictor importance estimates in the `OOBPermutedPredictorDeltaError` property of `Mdl`.

For more information on predictor selection, see `PredictorSelection` for classification trees or `PredictorSelection` for regression trees.

Algorithms

- `TreeBagger` generates in-bag samples by oversampling classes with large misclassification costs and undersampling classes with small misclassification costs. Consequently, out-of-bag samples have fewer observations from classes with large misclassification costs and more observations from classes with small misclassification costs. If you train a classification ensemble using a small data set and a highly skewed cost matrix, then the number of out-of-bag observations per class might be very low. Therefore, the estimated out-of-bag error might have a large variance and might be difficult to interpret. The same phenomenon can occur for classes with large prior probabilities.
- For details on selecting split predictors and node-splitting algorithms when growing decision trees, see “Algorithms” on page 32-2177 for classification trees and “Algorithms” on page 32-2681 for regression trees.

Alternative Functionality

Statistics and Machine Learning Toolbox offers three objects for bagging and random forest:

- `ClassificationBaggedEnsemble` created by `fitcensemble` for classification
- `RegressionBaggedEnsemble` created by `fitrensemble` for regression
- `TreeBagger` created by `TreeBagger` for classification and regression

For details about the differences between `TreeBagger` and bagged ensembles (`ClassificationBaggedEnsemble` and `RegressionBaggedEnsemble`), see “Comparison of `TreeBagger` and Bagged Ensembles” on page 18-56.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function supports tall arrays for out-of-memory data with the limitations:

- Supported syntaxes for tall X , Y , Tbl are:
 - $B = \text{TreeBagger}(\text{NumTrees}, Tbl, Y)$
 - $B = \text{TreeBagger}(\text{NumTrees}, X, Y)$
 - $B = \text{TreeBagger}(_, \text{Name}, \text{Value})$
- For tall arrays, `TreeBagger` supports classification but does not support regression.
- Supported name-value pairs are:
 - `'NumPredictorsToSample'` — Default value is the square root of the number of variables for classification.
 - `'MinLeafSize'` — Default value is 1 if the number of observations is less than 50,000. If the number of observations is 50,000 or greater, then the default value is $\max(1, \min(5, \text{floor}(0.01 * \text{NobsChunk})))$, where `NobsChunk` is the number of observations in a chunk.
 - `'ChunkSize'` (only for tall arrays) — Default value is 50000.

In addition, `TreeBagger` supports these optional arguments of `fitctree`:

- 'AlgorithmForCategorical'
 - 'CategoricalPredictors'
 - 'Cost' — The columns of the cost matrix C cannot contain Inf or NaN values.
 - 'MaxNumCategories'
 - 'MaxNumSplits'
 - 'MergeLeaves'
 - 'PredictorNames'
 - 'PredictorSelection'
 - 'Prior'
 - 'Prune'
 - 'PruneCriterion'
 - 'SplitCriterion'
 - 'Surrogate'
 - 'Weights'
- For tall data, `TreeBagger` returns a `CompactTreeBagger` object that contains most of the same properties as a full `TreeBagger` object. The main difference is that the compact object is more memory efficient. The compact object does not include properties that include the data, or that include an array of the same size as the data.
 - The number of trees contained in the returned `CompactTreeBagger` object can differ from the number of trees specified as input to the `TreeBagger` function. `TreeBagger` determines the number of trees to return based on factors that include the size of the input data set and the number of data chunks available to grow trees.
 - Supported `CompactTreeBagger` methods are:
 - `combine`
 - `error`
 - `margin`
 - `meanMargin`
 - `predict`
 - `setDefaultYfit`

The `error`, `margin`, `meanMargin`, and `predict` methods do not support the name-value pair arguments 'Trees', 'TreeWeights', or 'UseInstanceForTree'. The `meanMargin` method additionally does not support 'Weights'.

- **TreeBagger** creates a random forest by generating trees on disjoint chunks of the data. When more data is available than is required to create the random forest, the data is subsampled. For a similar example, see *Random Forests for Big Data* (Genuer, Poggi, Tuleau-Malot, Villa-Vialaneix 2015).

Depending on how the data is stored, it is possible that some chunks of data contain observations from only a few classes out of all the classes. In this case, **TreeBagger** might produce inferior results compared to the case where each chunk of data contains observations from most of the classes.

- During training of the **TreeBagger** algorithm, the speed, accuracy, and memory usage depend on a number of factors. These factors include values for `NumTrees`, `'ChunkSize'`, `'MinLeafSize'`, and `'MaxNumSplits'`.

For an n -by- p tall array X , **TreeBagger** implements sampling during training. This sampling depends on these variables:

- Number of trees `NumTrees`
- Chunk size `'ChunkSize'`
- Number of observations n
- Number of chunks r (approximately equal to $n / \text{'ChunkSize'}$)

Because the value of n is fixed for a given X , your settings for `NumTrees` and `'ChunkSize'` determine how **TreeBagger** samples X .

- 1 If $r > \text{NumTrees}$, then **TreeBagger** samples `'ChunkSize' * NumTrees` observations from X , and trains one tree per chunk (with each chunk containing `'ChunkSize'` number of observations). This scenario is the most common when you work with tall arrays.
 - 2 If $r \leq \text{NumTrees}$, then **TreeBagger** trains approximately $\text{NumTrees} / r$ trees in each chunk, using bootstrapping within the chunk.
 - 3 If $n \leq \text{'ChunkSize'}$, then **TreeBagger** uses bootstrapping to generate samples (each of size n) on which to train individual trees.
- When specifying a value for `NumTrees`, consider the following:
 - If you run your code on Apache Spark, and your data set is distributed with Hadoop Distributed File System (HDFS), start by specifying a value for `NumTrees` that is at least twice the number of partitions in HDFS for your data set. This setting prevents excessive data communication among Apache Spark executors and can improve performance of the **TreeBagger** algorithm.

- `TreeBagger` copies fitted trees into the client memory in the resulting `CompactTreeBagger` model. Therefore, the amount of memory available to the client creates an upper bound on the value you can set for `NumTrees`. You can tune the values of `'MinLeafSize'` and `'MaxNumSplits'` for more efficient speed and memory usage at the expense of some predictive accuracy. After tuning, if the value of `NumTrees` is less than twice the number of partitions in HDFS for your data set, then consider repartitioning your data in HDFS to have larger partitions.

After specifying a value for `NumTrees`, set `'ChunkSize'` to ensure that `TreeBagger` uses most of the data to grow trees. Ideally, `'ChunkSize' * NumTrees` should approximate n , the number of rows in your data. Note that the memory available in the workers for training individual trees can also determine an upper bound for `'ChunkSize'`.

You can adjust the Apache Spark memory properties to avoid out-of-memory errors and support your workflow. See `parallel.cluster.Hadoop` for more information.

For more information, see “Tall Arrays” (MATLAB).

Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the `'UseParallel'` option to `true`.

Set the `'UseParallel'` field of the options structure to `true` using `statset` and specify the `'Options'` name-value pair argument in the call to this function.

For example: `'Options',statset('UseParallel',true)`

For more information, see the `'Options'` name-value pair argument.

For more general information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

Introduced in R2009a

trimmean

Mean, excluding outliers

Syntax

```
m = trimmean(X,percent)
m = trimmean(X,percent,flag)
m = trimmean( ____, 'all' )
m = trimmean( ____, dim)
m = trimmean( ____, vecdim)
```

Description

`m = trimmean(X,percent)` returns the mean of values of `X`, computed after removing the outliers of `X`. For example, if `X` is a vector that has `n` values, `m` is the mean of `X` excluding the highest and lowest `k` data values, where $k = n * (\text{percent}/100) / 2$.

- If `X` is a vector, then `trimmean(X,percent)` is the mean of all the values of `X`, computed after removing the outliers.
- If `X` is a matrix, then `trimmean(X,percent)` is a row vector of column means, computed after removing the outliers.
- If `X` is a multidimensional array, then `trimmean` operates along the first nonsingleton dimension of `X`.

`m = trimmean(X,percent,flag)` specifies how to trim when `k` (half the number of outliers) is not an integer.

`m = trimmean(____, 'all')` returns the trimmed mean of all the values in `X` using any of the input argument combinations in the previous syntaxes.

`m = trimmean(____, dim)` returns the trimmed mean along the operating dimension `dim` of `X`.

`m = trimmean(____, vecdim)` returns the trimmed mean over the dimensions specified in the vector `vecdim`. For example, if `X` is a 2-by-3-by-4 array, then `trimmean(X,10,[1`

2]) returns a 1-by-1-by-4 array. Each value of the output array is the mean of the middle 90% of the values on the corresponding page of X.

Examples

Efficiency of Trimmed Mean

Find the relative efficiency of the 10% trimmed mean to the sample mean for a given data set.

Generate a 100-by-100 matrix of random numbers from the standard normal distribution. This matrix represents 100 samples, each containing 100 data points.

```
rng default; % For reproducibility
X = normrnd(0,1,100,100);
```

Compute the sample mean and the 10% trimmed mean for each column of the data matrix.

```
m = mean(X); % Sample mean
trim = trimmean(X,10); % Trimmed mean
```

Compute the relative efficiency of the trimmed mean to the sample mean. The relative efficiency is the variance of the sample mean divided by the variance of the trimmed mean.

```
vm = var(m) % Variance of the sample mean
vm = 0.0094

vtrim = var(trim) % Variance of the trimmed mean
vtrim = 0.0097

efficiency = vm/vtrim % Relative efficiency of the trimmed mean to the sample mean
efficiency = 0.9663
```

The sample mean has a smaller variance than the trimmed mean (efficiency < 1). Therefore, the trimmed mean is less efficient than the sample mean.

Control Trimming for Distribution with Outliers

Control the trimming for a distribution with outliers when k (half the number of outliers to be trimmed) is not an integer.

Generate a vector of random numbers from the Student's t distribution with degrees of freedom equal to 1. The Student's t distribution tends to have outliers.

```
rng default; % For reproducibility
nu = 1; % Degrees of freedom
n = 60; % Number of rows
m = 1; % Number of columns
x = trnd(nu,n,m); % Vector
```

Visualize the distribution using a normal probability plot.

```
probplot(x)
```

Although the distribution is symmetric around zero, several outliers affect the mean.

Find the mean of the data.

```
mn = mean(x)
```

```
mn = 1.6452
```

Find the 33% trimmed mean of the data.

```
trim = trimmean(x,33)
```

```
trim = 0.4940
```

The 33% trimmed mean is closer to zero, which is more representative of the data. For the 33% trimmed mean, k is not an integer ($k = 60 * (33/100) / 2$ gives a value of 9.9). Therefore, `trimmean` rounds k to the nearest integer (10) by default.

Control trimming by rounding k down to the next smaller integer (9). Specify the control for trimming to `'floor'`.

```
trim = trimmean(x,33,'floor')  
trim = 0.4933
```

Find Trimmed Mean Along Given Dimension

Find the trimmed mean along different dimensions for a matrix.

Generate a matrix of random numbers from the Student's t distribution. The Student's t distribution tends to have outliers.

```
rng('default')  
nu = 1; % Degrees of freedom  
n = 2; % Number of rows  
m = 100; % Number of columns  
X = trnd(nu,n,m);
```

Visualize the distribution for each row of X using a normal probability plot.

```
for i = 1:n  
    figure()  
    probplot(X(i,:))  
end
```

Find the mean for each row of X .

```
mn = mean(X,2)
```

```
mn = 2×1
```

```
-2.7379  
2.0087
```

Find the 30% trimmed mean for each row of X . Specify `dim = 2` as the operating dimension.

```
trim = trimmean(X,30,2)
```

```
trim = 2×1
    -0.0868
     0.1115
```

The 30% trimmed mean of each row is closer to zero, which is more representative of the data.

Trimmed Mean Along Vector of Dimensions

Calculate the trimmed mean over multiple dimensions by using the 'all' and vecdim input arguments.

Create a 5-by-4-by-2 array with some outlier values.

```
X = reshape(1:40,[5 4 2]);
X([3 37]) = -100
```

```
X =
X(:,:,1) =
```

```
     1     6    11    16
     2     7    12    17
  -100     8    13    18
     4     9    14    19
     5    10    15    20
```

```
X(:,:,2) =
```

```
    21    26    31    36
    22    27    32  -100
    23    28    33    38
    24    29    34    39
    25    30    35    40
```

Find the 10% trimmed mean of X.

```
mall = trimmean(X,10,'all')
mall = 19.4722
```

`mall` is the mean of the middle 90% of the values in `X`.

Find the 10% trimmed mean for each page of `X`.

```
mpage = trimmean(X,10,[1 2])
```

```
mpage =  
mpage(:, :, 1) =
```

```
    10.3889
```

```
mpage(:, :, 2) =
```

```
    29.6111
```

For example, `mpage(1, 1, 2)` is the mean of the middle 90% of the values in `X(:, :, 2)`.

Input Arguments

X — Input data

vector | matrix | multidimensional array

Input data that represents a sample from a population, specified as a vector, matrix, or multidimensional array.

- If `X` is a vector, then `trimmean(X, percent)` is the mean of all the values of `X`, computed after removing the outliers.
- If `X` is a matrix, then `trimmean(X, percent)` is a row vector of column means, computed after removing the outliers.
- If `X` is a multidimensional array, then `trimmean` operates along the first nonsingleton dimension of `X`.

To specify the operating dimension when `X` is a matrix or an array, use the `dim` input argument.

`trimmean` treats NaN values in `X` as missing values and removes them.

Data Types: `single` | `double`

percent — Percentage

scalar

Percentage of input data to be trimmed, specified as a scalar between 0 and 100.

`trimmean` uses the value of `percent` to determine the number of outliers (highest and lowest k values in X) to remove from X before computing the mean. For X with n values, $k = n * (\text{percent} / 100) / 2$.

Data Types: `single` | `double`

flag — Control for trimming

'round' (default) | 'floor' | 'weighted'

Control for trimming when k (half the number of outliers) is not an integer, specified as one of the values in this table.

Value	Description
'round'	Round k to the nearest integer (round to a smaller integer if k is a half integer). This value is the default.
'floor'	Round k down to the next smaller integer.
'weighted'	If $k = i + f$, where i is an integer and f is a fraction, compute a weighted mean with weight $(1 - f)$ for the $(i + 1)$ th and $(n - i)$ th values, and full weight for the values between them.

Data Types: `char` | `string`

dim — Dimension

positive integer scalar

Dimension along which to operate, specified as a positive integer scalar. If you do not specify a value, then the default value is the first array dimension of X whose size does not equal 1.

Consider a two-dimensional array X :

- If `dim` is equal to 1, then `trimmean(X, percent, 1)` returns a row vector containing the trimmed mean for each column in X .
- If `dim` is equal to 2, then `trimmean(X, percent, 2)` returns a column vector containing the trimmed mean for each row in X .

If `dim` is greater than `ndims(X)` or if `size(X, dim)` is 1, then `trimmean` returns X .

Data Types: `single` | `double`

vecdim — Vector of dimensions

positive integer vector

Vector of dimensions, specified as a positive integer vector. Each element of `vecdim` represents a dimension of the input array `X`. The output `m` has length 1 in the specified operating dimensions. The other dimension lengths are the same for `X` and `m`.

For example, if `X` is a 2-by-3-by-3 array, then `trimmean(X,10,[1 2])` returns a 1-by-1-by-3 array. Each element of the output is the mean of the middle 90% of the values on the corresponding page of `X`.

Data Types: `single` | `double`

Output Arguments

m — Trimmed mean

scalar | vector | matrix | multidimensional array

Trimmed mean values, returned as a scalar, vector, matrix, or multidimensional array.

Tips

- The trimmed mean is a robust estimate of the location of a data sample. If the data contains outliers, then the trimmed mean represents the center of the data better than the sample mean. However, if all the data is from the same probability distribution,

then the trimmed mean is less efficient than the sample mean as an estimator of the data location.

Extended Capabilities

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Usage notes and limitations:

- The 'all' and vecdim input arguments are not supported.

For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

Introduced before R2006a

trnd

Student's t random numbers

Syntax

```
r = trnd(nu)
r = trnd(nu,m,n,...)
r = trnd(nu,[m,n,...])
```

Description

`r = trnd(nu)` generates random numbers from Student's t distribution with `nu` degrees of freedom. `nu` can be a vector, a matrix, or a multidimensional array. The size of `r` is equal to the size of `nu`.

`r = trnd(nu,m,n,...)` or `r = trnd(nu,[m,n,...])` generates an `m`-by-`n`-by-... array. The `nu` parameter can be a scalar or an array of the same size as `r`.

Examples

Generate Student's t Distribution Random Numbers

```
r1 = trnd(ones(1,6))
```

```
r1 = 1×6
```

```
    0.2108    7.8450  -11.0511    0.4134    4.3293   -0.8323
```

```
r2 = trnd(1:6,[1 6])
```

```
r2 = 1×6
```

```
    8.9290   -0.1908    0.3496   -0.7658    1.3234   -1.2808
```

```
r3 = trnd(3,2,6)
```

```
r3 = 2×6
```

```
    1.3157    0.7010    0.1591   -1.3840    4.1354    0.2442  
    0.9789   -2.4700   -1.8884   -0.0116   -0.9496   -0.2340
```

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

The generated code can return a different sequence of numbers than MATLAB if either of the following is true:

- The output is nonscalar.
- An input parameter is invalid for the distribution.

For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “General Code Generation Workflow” on page 31-5.

truncate

Package: prob

Truncate probability distribution object

Syntax

```
t = truncate(pd, lower, upper)
```

Description

`t = truncate(pd, lower, upper)` returns a probability distribution `t`, which is the probability distribution `pd` truncated to the specified interval with lower limit, `lower`, and upper limit, `upper`.

Examples

Truncate a Probability Distribution

Create a standard normal probability distribution object.

```
pd = makedist('Normal')
```

```
pd =  
  NormalDistribution  
  
  Normal distribution  
    mu = 0  
    sigma = 1
```

Truncate the distribution to have a lower limit of -2 and an upper limit of 2.

```
t = truncate(pd, -2, 2)
```

```
t =  
NormalDistribution  
  
Normal distribution  
    mu = 0  
    sigma = 1  
Truncated to the interval [-2, 2]
```

Plot the pdf of the original and truncated distributions for a visual comparison.

```
x = linspace(-3,3,1000);  
figure  
plot(x,pdf(pd,x))  
hold on  
plot(x,pdf(t,x), 'LineStyle', '--')  
legend('Normal', 'Truncated')  
hold off
```

Generate Random Numbers from a Truncated Distribution

Create a standard normal probability distribution object.

```
pd = makedist('Normal')
```

```
pd =  
  NormalDistribution  
  
  Normal distribution  
  mu = 0
```

```
sigma = 1
```

Truncate the distribution by restricting it to positive values. Set the lower limit to 0 and the upper limit to infinity.

```
t = truncate(pd,0,inf)
```

```
t =
```

```
NormalDistribution
```

```
Normal distribution
```

```
mu = 0
```

```
sigma = 1
```

```
Truncated to the interval [0, Inf]
```

Generate random numbers from the truncated distribution and visualize with a histogram.

```
r = random(t,10000,1);
```

```
histogram(r,100)
```

Input Arguments

pd — Probability distribution

probability distribution object

Probability distribution, specified as a probability distribution object. Create a probability distribution object with specified parameter values using `makedist`.

Alternatively, for fittable distributions, create a probability distribution object by fitting it to data using `fitdist` or the **Distribution Fitter** app.

Lower — Lower truncation limit

scalar value

Lower truncation limit, specified as a scalar value.

Data Types: `single` | `double`**upper — Upper truncation limit**

scalar value

Upper truncation limit, specified as a scalar value.

Data Types: `single` | `double`

Output Arguments

t — Truncated distribution

probability distribution object

Truncated distribution, returned as a probability distribution object. The probability distribution function (pdf) of `t` is 0 outside the truncation interval. Inside the truncation interval, the pdf of `t` is equal to the pdf of `pd`, but divided by the probability assigned to that interval by `pd`.

Distribution Fitter | `fitdist` | `makedist`

Topics

“Working with Probability Distributions” on page 5-3

“Supported Distributions” on page 5-20

Introduced in R2013a

tsne

t-Distributed Stochastic Neighbor Embedding

Syntax

```
Y = tsne(X)
Y = tsne(X,Name,Value)
[Y,loss] = tsne( ___ )
```

Description

`Y = tsne(X)` returns a matrix of two-dimensional embeddings of the high-dimensional rows of `X`.

`Y = tsne(X,Name,Value)` modifies the embeddings using options specified by one or more name-value pair arguments.

`[Y,loss] = tsne(___)`, for any input arguments, also returns the Kullback-Leibler divergence between the joint distributions that model the data `X` and the embedding `Y`.

Examples

Visualize Fisher Iris Data

The Fisher iris data set has four-dimensional measurements of irises, and corresponding classification into species. Visualize this data by reducing the dimension using `tsne`.

```
load fisheriris
rng default % for reproducibility
Y = tsne(meas);
gscatter(Y(:,1),Y(:,2),species)
```

Compare Distance Metrics

Use various distance metrics to try to obtain a better separation between species in the Fisher iris data.

```
load fisheriris
```

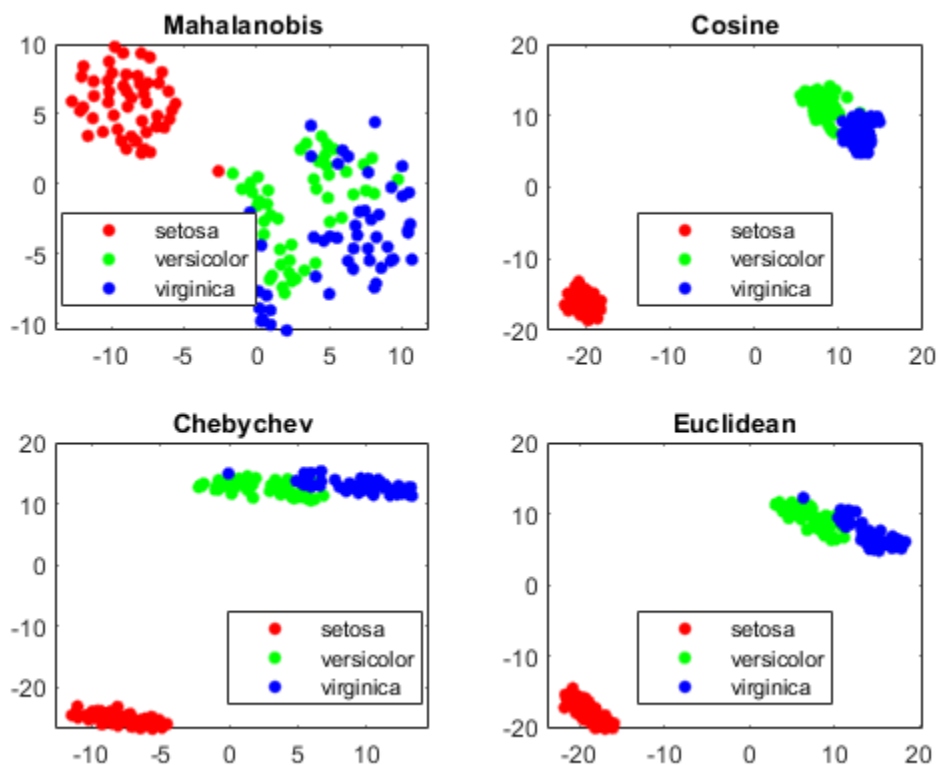

```
rng('default') % for reproducibility  
Y = tsne(meas,'Algorithm','exact','Distance','mahalanobis');  
subplot(2,2,1)  
gscatter(Y(:,1),Y(:,2),species)
```

```
title('Mahalanobis')

rng('default') % for fair comparison
Y = tsne(meas,'Algorithm','exact','Distance','cosine');
subplot(2,2,2)
gscatter(Y(:,1),Y(:,2),species)
title('Cosine')

rng('default') % for fair comparison
Y = tsne(meas,'Algorithm','exact','Distance','chebychev');
subplot(2,2,3)
gscatter(Y(:,1),Y(:,2),species)
title('Chebychev')

rng('default') % for fair comparison
Y = tsne(meas,'Algorithm','exact','Distance','euclidean');
subplot(2,2,4)
gscatter(Y(:,1),Y(:,2),species)
title('Euclidean')
```

In this case, the cosine, Chebychev, and Euclidean distance metrics give reasonably good separation of clusters. But the Mahalanobis distance metric does not give a good separation.

Plot Results with NaN Input Data

t-sne removes input data rows that contain any NaN entries. Therefore, you must remove any such rows from your classification data before plotting.

For example, change a few random entries in the Fisher iris data to NaN.

```
load fisheriris
rng default % for reproducibility
meas(rand(size(meas)) < 0.05) = NaN;
```

Embed the four-dimensional data into two dimensions using `tsne`.

```
Y = tsne(meas, 'Algorithm', 'exact');
```

Warning: Rows with NaN missing values in X or 'InitialY' values are removed.

Determine how many rows were eliminated from the embedding.

```
length(species) - length(Y)
```

```
ans = 22
```

Prepare to plot the result by locating the rows of `meas` that have no NaN values.

```
goodrows = not(any(isnan(meas), 2));
```

Plot the results using only the rows of `species` that correspond to rows of `meas` with no NaN values.

```
gscatter(Y(:,1), Y(:,2), species(goodrows))
```

Compare t-SNE Loss

Find both 2-D and 3-D embeddings of the Fisher iris data, and compare the loss for each embedding. It is likely that the loss is lower for a 3-D embedding, because this embedding has more freedom to match the original data.

```
load fisheriris
rng default % for reproducibility
[Y,loss] = tsne(meas,'Algorithm','exact');
rng default % for fair comparison
```

```
[Y2,loss2] = tsne(meas,'Algorithm','exact','NumDimensions',3);  
fprintf('2-D embedding has loss %g, and 3-D embedding has loss %g.\n',loss,loss2)
```

2-D embedding has loss 0.122669, and 3-D embedding has loss 0.0985112.

As expected, the 3-D embedding has lower loss.

View the embeddings. Use RGB colors [1 0 0], [0 1 0], and [0 0 1].

For the 3-D plot, convert the species to numeric values using the `categorical` command, then convert the numeric values to RGB colors using the `sparse` function as follows. If `v` is a vector of positive integers 1, 2, or 3, corresponding to the species data, then the command

```
sparse(1:numel(v),v,ones(size(v)))
```

is a sparse matrix whose rows are the RGB colors of the species.

```
gscatter(Y(:,1),Y(:,2),species,eye(3))  
title('2-D Embedding')
```

```
figure
v = double(categorical(species));
c = full(sparse(1:numel(v),v,ones(size(v)),numel(v),3));
scatter3(Y2(:,1),Y2(:,2),Y2(:,3),15,c,'filled')
title('3-D Embedding')
view(-50,8)
```

Input Arguments

X — Data points

n-by-*m* matrix

Data points, specified as an *n*-by-*m* matrix, where each row is one *m*-dimensional point.

`t_sne` removes rows of *X* that contain any NaN values before creating an embedding. See “Plot Results with NaN Input Data” on page 32-6933.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `Y = tsne(X,'Algorithm','Exact','NumPCAComponents',50)`

Algorithm Control

Algorithm — tsne algorithm

'barneshut' (default) | 'exact'

tsne algorithm, specified as 'barneshut' or 'exact'. The 'exact' algorithm optimizes the Kullback-Leibler divergence of distributions between the original space and the embedded space. The 'barneshut' algorithm performs an approximate optimization that is faster and uses less memory when the number of data rows is large.

Note For the 'barneshut' algorithm, tsne uses knnsearch to find the nearest neighbors.

Example: 'exact'

Distance — Distance metric

'euclidean' (default) | 'seuclidean' | 'cityblock' | 'chebychev' | 'minkowski' | 'mahalanobis' | 'cosine' | 'correlation' | 'spearman' | 'hamming' | 'jaccard' | function handle

Distance metric, specified by one of the following. For definitions of the distance metrics, see `pdist`.

- 'euclidean' — Euclidean distance.
- 'seuclidean' — Standardized Euclidean distance. Each coordinate difference between rows in `X` and the query matrix is scaled by dividing by the corresponding element of the standard deviation computed from `S = nanstd(X)`.
- 'cityblock' — City block distance.
- 'chebychev' — Chebychev distance, which is the maximum coordinate difference.
- 'minkowski' — Minkowski distance with exponent 2. This is the same as Euclidean distance.

- 'mahalanobis' — Mahalanobis distance, computed using the positive definite covariance matrix `nancov(X)`.
- 'cosine' — 1 minus the cosine of the included angle between observations (treated as vectors).
- 'correlation' — One minus the sample linear correlation between observations (treated as sequences of values).
- 'spearman' — One minus the sample Spearman's rank correlation between observations (treated as sequences of values).
- 'hamming' — Hamming distance, which is the percentage of coordinates that differ.
- 'jaccard' — One minus the Jaccard coefficient, which is the percentage of nonzero coordinates that differ.
- custom distance function — A distance function specified using `@` (for example, `@distfun`). For details, see “Definitions” on page 32-6944.

In all cases, `tsne` uses squared pairwise distances to calculate the Gaussian kernel in the joint distribution of X .

Example: 'mahalanobis'

Exaggeration — Size of natural clusters in data

4 (default) | scalar value 1 or greater

Size of natural clusters in data, specified as a scalar value 1 or greater.

A large exaggeration makes `tsne` learn larger joint probabilities of Y and creates relatively more space between clusters in Y . `tsne` uses exaggeration in the first 99 optimization iterations.

If the value of Kullback-Leibler divergence increases in the early stage of the optimization, try reducing the exaggeration. See “`tsne` Settings” on page 15-143.

Example: 10

Data Types: `single` | `double`

NumDimensions — Dimension of the output Y

2 (default) | positive integer

Dimension of the output Y , specified as a positive integer. Generally, set `NumDimensions` to 2 or 3.

Example: 3

Data Types: `single` | `double`

NumPCAComponents — PCA dimension reduction

0 (default) | nonnegative integer

PCA dimension reduction, specified as a nonnegative integer. Before `tsne` embeds the high-dimensional data, it first reduces the dimensionality of the data to `NumPCAComponents` using the `pca` function. When `NumPCAComponents` is 0, `tsne` does not use PCA.

Example: 50

Data Types: `single` | `double`

Perplexity — Effective number of local neighbors of each point

30 (default) | positive scalar

Effective number of local neighbors of each point, specified as a positive scalar. See “t-SNE Algorithm” on page 15-127.

Larger perplexity causes `tsne` to use more points as nearest neighbors. Use a larger value of `Perplexity` for a large dataset. Typical `Perplexity` values are from 5 to 50. In the Barnes-Hut algorithm, `tsne` uses $\min(3*\text{Perplexity}, N-1)$ as the number of nearest neighbors. See “`tsne` Settings” on page 15-143.

Example: 10

Data Types: `single` | `double`

Standardize — Normalize input data

false (default) | true

Normalize input data, specified as `false` or `true`. When `true`, `tsne` centers and scales `X` by dividing the columns by their standard deviations.

When features in `X` are on different scales, set '`Standardize`' to `true`. Do this because the learning process is based on nearest neighbors, so features with large scales can override the contribution of features with small scales.

Example: true

Data Types: `logical`

Optimization Control**InitialY — Initial embedded points**

`1e-4*randn(N, NumDimensions)` (default) | n-by-NumDimensions real matrix

Initial embedded points, specified as an n-by-NumDimensions real matrix, where n is the number of rows of X. The tsne optimization algorithm uses these points as initial values.

Data Types: `single` | `double`

LearnRate — Learning rate for optimization process

`500` (default) | positive scalar

Learning rate for optimization process, specified as a positive scalar. Typically, set values from 100 through 1000.

When LearnRate is too small, tsne can converge to a poor local minimum. When LearnRate is too large, the optimization can initially have the Kullback-Leibler divergence increase rather than decrease. See “tsne Settings” on page 15-143.

Example: `1000`

Data Types: `single` | `double`

NumPrint — Iterative display frequency

`20` (default) | positive integer

Iterative display frequency, specified as a positive integer. When the Verbose name-value pair is not 0, tsne returns iterative display after every NumPrint iterations. If the Options name-value pair contains a nonempty 'OutputFcn' entry, then output functions run after every NumPrint iterations.

Example: `20`

Data Types: `single` | `double`

Options — Optimization options

structure containing the fields 'MaxIter', 'OutputFcn', and 'TolFun'

Optimization options, specified as a structure containing the fields 'MaxIter', 'OutputFcn', and 'TolFun'. Create 'Options' using `statset` or `struct`.

- 'MaxIter' — Positive integer specifying the maximum number of optimization iterations. Default: `1000`.

- `'OutputFcn'` — Function handle or cell array of function handles specifying one or more functions to call after every `NumPrint` optimization iterations. For syntax details, see “t-SNE Output Function” on page 15-134. Default: `[]`.
- `'TolFun'` — Stopping criterion for the optimization. The optimization exits when the norm of the gradient of the Kullback-Leibler divergence is less than `'TolFun'`. Default: `1e-10`.

Example: `options = statset('MaxIter',500)`

Data Types: `struct`

Theta — Barnes-Hut tradeoff parameter

0.5 (default) | scalar from 0 through 1

Barnes-Hut tradeoff parameter, specified as a scalar from 0 through 1. Higher values give a faster but less accurate optimization. Applies only when `Algorithm` is `'barneshut'`.

Example: `0.1`

Data Types: `single` | `double`

Verbose — Iterative display

0 (default) | 1 | 2

Iterative display, specified as 0, 1, or 2. When `Verbose` is not 0, `tsne` prints a summary table of the Kullback-Leibler divergence and the norm of its gradient every `NumPrint` iterations.

When `Verbose` is 2, `tsne` also prints the variances of Gaussian kernels. `tsne` uses these kernels in its computation of the joint probability of `X`. If you see a large difference in the scales of the minimum and maximum variances, you can sometimes get more suitable results by rescaling `X`.

Example: `2`

Data Types: `single` | `double`

Output Arguments

Y — Embedded points

`n`-by-`NumDimensions` matrix

Embedded points, returned as an n -by-NumDimensions matrix. Each row represents one embedded point. n is the number of rows of data X that do not contain any NaN entries. See “Plot Results with NaN Input Data” on page 32-6933.

Loss — Kullback-Leibler divergence

nonnegative scalar

Kullback-Leibler divergence between modeled input and output distributions, returned as a nonnegative scalar. For details, see “t-SNE Algorithm” on page 15-127.

Definitions

Custom Distance Function

The syntax of a custom distance function is as follows.

```
function D2 = distfun(ZI,ZJ)
```

`tsne` passes ZI and ZJ to your function, and your function computes the distance.

- ZI is a 1-by- n vector containing a single row from X or Y .
- ZJ is an m -by- n matrix containing multiple rows of X or Y .

Your function returns $D2$, which is an m -by-1 vector of distances. The j th element of $D2$ is the distance between the observations ZI and $ZJ(j, :)$.

Tip If your data are not sparse, then usually the built-in distance functions are faster than a function handle.

Algorithms

`tsne` constructs a set of embedded points in a low-dimensional space whose relative similarities mimic those of the original high-dimensional points. The embedded points show the clustering in the original data.

Roughly, the algorithm models the original points as coming from a Gaussian distribution, and the embedded points as coming from a Student’s t distribution. The algorithm tries to

minimize the Kullback-Leibler divergence between these two distributions by moving the embedded points.

For details, see “t-SNE” on page 15-126.

Introduced in R2017a

tstat

Student's t mean and variance

Syntax

```
[m,v] = tstat(nu)
```

Description

`[m,v] = tstat(nu)` returns the mean of and variance for Student's t distribution using the degrees of freedom in `nu`. `nu` can a vectors, matrix, or multidimensional array. The returned values for `m` and `v` are the same size as `nu`.

Examples

Compute Student's t Mean and Variance

Compute the mean and variance for Student's t distributions with degrees of freedom `nu` equal to 1 through 30.

```
nu = reshape(1:30,6,5);  
[m,v] = tstat(nu)
```

```
m = 6×5
```

```
NaN    0    0    0    0  
0      0    0    0    0  
0      0    0    0    0  
0      0    0    0    0  
0      0    0    0    0  
0      0    0    0    0
```

```
v = 6×5
```

NaN	1.4000	1.1818	1.1176	1.0870
NaN	1.3333	1.1667	1.1111	1.0833
3.0000	1.2857	1.1538	1.1053	1.0800
2.0000	1.2500	1.1429	1.1000	1.0769

1.5000	1.2000	1.1250	1.0909	1.0714

Note that the variance does not exist for one and two degrees of freedom.

Definitions

Student's t Mean and Variance

The mean of the Student's t distribution is

$$\text{mean} = 0$$

for degrees of freedom ν greater than 1. If ν equals 1, then the mean is undefined.

The variance of the Student's t distribution is

$$\text{var} = \frac{\nu}{\nu - 2}$$

for degrees of freedom ν greater than 2. If ν is less than or equal to 2, then the variance is undefined.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU arrays. For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

“Student's t Distribution” on page B-173

Introduced before R2006a

ttest

One-sample and paired-sample *t*-test

Syntax

```
h = ttest(x)
```

```
h = ttest(x,y)  
h = ttest(x,y,Name,Value)
```

```
h = ttest(x,m)  
h = ttest(x,m,Name,Value)
```

```
[h,p] = ttest(____)  
[h,p,ci,stats] = ttest(____)
```

Description

`h = ttest(x)` returns a test decision for the null hypothesis that the data in `x` comes from a normal distribution with mean equal to zero and unknown variance, using the one-sample *t*-test on page 32-6956. The alternative hypothesis is that the population distribution does not have a mean equal to zero. The result `h` is 1 if the test rejects the null hypothesis at the 5% significance level, and 0 otherwise.

`h = ttest(x,y)` returns a test decision for the null hypothesis that the data in `x - y` comes from a normal distribution with mean equal to zero and unknown variance, using the paired-sample *t*-test.

`h = ttest(x,y,Name,Value)` returns a test decision for the paired-sample *t*-test with additional options specified by one or more name-value pair arguments. For example, you can change the significance level or conduct a one-sided test.

`h = ttest(x,m)` returns a test decision for the null hypothesis that the data in `x` comes from a normal distribution with mean `m` and unknown variance. The alternative hypothesis is that the mean is not `m`.

`h = ttest(x,m,Name,Value)` returns a test decision for the one-sample *t*-test with additional options specified by one or more name-value pair arguments. For example, you can change the significance level or conduct a one-sided test.

`[h,p] = ttest(____)` also returns the *p*-value, *p*, of the test, using any of the input arguments from the previous syntax groups.

`[h,p,ci,stats] = ttest(____)` also returns the confidence interval *ci* for the mean of *x*, or of *x* – *y* for the paired *t*-test, and the structure *stats* containing information about the test statistic.

Examples

t-Test for Mean Equal to Zero

Load the sample data. Create a vector containing the third column of the stock returns data.

```
load stockreturns
x = stocks(:,3);
```

Test the null hypothesis that the sample data comes from a population with mean equal to zero.

```
[h,p,ci,stats] = ttest(x)
```

```
h = 1
```

```
p = 0.0106
```

```
ci = 2×1
```

```
    -0.7357
```

```
    -0.0997
```

```
stats = struct with fields:
```

```
    tstat: -2.6065
```

```
     df: 99
```

```
     sd: 1.6027
```

The returned value $h = 1$ indicates that `ttest` rejects the null hypothesis at the 5% significance level.

t-Test at Different Significance Level

Load the sample data. Create a vector containing the third column of the stock returns data.

```
load stockreturns  
x = stocks(:,3);
```

Test the null hypothesis that the sample data are from a population with mean equal to zero at the 1% significance level.

```
h = ttest(x,0,'Alpha',0.01)  
  
h = 0
```

The returned value $h = 0$ indicates that `ttest` does not reject the null hypothesis at the 1% significance level.

Paired-Sample t-Test

Load the sample data. Create vectors containing the first and second columns of the data matrix to represent students' grades on two exams.

```
load examgrades  
x = grades(:,1);  
y = grades(:,2);
```

Test the null hypothesis that the pairwise difference between data vectors x and y has a mean equal to zero.

```
[h,p] = ttest(x,y)  
  
h = 0  
  
p = 0.9805
```

The returned value of $h = 0$ indicates that `ttest` does not reject the null hypothesis at the default 5% significance level.

Paired-Sample t-Test at Different Significance Level

Load the sample data. Create vectors containing the first and second columns of the data matrix to represent students' grades on two exams.

```
load examgrades
x = grades(:,1);
y = grades(:,2);
```

Test the null hypothesis that the pairwise difference between data vectors x and y has a mean equal to zero at the 1% significance level.

```
[h,p] = ttest(x,y,'Alpha',0.01)

h = 0

p = 0.9805
```

The returned value of $h = 0$ indicates that `ttest` does not reject the null hypothesis at the 1% significance level.

t-Test for a Hypothesized Mean

Load the sample data. Create a vector containing the first column of the students' exam grades data.

```
load examgrades
x = grades(:,1);
```

Test the null hypothesis that sample data comes from a distribution with mean $m = 75$.

```
h = ttest(x,75)

h = 0
```

The returned value of $h = 0$ indicates that `ttest` does not reject the null hypothesis at the 5% significance level.

One-Sided t-Test

Load the sample data. Create a vector containing the first column of the students' exam grades data.

```
load examgrades  
x = grades(:,1);
```

Test the null hypothesis that the data comes from a population with mean equal to 65, against the alternative that the mean is greater than 65.

```
h = ttest(x,65,'Tail','right')
```

```
h = 1
```

The returned value of `h = 1` indicates that `ttest` rejects the null hypothesis at the 5% significance level, in favor of the alternate hypothesis that the data comes from a population with a mean greater than 65.

Input Arguments

x — Sample data

vector | matrix | multidimensional array

Sample data, specified as a vector, matrix, or multidimensional array on page 32-6956. `ttest` performs a separate *t*-test along each column and returns a vector of results. If `y` sample data is specified, `x` and `y` must be the same size.

Data Types: `single` | `double`

y — Sample data

vector | matrix | multidimensional array

Sample data, specified as a vector, matrix, or multidimensional array on page 32-6956. If `y` sample data is specified, `x` and `y` must be the same size.

Data Types: `single` | `double`

m — Hypothesized population mean

0 (default) | scalar value

Hypothesized population mean, specified as a scalar value.

Data Types: single | double

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example: `'Tail', 'right', 'Alpha', 0.01` conducts a right-tailed hypothesis test at the 1% significance level.

Alpha — Significance level

0.05 (default) | scalar value in the range (0,1)

Significance level of the hypothesis test, specified as the comma-separated pair consisting of `'Alpha'` and a scalar value in the range (0,1).

Example: `'Alpha', 0.01`

Data Types: single | double

Dim — Dimension

first nonsingleton dimension (default) | positive integer value

Dimension of the input matrix along which to test the means, specified as the comma-separated pair consisting of `'Dim'` and a positive integer value. For example, specifying `'Dim', 1` tests the column means, while `'Dim', 2` tests the row means.

Example: `'Dim', 2`

Data Types: single | double

Tail — Type of alternative hypothesis

'both' (default) | 'right' | 'left'

Type of alternative hypothesis to evaluate, specified as the comma-separated pair consisting of `'Tail'` and one of the following.

'both'	Test the alternative hypothesis that the population mean is not m .
'right'	Test the alternative hypothesis that the population mean is greater than m .
'left'	Test the alternative hypothesis that the population mean is less than m .

Example: 'Tail', 'right'

Output Arguments

h — Hypothesis test result

1 | 0

Hypothesis test result, returned as 1 or 0.

- If $h = 1$, this indicates the rejection of the null hypothesis at the Alpha significance level.
- If $h = 0$, this indicates a failure to reject the null hypothesis at the Alpha significance level.

p — *p*-value

scalar value in the range [0,1]

p-value of the test, returned as a scalar value in the range [0,1]. p is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. Small values of p cast doubt on the validity of the null hypothesis.

ci — Confidence interval

vector

Confidence interval for the true population mean, returned as a two-element vector containing the lower and upper boundaries of the $100 \times (1 - \text{Alpha})\%$ confidence interval.

stats — Test statistics

structure

Test statistics, returned as a structure containing the following:

- **tstat** — Value of the test statistic.

- `df` — Degrees of freedom of the test.
- `sd` — Estimated population standard deviation. For a paired *t*-test, `sd` is the standard deviation of $x - y$.

Definitions

One-Sample *t*-Test

The one-sample *t*-test is a parametric test of the location parameter when the population standard deviation is unknown.

The test statistic is

$$t = \frac{\bar{x} - \mu}{s/\sqrt{n}},$$

where \bar{x} is the sample mean, μ is the hypothesized population mean, s is the sample standard deviation, and n is the sample size. Under the null hypothesis, the test statistic has Student's *t* distribution with $n - 1$ degrees of freedom.

Multidimensional Array

A multidimensional array has more than two dimensions. For example, if `x` is a 1-by-3-by-4 array, then `x` is a three-dimensional array.

First Nonsingleton Dimension

The first nonsingleton dimension is the first dimension of an array whose size is not equal to 1. For example, if `x` is a 1-by-2-by-3-by-4 array, then the second dimension is the first nonsingleton dimension of `x`.

Tips

- Use `sampsizepwr` to calculate:
 - The sample size that corresponds to specified power and parameter values;

- The power achieved for a particular sample size, given the true parameter value;
- The parameter value detectable with the specified sample size and power.

Extended Capabilities

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU arrays. For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

Introduced before R2006a

ttest2

Two-sample *t*-test

Syntax

```
h = ttest2(x,y)
h = ttest2(x,y,Name,Value)
[h,p] = ttest2(____)
[h,p,ci,stats] = ttest2(____)
```

Description

`h = ttest2(x,y)` returns a test decision for the null hypothesis that the data in vectors `x` and `y` comes from independent random samples from normal distributions with equal means and equal but unknown variances, using the two-sample *t*-test on page 32-6963. The alternative hypothesis is that the data in `x` and `y` comes from populations with unequal means. The result `h` is 1 if the test rejects the null hypothesis at the 5% significance level, and 0 otherwise.

`h = ttest2(x,y,Name,Value)` returns a test decision for the two-sample *t*-test with additional options specified by one or more name-value pair arguments. For example, you can change the significance level or conduct the test without assuming equal variances.

`[h,p] = ttest2(____)` also returns the *p*-value, `p`, of the test, using any of the input arguments in the previous syntaxes.

`[h,p,ci,stats] = ttest2(____)` also returns the confidence interval on the difference of the population means, `ci`, and the structure `stats` containing information about the test statistic.

Examples

Two-Sample t-Test for Equal Means

Load the data set. Create vectors containing the first and second columns of the data matrix to represent students' grades on two exams.

```
load examgrades
x = grades(:,1);
y = grades(:,2);
```

Test the null hypothesis that the two data samples are from populations with equal means.

```
[h,p,ci,stats] = ttest2(x,y)
```

```
h = 0
```

```
p = 0.9867
```

```
ci = 2×1
```

```
    -1.9438
     1.9771
```

```
stats = struct with fields:
    tstat: 0.0167
     df: 238
     sd: 7.7084
```

The returned value of $h = 0$ indicates that `ttest2` does not reject the null hypothesis at the default 5% significance level.

t-Test for Equal Means Without Assuming Equal Variances

Load the data set. Create vectors containing the first and second columns of the data matrix to represent students' grades on two exams.

```
load examgrades
x = grades(:,1);
y = grades(:,2);
```

Test the null hypothesis that the two data vectors are from populations with equal means, without assuming that the populations also have equal variances.

```
[h,p] = ttest2(x,y,'Vartype','unequal')
```

```
h = 0
```

```
p = 0.9867
```

The returned value of `h = 0` indicates that `ttest2` does not reject the null hypothesis at the default 5% significance level even if equal variances are not assumed.

Input Arguments

x — Sample data

vector | matrix | multidimensional array

Sample data, specified as a vector, matrix, or multidimensional array. `ttest2` treats NaN values as missing data and ignores them.

- If `x` and `y` are specified as vectors, they do not need to be the same length.
- If `x` and `y` are specified as matrices, they must have the same number of columns. `ttest2` performs a separate *t*-test along each column and returns a vector of results.
- If `x` and `y` are specified as multidimensional arrays on page 32-6964, they must have the same size along all but the first nonsingleton dimension on page 32-6964.

Data Types: `single` | `double`

y — Sample data

vector | matrix | multidimensional array

Sample data, specified as a vector, matrix, or multidimensional array. `ttest2` treats NaN values as missing data and ignores them.

- If `x` and `y` are specified as vectors, they do not need to be the same length.
- If `x` and `y` are specified as matrices, they must have the same number of columns. `ttest2` performs a separate *t*-test along each column and returns a vector of results.
- If `x` and `y` are specified as multidimensional arrays on page 32-6964, they must have the same size along all but the first nonsingleton dimension on page 32-6964. `ttest2` works along the first nonsingleton dimension.

Data Types: single | double

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'Tail','right','Alpha',0.01,'Vartype','unequal'` specifies a right-tailed test at the 1% significance level, and does not assume that `x` and `y` have equal population variances.

Alpha — Significance level

0.05 (default) | scalar value in the range (0,1)

Significance level of the hypothesis test, specified as the comma-separated pair consisting of `'Alpha'` and a scalar value in the range (0,1).

Example: `'Alpha',0.01`

Data Types: single | double

Dim — Dimension

first nonsingleton dimension (default) | positive integer value

Dimension of the input matrix along which to test the means, specified as the comma-separated pair consisting of `'Dim'` and a positive integer value. For example, specifying `'Dim',1` tests the column means, while `'Dim',2` tests the row means.

Example: `'Dim',2`

Data Types: single | double

Tail — Type of alternative hypothesis

'both' (default) | 'right' | 'left'

Type of alternative hypothesis to evaluate, specified as the comma-separated pair consisting of `'Tail'` and one of the following.

'both'	Test the alternative hypothesis that the population means are not equal.
--------	--

'right'	Test the alternative hypothesis that the population mean of x is greater than the population mean of y .
'left'	Test the alternative hypothesis that the population mean of x is less than the population mean of y .

Example: 'Tail', 'right'

Vartype — Variance type

'equal' (default) | 'unequal'

Variance type, specified as the comma-separated pair consisting of 'Vartype' and one of the following.

'equal'	Conduct test using the assumption that x and y are from normal distributions with unknown but equal variances.
'unequal'	Conduct test using the assumption that x and y are from normal distributions with unknown and unequal variances. This is called the Behrens-Fisher problem. <code>ttest2</code> uses Satterthwaite's approximation for the effective degrees of freedom.

Vartype must be a single variance type, even when x is a matrix or a multidimensional array.

Example: 'Vartype', 'unequal'

Output Arguments

h — Hypothesis test result

1 | 0

Hypothesis test result, returned as 1 or 0.

- If $h = 1$, this indicates the rejection of the null hypothesis at the Alpha significance level.
- If $h = 0$, this indicates a failure to reject the null hypothesis at the Alpha significance level.

p — p-value

scalar value in the range [0,1]

p -value of the test, returned as a scalar value in the range [0,1]. p is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. Small values of p cast doubt on the validity of the null hypothesis.

ci — Confidence interval

vector

Confidence interval for the difference in population means of x and y , returned as a two-element vector containing the lower and upper boundaries of the $100 \times (1 - \text{Alpha})\%$ confidence interval.

stats — Test statistics

structure

Test statistics for the two-sample t -test, returned as a structure containing the following:

- `tstat` — Value of the test statistic.
- `df` — Degrees of freedom of the test.
- `sd` — Pooled estimate of the population standard deviation (for the equal variance case) or a vector containing the unpooled estimates of the population standard deviations (for the unequal variance case).

Definitions

Two-Sample t -test

The two-sample t -test is a parametric test that compares the location parameter of two independent data samples.

The test statistic is

$$t = \frac{\bar{x} - \bar{y}}{\sqrt{\frac{s_x^2}{n} + \frac{s_y^2}{m}}},$$

where \bar{x} and \bar{y} are the sample means, s_x and s_y are the sample standard deviations, and n and m are the sample sizes.

In the case where it is assumed that the two data samples are from populations with equal variances, the test statistic under the null hypothesis has Student's t distribution

with $n + m - 2$ degrees of freedom, and the sample standard deviations are replaced by the pooled standard deviation

$$s = \sqrt{\frac{(n-1)s_x^2 + (m-1)s_y^2}{n+m-2}}.$$

In the case where it is not assumed that the two data samples are from populations with equal variances, the test statistic under the null hypothesis has an approximate Student's t distribution with a number of degrees of freedom given by Satterthwaite's approximation. This test is sometimes called Welch's t -test.

Multidimensional Array

A multidimensional array has more than two dimensions. For example, if x is a 1-by-3-by-4 array, then x is a three-dimensional array.

First Nonsingleton Dimension

The first nonsingleton dimension is the first dimension of an array whose size is not equal to 1. For example, if x is a 1-by-2-by-3-by-4 array, then the second dimension is the first nonsingleton dimension of x .

Tips

- Use `sampsizepwr` to calculate:
 - The sample size that corresponds to specified power and parameter values;
 - The power achieved for a particular sample size, given the true parameter value;
 - The parameter value detectable with the specified sample size and power.

BetaDistribution

Beta probability distribution object

Description

A `BetaDistribution` object consist of parameters, a model description, and sample data for a beta probability distribution.

The beta distribution describes a family of curves that are unique in that they are nonzero only on the interval $(0,1)$. A more general version of the distribution assigns parameters to the endpoints of the interval.

The beta distribution uses the following parameters.

Parameter	Description	Support
a	First shape parameter	$a > 0$
b	Second shape parameter	$b > 0$

Creation

There are several ways to create a `BetaDistribution` probability distribution object.

- Create a distribution with specified parameter values using `makedist`.
- Fit a distribution to data using `fitdist`.
- Interactively fit a distribution to data using the **Distribution Fitter** app.

Properties

Distribution Parameters

a — First shape parameter

positive scalar value

First shape parameter of the beta distribution, specified as a positive scalar value.

Data Types: `single` | `double`

b — Second shape parameter

positive scalar value

Second shape parameter of the beta distribution, specified as a positive scalar value.

Data Types: `single` | `double`

Distribution Characteristics

IsTruncated — Logical flag for truncated distribution

0 | 1

This property is read-only.

Logical flag for truncated distribution, specified as a logical value. If `IsTruncated` equals 0, the distribution is not truncated. If `IsTruncated` equals 1, the distribution is truncated.

Data Types: `logical`

NumParameters — Number of parameters

positive integer value

This property is read-only.

Number of parameters for the probability distribution, specified as a positive integer value.

Data Types: `double`

ParameterCovariance — Covariance matrix of the parameter estimates

matrix of scalar values

This property is read-only.

Covariance matrix of the parameter estimates, specified as a p -by- p matrix, where p is the number of parameters in the distribution. The (i,j) element is the covariance between the estimates of the i th parameter and the j th parameter. The (i,i) element is the estimated variance of the i th parameter. If parameter i is fixed rather than estimated by fitting the distribution to data, then the (i,i) elements of the covariance matrix are 0.

Data Types: `double`

ParameterIsFixed — Logical flag for fixed parameters

array of logical values

This property is read-only.

Logical flag for fixed parameters, specified as an array of logical values. If `0`, the corresponding parameter in the `ParameterNames` array is not fixed. If `1`, the corresponding parameter in the `ParameterNames` array is fixed.

Data Types: `logical`

ParameterValues — Distribution parameter values

vector of scalar values

This property is read-only.

Distribution parameter values, specified as a vector.

Data Types: `single` | `double`

Truncation — Truncation interval

vector of scalar values

This property is read-only.

Truncation interval for the probability distribution, specified as a vector containing the lower and upper truncation boundaries.

Data Types: `single` | `double`

Other Object Properties

DistributionName — Probability distribution name

character vector

This property is read-only.

Probability distribution name, specified as a character vector.

Data Types: `char`

InputData — Data used for distribution fitting

structure

This property is read-only.

Data used for distribution fitting, specified as a structure containing the following:

- **data**: Data vector used for distribution fitting.
- **cens**: Censoring vector, or empty if none.
- **freq**: Frequency vector, or empty if none.

Data Types: `struct`

ParameterDescription — Distribution parameter descriptions

cell array of character vectors

This property is read-only.

Distribution parameter descriptions, specified as a cell array of character vectors. Each cell contains a short description of one distribution parameter.

Data Types: `char`

ParameterNames — Distribution parameter names

cell array of character vectors

This property is read-only.

Distribution parameter names, specified as a cell array of character vectors.

Data Types: `char`

Object Functions

<code>cdf</code>	Cumulative distribution function
<code>icdf</code>	Inverse cumulative distribution function
<code>iqr</code>	Interquartile range
<code>mean</code>	Mean of probability distribution
<code>median</code>	Median of probability distribution
<code>negloglik</code>	Negative loglikelihood of probability distribution

proflik	Profile likelihood function for probability distribution
random	Random numbers
std	Standard deviation of probability distribution
truncate	Truncate probability distribution object
var	Variance of probability distribution

Examples

Create a Beta Distribution Object Using Default Parameters

Create a beta distribution object using the default parameter values.

```
pd = makedist('Beta')
```

```
pd =  
BetaDistribution  
  
Beta distribution  
a = 1  
b = 1
```

Create a Beta Distribution Object Using Specified Parameters

Create a beta distribution object by specifying the parameter values.

```
pd = makedist('Beta', 'a', 2, 'b', 4)
```

```
pd =  
BetaDistribution  
  
Beta distribution  
a = 2  
b = 4
```

Compute the mean of the distribution.

```
m = mean(pd)
```

```
m = 0.3333
```

BinomialDistribution

Binomial probability distribution object

Description

A `BinomialDistribution` object consists of parameters, a model description, and sample data for a binomial probability distribution

The binomial distribution models the total number of successes in repeated trials from an infinite population under the following conditions:

- Only two outcomes are possible for each of n trials.
- The probability of success for each trial is constant.
- All trials are independent of each other.

The binomial distribution uses the following parameters.

Parameter	Description	Support
N	Number of trials	positive integer
p	Probability of success	$0 \leq p \leq 1$

Creation

There are several ways to create a `BinomialDistribution` probability distribution object.

- Create a distribution with specified parameter values using `makedist`.
- Fit a distribution to data using `fitdist`.
- Interactively fit a distribution to data using the **Distribution Fitter** app.

Properties

Distribution Parameters

N — Number of trials

positive integer value

Number of trials for the binomial distribution, specified as a positive integer value.

Data Types: `single` | `double`

p — Probability of success

positive scalar value in the range $[0, 1]$

Probability of success of any individual trial for the binomial distribution, specified as a positive scalar value in the range $[0, 1]$.

Data Types: `single` | `double`

Distribution Characteristics

IsTruncated — Logical flag for truncated distribution

0 | 1

This property is read-only.

Logical flag for truncated distribution, specified as a logical value. If `IsTruncated` equals 0, the distribution is not truncated. If `IsTruncated` equals 1, the distribution is truncated.

Data Types: `logical`

NumParameters — Number of parameters

positive integer value

This property is read-only.

Number of parameters for the probability distribution, specified as a positive integer value.

Data Types: `double`

ParameterCovariance — Covariance matrix of the parameter estimates

matrix of scalar values

This property is read-only.

Covariance matrix of the parameter estimates, specified as a p -by- p matrix, where p is the number of parameters in the distribution. The (i,j) element is the covariance between the estimates of the i th parameter and the j th parameter. The (i,i) element is the estimated variance of the i th parameter. If parameter i is fixed rather than estimated by fitting the distribution to data, then the (i,i) elements of the covariance matrix are 0.

Data Types: double

ParameterIsFixed — Logical flag for fixed parameters

array of logical values

This property is read-only.

Logical flag for fixed parameters, specified as an array of logical values. If 0, the corresponding parameter in the `ParameterNames` array is not fixed. If 1, the corresponding parameter in the `ParameterNames` array is fixed.

Data Types: logical

ParameterValues — Distribution parameter values

vector of scalar values

This property is read-only.

Distribution parameter values, specified as a vector.

Data Types: single | double

Truncation — Truncation interval

vector of scalar values

This property is read-only.

Truncation interval for the probability distribution, specified as a vector containing the lower and upper truncation boundaries.

Data Types: single | double

Other Object Properties

DistributionName — Probability distribution name

character vector

This property is read-only.

Probability distribution name, specified as a character vector.

Data Types: `char`

InputData — Data used for distribution fitting

structure

This property is read-only.

Data used for distribution fitting, specified as a structure containing the following:

- `data`: Data vector used for distribution fitting.
- `cens`: Censoring vector, or empty if none.
- `freq`: Frequency vector, or empty if none.

Data Types: `struct`

ParameterDescription — Distribution parameter descriptions

cell array of character vectors

This property is read-only.

Distribution parameter descriptions, specified as a cell array of character vectors. Each cell contains a short description of one distribution parameter.

Data Types: `char`

ParameterNames — Distribution parameter names

cell array of character vectors

This property is read-only.

Distribution parameter names, specified as a cell array of character vectors.

Data Types: `char`

<code>proflik</code>	Profile likelihood function for probability distribution
<code>random</code>	Random numbers
<code>std</code>	Standard deviation of probability distribution
<code>truncate</code>	Truncate probability distribution object
<code>var</code>	Variance of probability distribution

Examples

Create a Negative Binomial Distribution Object Using Default Parameters

Create a negative binomial distribution object using the default parameter values.

```
pd = makedist('NegativeBinomial')  
  
pd =  
  NegativeBinomialDistribution  
  
  Negative Binomial distribution  
  R = 1  
  P = 0.5
```

Create a Binomial Distribution Object Using Specified Parameters

Create a binomial distribution object by specifying the parameter values.

```
pd = makedist('Binomial', 'N', 30, 'p', 0.25)  
  
pd =  
  BinomialDistribution
```

```
Binomial distribution
N = 30
p = 0.25
```

Compute the mean of the distribution.

```
m = mean(pd)
```

```
m = 7.5000
```

BirnbauSaundersDistribution

Birnbau-Saunders probability distribution object

Description

A `BirnbauSaundersDistribution` object consists of parameters, a model description, and sample data for a Birnbau-Saunders probability distribution.

The Birnbau-Saunders distribution was originally proposed as a lifetime model for materials subject to cyclic patterns of stress and strain, where the ultimate failure of the material comes from the growth of a prominent flaw. In materials science, Miner's Rule suggests that the damage occurring after n cycles, at a stress level with an expected lifetime of N cycles, is proportional to n / N . Whenever Miner's Rule applies, the Birnbau-Saunders model is a reasonable choice for a lifetime distribution model.

The Birnbau-Saunders distribution uses the following parameters.

Parameter	Description	Support
beta	scale parameter	$\beta > 0$
gamma	shape parameter	$\gamma > 0$

Creation

There are several ways to create a `BirnbauSaundersDistribution` probability distribution object.

- Create a distribution with specified parameter values using `makedist`.
- Fit a distribution to data using `fitdist`.
- Interactively fit a distribution to data using the **Distribution Fitter** app.

Properties

Distribution Parameters

beta — Scale parameter

positive scalar value

Scale parameter of the Birnbaum-Saunders distribution, specified as a positive scalar value.

Data Types: `single` | `double`

gamma — Shape parameter

positive scalar value

Shape parameter of the Birnbaum-Saunders distribution, specified as a positive scalar value.

Data Types: `single` | `double`

Distribution Characteristics

IsTruncated — Logical flag for truncated distribution

0 | 1

This property is read-only.

Logical flag for truncated distribution, specified as a logical value. If `IsTruncated` equals 0, the distribution is not truncated. If `IsTruncated` equals 1, the distribution is truncated.

Data Types: `logical`

NumParameters — Number of parameters

positive integer value

This property is read-only.

Number of parameters for the probability distribution, specified as a positive integer value.

Data Types: `double`

ParameterCovariance — Covariance matrix of the parameter estimates

matrix of scalar values

This property is read-only.

Covariance matrix of the parameter estimates, specified as a p -by- p matrix, where p is the number of parameters in the distribution. The (i,j) element is the covariance between the estimates of the i th parameter and the j th parameter. The (i,i) element is the estimated variance of the i th parameter. If parameter i is fixed rather than estimated by fitting the distribution to data, then the (i,i) elements of the covariance matrix are 0.

Data Types: double

ParameterIsFixed — Logical flag for fixed parameters

array of logical values

This property is read-only.

Logical flag for fixed parameters, specified as an array of logical values. If 0, the corresponding parameter in the `ParameterNames` array is not fixed. If 1, the corresponding parameter in the `ParameterNames` array is fixed.

Data Types: logical

ParameterValues — Distribution parameter values

vector of scalar values

This property is read-only.

Distribution parameter values, specified as a vector.

Data Types: single | double

Truncation — Truncation interval

vector of scalar values

This property is read-only.

Truncation interval for the probability distribution, specified as a vector containing the lower and upper truncation boundaries.

Data Types: single | double

Other Object Properties

DistributionName — Probability distribution name

character vector

This property is read-only.

Probability distribution name, specified as a character vector.

Data Types: `char`

InputData — Data used for distribution fitting

structure

This property is read-only.

Data used for distribution fitting, specified as a structure containing the following:

- `data`: Data vector used for distribution fitting.
- `cens`: Censoring vector, or empty if none.
- `freq`: Frequency vector, or empty if none.

Data Types: `struct`

ParameterDescription — Distribution parameter descriptions

cell array of character vectors

This property is read-only.

Distribution parameter descriptions, specified as a cell array of character vectors. Each cell contains a short description of one distribution parameter.

Data Types: `char`

ParameterNames — Distribution parameter names

cell array of character vectors

This property is read-only.

Distribution parameter names, specified as a cell array of character vectors.

Data Types: `char`

Object Functions

<code>cdf</code>	Cumulative distribution function

<code>paramci</code>	Confidence intervals for probability distribution parameters
<code>pdf</code>	Probability density function
<code>proflik</code>	Profile likelihood function for probability distribution
<code>random</code>	Random numbers
<code>std</code>	Standard deviation of probability distribution
<code>truncate</code>	Truncate probability distribution object
<code>var</code>	Variance of probability distribution

Examples

Create a Birnbau-Saunders Distribution Object Using Default Parameters

Create a Birnbau-Saunders distribution object using the default parameter values.

```
pd = makedist('BirnbauSaunders')  
  
pd =  
  BirnbauSaundersDistribution  
  
  Birnbau-Saunders distribution  
    beta = 1  
    gamma = 1
```

Create a Birnbau-Saunders Distribution Object Using Specified Parameter Values

Create a Birnbau-Saunders distribution object by specifying the parameter values.

```
pd = makedist('BirnbauSaunders', 'beta', 2, 'gamma', 5)  
  
pd =  
  BirnbauSaundersDistribution
```

```
Birnbaum-Saunders distribution  
  beta = 2  
  gamma = 5
```

Compute the mean of the distribution.

```
m = mean(pd)
```

```
m = 27
```

BurrDistribution

Burr probability distribution object

Description

A `BurrDistribution` object consists of parameters, a model description, and sample data for a Burr probability distribution.

The Burr distribution is a three-parameter family of distributions on the positive real line. It can fit a wide range of empirical data, and is used in various fields such as finance, hydrology, and reliability to model a variety of data types.

The Burr distribution uses the following parameters.

Parameter	Description	Support
alpha	Scale parameter	$\alpha > 0$
c	First shape parameter	$c > 0$
k	Second shape parameter	$k > 0$

Creation

There are several ways to create a `BurrDistribution` probability distribution object.

- Create a distribution with specified parameter values using `makedist`.
- Fit a distribution to data using `fitdist`.
- Interactively fit a distribution to data using the **Distribution Fitter** app.

Properties

Distribution Parameters

alpha — Scale parameter

positive scalar value

Scale parameter of the Burr distribution, specified as a positive scalar value.

Data Types: `single` | `double`

c — First shape parameter

positive scalar value

First shape parameter of the Burr distribution, specified as a positive scalar value.

Data Types: `single` | `double`

k — Second shape parameter

positive scalar value

Second shape parameter of the Burr distribution, specified as a positive scalar value.

Data Types: `single` | `double`

Distribution Characteristics

IsTruncated — Logical flag for truncated distribution

0 | 1

This property is read-only.

Logical flag for truncated distribution, specified as a logical value. If `IsTruncated` equals 0, the distribution is not truncated. If `IsTruncated` equals 1, the distribution is truncated.

Data Types: `logical`

NumParameters — Number of parameters

positive integer value

This property is read-only.

Number of parameters for the probability distribution, specified as a positive integer value.

Data Types: `double`

ParameterCovariance — Covariance matrix of the parameter estimates

matrix of scalar values

This property is read-only.

Covariance matrix of the parameter estimates, specified as a p -by- p matrix, where p is the number of parameters in the distribution. The (i,j) element is the covariance between the estimates of the i th parameter and the j th parameter. The (i,i) element is the estimated variance of the i th parameter. If parameter i is fixed rather than estimated by fitting the distribution to data, then the (i,i) elements of the covariance matrix are 0.

Data Types: `double`

ParameterIsFixed — Logical flag for fixed parameters

array of logical values

This property is read-only.

Logical flag for fixed parameters, specified as an array of logical values. If 0, the corresponding parameter in the `ParameterNames` array is not fixed. If 1, the corresponding parameter in the `ParameterNames` array is fixed.

Data Types: `logical`

ParameterValues — Distribution parameter values

vector of scalar values

This property is read-only.

Distribution parameter values, specified as a vector.

Data Types: `single` | `double`

Truncation — Truncation interval

vector of scalar values

This property is read-only.

Truncation interval for the probability distribution, specified as a vector containing the lower and upper truncation boundaries.

Data Types: `single` | `double`

Other Object Properties

DistributionName — Probability distribution name

character vector

This property is read-only.

Probability distribution name, specified as a character vector.

Data Types: `char`

InputData — Data used for distribution fitting

structure

This property is read-only.

Data used for distribution fitting, specified as a structure containing the following:

- `data`: Data vector used for distribution fitting.
- `cens`: Censoring vector, or empty if none.
- `freq`: Frequency vector, or empty if none.

Data Types: `struct`

ParameterDescription — Distribution parameter descriptions

cell array of character vectors

This property is read-only.

Distribution parameter descriptions, specified as a cell array of character vectors. Each cell contains a short description of one distribution parameter.

Data Types: `char`

ParameterNames — Distribution parameter names

cell array of character vectors

This property is read-only.

Distribution parameter names, specified as a cell array of character vectors.

Data Types: char

Object Functions

cdf	Cumulative distribution function
icdf	Inverse cumulative distribution function
iqr	Interquartile range
mean	Mean of probability distribution
median	Median of probability distribution
negloglik	Negative loglikelihood of probability distribution
paramci	Confidence intervals for probability distribution parameters
pdf	Probability density function
proflik	Profile likelihood function for probability distribution
random	Random numbers
std	Standard deviation of probability distribution
truncate	Truncate probability distribution object
var	Variance of probability distribution

Examples

Create a Burr Distribution Object Using Default Parameters

Create a Burr distribution object using the default parameter values.

```
pd = makedist('Burr')  
  
pd =  
    BurrDistribution  
  
    Burr distribution  
    alpha = 1  
    c = 1  
    k = 1
```

Create a Burr Distribution Object Using Specified Parameters

Create a Burr distribution object by specifying parameter values.

```
pd = makedist('Burr', 'alpha', 1, 'c', 2, 'k', 5)
```

```
pd =  
  BurrDistribution  
  
  Burr distribution  
    alpha = 1  
      c = 2  
      k = 5
```

Compute the mean of the distribution.

```
m = mean(pd)
```

```
m = 0.4295
```

ExponentialDistribution

Exponential probability distribution object

Description

An `ExponentialDistribution` object consists of parameters, a model description, and sample data for an exponential probability distribution.

The exponential distribution is used to model events that occur randomly over time, and its main application area is studies of lifetimes. It is a special case of the gamma distribution with the shape parameter $a = 1$.

The exponential distribution uses the following parameters.

Parameter	Description	Support
<code>mu</code>	Mean	$\mu > 0$

Creation

There are several ways to create a `ExponentialDistribution` probability distribution object.

- Create a distribution with specified parameter values using `makedist`.
- Fit a distribution to data using `fitdist`.
- Interactively fit a distribution to data using the **Distribution Fitter** app.

Properties

Distribution Parameter

mu — Mean

positive scalar value

Mean of the exponential distribution, specified as a positive scalar value.

Data Types: `single` | `double`

Distribution Characteristics

IsTruncated — Logical flag for truncated distribution

`0` | `1`

This property is read-only.

Logical flag for truncated distribution, specified as a logical value. If `IsTruncated` equals `0`, the distribution is not truncated. If `IsTruncated` equals `1`, the distribution is truncated.

Data Types: `logical`

NumParameters — Number of parameters

positive integer value

This property is read-only.

Number of parameters for the probability distribution, specified as a positive integer value.

Data Types: `double`

ParameterCovariance — Covariance matrix of the parameter estimates

matrix of scalar values

This property is read-only.

Covariance matrix of the parameter estimates, specified as a p -by- p matrix, where p is the number of parameters in the distribution. The (i,j) element is the covariance between the estimates of the i th parameter and the j th parameter. The (i,i) element is the estimated variance of the i th parameter. If parameter i is fixed rather than estimated by fitting the distribution to data, then the (i,i) elements of the covariance matrix are 0.

Data Types: `double`

ParameterIsFixed — Logical flag for fixed parameters

array of logical values

This property is read-only.

Logical flag for fixed parameters, specified as an array of logical values. If 0, the corresponding parameter in the `ParameterNames` array is not fixed. If 1, the corresponding parameter in the `ParameterNames` array is fixed.

Data Types: `logical`

ParameterValues — Distribution parameter values

vector of scalar values

This property is read-only.

Distribution parameter values, specified as a vector.

Data Types: `single` | `double`

Truncation — Truncation interval

vector of scalar values

This property is read-only.

Truncation interval for the probability distribution, specified as a vector containing the lower and upper truncation boundaries.

Data Types: `single` | `double`

Other Object Properties

DistributionName — Probability distribution name

character vector

This property is read-only.

Probability distribution name, specified as a character vector.

Data Types: `char`

InputData — Data used for distribution fitting

structure

This property is read-only.

Data used for distribution fitting, specified as a structure containing the following:

- **data**: Data vector used for distribution fitting.
- **cens**: Censoring vector, or empty if none.
- **freq**: Frequency vector, or empty if none.

Data Types: `struct`

ParameterDescription — Distribution parameter descriptions

cell array of character vectors

This property is read-only.

Distribution parameter descriptions, specified as a cell array of character vectors. Each cell contains a short description of one distribution parameter.

Data Types: `char`

ParameterNames — Distribution parameter names

cell array of character vectors

This property is read-only.

Distribution parameter names, specified as a cell array of character vectors.

Data Types: `char`

Object Functions

<code>cdf</code>	Cumulative distribution function
<code>icdf</code>	Inverse cumulative distribution function
<code>iqr</code>	Interquartile range
<code>mean</code>	Mean of probability distribution
<code>median</code>	Median of probability distribution
<code>negloglik</code>	Negative loglikelihood of probability distribution
<code>paramci</code>	Confidence intervals for probability distribution parameters
<code>pdf</code>	Probability density function
<code>proflik</code>	Profile likelihood function for probability distribution
<code>random</code>	Random numbers
<code>std</code>	Standard deviation of probability distribution
<code>truncate</code>	Truncate probability distribution object
<code>var</code>	Variance of probability distribution

Examples

Create an Exponential Distribution Object Using Default Parameters

Create an exponential distribution object using the default parameter values.

```
pd = makedist('Exponential')  
  
pd =  
    ExponentialDistribution  
  
    Exponential distribution  
    mu = 1
```

Create an Exponential Distribution Object Using Specified Parameters

Create an exponential distribution object by specifying the parameter values.

```
pd = makedist('Exponential','mu',2)  
  
pd =  
    ExponentialDistribution  
  
    Exponential distribution  
    mu = 2
```

Compute the variance of the distribution.

```
v = var(pd)  
  
v = 4
```

ExtremeValueDistribution

Extreme value probability distribution object

Description

An `ExtremeValueDistribution` object consists of parameters, a model description, and sample data for an extreme value probability distribution.

The extreme value distribution is appropriate for modeling the smallest value from a distribution whose tails decay exponentially fast, for example, the normal distribution. It can also model the largest value from a distribution, such as the normal or exponential distributions, by using the negative of the original values.

The extreme value distribution uses the following parameters.

Parameter	Description	Support
<code>mu</code>	Location parameter	$-\infty < \mu < \infty$
<code>sigma</code>	Scale parameter	$\sigma \geq 0$

Creation

There are several ways to create a `ExtremeValueDistribution` probability distribution object.

- Create a distribution with specified parameter values using `makedist`.
- Fit a distribution to data using `fitdist`.
- Interactively fit a distribution to data using the **Distribution Fitter** app.

Properties

Distribution Parameters

mu — Location parameter

scalar value

Location parameter of the extreme value distribution, specified as a scalar value.

Data Types: `single` | `double`

sigma — Scale parameter

nonnegative scalar value

Scale parameter of the extreme value distribution, specified as a nonnegative scalar value.

Data Types: `single` | `double`

Distribution Characteristics

IsTruncated — Logical flag for truncated distribution

0 | 1

This property is read-only.

Logical flag for truncated distribution, specified as a logical value. If `IsTruncated` equals 0, the distribution is not truncated. If `IsTruncated` equals 1, the distribution is truncated.

Data Types: `logical`

NumParameters — Number of parameters

positive integer value

This property is read-only.

Number of parameters for the probability distribution, specified as a positive integer value.

Data Types: `double`

ParameterCovariance — Covariance matrix of the parameter estimates

matrix of scalar values

This property is read-only.

Covariance matrix of the parameter estimates, specified as a p -by- p matrix, where p is the number of parameters in the distribution. The (i,j) element is the covariance between the estimates of the i th parameter and the j th parameter. The (i,i) element is the estimated variance of the i th parameter. If parameter i is fixed rather than estimated by fitting the distribution to data, then the (i,i) elements of the covariance matrix are 0.

Data Types: double

ParameterIsFixed — Logical flag for fixed parameters

array of logical values

This property is read-only.

Logical flag for fixed parameters, specified as an array of logical values. If 0, the corresponding parameter in the `ParameterNames` array is not fixed. If 1, the corresponding parameter in the `ParameterNames` array is fixed.

Data Types: logical

ParameterValues — Distribution parameter values

vector of scalar values

This property is read-only.

Distribution parameter values, specified as a vector.

Data Types: single | double

Truncation — Truncation interval

vector of scalar values

This property is read-only.

Truncation interval for the probability distribution, specified as a vector containing the lower and upper truncation boundaries.

Data Types: single | double

Other Object Properties

DistributionName — Probability distribution name

character vector

This property is read-only.

Probability distribution name, specified as a character vector.

Data Types: `char`

InputData — Data used for distribution fitting

structure

This property is read-only.

Data used for distribution fitting, specified as a structure containing the following:

- `data`: Data vector used for distribution fitting.
- `cens`: Censoring vector, or empty if none.
- `freq`: Frequency vector, or empty if none.

Data Types: `struct`

ParameterDescription — Distribution parameter descriptions

cell array of character vectors

This property is read-only.

Distribution parameter descriptions, specified as a cell array of character vectors. Each cell contains a short description of one distribution parameter.

Data Types: `char`

ParameterNames — Distribution parameter names

cell array of character vectors

This property is read-only.

Distribution parameter names, specified as a cell array of character vectors.

Data Types: `char`

Object Functions

<code>cdf</code>	Cumulative distribution function
<code>icdf</code>	Inverse cumulative distribution function
<code>iqr</code>	Interquartile range
<code>mean</code>	Mean of probability distribution

<code>negloglik</code>	Negative loglikelihood of probability distribution
<code>paramci</code>	Confidence intervals for probability distribution parameters
<code>pdf</code>	Probability density function
<code>proflik</code>	Profile likelihood function for probability distribution
<code>random</code>	Random numbers
<code>std</code>	Standard deviation of probability distribution
<code>truncate</code>	Truncate probability distribution object
<code>var</code>	Variance of probability distribution

Examples

Create an Extreme Value Distribution Object Using Default Parameters

Create an extreme value distribution object using the default parameter values.

```
pd = makedist('ExtremeValue')  
  
pd =  
  ExtremeValueDistribution  
  
  Extreme Value distribution  
    mu = 0  
    sigma = 1
```

Create an Extreme Value Distribution Object Using Specified Parameters

Create an extreme value distribution object by specifying the parameter values.

```
pd = makedist('ExtremeValue', 'mu', -1, 'sigma', 2)  
  
pd =  
  ExtremeValueDistribution
```

```
Extreme Value distribution
  mu = -1
  sigma = 2
```

Compute the standard deviation for the distribution.

```
s = std(pd)
```

```
s = 2.5651
```

GammaDistribution

Gamma probability distribution object

Description

A `GammaDistribution` object consists of parameters, a model description, and sample data for a gamma probability distribution.

The gamma distribution is a two-parameter family of distributions used to model sums of exponentially distributed random variables. The chi-square and the exponential distributions, which are special cases of the gamma distribution, are one-parameter distributions that fix one of the two gamma parameters.

The gamma distribution uses the following parameters.

Parameter	Description	Support
a	Shape parameter	$a > 0$
b	Scale parameter	$b > 0$

Creation

There are several ways to create a `GammaDistribution` probability distribution object.

- Create a distribution with specified parameter values using `makedist`.
- Fit a distribution to data using `fitdist`.
- Interactively fit a distribution to data using the **Distribution Fitter** app.

Properties

Distribution Parameters

a — Shape parameter

positive scalar value

Shape parameter for the gamma distribution, specified as a positive scalar value.

Data Types: `single` | `double`

b — Scale parameter

nonnegative scalar value

Scale parameter for the gamma distribution, specified as a nonnegative scalar value.

Data Types: `single` | `double`

Distribution Characteristics

IsTruncated — Logical flag for truncated distribution

0 | 1

This property is read-only.

Logical flag for truncated distribution, specified as a logical value. If `IsTruncated` equals 0, the distribution is not truncated. If `IsTruncated` equals 1, the distribution is truncated.

Data Types: `logical`

NumParameters — Number of parameters

positive integer value

This property is read-only.

Number of parameters for the probability distribution, specified as a positive integer value.

Data Types: `double`

ParameterCovariance — Covariance matrix of the parameter estimates

matrix of scalar values

This property is read-only.

Covariance matrix of the parameter estimates, specified as a p -by- p matrix, where p is the number of parameters in the distribution. The (i,j) element is the covariance between the estimates of the i th parameter and the j th parameter. The (i,i) element is the estimated variance of the i th parameter. If parameter i is fixed rather than estimated by fitting the distribution to data, then the (i,i) elements of the covariance matrix are 0.

Data Types: `double`

ParameterIsFixed — Logical flag for fixed parameters

array of logical values

This property is read-only.

Logical flag for fixed parameters, specified as an array of logical values. If `0`, the corresponding parameter in the `ParameterNames` array is not fixed. If `1`, the corresponding parameter in the `ParameterNames` array is fixed.

Data Types: `logical`

ParameterValues — Distribution parameter values

vector of scalar values

This property is read-only.

Distribution parameter values, specified as a vector.

Data Types: `single` | `double`

Truncation — Truncation interval

vector of scalar values

This property is read-only.

Truncation interval for the probability distribution, specified as a vector containing the lower and upper truncation boundaries.

Data Types: `single` | `double`

Other Object Properties

DistributionName — Probability distribution name

character vector

This property is read-only.

Probability distribution name, specified as a character vector.

Data Types: `char`

InputData — Data used for distribution fitting

structure

This property is read-only.

Data used for distribution fitting, specified as a structure containing the following:

- **data**: Data vector used for distribution fitting.
- **cens**: Censoring vector, or empty if none.
- **freq**: Frequency vector, or empty if none.

Data Types: `struct`

ParameterDescription — Distribution parameter descriptions

cell array of character vectors

This property is read-only.

Distribution parameter descriptions, specified as a cell array of character vectors. Each cell contains a short description of one distribution parameter.

Data Types: `char`

ParameterNames — Distribution parameter names

cell array of character vectors

This property is read-only.

Distribution parameter names, specified as a cell array of character vectors.

GeneralizedExtremeValueDistribution

Generalized extreme value probability distribution object

Description

A `GeneralizedExtremeValueDistribution` object consists of parameters, a model description, and sample data for a generalized extreme value probability distribution.

The generalized extreme value distribution is often used to model the smallest or largest value among a large set of independent, identically distributed random values representing measurements or observations. It combines three simpler distributions into a single form, allowing a continuous range of possible shapes that include all three of the simpler distributions.

The three distribution types correspond to the limiting distribution of block maxima from different classes of underlying distributions:

- Type 1 — Distributions whose tails decrease exponentially, such as the normal distribution
- Type 2 — Distributions whose tails decrease as a polynomial, such as Student's t distribution
- Type 3 — Distributions whose tails are finite, such as the beta distribution

The generalized extreme value distribution uses the following parameters.

Parameter	Description	Support
<code>k</code>	Shape parameter	$-\infty \leq k \leq \infty$
<code>sigma</code>	Scale parameter	$\sigma \geq 0$
<code>mu</code>	Location parameter	$-\infty \leq \mu \leq \infty$

Creation

There are several ways to create a `GeneralizedExtremeValueDistribution` probability distribution object.

- Create a distribution with specified parameter values using `makedist`.
- Fit a distribution to data using `fitdist`.
- Interactively fit a distribution to data using the **Distribution Fitter** app.

Properties

Distribution Parameters

k — Shape parameter

scalar value

Shape parameter of the generalized extreme value distribution, specified as a scalar value.

Data Types: `single` | `double`

sigma — Scale parameter

nonnegative scalar value

Scale parameter of the generalized extreme value distribution, specified as a nonnegative scalar value.

Data Types: `single` | `double`

mu — Location parameter

scalar value

Location parameter of the generalized extreme value distribution, specified as a scalar value.

Data Types: `single` | `double`

Distribution Characteristics

IsTruncated — Logical flag for truncated distribution

0 | 1

This property is read-only.

Logical flag for truncated distribution, specified as a logical value. If `IsTruncated` equals `0`, the distribution is not truncated. If `IsTruncated` equals `1`, the distribution is truncated.

Data Types: `logical`

NumParameters — Number of parameters

positive integer value

This property is read-only.

Number of parameters for the probability distribution, specified as a positive integer value.

Data Types: `double`

ParameterCovariance — Covariance matrix of the parameter estimates

matrix of scalar values

This property is read-only.

Covariance matrix of the parameter estimates, specified as a p -by- p matrix, where p is the number of parameters in the distribution. The (i,j) element is the covariance between the estimates of the i th parameter and the j th parameter. The (i,i) element is the estimated variance of the i th parameter. If parameter i is fixed rather than estimated by fitting the distribution to data, then the (i,i) elements of the covariance matrix are 0.

Data Types: `double`

ParameterIsFixed — Logical flag for fixed parameters

array of logical values

This property is read-only.

Logical flag for fixed parameters, specified as an array of logical values. If `0`, the corresponding parameter in the `ParameterNames` array is not fixed. If `1`, the corresponding parameter in the `ParameterNames` array is fixed.

Data Types: `logical`

ParameterValues — Distribution parameter values

vector of scalar values

This property is read-only.

Distribution parameter values, specified as a vector.

Data Types: `single` | `double`

Truncation — Truncation interval

vector of scalar values

This property is read-only.

Truncation interval for the probability distribution, specified as a vector containing the lower and upper truncation boundaries.

Data Types: `single` | `double`

Other Object Properties**DistributionName — Probability distribution name**

character vector

This property is read-only.

Probability distribution name, specified as a character vector.

Data Types: `char`

InputData — Data used for distribution fitting

structure

This property is read-only.

Data used for distribution fitting, specified as a structure containing the following:

- `data`: Data vector used for distribution fitting.
- `cens`: Censoring vector, or empty if none.
- `freq`: Frequency vector, or empty if none.

Data Types: `struct`

ParameterDescription — Distribution parameter descriptions

cell array of character vectors

This property is read-only.

Distribution parameter descriptions, specified as a cell array of character vectors. Each cell contains a short description of one distribution parameter.

Data Types: char

ParameterNames — Distribution parameter names

cell array of character vectors

This property is read-only.

Distribution parameter names, specified as a cell array of character vectors.

Data Types: char

Object Functions

cdf	Cumulative distribution function
icdf	Inverse cumulative distribution function
iqr	Interquartile range
mean	Mean of probability distribution
median	Median of probability distribution

paramci	Confidence intervals for probability distribution parameters
pdf	Probability density function
proflik	Profile likelihood function for probability distribution
random	Random numbers
std	Standard deviation of probability distribution
truncate	Truncate probability distribution object
var	Variance of probability distribution

Examples

Create a Generalized Extreme Value Distribution Object Using Default Parameters

Create a generalized extreme value distribution object using the default parameter values.

```
pd = makedist('GeneralizedExtremeValue')
pd =
    GeneralizedExtremeValueDistribution
```

```
Generalized Extreme Value distribution
  k = 0
  sigma = 1
  mu = 0
```

Create a Generalized Extreme Value Distribution Object Using Specified Parameters

Create a generalized extreme value distribution object by specifying values for the parameters.

```
pd = makedist('GeneralizedExtremeValue', 'k', 0, 'sigma', 2, 'mu', 1)
```

```
pd =
  GeneralizedExtremeValueDistribution

  Generalized Extreme Value distribution
    k = 0
    sigma = 2
    mu = 1
```

Compute the mean of the distribution.

```
m = mean(pd)
```

```
m = 2.1544
```

GeneralizedParetoDistribution

Generalized Pareto probability distribution object

Description

A `GeneralizedParetoDistribution` object consists of parameters, a model description, and sample data for a generalized Pareto probability distribution.

The generalized Pareto distribution is used to model the tails of another distribution. It allows a continuous range of possible shapes that include both the exponential and Pareto distributions as special cases. It has three basic forms, each corresponding to a limiting distribution of exceedence data from a different class of underlying distributions.

- Distributions whose tails decrease exponentially, such as the normal, lead to a generalized Pareto shape parameter of zero.
- Distributions whose tails decrease polynomially, such as the Student's t , lead to a positive shape parameter.
- Distributions whose tails are finite, such as the beta, lead to a negative shape parameter.

The generalized Pareto distribution uses the following parameters.

Parameter	Description	Support
<code>k</code>	Shape parameter	$-\infty < k < \infty$
<code>sigma</code>	Scale parameter	$\sigma \geq 0$
<code>theta</code>	Location parameter	$-\infty < \theta < \infty$

Creation

There are several ways to create a `GeneralizedParetoDistribution` probability distribution object.

- Create a distribution with specified parameter values using `makedist`.

- Fit a distribution to data using `fitdist`.
- Interactively fit a distribution to data using the **Distribution Fitter** app.

Properties

Distribution Parameters

k — Shape parameter

scalar value

Shape parameter for the generalized Pareto distribution, specified as a scalar value.

Data Types: `single` | `double`

sigma — Scale parameter

nonnegative scalar value

Scale parameter for the generalized Pareto distribution, specified as a nonnegative scalar value.

Data Types: `single` | `double`

theta — Location parameter

scalar value

Location parameter for the generalized Pareto distribution, specified as a scalar value.

Data Types: `single` | `double`

Distribution Characteristics

IsTruncated — Logical flag for truncated distribution

0 | 1

This property is read-only.

Logical flag for truncated distribution, specified as a logical value. If `IsTruncated` equals 0, the distribution is not truncated. If `IsTruncated` equals 1, the distribution is truncated.

Data Types: `logical`

NumParameters — Number of parameters

positive integer value

This property is read-only.

Number of parameters for the probability distribution, specified as a positive integer value.

Data Types: double

ParameterCovariance — Covariance matrix of the parameter estimates

matrix of scalar values

This property is read-only.

Covariance matrix of the parameter estimates, specified as a p -by- p matrix, where p is the number of parameters in the distribution. The (i,j) element is the covariance between the estimates of the i th parameter and the j th parameter. The (i,i) element is the estimated variance of the i th parameter. If parameter i is fixed rather than estimated by fitting the distribution to data, then the (i,i) elements of the covariance matrix are 0.

Data Types: double

ParameterIsFixed — Logical flag for fixed parameters

array of logical values

This property is read-only.

Logical flag for fixed parameters, specified as an array of logical values. If 0, the corresponding parameter in the `ParameterNames` array is not fixed. If 1, the corresponding parameter in the `ParameterNames` array is fixed.

Data Types: logical

ParameterValues — Distribution parameter values

vector of scalar values

This property is read-only.

Distribution parameter values, specified as a vector.

Data Types: single | double

Truncation — Truncation interval

vector of scalar values

This property is read-only.

Truncation interval for the probability distribution, specified as a vector containing the lower and upper truncation boundaries.

Data Types: `single` | `double`

Other Object Properties

DistributionName — Probability distribution name

character vector

This property is read-only.

Probability distribution name, specified as a character vector.

Data Types: `char`

InputData — Data used for distribution fitting

structure

This property is read-only.

Data used for distribution fitting, specified as a structure containing the following:

- `data`: Data vector used for distribution fitting.
- `cens`: Censoring vector, or empty if none.
- `freq`: Frequency vector, or empty if none.

Data Types: `struct`

ParameterDescription — Distribution parameter descriptions

cell array of character vectors

This property is read-only.

Distribution parameter descriptions, specified as a cell array of character vectors. Each cell contains a short description of one distribution parameter.

Data Types: `char`

ParameterNames — Distribution parameter names

cell array of character vectors

This property is read-only.

Distribution parameter names, specified as a cell array of character vectors.

Data Types: char

Examples

Create a Generalized Pareto Distribution Object Using Default Parameters

Create a generalized Pareto distribution object using the default parameter values.

```
pd = makedist('GeneralizedPareto')  
  
pd =  
    GeneralizedParetoDistribution  
  
    Generalized Pareto distribution  
        k = 1  
        sigma = 1  
        theta = 1
```

Create a Generalized Pareto Distribution Object Using Specified Parameters

Create a generalized Pareto distribution object by specifying parameter values.

```
pd = makedist('GeneralizedPareto','k',0,'sigma',2,'theta',1)
```

```
pd =  
  GeneralizedParetoDistribution  
  
  Generalized Pareto distribution  
    k = 0  
  sigma = 2  
  theta = 1
```

Compute the mean of the distribution.

```
m = mean(pd)
```

```
m = 3
```

HalfNormalDistribution

Half-normal probability distribution object

Description

A `HalfNormalDistribution` object consists of parameters, a model description, and sample data for a half-normal probability distribution.

The half-normal distribution is a special case of the folded normal and truncated normal distribution. Applications of the half-normal distribution include modeling measurement data and lifetime data.

The half-normal distribution uses the following parameters:

Parameter	Description	Support
<code>mu</code>	Location	$-\infty < \mu < \infty$
<code>sigma</code>	Scale	$\sigma \geq 0$

For more information about the half-normal distribution, see “Half-Normal Distribution” on page B-68.

Creation

There are several ways to create a `HalfNormalDistribution` probability distribution object.

- Create a distribution with specified parameter values using `makedist`.
- Fit a distribution to data using `fitdist`.
- Interactively fit a distribution to data using the **Distribution Fitter** app.

Properties

Distribution Parameters

mu — Location parameter

scalar value

Location parameter of the half-normal distribution, specified as a scalar value. The μ parameter is also the lower limit of the half-normal distribution.

The Statistics and Machine Learning Toolbox implementation of the half-normal distribution assumes a fixed value for the location parameter μ . You can specify a value for the μ parameter when creating a `HalfNormalDistribution` object.

Data Types: `single` | `double`**sigma — Scale parameter**

nonnegative scalar value

Scale parameter of the half-normal distribution, specified as a nonnegative scalar value.

Data Types: `single` | `double`

Distribution Characteristics

IsTruncated — Logical flag for truncated distribution

0 | 1

This property is read-only.

Logical flag for truncated distribution, specified as a logical value. If `IsTruncated` equals 0, the distribution is not truncated. If `IsTruncated` equals 1, the distribution is truncated.

Data Types: `logical`**NumParameters — Number of parameters**

positive integer value

This property is read-only.

Number of parameters for the probability distribution, specified as a positive integer value.

Data Types: `double`

ParameterCovariance — Covariance matrix of the parameter estimates

matrix of scalar values

This property is read-only.

Covariance matrix of the parameter estimates, specified as a p -by- p matrix, where p is the number of parameters in the distribution. The (i,j) element is the covariance between the estimates of the i th parameter and the j th parameter. The (i,i) element is the estimated variance of the i th parameter. If parameter i is fixed rather than estimated by fitting the distribution to data, then the (i,i) elements of the covariance matrix are 0.

Data Types: `double`

ParameterIsFixed — Logical flag for fixed parameters

array of logical values

This property is read-only.

Logical flag for fixed parameters, specified as an array of logical values. If 0, the corresponding parameter in the `ParameterNames` array is not fixed. If 1, the corresponding parameter in the `ParameterNames` array is fixed.

Data Types: `logical`

ParameterValues — Distribution parameter values

vector of scalar values

This property is read-only.

Distribution parameter values, specified as a vector.

Data Types: `single` | `double`

Truncation — Truncation interval

vector of scalar values

This property is read-only.

Truncation interval for the probability distribution, specified as a vector containing the lower and upper truncation boundaries.

Data Types: `single` | `double`

Other Object Properties

DistributionName — Probability distribution name

character vector

This property is read-only.

Probability distribution name, specified as a character vector.

Data Types: `char`

InputData — Data used for distribution fitting

structure

This property is read-only.

Data used for distribution fitting, specified as a structure containing the following:

- `data`: Data vector used for distribution fitting.
- `cens`: Censoring vector, or empty if none.
- `freq`: Frequency vector, or empty if none.

Data Types: `struct`

ParameterDescription — Distribution parameter descriptions

cell array of character vectors

This property is read-only.

Distribution parameter descriptions, specified as a cell array of character vectors. Each cell contains a short description of one distribution parameter.

Data Types: `char`

ParameterNames — Distribution parameter names

cell array of character vectors

This property is read-only.

Distribution parameter names, specified as a cell array of character vectors.

Data Types: char

Object Functions

<code>cdf</code>	Cumulative distribution function

<code>paramci</code>	Confidence intervals for probability distribution parameters
<code>pdf</code>	Probability density function
<code>proflik</code>	Profile likelihood function for probability distribution
<code>random</code>	Random numbers
<code>std</code>	Standard deviation of probability distribution
<code>truncate</code>	Truncate probability distribution object
<code>var</code>	Variance of probability distribution

Examples

Create a Half-Normal Distribution Object Using Default Parameters

```
pd = makedist('HalfNormal')

pd =
  HalfNormalDistribution

  Half Normal distribution
      mu = 0
      sigma = 1
```

Create a Half-Normal Distribution Object Using Specified Parameters

Create a half-normal distribution object. Specify `mu` equal to 0 and `sigma` equal to 1.5.

```
pd = makedist('HalfNormal','mu',0,'sigma',1.5)
```

```
pd =  
  HalfNormalDistribution  
  
  Half Normal distribution  
    mu = 0  
    sigma = 1.5
```

Compute the mean and standard deviation of the distribution.

```
m = mean(pd)  
m = 1.1968  
s = std(pd)  
s = 0.9042
```

Fit a Half-Normal Distribution Object

Generate 100 random numbers from a standard normal distribution and compute their absolute value.

```
rng default % For reproducibility  
x = abs(random(makedist('Normal'),100,1));
```

Fit a half-normal distribution object to the sample data.

```
pd = fitdist(x,'HalfNormal')  
  
pd =  
  HalfNormalDistribution  
  
  Half Normal distribution  
    mu = 0  
    sigma = 1.1631 [1.02184, 1.35006]
```

Calculate the mean of the fitted half-normal distribution using the probability distribution object.

```
m = mean(pd)
```

```
m = 0.9280
```

Calculate the mean of the half-normal distribution by substituting the fitted `mu` and `sigma` parameter values into the formula

$$mean = \mu + \sigma \sqrt{\frac{2}{\pi}}$$

```
mcalc = pd.mu + pd.sigma*(sqrt(2/pi))
```

```
mcalc = 0.9280
```

InverseGaussianDistribution

Inverse Gaussian probability distribution object

Description

An `InverseGaussianDistribution` object consists of parameters, a model description, and sample data for an inverse Gaussian probability distribution.

Also known as the Wald distribution, the inverse Gaussian is used to model nonnegative positively skewed data. Inverse Gaussian distributions have many similarities to standard Gaussian (normal) distributions, which lead to applications in inferential statistics.

The inverse Gaussian distribution uses the following parameters.

Parameter	Description	Support
<code>mu</code>	Scale parameter	$\mu > 0$
<code>lambda</code>	Shape parameter	$\lambda > 0$

Creation

There are several ways to create a `InverseGaussianDistribution` probability distribution object.

- Create a distribution with specified parameter values using `makedist`.
- Fit a distribution to data using `fitdist`.
- Interactively fit a distribution to data using the **Distribution Fitter** app.

Properties

Distribution Parameters

mu — Scale parameter

positive scalar value

Scale parameter for the inverse Gaussian distribution, specified as a positive scalar value.

Data Types: `single` | `double`

Lambda — Shape parameter

positive scalar value

Shape parameter for the inverse Gaussian distribution, specified as a positive scalar value.

Data Types: `single` | `double`

Distribution Characteristics

IsTruncated — Logical flag for truncated distribution

0 | 1

This property is read-only.

Logical flag for truncated distribution, specified as a logical value. If `IsTruncated` equals 0, the distribution is not truncated. If `IsTruncated` equals 1, the distribution is truncated.

Data Types: `logical`

NumParameters — Number of parameters

positive integer value

This property is read-only.

Number of parameters for the probability distribution, specified as a positive integer value.

Data Types: `double`

ParameterCovariance — Covariance matrix of the parameter estimates

matrix of scalar values

This property is read-only.

Covariance matrix of the parameter estimates, specified as a p -by- p matrix, where p is the number of parameters in the distribution. The (i,j) element is the covariance between the estimates of the i th parameter and the j th parameter. The (i,i) element is the

estimated variance of the i th parameter. If parameter i is fixed rather than estimated by fitting the distribution to data, then the (i,i) elements of the covariance matrix are 0.

Data Types: `double`

ParameterIsFixed — Logical flag for fixed parameters

array of logical values

This property is read-only.

Logical flag for fixed parameters, specified as an array of logical values. If 0, the corresponding parameter in the `ParameterNames` array is not fixed. If 1, the corresponding parameter in the `ParameterNames` array is fixed.

Data Types: `logical`

ParameterValues — Distribution parameter values

vector of scalar values

This property is read-only.

Distribution parameter values, specified as a vector.

Data Types: `single` | `double`

Truncation — Truncation interval

vector of scalar values

This property is read-only.

Truncation interval for the probability distribution, specified as a vector containing the lower and upper truncation boundaries.

Data Types: `single` | `double`

Other Object Properties**DistributionName** — Probability distribution name

character vector

This property is read-only.

Probability distribution name, specified as a character vector.

Data Types: `char`

InputData — Data used for distribution fitting

structure

This property is read-only.

Data used for distribution fitting, specified as a structure containing the following:

- `data`: Data vector used for distribution fitting.
- `cens`: Censoring vector, or empty if none.
- `freq`: Frequency vector, or empty if none.

Data Types: `struct`

ParameterDescription — Distribution parameter descriptions

cell array of character vectors

This property is read-only.

Distribution parameter descriptions, specified as a cell array of character vectors. Each cell contains a short description of one distribution parameter.

Data Types: `char`

ParameterNames — Distribution parameter names

cell array of character vectors

This property is read-only.

Distribution parameter names, specified as a cell array of character vectors.

Data Types: `char`

Examples

Create an Inverse Gaussian Distribution Object Using Default Parameters

Create an inverse Gaussian distribution object using the default parameter values.

```
pd = makedist('InverseGaussian')  
  
pd =  
  InverseGaussianDistribution  
  
  Inverse Gaussian distribution  
    mu = 1  
    lambda = 1
```

Create an Inverse Gaussian Distribution Object Using Specified Parameters

Create an inverse Gaussian distribution object by specifying parameter values.

```
pd = makedist('InverseGaussian', 'mu', 2, 'lambda', 4)  
  
pd =  
  InverseGaussianDistribution  
  
  Inverse Gaussian distribution  
    mu = 2  
    lambda = 4
```

Compute the standard deviation of the distribution.

```
s = std(pd)
```

s = 1.4142

KernelDistribution

Kernel probability distribution object

Description

A `KernelDistribution` object consists of parameters, a model description, and sample data for a nonparametric kernel-smoothing distribution.

The kernel distribution is a nonparametric estimation of the probability density function (pdf) of a random variable.

The kernel distribution uses the following options.

Option	Description	Possible Values
Kernel	Kernel function type	normal, box, triangle, epanechnikov
BandWidth	Kernel smoothing parameter	BandWidth > 0

Creation

There are several ways to create a `KernelDistribution` probability distribution object.

- Fit a distribution to data using `fitdist`.
- Interactively fit a distribution to data using the **Distribution Fitter** app.

Properties

Distribution Parameters

Kernel — Kernel smoother type

`'normal' | 'box' | 'triangle' | 'epanechnikov'`

Kernel function type, specified as a valid kernel function type name.

BandWidth — Bandwidth of kernel smoothing window

positive scalar value

Bandwidth of the kernel smoothing window, specified as a positive scalar value.

Data Types: `single` | `double`

Distribution Characteristics**IsTruncated — Logical flag for truncated distribution**

0 | 1

This property is read-only.

Logical flag for truncated distribution, specified as a logical value. If `IsTruncated` equals 0, the distribution is not truncated. If `IsTruncated` equals 1, the distribution is truncated.

Data Types: `logical`

Truncation — Truncation interval

vector of scalar values

This property is read-only.

Truncation interval for the probability distribution, specified as a vector containing the lower and upper truncation boundaries.

Data Types: `single` | `double`

Other Object Properties**DistributionName — Probability distribution name**

character vector

This property is read-only.

Probability distribution name, specified as a character vector.

Data Types: `char`

InputData — Data used for distribution fitting

structure

This property is read-only.

Data used for distribution fitting, specified as a structure containing the following:

- **data**: Data vector used for distribution fitting.
- **cens**: Censoring vector, or empty if none.
- **freq**: Frequency vector, or empty if none.

Data Types: `struct`

Object Functions

<code>cdf</code>	Cumulative distribution function
<code>icdf</code>	Inverse cumulative distribution function
<code>iqr</code>	Interquartile range
<code>mean</code>	Mean of probability distribution
<code>median</code>	Median of probability distribution
<code>negloglik</code>	Negative loglikelihood of probability distribution
<code>pdf</code>	Probability density function
<code>random</code>	Random numbers
<code>std</code>	Standard deviation of probability distribution
<code>truncate</code>	Truncate probability distribution object
<code>var</code>	Variance of probability distribution

Examples

Fit a Kernel Distribution Object to Data

Load the sample data. Visualize the patient weight data using a histogram.

```
load hospital
histogram(hospital.Weight)
```

The histogram shows that the data has two modes, one for female patients and one for male patients.

Create a probability distribution object by fitting a kernel distribution to the patient weight data.

```
pd_kernel = fitdist(hospital.Weight, 'Kernel')
```

```
pd_kernel =  
  KernelDistribution
```

```
  Kernel = normal  
  Bandwidth = 14.3792
```

Support = unbounded

For comparison, create another probability distribution object by fitting a normal distribution to the patient weight data.

```
pd_normal = fitdist(hospital.Weight, 'Normal')  
  
pd_normal =  
    NormalDistribution  
  
    Normal distribution  
        mu =      154    [148.728, 159.272]  
        sigma = 26.5714 [23.3299, 30.8674]
```

Define the x values and compute the pdf of each distribution.

```
x = 50:1:250;  
pdf_kernel = pdf(pd_kernel,x);  
pdf_normal = pdf(pd_normal,x);
```

Plot the pdf of each distribution.

```
plot(x,pdf_kernel, 'Color', 'b', 'LineWidth',2);  
hold on;  
plot(x,pdf_normal, 'Color', 'r', 'LineStyle', ':', 'LineWidth',2);  
legend('Kernel Distribution', 'Normal Distribution', 'Location', 'SouthEast');  
hold off;
```

Fitting a kernel distribution instead of a unimodal distribution such as the normal reveals the separate modes for the female and male patients.

LogisticDistribution

Logistic probability distribution object

Description

A `LogisticDistribution` object consists of parameters, a model description, and sample data for a logistic probability distribution.

The logistic distribution is used for growth models and in logistic regression. It has longer tails and a higher kurtosis than the normal distribution.

The logistic distribution uses the following parameters.

Parameter	Description	Support
<code>mu</code>	Mean	$-\infty < \mu < \infty$
<code>sigma</code>	Scale parameter	$\sigma \geq 0$

Creation

There are several ways to create a `LogisticDistribution` probability distribution object.

- Create a distribution with specified parameter values using `makedist`.
- Fit a distribution to data using `fitdist`.
- Interactively fit a distribution to data using the **Distribution Fitter** app.

Properties

Distribution Parameters

mu — Mean
scalar value

Mean of the logistic distribution, specified as a scalar value.

Data Types: `single` | `double`

sigma — Scale parameter

nonnegative scalar value

Scale parameter of the logistic distribution, specified as a nonnegative scalar value.

Data Types: `single` | `double`

Distribution Characteristics

IsTruncated — Logical flag for truncated distribution

0 | 1

This property is read-only.

Logical flag for truncated distribution, specified as a logical value. If `IsTruncated` equals 0, the distribution is not truncated. If `IsTruncated` equals 1, the distribution is truncated.

Data Types: `logical`

NumParameters — Number of parameters

positive integer value

This property is read-only.

Number of parameters for the probability distribution, specified as a positive integer value.

Data Types: `double`

ParameterCovariance — Covariance matrix of the parameter estimates

matrix of scalar values

This property is read-only.

Covariance matrix of the parameter estimates, specified as a p -by- p matrix, where p is the number of parameters in the distribution. The (i,j) element is the covariance between the estimates of the i th parameter and the j th parameter. The (i,i) element is the estimated variance of the i th parameter. If parameter i is fixed rather than estimated by fitting the distribution to data, then the (i,i) elements of the covariance matrix are 0.

Data Types: `double`

ParameterIsFixed — Logical flag for fixed parameters

array of logical values

This property is read-only.

Logical flag for fixed parameters, specified as an array of logical values. If `0`, the corresponding parameter in the `ParameterNames` array is not fixed. If `1`, the corresponding parameter in the `ParameterNames` array is fixed.

Data Types: `logical`

ParameterValues — Distribution parameter values

vector of scalar values

This property is read-only.

Distribution parameter values, specified as a vector.

Data Types: `single` | `double`

Truncation — Truncation interval

vector of scalar values

This property is read-only.

Truncation interval for the probability distribution, specified as a vector containing the lower and upper truncation boundaries.

Data Types: `single` | `double`

Other Object Properties

DistributionName — Probability distribution name

character vector

This property is read-only.

Probability distribution name, specified as a character vector.

Data Types: `char`

InputData — Data used for distribution fitting

structure

This property is read-only.

Data used for distribution fitting, specified as a structure containing the following:

- **data**: Data vector used for distribution fitting.
- **cens**: Censoring vector, or empty if none.
- **freq**: Frequency vector, or empty if none.

Data Types: `struct`

ParameterDescription — Distribution parameter descriptions

cell array of character vectors

This property is read-only.

Distribution parameter descriptions, specified as a cell array of character vectors. Each cell contains a short description of one distribution parameter.

Data Types: `char`

ParameterNames — Distribution parameter names

cell array of character vectors

This property is read-only.

Distribution parameter names, specified as a cell array of character vectors.

Data Types: `char`

LoglogisticDistribution

Loglogistic probability distribution object

Description

A `LoglogisticDistribution` object consists of parameters, a model description, and sample data for a loglogistic probability distribution.

The loglogistic distribution is closely related to the logistic distribution. If x is distributed loglogistically with parameters μ and σ , then $\log(x)$ is distributed logistically with mean and standard deviation. This distribution is often used in survival analysis to model events that experience an initial rate increase, followed by a rate decrease.

The loglogistic distribution uses the following parameters.

Parameter	Description	Support
<code>mu</code>	Mean of logarithmic values	$\mu > 0$
<code>sigma</code>	Scale parameter of logarithmic values	$\sigma > 0$

Creation

There are several ways to create a `LoglogisticDistribution` probability distribution object.

- Create a distribution with specified parameter values using `makedist`.
- Fit a distribution to data using `fitdist`.
- Interactively fit a distribution to data using the **Distribution Fitter** app.

Properties

Distribution Parameters

mu — Mean of logarithmic values

positive scalar value

Mean of logarithmic values for the loglogistic distribution, specified as a positive scalar value.

Data Types: `single` | `double`

sigma — Scale parameter of logarithmic values

positive scalar value

Scale parameter of logarithmic values for the loglogistic distribution, specified as a positive scalar value.

Data Types: `single` | `double`

Distribution Characteristics

IsTruncated — Logical flag for truncated distribution

0 | 1

This property is read-only.

Logical flag for truncated distribution, specified as a logical value. If `IsTruncated` equals 0, the distribution is not truncated. If `IsTruncated` equals 1, the distribution is truncated.

Data Types: `logical`

NumParameters — Number of parameters

positive integer value

This property is read-only.

Number of parameters for the probability distribution, specified as a positive integer value.

Data Types: `double`

ParameterCovariance — Covariance matrix of the parameter estimates

matrix of scalar values

This property is read-only.

Covariance matrix of the parameter estimates, specified as a p -by- p matrix, where p is the number of parameters in the distribution. The (i,j) element is the covariance between the estimates of the i th parameter and the j th parameter. The (i,i) element is the estimated variance of the i th parameter. If parameter i is fixed rather than estimated by fitting the distribution to data, then the (i,i) elements of the covariance matrix are 0.

Data Types: double

ParameterIsFixed — Logical flag for fixed parameters

array of logical values

This property is read-only.

Logical flag for fixed parameters, specified as an array of logical values. If 0, the corresponding parameter in the `ParameterNames` array is not fixed. If 1, the corresponding parameter in the `ParameterNames` array is fixed.

Data Types: logical

ParameterValues — Distribution parameter values

vector of scalar values

This property is read-only.

Distribution parameter values, specified as a vector.

Data Types: single | double

Truncation — Truncation interval

vector of scalar values

This property is read-only.

Truncation interval for the probability distribution, specified as a vector containing the lower and upper truncation boundaries.

Data Types: single | double

Other Object Properties

DistributionName — Probability distribution name

character vector

This property is read-only.

Probability distribution name, specified as a character vector.

Data Types: `char`

InputData — Data used for distribution fitting

structure

This property is read-only.

Data used for distribution fitting, specified as a structure containing the following:

- `data`: Data vector used for distribution fitting.
- `cens`: Censoring vector, or empty if none.
- `freq`: Frequency vector, or empty if none.

Data Types: `struct`

ParameterDescription — Distribution parameter descriptions

cell array of character vectors

This property is read-only.

Distribution parameter descriptions, specified as a cell array of character vectors. Each cell contains a short description of one distribution parameter.

Data Types: `char`

ParameterNames — Distribution parameter names

cell array of character vectors

This property is read-only.

Distribution parameter names, specified as a cell array of character vectors.

Data Types: `char`

<code>std</code>	Standard deviation of probability distribution
<code>truncate</code>	Truncate probability distribution object
<code>var</code>	Variance of probability distribution

Examples

Create a Loglogistic Distribution Object Using Default Parameters

Create a loglogistic distribution object using the default parameter values.

```
pd = makedist('Loglogistic')  
  
pd =  
  LoglogisticDistribution  
  
  Log-Logistic distribution  
    mu = 0  
    sigma = 1
```

Create a Loglogistic Distribution Object Using Specified Parameters

Create a loglogistic distribution object by specifying the parameter values.

```
pd = makedist('Loglogistic', 'mu', 5, 'sigma', 2)  
  
pd =  
  LoglogisticDistribution
```

```
Log-Logistic distribution
mu = 5
sigma = 2
```

Generate random numbers from the loglogistic distribution and compute their log values.

```
rng(19) % for reproducibility
x = random(pd,10000,1);
logx = log(x);
```

Compute the mean of the log values.

```
m = mean(logx)
```

```
m = 4.9828
```

The mean of the log of x is equal to the μ parameter of x , since x has a loglogistic distribution.

Plot $\log x$.

```
histogram(logx,50)
```

The plot shows that the log values of x have a logistic distribution.

LognormalDistribution

Lognormal probability distribution object

Description

A `LognormalDistribution` object consists of parameters, a model description, and sample data for a lognormal probability distribution.

The lognormal distribution, sometimes called the Galton distribution, is a probability distribution whose logarithm has a normal distribution. The lognormal distribution is applicable when the quantity of interest must be positive, because $\log(x)$ exists only when x is positive.

The lognormal distribution uses the following parameters.

Parameter	Description	Support
μ (μ)	Mean of logarithmic values	$-\infty < \mu < \infty$
σ (σ)	Standard deviation of logarithmic values	$\sigma \geq 0$

Creation

There are several ways to create a `LognormalDistribution` probability distribution object.

- Create a distribution with specified parameter values using `makedist`.
- Fit a distribution to data using `fitdist`.
- Interactively fit a distribution to data using the **Distribution Fitter** app.

Properties

Distribution Parameters

mu — Mean of logarithmic values

scalar value

Mean of logarithmic values for the lognormal distribution, specified as a scalar value.

Data Types: `single` | `double`

sigma — Standard deviation of logarithmic values

nonnegative scalar value

Standard deviation of logarithmic values for the lognormal distribution, specified as a nonnegative scalar value.

You can specify `sigma` to be zero when you create an object by using `makedist`. Some object functions support an object `pd` with zero standard deviation. For example, `random(pd)` always returns `exp(mu)`.

Data Types: `single` | `double`

Distribution Characteristics

IsTruncated — Logical flag for truncated distribution

`0` | `1`

This property is read-only.

Logical flag for truncated distribution, specified as a logical value. If `IsTruncated` equals `0`, the distribution is not truncated. If `IsTruncated` equals `1`, the distribution is truncated.

Data Types: `logical`

NumParameters — Number of parameters

positive integer value

This property is read-only.

Number of parameters for the probability distribution, specified as a positive integer value.

Data Types: `double`

ParameterCovariance — Covariance matrix of the parameter estimates

matrix of scalar values

This property is read-only.

Covariance matrix of the parameter estimates, specified as a p -by- p matrix, where p is the number of parameters in the distribution. The (i,j) element is the covariance between the estimates of the i th parameter and the j th parameter. The (i,i) element is the estimated variance of the i th parameter. If parameter i is fixed rather than estimated by fitting the distribution to data, then the (i,i) elements of the covariance matrix are 0.

Data Types: `double`

ParameterIsFixed — Logical flag for fixed parameters

array of logical values

This property is read-only.

Logical flag for fixed parameters, specified as an array of logical values. If 0, the corresponding parameter in the `ParameterNames` array is not fixed. If 1, the corresponding parameter in the `ParameterNames` array is fixed.

Data Types: `logical`

ParameterValues — Distribution parameter values

vector of scalar values

This property is read-only.

Distribution parameter values, specified as a vector.

Data Types: `single` | `double`

Truncation — Truncation interval

vector of scalar values

This property is read-only.

Truncation interval for the probability distribution, specified as a vector containing the lower and upper truncation boundaries.

Data Types: `single` | `double`

Other Object Properties

DistributionName — Probability distribution name

character vector

This property is read-only.

Probability distribution name, specified as a character vector.

Data Types: `char`

InputData — Data used for distribution fitting

structure

This property is read-only.

Data used for distribution fitting, specified as a structure containing the following:

- `data`: Data vector used for distribution fitting.
- `cens`: Censoring vector, or empty if none.
- `freq`: Frequency vector, or empty if none.

Data Types: `struct`

ParameterDescription — Distribution parameter descriptions

cell array of character vectors

This property is read-only.

Distribution parameter descriptions, specified as a cell array of character vectors. Each cell contains a short description of one distribution parameter.

Data Types: `char`

ParameterNames — Distribution parameter names

cell array of character vectors

This property is read-only.

Distribution parameter names, specified as a cell array of character vectors.

Data Types: char

Object Functions

<code>cdf</code>	Cumulative distribution function
<code>icdf</code>	Inverse cumulative distribution function
<code>iqr</code>	Interquartile range

Examples

Create a Lognormal Distribution Object Using Default Parameters

Create a lognormal distribution object using the default parameter values.

```
pd = makedist('Lognormal')  
  
pd =  
  LognormalDistribution  
  
  Lognormal distribution  
    mu = 0  
    sigma = 1
```

Create Lognormal Distribution Object Using Specified Parameters

Create a lognormal distribution object by specifying the parameter values.

```
pd = makedist('Lognormal', 'mu', 5, 'sigma', 2)
```

```
pd =  
  LognormalDistribution  
  
  Lognormal distribution  
    mu = 5  
    sigma = 2
```

Compute the mean of the lognormal distribution.

```
mean(pd)  
ans = 1.0966e+03
```

MultinomialDistribution

Multinomial probability distribution object

Description

A `MultinomialDistribution` object consists of parameters and a model description for a multinomial probability distribution.

The multinomial distribution is a generalization of the binomial distribution. While the binomial distribution gives the probability of the number of “successes” in n independent trials of a two-outcome process, the multinomial distribution gives the probability of each combination of outcomes in n independent trials of a k -outcome process. The probability of each outcome in any one trial is given by the fixed probabilities p_1, \dots, p_k .

The multinomial distribution uses the following parameters.

Parameter	Description	Support
probabilities	Outcome probabilities	$0 \leq \text{probabilities}(i) \leq 1 ; \sum_{\text{all}(i)} \text{probabilities}(i) = 1$

Creation

Create a `MultinomialDistribution` probability distribution with specified parameter values object using `makedist`.

Properties

Distribution Parameter

Probabilities — outcome probabilities

vector of scalar values in the range $[0, 1]$

Outcome probabilities for the multinomial distribution, stored as a vector of scalar values in the range $[0, 1]$. The values in probabilities must sum to 1.

Data Types: `single` | `double`

Distribution Characteristics

IsTruncated — Logical flag for truncated distribution

`0` | `1`

This property is read-only.

Logical flag for truncated distribution, specified as a logical value. If `IsTruncated` equals `0`, the distribution is not truncated. If `IsTruncated` equals `1`, the distribution is truncated.

Data Types: `logical`

NumParameters — Number of parameters

positive integer value

This property is read-only.

Number of parameters for the probability distribution, specified as a positive integer value.

Data Types: `double`

ParameterValues — Distribution parameter values

vector of scalar values

This property is read-only.

Distribution parameter values, specified as a vector.

Data Types: `single` | `double`

Truncation — Truncation interval

vector of scalar values

This property is read-only.

Truncation interval for the probability distribution, specified as a vector containing the lower and upper truncation boundaries.

Data Types: `single` | `double`

Other Object Properties

DistributionName — Probability distribution name

character vector

This property is read-only.

Probability distribution name, specified as a character vector.

Data Types: `char`

ParameterDescription — Distribution parameter descriptions

cell array of character vectors

This property is read-only.

Distribution parameter descriptions, specified as a cell array of character vectors. Each cell contains a short description of one distribution parameter.

Data Types: `char`

ParameterNames — Distribution parameter names

cell array of character vectors

This property is read-only.

Distribution parameter names, specified as a cell array of character vectors.

Data Types: `char`

Object Functions

<code>cdf</code>	Cumulative distribution function
<code>icdf</code>	Inverse cumulative distribution function
<code>iqr</code>	Interquartile range
<code>mean</code>	Mean of probability distribution
<code>median</code>	Median of probability distribution
<code>pdf</code>	Probability density function
<code>random</code>	Random numbers
<code>std</code>	Standard deviation of probability distribution

truncate Truncate probability distribution object
var Variance of probability distribution

Examples

Create a Multinomial Distribution Object Using Default Parameters

Create a multinomial distribution object using the default parameter values.

```
pd = makedist('Multinomial')  
  
pd =  
  MultinomialDistribution  
  
  Probabilities:  
    0.5000    0.5000
```

Create a Multinomial Distribution Object Using Specified Parameters

Create a multinomial distribution object for a distribution with three possible outcomes. Outcome 1 has a probability of 1/2, outcome 2 has a probability of 1/3, and outcome 3 has a probability of 1/6.

```
pd = makedist('Multinomial','probabilities',[1/2 1/3 1/6])  
  
pd =  
  MultinomialDistribution  
  
  Probabilities:  
    0.5000    0.3333    0.1667
```

Generate a random outcome from the distribution.

```
rng('default'); % for reproducibility  
r = random(pd)  
  
r = 2
```

The result of this trial is outcome 2. By default, the number of trials in each experiment, n , equals 1.

Generate random outcomes from the distribution when the number of trials in each experiment, n , equals 1, and the experiment is repeated ten times.

```
rng('default'); % for reproducibility  
r = random(pd,10,1)
```

```
r = 10×1
```

```
2  
3  
1  
3  
2  
1  
1  
2  
3  
3
```

Each element in the array is the outcome of an individual experiment that contains one trial.

Generate random outcomes from the distribution when the number of trials in each experiment, n , equals 5, and the experiment is repeated ten times.

```
rng('default'); % for reproducibility  
r = random(pd,10,5)
```

```
r = 10×5
```

```
2    1    2    2    1  
3    3    1    1    1  
1    3    3    1    2  
3    1    3    1    2  
2    2    2    1    1  
1    1    2    2    1  
1    1    2    2    1  
2    3    1    1    2  
3    2    2    3    2  
3    3    1    1    2
```

Each element in the resulting matrix is the outcome of one trial. The columns correspond to the five trials in each experiment, and the rows correspond to the ten experiments. For example, in the first experiment (corresponding to the first row), 2 of the 5 trials resulted in outcome 1, and 3 of the 5 trials resulted in outcome 2.

NakagamiDistribution

Nakagami probability distribution object

Description

A `NakagamiDistribution` object consists of parameters, a model description, and sample data for a Nakagami probability distribution.

The Nakagami distribution is commonly used in communication theory to model scattered signals that reach a receiver using multiple paths.

The Nakagami distribution uses the following parameters.

Parameter	Description	Support
<code>mu</code>	Shape parameter	$\mu > 0$
<code>omega</code>	Scale parameter	$\omega > 0$

Creation

There are several ways to create a `NakagamiDistribution` probability distribution object.

- Create a distribution with specified parameter values using `makedist`.
- Fit a distribution to data using `fitdist`.
- Interactively fit a distribution to data using the **Distribution Fitter** app.

Properties

Distribution Parameters

mu — Shape parameter
positive scalar value

Shape parameter for the Nakagami distribution, specified as a positive scalar value.

Data Types: `single` | `double`

omega — Scale parameter

positive scalar value

Scale parameter for the Nakagami distribution, specified as a positive scalar value.

Data Types: `single` | `double`

Distribution Characteristics

IsTruncated — Logical flag for truncated distribution

0 | 1

This property is read-only.

Logical flag for truncated distribution, specified as a logical value. If `IsTruncated` equals 0, the distribution is not truncated. If `IsTruncated` equals 1, the distribution is truncated.

Data Types: `logical`

NumParameters — Number of parameters

positive integer value

This property is read-only.

Number of parameters for the probability distribution, specified as a positive integer value.

Data Types: `double`

ParameterCovariance — Covariance matrix of the parameter estimates

matrix of scalar values

This property is read-only.

Covariance matrix of the parameter estimates, specified as a p -by- p matrix, where p is the number of parameters in the distribution. The (i,j) element is the covariance between the estimates of the i th parameter and the j th parameter. The (i,i) element is the estimated variance of the i th parameter. If parameter i is fixed rather than estimated by fitting the distribution to data, then the (i,i) elements of the covariance matrix are 0.

Data Types: `double`

ParameterIsFixed — Logical flag for fixed parameters

array of logical values

This property is read-only.

Logical flag for fixed parameters, specified as an array of logical values. If `0`, the corresponding parameter in the `ParameterNames` array is not fixed. If `1`, the corresponding parameter in the `ParameterNames` array is fixed.

Data Types: `logical`

ParameterValues — Distribution parameter values

vector of scalar values

This property is read-only.

Distribution parameter values, specified as a vector.

Data Types: `single` | `double`

Truncation — Truncation interval

vector of scalar values

This property is read-only.

Truncation interval for the probability distribution, specified as a vector containing the lower and upper truncation boundaries.

Data Types: `single` | `double`

Other Object Properties**DistributionName** — Probability distribution name

character vector

This property is read-only.

Probability distribution name, specified as a character vector.

Data Types: `char`

InputData — Data used for distribution fitting

structure

This property is read-only.

Data used for distribution fitting, specified as a structure containing the following:

- **data**: Data vector used for distribution fitting.
- **cens**: Censoring vector, or empty if none.
- **freq**: Frequency vector, or empty if none.

Data Types: `struct`

ParameterDescription — Distribution parameter descriptions

cell array of character vectors

This property is read-only.

Distribution parameter descriptions, specified as a cell array of character vectors. Each cell contains a short description of one distribution parameter.

Data Types: `char`

ParameterNames — Distribution parameter names

cell array of character vectors

This property is read-only.

Distribution parameter names, specified as a cell array of character vectors.

Data Types: `char`

Object Functions

<code>cdf</code>	Cumulative distribution function
<code>icdf</code>	Inverse cumulative distribution function
<code>iqr</code>	Interquartile range
<code>mean</code>	Mean of probability distribution
<code>median</code>	Median of probability distribution
<code>negloglik</code>	Negative loglikelihood of probability distribution
<code>paramci</code>	Confidence intervals for probability distribution parameters

pdf	Probability density function
proflik	Profile likelihood function for probability distribution
random	Random numbers
std	Standard deviation of probability distribution
truncate	Truncate probability distribution object
var	Variance of probability distribution

Examples

Create a Nakagami Distribution Object Using Default Parameters

Create a Nakagami distribution object using the default parameter values.

```
pd = makedist('Nakagami')  
  
pd =  
  NakagamiDistribution  
  
  Nakagami distribution  
    mu = 1  
    omega = 1
```

Create a Nakagami Distribution Object Using Specified Parameters

Create a Nakagami distribution object by specifying parameter values.

```
pd = makedist('Nakagami', 'mu', 5, 'omega', 2)  
  
pd =  
  NakagamiDistribution  
  
  Nakagami distribution  
    mu = 5  
    omega = 2
```

Compute the mean of the distribution.

```
m = mean(pd)  
  
m = 1.3794
```

NegativeBinomialDistribution

Negative binomial distribution object

Description

A `NegativeBinomialDistribution` object consists of parameters, a model description, and sample data for a negative binomial probability distribution.

The negative binomial distribution models the number of failures x before a specified number of successes, R , is reached in a series of independent, identical trials. This distribution can also model count data, in which case R does not need to be an integer value.

The negative binomial distribution uses the following parameters.

Parameter	Description	Support
R	Number of successes	$r > 0$
p	Probability of success	$0 < p \leq 1$

Creation

There are several ways to create a `NegativeBinomialDistribution` probability distribution object.

- Create a distribution with specified parameter values using `makedist`.
- Fit a distribution to data using `fitdist`.
- Interactively fit a distribution to data using the **Distribution Fitter** app.

Properties

Distribution Parameters

R — Number of successes

positive scalar value

Number of successes for the negative binomial distribution, specified as a positive scalar value.

Data Types: `single` | `double`

p — Probability of success

positive scalar value in the range (0,1]

Probability of success of any individual trial for the negative binomial distribution, specified as a positive scalar value in the range (0,1].

Data Types: `single` | `double`

Distribution Characteristics

IsTruncated — Logical flag for truncated distribution

0 | 1

This property is read-only.

Logical flag for truncated distribution, specified as a logical value. If `IsTruncated` equals 0, the distribution is not truncated. If `IsTruncated` equals 1, the distribution is truncated.

Data Types: `logical`

NumParameters — Number of parameters

positive integer value

This property is read-only.

Number of parameters for the probability distribution, specified as a positive integer value.

Data Types: `double`

ParameterCovariance — Covariance matrix of the parameter estimates

matrix of scalar values

This property is read-only.

Covariance matrix of the parameter estimates, specified as a p -by- p matrix, where p is the number of parameters in the distribution. The (i,j) element is the covariance between the estimates of the i th parameter and the j th parameter. The (i,i) element is the estimated variance of the i th parameter. If parameter i is fixed rather than estimated by fitting the distribution to data, then the (i,i) elements of the covariance matrix are 0.

Data Types: double

ParameterIsFixed — Logical flag for fixed parameters

array of logical values

This property is read-only.

Logical flag for fixed parameters, specified as an array of logical values. If 0, the corresponding parameter in the `ParameterNames` array is not fixed. If 1, the corresponding parameter in the `ParameterNames` array is fixed.

Data Types: logical

ParameterValues — Distribution parameter values

vector of scalar values

This property is read-only.

Distribution parameter values, specified as a vector.

Data Types: single | double

Truncation — Truncation interval

vector of scalar values

This property is read-only.

Truncation interval for the probability distribution, specified as a vector containing the lower and upper truncation boundaries.

Data Types: single | double

Other Object Properties

DistributionName — Probability distribution name

character vector

This property is read-only.

Probability distribution name, specified as a character vector.

Data Types: `char`

InputData — Data used for distribution fitting

structure

This property is read-only.

Data used for distribution fitting, specified as a structure containing the following:

- `data`: Data vector used for distribution fitting.
- `cens`: Censoring vector, or empty if none.
- `freq`: Frequency vector, or empty if none.

Data Types: `struct`

ParameterDescription — Distribution parameter descriptions

cell array of character vectors

This property is read-only.

Distribution parameter descriptions, specified as a cell array of character vectors. Each cell contains a short description of one distribution parameter.

Data Types: `char`

ParameterNames — Distribution parameter names

cell array of character vectors

This property is read-only.

Distribution parameter names, specified as a cell array of character vectors.

Data Types: `char`

NormalDistribution

Normal probability distribution object

Description

A `NormalDistribution` object consists of parameters, a model description, and sample data for a normal probability distribution.

The normal distribution, sometimes called the Gaussian distribution, is a two-parameter family of curves. The usual justification for using the normal distribution for modeling is the Central Limit theorem, which states (roughly) that the sum of independent samples from any distribution with finite mean and variance converges to the normal distribution as the sample size goes to infinity.

The normal distribution uses the following parameters.

Parameter	Description	Support
μ (μ)	Mean	$-\infty < \mu < \infty$
σ (σ)	Standard deviation	$\sigma \geq 0$

Creation

There are several ways to create a `NormalDistribution` probability distribution object.

- Create a distribution with specified parameter values using `makedist`.
- Fit a distribution to data using `fitdist`.
- Interactively fit a distribution to data using the **Distribution Fitter** app.

Properties

Distribution Parameters

mu — Mean

scalar value

Mean of the normal distribution, specified as a scalar value.

Data Types: `single` | `double`

sigma — Standard deviation

nonnegative scalar value

Standard deviation of the normal distribution, specified as a nonnegative scalar value.

You can specify `sigma` to be zero when you create an object by using `makedist`. Some object functions support an object `pd` with zero standard deviation. For example, `random(pd)` always returns `mu`, and `cdf(pd, x)` returns either 0 or 1. The output is 0 if `x` is smaller than `mu`, and 1 otherwise. `mean`, `std`, and `var` return the mean, standard deviation, and variance of `pd`, respectively.

Data Types: `single` | `double`

Distribution Characteristics

IsTruncated — Logical flag for truncated distribution

0 | 1

This property is read-only.

Logical flag for truncated distribution, specified as a logical value. If `IsTruncated` equals 0, the distribution is not truncated. If `IsTruncated` equals 1, the distribution is truncated.

Data Types: `logical`

NumParameters — Number of parameters

positive integer value

This property is read-only.

Number of parameters for the probability distribution, specified as a positive integer value.

Data Types: `double`

ParameterCovariance — Covariance matrix of the parameter estimates

matrix of scalar values

This property is read-only.

Covariance matrix of the parameter estimates, specified as a p -by- p matrix, where p is the number of parameters in the distribution. The (i,j) element is the covariance between the estimates of the i th parameter and the j th parameter. The (i,i) element is the estimated variance of the i th parameter. If parameter i is fixed rather than estimated by fitting the distribution to data, then the (i,i) elements of the covariance matrix are 0.

Data Types: `double`

ParameterIsFixed — Logical flag for fixed parameters

array of logical values

This property is read-only.

Logical flag for fixed parameters, specified as an array of logical values. If 0, the corresponding parameter in the `ParameterNames` array is not fixed. If 1, the corresponding parameter in the `ParameterNames` array is fixed.

Data Types: `logical`

ParameterValues — Distribution parameter values

vector of scalar values

This property is read-only.

Distribution parameter values, specified as a vector.

Data Types: `single` | `double`

Truncation — Truncation interval

vector of scalar values

This property is read-only.

Truncation interval for the probability distribution, specified as a vector containing the lower and upper truncation boundaries.

Data Types: `single` | `double`

Other Object Properties

DistributionName — Probability distribution name

character vector

This property is read-only.

Probability distribution name, specified as a character vector.

Data Types: `char`

InputData — Data used for distribution fitting

structure

This property is read-only.

Data used for distribution fitting, specified as a structure containing the following:

- `data`: Data vector used for distribution fitting.
- `cens`: Censoring vector, or empty if none.
- `freq`: Frequency vector, or empty if none.

Data Types: `struct`

ParameterDescription — Distribution parameter descriptions

cell array of character vectors

This property is read-only.

Distribution parameter descriptions, specified as a cell array of character vectors. Each cell contains a short description of one distribution parameter.

Data Types: `char`

ParameterNames — Distribution parameter names

cell array of character vectors

This property is read-only.

Distribution parameter names, specified as a cell array of character vectors.

Data Types: char

Object Functions

<code>cdf</code>	Cumulative distribution function
<code>icdf</code>	Inverse cumulative distribution function
<code>iqr</code>	Interquartile range
<code>mean</code>	Mean of probability distribution
<code>median</code>	Median of probability distribution
<code>negloglik</code>	Negative loglikelihood of probability distribution
<code>paramci</code>	Confidence intervals for probability distribution parameters
<code>pdf</code>	Probability density function
<code>proflik</code>	Profile likelihood function for probability distribution
<code>random</code>	Random numbers
<code>std</code>	Standard deviation of probability distribution
<code>truncate</code>	Truncate probability distribution object
<code>var</code>	Variance of probability distribution

Examples

Create a Normal Distribution Object Using Default Parameters

Create a normal distribution object using the default parameter values.

```
pd = makedist('Normal')  
  
pd =  
  NormalDistribution  
  
  Normal distribution  
    mu = 0  
    sigma = 1
```

Create a Normal Distribution Object Using Specified Parameters

Create a normal distribution object by specifying the parameter values.

```
pd = makedist('Normal', 'mu', 75, 'sigma', 10)
```

```
pd =  
  NormalDistribution  
  
  Normal distribution  
    mu = 75  
    sigma = 10
```

Compute the interquartile range of the distribution.

```
r = iqr(pd)  
  
r = 13.4898
```

Fit Normal Distribution Object

Load the sample data and create a vector containing the first column of student exam grade data.

```
load examgrades  
x = grades(:,1);
```

Create a normal distribution object by fitting it to the data.

```
pd = fitdist(x, 'Normal')  
  
pd =  
  NormalDistribution  
  
  Normal distribution  
    mu = 75.0083   [73.4321, 76.5846]  
    sigma = 8.7202 [7.7391, 9.98843]
```

The intervals next to the parameter estimates are the 95% confidence intervals for the distribution parameters.

PiecewiseLinearDistribution

Piecewise linear probability distribution object

Description

A `PiecewiseLinearDistribution` object consists of a model description for a piecewise linear probability distribution.

The piecewise linear distribution is a nonparametric probability distribution created using a piecewise linear representation of the cumulative distribution function (cdf). The options specified for the piecewise linear distribution specify the form of the cdf. The probability density function (pdf) is a step function.

The piecewise linear distribution uses the following parameters.

Parameter	Description
<code>x</code>	Vector of <code>x</code> values at which the cdf changes slope
<code>Fx</code>	Vector of cdf values that correspond to each value in <code>x</code>

Creation

Create a `PiecewiseLinearDistribution` probability distribution with specified parameter values object using `makedist`.

Properties

Distribution Parameters

x — Data values

vector of scalar values

Data values at which the cumulative distribution function (cdf) changes slope, specified as a vector of scalar values.

Data Types: `single` | `double`

Fx — cdf value

vector of scalar values

cdf value at each value in `x`, specified as a vector of scalar values.

Data Types: `single` | `double`

Distribution Characteristics

IsTruncated — Logical flag for truncated distribution

`0` | `1`

This property is read-only.

Logical flag for truncated distribution, specified as a logical value. If `IsTruncated` equals `0`, the distribution is not truncated. If `IsTruncated` equals `1`, the distribution is truncated.

Data Types: `logical`

NumParameters — Number of parameters

positive integer value

This property is read-only.

Number of parameters for the probability distribution, specified as a positive integer value.

Data Types: `double`

ParameterValues — Distribution parameter values

vector of scalar values

This property is read-only.

Distribution parameter values, specified as a vector.

Data Types: `single` | `double`

Truncation — Truncation interval

vector of scalar values

This property is read-only.

Truncation interval for the probability distribution, specified as a vector containing the lower and upper truncation boundaries.

Data Types: `single` | `double`

Other Object Properties**DistributionName — Probability distribution name**

character vector

This property is read-only.

Probability distribution name, specified as a character vector.

Data Types: `char`

ParameterDescription — Distribution parameter descriptions

cell array of character vectors

This property is read-only.

Distribution parameter descriptions, specified as a cell array of character vectors. Each cell contains a short description of one distribution parameter.

Data Types: `char`

ParameterNames — Distribution parameter names

cell array of character vectors

This property is read-only.

Distribution parameter names, specified as a cell array of character vectors.

Data Types: `char`

Object Functions

<code>cdf</code>	Cumulative distribution function
<code>icdf</code>	Inverse cumulative distribution function
<code>iqr</code>	Interquartile range
<code>mean</code>	Mean of probability distribution
<code>median</code>	Median of probability distribution
<code>pdf</code>	Probability density function
<code>random</code>	Random numbers
<code>std</code>	Standard deviation of probability distribution
<code>truncate</code>	Truncate probability distribution object
<code>var</code>	Variance of probability distribution

Examples

Create a Piecewise Linear Distribution Object Using Default Parameters

Create a piecewise linear distribution object using the default parameter values.

```
pd = makedist('PiecewiseLinear')
```

```
pd =  
  PiecewiseLinearDistribution
```

```
F(0) = 0
```

```
F(1) = 1
```

Create a Piecewise Linear Distribution Object Using Specified Parameters

Load the sample data. Visualize the patient weight data using a histogram.

```
load hospital  
histogram(hospital.Weight)
```

The histogram shows that the data has two modes, one for female patients and one for male patients.

Compute the empirical cumulative distribution function (ecdf) for the data.

```
[f,x] = ecdf(hospital.Weight);
```

Construct a piecewise linear approximation to the ecdf and plot both functions.

```
f = f(1:5:end); % keep a less dense grid of points  
x = x(1:5:end);
```

```
figure;  
ecdf(hospital.Weight)
```

```

hold on
plot(x,f,'ro','MarkerFace','r') % overlay grid
plot(x,f,'k') % show interpolation

```

Create a piecewise linear probability distribution object using the piecewise approximation of the ecdf.

```
pd = makedist('PiecewiseLinear','x',x,'Fx',f)
```

```
pd =
  PiecewiseLinearDistribution
```

```
F(111) = 0
F(118) = 0.05
```

```
F(124) = 0.13  
F(130) = 0.25  
F(135) = 0.37  
F(142) = 0.5  
F(163) = 0.55  
F(171) = 0.61  
F(178) = 0.7  
F(183) = 0.82  
F(189) = 0.94  
F(202) = 1
```

Generate 100 random numbers from the distribution.

```
rw = random(pd,100,1);
```

Plot the random numbers to visually compare their distribution to the original data.

```
figure;  
histogram(rw)
```

The random numbers generated from the piecewise linear distribution have the same bimodal distribution as the original data.

PoissonDistribution

Poisson probability distribution object

Description

A `PoissonDistribution` object consists of parameters, a model description, and sample data for a Poisson probability distribution.

The Poisson distribution is appropriate for applications that involve counting the number of times a random event occurs in a given amount of time, distance, area, etc. If the number of counts follows the Poisson distribution, then the interval between individual counts follows the exponential distribution.

The Poisson distribution uses the following parameters.

Parameter	Description	Support
<code>lambda</code>	Mean	$\lambda \geq 0$

Creation

There are several ways to create a `PoissonDistribution` probability distribution object.

- Create a distribution with specified parameter values using `makedist`.
- Fit a distribution to data using `fitdist`.
- Interactively fit a distribution to data using the **Distribution Fitter** app.

Properties

Distribution Parameter

`lambda` — Mean

nonnegative scalar value

Mean of the Poisson distribution, stored as a nonnegative scalar value.

Data Types: `single` | `double`

Distribution Characteristics

IsTruncated — Logical flag for truncated distribution

`0` | `1`

This property is read-only.

Logical flag for truncated distribution, specified as a logical value. If `IsTruncated` equals `0`, the distribution is not truncated. If `IsTruncated` equals `1`, the distribution is truncated.

Data Types: `logical`

NumParameters — Number of parameters

positive integer value

This property is read-only.

Number of parameters for the probability distribution, specified as a positive integer value.

Data Types: `double`

ParameterCovariance — Covariance matrix of the parameter estimates

matrix of scalar values

This property is read-only.

Covariance matrix of the parameter estimates, specified as a p -by- p matrix, where p is the number of parameters in the distribution. The (i,j) element is the covariance between the estimates of the i th parameter and the j th parameter. The (i,i) element is the estimated variance of the i th parameter. If parameter i is fixed rather than estimated by fitting the distribution to data, then the (i,i) elements of the covariance matrix are 0.

Data Types: `double`

ParameterIsFixed — Logical flag for fixed parameters

array of logical values

This property is read-only.

Logical flag for fixed parameters, specified as an array of logical values. If 0, the corresponding parameter in the `ParameterNames` array is not fixed. If 1, the corresponding parameter in the `ParameterNames` array is fixed.

Data Types: `logical`

ParameterValues — Distribution parameter values

vector of scalar values

This property is read-only.

Distribution parameter values, specified as a vector.

Data Types: `single` | `double`

Truncation — Truncation interval

vector of scalar values

This property is read-only.

Truncation interval for the probability distribution, specified as a vector containing the lower and upper truncation boundaries.

Data Types: `single` | `double`

Other Object Properties**DistributionName — Probability distribution name**

character vector

This property is read-only.

Probability distribution name, specified as a character vector.

Data Types: `char`

InputData — Data used for distribution fitting

structure

This property is read-only.

Data used for distribution fitting, specified as a structure containing the following:

- **data**: Data vector used for distribution fitting.
- **cens**: Censoring vector, or empty if none.
- **freq**: Frequency vector, or empty if none.

Data Types: `struct`

ParameterDescription — Distribution parameter descriptions

cell array of character vectors

This property is read-only.

Distribution parameter descriptions, specified as a cell array of character vectors. Each cell contains a short description of one distribution parameter.

Data Types: `char`

ParameterNames — Distribution parameter names

cell array of character vectors

This property is read-only.

Distribution parameter names, specified as a cell array of character vectors.

Data Types: `char`

Object Functions

<code>cdf</code>	Cumulative distribution function
<code>icdf</code>	Inverse cumulative distribution function
<code>iqr</code>	Interquartile range
<code>mean</code>	Mean of probability distribution
<code>median</code>	Median of probability distribution
<code>negloglik</code>	Negative loglikelihood of probability distribution
<code>paramci</code>	Confidence intervals for probability distribution parameters
<code>pdf</code>	Probability density function
<code>proflik</code>	Profile likelihood function for probability distribution
<code>random</code>	Random numbers
<code>std</code>	Standard deviation of probability distribution
<code>truncate</code>	Truncate probability distribution object
<code>var</code>	Variance of probability distribution

Examples

Create a Poisson Distribution Object Using Default Parameters

Create a Poisson distribution object using the default parameter values.

```
pd = makedist('Poisson')

pd =
  PoissonDistribution

  Poisson distribution
  lambda = 1
```

Create a Poisson Distribution Object Using Specified Parameters

Create a Poisson distribution object by specifying the parameter values.

```
pd = makedist('Poisson','lambda',5)

pd =
  PoissonDistribution

  Poisson distribution
  lambda = 5
```

Compute the variance of the distribution.

```
v = var(pd)

v = 5
```

For the Poisson distribution, both the mean and variance are equal to the parameter `lambda`.

RayleighDistribution

Rayleigh probability distribution object

Description

A `RayleighDistribution` object consists of parameters, a model description, and sample data for a normal probability distribution.

The Rayleigh distribution is a special case of the Weibull distribution. It is often used in communication theory to model scattered signals that reach a receiver by multiple paths.

The Rayleigh distribution uses the following parameter.

Parameter	Description	Support
<code>b</code>	Defining parameter	$b > 0$

Creation

There are several ways to create a `RayleighDistribution` probability distribution object.

- Create a distribution with specified parameter values using `makedist`.
- Fit a distribution to data using `fitdist`.
- Interactively fit a distribution to data using the **Distribution Fitter** app.

Properties

Distribution Parameter

b — Defining parameter

positive scalar value

Defining parameter for the Rayleigh distribution, specified as a positive scalar value.

Data Types: `single` | `double`

Distribution Characteristics

IsTruncated — Logical flag for truncated distribution

`0` | `1`

This property is read-only.

Logical flag for truncated distribution, specified as a logical value. If `IsTruncated` equals `0`, the distribution is not truncated. If `IsTruncated` equals `1`, the distribution is truncated.

Data Types: `logical`

NumParameters — Number of parameters

positive integer value

This property is read-only.

Number of parameters for the probability distribution, specified as a positive integer value.

Data Types: `double`

ParameterCovariance — Covariance matrix of the parameter estimates

matrix of scalar values

This property is read-only.

Covariance matrix of the parameter estimates, specified as a p -by- p matrix, where p is the number of parameters in the distribution. The (i,j) element is the covariance between the estimates of the i th parameter and the j th parameter. The (i,i) element is the estimated variance of the i th parameter. If parameter i is fixed rather than estimated by fitting the distribution to data, then the (i,i) elements of the covariance matrix are 0.

Data Types: `double`

ParameterIsFixed — Logical flag for fixed parameters

array of logical values

This property is read-only.

Logical flag for fixed parameters, specified as an array of logical values. If 0, the corresponding parameter in the `ParameterNames` array is not fixed. If 1, the corresponding parameter in the `ParameterNames` array is fixed.

Data Types: `logical`

ParameterValues — Distribution parameter values

vector of scalar values

This property is read-only.

Distribution parameter values, specified as a vector.

Data Types: `single` | `double`

Truncation — Truncation interval

vector of scalar values

This property is read-only.

Truncation interval for the probability distribution, specified as a vector containing the lower and upper truncation boundaries.

Data Types: `single` | `double`

Other Object Properties**DistributionName — Probability distribution name**

character vector

This property is read-only.

Probability distribution name, specified as a character vector.

Data Types: `char`

InputData — Data used for distribution fitting

structure

This property is read-only.

Data used for distribution fitting, specified as a structure containing the following:

- **data**: Data vector used for distribution fitting.
- **cens**: Censoring vector, or empty if none.
- **freq**: Frequency vector, or empty if none.

Data Types: `struct`

ParameterDescription — Distribution parameter descriptions

cell array of character vectors

This property is read-only.

Distribution parameter descriptions, specified as a cell array of character vectors. Each cell contains a short description of one distribution parameter.

Data Types: `char`

ParameterNames — Distribution parameter names

cell array of character vectors

This property is read-only.

Distribution parameter names, specified as a cell array of character vectors.

Data Types: `char`

Object Functions

<code>cdf</code>	Cumulative distribution function
<code>icdf</code>	Inverse cumulative distribution function

<code>paramci</code>	Confidence intervals for probability distribution parameters
<code>pdf</code>	Probability density function
<code>proflik</code>	Profile likelihood function for probability distribution
<code>random</code>	Random numbers
<code>std</code>	Standard deviation of probability distribution
<code>truncate</code>	Truncate probability distribution object
<code>var</code>	Variance of probability distribution

Examples

Create a Rayleigh Distribution Object Using Default Parameters

Create a Rayleigh distribution object using the default parameter values.

```
pd = makedist('Rayleigh')  
  
pd =  
  RayleighDistribution  
  
  Rayleigh distribution  
  B = 1
```

Create a Rayleigh Distribution Object Using Specified Parameters

Create a Rayleigh distribution object by specifying the parameter values.

```
pd = makedist('Rayleigh','b',3)  
  
pd =  
  RayleighDistribution  
  
  Rayleigh distribution  
  B = 3
```

Compute the mean of the distribution.

```
m = mean(pd)  
  
m = 3.7599
```

RicianDistribution

Rician probability distribution object

Description

A `RicianDistribution` object consists of parameters, a model description, and sample data for a Rician probability distribution.

The Rician distribution is used in communications theory to model scattered signals that reach a receiver using multiple paths.

The Rician distribution uses the following parameters.

Name	Description	Support
s	Noncentrality parameter	$s \geq 0$
sigma	Scale parameter	$\sigma > 0$

Creation

There are several ways to create a `RicianDistribution` probability distribution object.

- Create a distribution with specified parameter values using `makedist`.
- Fit a distribution to data using `fitdist`.
- Interactively fit a distribution to data using the **Distribution Fitter** app.

Properties

Distribution Parameters

s — Noncentrality parameter

nonnegative scalar value

Noncentrality parameter of the Rician distribution, specified as a nonnegative scalar value.

Data Types: `single` | `double`

sigma — scale parameter

positive scalar value

Scale parameter for the Rician distribution, specified as a positive scalar value.

Data Types: `single` | `double`

Distribution Characteristics

IsTruncated — Logical flag for truncated distribution

0 | 1

This property is read-only.

Logical flag for truncated distribution, specified as a logical value. If `IsTruncated` equals 0, the distribution is not truncated. If `IsTruncated` equals 1, the distribution is truncated.

Data Types: `logical`

NumParameters — Number of parameters

positive integer value

This property is read-only.

Number of parameters for the probability distribution, specified as a positive integer value.

Data Types: `double`

ParameterCovariance — Covariance matrix of the parameter estimates

matrix of scalar values

This property is read-only.

Covariance matrix of the parameter estimates, specified as a p -by- p matrix, where p is the number of parameters in the distribution. The (i,j) element is the covariance between the estimates of the i th parameter and the j th parameter. The (i,i) element is the

estimated variance of the i th parameter. If parameter i is fixed rather than estimated by fitting the distribution to data, then the (i,i) elements of the covariance matrix are 0.

Data Types: `double`

ParameterIsFixed — Logical flag for fixed parameters

array of logical values

This property is read-only.

Logical flag for fixed parameters, specified as an array of logical values. If 0, the corresponding parameter in the `ParameterNames` array is not fixed. If 1, the corresponding parameter in the `ParameterNames` array is fixed.

Data Types: `logical`

ParameterValues — Distribution parameter values

vector of scalar values

This property is read-only.

Distribution parameter values, specified as a vector.

Data Types: `single` | `double`

Truncation — Truncation interval

vector of scalar values

This property is read-only.

Truncation interval for the probability distribution, specified as a vector containing the lower and upper truncation boundaries.

Data Types: `single` | `double`

Other Object Properties**DistributionName** — Probability distribution name

character vector

This property is read-only.

Probability distribution name, specified as a character vector.

Data Types: `char`

InputData — Data used for distribution fitting

structure

This property is read-only.

Data used for distribution fitting, specified as a structure containing the following:

- **data**: Data vector used for distribution fitting.
- **cens**: Censoring vector, or empty if none.
- **freq**: Frequency vector, or empty if none.

Data Types: `struct`

ParameterDescription — Distribution parameter descriptions

cell array of character vectors

This property is read-only.

Distribution parameter descriptions, specified as a cell array of character vectors. Each cell contains a short description of one distribution parameter.

Data Types: `char`

StableDistribution

Stable probability distribution object

Description

`StableDistribution` is an object consisting of parameters, a model description, and sample data for a stable probability distribution.

The stable distribution uses the following parameters.

Parameter	Description	Support
alpha	First shape parameter	$0 < \alpha \leq 2$
beta	Second shape parameter	$-1 \leq \beta \leq 1$
gam	Scale parameter	$0 < \gamma < \infty$
delta	Location parameter	$-\infty < \delta < \infty$

Creation

There are several ways to create a `StableDistribution` probability distribution object.

- Create a distribution with specified parameter values using `makedist`.
- Fit a distribution to data using `fitdist`.
- Interactively fit a distribution to data using the **Distribution Fitter** app.

Properties

Distribution Parameters

alpha — First shape parameter

scalar value in the range (0,2]

First shape parameter of the stable distribution, specified as a scalar value in the range $(0,2]$.

Data Types: `single` | `double`

beta — Second shape parameter

scalar value in the range $[-1,1]$

Second shape parameter of the stable distribution, specified as a scalar value in the range $[-1,1]$.

Data Types: `single` | `double`

gam — Scale parameter

scalar value in the range $(0,\infty)$

Scale parameter of the stable distribution, specified as a scalar value in the range $(0,\infty)$.

Data Types: `single` | `double`

delta — Location parameter

scalar value

Location parameter of the stable distribution, specified as a scalar value.

Data Types: `single` | `double`

Distribution Characteristics

IsTruncated — Logical flag for truncated distribution

`0` | `1`

This property is read-only.

Logical flag for truncated distribution, specified as a logical value. If `IsTruncated` equals `0`, the distribution is not truncated. If `IsTruncated` equals `1`, the distribution is truncated.

Data Types: `logical`

NumParameters — Number of parameters

positive integer value

This property is read-only.

Number of parameters for the probability distribution, specified as a positive integer value.

Data Types: `double`

ParameterCovariance — Covariance matrix of the parameter estimates

matrix of scalar values

This property is read-only.

Covariance matrix of the parameter estimates, specified as a p -by- p matrix, where p is the number of parameters in the distribution. The (i,j) element is the covariance between the estimates of the i th parameter and the j th parameter. The (i,i) element is the estimated variance of the i th parameter. If parameter i is fixed rather than estimated by fitting the distribution to data, then the (i,i) elements of the covariance matrix are 0.

Data Types: `double`

ParameterIsFixed — Logical flag for fixed parameters

array of logical values

This property is read-only.

Logical flag for fixed parameters, specified as an array of logical values. If 0, the corresponding parameter in the `ParameterNames` array is not fixed. If 1, the corresponding parameter in the `ParameterNames` array is fixed.

Data Types: `logical`

ParameterValues — Distribution parameter values

vector of scalar values

This property is read-only.

Distribution parameter values, specified as a vector.

Data Types: `single` | `double`

Truncation — Truncation interval

vector of scalar values

This property is read-only.

Truncation interval for the probability distribution, specified as a vector containing the lower and upper truncation boundaries.

Data Types: `single` | `double`

Other Object Properties

DistributionName — Probability distribution name

character vector

This property is read-only.

Probability distribution name, specified as a character vector.

Data Types: `char`

InputData — Data used for distribution fitting

structure

This property is read-only.

Data used for distribution fitting, specified as a structure containing the following:

- `data`: Data vector used for distribution fitting.
- `cens`: Censoring vector, or empty if none.
- `freq`: Frequency vector, or empty if none.

Data Types: `struct`

ParameterDescription — Distribution parameter descriptions

cell array of character vectors

This property is read-only.

Distribution parameter descriptions, specified as a cell array of character vectors. Each cell contains a short description of one distribution parameter.

Data Types: `char`

ParameterNames — Distribution parameter names

cell array of character vectors

This property is read-only.

Distribution parameter names, specified as a cell array of character vectors.

<code>proflik</code>	Profile likelihood function for probability distribution
<code>random</code>	Random numbers
<code>std</code>	Standard deviation of probability distribution
<code>truncate</code>	Truncate probability distribution object
<code>var</code>	Variance of probability distribution

Examples

Create a Stable Distribution Object Using Default Parameters

Create a stable distribution object using the default parameter values.

```
pd = makedist('Stable')

pd =
  StableDistribution

  Stable distribution
  alpha = 2
  beta = 0
  gam = 1
  delta = 0
```

Create a Stable Distribution Object Using Specified Parameters

Create a stable distribution object by specifying the parameter values $\alpha = 0.5$, $\beta = 0$, $\gamma = 1$, and $\delta = 0$.

```
pd = makedist('Stable', 'alpha', 0.5, 'beta', 0, 'gam', 1, 'delta', 0);
```

Calculate the mean of the distribution.

```
m = mean(pd)
```

```
m = NaN
```

The mean of the stable distribution is undefined for values of α less than or equal to 1.

tLocationScaleDistribution

t Location-Scale probability distribution object

Description

A `tLocationScaleDistribution` object consists of parameters, a model description, and sample data for a *t* location-scale probability distribution.

The *t* location-scale distribution is useful for modeling data distributions with heavier tails (more prone to outliers) than the normal distribution. It approaches the normal distribution as ν approaches infinity, and smaller values of ν yield heavier tails.

The *t* location-scale distribution uses the following parameters.

Parameter	Description	Support
<code>mu</code>	Location parameter	$-\infty < \mu < \infty$
<code>sigma</code>	Scale parameter	$\sigma > 0$
<code>nu</code>	Shape parameter	$\nu > 0$

Creation

There are several ways to create a `tLocationScaleDistribution` probability distribution object.

- Create a distribution with specified parameter values using `makedist`.
- Fit a distribution to data using `fitdist`.
- Interactively fit a distribution to data using the **Distribution Fitter** app.

Properties

Distribution Parameters

mu — Location parameter

scalar value

Location parameter of the t location-scale distribution, specified as a scalar value.

Data Types: `single` | `double`

sigma — Scale parameter

positive scalar value

Scale parameter of the t location-scale distribution, specified as a positive scalar value.

Data Types: `single` | `double`

nu — Degrees of freedom

positive scalar value

Degrees of freedom of the t location-scale distribution, specified as a positive scalar value.

Data Types: `single` | `double`

Distribution Characteristics

IsTruncated — Logical flag for truncated distribution`0` | `1`

This property is read-only.

Logical flag for truncated distribution, specified as a logical value. If `IsTruncated` equals `0`, the distribution is not truncated. If `IsTruncated` equals `1`, the distribution is truncated.

Data Types: `logical`

NumParameters — Number of parameters

positive integer value

This property is read-only.

Number of parameters for the probability distribution, specified as a positive integer value.

Data Types: `double`

ParameterCovariance — Covariance matrix of the parameter estimates

matrix of scalar values

This property is read-only.

Covariance matrix of the parameter estimates, specified as a p -by- p matrix, where p is the number of parameters in the distribution. The (i,j) element is the covariance between the estimates of the i th parameter and the j th parameter. The (i,i) element is the estimated variance of the i th parameter. If parameter i is fixed rather than estimated by fitting the distribution to data, then the (i,i) elements of the covariance matrix are 0.

Data Types: `double`

ParameterIsFixed — Logical flag for fixed parameters

array of logical values

This property is read-only.

Logical flag for fixed parameters, specified as an array of logical values. If 0, the corresponding parameter in the `ParameterNames` array is not fixed. If 1, the corresponding parameter in the `ParameterNames` array is fixed.

Data Types: `logical`

ParameterValues — Distribution parameter values

vector of scalar values

This property is read-only.

Distribution parameter values, specified as a vector.

Data Types: `single` | `double`

Truncation — Truncation interval

vector of scalar values

This property is read-only.

Truncation interval for the probability distribution, specified as a vector containing the lower and upper truncation boundaries.

Data Types: `single` | `double`

Other Object Properties

DistributionName — Probability distribution name

character vector

This property is read-only.

Probability distribution name, specified as a character vector.

Data Types: `char`

InputData — Data used for distribution fitting

structure

This property is read-only.

Data used for distribution fitting, specified as a structure containing the following:

- `data`: Data vector used for distribution fitting.
- `cens`: Censoring vector, or empty if none.
- `freq`: Frequency vector, or empty if none.

Data Types: `struct`

ParameterDescription — Distribution parameter descriptions

cell array of character vectors

This property is read-only.

Distribution parameter descriptions, specified as a cell array of character vectors. Each cell contains a short description of one distribution parameter.

Data Types: `char`

ParameterNames — Distribution parameter names

cell array of character vectors

This property is read-only.

Distribution parameter names, specified as a cell array of character vectors.

Data Types: char

Examples

Create a *t* Location-Scale Distribution Object Using Default Parameters

Create a *t* location scale distribution object using the default parameter values.

```
pd = makedist('tLocationScale')

pd =
  tLocationScaleDistribution

  t Location-Scale distribution
    mu = 0
    sigma = 1
    nu = 5
```

Create a *t* Location-Scale Distribution Object Using Specified Parameters

Create a *t* location-scale distribution object by specifying the parameter values.

```
pd = makedist('tLocationScale', 'mu', -2, 'sigma', 1, 'nu', 20)
```

```
pd =  
  tLocationScaleDistribution  
  
  t Location-Scale distribution  
    mu = -2  
    sigma = 1  
    nu = 20
```

Compute the interquartile range of the distribution.

```
r = iqr(pd)  
r = 1.3739
```

Triangular probability distribution object

Description

A `TriangularDistribution` object consists of parameters and a model description for a triangular probability distribution.

The triangular distribution is frequently used in simulations when limited sample data is available. The lower and upper limits represent the smallest and largest values, and the location of the peak represents an estimate of the mode.

The triangular distribution uses the following parameters.

Parameter	Description	Support
a	Lower limit	$a \leq b$
b	Peak location	$a \leq b \leq c$
c	Upper limit	$c \geq b$

Creation

Create a `TriangularDistribution` probability distribution with specified parameter values object using `makedist`.

Properties

Distribution Parameters

a — Lower limit

scalar value

Lower limit for the triangular distribution, specified as a scalar value.

Data Types: `single` | `double`

b — Peak location

scalar value

Location of the peak for the triangular distribution, specified as a scalar value greater than or equal to **a**.

Data Types: `single` | `double`

c — Upper limit

scalar value

Upper limit for the triangular distribution, specified as a scalar value greater than or equal to **b**.

Data Types: `single` | `double`

Distribution Characteristics

IsTruncated — Logical flag for truncated distribution

`0` | `1`

This property is read-only.

Logical flag for truncated distribution, specified as a logical value. If `IsTruncated` equals `0`, the distribution is not truncated. If `IsTruncated` equals `1`, the distribution is truncated.

Data Types: `logical`

NumParameters — Number of parameters

positive integer value

This property is read-only.

Number of parameters for the probability distribution, specified as a positive integer value.

Data Types: `double`

ParameterValues — Distribution parameter values

vector of scalar values

This property is read-only.

Distribution parameter values, specified as a vector.

Data Types: `single` | `double`

Truncation — Truncation interval

vector of scalar values

This property is read-only.

Truncation interval for the probability distribution, specified as a vector containing the lower and upper truncation boundaries.

Data Types: `single` | `double`

Other Object Properties**DistributionName — Probability distribution name**

character vector

This property is read-only.

Probability distribution name, specified as a character vector.

Data Types: `char`

ParameterDescription — Distribution parameter descriptions

cell array of character vectors

This property is read-only.

Distribution parameter descriptions, specified as a cell array of character vectors. Each cell contains a short description of one distribution parameter.

Data Types: `char`

ParameterNames — Distribution parameter names

cell array of character vectors

This property is read-only.

Distribution parameter names, specified as a cell array of character vectors.

Data Types: `char`

Object Functions

cdf	Cumulative distribution function
icdf	Inverse cumulative distribution function
iqr	Interquartile range
mean	Mean of probability distribution
median	Median of probability distribution
pdf	Probability density function
random	Random numbers
std	Standard deviation of probability distribution
truncate	Truncate probability distribution object
var	Variance of probability distribution

Examples

Create a Triangular Distribution Object Using Default Parameters

Create a triangular distribution object using the default parameter values.

```
pd = makedist('Triangular')  
  
pd =  
    TriangularDistribution  
  
A = 0, B = 0.5, C = 1
```

Create a Triangular Distribution Object Using Specified Parameters

Create a triangular distribution object by specifying parameter values.

```
pd = makedist('Triangular', 'a', -2, 'b', 1, 'c', 5)  
  
pd =  
    TriangularDistribution  
  
A = -2, B = 1, C = 5
```

Compute the mean of the distribution.

```
m = mean(pd)
```

```
m =
```

```
1.3333
```

UniformDistribution

Uniform probability distribution object

Description

A `UniformDistribution` object consists of parameters and a model description for a uniform probability distribution.

The uniform distribution has a constant probability density function between its two parameters, `lower` (the minimum) and `upper` (the maximum). This distribution is appropriate for representing round-off errors in values tabulated to a particular number of decimal places.

The uniform distribution uses the following parameters.

Parameter	Description	Support
<code>lower</code>	Lower parameter	$-\infty < lower < upper$
<code>upper</code>	Upper parameter	$lower < upper < \infty$

Creation

Create a `UniformDistribution` probability distribution with specified parameter values object using `makedist`.

Properties

Distribution Parameters

lower — Lower parameter

scalar value

Lower parameter for the uniform distribution, specified as a scalar value.

Data Types: `single` | `double`

upper — Upper parameter

scalar value

Upper parameter for the uniform distribution, specified as a scalar value greater than lower.

Data Types: `single` | `double`

Distribution Characteristics**IsTruncated** — Logical flag for truncated distribution

`0` | `1`

This property is read-only.

Logical flag for truncated distribution, specified as a logical value. If `IsTruncated` equals `0`, the distribution is not truncated. If `IsTruncated` equals `1`, the distribution is truncated.

Data Types: `logical`

NumParameters — Number of parameters

positive integer value

This property is read-only.

Number of parameters for the probability distribution, specified as a positive integer value.

Data Types: `double`

ParameterValues — Distribution parameter values

vector of scalar values

This property is read-only.

Distribution parameter values, specified as a vector.

Data Types: `single` | `double`

Truncation — Truncation interval

vector of scalar values

This property is read-only.

Truncation interval for the probability distribution, specified as a vector containing the lower and upper truncation boundaries.

Data Types: `single` | `double`

Other Object Properties

DistributionName — Probability distribution name

character vector

This property is read-only.

Probability distribution name, specified as a character vector.

Data Types: `char`

ParameterDescription — Distribution parameter descriptions

cell array of character vectors

This property is read-only.

Distribution parameter descriptions, specified as a cell array of character vectors. Each cell contains a short description of one distribution parameter.

Data Types: `char`

ParameterNames — Distribution parameter names

cell array of character vectors

This property is read-only.

Distribution parameter names, specified as a cell array of character vectors.

Data Types: `char`

Object Functions

<code>cdf</code>	Cumulative distribution function
<code>icdf</code>	Inverse cumulative distribution function
<code>iqr</code>	Interquartile range

mean	Mean of probability distribution
median	Median of probability distribution
pdf	Probability density function
random	Random numbers
std	Standard deviation of probability distribution
truncate	Truncate probability distribution object
var	Variance of probability distribution

Examples

Create a Uniform Distribution Object Using Default Parameters

Create a uniform distribution object using the default parameter values.

```
pd = makedist('Uniform')

pd =
  UniformDistribution

  Uniform distribution
  Lower = 0
  Upper = 1
```

Create a Uniform Distribution Object Using Specified Parameters

Create a uniform distribution object by specifying parameter values.

```
pd = makedist('Uniform', 'Lower', -4, 'Upper', 2)

pd =
  UniformDistribution

  Uniform distribution
  Lower = -4
  Upper = 2
```

Compute the interquartile range of the distribution

```
r = iqr(pd)
```

`r = 3`

WeibullDistribution

Weibull probability distribution object

Description

A `WeibullDistribution` object consists of parameters, a model description, and sample data for a Weibull probability distribution.

The Weibull distribution is used in reliability and lifetime modeling, and to model the breaking strength of materials.

The Weibull distribution uses the following parameters.

Parameter	Description	Support
a	Scale parameter	$a > 0$
b	Shape parameter	$b > 0$

Creation

There are several ways to create a `WeibullDistribution` probability distribution object.

- Create a distribution with specified parameter values using `makedist`.
- Fit a distribution to data using `fitdist`.
- Interactively fit a distribution to data using the **Distribution Fitter** app.

Properties

Distribution Parameters

a — Scale parameter
positive scalar value

Scale parameter of the Weibull distribution, specified as a positive scalar value.

Data Types: `single` | `double`

b — Shape parameter

positive scalar value

Shape parameter of the Weibull distribution, specified as a positive scalar value.

Data Types: `single` | `double`

Distribution Characteristics

IsTruncated — Logical flag for truncated distribution

`0` | `1`

This property is read-only.

Logical flag for truncated distribution, specified as a logical value. If `IsTruncated` equals `0`, the distribution is not truncated. If `IsTruncated` equals `1`, the distribution is truncated.

Data Types: `logical`

NumParameters — Number of parameters

positive integer value

This property is read-only.

Number of parameters for the probability distribution, specified as a positive integer value.

Data Types: `double`

ParameterCovariance — Covariance matrix of the parameter estimates

matrix of scalar values

This property is read-only.

Covariance matrix of the parameter estimates, specified as a p -by- p matrix, where p is the number of parameters in the distribution. The (i,j) element is the covariance between the estimates of the i th parameter and the j th parameter. The (i,i) element is the estimated variance of the i th parameter. If parameter i is fixed rather than estimated by fitting the distribution to data, then the (i,i) elements of the covariance matrix are 0.

Data Types: `double`

ParameterIsFixed — Logical flag for fixed parameters

array of logical values

This property is read-only.

Logical flag for fixed parameters, specified as an array of logical values. If `0`, the corresponding parameter in the `ParameterNames` array is not fixed. If `1`, the corresponding parameter in the `ParameterNames` array is fixed.

Data Types: `logical`

ParameterValues — Distribution parameter values

vector of scalar values

This property is read-only.

Distribution parameter values, specified as a vector.

Data Types: `single` | `double`

Truncation — Truncation interval

vector of scalar values

This property is read-only.

Truncation interval for the probability distribution, specified as a vector containing the lower and upper truncation boundaries.

Data Types: `single` | `double`

Other Object Properties**DistributionName** — Probability distribution name

character vector

This property is read-only.

Probability distribution name, specified as a character vector.

Data Types: `char`

InputData — Data used for distribution fitting

structure

This property is read-only.

Data used for distribution fitting, specified as a structure containing the following:

- **data**: Data vector used for distribution fitting.
- **cens**: Censoring vector, or empty if none.
- **freq**: Frequency vector, or empty if none.

Data Types: `struct`

ParameterDescription — Distribution parameter descriptions

cell array of character vectors

This property is read-only.

Distribution parameter descriptions, specified as a cell array of character vectors. Each cell contains a short description of one distribution parameter.

Data Types: `char`

ParameterNames — Distribution parameter names

cell array of character vectors

This property is read-only.

Distribution parameter names, specified as a cell array of character vectors.

Data Types: `char`

Object Functions

<code>cdf</code>	Cumulative distribution function
<code>icdf</code>	Inverse cumulative distribution function
<code>iqr</code>	Interquartile range
<code>mean</code>	Mean of probability distribution
<code>median</code>	Median of probability distribution
<code>negloglik</code>	Negative loglikelihood of probability distribution
<code>paramci</code>	Confidence intervals for probability distribution parameters

pdf	Probability density function
proflik	Profile likelihood function for probability distribution
random	Random numbers
std	Standard deviation of probability distribution
truncate	Truncate probability distribution object
var	Variance of probability distribution

Examples

Create a Weibull Distribution Object Using Default Parameters

Create a Weibull distribution object using the default parameter values.

```
pd = makedist('Weibull')  
  
pd =  
  WeibullDistribution  
  
  Weibull distribution  
  A = 1  
  B = 1
```

Create a Weibull Distribution Object Using Specified Parameter Values

Create a Weibull distribution object by specifying the parameter values.

```
pd = makedist('Weibull','a',2,'b',5)  
  
pd =  
  WeibullDistribution  
  
  Weibull distribution  
  A = 2  
  B = 5
```

Compute the mean of the distribution.

```
m = mean(pd)  
  
m = 1.8363
```

Introduced in R2013a

union

Class: dataset

Set union for dataset array observations

Note The dataset data type might be removed in a future release. To work with heterogeneous data, use the MATLAB® table data type instead. See MATLAB table documentation for more information.

Syntax

```
C = union(A,B)
C = union(A,B,vars)
C = union(A,B,vars,setOrder)
[C,iA,iB] = union( ___ )
```

Description

`C = union(A,B)` for dataset arrays `A` and `B` returns the combined set of observations from the two arrays, with repetitions removed. The observations in the dataset array `C` are sorted.

`C = union(A,B,vars)` returns the combined set of observations from the two arrays, with repetitions of unique combinations of the variables specified in `vars` removed. The observations in the dataset array `C` are sorted by those variables.

The values for variables not specified in `vars` for each observation in `C` are taken from the corresponding observation in `A` or `B`, or from `A` if there are common observations in both `A` and `B`. If there are multiple observations in `A` or `B` that correspond to an observation in `C`, those values are taken from the first occurrence.

`C = union(A,B,vars,setOrder)` returns the observations in `C` in the order specified by `setOrder`.

`[C,iA,iB] = union(___)` also returns index vectors `iA` and `iB` such that `C` is a sorted combination of the values `A(iA, :)` and `B(iB, :)`. If there are common observations in `A`

and B, then `union` returns only the index from A, in `iA`. If there are repeated observations in A or B, then the index of the first occurrence is returned. You can use any of the previous input arguments.

Input Arguments

A, B

Input dataset arrays.

vars

String array or cell array of character vectors containing variable names, or a vector of integers containing variable column numbers. `vars` indicates the variables for which `union` removes repetitions of unique combinations of the variables.

Specify `vars` as `[]` to use its default value of all variables.

setOrder

Flag indicating the sorting order for the observations in C. The possible values of `setOrder` are:

'sorted'	Observations in C are in sorted order (default).
'stable'	Observations in C are in the same order that they appear in A, then B.

Output Arguments

C

Dataset array with the combined observations of A and B, with repetitions removed. C is in sorted order (by default), or the order specified by `setOrder`.

iA

Index vector, indicating the observations in A that contribute to the union. `iA` contains the index to the first occurrence of any repeated observations in A.

iB

Index vector, indicating the observations in B that contribute to the union. If there are common observations in A and B, then `union` returns only the index from A, in `iA`. `iB` contains the index to the first occurrence of any repeated observations in B.

Examples

Union of Two Dataset Arrays

Load sample data.

```
A = dataset('XLSFile',fullfile(matlabroot,'help/toolbox/stats/examples','hospitalSmall  
B = dataset('XLSFile',fullfile(matlabroot,'help/toolbox/stats/examples','hospitalSmall  
[length(A) length(B)]
```

```
ans =
```

```
14     8
```

The first dataset array, A, has 14 observations. The second dataset array, B, has 8 observations.

Return the union.

```
C = union(A,B);  
length(C)
```

```
ans =
```

```
21
```

The union of the two dataset arrays has 21 observations, indicating that there was one observation replicated in A and B.

unique

Class: dataset

Unique observations in dataset array

Note The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB® `table` data type instead. See MATLAB `table` documentation for more information.

Syntax

```
C = unique(A)
[C,ia,ic] = unique(A)
C = unique(A,vars)
[C,ia,ic] = unique(A,vars)
[...] = unique(A,vars,occurrence)
[...] = unique(...,'R2012a')
[...] = unique(...,'legacy')
[...] = unique(A,vars,setOrder)
```

Description

Note The behavior of `dataset.unique` is consistent with the MATLAB function `unique`. For a demonstration of using the `'legacy'` flag to preserve the behavior from R2012b and prior in your existing code, see the documentation for `unique`.

`C = unique(A)` returns a copy of the dataset `A` that contains only the sorted unique observations. `A` must contain only variables whose class has a `unique` method, including:

- numeric
- character
- logical

- categorical
- string
- cell arrays of character vectors

For a variable with multiple columns, its class's `unique` method must support the `'rows'` flag.

`[C,ia,ic] = unique(A)` also returns index vectors `ia` and `ic` such that `C = A(ia,:)` and `A = C(ic,:)`.

`C = unique(A,vars)` returns a dataset that contains only one observation for each unique combination of values for the variables in `A` specified in `vars`. `vars` is a positive integer, a vector of positive integers, a character vector, a string array, a cell array of character vectors, or a logical vector. `C` includes all variables from `A`. The values in `C` for the variables not specified in `vars` are taken from the last occurrence among observations in `A` with each unique combination of values for the variables specified in `vars`.

`[C,ia,ic] = unique(A,vars)` also returns index vectors `ia` and `ic` such that `C = A(ia,:)` and `A(:,vars) = C(ic,vars)`.

`[...] = unique(A,vars,occurrence)` specifies which index is returned in `ia` in the case of repeated observations in `A`. The default value is `occurrence='first'`, which returns the index of the first occurrence of each repeated observation in `A`. `occurrence='last'` returns the index of the last occurrence of each repeated observation in `A`. The values in `C` for variables not specified in `vars` are taken from the observations `A(ia,:)`. Specify `vars` as `[]` to use the default value of all variables.

`[...] = unique(...,'R2012a')` adopts the future behavior of `unique`. You can specify the flag as the final argument with any previous syntax that accepts `A`, `vars`, or `occurrence`.

`[...] = unique(...,'legacy')` preserves the current behavior of `unique`. You can specify the flag as the final argument with any previous syntax that accepts `A`, `vars`, or `occurrence`.

`[...] = unique(A,vars,setOrder)` returns the observations of `C` in a specific order. `setOrder='sorted'` returns the values of `C` in sorted order. `setOrder='stable'` returns the values of `C` in the same order as `A`. If there are repeated observations in `A`, then `ia` returns the index of the first occurrence of each repeated observation. Specify `vars` as `[]` to use the default value of all variables.

See Also

dataset | set | subsasgn

Units property

Class: dataset

Units of variables in data set

Note The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB® `table` data type instead. See MATLAB `table` documentation for more information.

Description

A cell array of character vectors giving the units of the variables in the data set. This property may be empty, but if not empty, the number of character vectors must equal the number of variables. Any individual character vector may be empty for a variable that does not have units defined. The default is an empty cell array.

unidcdf

Discrete uniform cumulative distribution function

Syntax

```
p = unidcdf(x,N)
p = unidcdf(x,N,'upper')
```

Description

`p = unidcdf(x,N)` returns the discrete uniform cdf at each value in `x` using the corresponding maximum observable value in `N`. `x` and `N` can be vectors, matrices, or multidimensional arrays that have the same size. A scalar input is expanded to a constant array with the same dimensions as the other inputs. The maximum observable values in `N` must be positive integers.

`p = unidcdf(x,N,'upper')` returns the complement of the discrete uniform cdf at each value in `x`, using an algorithm that more accurately computes the extreme upper tail probabilities.

The discrete uniform cdf is

$$p = F(x|N) = \frac{\text{floor}(x)}{N} I_{(1, \dots, N)}(x)$$

The result, p , is the probability that a single observation from the discrete uniform distribution with maximum N will be a positive integer less than or equal to x . The values x do not need to be integers.

Examples

Compute Discrete Uniform Distribution `unidcdf`

What is the probability of drawing a number 20 or less from a hat with the numbers from 1 to 50 inside?

```
probability = unidcdf(20,50)
```

```
probability = 0.4000
```

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU arrays. For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

See Also

`cdf` | `mle` | `unidinv` | `unidpdf` | `unidrnd` | `unidstat`

Topics

“Uniform Distribution (Discrete)” on page B-196

Introduced before R2006a

unidinv

Discrete uniform inverse cumulative distribution function

Syntax

```
X = unidinv(P,N)
```

Description

`X = unidinv(P,N)` returns the smallest positive integer `X` such that the discrete uniform cdf evaluated at `X` is equal to or exceeds `P`. You can think of `P` as the probability of drawing a number as large as `X` out of a hat with the numbers 1 through `N` inside.

`P` and `N` can be vectors, matrices, or multidimensional arrays that have the same size, which is also the size of `X`. A scalar input for `N` or `P` is expanded to a constant array with the same dimensions as the other input. The values in `P` must lie on the interval `[0 1]` and the values in `N` must be positive integers.

Examples

```
x = unidinv(0.7,20)
x =
    14
```

```
y = unidinv(0.7 + eps,20)
y =
    15
```

A small change in the first parameter produces a large jump in output. The cdf and its inverse are both step functions. The example shows what happens at a step.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Topics

“Uniform Distribution (Discrete)” on page B-196

Introduced before R2006a

unidpdf

Discrete uniform probability density function

Syntax

```
Y = unidpdf(X,N)
```

Description

`Y = unidpdf(X,N)` computes the discrete uniform pdf at each of the values in `X` using the corresponding maximum observable value in `N`. `X` and `N` can be vectors, matrices, or multidimensional arrays that have the same size. A scalar input is expanded to a constant array with the same dimensions as the other inputs. The parameters in `N` must be positive integers.

The discrete uniform pdf is

$$y = f(x|N) = \frac{1}{N}I_{(1, \dots, N)}(x)$$

You can think of `y` as the probability of observing any one number between 1 and `n`.

Examples

For fixed `n`, the uniform discrete pdf is a constant.

```
y = unidpdf(1:6,10)
y =
    0.1000    0.1000    0.1000    0.1000    0.1000    0.1000
```

Now fix `x`, and vary `n`.

```
likelihood = unidpdf(5,4:9)
likelihood =
    0    0.2000    0.1667    0.1429    0.1250    0.1111
```

Extended Capabilities

pdf | unidcdf | unidinv | unidrnd | unidstat

Topics

“Uniform Distribution (Discrete)” on page B-196

Introduced before R2006a

unidrnd

Random numbers from discrete uniform distribution

Syntax

```
r = unidrnd(n)
r = unidrnd(n,sz1,...,szN)
r = unidrnd(n,[sz1,...,szN])
```

Description

`r = unidrnd(n)` generates random numbers from the discrete uniform distribution specified by its maximum value `n`.

`n` can be a scalar, vector, matrix, or multidimensional array.

`r = unidrnd(n,sz1,...,szN)` or `r = unidrnd(n,[sz1,...,szN])` generates an `sz1-by-...-by-szN` array containing random numbers from the discrete uniform distribution with the scalar maximum value `n`.

Examples

Array of Random Numbers from Several Discrete Uniform Distributions

Generate an array of random numbers from the discrete uniform distributions. For each distribution, specify its maximum value.

Specify the maximum values of the distributions.

```
n = 1:10:100;
```

Generate random numbers from the discrete uniform distributions.

```
r = unidrnd(n)
```

```
r = 1×10
```

```
    1    10     3    29    26     5    17    39    78    88
```

Array of Random Numbers from One Discrete Uniform Distribution

Generate an array of random numbers from one discrete uniform distribution. Here, the maximum value n is a scalar.

Use the `unidrnd` function to generate random numbers from the discrete uniform distribution with the maximum value 100. The function returns one number.

```
R_scalar = unidrnd(100)
```

```
R_scalar = 82
```

Generate a 2-by-3 array of random numbers from the same distribution by specifying the required array dimensions.

```
R_array = unidrnd(100,2,3)
```

```
R_array = 2×3
```

```
    91    92    10  
    13    64    28
```

Alternatively, specify the required array dimensions as a vector.

```
R_array = unidrnd(100,[2,3])
```

```
R_array = 2×3
```

```
    55    97    98  
    96    16    96
```

Input Arguments

n — Maximum value

positive integer | array of positive integers

Maximum value, specified as a positive integer or array of positive integers.

Example: `unidrnd(10)`

Data Types: `single` | `double`

sz1, ..., szN — Size of each dimension

integers | row vector of integers

Size of each dimension, specified as integers or a row vector of integers. For example, specifying `5, 3, 2` or `[5, 3, 2]` generates a 5-by-3-by-2 array of random numbers from the discrete uniform distribution.

If `n` is an array, then the specified dimensions `sz1, ..., szN` must match the dimensions of `n`.

- If you specify a single value `sz1`, then `r` is a square matrix of size `sz1`.
- If the size of any dimension is `0` or negative, then `r` is an empty array.
- Beyond the second dimension, `unidrnd` ignores trailing dimensions with a size of `1`. For example, `unidrnd(3, 1, 1, 1)` produces a 3-by-1 vector of random numbers.

Example: `5, 3, 2` or `[5, 3, 2]`

Data Types: `single` | `double`

Output Arguments

r — Random numbers from discrete uniform distribution

scalar value | array of scalar values

Random numbers from the discrete uniform distribution, returned as a scalar value or an array of scalar values.

Data Types: `single` | `double`

Alternative Functionality

- `unidrnd` is a function specific to discrete uniform distribution. Statistics and Machine Learning Toolbox also offers the generic function `random`, which supports various probability distributions. To use `random`, specify the probability distribution name and its parameters. Note that the distribution-specific function `unidrnd` is faster than the generic function `random`.
- To generate random numbers interactively, use `randtool`, a random number generation user interface.

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

unidstat

Discrete uniform mean and variance

Syntax

```
[M,V] = unidstat(N)
```

Description

`[M,V] = unidstat(N)` returns the mean and variance of the discrete uniform distribution with minimum value 1 and maximum value N .

The mean of the discrete uniform distribution with parameter N is $(N + 1)/2$. The variance is $(N^2 - 1)/12$.

Examples

```
[m,v] = unidstat(1:6)
m =
    1.0000    1.5000    2.0000    2.5000    3.0000    3.5000
v =
    0    0.2500    0.6667    1.2500    2.0000    2.9167
```

Extended Capabilities

C/C++ Code Generation

unifcdf

Continuous uniform cumulative distribution function

Syntax

```
p = unifcdf(x,a,b)
p = unifcdf(x,a,b,'upper')
```

Description

`p = unifcdf(x,a,b)` returns the uniform cdf at each value in `x` using the corresponding lower endpoint (minimum), `a` and upper endpoint (maximum), `b`. `x`, `a`, and `b` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant matrix with the same dimensions as the other inputs.

`p = unifcdf(x,a,b,'upper')` returns the complement of the uniform cdf at each value in `x`, using an algorithm that more accurately computes the extreme upper tail probabilities.

The uniform cdf is

$$p = F(x|a,b) = \frac{x-a}{b-a}I_{[a,b]}(x)$$

The standard uniform distribution has $a = 0$ and $b = 1$.

Examples

Compute Uniform Distribution cdf

What is the probability that an observation from a standard uniform distribution will be less than 0.75?

```
probability = unifcdf(0.75)
```

```
probability = 0.7500
```

What is the probability that an observation from a uniform distribution with $a = -1$ and $b = 1$ will be less than 0.75?

```
probability = unifcdf(0.75,-1,1)
```

```
probability = 0.8750
```

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

unifinv

Continuous uniform inverse cumulative distribution function

Syntax

```
X = unifinv(P,A,B)
```

Description

`X = unifinv(P,A,B)` computes the inverse of the uniform cdf with parameters A and B (the minimum and maximum values, respectively) at the corresponding probabilities in P. P, A, and B can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other inputs.

The inverse of the uniform cdf is

$$x = F^{-1}(p|a, b) = a + p(a - b)I_{[0,1]}(p)$$

The standard uniform distribution has $A = 0$ and $B = 1$.

Examples

What is the median of the standard uniform distribution?

```
median_value = unifinv(0.5)
median_value =
    0.5000
```

What is the 99th percentile of the uniform distribution between -1 and 1?

```
percentile = unifinv(0.99, -1, 1)
percentile =
    0.9800
```

Extended Capabilities

unifit

Continuous uniform parameter estimates

Syntax

```
[ahat,bhat] = unifit(data)
[ahat,bhat,ACI,BCI] = unifit(data)
[ahat,bhat,ACI,BCI] = unifit(data,alpha)
```

Description

`[ahat,bhat] = unifit(data)` returns the maximum likelihood estimates (MLEs) of the parameters of the uniform distribution given the data in `data`.

`[ahat,bhat,ACI,BCI] = unifit(data)` also returns 95% confidence intervals, `ACI` and `BCI`, which are matrices with two rows. The first row contains the lower bound of the interval for each column of the matrix `data`. The second row contains the upper bound of the interval.

`[ahat,bhat,ACI,BCI] = unifit(data,alpha)` controls the confidence level by using `alpha`. For example, if `alpha = 0.01`, then `ACI` and `BCI` are 99% confidence intervals.

Examples

```
r = unifrnd(10,12,100,2);
[ahat,bhat,aci,bci] = unifit(r)
ahat =
    10.0154    10.0060
bhat =
    11.9989    11.9743
aci =
     9.9551     9.9461
    10.0154    10.0060
bci =
```

unifpdf

Continuous uniform probability density function

Syntax

```
Y = unifpdf(X,A,B)
```

Description

`Y = unifpdf(X,A,B)` computes the continuous uniform pdf at each of the values in `X` using the corresponding lower endpoint (minimum), `A` and upper endpoint (maximum), `B`. `X`, `A`, and `B` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array with the same dimensions as the other inputs. The parameters in `B` must be greater than those in `A`.

The continuous uniform distribution pdf is

$$y = f(x|a,b) = \frac{1}{b-a}I_{[a,b]}(x)$$

The standard uniform distribution has `A = 0` and `B = 1`.

Examples

For fixed `a` and `b`, the uniform pdf is constant.

```
x = 0.1:0.1:0.6;  
y = unifpdf(x)  
y =  
    1    1    1    1    1    1
```

What if `x` is not between `a` and `b`?

```
y = unifpdf(-1,0,1)  
y =  
    0
```

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

unifrnd

Continuous uniform random numbers

Syntax

```
R = unifrnd(A,B)
R = unifrnd(A,B,m,n,...)
R = unifrnd(A,B,[m,n,...])
```

Description

`R = unifrnd(A,B)` returns an array `R` of random numbers generated from the continuous uniform distributions with lower and upper endpoints specified by `A` and `B`, respectively. If `A` and `B` are arrays, `R(i,j)` is generated from the distribution specified by the corresponding elements of `A` and `B`. If either `A` or `B` is a scalar, it is expanded to the size of the other input.

`R = unifrnd(A,B,m,n,...)` or `R = unifrnd(A,B,[m,n,...])` returns an `m`-by-`n`-by-... array. If `A` and `B` are scalars, all elements of `R` are generated from the same distribution. If either `A` or `B` is an array, they must be `m`-by-`n`-by-... .

Examples

Generate one random number each from the continuous uniform distributions on the intervals (0,1), (0,2), ..., (0,5):

```
a = 0; b = 1:5;
r1 = unifrnd(a,b)
r1 =
    0.8147    1.8116    0.3810    3.6535    3.1618
```

Generate five random numbers each from the same distributions:

```
B = repmat(b,5,1);
R = unifrnd(a,B)
```

```
R =
    0.0975    0.3152    0.4257    2.6230    3.7887
    0.2785    1.9412    1.2653    0.1428    3.7157
    0.5469    1.9143    2.7472    3.3965    1.9611
    0.9575    0.9708    2.3766    3.7360    3.2774
    0.9649    1.6006    2.8785    2.7149    0.8559
```

Generate five random numbers from the continuous uniform distribution on (0,2):

```
r2 = unifrnd(a,b(2),1,5)
r2 =
    1.4121    0.0637    0.5538    0.0923    0.1943
```

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

The generated code can return a different sequence of numbers than MATLAB if either of the following is true:

- The output is nonscalar.
- An input parameter is invalid for the distribution.

For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “General Code Generation Workflow” on page 31-5.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU arrays. For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

unifstat

Continuous uniform mean and variance

Syntax

```
[M,V] = unifstat(A,B)
```

Description

`[M,V] = unifstat(A,B)` returns the mean of and variance for the continuous uniform distribution using the corresponding lower endpoint (minimum), *A* and upper endpoint (maximum), *B*. Vector or matrix inputs for *A* and *B* must have the same size, which is also the size of *M* and *V*. A scalar input for *A* or *B* is expanded to a constant matrix with the same dimensions as the other input.

The mean of the continuous uniform distribution with parameters *a* and *b* is $(a + b)/2$, and the variance is $(a - b)^2/12$.

Examples

```
a = 1:6;  
b = 2.*a;  
[m,v] = unifstat(a,b)  
m =  
    1.5000    3.0000    4.5000    6.0000    7.5000    9.0000  
v =  
    0.0833    0.3333    0.7500    1.3333    2.0833    3.0000
```

Extended Capabilities

unstack

Class: dataset

Unstack data from single variable into multiple variables

Note The dataset data type might be removed in a future release. To work with heterogeneous data, use the MATLAB® table data type instead. See MATLAB table documentation for more information.

Syntax

```
A = unstack(B,datavar,indvar)
[A,iB] = unstack(B,datavar,indvar)
A = unstack(B,datavar,indvar,'Parameter',value)
```

Description

`A = unstack(B,datavar,indvar)` unstacks a single variable in dataset array `B` into multiple variables in `A`. In general `A` contains more variables, but fewer observations, than `B`.

`datavar` specifies the data variable in `B` to unstack. `indvar` specifies an indicator variable in `B` that determines which variable in `A` each value in `datavar` is unstacked into. `unstack` treats the remaining variables in `B` as grouping variables. Each unique combination of their values defines a group of observations in `B` that will be unstacked into a single observation in `A`.

`unstack` creates `m` data variables in `A`, where `m` is the number of group levels in `indvar`. The values in `indvar` indicate which of those `m` variables receive which values from `datavar`. The `j`-th data variable in `A` contains the values from `datavar` that correspond to observations whose `indvar` value was the `j`-th of the `m` possible levels. Elements of those `m` variables for which no corresponding data value in `B` exists contain a default value.

`datavar` is a positive integer, a character vector, a string scalar, or a logical vector containing a single true value. `indvar` is a positive integer, a variable name, or a logical vector containing a single true value.

`[A, iB] = unstack(B, datavar, indvar)` returns an index vector `iB` indicating the correspondence between observations in `A` and those in `B`. For each observation in `A`, `iB` contains the index of the first in the corresponding group of observations in `B`.

For more information on grouping variables, see “Grouping Variables” on page 2-57.

Input Arguments

`A = unstack(B, datavar, indvar, 'Parameter', value)` uses the following parameter name/value pairs to control how `unstack` converts variables in `B` to variables in `A`:

'GroupVars'	Grouping variables in <code>B</code> that define groups of observations. <code>groupvars</code> is a positive integer, a vector of positive integers, a character vector, a string array, a cell array of character vectors, or a logical vector. The default is all variables in <code>B</code> not listed in <code>datavar</code> or <code>indvar</code> .
'NewDataVarNames'	A string array or cell array of character vectors containing names for the data variables <code>unstack</code> should create in <code>A</code> . Default is the group names of the grouping variable specified in <code>indvar</code> .
'AggregationFun'	A function handle that accepts a subset of values from <code>datavar</code> and returns a single value. <code>stack</code> applies this function to observations from the same group that have the same value of <code>indvar</code> . The function must aggregate the data values into a single value, and in such cases it is not possible to recover <code>B</code> from <code>A</code> using <code>stack</code> . The default is <code>@sum</code> for numeric data variables. For non-numeric variables, there is no default, and you must specify 'AggregationFun' if multiple observations in the same group have the same values of <code>indvar</code> .

'ConstVars'	Variables in B to copy to A without unstacking. The values for these variables in A are taken from the first observation in each group in B, so these variables should typically be constant within each group. ConstVars is a positive integer, a vector of positive integers, a character vector, a string array, a cell array of character vectors, or a logical vector. The default is no variables.
-------------	--

You can also specify more than one data variable in B, each of which becomes a set of m variables in A. In this case, specify `datavar` as a vector of positive integers, a string array or cell array containing variable names, or a logical vector. You may specify only one variable with `indvar`. The names of each set of data variables in A are the name of the corresponding data variable in B concatenated with the names specified in `'NewDataVarNames'`. The function specified in `'AggregationFun'` must return a value with a single row.

Examples

Combine several variables for estimated influenza rates into a single variable. Then unstack the estimated influenza rates by date.

```
load flu
```

```
% FLU has a 'Date' variable, and 10 variables for estimated influenza rates
% (in 9 different regions, estimated from Google searches, plus a
% nationwide estimate from the CDC). Combine those 10 variables into an
% array that has a single data variable, 'FluRate', and an indicator
% variable, 'Region', that says which region each estimate is from.
[flu2,iflu] = stack(flu, 2:11, 'NewDataVarName','FluRate', ...
    'IndVarName','Region')
```

```
% The second observation in FLU is for 10/16/2005. Find the observations
% in FLU2 that correspond to that date.
flu(2,:)
flu2(iflu==2,:)
```

```
% Use the 'Date' variable from that array to split 'FluRate' into 52
% separate variables, each containing the estimated influenza rates for
% each unique date. The new array has one observation for each region. In
% effect, this is the original array FLU "on its side".
dateNames = cellstr(datestr(flu.Date,'mmm_DD_YYYY'));
```

```
[flu3,iflu2] = unstack(flu2, 'FluRate', 'Date', ...  
    'NewDataVarNames',dateNames)
```

```
% Since observations in FLU3 represent regions, IFLU2 indicates the first  
% occurrence in FLU2 of each region.  
flu2(iflu2,:)
```

update

Package: classreg.learning.classif

Update model parameters for code generation

Generate C/C++ code for the `predict` and `update` functions of a machine learning model by using a coder configurer object. Create this object by using `LearnerCoderConfigurer` and its object function `generateCode`. Then you can use the `update` function to update model parameters in the generated code without having to regenerate the code. This feature reduces the effort required to regenerate, redeploy, and reverify C/C++ code when you retrain a model with new data or settings.

This flow chart shows the code generation workflow using a coder configurer. Use `update` for the highlighted step.

If you do not generate code, then you do not need to use the `update` function. When you retrain a model in MATLAB, the returned model already includes modified parameters.

Syntax

```
updatedMdl = update(Mdl, params)
```

Description

`updatedMdl = update(Mdl, params)` returns an updated version of `Mdl` that contains new parameters in `params`.

After retraining a model, use the `validatedUpdateInputs` function to detect modified parameters in the retrained model and validate whether the modified parameter values satisfy the coder attributes of the parameters. Use the output of `validatedUpdateInputs`, the validated parameters, as the input params to update model parameters.

Examples

Update Parameters of SVM Regression Model in Generated Code

Train a support vector machine (SVM) model using a partial data set and create a coder configurer for the model. Use the properties of the coder configurer to specify coder attributes of the SVM model parameters. Use the object function of the coder configurer to generate C code that predicts responses for new predictor data. Then retrain the model using the whole data set and update parameters in the generated code without regenerating the code.

Train Model

Load the `carsmall` data set and train an SVM regression model using the first 50 observations.

```
load carsmall
X = [Horsepower,Weight];
Y = MPG;
Mdl = fitrsvm(X(1:50,:),Y(1:50));
```

`Mdl` is a `RegressionSVM` object.

Create Coder Configurer

Create a coder configurer for the `RegressionSVM` model by using `learnerCoderConfigurer`. Specify the predictor data `X`. The `learnerCoderConfigurer` function uses the input `X` to configure the coder attributes of the predict function input.

```
configurer = learnerCoderConfigurer(Mdl,X(1:50,:));
```

`configurer` is a `RegressionSVMCoderConfigurer` object, which is a coder configurer of a `RegressionSVM` object.

Specify Coder Attributes of Parameters

Specify the coder attributes of the SVM regression model parameters so that you can update the parameters in the generated code after retraining the model. This example specifies the coder attributes of predictor data that you want to pass to the generated code and the coder attributes of the support vectors of the SVM regression model.

First, specify the coder attributes of `X` so that the generated code accepts any number of observations. Modify the `SizeVector` and `VariableDimensions` attributes. The `SizeVector` attribute specifies the upper bound of the predictor data size, and the `VariableDimensions` attribute specifies whether each dimension of the predictor data has a variable size or fixed size.

```
configurer.X.SizeVector = [Inf 2];  
configurer.X.VariableDimensions = [true false];
```

The size of the first dimension is the number of observations. In this case, the code specifies that the upper bound of the size is `Inf` and the size is variable, meaning that `X` can have any number of observations. This specification is convenient if you do not know the number of observations when generating code.

The size of the second dimension is the number of predictor variables. This value must be fixed for a machine learning model. `X` contains two predictors, so the value of the `SizeVector` attribute must be two and the value of the `VariableDimensions` attribute must be `false`.

If you retrain the SVM model using new data or different settings, the number of support vectors can vary. Therefore, specify the coder attributes of `SupportVectors` so that you can update the support vectors in the generated code.

```
configurer.SupportVectors.SizeVector = [250 2];
```

`SizeVector` attribute for Alpha has been modified to satisfy configuration constraints.

```
configurer.SupportVectors.VariableDimensions = [true false];
```

`VariableDimensions` attribute for Alpha has been modified to satisfy configuration constraints.

If you modify the coder attributes of `SupportVectors`, then the software modifies the coder attributes of `Alpha` to satisfy configuration constraints. If the modification of the coder attributes of one parameter requires subsequent changes to other dependent parameters to satisfy configuration constraints, then the software changes the coder attributes of the dependent parameters.

Generate Code

To generate C/C++ code, you must have access to a C/C++ compiler that is configured properly. MATLAB Coder locates and uses a supported, installed compiler. You can use `mex -setup` to view and change the default compiler. For more details, see “Change Default Compiler” (MATLAB).

Use `generateCode` to generate code for the `predict` and `update` functions of the SVM regression model (`Mdl`) with default settings.

```
generateCode(configurer)
```

`generateCode` creates these files in output folder:
'initialize.m', 'predict.m', 'update.m', 'RegressionSVMModel.mat'

`generateCode` generates the MATLAB files required to generate code, including the two entry-point functions `predict.m` and `update.m` for the `predict` and `update` functions of `Mdl`, respectively. Then `generateCode` creates a MEX function named `RegressionSVMModel` for the two entry-point functions in the `codegen\mex\RegressionSVMModel` folder and copies the MEX function to the current folder.

Verify Generated Code

Pass some predictor data to verify whether the `predict` function of `Mdl` and the `predict` function in the MEX function return the same predicted responses. To call an entry-point function in a MEX function that has more than one entry point, specify the function name as the first input argument.

```
yfit = predict(Mdl,X);  
yfit_mex = RegressionSVMModel('predict',X);
```

`yfit_mex` might include round-off differences compared with `yfit`. In this case, compare `yfit` and `yfit_mex`, allowing a small tolerance.

```
find(abs(yfit-yfit_mex) > 1e-6)
```

```
ans =
```

```
0x1 empty double column vector
```

The comparison confirms that `yfit` and `yfit_mex` are equal within the tolerance $1e-6$.

Retrain Model and Update Parameters in Generated Code

Retrain the model using the entire data set.

```
retrainedMdl = fitrsvm(X,Y);
```

Extract parameters to update by using `validatedUpdateInputs`. This function detects the modified model parameters in `retrainedMdl` and validates whether the modified parameter values satisfy the coder attributes of the parameters.

```
params = validatedUpdateInputs(configurer,retrainedMdl);
```

Update parameters in the generated code.

```
RegressionSVMModel('update',params)
```

Verify Generated Code

Compare the outputs from the `predict` function of `retrainedMdl` and the `predict` function in the updated MEX function.

```
yfit = predict(retrainedMdl,X);
yfit_mex = RegressionSVMModel('predict',X);
find(abs(yfit-yfit_mex) > 1e-6)
```

```
ans =
```

```
0x1 empty double column vector
```

The comparison confirms that `yfit` and `yfit_mex` are equal within the tolerance `1e-6`.

Update Parameters of SVM Classification Model in Generated Code

Train a SVM model using a partial data set and create a coder configurer for the model. Use the properties of the coder configurer to specify coder attributes of the SVM model parameters. Use the object function of the coder configurer to generate C code that predicts labels for new predictor data. Then retrain the model using the whole data set and update parameters in the generated code without regenerating the code.

Train Model

Load the `ionosphere` data set. This data set has 34 predictors and 351 binary responses for radar returns, either bad ('b') or good ('g'). Train a binary SVM classification model using the first 50 observations.

```
load ionosphere
Mdl = fitcsvm(X(1:50,:),Y(1:50));
```

Mdl is a `ClassificationSVM` object.

Create Coder Configurer

Create a coder configurer for the `ClassificationSVM` model by using `learnerCoderConfigurer`. Specify the predictor data `X`. The `learnerCoderConfigurer` function uses the input `X` to configure the coder attributes of the `predict` function input. Also, set the number of outputs to 2 so that the generated code returns predicted labels and scores.

```
configurer = learnerCoderConfigurer(Mdl,X(1:50,:), 'NumOutputs',2);
```

`configurer` is a `ClassificationSVMCoderConfigurer` object, which is a coder configurer of a `ClassificationSVM` object.

Specify Coder Attributes of Parameters

Specify the coder attributes of the SVM classification model parameters so that you can update the parameters in the generated code after retraining the model. This example specifies the coder attributes of predictor data that you want to pass to the generated code and the coder attributes of the support vectors of the SVM model.

First, specify the coder attributes of `X` so that the generated code accepts any number of observations. Modify the `SizeVector` and `VariableDimensions` attributes. The `SizeVector` attribute specifies the upper bound of the predictor data size, and the `VariableDimensions` attribute specifies whether each dimension of the predictor data has a variable size or fixed size.

```
configurer.X.SizeVector = [Inf 34];  
configurer.X.VariableDimensions = [true false];
```

The size of the first dimension is the number of observations. In this case, the code specifies that the upper bound of the size is `Inf` and the size is variable, meaning that `X` can have any number of observations. This specification is convenient if you do not know the number of observations when generating code.

The size of the second dimension is the number of predictor variables. This value must be fixed for a machine learning model. `X` contains 34 predictors, so the value of the `SizeVector` attribute must be 34 and the value of the `VariableDimensions` attribute must be `false`.

If you retrain the SVM model using new data or different settings, the number of support vectors can vary. Therefore, specify the coder attributes of `SupportVectors` so that you can update the support vectors in the generated code.

```
configurer.SupportVectors.SizeVector = [250 34];
```

`SizeVector` attribute for `Alpha` has been modified to satisfy configuration constraints.
`SizeVector` attribute for `SupportVectorLabels` has been modified to satisfy configuration constraints.

```
configurer.SupportVectors.VariableDimensions = [true false];
```

`VariableDimensions` attribute for `Alpha` has been modified to satisfy configuration constraints.
`VariableDimensions` attribute for `SupportVectorLabels` has been modified to satisfy configuration constraints.

If you modify the coder attributes of `SupportVectors`, then the software modifies the coder attributes of `Alpha` and `SupportVectorLabels` to satisfy configuration constraints. If the modification of the coder attributes of one parameter requires subsequent changes to other dependent parameters to satisfy configuration constraints, then the software changes the coder attributes of the dependent parameters.

Generate Code

To generate C/C++ code, you must have access to a C/C++ compiler that is configured properly. MATLAB Coder locates and uses a supported, installed compiler. You can use `mex -setup` to view and change the default compiler. For more details, see “Change Default Compiler” (MATLAB).

Use `generateCode` to generate code for the `predict` and `update` functions of the SVM classification model (`Mdl`) with default settings.

```
generateCode(configurer)
```

`generateCode` creates these files in output folder:
`'initialize.m', 'predict.m', 'update.m', 'ClassificationSVMModel.mat'`

`generateCode` generates the MATLAB files required to generate code, including the two entry-point functions `predict.m` and `update.m` for the `predict` and `update` functions of `Mdl`, respectively. Then `generateCode` creates a MEX function named `ClassificationSVMModel` for the two entry-point functions in the `codegen\mex\ClassificationSVMModel` folder and copies the MEX function to the current folder.

Verify Generated Code

Pass some predictor data to verify whether the `predict` function of `Mdl` and the `predict` function in the MEX function return the same labels. To call an entry-point

function in a MEX function that has more than one entry point, specify the function name as the first input argument.

```
[label,score] = predict(Mdl,X);  
[label_mex,score_mex] = ClassificationSVMModel('predict',X);
```

Compare `label` and `label_mex` by using `isequal`.

```
isequal(label,label_mex)
```

```
ans = logical  
     1
```

`isequal` returns logical 1 (true) if all the inputs are equal. The comparison confirms that the `predict` function of `Mdl` and the `predict` function in the MEX function return the same labels.

`score_mex` might include round-off differences compared with `score`. In this case, compare `score_mex` and `score`, allowing a small tolerance.

```
find(abs(score-score_mex) > 1e-8)
```

```
ans =
```

```
     0x1 empty double column vector
```

The comparison confirms that `score` and `score_mex` are equal within the tolerance `1e-8`.

Retrain Model and Update Parameters in Generated Code

Retrain the model using the entire data set.

```
retrainedMdl = fitcsvm(X,Y);
```

Extract parameters to update by using `validatedUpdateInputs`. This function detects the modified model parameters in `retrainedMdl` and validates whether the modified parameter values satisfy the coder attributes of the parameters.

```
params = validatedUpdateInputs(configurer,retrainedMdl);
```

Update parameters in the generated code.

```
ClassificationSVMModel('update',params)
```

Verify Generated Code

Compare the outputs from the `predict` function of `retrainedMdl` and the `predict` function in the updated MEX function.

```
[label,score] = predict(retrainedMdl,X);  
[label_mex,score_mex] = ClassificationSVMModel('predict',X);  
isequal(label,label_mex)
```

```
ans = logical  
     1
```

```
find(abs(score-score_mex) > 1e-8)
```

```
ans =
```

```
     0x1 empty double column vector
```

The comparison confirms that `labels` and `labels_mex` are equal, and the score values are equal within the tolerance.

Update Parameters of ECOC Classification Model in Generated Code

Train an error-correcting output codes (ECOC) model using SVM binary learners and create a coder configurer for the model. Use the properties of the coder configurer to specify coder attributes of the ECOC model parameters. Use the object function of the coder configurer to generate C code that predicts labels for new predictor data. Then retrain the model using different settings, and update parameters in the generated code without regenerating the code.

Train Model

Load Fisher's iris data set.

```
load fisheriris  
X = meas;  
Y = species;
```

Create an SVM binary learner template to use a Gaussian kernel function and to standardize predictor data.

```
t = templateSVM('KernelFunction','gaussian','Standardize',true);
```

Train a multiclass ECOC model using the template `t`.

```
Mdl = fitcecoc(X,Y,'Learners',t);
```

`Mdl` is a `ClassificationECOC` object.

Create Coder Configurer

Create a coder configurer for the `ClassificationECOC` model by using `learnerCoderConfigurer`. Specify the predictor data `X`. The `learnerCoderConfigurer` function uses the input `X` to configure the coder attributes of the `predict` function input. Also, set the number of outputs to 2 so that the generated code returns the first two outputs of the `predict` function, which are the predicted labels and negated average binary losses.

```
configurer = learnerCoderConfigurer(Mdl,X,'NumOutputs',2)
```

```
configurer =  
  ClassificationECOCoderConfigurer with properties:  
  
  Update Inputs:  
    BinaryLearners: [1x1 ClassificationSVMCoderConfigurer]  
      Prior: [1x1 LearnerCoderInput]  
      Cost: [1x1 LearnerCoderInput]  
  
  Predict Inputs:  
    X: [1x1 LearnerCoderInput]  
  
  Code Generation Parameters:  
    NumOutputs: 2  
    OutputFileName: 'ClassificationECOCModel'
```

Properties, Methods

`configurer` is a `ClassificationECOCoderConfigurer` object, which is a coder configurer of a `ClassificationECOC` object. The display shows the tunable input arguments of `predict` and `update`: `X`, `BinaryLearners`, `Prior`, and `Cost`.

Specify Coder Attributes of Parameters

Specify the coder attributes of `predict` arguments (predictor data and the name-value pair arguments `'Decoding'` and `'BinaryLoss'`) and `update` arguments (support

vectors of the SVM learners) so that you can use these arguments as the input arguments of `predict` and `update` in the generated code.

First, specify the coder attributes of `X` so that the generated code accepts any number of observations. Modify the `SizeVector` and `VariableDimensions` attributes. The `SizeVector` attribute specifies the upper bound of the predictor data size, and the `VariableDimensions` attribute specifies whether each dimension of the predictor data has a variable size or fixed size.

```
configurer.X.SizeVector = [Inf 4];
configurer.X.VariableDimensions = [true false];
```

The size of the first dimension is the number of observations. In this case, the code specifies that the upper bound of the size is `Inf` and the size is variable, meaning that `X` can have any number of observations. This specification is convenient if you do not know the number of observations when generating code.

The size of the second dimension is the number of predictor variables. This value must be fixed for a machine learning model. `X` contains 4 predictors, so the second value of the `SizeVector` attribute must be 4 and the second value of the `VariableDimensions` attribute must be `false`.

Next, modify the coder attributes of `BinaryLoss` and `Decoding` to use the `'BinaryLoss'` and `'Decoding'` name-value pair arguments in the generated code. Display the coder attributes of `BinaryLoss`.

```
configurer.BinaryLoss
ans =
    EnumeratedInput with properties:
        Value: 'hinge'
        SelectedOption: 'Built-in'
        BuiltInOptions: {'hamming' 'linear' 'quadratic' 'exponential' 'binodeviance'}
        IsConstant: 1
        Tunability: 0
```

To use a nondefault value in the generated code, you must specify the value before generating the code. Specify the `Value` attribute of `BinaryLoss` as `'exponential'`.

```
configurer.BinaryLoss.Value = 'exponential';
configurer.BinaryLoss
```

```
ans =
  EnumeratedInput with properties:

      Value: 'exponential'
  SelectedOption: 'Built-in'
  BuiltInOptions: {'hamming' 'linear' 'quadratic' 'exponential' 'binodeviance'
  IsConstant: 1
  Tunability: 1
```

If you modify attribute values when `Tunability` is `false` (logical 0), the software sets the `Tunability` to `true` (logical 1).

Display the coder attributes of `Decoding`.

```
configurer.Decoding
```

```
ans =
  EnumeratedInput with properties:

      Value: 'lossweighted'
  SelectedOption: 'Built-in'
  BuiltInOptions: {'lossweighted' 'lossbased'}
  IsConstant: 1
  Tunability: 0
```

Specify the `IsConstant` attribute of `Decoding` as `false` so that you can use all available values in `BuiltInOptions` in the generated code.

```
configurer.Decoding.IsConstant = false;
configurer.Decoding
```

```
ans =
  EnumeratedInput with properties:

      Value: [1x1 LearnerCoderInput]
  SelectedOption: 'NonConstant'
  BuiltInOptions: {'lossweighted' 'lossbased'}
  IsConstant: 0
  Tunability: 1
```

The software changes the `Value` attribute of `Decoding` to a `LearnerCoderInput` object so that you can use both `'lossweighted'` and `'lossbased'` as the value of

'Decoding'. Also, the software sets the `SelectedOption` to 'NonConstant' and the `Tunability` to true.

Finally, modify the coder attributes of `SupportVectors` in `BinaryLearners`. Display the coder attributes of `SupportVectors`.

```
configurer.BinaryLearners.SupportVectors
```

```
ans =
  LearnerCoderInput with properties:
      SizeVector: [54 4]
  VariableDimensions: [1 0]
      DataType: 'double'
      Tunability: 1
```

The default value of `VariableDimensions` is `[true false]` because each learner has a different number of support vectors. If you retrain the ECOC model using new data or different settings, the number of support vectors in the SVM learners can vary. Therefore, increase the upper bound of the number of support vectors.

```
configurer.BinaryLearners.SupportVectors.SizeVector = [150 4];
```

```
SizeVector attribute for Alpha has been modified to satisfy configuration constraints.
SizeVector attribute for SupportVectorLabels has been modified to satisfy configuration
```

If you modify the coder attributes of `SupportVectors`, then the software modifies the coder attributes of `Alpha` and `SupportVectorLabels` to satisfy configuration constraints. If the modification of the coder attributes of one parameter requires subsequent changes to other dependent parameters to satisfy configuration constraints, then the software changes the coder attributes of the dependent parameters.

Display the coder configurer.

```
configurer
```

```
configurer =
  ClassificationECOCoderConfigurer with properties:
      Update Inputs:
      BinaryLearners: [1x1 ClassificationSVMCoderConfigurer]
      Prior: [1x1 LearnerCoderInput]
      Cost: [1x1 LearnerCoderInput]
```

```
Predict Inputs:
    X: [1x1 LearnerCoderInput]
    BinaryLoss: [1x1 EnumeratedInput]
    Decoding: [1x1 EnumeratedInput]

Code Generation Parameters:
    NumOutputs: 2
    OutputFileName: 'ClassificationECOCModel'
```

Properties, Methods

The display now includes `BinaryLoss` and `Decoding` as well.

Generate Code

To generate C/C++ code, you must have access to a C/C++ compiler that is configured properly. MATLAB Coder locates and uses a supported, installed compiler. You can use `mex -setup` to view and change the default compiler. For more details, see “Change Default Compiler” (MATLAB).

Generate code for the `predict` and `update` functions of the ECOC classification model (Mdl) with default settings.

```
generateCode(configurer)
```

```
generateCode creates these files in output folder:
'initialize.m', 'predict.m', 'update.m', 'ClassificationECOCModel.mat'
```

The `generateCode` function completes these actions:

- Generate the MATLAB files required to generate code, including the two entry-point functions `predict.m` and `update.m` for the `predict` and `update` functions of `Mdl`, respectively.
- Create a MEX function named `ClassificationECOCModel` for the two entry-point functions.
- Create the code for the MEX function in the `codegen\mex\ClassificationECOCModel` folder.
- Copy the MEX function to the current folder.

Verify Generated Code

Pass some predictor data to verify whether the `predict` function of `Mdl` and the `predict` function in the MEX function return the same labels. To call an entry-point function in a MEX function that has more than one entry point, specify the function name as the first input argument. Because you specified `'Decoding'` as a tunable input argument by changing the `IsConstant` attribute before generating the code, you also need to specify it in the call to the MEX function, even though `'lossweighted'` is the default value of `'Decoding'`.

```
[label,NegLoss] = predict(Mdl,X,'BinaryLoss','exponential');
[label_mex,NegLoss_mex] = ClassificationECOCModel('predict',X,'BinaryLoss','exponential');
```

Compare `label` to `label_mex` by using `isequal`.

```
isequal(label,label_mex)
```

```
ans = logical
     1
```

`isequal` returns logical 1 (true) if all the inputs are equal. The comparison confirms that the `predict` function of `Mdl` and the `predict` function in the MEX function return the same labels.

`NegLoss_mex` might include round-off differences compared to `NegLoss`. In this case, compare `NegLoss_mex` to `NegLoss`, allowing a small tolerance.

```
find(abs(NegLoss-NegLoss_mex) > 1e-8)
```

```
ans =
```

```
0×1 empty double column vector
```

The comparison confirms that `NegLoss` and `NegLoss_mex` are equal within the tolerance $1e-8$.

Retrain Model and Update Parameters in Generated Code

Retrain the model using a different setting. Specify `'KernelScale'` as `'auto'` so that the software selects an appropriate scale factor using a heuristic procedure.

```
t_new = templateSVM('KernelFunction','gaussian','Standardize',true,'KernelScale','auto');
retrainedMdl = fitcecoc(X,Y,'Learners',t_new);
```

Extract parameters to update by using `validatedUpdateInputs`. This function detects the modified model parameters in `retrainedMdl` and validates whether the modified parameter values satisfy the coder attributes of the parameters.

```
params = validatedUpdateInputs(configurer,retrainedMdl);
```

Update parameters in the generated code.

```
ClassificationECOCModel('update',params)
```

Verify Generated Code

Compare the outputs from the `predict` function of `retrainedMdl` to the outputs from the `predict` function in the updated MEX function.

```
[label,NegLoss] = predict(retrainedMdl,X,'BinaryLoss','exponential','Decoding','lossba
[label_mex,NegLoss_mex] = ClassificationECOCModel('predict',X,'BinaryLoss','exponential
isequal(label,label_mex)
```

```
ans = logical
     1
```

```
find(abs(NegLoss-NegLoss_mex) > 1e-8)
```

```
ans =
```

```
0×1 empty double column vector
```

The comparison confirms that `labels` and `labels_mex` are equal, and `NegLoss` and `NegLoss_mex` are equal within the tolerance.

Input Arguments

Mdl — Machine learning model

compact model object

Machine learning model, specified as a compact model object, as given in this table of supported models.

Model	Compact Model Object
Support vector machine (SVM) regression	CompactRegressionSVM

Model	Compact Model Object
SVM for one-class and binary classification	CompactClassificationSVM
Multiclass model for SVMs	CompactClassificationECOC

For the code generation usage notes and limitations of a machine learning model, see the Code Generation section of the model object page.

params — Parameters to update

structure

Parameters to update in the machine learning model, specified as a structure with a field for each parameter to update.

The set of parameters that you can update varies depending on the machine learning model, as described in this table.

Model	Parameters to Update
SVM regression	<ul style="list-style-type: none"> If you train an SVM regression model (Mdl) with a linear kernel function and discard support vectors by using <code>discardSupportVectors</code>, then <code>params</code> can include <code>Beta</code>, <code>Bias</code>, <code>Mu</code>, <code>Scale</code> (kernel scale parameter in <code>KernelParameters</code>), and <code>Sigma</code>. Otherwise, <code>params</code> can include <code>Alpha</code>, <code>Bias</code>, <code>Mu</code>, <code>Scale</code> (kernel scale parameter in <code>KernelParameters</code>), <code>Sigma</code>, and <code>SupportVectors</code>.
SVM for one-class and binary classification	<ul style="list-style-type: none"> If you train an SVM classification model (Mdl) with a linear kernel function and discard support vectors by using <code>discardSupportVectors</code>, then <code>params</code> can include <code>Beta</code>, <code>Bias</code>, <code>Cost</code>, <code>Mu</code>, <code>Prior</code>, <code>Scale</code> (kernel scale parameter in <code>KernelParameters</code>), and <code>Sigma</code>. Otherwise, <code>params</code> can include <code>Alpha</code>, <code>Beta</code>, <code>Cost</code>, <code>Mu</code>, <code>Prior</code>, <code>Scale</code> (kernel scale parameter in <code>KernelParameters</code>), <code>Sigma</code>, <code>SupportVectorLabels</code>, and <code>SupportVectors</code>. If Mdl is a one-class SVM classification model, then <code>params</code> cannot include <code>Cost</code> or <code>Prior</code>.
Multiclass model for SVMs	<code>BinaryLearners</code> , <code>Cost</code> , <code>Prior</code>

You can create `params` by using the `validatedUpdateInputs` function. This function detects modified parameters in the retrained model, validates whether the modified parameter values satisfy the coder attributes of the parameters, and returns the parameters to update as a structure.

Output Arguments

updatedMdl — Updated machine learning model

compact model object

Updated machine learning model, returned as a compact model object that is the same type of object as `Mdl`. The output `updatedMdl` is an updated version of the input `Mdl` that contains new parameters in `params`.

Tips

- If you modify any of the name-value pair arguments listed in this table when you retrain a model, you cannot use `update` to update the parameters. You must generate C/C++ code again.

Model	Arguments Not Supported for Update
SVM regression	Arguments of <code>fitrsvm</code> — 'KernelFunction', 'PolynomialOrder', 'ResponseTransform', 'Standardize'
SVM for one-class and binary classification	Arguments of <code>fitcsvm</code> — 'ClassNames', 'KernelFunction', 'PolynomialOrder', 'ScoreTransform', 'Standardize'
Multiclass model for SVMs	Arguments of <code>fitcecoc</code> — 'ClassNames', 'ScoreTransform' Arguments of <code>templateSVM</code> — 'KernelFunction', 'PolynomialOrder', 'Standardize'

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- Create a coder configurer by using `learnerCoderConfigurer` and then generate code for `predict` and `update` by using the object function `generateCode`.
- For the code generation usage notes and limitations of the machine learning model `Mdl`, see the Code Generation section of the model object page.

Model	Compact Model Object
Support vector machine (SVM) regression	<code>CompactRegressionSVM</code>
SVM for one-class and binary classification	<code>CompactClassificationSVM</code>
Multiclass model for SVMs	<code>CompactClassificationECOC</code>

Introduced in R2018b

upperparams

Upper Pareto tail parameters

Syntax

```
params = upperparams(pd)
```

Description

`params = upperparams(pd)` returns the two-element vector `params`, which includes the shape and scale parameters of the generalized Pareto distribution (GPD) in the upper tail of `pd`.

`upperparams` does not return the location parameter of the GPD. The location parameter is the quantile value corresponding to the upper tail cumulative probability. Use the `boundary` function to return the location parameter.

Examples

Parameters of Upper Pareto Tail

Generate a sample data set and fit a piecewise distribution with Pareto tails to the data by using `paretotails`. Find the distribution parameters of the upper Pareto tail by using the object function `upperparams`.

Generate a sample data set containing 20% outliers.

```
rng('default'); % For reproducibility
left_tail = -exprnd(1,100,1);
right_tail = exprnd(5,100,1);
center = randn(800,1);
x = [left_tail;center;right_tail];
```

Create a `paretotails` object by fitting a piecewise distribution to `x`. Specify the boundaries of the tails using the lower and upper tail cumulative probabilities so that a

fitted object consists of the empirical distribution for the middle 80% of the data set and GPDs for the lower and upper 10% of the data set.

```
pd = paretotails(x,0.1,0.9)
```

```
pd =
Piecewise distribution with 3 segments
  -Inf < x < -1.33251    (0 < p < 0.1): lower tail, GPD(-0.0063504,0.567017)
 -1.33251 < x < 1.80149 (0.1 < p < 0.9): interpolated empirical cdf
  1.80149 < x < Inf     (0.9 < p < 1): upper tail, GPD(0.24874,3.00974)
```

Return the shape and scale parameters of the fitted GPD of the upper tail by using the `upperparams` function.

```
params = upperparams(pd)
```

```
params = 1×2
    0.2487    3.0097
```

You can also get the upper Pareto tail parameters by using the `UpperParameters` property. Access the `UpperParameters` property by using dot notation.

```
pd.UpperParameters
```

```
ans = 1×2
    0.2487    3.0097
```

The location parameter of the GPD is equal to the quantile value of the upper tail cumulative probability. Return the location parameter by using the `boundary` function.

```
[p,q] = boundary(pd)
```

```
p = 2×1
    0.1000
    0.9000
```

```
q = 2×1
   -1.3325
```

1.8015

The values in p are the cumulative probabilities at the boundaries, and the values in q are the corresponding quantiles. $q(1)$ is the location parameter of the GPD of the upper tail.

Use the `lowerparams` function or the `LowerParameters` property to get the lower Pareto tail parameters.

Input Arguments

pd — Piecewise distribution with Pareto tails

`paretotails` object

Piecewise distribution with Pareto tails, specified as a `paretotails` object.

UserData property

Class: dataset

Variable containing additional information associated with data set

Note The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB® `table` data type instead. See MATLAB `table` documentation for more information.

Description

Any variable containing additional information to be associated with the data set. The default is an empty array.

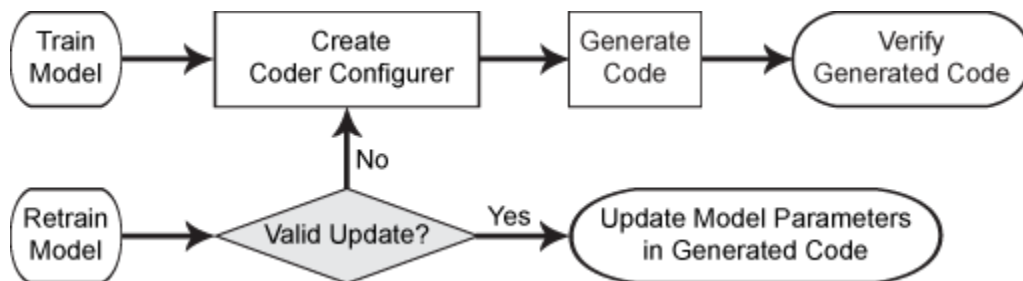

validatedUpdateInputs

Package: classreg.learning.coder.config.svm

Validate and extract machine learning model parameters to update

Generate C/C++ code for the `predict` and `update` functions of a machine learning model by using a coder configurer object. Create this object by using `learnerCoderConfigurer` and its object function `generateCode`. After retraining the model with new data or settings, you can update model parameters in the generated code without having to regenerate the code. Use `validatedUpdateInputs` to validate and extract the model parameters to update. This function helps you identify potential problems before you update the model parameters in the generated code. You can use the output of `validatedUpdateInputs`, the validated parameters, as an input argument of the `update` function to update model parameters.

This flow chart shows the code generation workflow using a coder configurer. Use `validatedUpdateInputs` for the highlighted step.

Syntax

```
params = validatedUpdateInputs(configurer, retrainedMdl)
```

Description

`params = validatedUpdateInputs(configurer, retrainedMdl)` returns the validated machine learning model parameters to update. `validatedUpdateInputs`

detects the modified model parameters in `retrainedMdl` and validates whether they satisfy the coder attributes stored in `configurer`.

Examples

Update Parameters of SVM Regression Model in Generated Code

Train a support vector machine (SVM) model using a partial data set and create a coder configurer for the model. Use the properties of the coder configurer to specify coder attributes of the SVM model parameters. Use the object function of the coder configurer to generate C code that predicts responses for new predictor data. Then retrain the model using the whole data set and update parameters in the generated code without regenerating the code.

Train Model

Load the `carsmall` data set and train an SVM regression model using the first 50 observations.

```
load carsmall
X = [Horsepower,Weight];
Y = MPG;
Mdl = fitrsvm(X(1:50,:),Y(1:50));
```

`Mdl` is a `RegressionSVM` object.

Create Coder Configurer

Create a coder configurer for the `RegressionSVM` model by using `learnerCoderConfigurer`. Specify the predictor data `X`. The `learnerCoderConfigurer` function uses the input `X` to configure the coder attributes of the `predict` function input.

```
configurer = learnerCoderConfigurer(Mdl,X(1:50,:));
```

`configurer` is a `RegressionSVMCoderConfigurer` object, which is a coder configurer of a `RegressionSVM` object.

Specify Coder Attributes of Parameters

Specify the coder attributes of the SVM regression model parameters so that you can update the parameters in the generated code after retraining the model. This example

specifies the coder attributes of predictor data that you want to pass to the generated code and the coder attributes of the support vectors of the SVM regression model.

First, specify the coder attributes of `X` so that the generated code accepts any number of observations. Modify the `SizeVector` and `VariableDimensions` attributes. The `SizeVector` attribute specifies the upper bound of the predictor data size, and the `VariableDimensions` attribute specifies whether each dimension of the predictor data has a variable size or fixed size.

```
configurer.X.SizeVector = [Inf 2];  
configurer.X.VariableDimensions = [true false];
```

The size of the first dimension is the number of observations. In this case, the code specifies that the upper bound of the size is `Inf` and the size is variable, meaning that `X` can have any number of observations. This specification is convenient if you do not know the number of observations when generating code.

The size of the second dimension is the number of predictor variables. This value must be fixed for a machine learning model. `X` contains two predictors, so the value of the `SizeVector` attribute must be two and the value of the `VariableDimensions` attribute must be `false`.

If you retrain the SVM model using new data or different settings, the number of support vectors can vary. Therefore, specify the coder attributes of `SupportVectors` so that you can update the support vectors in the generated code.

```
configurer.SupportVectors.SizeVector = [250 2];
```

`SizeVector` attribute for `Alpha` has been modified to satisfy configuration constraints.

```
configurer.SupportVectors.VariableDimensions = [true false];
```

`VariableDimensions` attribute for `Alpha` has been modified to satisfy configuration constraints.

If you modify the coder attributes of `SupportVectors`, then the software modifies the coder attributes of `Alpha` to satisfy configuration constraints. If the modification of the coder attributes of one parameter requires subsequent changes to other dependent parameters to satisfy configuration constraints, then the software changes the coder attributes of the dependent parameters.

Generate Code

To generate C/C++ code, you must have access to a C/C++ compiler that is configured properly. MATLAB Coder locates and uses a supported, installed compiler. You can use

`mex -setup` to view and change the default compiler. For more details, see “Change Default Compiler” (MATLAB).

Use `generateCode` to generate code for the `predict` and `update` functions of the SVM regression model (Mdl) with default settings.

```
generateCode(configurer)
```

`generateCode` creates these files in output folder:
'initialize.m', 'predict.m', 'update.m', 'RegressionSVMModel.mat'

`generateCode` generates the MATLAB files required to generate code, including the two entry-point functions `predict.m` and `update.m` for the `predict` and `update` functions of Mdl, respectively. Then `generateCode` creates a MEX function named `RegressionSVMModel` for the two entry-point functions in the `codegen\mex\RegressionSVMModel` folder and copies the MEX function to the current folder.

Verify Generated Code

Pass some predictor data to verify whether the `predict` function of Mdl and the `predict` function in the MEX function return the same predicted responses. To call an entry-point function in a MEX function that has more than one entry point, specify the function name as the first input argument.

```
yfit = predict(Mdl,X);  
yfit_mex = RegressionSVMModel('predict',X);
```

`yfit_mex` might include round-off differences compared with `yfit`. In this case, compare `yfit` and `yfit_mex`, allowing a small tolerance.

```
find(abs(yfit-yfit_mex) > 1e-6)
```

```
ans =
```

```
0x1 empty double column vector
```

The comparison confirms that `yfit` and `yfit_mex` are equal within the tolerance $1e-6$.

Retrain Model and Update Parameters in Generated Code

Retrain the model using the entire data set.

```
retrainedMdl = fitrsvm(X,Y);
```

Extract parameters to update by using `validatedUpdateInputs`. This function detects the modified model parameters in `retrainedMdl` and validates whether the modified parameter values satisfy the coder attributes of the parameters.

```
params = validatedUpdateInputs(configurer,retrainedMdl);
```

Update parameters in the generated code.

```
RegressionSVMModel('update',params)
```

Verify Generated Code

Compare the outputs from the `predict` function of `retrainedMdl` and the `predict` function in the updated MEX function.

```
yfit = predict(retrainedMdl,X);  
yfit_mex = RegressionSVMModel('predict',X);  
find(abs(yfit-yfit_mex) > 1e-6)
```

```
ans =
```

```
0x1 empty double column vector
```

The comparison confirms that `yfit` and `yfit_mex` are equal within the tolerance `1e-6`.

Update Parameters of SVM Classification Model in Generated Code

Train a SVM model using a partial data set and create a coder configurer for the model. Use the properties of the coder configurer to specify coder attributes of the SVM model parameters. Use the object function of the coder configurer to generate C code that predicts labels for new predictor data. Then retrain the model using the whole data set and update parameters in the generated code without regenerating the code.

Train Model

Load the `ionosphere` data set. This data set has 34 predictors and 351 binary responses for radar returns, either bad ('b') or good ('g'). Train a binary SVM classification model using the first 50 observations.

```
load ionosphere  
Mdl = fitcsvm(X(1:50,:),Y(1:50));
```

`Mdl` is a `ClassificationSVM` object.

Create Coder Configurer

Create a coder configurer for the `ClassificationSVM` model by using `learnerCoderConfigurer`. Specify the predictor data `X`. The `learnerCoderConfigurer` function uses the input `X` to configure the coder attributes of the `predict` function input. Also, set the number of outputs to 2 so that the generated code returns predicted labels and scores.

```
configurer = learnerCoderConfigurer(Mdl,X(1:50,:), 'NumOutputs',2);
```

`configurer` is a `ClassificationSVMCoderConfigurer` object, which is a coder configurer of a `ClassificationSVM` object.

Specify Coder Attributes of Parameters

Specify the coder attributes of the SVM classification model parameters so that you can update the parameters in the generated code after retraining the model. This example specifies the coder attributes of predictor data that you want to pass to the generated code and the coder attributes of the support vectors of the SVM model.

First, specify the coder attributes of `X` so that the generated code accepts any number of observations. Modify the `SizeVector` and `VariableDimensions` attributes. The `SizeVector` attribute specifies the upper bound of the predictor data size, and the `VariableDimensions` attribute specifies whether each dimension of the predictor data has a variable size or fixed size.

```
configurer.X.SizeVector = [Inf 34];  
configurer.X.VariableDimensions = [true false];
```

The size of the first dimension is the number of observations. In this case, the code specifies that the upper bound of the size is `Inf` and the size is variable, meaning that `X` can have any number of observations. This specification is convenient if you do not know the number of observations when generating code.

The size of the second dimension is the number of predictor variables. This value must be fixed for a machine learning model. `X` contains 34 predictors, so the value of the `SizeVector` attribute must be 34 and the value of the `VariableDimensions` attribute must be `false`.

If you retrain the SVM model using new data or different settings, the number of support vectors can vary. Therefore, specify the coder attributes of `SupportVectors` so that you can update the support vectors in the generated code.

```
configurer.SupportVectors.SizeVector = [250 34];
```

SizeVector attribute for Alpha has been modified to satisfy configuration constraints.
SizeVector attribute for SupportVectorLabels has been modified to satisfy configuration

```
configurer.SupportVectors.VariableDimensions = [true false];
```

VariableDimensions attribute for Alpha has been modified to satisfy configuration constraints.
VariableDimensions attribute for SupportVectorLabels has been modified to satisfy configuration

If you modify the coder attributes of `SupportVectors`, then the software modifies the coder attributes of `Alpha` and `SupportVectorLabels` to satisfy configuration constraints. If the modification of the coder attributes of one parameter requires subsequent changes to other dependent parameters to satisfy configuration constraints, then the software changes the coder attributes of the dependent parameters.

Generate Code

To generate C/C++ code, you must have access to a C/C++ compiler that is configured properly. MATLAB Coder locates and uses a supported, installed compiler. You can use `mex -setup` to view and change the default compiler. For more details, see “Change Default Compiler” (MATLAB).

Use `generateCode` to generate code for the `predict` and `update` functions of the SVM classification model (`Mdl`) with default settings.

```
generateCode(configurer)
```

`generateCode` creates these files in output folder:
'initialize.m', 'predict.m', 'update.m', 'ClassificationSVMModel.mat'

`generateCode` generates the MATLAB files required to generate code, including the two entry-point functions `predict.m` and `update.m` for the `predict` and `update` functions of `Mdl`, respectively. Then `generateCode` creates a MEX function named `ClassificationSVMModel` for the two entry-point functions in the `codegen\mex\ClassificationSVMModel` folder and copies the MEX function to the current folder.

Verify Generated Code

Pass some predictor data to verify whether the `predict` function of `Mdl` and the `predict` function in the MEX function return the same labels. To call an entry-point function in a MEX function that has more than one entry point, specify the function name as the first input argument.

```
[label,score] = predict(Mdl,X);  
[label_mex,score_mex] = ClassificationSVMModel('predict',X);
```

Compare `label` and `label_mex` by using `isequal`.

```
isequal(label,label_mex)
```

```
ans = logical  
     1
```

`isequal` returns logical 1 (true) if all the inputs are equal. The comparison confirms that the `predict` function of `Mdl` and the `predict` function in the MEX function return the same labels.

`score_mex` might include round-off differences compared with `score`. In this case, compare `score_mex` and `score`, allowing a small tolerance.

```
find(abs(score-score_mex) > 1e-8)
```

```
ans =
```

```
     0x1 empty double column vector
```

The comparison confirms that `score` and `score_mex` are equal within the tolerance `1e-8`.

Retrain Model and Update Parameters in Generated Code

Retrain the model using the entire data set.

```
retrainedMdl = fitcsvm(X,Y);
```

Extract parameters to update by using `validatedUpdateInputs`. This function detects the modified model parameters in `retrainedMdl` and validates whether the modified parameter values satisfy the coder attributes of the parameters.

```
params = validatedUpdateInputs(configurer,retrainedMdl);
```

Update parameters in the generated code.

```
ClassificationSVMModel('update',params)
```

Verify Generated Code

Compare the outputs from the `predict` function of `retrainedMdl` and the `predict` function in the updated MEX function.

```
[label,score] = predict(retrainedMdl,X);  
[label_mex,score_mex] = ClassificationSVMModel('predict',X);  
isequal(label,label_mex)
```

```
ans = logical  
     1
```

```
find(abs(score-score_mex) > 1e-8)
```

```
ans =
```

```
     0x1 empty double column vector
```

The comparison confirms that `labels` and `labels_mex` are equal, and the score values are equal within the tolerance.

Update Parameters of ECOC Classification Model in Generated Code

Train an error-correcting output codes (ECOC) model using SVM binary learners and create a coder configurer for the model. Use the properties of the coder configurer to specify coder attributes of the ECOC model parameters. Use the object function of the coder configurer to generate C code that predicts labels for new predictor data. Then retrain the model using different settings, and update parameters in the generated code without regenerating the code.

Train Model

Load Fisher's iris data set.

```
load fisheriris  
X = meas;  
Y = species;
```

Create an SVM binary learner template to use a Gaussian kernel function and to standardize predictor data.

```
t = templateSVM('KernelFunction','gaussian','Standardize',true);
```

Train a multiclass ECOC model using the template `t`.

```
Mdl = fitcecoc(X,Y,'Learners',t);
```

`Mdl` is a `ClassificationECOC` object.

Create Coder Configurer

Create a coder configurer for the `ClassificationECOC` model by using `learnerCoderConfigurer`. Specify the predictor data `X`. The `learnerCoderConfigurer` function uses the input `X` to configure the coder attributes of the `predict` function input. Also, set the number of outputs to 2 so that the generated code returns the first two outputs of the `predict` function, which are the predicted labels and negated average binary losses.

```
configurer = learnerCoderConfigurer(Mdl,X,'NumOutputs',2)
```

```
configurer =
  ClassificationECOCoderConfigurer with properties:

  Update Inputs:
    BinaryLearners: [1x1 ClassificationSVMCoderConfigurer]
                   Prior: [1x1 LearnerCoderInput]
                   Cost: [1x1 LearnerCoderInput]

  Predict Inputs:
    X: [1x1 LearnerCoderInput]

  Code Generation Parameters:
    NumOutputs: 2
    OutputFileName: 'ClassificationECOCModel'
```

Properties, Methods

`configurer` is a `ClassificationECOCoderConfigurer` object, which is a coder configurer of a `ClassificationECOC` object. The display shows the tunable input arguments of `predict` and `update`: `X`, `BinaryLearners`, `Prior`, and `Cost`.

Specify Coder Attributes of Parameters

Specify the coder attributes of `predict` arguments (predictor data and the name-value pair arguments `'Decoding'` and `'BinaryLoss'`) and `update` arguments (support

vectors of the SVM learners) so that you can use these arguments as the input arguments of `predict` and `update` in the generated code.

First, specify the coder attributes of `X` so that the generated code accepts any number of observations. Modify the `SizeVector` and `VariableDimensions` attributes. The `SizeVector` attribute specifies the upper bound of the predictor data size, and the `VariableDimensions` attribute specifies whether each dimension of the predictor data has a variable size or fixed size.

```
configurer.X.SizeVector = [Inf 4];  
configurer.X.VariableDimensions = [true false];
```

The size of the first dimension is the number of observations. In this case, the code specifies that the upper bound of the size is `Inf` and the size is variable, meaning that `X` can have any number of observations. This specification is convenient if you do not know the number of observations when generating code.

The size of the second dimension is the number of predictor variables. This value must be fixed for a machine learning model. `X` contains 4 predictors, so the second value of the `SizeVector` attribute must be 4 and the second value of the `VariableDimensions` attribute must be `false`.

Next, modify the coder attributes of `BinaryLoss` and `Decoding` to use the `'BinaryLoss'` and `'Decoding'` name-value pair arguments in the generated code. Display the coder attributes of `BinaryLoss`.

```
configurer.BinaryLoss  
  
ans =  
    EnumeratedInput with properties:  
  
        Value: 'hinge'  
    SelectedOption: 'Built-in'  
    BuiltInOptions: {'hamming' 'linear' 'quadratic' 'exponential' 'binodeviance'  
    IsConstant: 1  
    Tunability: 0
```

To use a nondefault value in the generated code, you must specify the value before generating the code. Specify the `Value` attribute of `BinaryLoss` as `'exponential'`.

```
configurer.BinaryLoss.Value = 'exponential';  
configurer.BinaryLoss
```

```
ans =
  EnumeratedInput with properties:

      Value: 'exponential'
  SelectedOption: 'Built-in'
  BuiltInOptions: {'hamming' 'linear' 'quadratic' 'exponential' 'binodeviance'
  IsConstant: 1
  Tunability: 1
```

If you modify attribute values when `Tunability` is `false` (logical 0), the software sets the `Tunability` to `true` (logical 1).

Display the coder attributes of `Decoding`.

```
configurer.Decoding
```

```
ans =
  EnumeratedInput with properties:

      Value: 'lossweighted'
  SelectedOption: 'Built-in'
  BuiltInOptions: {'lossweighted' 'lossbased'}
  IsConstant: 1
  Tunability: 0
```

Specify the `IsConstant` attribute of `Decoding` as `false` so that you can use all available values in `BuiltInOptions` in the generated code.

```
configurer.Decoding.IsConstant = false;
configurer.Decoding
```

```
ans =
  EnumeratedInput with properties:

      Value: [1x1 LearnerCoderInput]
  SelectedOption: 'NonConstant'
  BuiltInOptions: {'lossweighted' 'lossbased'}
  IsConstant: 0
  Tunability: 1
```

The software changes the `Value` attribute of `Decoding` to a `LearnerCoderInput` object so that you can use both `'lossweighted'` and `'lossbased'` as the value of

'Decoding'. Also, the software sets the `SelectedOption` to 'NonConstant' and the `Tunability` to true.

Finally, modify the coder attributes of `SupportVectors` in `BinaryLearners`. Display the coder attributes of `SupportVectors`.

```
configurer.BinaryLearners.SupportVectors
```

```
ans =  
LearnerCoderInput with properties:  
  
    SizeVector: [54 4]  
VariableDimensions: [1 0]  
    DataType: 'double'  
    Tunability: 1
```

The default value of `VariableDimensions` is `[true false]` because each learner has a different number of support vectors. If you retrain the ECOC model using new data or different settings, the number of support vectors in the SVM learners can vary. Therefore, increase the upper bound of the number of support vectors.

```
configurer.BinaryLearners.SupportVectors.SizeVector = [150 4];
```

```
SizeVector attribute for Alpha has been modified to satisfy configuration constraints.  
SizeVector attribute for SupportVectorLabels has been modified to satisfy configuration
```

If you modify the coder attributes of `SupportVectors`, then the software modifies the coder attributes of `Alpha` and `SupportVectorLabels` to satisfy configuration constraints. If the modification of the coder attributes of one parameter requires subsequent changes to other dependent parameters to satisfy configuration constraints, then the software changes the coder attributes of the dependent parameters.

Display the coder configurer.

```
configurer
```

```
configurer =  
ClassificationECOCoderConfigurer with properties:  
  
Update Inputs:  
    BinaryLearners: [1x1 ClassificationSVMCoderConfigurer]  
        Prior: [1x1 LearnerCoderInput]  
        Cost: [1x1 LearnerCoderInput]
```

```

Predict Inputs:
    X: [1x1 LearnerCoderInput]
    BinaryLoss: [1x1 EnumeratedInput]
    Decoding: [1x1 EnumeratedInput]

Code Generation Parameters:
    NumOutputs: 2
    OutputFileName: 'ClassificationECOCModel'

```

Properties, Methods

The display now includes `BinaryLoss` and `Decoding` as well.

Generate Code

To generate C/C++ code, you must have access to a C/C++ compiler that is configured properly. MATLAB Coder locates and uses a supported, installed compiler. You can use `mex -setup` to view and change the default compiler. For more details, see “Change Default Compiler” (MATLAB).

Generate code for the `predict` and `update` functions of the ECOC classification model (Mdl) with default settings.

```
generateCode(configurer)
```

`generateCode` creates these files in output folder:
'initialize.m', 'predict.m', 'update.m', 'ClassificationECOCModel.mat'

The `generateCode` function completes these actions:

- Generate the MATLAB files required to generate code, including the two entry-point functions `predict.m` and `update.m` for the `predict` and `update` functions of Mdl, respectively.
- Create a MEX function named `ClassificationECOCModel` for the two entry-point functions.
- Create the code for the MEX function in the `codegen\mex\ClassificationECOCModel` folder.
- Copy the MEX function to the current folder.

Verify Generated Code

Pass some predictor data to verify whether the `predict` function of `Mdl` and the `predict` function in the MEX function return the same labels. To call an entry-point function in a MEX function that has more than one entry point, specify the function name as the first input argument. Because you specified `'Decoding'` as a tunable input argument by changing the `IsConstant` attribute before generating the code, you also need to specify it in the call to the MEX function, even though `'lossweighted'` is the default value of `'Decoding'`.

```
[label,NegLoss] = predict(Mdl,X,'BinaryLoss','exponential');  
[label_mex,NegLoss_mex] = ClassificationECOCModel('predict',X,'BinaryLoss','exponential');
```

Compare `label` to `label_mex` by using `isequal`.

```
isequal(label,label_mex)
```

```
ans = logical  
     1
```

`isequal` returns logical 1 (true) if all the inputs are equal. The comparison confirms that the `predict` function of `Mdl` and the `predict` function in the MEX function return the same labels.

`NegLoss_mex` might include round-off differences compared to `NegLoss`. In this case, compare `NegLoss_mex` to `NegLoss`, allowing a small tolerance.

```
find(abs(NegLoss-NegLoss_mex) > 1e-8)
```

```
ans =
```

```
0×1 empty double column vector
```

The comparison confirms that `NegLoss` and `NegLoss_mex` are equal within the tolerance `1e-8`.

Retrain Model and Update Parameters in Generated Code

Retrain the model using a different setting. Specify `'KernelScale'` as `'auto'` so that the software selects an appropriate scale factor using a heuristic procedure.

```
t_new = templateSVM('KernelFunction','gaussian','Standardize',true,'KernelScale','auto');  
retrainedMdl = fitcecoc(X,Y,'Learners',t_new);
```

Extract parameters to update by using `validatedUpdateInputs`. This function detects the modified model parameters in `retrainedMdl` and validates whether the modified parameter values satisfy the coder attributes of the parameters.

```
params = validatedUpdateInputs(configurer,retrainedMdl);
```

Update parameters in the generated code.

```
ClassificationECOCModel('update',params)
```

Verify Generated Code

Compare the outputs from the `predict` function of `retrainedMdl` to the outputs from the `predict` function in the updated MEX function.

```
[label,NegLoss] = predict(retrainedMdl,X,'BinaryLoss','exponential','Decoding','lossba
[label_mex,NegLoss_mex] = ClassificationECOCModel('predict',X,'BinaryLoss','exponential
isequal(label,label_mex)
```

```
ans = logical
     1
```

```
find(abs(NegLoss-NegLoss_mex) > 1e-8)
```

```
ans =
```

```
0×1 empty double column vector
```

The comparison confirms that `labels` and `labels_mex` are equal, and `NegLoss` and `NegLoss_mex` are equal within the tolerance.

Input Arguments

configurer — Coder configurer

coder configurer object

Coder configurer of a machine learning model, specified as a coder configurer object created by using `learnerCoderConfigurer`.

Model	Coder Configurer Object
Support vector machine (SVM) regression	RegressionSVMCoderConfigurer

Model	Coder Configurer Object
SVM for one-class and binary classification	ClassificationSVMConfigurer
Multiclass model for SVMs	ClassificationECOCConfigurer

retrainedMdl — Retrained machine learning model

full model object | compact model object

Retrained machine learning model, specified as a full or compact model object, as given in this table of supported models.

Model	Full/Compact Model Object	Training Function
Support vector machine (SVM) regression	RegressionSVM, CompactRegressionSVM	fitrsvm
SVM for one-class and binary classification	ClassificationSVM, CompactClassificationSVM	fitcsvm
Multiclass model for SVMs	ClassificationECOC, CompactClassificationECOC	fitcecoc

Output Arguments

params — Validated parameters to update

structure

Validated parameters to update in the machine learning model, specified as a structure with a field for each parameter extracted from `retrainedMdl`.

The model parameters in `params` include all parameters listed in the `UpdateInputs` property of `configurer`, which is the list of tunable model parameters.

You can use `params` as an input argument of `update` to update model parameters.

Tips

- `validatedUpdateInputs` returns an error message if you modify any of the name-value pair arguments listed in this table when you retrain the model `retrainedMdl`. In this case, you cannot use `update` to update the parameters. You must generate C/C++ code again.

Model	Arguments Not Supported for Update
SVM regression	Arguments of <code>fitrsvm</code> — 'KernelFunction', 'PolynomialOrder', 'ResponseTransform', 'Standardize'
SVM for one-class and binary classification	Arguments of <code>fitcsvm</code> — 'ClassNames', 'KernelFunction', 'PolynomialOrder', 'ScoreTransform', 'Standardize'
Multiclass model for SVMs	Arguments of <code>fitcecoc</code> — 'ClassNames', 'ScoreTransform' Arguments of <code>templateSVM</code> — 'KernelFunction', 'PolynomialOrder', 'Standardize'

- `validatedUpdateInputs` displays a warning message if the machine learning model parameters in `configurer` and `retrainedMdl` are identical.

Introduced in R2018b

var

Package: prob

Variance of probability distribution

Syntax

```
v = var(pd)
```

Description

`v = var(pd)` returns the variance `v` of the probability distribution `pd`.

Examples

Variance of a Fitted Distribution

Load the sample data. Create a vector containing the first column of students' exam grade data.

```
load examgrades
x = grades(:,1);
```

Fit a normal distribution object to the data.

```
pd = fitdist(x, 'Normal')

pd =
  NormalDistribution

  Normal distribution
      mu = 75.0083    [73.4321, 76.5846]
      sigma = 8.7202    [7.7391, 9.98843]
```

Compute the variance of the fitted distribution.

```
v = var(pd)
```

```
v = 76.0419
```

For a normal distribution, the variance is equal to the square of the parameter σ .

Variance of a Skewed Distribution

Create a Weibull probability distribution object.

```
pd = makedist('Weibull', 'a', 5, 'b', 2)
```

```
pd =  
  WeibullDistribution  
  
  Weibull distribution  
    A = 5  
    B = 2
```

Compute the variance of the distribution.

```
v = var(pd)
```

```
v = 5.3650
```

Variance of a Triangular Distribution

Create a triangular distribution object.

```
pd = makedist('Triangular', 'a', -3, 'b', 1, 'c', 3)
```

```
pd =  
  TriangularDistribution
```

```
A = -3, B = 1, C = 3
```

Compute the variance of the distribution.

```
v = var(pd)
```

```
v = 1.5556
```

Variance of a Kernel Distribution

Load the sample data. Create a vector containing the first column of students' exam grade data.

```
load examgrades;  
x = grades(:,1);
```

Fit a kernel distribution object to the data.

```
pd = fitdist(x, 'Kernel')  
  
pd =  
    KernelDistribution  
  
    Kernel = normal  
    Bandwidth = 3.61677  
    Support = unbounded
```

Compute the variance of the fitted distribution.

```
v = var(pd)  
  
v = 88.4893
```

Input Arguments

pd — Probability distribution

probability distribution object

Probability distribution, specified as a probability distribution object created using one of the following.

Function or App	Description
makedist	Create a probability distribution object using specified parameter values.
fitdist	Fit a probability distribution object to sample data.

Function or App	Description
Distribution Fitter	Fit a probability distribution to sample data using the interactive Distribution Fitter app and export the fitted object to the workspace.

Output Arguments

v – Variance

nonnegative scalar value

Variance of the probability distribution, returned as a nonnegative scalar value.

“Working with Probability Distributions” on page 5-3

“Supported Distributions” on page 5-20

Introduced in R2013a

VarDescription property

Class: dataset

Cell array of character vectors giving descriptions of variables in data set

Note The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB® `table` data type instead. See MATLAB `table` documentation for more information.

Description

A cell array of character vectors giving the descriptions of the variables in the data set. This property may be empty, but if not empty, the number of character vectors must equal the number of variables. Any individual character vector may be empty for a variable that does not have a description defined. The default is an empty cell array.

VarNames property

Class: dataset

Cell array giving names of variables in data set

Note The `dataset` data type might be removed in a future release. To work with heterogeneous data, use the MATLAB® `table` data type instead. See MATLAB `table` documentation for more information.

Description

A cell array of nonempty, distinct character vectors giving the names of the variables in the data set. The number of character vectors must equal the number of variables. The default is the cell array of names for the variables used to create the data set.

vartest

Chi-square variance test

Syntax

```
h = vartest(x,v)
h = vartest(x,v,Name,Value)
[h,p] = vartest( ___ )
[h,p,ci,stats] = vartest( ___ )
```

Description

`h = vartest(x,v)` returns a test decision for the null hypothesis that the data in vector `x` comes from a normal distribution with variance `v`, using the chi-square variance test on page 32-7228. The alternative hypothesis is that `x` comes from a normal distribution with a different variance. The result `h` is 1 if the test rejects the null hypothesis at the 5% significance level, and 0 otherwise.

`h = vartest(x,v,Name,Value)` performs the chi-square variance test with additional options specified by one or more name-value pair arguments. For example, you can change the significance level or conduct a one-sided test.

`[h,p] = vartest(___)` also returns the *p*-value of the test, `p`, using any of the input arguments in the previous syntaxes.

`[h,p,ci,stats] = vartest(___)` also returns the confidence interval for the true variance, `ci`, and the structure `stats` containing information about the test statistic.

Examples

Chi-Squared Test for Specified Variance

Load the sample data. Create a vector containing the first column of the students' exam grades matrix.

```
load examgrades
x = grades(:,1);
```

Test the null hypothesis that the data comes from a distribution with a variance of 25.

```
[h,p,ci,stats] = vartest(x,25)
```

```
h = 1
```

```
p = 0
```

```
ci = 2×1
```

```
59.8936
99.7688
```

```
stats = struct with fields:
  chisqstat: 361.9597
  df: 119
```

The returned value $h = 1$ indicates that `vartest` rejects the null hypothesis at the default 5% significance level. `ci` shows the lower and upper boundaries of the 95% confidence interval for the true variance, and suggests that the true variance is greater than 25.

Chi-Squared Test Using One-Sided Hypothesis

Load the sample data. Create a vector containing the first column of the students' exam grades matrix.

```
load examgrades
x = grades(:,1);
```

Test the null hypothesis that the data comes from a distribution with a variance of 25, against the alternative hypothesis that the variance is greater than 25.

```
[h,p] = vartest(x,25,'Tail','right')
```

```
h = 1
```

```
p = 2.4269e-26
```

The returned value of `h = 1` indicates that `vartest` rejects the null hypothesis at the default 5% significance level, in favor of the alternative hypothesis that the variance is greater than 25.

Input Arguments

x — Sample data

vector | matrix | multidimensional array

Sample data, specified as a vector, matrix, or multidimensional array. For matrices, `vartest` performs separate tests along each column of `x`, and returns a row vector of results. For multidimensional arrays on page 32-7229, `vartest` works along the first nonsingleton dimension on page 32-7229 of `x`.

Data Types: `single` | `double`

v — Hypothesized variance

nonnegative scalar value

Hypothesized variance, specified as a nonnegative scalar value.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'Tail', 'right', 'Alpha', 0.01` specifies a right-tailed hypothesis test at the 1% significance level.

Alpha — Significance level

0.05 (default) | scalar value in the range (0,1)

Significance level of the hypothesis test, specified as the comma-separated pair consisting of `'Alpha'` and a scalar value in the range (0,1).

Example: `'Alpha', 0.01`

Data Types: `single` | `double`

Dim — Dimension

first nonsingleton dimension (default) | positive integer value

Dimension of the input matrix to test along, specified as the comma-separated pair consisting of `'Dim'` and a positive integer value. For example, specifying `'Dim',1` tests the data in each column for equality to the hypothesized variance, while `'Dim',2` tests the data in each row.

Example: `'Dim',2`

Data Types: `single` | `double`

Tail — Type of alternative hypothesis

`'both'` (default) | `'right'` | `'left'`

Type of alternative hypothesis to evaluate, specified as the comma-separated pair consisting of `'Tail'` and one of the following.

<code>'both'</code>	Test the alternative hypothesis that the population variance is not v .
<code>'right'</code>	Test the alternative hypothesis that the population variance is greater than v .
<code>'left'</code>	Test the alternative hypothesis that the population variance is less than v .

Example: `'Tail','right'`

Output Arguments

h — Hypothesis test result

1 | 0

Hypothesis test result, returned as 1 or 0.

- If $h = 1$, this indicates the rejection of the null hypothesis at the α significance level.
- If $h = 0$, this indicates a failure to reject the null hypothesis at the α significance level.

p — p-value

scalar value in the range [0,1]

p-value of the test, returned as a scalar value in the range [0,1]. p is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. Small values of p cast doubt on the validity of the null hypothesis.

ci — Confidence interval

vector

Confidence interval for the true variance, returned as a two-element vector containing the lower and upper boundaries of the $100 \times (1 - \text{Alpha})\%$ confidence interval.

stats — Test statistics

structure

Test statistics for the chi-square variance test, returned as a structure containing:

- `chisqstat` — Value of the test statistic.
- `df` — Degrees of freedom of the test.

Definitions

Chi-Square Variance Test

The chi-square variance test is used to test whether the variance of a population is equal to a hypothesized value.

The test statistic is

$$T = (n - 1) \left(\frac{s}{\sigma_0} \right)^2,$$

where n is the sample size, s is the sample standard deviation, and σ_0 is the hypothesized standard deviation. The denominator is the ratio of the sample standard deviation to the hypothesized standard deviation. The further this ratio deviates from 1, the more likely you are to reject the null hypothesis. The test statistic T has a chi-square distribution with $n - 1$ degrees of freedom under the null hypothesis.

Multidimensional Array

A multidimensional array has more than two dimensions. For example, if x is a 1-by-3-by-4 array, then x is a three-dimensional array.

First Nonsingleton Dimension

The first nonsingleton dimension is the first dimension of an array whose size is not equal to 1. For example, if x is a 1-by-2-by-3-by-4 array, then the second dimension is the first nonsingleton dimension of x .

Tips

- Use `sampsizepwr` to calculate:
 - The sample size that corresponds to specified power and parameter values;
 - The power achieved for a particular sample size, given the true parameter value;
 - The parameter value detectable with the specified sample size and power.

Extended Capabilities

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU arrays. For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

`sampsizepwr` | `vartest2` | `vartestn`

Introduced before R2006a

vartest2

Two-sample F -test for equal variances

Syntax

```
h = vartest2(x,y)
h = vartest2(x,y,Name,Value)
[h,p] = vartest2( ___ )
[h,p,ci,stats] = vartest2( ___ )
```

Description

`h = vartest2(x,y)` returns a test decision for the null hypothesis that the data in vectors `x` and `y` comes from normal distributions with the same variance, using the two-sample F -test on page 32-7235. The alternative hypothesis is that they come from normal distributions with different variances. The result `h` is 1 if the test rejects the null hypothesis at the 5% significance level, and 0 otherwise.

`h = vartest2(x,y,Name,Value)` returns a test decision for the two-sample F -test with additional options specified by one or more name-value pair arguments. For example, you can change the significance level or conduct a one-sided test.

`[h,p] = vartest2(___)` also returns the p -value of the test, `p`, using any of the input arguments in the previous syntaxes.

`[h,p,ci,stats] = vartest2(___)` also returns the confidence interval for the true variance ratio, `ci`, and the structure `stats` containing information about the test statistic.

Examples

Test for Equal Variances

Load the sample data. Create vectors containing the first and second columns of the data matrix to represent students' grades on two exams.

```
load examgrades;
x = grades(:,1);
y = grades(:,2);
```

Test the null hypothesis that the data in `x` and `y` comes from distributions with the same variance.

```
[h,p,ci,stats] = vartest2(x,y)
```

```
h = 1
```

```
p = 0.0019
```

```
ci = 2×1
```

```
    1.2383
```

```
    2.5494
```

```
stats = struct with fields:
```

```
  fstat: 1.7768
```

```
   df1: 119
```

```
   df2: 119
```

The returned result `h = 1` indicates that `vartest2` rejects the null hypothesis at the default 5% significance level. `ci` contains the lower and upper boundaries of the 95% confidence interval for the true variance ratio. `stats` contains the value of the test statistic for the F -test and the numerator and denominator degrees of freedom.

One-Sided Hypothesis Test

Load the sample data. Create vectors containing the first and second columns of the data matrix to represent students' grades on two exams.

```
load examgrades;
x = grades(:,1);
y = grades(:,2);
```

Test the null hypothesis that the data in `x` and `y` comes from distributions with the same variance, against the alternative that the population variance of `x` is greater than that of `y`.

```
varTest2(x,y, 'Tail', 'right')
```

```
ans = 1
```

The returned result `h = 1` indicates that `varTest2` rejects the null hypothesis at the default 5% significance level, in favor of the alternative hypothesis that the population variance of `x` is greater than that of `y`.

Input Arguments

x — Sample data

vector | matrix | multidimensional array

Sample data, specified as a vector, matrix, or multidimensional array on page 32-7235.

- If `x` and `y` are vectors, they do not need to be the same length.
- If `x` and `y` are matrices, they must have the same number of columns, but do not need to have the same number of rows. `varTest2` performs separate tests along each column and returns a vector of the results.
- If `x` and `y` are multidimensional arrays, they must have the same number of dimensions, and the same size along all but the first nonsingleton dimension on page 32-7235.

Data Types: `single` | `double`

y — Sample data

vector | matrix | multidimensional array

Sample data, specified as a vector, matrix, or multidimensional array on page 32-7235.

- If `x` and `y` are vectors, they do not need to be the same length.
- If `x` and `y` are matrices, they must have the same number of columns, but do not need to have the same number of rows. `varTest2` performs separate tests along each column and returns a vector of the results.

- If x and y are multidimensional arrays, they must have the same number of dimensions, and the same size along all but the first nonsingleton dimension on page 32-7235.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'Tail', 'right', 'Alpha', 0.01` specifies a right-tailed hypothesis test at the 1% significance level.

Alpha — Significance level

`0.05` (default) | scalar value in the range (0,1)

Significance level of the hypothesis test, specified as the comma-separated pair consisting of `'Alpha'` and a scalar value in the range (0,1).

Example: `'Alpha', 0.01`

Data Types: `single` | `double`

Dim — Dimension

first nonsingleton dimension (default) | positive integer value

Dimension of the input matrix to test along, specified as the comma-separated pair consisting of `'Dim'` and a positive integer value. For example, specifying `'Dim', 1` tests the data in each column for variance equality, while `'Dim', 2` tests the data in each row.

Example: `'Dim', 2`

Data Types: `single` | `double`

Tail — Type of alternative hypothesis

`'both'` (default) | `'right'` | `'left'`

Type of alternative hypothesis to evaluate using the F -test, specified as the comma-separated pair consisting of `'Tail'` and one of the following.

'both'	Test the alternative hypothesis that the population variances are not equal.
'right'	Test the alternative hypothesis that the population variance of x is greater than that of y .
'left'	Test the alternative hypothesis that the population variance of x is less than that of y .

Example: 'Tail', 'right'

Output Arguments

h — Hypothesis test result

1 | 0

Hypothesis test result, returned as 1 or 0.

- If $h = 1$, this indicates the rejection of the null hypothesis at the Alpha significance level.
- If $h = 0$, this indicates a failure to reject the null hypothesis at the Alpha significance level.

p — *p*-value

scalar value in the range [0,1]

p-value of the test, returned as a scalar value in the range [0,1]. *p* is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. Small values of *p* cast doubt on the validity of the null hypothesis.

ci — Confidence interval

vector

Confidence interval for the true ratio of the population variances, returned as a two-element vector containing the lower and upper boundaries of the $100 \times (1 - \text{Alpha})\%$ confidence interval.

stats — Test statistics

structure

Test statistics for the hypothesis test, returned as a structure containing:

- `fstat` — Value of the test statistic.
- `df1` — Numerator degrees of freedom of the test.
- `df2` — Denominator degrees of freedom of the test.

Definitions

Two-Sample *F*-Test

The two-sample *F*-test is used to test if the variances of two populations are equal.

The test statistic is

$$F = \frac{s_1^2}{s_2^2},$$

where s_1 and s_2 are the sample standard deviations. The test statistic is a ratio of the two sample variances. The further this ratio deviates from 1, the more likely you are to reject the null hypothesis. Under the null hypothesis, the test statistic F has a *F*-distribution with numerator degrees of freedom equal to $N_1 - 1$ and denominator degrees of freedom equal to $N_2 - 1$, where N_1 and N_2 are the sample sizes of the two data sets.

Multidimensional Array

A multidimensional array has more than two dimensions. For example, if x is a 1-by-3-by-4 array, then x is a three-dimensional array.

First Nonsingleton Dimension

The first nonsingleton dimension is the first dimension of an array whose size is not equal to 1. For example, if x is a 1-by-2-by-3-by-4 array, then the second dimension is the first nonsingleton dimension of x .

vartest | vartestn

Introduced before R2006a

vartestn

Multiple-sample tests for equal variances

Syntax

```
vartestn(x)  
vartestn(x,Name,Value)  
  
vartestn(x,group)  
vartestn(x,group,Name,Value)  
  
p = vartestn( ___ )  
[p,stats] = vartestn( ___ )
```

Description

`vartestn(x)` returns a summary table of statistics and a box plot for a Bartlett test of the null hypothesis that the columns of data vector `x` come from normal distributions with the same variance. The alternative hypothesis is that not all columns of data have the same variance.

`vartestn(x,Name,Value)` returns a summary table of statistics and a box plot for a test of unequal variances with additional options specified by one or more name-value pair arguments. For example, you can specify a different type of hypothesis test or change the display settings for the test results.

`vartestn(x,group)` returns a summary table of statistics and a box plot for a Bartlett test of the null hypothesis that the data in each categorical group comes from normal distributions with the same variance. The alternative hypothesis is that not all groups have the same variance.

`vartestn(x,group,Name,Value)` returns a summary table of statistics and a box plot for a test of unequal variances with additional options specified by one or more name-value pair arguments. For example, you can specify a different type of hypothesis test or change the display settings for the test results.

`p = vartestn(___)` also returns the p -value of the test, `p`, using any of the input arguments in the previous syntaxes.

`[p,stats] = vartestn(___)` also returns the structure `stats` containing information about the test statistic.

Examples

Test Data for Equal Variances

Load the sample data.

```
load examgrades
```

Test the null hypothesis that the variances are equal across the five columns of data in the students' exam grades matrix, `grades`.

```
vartestn(grades)
```

Group Summary Table

Group	Count	Mean	Std Dev
1	120	75.0083	8.7202
2	120	74.9917	6.54204
3	120	74.9917	7.43091
4	120	75.0333	8.60128
5	120	74.9917	5.25884
Pooled	600	75.0033	7.42558

Bartlett's statistic 38.7332

Degrees of freedom 4

p-value 0

```
ans = 7.9086e-08
```

The low p -value, $p = 0$, indicates that `vartestn` rejects the null hypothesis that the variances are equal across all five columns, in favor of the alternative hypothesis that at least one column has a different variance.

Test Grouped Data for Equal Variances

Load the sample data.

```
load carsmall
```

Test the null hypothesis that the variances in miles per gallon (MPG) are equal across different model years.

```
vartestn(MPG,Model_Year)
```

Group Summary Table

Group	Count	Mean	Std Dev
70	29	17.6897	5.33923
76	34	21.5735	5.8893
82	31	31.7097	5.39255
Pooled	94	23.7181	5.562
Bartlett's statistic	0.36619		
Degrees of freedom	2		
p-value	0.83269		

```
ans = 0.8327
```

The high p -value, $p = 0.83269$, indicates that `vartestn` does not reject the null hypothesis that the variances in miles per gallon (MPG) are equal across different model years.

Test for Equal Variances Using Levene's Test

Load the sample data.

```
load carsmall
```

Use Levene's test to test the null hypothesis that the variances in miles per gallon (MPG) are equal across different model years.

```
p = vartestn(MPG,Model_Year, 'TestType', 'LeveneAbsolute')
```

Group Summary Table

Group	Count	Mean	Std Dev
70	29	17.6897	5.33923
76	34	21.5735	5.8893
82	31	31.7097	5.39255
Pooled	94	23.7181	5.562
Levene's statistic (absolute)	0.46126		
Degrees of freedom	2, 91		
p-value	0.63195		

$p = 0.6320$

The high p -value, $p = 0.63195$, indicates that `vartestn` does not reject the null hypothesis that the variances in miles per gallon (MPG) are equal across different model years.

Test for Equal Variances Using the Brown-Forsythe Test

Load the sample data.

```
load examgrades
```

Test the null hypothesis that the variances are equal across the five columns of data in the students' exam grades matrix, `grades`, using the Brown-Forsythe test. Suppress the display of the summary table of statistics and the box plot.

```
[p,stats] = vartestn(grades,'TestType','BrownForsythe','Display','off')
p = 1.3121e-06
stats = struct with fields:
    fstat: 8.4160
    df: [4 595]
```

The small p -value, $p = 1.3121e-06$, indicates that `vartestn` rejects the null hypothesis that the variances are equal across all five columns, in favor of the alternative hypothesis that at least one column has a different variance.

Input Arguments

x — Sample data

matrix | column vector

Sample data, specified as a matrix or column vector. If a grouping variable `group` is specified, then `x` must be a column vector. If a grouping variable is not specified, `x` must be a matrix. In either case, `vartestn` treats NaN values as missing values and ignores them.

Data Types: `single` | `double`

group — Grouping variable

categorical array | logical or numeric vector | character array | string array | cell array of character vectors

Grouping variable, specified as a categorical array, logical or numeric vector, character array, string array, or cell array of character vectors with one row for each element of `x`. Each unique value in a grouping variable defines a group. `vartestn` treats NaN values as missing values and ignores them.

For example, if `Gender` is a cell array of character vectors with values 'Male' and 'Female', you can use `Gender` as a grouping variable to test your data by gender.

Example: `Gender`

Data Types: `categorical` | `single` | `double` | `logical` | `string` | `cell` | `char`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'TestType', 'BrownForsythe', 'Display', 'off'` specifies a Brown-Forsythe test and omits the plot of the results.

Display — Display settings for test results

`'on'` (default) | `'off'`

Display settings for test results, specified as the comma-separated pair consisting of `'Display'` and one of the following.

<code>'on'</code>	Display a box plot and table of summary statistics.
<code>'off'</code>	Do not display a box plot and table of summary statistics.

Example: `'display', 'off'`

TestType — Type of hypothesis test

`'Bartlett'` (default) | `'LeveneQuadratic'` | `'LeveneAbsolute'` | `'BrownForsythe'` | `'OBrien'`

Type of hypothesis test to perform, specified as the comma-separated pair consisting of `'TestType'` and one of the following.

<code>'Bartlett'</code>	Bartlett's test.
<code>'LeveneQuadratic'</code>	Levene's test computed by performing ANOVA on the squared deviations of the data values from their group means.
<code>'LeveneAbsolute'</code>	Levene's test computed by performing ANOVA on the absolute deviations of the data values from their group means.
<code>'BrownForsythe'</code>	Brown-Forsythe test computed by performing ANOVA on the absolute deviations of the data values from the group medians.
<code>'OBrien'</code>	O'Brien's modification of Levene's test with $W = 0.5$.

Example: `'TestType', 'OBrien'`

Output Arguments

p — *p*-value

scalar value in the range [0,1]

p-value of the test, returned as a scalar value in the range [0,1]. *p* is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. Small values of *p* cast doubt on the validity of the null hypothesis.

stats — Test statistics

structure

Test statistics for the hypothesis test, returned as a structure containing:

- **chistat**: Value of the test statistic.
- **df**: Degrees of freedom of the test.

Definitions

Bartlett's Test

Bartlett's test is used to test whether multiple data samples have equal variances, against the alternative that at least two of the data samples do not have equal variances.

The test statistic is

$$T = \frac{(N - k) \ln s_p^2 - \sum_{i=1}^k (N_i - 1) \ln s_i^2}{1 + (1/(3(k - 1))) \left(\left(\sum_{i=1}^k 1/(N_i - 1) \right) - 1/(N - k) \right)},$$

where s_i^2 is the variance of the i th group, N is the total sample size, N_i is the sample size of the i th group, k is the number of groups, and s_p^2 is the pooled variance. The pooled variance is defined as

$$s_p^2 = \sum_{i=1}^k (N_i - 1) s_i^2 / (N - k).$$

The test statistic has a chi-square distribution with $k - 1$ degrees of freedom under the null hypothesis.

Bartlett's test is sensitive to departures from normality. If your data comes from a nonnormal distribution, Levene's test could provide a more accurate result.

Levene, Brown-Forsythe, and O'Brien Tests

The Levene, Brown-Forsythe, and O'Brien tests are used to test if multiple data samples have equal variances, against the alternative that at least two of the data samples do not have equal variances.

The test statistic is

$$W = \frac{(N - k) \sum_{i=1}^k N_i (\bar{Z}_{i.} - \bar{Z}_{..})^2}{(k - 1) \sum_{i=1}^k \sum_{j=1}^{N_i} (Z_{ij} - \bar{Z}_{i.})^2},$$

where N_i is the sample size of the i th group, and k is the number of groups. Depending on the type of test specified with the `TestType` name-value pair arguments, Z_{ij} can have one of four definitions:

- If you specify `LeveneAbsolute`, `vartestn` uses $Z_{ij} = |Y_{ij} - \bar{Y}_{i.}|$, where $\bar{Y}_{i.}$ is the mean of the i th subgroup.
- If you specify `LeveneQuadratic`, `vartestn` uses $Z_{ij}^2 = (Y_{ij} - \bar{Y}_{i.})^2$, where $\bar{Y}_{i.}$ is the mean of the i th subgroup.
- If you specify `BrownForsythe`, `vartestn` uses $Z_{ij} = |Y_{ij} - \tilde{Y}_{i.}|$, where $\tilde{Y}_{i.}$ is the median of the i th subgroup.
- If you specify `OBrien`, `vartestn` uses

$$Z_{ij} = \frac{(0.5 + n_i - 2)n_i(y_{ij} - \bar{y}_i)^2 - 0.5(n_i - 1)\sigma_i^2}{(n_i - 1)(n_i - 2)},$$

where n_i is the size of the i th group, σ_i^2 is its sample variance.

In all cases, the test statistic has an F -distribution with $k - 1$ numerator degrees of freedom, and $N - k$ denominator degrees of freedom.

The Levene, Brown-Forsythe, and O'Brien tests are less sensitive to departures from normality than Bartlett's test, so they are useful alternatives if you suspect the samples come from nonnormal distributions.

Introduced before R2006a

vertcat

Class: dataset

Vertical concatenation for dataset arrays

Note The dataset data type might be removed in a future release. To work with heterogeneous data, use the MATLAB® table data type instead. See MATLAB table documentation for more information.

Syntax

```
ds = vertcat(ds1, ds2, ...)
```

Description

`ds = vertcat(ds1, ds2, ...)` vertically concatenates the dataset arrays `ds1`, `ds2`, Observation names, when present, must be unique across datasets. `vertcat` fills in default observation names for the output when some of the inputs have names and some do not.

Variable names for all dataset arrays must be identical except for order. `vertcat` concatenates by matching variable names. `vertcat` assigns values for the "per-variable" properties (e.g., `Units` and `VarDescription`) in `ds` from the corresponding property values in `ds1`.

See Also

`cat` | `horzcat`

compact

Class: clustering.evaluation.ClusterCriterion

Package: clustering.evaluation

Compact clustering evaluation object

Syntax

```
c = compact(eva)
```

Description

`c = compact(eva)` returns a compact clustering evaluation object, which contains a subset of information about the clustering solution in `eva`. Compacting a clustering evaluation object reduces the memory requirements of the object, which is useful when clustering a large data set.

Input Arguments

eva — Clustering evaluation data

clustering evaluation object

Clustering evaluation data, specified as a clustering evaluation object. Create a clustering evaluation object using `evalclusters`.

Output Arguments

c — Compact clustering evaluation object

clustering evaluation object

Compact clustering evaluation object, returned as a clustering evaluation object. The compact object includes the clustering evaluation results. In the compact object, the

properties for the input data `X`, optimal clustering solution `OptimalY`, and the list of excluded data `Missing` are empty.

Examples

Create a Compact Clustering Evaluation Object

Create a compact clustering evaluation object from a full clustering evaluation object.

Load the sample data.

```
load fisheriris;
```

The data contains length and width measurements from the sepals and petals of three species of iris flowers.

Create a clustering evaluation object. Cluster the data using `kmeans`, and evaluate the optimal number of clusters using the gap criterion.

```
rng('default'); % For reproducibility
eva = evalclusters(meas, 'kmeans', 'Gap', 'KList', [1:6])
```

```
eva =
  GapEvaluation with properties:
    NumObservations: 150
    InspectedK: [1 2 3 4 5 6]
    CriterionValues: [0.0720 0.5928 0.8762 1.0114 1.0534 1.0720]
    OptimalK: 5
```

Create a compact clustering evaluation object from `eva`.

```
c = compact(eva)
```

```
c =
  GapEvaluation with properties:
    NumObservations: 150
    InspectedK: [1 2 3 4 5 6]
    CriterionValues: [0.0720 0.5928 0.8762 1.0114 1.0534 1.0720]
```

OptimalK: 5

The displayed output of the compact object `c` is the same as the original object `eva`, but some properties not shown in the display are different. For example, in the compact object, the properties `x`, `OptimalY`, and `Missing` are empty.

Display the optimal clustering solution `OptimalY` for `c`.

```
c.OptimalY
```

```
ans =
```

```
 []
```

See Also

`evalclusters`

view

View tree

Syntax

```
view(tree)  
view(tree,Name,Value)
```

Description

`view(tree)` returns a text description of `tree`, a decision tree.

`view(tree,Name,Value)` describes `tree` with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

tree

A classification tree or compact classification tree created by `fitctree` or `compact`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Mode

Value describing the display of `tree`, either `'graph'` or `'text'`. `'graph'` opens a user interface displaying `tree`, and containing controls for querying the tree. `'text'` sends output to the Command Window describing `tree`.

Default: `'text'`

Examples

View Trained Classification Tree

View textual and graphical displays of a trained classification tree.

Load Fisher's iris data set.

```
load fisheriris
```

Train a classification tree using all measurements.

```
Mdl = fitctree(meas,species);
```

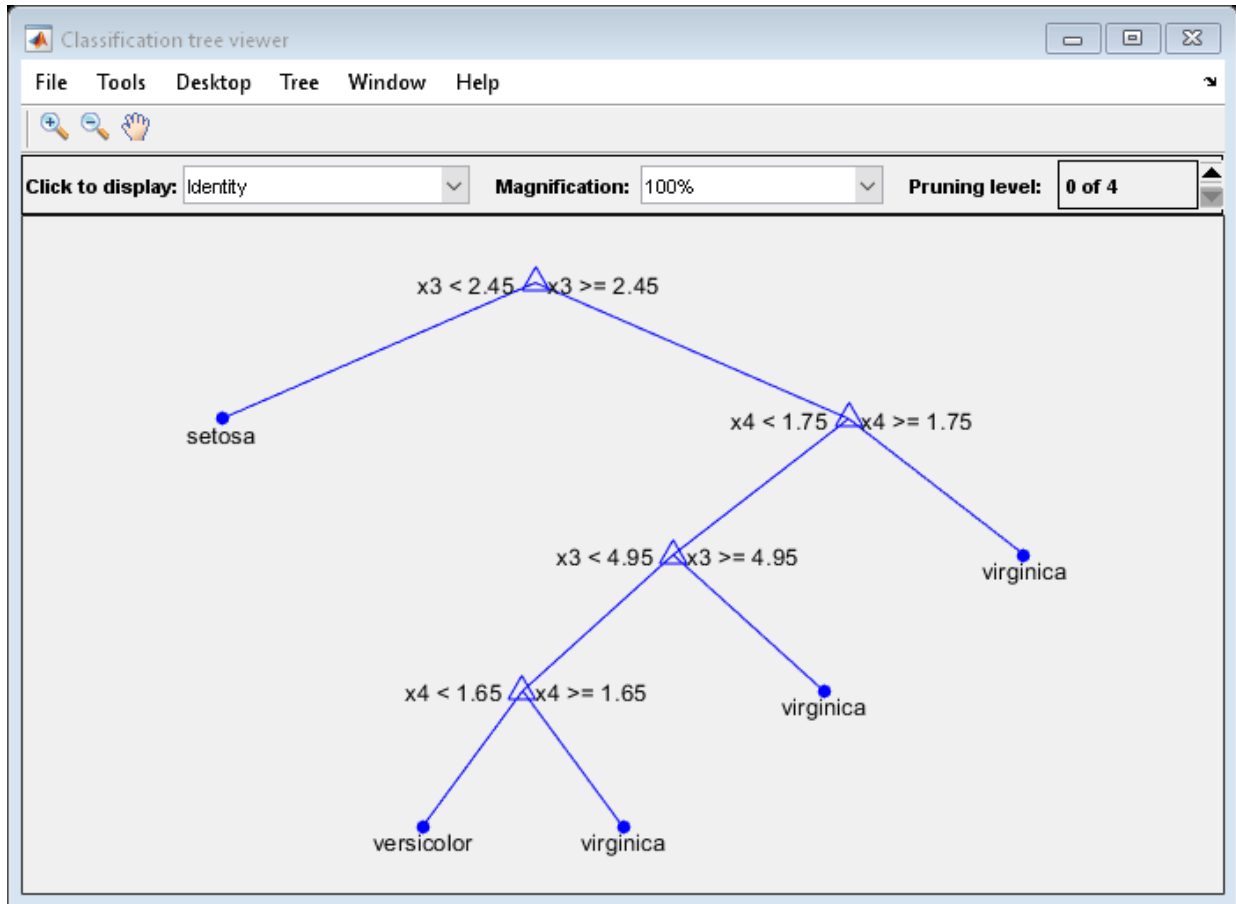

View textual display of the trained classification tree.

```
view(Mdl)
```

```
Decision tree for classification
1  if x3<2.45 then node 2 elseif x3>=2.45 then node 3 else setosa
2  class = setosa
3  if x4<1.75 then node 4 elseif x4>=1.75 then node 5 else versicolor
4  if x3<4.95 then node 6 elseif x3>=4.95 then node 7 else versicolor
5  class = virginica
6  if x4<1.65 then node 8 elseif x4>=1.65 then node 9 else versicolor
7  class = virginica
8  class = versicolor
9  class = virginica
```

View graphical display of the trained classification tree.

```
view(Mdl, 'Mode', 'graph');
```

View Tree from Bag of Trees

Load Fisher's iris data set.

```
load fisheriris
```

Grow a bag of 100 classification trees using all measurements.

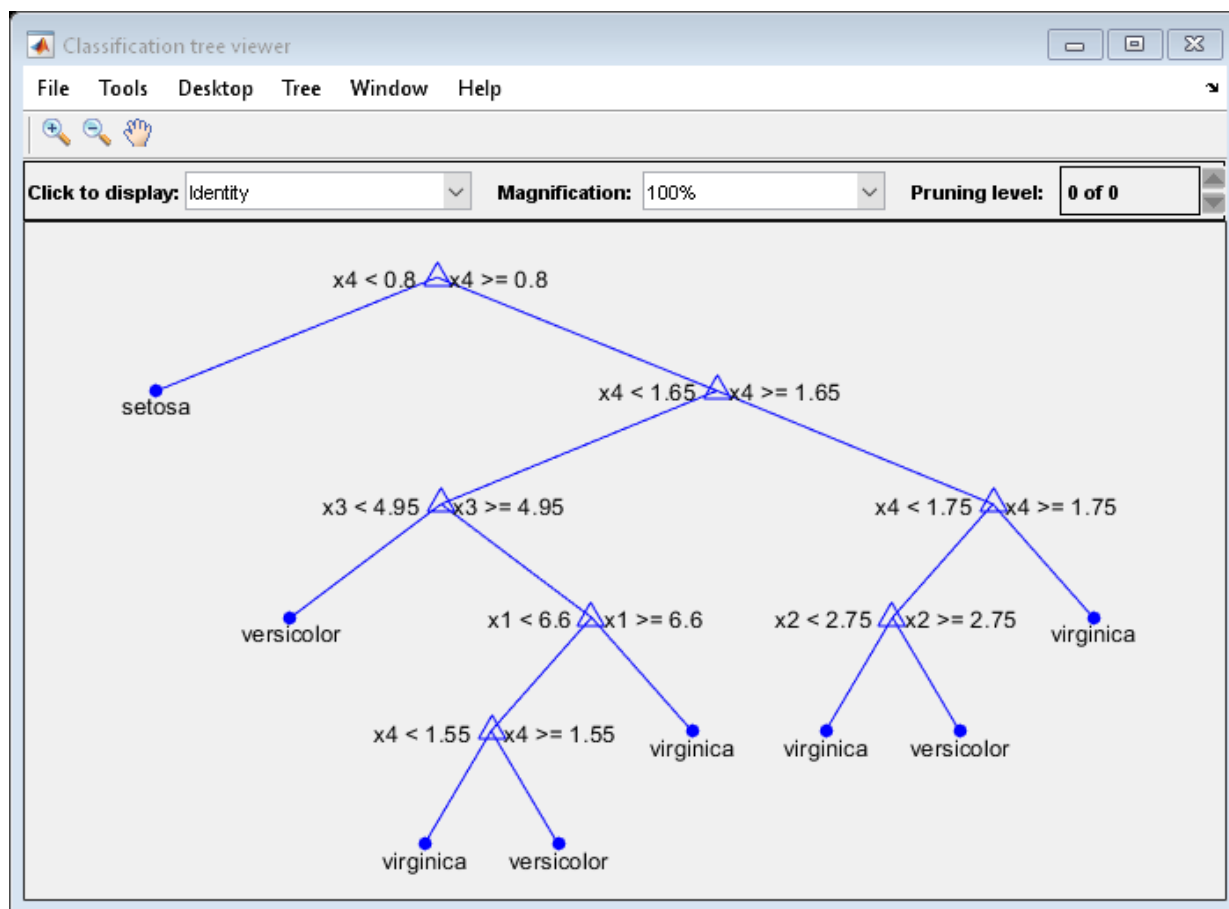

```
rng(1) % For reproducibility
Mdl = TreeBagger(100,meas,species);
```

Alternatively, you can use `fitcensemble` to grow a bag of classification trees.

`Mdl` is a `TreeBagger` model object. `Mdl.Trees` stores the bag of 100 trained classification trees in a 100-by-1 cell array. That is, each cell in `Mdl.Trees` contains a `CompactClassificationTree` model object.

View a graph of the 10th classification tree in the bag.

```
Tree10 = Mdl.Trees{10};
view(Tree10, 'Mode', 'graph');
```

By default, the software grows deep trees for bags of trees.

View Tree from Boosted Ensemble

Load Fisher's iris data set.

```
load fisheriris
```

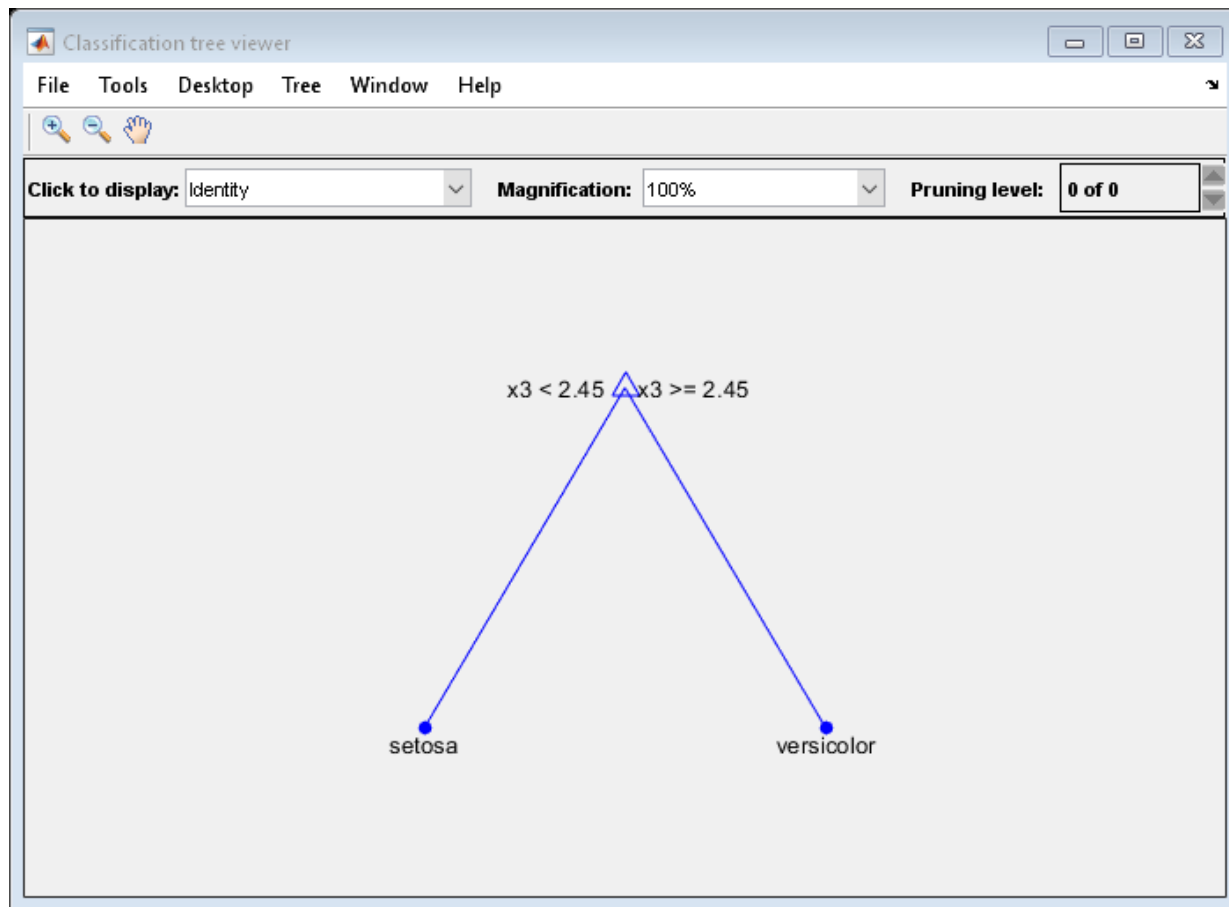

Boost an ensemble of 100 classification trees using all measurements. Specify tree stumps as the weak learners.

```
t = templateTree('MaxNumSplits',1);  
Mdl = fitcensemble(meas,species,'Method','AdaBoostM2','Learners',t);
```

Mdl is a `ClassificationEnsemble` model object. `Mdl.Trained` stores the ensemble of 100 trained classification trees in a 100-by-1 cell array. That is, each cell in `Mdl.Trained` contains a `CompactClassificationTree` model object.

View a graph of the 10th classification tree in the ensemble.

```
Tree10 = Mdl.Trained{10};  
view(Tree10,'Mode','graph');
```

The graph shows a tree stump because you specified stumps as the weak learners for the ensemble. However, this behavior is not the default for `fitensemble`. By default, `fitensemble` grows shallow trees for boosted ensembles of trees. That is, 'Learners' is `templateTree('MaxNumSplits',10)`.

Tip

To view tree t from an ensemble of trees, enter one of these lines of code

```
view(Ens.Trained{t})  
view(Bag.Trees{t})
```

- `Ens` is a full ensemble returned by `fitcensemble` or a compact ensemble returned by `compact`.
- `Bag` is a full bag of trees returned by `TreeBagger` or a compact bag of trees returned by `compact`.

To save `tree` in the Command Window, get a figure handle by using the `findall` and `setdiff` functions, and then save `tree` using the function `saveas`.

```
before = findall(groot, 'Type', 'figure'); % Find all figures  
view(Mdl, 'Mode', 'graph')  
after = findall(groot, 'Type', 'figure');  
h = setdiff(after, before); % Get the figure handle of the tree viewer  
saveas(h, 'a.png')
```

See Also

[ClassificationTree](#) | [fitctree](#)

view

View tree

Syntax

```
view(tree)
view(tree,Name,Value)
```

Description

`view(tree)` returns a text description of `tree`, a decision tree.

`view(tree,Name,Value)` describes `tree` with additional options specified by one or more `Name,Value` pair arguments.

Input Arguments

tree

A regression tree or compact regression tree created by `fitrtree` or `compact`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name,Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Mode

Display of `tree`, either `'graph'` or `'text'`. `'graph'` opens a GUI displaying `tree`, and containing controls for querying the tree. `'text'` sends output to the Command Window describing `tree`.

Default: `'text'`

Examples

View Trained Regression Tree

View textual and graphical displays of a trained regression tree.

Load the `carsmall` data set. Consider a model that explains a car's fuel economy (MPG) using its weight (Weight) and number of cylinders (Cylinders).

```
load carsmall
X = [Weight Cylinders];
Y = MPG;
```

Train a regression tree using all measurements.

```
Mdl = fitrtree(X,Y);
```

View textual display of the trained regression tree.

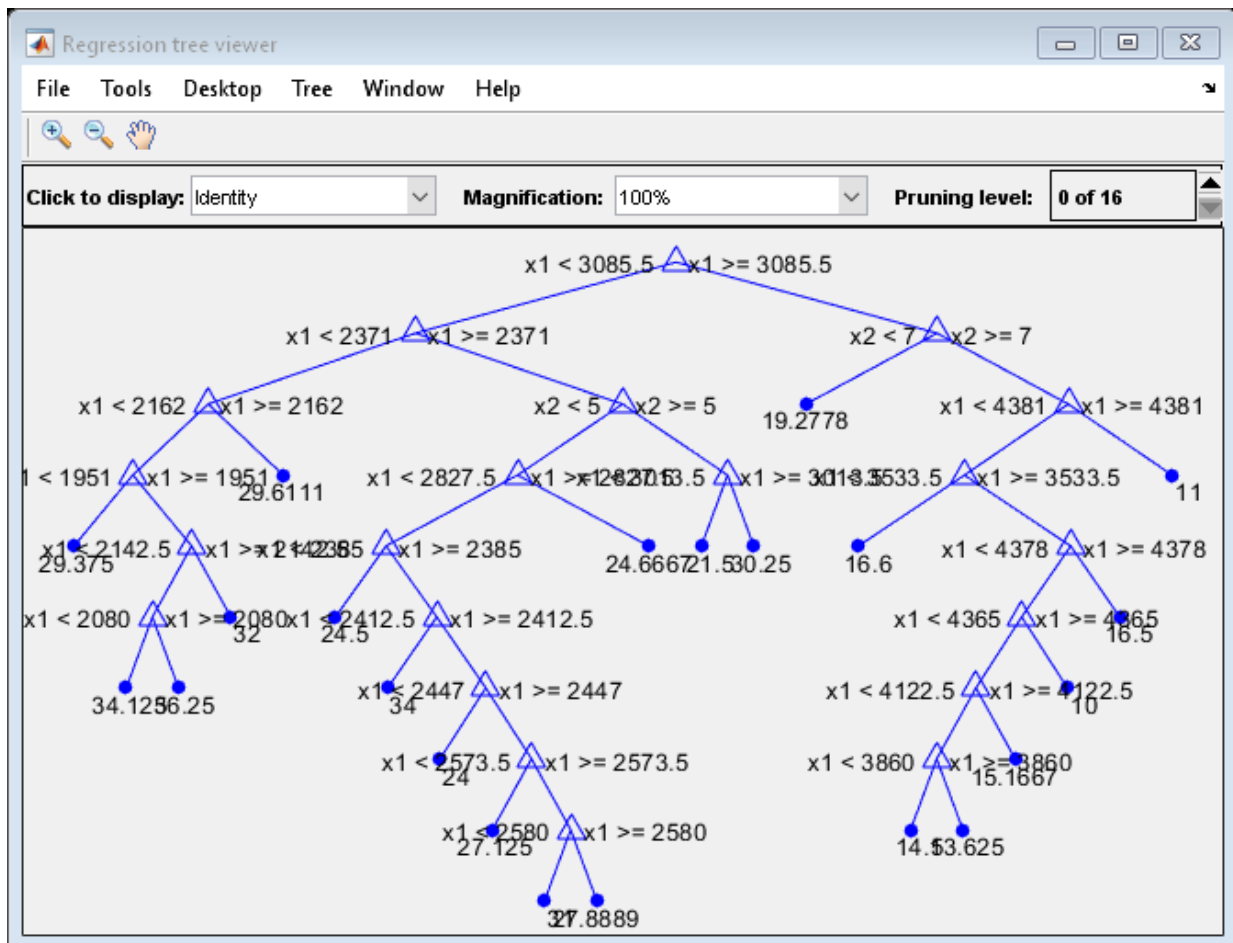

```
view(Mdl)
```

```

38 fit = 27.125
39 if x1<2580 then node 42 elseif x1>=2580 then node 43 else 28.2
40 fit = 14.5
41 fit = 13.625
42 fit = 31
43 fit = 27.8889
```

View graphical display of the trained regression tree.

```
view(Mdl, 'Mode', 'graph');
```

View Tree from Bag of Trees

Load the `carsmall` data set. Consider a model that explains a car's fuel economy (MPG) using its weight (Weight) and number of cylinders (Cylinders).

```
load carsmall
X = [Weight Cylinders];
Y = MPG;
```

Grow a bag of 100 regression trees using all measurements.

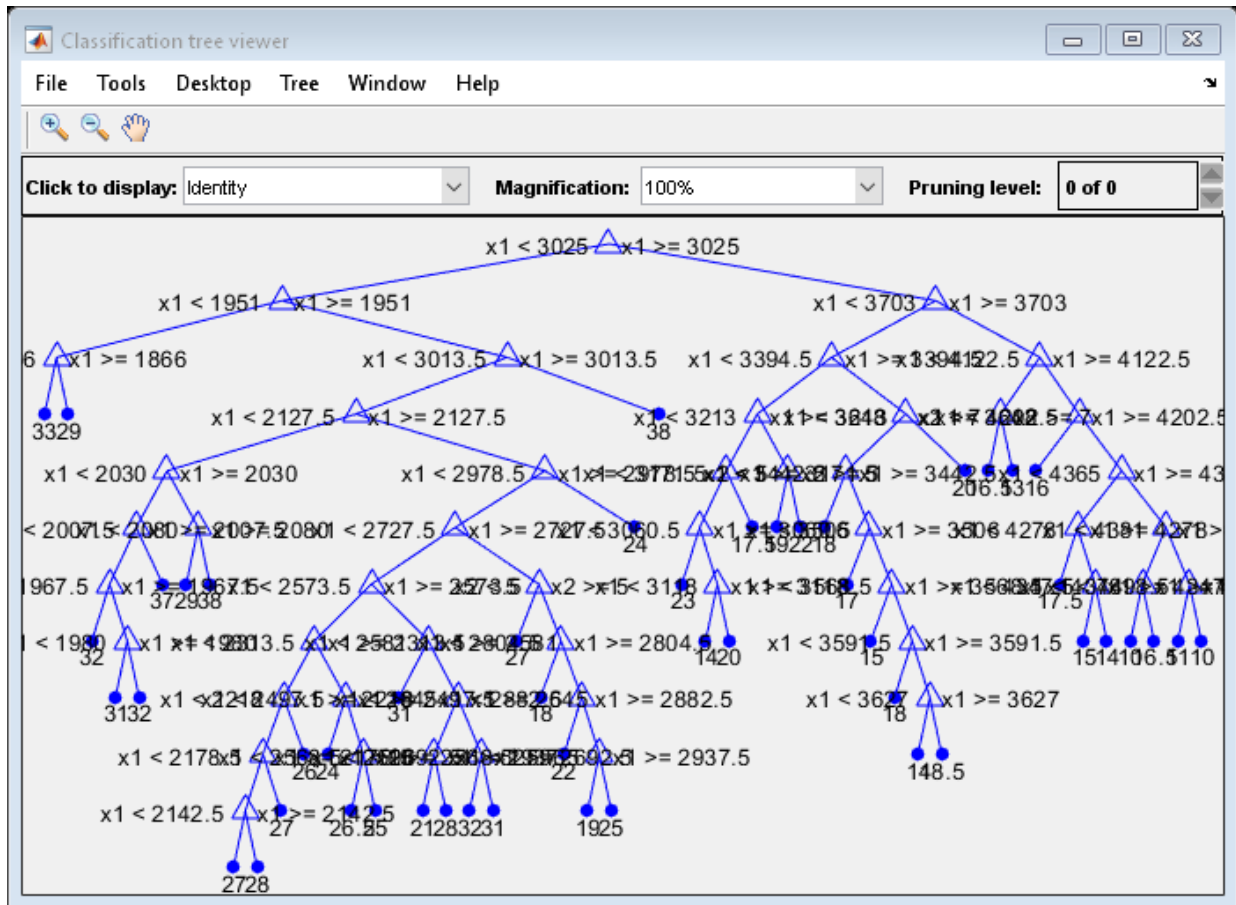

```
rng(1) % For reproducibility
Mdl = TreeBagger(100,X,Y);
```

Alternatively, you can use `fitrensemble` to grow a bag of regression trees.

`Mdl` is a `TreeBagger` model object. `Mdl.Trees` stores the bag of 100 trained regression trees in a 100-by-1 cell array. That is, each cell in `Mdl.Trees` contains a `CompactRegressionTree` model object.

View a graph of the 10th regression tree in the bag.

```
Tree10 = Mdl.Trees{10};
view(Tree10, 'Mode', 'graph');
```

By default, the software grows deep trees for bags of trees.

View Tree from Boosted Ensemble

Load the `carsmall` data set. Consider a model that explains a car's fuel economy (MPG) using its weight (`Weight`) and number of cylinders (`Cylinders`).

```
load carsmall
X = [Weight Cylinders];
Y = MPG;
```

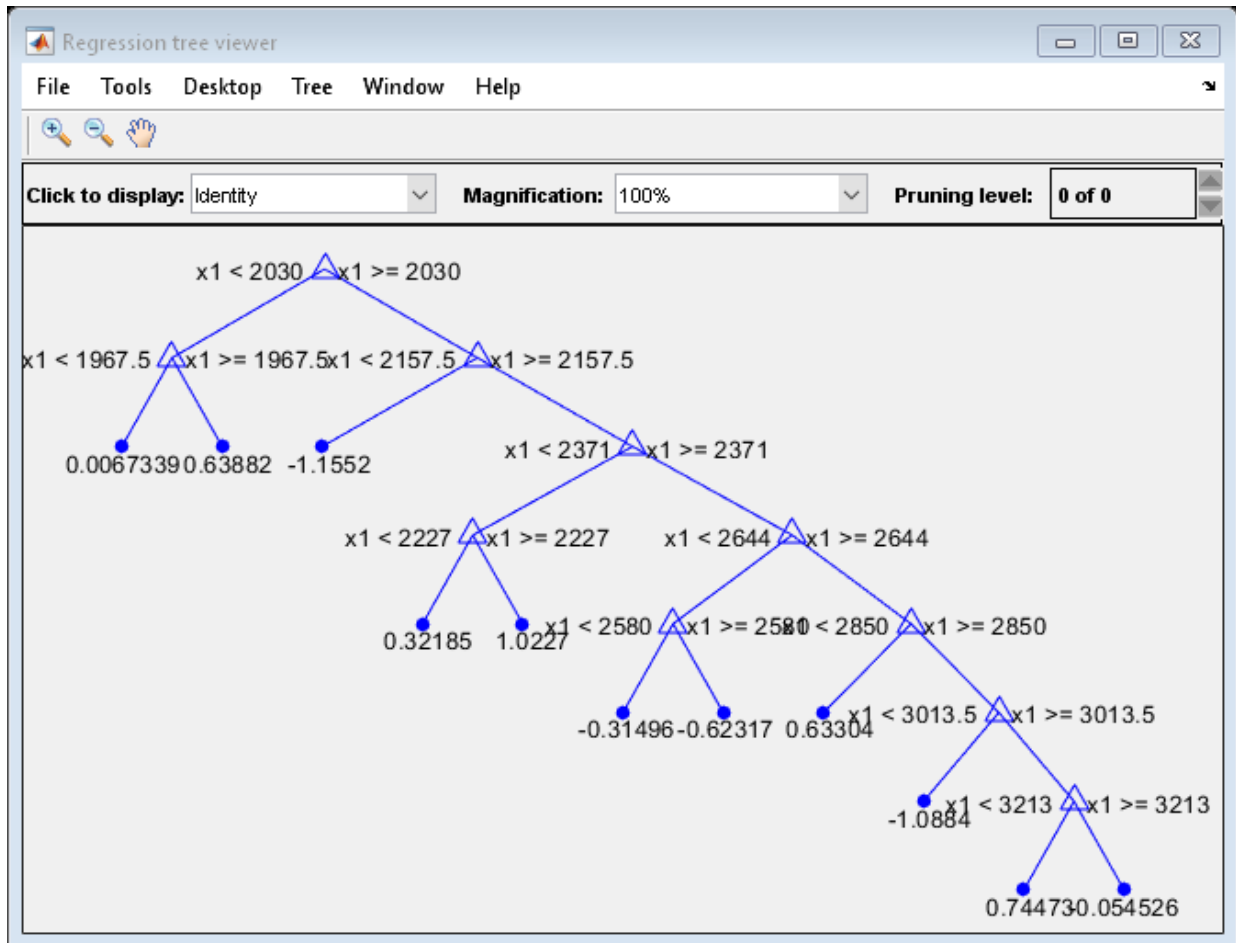

Boost an ensemble of 100 regression trees using all measurements.

```
Mdl = fitensemble(X,Y, 'Method', 'LSBoost');
```

Mdl is a RegressionEnsemble model object. Mdl.Trained stores the ensemble of 100 trained regression trees in a 100-by-1 cell array. That is, each cell in Mdl.Trained contains a CompactRegressionTree model object.

View a graph of the 10th regression tree in the ensemble.

```
Tree10 = Mdl.Trained{10};
view(Tree10, 'Mode', 'graph');
```

By default, `fitrensemble` grows shallow trees for boosted ensembles of trees. That is, 'Learners' is `templateTree('MaxNumSplits', 10)`.

Tip

To view tree `t` from an ensemble of trees, enter one of these lines of code

```
view(Ens.Trained{t})  
view(Bag.Trees{t})
```

- `Ens` is a full ensemble returned by `fitrensemble` or a compact ensemble returned by `compact`.
- `Bag` is a full bag of trees returned by `TreeBagger` or a compact bag of trees returned by `compact`.

To save `tree` in the Command Window, get a figure handle by using the `findall` and `setdiff` functions, and then save `tree` using the function `saveas`.

```
before = findall(groot, 'Type', 'figure'); % Find all figures  
view(Mdl, 'Mode', 'graph')  
after = findall(groot, 'Type', 'figure');  
h = setdiff(after, before); % Get the figure handle of the tree viewer  
saveas(h, 'a.png')
```

RegressionTree | `fitrtree`

wblcdf

Weibull cumulative distribution function

Syntax

```
p = wblcdf(x,a,b)
[p,plo,pup] = wblcdf(x,a,b,pcov,alpha)
[p,plo,pup] = wblcdf( __ , 'upper')
```

Description

`p = wblcdf(x,a,b)` returns the cdf of the Weibull distribution with scale parameter `a` and shape parameter `b`, at each value in `x`. `x`, `a`, and `b` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array of the same size as the other inputs. The default values for `a` and `b` are both 1. The parameters `a` and `b` must be positive.

`[p,plo,pup] = wblcdf(x,a,b,pcov,alpha)` returns confidence bounds for `p` when the input parameters `a` and `b` are estimates. `pcov` is the 2-by-2 covariance matrix of the estimated parameters. `alpha` has a default value of 0.05, and specifies `100(1 - alpha)%` confidence bounds. `plo` and `pup` are arrays of the same size as `p` containing the lower and upper confidence bounds.

`[p,plo,pup] = wblcdf(__ , 'upper')` returns the complement of the Weibull cdf for each value in `x`, using an algorithm that more accurately computes the extreme upper tail probabilities. You can use `'upper'` with any of the previous syntaxes.

The function `wblcdf` computes confidence bounds for `p` using a normal approximation to the distribution of the estimate

$$\widehat{b}(\log x - \log \widehat{a})$$

and then transforms those bounds to the scale of the output `p`. The computed bounds give approximately the desired confidence level when you estimate `mu`, `sigma`, and `pcov` from large samples, but in smaller samples other methods of computing the confidence bounds might be more accurate.

The Weibull cdf is

$$p = F(x|a, b) = \int_0^x ba^{-b}t^{b-1}e^{-\left(\frac{t}{a}\right)^b} dt = 1 - e^{-\left(\frac{x}{a}\right)^b} I_{(0, \infty)}(x)$$

Examples

Weibull Distribution cdf

What is the probability that a value from a Weibull distribution with parameters $a = 0.15$ and $b = 0.8$ is less than 0.5?

```
probability = wblcdf(0.5, 0.15, 0.8)
```

```
probability = 0.9272
```

How sensitive is this result to small changes in the parameters?

```
[A, B] = meshgrid(0.1:0.05:0.2, 0.2:0.05:0.3);
```

```
probability = wblcdf(0.5, A, B)
```

```
probability = 3x3
```

```
0.7484    0.7198    0.6991
0.7758    0.7411    0.7156
0.8022    0.7619    0.7319
```

Introduced before R2006a

wblfit

Weibull parameter estimates

Syntax

```
parmhat = wblfit(data)
[parmhat,parmci] = wblfit(data)
[parmhat,parmci] = wblfit(data,alpha)
[...] = wblfit(data,alpha,censoring)
[...] = wblfit(data,alpha,censoring,freq)
[...] = wblfit(...,options)
```

Description

`parmhat = wblfit(data)` returns the maximum likelihood estimates, `parmhat`, of the parameters of the Weibull distribution given the values in the vector `data`, which must be positive. `parmhat` is a two-element row vector: `parmhat(1)` estimates the Weibull parameter a , and `parmhat(2)` estimates the Weibull parameter b , in the pdf

$$y = f(x|a, b) = ba^{-b}x^{b-1}e^{-\left(\frac{x}{a}\right)^b} I_{(0, \infty)}(x)$$

`[parmhat,parmci] = wblfit(data)` returns 95% confidence intervals for the estimates of a and b in the 2-by-2 matrix `parmci`. The first row contains the lower bounds of the confidence intervals for the parameters, and the second row contains the upper bounds of the confidence intervals.

`[[parmhat,parmci] = wblfit(data,alpha)` returns 100(1 - alpha)% confidence intervals for the parameter estimates.

`[...] = wblfit(data,alpha,censoring)` accepts a Boolean vector, `censoring`, of the same size as `data`, which is 1 for observations that are right-censored and 0 for observations that are observed exactly.

`[...] = wblfit(data,alpha,censoring,freq)` accepts a frequency vector, `freq`, of the same size as `data`. The vector `freq` typically contains integer frequencies for the

corresponding elements in `data`, but can contain any non-negative values. Pass in `[]` for `alpha`, `censoring`, or `freq` to use their default values.

`[...] = wblfit(...,options)` accepts a structure, `options`, that specifies control parameters for the iterative algorithm the function uses to compute maximum likelihood estimates. The Weibull fit function accepts an `options` structure that can be created using the function `statset`. Enter `statset ('wblfit')` to see the names and default values of the parameters that `lognfit` accepts in the `options` structure. See the reference page for `statset` for more information about these options.

Examples

```
data = wblrnd(0.5,0.8,100,1);
[parmhat, parmci] = wblfit(data)
parmhat =
    0.5861    0.8567
parmci =
    0.4606    0.7360
    0.7459    0.9973
```

Topics

“Weibull Distribution” on page B-199

Introduced before R2006a

wblinv

Weibull inverse cumulative distribution function

Syntax

```
X = wblinv(P,A,B)
[X,XLO,XUP] = wblinv(P,A,B,PCOV,alpha)
```

Description

`X = wblinv(P,A,B)` returns the inverse cumulative distribution function (cdf) for a Weibull distribution with scale parameter `A` and shape parameter `B`, evaluated at the values in `P`. `P`, `A`, and `B` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array of the same size as the other inputs. The default values for `A` and `B` are both 1.

`[X,XLO,XUP] = wblinv(P,A,B,PCOV,alpha)` returns confidence bounds for `X` when the input parameters `A` and `B` are estimates. `PCOV` is a 2-by-2 matrix containing the covariance matrix of the estimated parameters. `alpha` has a default value of 0.05, and specifies $100(1 - \text{alpha})\%$ confidence bounds. `XLO` and `XUP` are arrays of the same size as `X` containing the lower and upper confidence bounds.

The function `wblinv` computes confidence bounds for `X` using a normal approximation to the distribution of the estimate

$$\log \hat{a} + \frac{\log q}{\hat{b}}$$

where q is the P th quantile from a Weibull distribution with scale and shape parameters both equal to 1. The computed bounds give approximately the desired confidence level when you estimate `mu`, `sigma`, and `PCOV` from large samples, but in smaller samples other methods of computing the confidence bounds might be more accurate.

The inverse of the Weibull cdf is

$$x = F^{-1}(p | a, b) = -a[\ln(1 - p)]^{1/b} I_{[0, 1]}(p)$$

Examples

The lifetimes (in hours) of a batch of light bulbs has a Weibull distribution with parameters $a = 200$ and $b = 6$.

Find the median lifetime of the bulbs:

```
life = wblinv(0.5, 200, 6)
life =
    188.1486
```

Generate 100 random values from this distribution, and estimate the 90th percentile (with confidence bounds) from the random sample

```
x = wblrnd(200,6,100,1);
p = wblfit(x)
[nlogl,pcov] = wbllike(p,x)
[q90,q90lo,q90up] = wblinv(0.9,p(1),p(2),pcov)
p =
```

```
    204.8918    6.3920
```

```
nlogl =
```

```
    496.8915
```

```
pcov =
```

```
    11.3392    0.5233
     0.5233    0.2573
```

```
q90 =
```

```
    233.4489
```

```
q90lo =
```

```
    226.0092
```

q90up =
241.1335

“Weibull Distribution” on page B-199

Introduced before R2006a

wbllike

Weibull negative log-likelihood

Syntax

```
nlogL = wbllike(params,data)
[logL,AVAR] = wbllike(params,data)
[...] = wbllike(params,data,censoring)
[...] = wbllike(params,data,censoring,freq)
```

Description

`nlogL = wbllike(params,data)` returns the Weibull log-likelihood. `params(1)` is the scale parameter, `A`, and `params(2)` is the shape parameter, `B`.

`[logL,AVAR] = wbllike(params,data)` also returns `AVAR`, which is the asymptotic variance-covariance matrix of the parameter estimates if the values in `params` are the maximum likelihood estimates. `AVAR` is the inverse of Fisher's information matrix. The diagonal elements of `AVAR` are the asymptotic variances of their respective parameters.

`[...] = wbllike(params,data,censoring)` accepts a Boolean vector, `censoring`, of the same size as `data`, which is 1 for observations that are right-censored and 0 for observations that are observed exactly.

`[...] = wbllike(params,data,censoring,freq)` accepts a frequency vector, `freq`, of the same size as `data`. `freq` typically contains integer frequencies for the corresponding elements in `data`, but can contain any nonnegative values. Pass in `[]` for `censoring` to use its default value.

The Weibull negative log-likelihood for uncensored data is

$$(-\log L) = -\log \prod_{i=1}^n f(a,b|x_i) = -\sum_{i=1}^n \log f(a,b|x_i)$$

where f is the Weibull pdf.

wbllike is a utility function for maximum likelihood estimation.

Examples

This example continues the example from `wblfit`.

```
r = wblrnd(0.5,0.8,100,1);
[logL, AVAR] = wbllike(wblfit(r),r)
logL =
    47.3349
AVAR =
    0.0048    0.0014
    0.0014    0.0040
```

Topics

“Weibull Distribution” on page B-199

Introduced before R2006a

wblpdf

Weibull probability density function

Syntax

```
Y = wblpdf(X,A,B)
```

Description

`Y = wblpdf(X,A,B)` computes the Weibull pdf at each of the values in `X` using the corresponding scale parameter, `A` and shape parameter, `B`. `X`, `A`, and `B` can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array of the same size as the other inputs. The parameters in `A` and `B` must be positive.

The Weibull pdf is

$$f(x|a,b) = \frac{b}{a} \left(\frac{x}{a}\right)^{b-1} e^{-(x/a)^b}.$$

Some references refer to the Weibull distribution with a single parameter. This corresponds to `wblpdf` with `A = 1`.

Examples

The exponential distribution is a special case of the Weibull distribution.

```
lambda = 1:6;  
y = wblpdf(0.1:0.1:0.6,lambda,1)  
y =  
    0.9048    0.4524    0.3016    0.2262    0.1810    0.1508  
  
y1 = exppdf(0.1:0.1:0.6,lambda)  
y1 =  
    0.9048    0.4524    0.3016    0.2262    0.1810    0.1508
```

Topics

“Weibull Distribution” on page B-199

Introduced before R2006a

wblplot

Weibull probability plot

Syntax

```
wblplot(x)  
wblplot(ax,x)  
h = wblplot( ___ )
```

Description

`wblplot(x)` creates a Weibull probability plot comparing the distribution of the data in `x` to the Weibull distribution.

`wblplot` plots each data point in `x` using plus sign ('+') markers and draws two reference lines that represent the theoretical distribution. A solid reference line connects the first and third quartiles of the data, and a dashed reference line extends the solid line to the ends of the data. If the sample data has a Weibull distribution, then the data points appear along the reference line. A distribution other than Weibull introduces curvature in the data plot.

`wblplot(ax,x)` adds a Weibull probability plot into the axes specified by `ax`.

`h = wblplot(___)` returns graphics handles corresponding to the plotted lines, using any of the input arguments in the previous syntaxes.

Examples

Create Weibull Probability Plot

Generate a vector `r` containing 50 random numbers from the Weibull distribution with the scale parameter 1.2 and the shape parameter 1.5.

```
rng('default') % For reproducibility  
r = wblrnd(1.2,1.5,50,1);
```

Create a Weibull probability plot to visually determine if the data comes from a Weibull distribution.

```
wblplot(r)
```

The plot indicates that the data likely comes from a Weibull distribution.

Test for Weibull Distribution

Generate two sample data sets, one from a Weibull distribution and another from a lognormal distribution. Perform the Lilliefors test to assess whether each data set is from

a Weibull distribution. Confirm the test decision by performing a visual comparison using a Weibull probability plot (`wblplot`).

Generate samples from a Weibull distribution.

```
rng('default')
data1 = wblrnd(0.5,2,[500,1]);
```

Perform the Lilliefors test by using the `lillietest`. To test data for a Weibull distribution, test if the logarithm of the data has an extreme value distribution.

```
h1 = lillietest(log(data1), 'Distribution', 'extreme value')
```

```
h1 = 0
```

The returned value of `h1 = 0` indicates that `lillietest` fails to reject the null hypothesis at the default 5% significance level. Confirm the test decision using a Weibull probability plot.

```
wblplot(data1)
```

The plot indicates that the data follows a Weibull distribution.

Generate samples from a lognormal distribution.

```
data2 =lognrnd(5,2,[500,1]);
```

Perform the Lilliefors test.

```
h2 = lillietest(log(data2), 'Distribution', 'extreme value')
```

```
h2 = 1
```

The returned value of $h2 = 1$ indicates that `lillietest` rejects the null hypothesis at the default 5% significance level. Confirm the test decision using a Weibull probability plot.

```
wblplot(data2)
```

The plot indicates that the data does not follow a Weibull distribution.

Input Arguments

x — Sample data

numeric vector | numeric matrix

Sample data, specified as a numeric vector or numeric matrix. `wblplot` displays each value in `x` using the symbol '+'. If `x` is a matrix, then `wblplot` displays a separate line for each column of `x`.

Data Types: `single` | `double`

ax — Target axes

Axes object | UIAxes object

Target axes, specified as an `Axes` object or a `UIAxes` object. `wblplot` adds an additional plot into the axes specified by `ax`. For details, see `Axes Properties` and `UIAxes Properties`.

Use `gca` to return the current axes for the current figure.

Output Arguments

h — Graphics handles for line objects

vector of `Line` graphics handles

Graphics handles for line objects, returned as a vector of `Line` graphics handles. Graphics handles are unique identifiers that you can use to query and modify the properties of a specific line on the plot. For each column of `x`, `wblplot` returns three handles:

- The line representing the data points. `wblplot` represents each data point in `x` using plus sign ('+') markers.
- The line joining the first and third quartiles of each column of `x`, represented as a solid line.
- The extrapolation of the quartile line, extended to the minimum and maximum values of `x`, represented as a dashed line.

To view and set properties of line objects, use dot notation. For information on using dot notation, see “Access Property Values” (MATLAB). For information on the `Line` properties that you can set, see `Primitive Line`.

Algorithms

`wblplot` matches the quantiles of sample data to the quantiles of a Weibull distribution. The sample data is sorted, scaled logarithmically, and plotted on the x-axis. The y-axis represents the quantiles of the Weibull distribution, converted into probability values. Therefore, the y-axis scaling is not linear.

Where the x-axis value is the i th sorted value from a sample of size N , the y-axis value is the midpoint between evaluation points of the empirical cumulative distribution function of the data. The midpoint is equal to $\frac{(i - 0.5)}{N}$.

`wblplot` superimposes a reference line to assess the linearity of the plot. The line goes through the first and third quartiles of the data.

Alternative Functionality

You can use the `probplot` function to create a probability plot. The `probplot` function enables you to indicate censored data and specify the distribution for a probability plot.

wblrnd

Weibull random numbers

Syntax

```
R = wblrnd(A,B)
R = wblrnd(A,B,m,n,...)
R = wblrnd(A,B,[m,n,...])
```

Description

`R = wblrnd(A,B)` generates random numbers for the Weibull distribution with scale parameter, `A` and shape parameter, `B`. The input arguments `A` and `B` can be either scalars or matrices. `A` and `B`, can be vectors, matrices, or multidimensional arrays that all have the same size. A scalar input is expanded to a constant array of the same size as the other input.

`R = wblrnd(A,B,m,n,...)` or `R = wblrnd(A,B,[m,n,...])` generates an `m`-by-`n`-by-... array. The `A`, `B` parameters can each be scalars or arrays of the same size as `R`.

Devroye [1] refers to the Weibull distribution with a single parameter; this is `wblrnd` with `A = 1`.

Examples

```
n1 = wblrnd(0.5:0.5:2,0.5:0.5:2)
n1 =
    0.0178    0.0860    2.5216    0.9124

n2 = wblrnd(1/2,1/2,[1 6])
n2 =
    0.0046    1.7214    2.2108    0.0367    0.0531    0.0917
```

Extended Capabilities

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

The generated code can return a different sequence of numbers than MATLAB if either of the following is true:

- The output is nonscalar.
- An input parameter is invalid for the distribution.

For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “General Code Generation Workflow” on page 31-5.

wblstat

Weibull mean and variance

Syntax

```
[M,V] = wblstat(A,B)
```

Description

`[M,V] = wblstat(A,B)` returns the mean of and variance for the Weibull distribution with scale parameter, *A* and shape parameter, *B*. Vector or matrix inputs for *A* and *B* must have the same size, which is also the size of *M* and *V*. A scalar input for *A* or *B* is expanded to a constant matrix with the same dimensions as the other input.

The mean of the Weibull distribution with parameters *a* and *b* is

$$a[\Gamma(1 + b^{-1})]$$

and the variance is

$$a^2[\Gamma(1 + 2b^{-1}) - \Gamma(1 + b^{-1})^2]$$

Examples

```
[m,v] = wblstat(1:4,1:4)
m =
  1.0000  1.7725  2.6789  3.6256
v =
  1.0000  0.8584  0.9480  1.0346

wblstat(0.5,0.7)
ans =
  0.6329
```

wishrnd

Wishart random numbers

Syntax

```
W = wishrnd(Sigma,df)
W = wishrnd(Sigma,df,D)
[W,D] = wishrnd(Sigma,df)
```

Description

`W = wishrnd(Sigma,df)` generates a random matrix `W` having the Wishart distribution with covariance matrix `Sigma` and with `df` degrees of freedom. The inverse of `W` has the Inverse Wishart distribution with parameters `Tau = inv(Sigma)` and `df` degrees of freedom.

`W = wishrnd(Sigma,df,D)` expects `D` to be the Cholesky factor of `Sigma`. If you call `wishrnd` multiple times using the same value of `Sigma`, it's more efficient to supply `D` instead of computing it each time.

`[W,D] = wishrnd(Sigma,df)` returns `D` so you can provide it as input in future calls to `wishrnd`.

This function defines the parameter `Sigma` so that the mean of the output matrix is `Sigma*df`

xptread

Create table from data stored in SAS XPORT format file

Syntax

```
data = xptread
data = xptread(filename)
[data,missing] = xptread(filename)
xptread(..., 'ReadObsNames', true)
```

Description

`data = xptread` displays a dialog box for selecting a file, then reads data from the file into a table. The file must be in the SAS XPORT format.

`data = xptread(filename)` retrieves data from a SAS XPORT format file `filename`. For example, to open a SAS XPORT file named `sample.xpt`, type `data = xptread('sample.xpt')` at the command prompt.

`[data,missing] = xptread(filename)` returns a nominal array, `missing`, that contains the missing data type information from the XPORT format file.

The XPORT format allows for 28 missing data types, represented in the file by an upper case letter or the characters `'.'` or `'_'`. If the XPORT file contains missing values, `xptread` converts them to NaN values in the output table, `data`. However, if you need the specific missing types, you can recover this information by specifying a second output, `missing`. The entries in `missing` are one of the 28 missing data type values from the XPORT format file (`'.'`, `'_'`, `'A'`, ..., `'Z'`), or are undefined for values that are not present at all in the XPORT format file. The outputs `missing` and `data` are the same size.

`xptread(..., 'ReadObsNames', true)` treats the first variable in the file as observation names. The default value is `false`.

`xptread` only supports single data sets per file. `xptread` does not support compressed files.

x2fx

Convert predictor matrix to design matrix

Syntax

```
D = x2fx(X,model)
D = x2fx(X,model,categ)
D = x2fx(X,model,categ,catlevels)
```

Description

`D = x2fx(X,model)` converts a matrix of predictors X to a design matrix D for regression analysis. Distinct predictor variables should appear in different columns of X .

The optional input `model` controls the regression model. By default, `x2fx` returns the design matrix for a linear additive model with a constant term. `model` is one of the following:

- 'linear' — Constant and linear terms. This is the default.
- 'interaction' — Constant, linear, and interaction terms
- 'quadratic' — Constant, linear, interaction, and squared terms
- 'purequadratic' — Constant, linear, and squared terms

If X has n columns, the order of the columns of D for a full quadratic model is:

- 1 The constant term
- 2 The linear terms (the columns of X , in order 1, 2, ..., n)
- 3 The interaction terms (pairwise products of the columns of X , in order (1, 2), (1, 3), ..., (1, n), (2, 3), ..., ($n-1$, n))
- 4 The squared terms (in order 1, 2, ..., n)

Other models use a subset of these terms, in the same order.

Alternatively, `model` can be a matrix specifying polynomial terms of arbitrary order. In this case, `model` should have one column for each column in X and one row for each term

in the model. The entries in any row of *model* are powers for the corresponding columns of *X*. For example, if *X* has columns *X1*, *X2*, and *X3*, then a row $[0 \ 1 \ 2]$ in *model* specifies the term $(X1.^0) \cdot (X2.^1) \cdot (X3.^2)$. A row of all zeros in *model* specifies a constant term, which can be omitted.

`D = x2fx(X,model,categ)` treats columns with numbers listed in the vector *categ* as categorical variables. Terms involving categorical variables produce dummy variable columns in *D*. Dummy variables are computed under the assumption that possible categorical levels are completely enumerated by the unique values that appear in the corresponding column of *X*.

`D = x2fx(X,model,categ,catlevels)` accepts a vector *catlevels* the same length as *categ*, specifying the number of levels in each categorical variable. In this case, values in the corresponding column of *X* must be integers in the range from 1 to the specified number of levels. Not all of the levels need to appear in *X*.

Examples

Example 1

The following converts 2 predictors *X1* and *X2* (the columns of *X*) into a design matrix for a full quadratic model with terms constant, *X1*, *X2*, *X1.*X2*, *X1.^2*, and *X2.^2*.

```
X = [1 10
     2 20
     3 10
     4 20
     5 15
     6 15];
```

```
D = x2fx(X,'quadratic')
D =
     1     1    10    10     1    100
     1     2    20    40     4    400
     1     3    10    30     9    100
     1     4    20    80    16    400
     1     5    15    75    25    225
     1     6    15    90    36    225
```

Example 2

The following converts 2 predictors X1 and X2 (the columns of X) into a design matrix for a quadratic model with terms constant, X1, X2, X1.*X2, and X1.^2.

```
X = [1 10
     2 20
     3 10
     4 20
     5 15
     6 15];
model = [0 0
         1 0
         0 1
         1 1
         2 0];

D = x2fx(X,model)
D =
     1     1    10    10     1
     1     2    20    40     4
     1     3    10    30     9
     1     4    20    80    16
     1     5    15    75    25
     1     6    15    90    36
```

zscore

Standardized z-scores

Syntax

```
Z = zscore(X)
Z = zscore(X, flag)
Z = zscore(X, flag, 'all')
Z = zscore(X, flag, dim)
Z = zscore(X, flag, vecdim)
[Z, mu, sigma] = zscore( ___ )
```

Description

`Z = zscore(X)` returns the z-score on page 32-7310 for each element of `X` such that columns of `X` are centered to have mean 0 and scaled to have standard deviation 1. `Z` is the same size as `X`.

- If `X` is a vector, then `Z` is a vector of z-scores.
- If `X` is a matrix, then `Z` is a matrix of the same size as `X`, and each column of `Z` has mean 0 and standard deviation 1.
- For multidimensional arrays on page 32-7311, z-scores in `Z` are computed along the first nonsingleton dimension on page 32-7311 of `X`.

`Z = zscore(X, flag)` scales `X` using the standard deviation indicated by `flag`.

- If `flag` is 0 (default), then `zscore` scales `X` using the sample standard deviation on page 32-7311, with $n - 1$ in the denominator of the standard deviation formula. `zscore(X, 0)` is the same as `zscore(X)`.
- If `flag` is 1, then `zscore` scales `X` using the population standard deviation on page 32-7312, with n in the denominator of standard deviation formula.

`Z = zscore(X, flag, 'all')` standardizes `X` by using the mean and standard deviation of all the values in `X`.

`Z = zscore(X, flag, dim)` standardizes `X` along the operating dimension `dim`. For example, for a matrix `X`, if `dim = 1`, then `zscore` uses the means and standard deviations along the columns of `X`, if `dim = 2`, then `zscore` uses the means and standard deviations along the rows of `X`.

`Z = zscore(X, flag, vecdim)` standardizes `X` over the dimensions specified by the vector `vecdim`. For example, if `X` is a matrix, then `zscore(X, 0, [1 2])` is equivalent to `zscore(X, 0, 'all')` because every element of a matrix is contained in the array slice defined by dimensions 1 and 2.

`[Z, mu, sigma] = zscore(___)` also returns the means and standard deviations used for centering and scaling, `mu` and `sigma`, respectively. You can use any of the input arguments in the previous syntaxes.

Examples

Z-Scores of Two Data Vectors

Compute and plot the z-scores of two data vectors, and then compare the results.

Load the sample data.

```
load lawdata
```

Two variables load into the workspace: `gpa` and `lsat`.

Plot both variables on the same axes.

```
plot([gpa,lsat])  
legend('gpa','lsat','Location','East')
```

It is difficult to compare these two measures because they are on a very different scale.

Plot the z-scores of gpa and lsat on the same axes.

```
Zgpa = zscore(gpa);  
Zlsat = zscore(lsat);  
plot([Zgpa, Zlsat])  
legend('gpa z-scores', 'lsat z-scores', 'Location', 'Northeast')
```

Now, you can see the relative performance of individuals with respect to both their `gpa` and `lsat` results. For example, the third individual's `gpa` and `lsat` results are both one standard deviation below the sample mean. The eleventh individual's `gpa` is around the sample mean but has an `lsat` score almost 1.25 standard deviations above the sample average.

Check the mean and standard deviation of the `z`-scores you created.

```
mean([Zgpa, Zlsat])
```

```
ans = 1×2  
10-14 ×
```

```

-0.1088    0.0357

std([Zgpa,Zlsat])
ans = 1x2
     1     1

```

By definition, z-scores of `gpa` and `lsat` have mean 0 and standard deviation 1.

Z-Scores for a Population vs. Sample

Load the sample data.

```
load lawdata
```

Two variables load into the workspace: `gpa` and `lsat`.

Compute the z-scores of `gpa` using the population formula for standard deviation.

```
Z1 = zscore(gpa,1); % population formula
Z0 = zscore(gpa,0); % sample formula
disp([Z1 Z0])
```

```

1.2554    1.2128
0.8728    0.8432
-1.2100   -1.1690
-0.2749   -0.2656
1.4679    1.4181
-0.1049   -0.1013
-0.4024   -0.3888
1.4254    1.3771
1.1279    1.0896
0.1502    0.1451
0.1077    0.1040
-1.5076   -1.4565
-1.4226   -1.3743
-0.9125   -0.8815
-0.5724   -0.5530

```

For a sample from a population, the population standard deviation formula with n in the denominator corresponds to the maximum likelihood estimate of the population standard

deviation, and might be biased. The sample standard deviation formula, on the other hand, is the unbiased estimator of the population standard deviation for a sample.

Z-Scores of a Data Matrix

Compute z-scores using the mean and standard deviation computed along the columns or rows of a data matrix.

Load the sample data.

```
load flu
```

The dataset array `flu` is loaded in the workspace. `flu` has 52 observations on 11 variables. The first variable contains dates (in weeks). The other variables contain the flu estimates for different regions in the U.S.

Convert the dataset array to a data matrix.

```
flu2 = double(flu(:,2:end));
```

The new data matrix, `flu2`, is a 52-by-10 double data matrix. The rows correspond to the weeks and the columns correspond to the U.S. regions in the data set array `flu`.

Standardize the flu estimate for each region (the *columns* of `flu2`).

```
Z1 = zscore(flu2,[ ],1);
```

You can see the z-scores in the variable editor by double-clicking on the matrix `Z1` created in the workspace.

Standardize the flu estimate for each week (the *rows* of `flu2`).

```
Z2 = zscore(flu2,[ ],2);
```

Z-Scores of Multidimensional Array

Find the z-scores of a multidimensional array by specifying to standardize the data along different dimensions. Compare the results when using the `'all'`, `dim`, and `vecdim` input arguments.

Create a 3-by-4-by-2 array.

```
X = reshape(1:24,[3 4 2])
```

```
X =
```

```
X(:,:,1) =
```

```

     1     4     7    10
     2     5     8    11
     3     6     9    12
```

```
X(:,:,2) =
```

```

    13    16    19    22
    14    17    20    23
    15    18    21    24
```

Standardize X by using the mean and standard deviation of all the values in X.

```
Zall = zscore(X,0,'all')
```

```
Zall =
```

```
Zall(:,:,1) =
```

```

 -1.6263  -1.2021  -0.7778  -0.3536
 -1.4849  -1.0607  -0.6364  -0.2121
 -1.3435  -0.9192  -0.4950  -0.0707
```

```
Zall(:,:,2) =
```

```

  0.0707   0.4950   0.9192   1.3435
  0.2121   0.6364   1.0607   1.4849
  0.3536   0.7778   1.2021   1.6263
```

The resulting multidimensional array of z-scores has mean 0 and standard deviation 1. For example, compute the mean and standard deviation of Zall.

```
mZall = mean(Zall(:,:,:), 'all')
```

```
mZall = -9.2519e-18
```

```
sZall = std(Zall(:,:,:),0, 'all')
```

```
sZall = 1.0000
```

Now standardize X along the second dimension.

```
Zdim = zscore(X,0,2)
```

```
Zdim =
```

```
Zdim(:,:,1) =
```

```
-1.1619   -0.3873    0.3873    1.1619
-1.1619   -0.3873    0.3873    1.1619
-1.1619   -0.3873    0.3873    1.1619
```

```
Zdim(:,:,2) =
```

```
-1.1619   -0.3873    0.3873    1.1619
-1.1619   -0.3873    0.3873    1.1619
-1.1619   -0.3873    0.3873    1.1619
```

The elements in each row of each page of Zdim have mean 0 and standard deviation 1. For example, compute the mean and standard deviation of the first row of the second page of Zdim.

```
mZdim = mean(Zdim(1,:,2),'all')
```

```
mZdim = 0
```

```
sZdim = std(Zdim(1,:,2),0,'all')
```

```
sZdim = 1
```

Finally, standardize X based on the second and third dimensions.

```
Zvecdim = zscore(X,0,[2 3])
```

```
Zvecdim =
```

```
Zvecdim(:,:,1) =
```

```
-1.4289   -1.0206   -0.6124   -0.2041
-1.4289   -1.0206   -0.6124   -0.2041
-1.4289   -1.0206   -0.6124   -0.2041
```

```
Zvecdim(:,:,2) =
```

```

0.2041    0.6124    1.0206    1.4289
0.2041    0.6124    1.0206    1.4289
0.2041    0.6124    1.0206    1.4289

```

The elements in each `Zvecdim(i, :, :)` slice have mean 0 and standard deviation 1. For example, compute the mean and standard deviation of the elements in `Zvecdim(1, :, :)`.

```

mZvecdim = mean(Zvecdim(1, :, :), 'all')
mZvecdim = 2.7756e-17
sZvecdim = std(Zvecdim(1, :, :), 0, 'all')
sZvecdim = 1

```

Z-Scores, Mean, and Standard Deviation

Return the mean and standard deviation used to compute the z-scores.

Load the sample data.

```
load lawdata
```

Two variables load into the workspace: `gpa` and `lsat`.

Return the z-scores, mean, and standard deviation of `gpa`.

```
[Z, gpamean, gpastdev] = zscore(gpa)
```

```
Z = 15×1
```

```

```

Input Arguments

X — Input data

vector | matrix | multidimensional array

Input data, specified as a vector, matrix, or multidimensional array.

Data Types: double | single

flag — Indicator for the standard deviation

0 (default) | 1

Indicator for the standard deviation used to compute the z-scores, specified as 0 or 1.

- If **flag** is 0 (default), then `zscore` scales X using the sample standard deviation on page 32-7311. `zscore(X,0)` is the same as `zscore(X)`.
- If **flag** is 1, then `zscore` scales X using the population standard deviation on page 32-7312.

dim — Dimension

positive integer scalar

Dimension along which to calculate the z-scores of X , specified as a positive integer scalar. If you do not specify a value, then the default value is the first array dimension whose size does not equal 1.

For example, for a matrix X , if `dim = 1`, then `zscore` uses the means and standard deviations along the columns of X , and if `dim = 2`, then `zscore` uses the means and standard deviations along the rows of X .

vecdim — Vector of dimensions

positive integer vector

Vector of dimensions along which to calculate the z-scores of X , specified as a positive integer vector. Each element of `vecdim` represents a dimension of the input array X . The

output Z has the same dimensions as X , but the mean μ and standard deviation σ each have length 1 in the operating dimensions. The other dimension lengths are the same for X , μ , and σ .

For example, if X is a 2-by-3-by-3 array, then `zscore(X,0,[1 2])` uses the means and standard deviations along the pages of X to standardize the values of X .

Data Types: `single` | `double`

Output Arguments

Z — z-scores

`vector` | `matrix` | `multidimensional array`

z-scores, returned as a vector, matrix, or multidimensional array. Z has the same dimensions as X .

The values of Z depend on whether you specify `'all'`, `dim`, or `vecdim`. If you do not specify any of these input arguments, then the following conditions apply:

- If X is a vector, then Z is a vector of z-scores with mean 0 and variance 1.
- If X is an array, then `zscore` standardizes along the first nonsingleton dimension of X .

For an example that demonstrates the differences in Z when you use `'all'`, `dim`, and `vecdim`, see “Z-Scores of Multidimensional Array” on page 32-7304.

mu — Mean

`scalar` | `vector` | `matrix` | `multidimensional array`

Mean of X used to compute the z-scores, returned as a scalar, vector, matrix, or multidimensional array. μ has length 1 in the specified operating dimensions. The other dimension lengths are the same for X and μ .

For example, if X is a 2-by-3-by-3 array and `vecdim` is `[1 2]`, then μ is a 1-by-1-by-3 array of means. Each value in μ corresponds to the mean of a page in X .

sigma — Standard deviation

scalar | vector | matrix | multidimensional array

Standard deviation of X used to compute the z -scores, returned as a scalar, vector, matrix, or multidimensional array. **sigma** has length 1 in the specified operating dimensions. The other dimension lengths are the same for X and **sigma**.

For example, if X is a 2-by-3-by-3 array and `vecdim` is `[1 2]`, then **sigma** is a 1-by-1-by-3 array of standard deviations. Each value in **sigma** corresponds to the standard deviation of a page in X .

Definitions

Z-Score

For a random variable X with mean μ and standard deviation σ , the z -score of a value x is

$$z = \frac{(x - \mu)}{\sigma}.$$

For sample data with mean \bar{X} and standard deviation S , the z -score of a data point x is

$$z = \frac{(x - \bar{X})}{S}.$$

z -scores measure the distance of a data point from the mean in terms of the standard deviation. This is also called *standardization* of data. The standardized data set has mean 0 and standard deviation 1, and retains the shape properties of the original data set (same skewness and kurtosis).

You can use z -scores to put data on the same scale before further analysis. This lets you to compare two or more data sets with different units.

Multidimensional Array

A *multidimensional array* is an array with more than two dimensions. For example, if X is a 1-by-3-by-4 array, then X is a three-dimensional array.

First Nonsingleton Dimension

A *first nonsingleton dimension* is the first dimension of an array whose size is not equal to 1. For example, if X is a 1-by-2-by-3-by-4 array, then the second dimension is the first nonsingleton dimension of X .

Sample Standard Deviation

The *sample standard deviation* S is given by

$$S = \sqrt{\frac{\sum_{i=1}^n (x_i - \bar{X})^2}{n - 1}}.$$

S is the square root of an unbiased estimator of the variance of the population from which X is drawn, as long as X consists of independent, identically distributed samples. \bar{X} is the sample mean.

Notice that the denominator in this variance formula is $n - 1$.

Population Standard Deviation

If the data is the entire population of values, then you can use the *population standard deviation*,

$$\sigma = \sqrt{\frac{\sum_{i=1}^n (x_i - \mu)^2}{n}}.$$

If X is a random sample from a population, then the mean μ is estimated by the sample mean, and σ is the biased maximum likelihood estimator of the population standard deviation.

Notice that the denominator in this variance formula is n .

Algorithms

`zscore` returns NaNs for any sample containing NaNs.

`zscore` returns 0s for any sample that is constant (all values are the same). For example, if X is a vector of the same numeric value, then Z is a vector of 0s.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. For more information, see “Tall Arrays” (MATLAB).

C/C++ Code Generation

Generate C and C++ code using MATLAB® Coder™.

Usage notes and limitations:

- The 'all' and `vecdim` input arguments are not supported.

- The `dim` input argument must be a compile-time constant.
- If you do not specify the `dim` input argument, the working (or operating) dimension can be different in the generated code. As a result, run-time errors can occur. For more details, see “Automatic dimension restriction” (MATLAB Coder).

For more information on code generation, see “Introduction to Code Generation” on page 31-2 and “General Code Generation Workflow” on page 31-5.

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

Usage notes and limitations:

- The `'all'` and `vecdim` input arguments are not supported.

For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

ztest

z-test

Syntax

```
h = ztest(x,m,sigma)
h= ztest(x,m,sigma,Name,Value)
[h,p] = ztest( ___ )
[h,p,ci,zval] = ztest( ___ )
```

Description

`h = ztest(x,m,sigma)` returns a test decision for the null hypothesis that the data in the vector `x` comes from a normal distribution with mean `m` and a standard deviation `sigma`, using the z-test on page 32-7318. The alternative hypothesis is that the mean is not `m`. The result `h` is 1 if the test rejects the null hypothesis at the 5% significance level, and 0 otherwise.

`h= ztest(x,m,sigma,Name,Value)` returns a test decision for the z-test with additional options specified by one or more name-value pair arguments. For example, you can change the significance level or conduct a one-sided test.

`[h,p] = ztest(___)` also returns the *p*-value of the test, using any of the input arguments from previous syntaxes.

`[h,p,ci,zval] = ztest(___)` also returns the confidence interval of the population mean, `ci`, and the value of the test statistic, `zval`.

Examples

z-Test for a Hypothesized Mean

Load the sample data. Create a vector containing the first column of the students' exam grades data.

```
load examgrades
x = grades(:,1);
```

Test the null hypothesis that the data comes from a normal distribution with mean $m = 75$ and standard deviation $\sigma = 10$.

```
[h,p,ci,zval] = ztest(x,75,10)
```

```
h = 0
```

```
p = 0.9927
```

```
ci = 2×1
```

```
    73.2191
    76.7975
```

```
zval = 0.0091
```

The returned value of $h = 0$ indicates that `ztest` does not reject the null hypothesis at the default 5% significance level.

One-Sided z-Test

Load the sample data. Create a vector containing the first column of the students' exam grades data.

```
load examgrades
x = grades(:,1);
```

Test the null hypothesis that the data comes from a normal distribution with mean $m = 65$ and standard deviation $\sigma = 10$, against the alternative that the mean is greater than 65.

```
[h,p] = ztest(x,65,10,'Tail','right')
```

```
h = 1
```

```
p = 2.8596e-28
```

The returned value of `h = 1` indicates that `ztest` rejects the null hypothesis at the default 5% significance level, in favor of the alternative hypothesis that the population mean is greater than 65.

Input Arguments

x — Sample data

vector | matrix | multidimensional array

Sample data, specified as a vector, matrix, or multidimensional array.

- If `x` is specified as a vector, `ztest` returns a single value for each output argument.
- If `x` is specified as a matrix, `ztest` performs a separate *z*-test along each column of `x` and returns a vector of results.
- If `x` is specified as a multidimensional array on page 32-7319, `ztest` works along the first nonsingleton dimension on page 32-7319 of `x`.

In all cases, `ztest` treats NaN values as missing data and ignores them.

Data Types: `single` | `double`

m — Hypothesized mean

scalar value

Hypothesized mean, specified as a scalar value.

Data Types: `single` | `double`

sigma — Population standard deviation

scalar value

Population standard deviation, specified as a scalar value.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes.

You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'Tail', 'right', 'Alpha', 0.01` specifies a right-tailed hypothesis test at the 1% significance level.

Alpha — Significance level

`0.05` (default) | scalar value in the range (0,1)

Significance level of the hypothesis test, specified as the comma-separated pair consisting of `'Alpha'` and a scalar value in the range (0,1).

Example: `'Alpha', 0.01`

Data Types: `single` | `double`

Dim — Dimension

first nonsingleton dimension (default) | positive integer value

Dimension of the input matrix along which to test the means, specified as the comma-separated pair consisting of `'Dim'` and a positive integer value. For example, specifying `'Dim', 1` tests the column means, while `'Dim', 2` tests the row means.

Example: `'Dim', 2`

Data Types: `single` | `double`

Tail — Type of alternative hypothesis

`'both'` (default) | `'right'` | `'left'`

Type of alternative hypothesis to evaluate, specified as the comma-separated pair consisting of `'Tail'` and one of the following.

<code>'both'</code>	Test the alternative hypothesis that the population mean is not equal to m .
<code>'right'</code>	Test the alternative hypothesis that the population mean is greater than m .
<code>'left'</code>	Test the alternative hypothesis that the population mean is less than m .

Example: `'Tail', 'right'`

Output Arguments

h — Hypothesis test result

1 | 0

Hypothesis test result, returned as 1 or 0.

- If $h = 1$, this indicates the rejection of the null hypothesis at the `Alpha` significance level.
- If $h = 0$, this indicates a failure to reject the null hypothesis at the `Alpha` significance level.

p — *p*-value

scalar value in the range [0,1]

p-value of the test, returned as a scalar value in the range [0,1]. *p* is the probability of observing a test statistic as extreme as, or more extreme than, the observed value under the null hypothesis. Small values of *p* cast doubt on the validity of the null hypothesis.

ci — Confidence interval

vector

Confidence interval for the true population mean, returned as a two-element vector containing the lower and upper boundaries of the $100 \times (1 - \text{Alpha})\%$ confidence interval.

zval — Test statistic

nonnegative scalar value

Test statistic, returned as a nonnegative scalar value.

Definitions

z-Test

The *z*-test is a parametric hypothesis test used to determine whether a sample data set comes from a population with a particular mean. The test assumes that the sample data comes from a population with a normal distribution and a known standard deviation.

The test statistic is

$$z = \frac{\bar{x} - \mu}{\sigma/\sqrt{n}},$$

where \bar{x} is the sample mean, μ is the population mean, σ is the population standard deviation, and n is the sample size. Under the null hypothesis, the test statistic has a standard normal distribution.

Multidimensional Array

A multidimensional array has more than two dimensions. For example, if x is a 1-by-3-by-4 array, then x is a three-dimensional array.

First Nonsingleton Dimension

The first nonsingleton dimension is the first dimension of an array whose size is not equal to 1. For example, if x is a 1-by-2-by-3-by-4 array, then the second dimension is the first nonsingleton dimension of x .

Tips

- Use `sampsizepwr` to calculate:
 - The sample size that corresponds to specified power and parameter values;
 - The power achieved for a particular sample size, given the true parameter value;
 - The parameter value detectable with the specified sample size and power.

Extended Capabilities

GPU Arrays

Accelerate code by running on a graphics processing unit (GPU) using Parallel Computing Toolbox™.

This function fully supports GPU arrays. For more information, see “Run MATLAB Functions on a GPU” (Parallel Computing Toolbox).

Introduced before R2006a

hmcSampler

Hamiltonian Monte Carlo (HMC) sampler

Syntax

```
hmc = hmcSampler(logpdf,startpoint)
hmc = hmcSampler( ____,Name,Value)
```

Description

`hmc = hmcSampler(logpdf,startpoint)` creates a Hamiltonian Monte Carlo (HMC) sampler, returned as a `HamiltonianSampler` object. `logpdf` is a function handle that evaluates the logarithm of the probability density of the equilibrium distribution and its gradient. The column vector `startpoint` is the initial point from which to start HMC sampling.

After you create the sampler, you can compute MAP (maximum-a-posteriori) point estimates, tune the sampler, draw samples, and check convergence diagnostics using the methods of the `HamiltonianSampler` class. For an example of this workflow, see [Bayesian Linear Regression Using Hamiltonian Monte Carlo](#) on page 7-33.

`hmc = hmcSampler(____,Name,Value)` specifies additional options using one or more name-value pair arguments. Specify name-value pair arguments after all other input arguments.

Examples

Create Hamiltonian Monte Carlo Sampler

Create a Hamiltonian Monte Carlo (HMC) sampler to sample from a normal distribution.

First, save a function `normalDistGrad` on the MATLAB® path that returns the multivariate normal log probability density and its gradient (`normalDistGrad` is defined

at the end of this example). Then, call the function with arguments to define the `logpdf` input argument to the `hmcSampler` function.

```
means = [1;-3];
standevs = [1;2];
logpdf = @(theta)normalDistGrad(theta,means,standevs);
```

Choose a starting point for the HMC sampler.

```
startpoint = randn(2,1);
```

Create the HMC sampler and display its properties.

```
smp = hmcSampler(logpdf,startpoint);
```

```
smp
```

```
smp =
  HamiltonianSampler with properties:
        StepSize: 0.1000
        NumSteps: 50
        MassVector: [2x1 double]
        JitterMethod: 'jitter-both'
        StepSizeTuningMethod: 'dual-averaging'
        MassVectorTuningMethod: 'iterative-sampling'
        LogPDF: @(theta)normalDistGrad(theta,means,standevs)
        VariableNames: {2x1 cell}
        StartPoint: [2x1 double]
```

The `normalDistGrad` function returns the logarithm of the multivariate normal probability density with means in `Mu` and standard deviations in `Sigma`, specified as scalars or columns vectors the same length as `startpoint`. The second output argument is the corresponding gradient.

```
function [lpdf,glpdf] = normalDistGrad(X,Mu,Sigma)
Z = (X - Mu)./Sigma;
lpdf = sum(-log(Sigma) - .5*log(2*pi) - .5*(Z.^2));
glpdf = -Z./Sigma;
end
```

Input Arguments

logpdf — Logarithm of target density and its gradient

function handle

Logarithm of target density and its gradient, specified as a function handle.

`logpdf` must return two output arguments: `[lpdf,glpdf] = logpdf(X)`. Here, `lpdf` is the base-e log probability density (up to an additive constant), `glpdf` is the gradient of the log density, and the point `X` is a column vector with the same number of elements as `startpoint`.

The input argument `X` to `logpdf` must be unconstrained, meaning that every element of `X` can be any real number. Transform any constrained sampling parameters into unconstrained variables before using the HMC sampler.

If the `'UseNumericalGradient'` value is set to `true`, then `logpdf` does not need to return the gradient as the second output. Using a numerical gradient can be easier since `logpdf` does not need to compute the gradient, but it can make sampling slower.

Data Types: `function_handle`

startpoint — Initial point to start sampling from

numeric column vector

Initial point to start sampling from, specified as a numeric column vector.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'VariableNames', {'Intercept','Beta'}, 'MassVectorTuningMethod', 'hessian'` specifies sampling variable names and the mass vector tuning method to be `'hessian'`.

StepSize — Step size of Hamiltonian dynamics

0.1 (default) | positive scalar

Step size of Hamiltonian dynamics, specified as the comma-separated pair consisting of 'StepSize' and a positive scalar.

To propose a new state for the Markov chain, the HMC sampler integrates the Hamiltonian dynamics using leapfrog integration. This argument controls the step size of that leapfrog integration.

You can automatically tune the step size using `tuneSampler`.

Example: `'StepSize', 0.2`

Data Types: `single` | `double`

NumSteps — Number of steps of Hamiltonian dynamics

50 (default) | positive integer

Number of steps of Hamiltonian dynamics, specified as the comma-separated pair consisting of 'NumSteps' and a positive integer.

To propose a new state for the Markov chain, the HMC sampler integrates the Hamiltonian dynamics using leapfrog integration. This argument controls the number of steps of that leapfrog integration.

You can automatically tune the number of steps using `tuneSampler`.

Example: `'NumSteps', 20`

Data Types: `single` | `double`

MassVector — Mass vector of momentum variables

`ones(size(startpoint,1),1)` (default) | numeric column vector

Mass vector of momentum variables, specified as the comma-separated pair consisting of 'MassVector' and a numeric column vector with positive values and the same length as `startpoint`.

The “masses” of the momentum variables associated with the variables of interest control the Hamiltonian dynamics in each Markov chain proposal.

You can automatically tune the mass vector using `tuneSampler`.

Example: `'MassVector', rand(3,1)`

Data Types: `single` | `double`

JitterMethod — Method for jittering step size and number of steps

'jitter-both' (default) | 'jitter-numsteps' | 'none'

Method for jittering the step size and the number of steps, specified as the comma-separated pair consisting of 'JitterMethod' and one of the following values.

Value	Description
'jitter-both'	Randomly jitter the step size and number of steps for each leapfrog trajectory.
'jitter-numsteps'	Jitter only the number of steps of each leapfrog trajectory.
'none'	Perform no jittering.

With jittering, the sampler randomly selects the step size or the number of steps of each leapfrog trajectory as values smaller than the 'StepSize' and 'NumSteps' values. Use jittering to improve the stability of the leapfrog integration of the Hamiltonian dynamics.

Example: 'JitterMethod', 'jitter-both'

StepSizeTuningMethod — Method for tuning sampler step size

'dual-averaging' (default) | 'none'

Method for tuning the sampler step size, specified as the comma-separated pair consisting of 'StepSizeTuningMethod' and 'dual-averaging' or 'none'.

If the 'StepSizeTuningMethod' value is set to 'dual-averaging', then `tuneSampler` tunes the leapfrog step size of the HMC sampler to achieve a certain acceptance ratio for a fixed value of the simulation length. The simulation length equals the step size multiplied by the number of steps. To set the target acceptance ratio, use the 'TargetAcceptanceRatio' name-value pair argument of the `tuneSampler` method.

Example: 'StepSizeTuningMethod', 'none'

MassVectorTuningMethod — Method for tuning sampler mass vector

'iterative-sampling' (default) | 'hessian' | 'none'

Method for tuning the sampler mass vector, specified as the comma-separated pair consisting of 'MassVectorTuningMethod' and one of the following values.

Value	Description
'iterative-sampling'	Tune the <code>MassVector</code> via successive approximations by drawing samples using a sequence of mass vector estimates.
'hessian'	Set the <code>MassVector</code> equal to the negative diagonal Hessian of the <code>logpdf</code> at the <code>startpoint</code> .
'none'	Perform no tuning of the <code>MassVector</code> .

To perform the tuning, use the `tuneSampler` method.

Example: `'MassVectorTuningMethod', 'hessian'`

CheckGradient — Flag for checking analytical gradient

`true` (or 1) (default) | `false` (or 0)

Flag for checking the analytical gradient, specified as the comma-separated pair consisting of `'CheckGradient'` and either `true` (or 1) or `false` (or 0).

If `'CheckGradient'` is `true`, then the sampler calculates the numerical gradient at the `startpoint` and compares it to the analytical gradient returned by `logpdf`.

Example: `'CheckGradient', true`

VariableNames — Sampling variable names

`{'x1', 'x2', ...}` (default) | string array | cell array of character vectors

Sampling variable names, specified as the comma-separated pair consisting of `'VariableNames'` and a string array or a cell array of character vectors. Elements of the array must be unique. The length of the array must be the same as the length of `startpoint`.

Supply a `'VariableNames'` value to label the components of the vector you want to sample using the HMC sampler.

Example: `'VariableNames', {'Intercept', 'Beta'}`

Data Types: `string` | `cell`

UseNumericalGradient — Flag for using numerical gradient

`false` (or 0) (default) | `true` (or 1)

Flag for using numerical gradient, specified as the comma-separated pair consisting of 'UseNumericalGradient' and either `true` (or 1) or `false` (or 0).

If you set the 'UseNumericalGradient' value to `true`, then the HMC sampler numerically estimates the gradient from the log density returned by `logpdf`. In this case, the `logpdf` function does not need to return the gradient of the log density as the second output. Using a numerical gradient makes HMC sampling slower.

Example: 'UseNumericalGradient',true

Output Arguments

hmc — Hamiltonian Monte Carlo sampler

HamiltonianSampler object

Hamiltonian Monte Carlo sampler, returned as a HamiltonianSampler object.

Introduced in R2017a

HamiltonianSampler class

Hamiltonian Monte Carlo (HMC) sampler

Description

A Hamiltonian Monte Carlo (HMC) sampler is a gradient-based Markov Chain Monte Carlo sampler that you can use to generate samples from a probability density $P(x)$. HMC sampling requires specification of $\log P(x)$ and its gradient.

The parameter vector x must be unconstrained, meaning that every element of x can be any real number. To sample constrained parameters, transform these parameters into unconstrained variables before using the HMC sampler.

After creating a sampler, you can compute MAP (maximum-a-posteriori) point estimates, tune the sampler, draw samples, and check convergence diagnostics using the methods of this class. For an example of this workflow, see Bayesian Linear Regression Using Hamiltonian Monte Carlo on page 7-33.

Construction

`hmc = hmcSampler(logpdf, startpoint)` creates a Hamiltonian Monte Carlo (HMC) sampler, returned as a `HamiltonianSampler` object. `logpdf` is a function handle that evaluates the logarithm of the probability density of the equilibrium distribution and its gradient. The column vector `startpoint` is the initial point from which to start HMC sampling.

`hmc = hmcSampler(____, Name, Value)` specifies additional options using one or more name-value pair arguments. Specify name-value pair arguments after all other input arguments.

Input Arguments

logpdf — Logarithm of target density and its gradient
function handle

Logarithm of target density and its gradient, specified as a function handle.

`logpdf` must return two output arguments: `[lpdf,glpdf] = logpdf(X)`. Here, `lpdf` is the base-e log probability density (up to an additive constant), `glpdf` is the gradient of the log density, and the point `X` is a column vector with the same number of elements as `startpoint`.

The input argument `X` to `logpdf` must be unconstrained, meaning that every element of `X` can be any real number. Transform any constrained sampling parameters into unconstrained variables before using the HMC sampler.

If the `'UseNumericalGradient'` value is set to `true`, then `logpdf` does not need to return the gradient as the second output. Using a numerical gradient can be easier since `logpdf` does not need to compute the gradient, but it can make sampling slower.

Data Types: `function_handle`

startpoint — Initial point to start sampling from

numeric column vector

Initial point to start sampling from, specified as a numeric column vector.

Data Types: `single` | `double`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1,Value1,...,NameN,ValueN`.

Example: `'VariableNames', {'Intercept','Beta'}, 'MassVectorTuningMethod', 'hessian'` specifies sampling variable names and the mass vector tuning method to be `'hessian'`.

StepSize — Step size of Hamiltonian dynamics

0.1 (default) | positive scalar

Step size of Hamiltonian dynamics, specified as the comma-separated pair consisting of `'StepSize'` and a positive scalar.

To propose a new state for the Markov chain, the HMC sampler integrates the Hamiltonian dynamics using leapfrog integration. This argument controls the step size of that leapfrog integration.

You can automatically tune the step size using `tuneSampler`.

Example: `'StepSize', 0.2`

NumSteps — Number of steps of Hamiltonian dynamics

50 (default) | positive integer

Number of steps of Hamiltonian dynamics, specified as the comma-separated pair consisting of `'NumSteps'` and a positive integer.

To propose a new state for the Markov chain, the HMC sampler integrates the Hamiltonian dynamics using leapfrog integration. This argument controls the number of steps of that leapfrog integration.

You can automatically tune the number of steps using `tuneSampler`.

Example: `'NumSteps', 20`

MassVector — Mass vector of momentum variables

`ones(size(startpoint,1),1)` (default) | numeric column vector

Mass vector of momentum variables, specified as the comma-separated pair consisting of `'MassVector'` and a numeric column vector with positive values and the same length as `startpoint`.

The “masses” of the momentum variables associated with the variables of interest control the Hamiltonian dynamics in each Markov chain proposal.

You can automatically tune the mass vector using `tuneSampler`.

Example: `'MassVector', rand(3,1)`

JitterMethod — Method for jittering step size and number of steps

`'jitter-both'` (default) | `'jitter-numsteps'` | `'none'`

Method for jittering the step size and number of steps, specified as the comma-separated pair consisting of `'JitterMethod'` and one of the following:

Value	Description
<code>'jitter-both'</code>	Randomly jitter the step size and number of steps for each leapfrog trajectory.

Value	Description
'jitter-numsteps'	Jitter only the number of steps of each leapfrog trajectory.
'none'	Perform no jittering.

With jittering, the sampler randomly selects the step size or the number of steps of each leapfrog trajectory as values smaller than the 'StepSize' and 'NumSteps' values. Use jittering to improve the stability of the leapfrog integration of the Hamiltonian dynamics.

Example: 'JitterMethod', 'jitter-both'

StepSizeTuningMethod – Method for tuning sampler step size

'dual-averaging' (default) | 'none'

Method for tuning the sampler step size, specified as the comma-separated pair consisting of 'StepSizeTuningMethod' and 'dual-averaging' or 'none'.

If the 'StepSizeTuningMethod' value is set to 'dual-averaging', then tuneSampler tunes the leapfrog step size of the HMC sampler to achieve a certain acceptance ratio for a fixed value of the simulation length. The simulation length equals the step size multiplied by the number of steps. To set the target acceptance ratio, use the 'TargetAcceptanceRatio' name-value pair argument of the tuneSampler method.

Example: 'StepSizeTuningMethod', 'none'

MassVectorTuningMethod – Method for tuning sampler mass vector

'iterative-sampling' (default) | 'hessian' | 'none'

Method for tuning the sampler mass vector, specified as the comma-separated pair consisting of 'MassVectorTuningMethod' and one of the following values

Value	Description
'iterative-sampling'	Tune the MassVector via successive approximations by drawing samples using a sequence of mass vector estimates.
'hessian'	Set the MassVector equal to the negative diagonal Hessian of the logpdf at the startpoint.
'none'	Perform no tuning of the MassVector.

To perform the tuning, use the `tuneSampler` method.

Example: `'MassVectorTuningMethod', 'hessian'`

CheckGradient — Flag for checking analytical gradient

`true` (or 1) (default) | `false` (or 0)

Flag for checking the analytical gradient, specified as the comma-separated pair consisting of `'CheckGradient'` and either `true` (or 1) or `false` (or 0).

If `'CheckGradient'` is `true`, then the sampler calculates the numerical gradient at the `startpoint` and compares it to the analytical gradient returned by `logpdf`.

Example: `'CheckGradient', true`

VariableNames — Sampling variable names

`{'x1', 'x2', ...}` (default) | string array | cell array of character vectors

Sampling variable names, specified as the comma-separated pair consisting of `'VariableNames'` and a string array or cell array of character vectors. Elements of the array must be unique. The length of the array must be the same as the length of `startpoint`.

Supply a `'VariableNames'` value to label the components of the vector you want to sample using the HMC sampler.

Example: `'VariableNames', {'Intercept', 'Beta'}`

UseNumericalGradient — Flag for using numerical gradient

`false` (or 0) (default) | `true` (or 1)

Flag for using numerical gradient, specified as the comma-separated pair consisting of `'UseNumericalGradient'` and either `true` (or 1) or `false` (or 0).

If you set the `'UseNumericalGradient'` value to `true`, then the HMC sampler numerically estimates the gradient from the log density returned by `logpdf`. In this case, the `logpdf` function does not need to return the gradient of the log density as the second output. Using a numerical gradient makes HMC sampling slower.

Example: `'UseNumericalGradient', true`

Properties

StepSize — Step size of Hamiltonian dynamics

0.1 (default) | positive scalar

Step size of Hamiltonian dynamics, specified as a positive scalar.

To propose a new state for the Markov chain, the HMC sampler integrates the Hamiltonian dynamics using leapfrog integration. The value of this property controls the step size of that leapfrog integration.

NumSteps — Number of steps of Hamiltonian dynamics

50 (default) | positive integer

Number of steps of Hamiltonian dynamics, specified as a positive integer.

To propose a new state for the Markov chain, the HMC sampler integrates the Hamiltonian dynamics using leapfrog integration. The value of this property controls the number of steps of that leapfrog integration.

MassVector — Mass vector of momentum variables

ones(size(startpoint,1),1) (default) | numeric column vector

Mass vector of momentum variables, specified as a numeric column vector with positive values and the same length as `startpoint`.

The “masses” of the momentum variables associated with the variables of interest control the Hamiltonian dynamics in each Markov chain proposal.

JitterMethod — Method for jittering step size and number of steps

'jitter-both' (default) | 'jitter-numsteps' | 'none'

Method for jittering the step size and the number of steps, specified as one of the following values.

Value	Description
'jitter-both'	Randomly jitter the step size and number of steps of each leapfrog trajectory.
'jitter-numsteps'	Jitter only the number of steps of each leapfrog trajectory.

Value	Description
'none'	Perform no jittering.

With jittering, the sampler randomly selects the step size or the number of steps of each leapfrog trajectory as values smaller than the 'StepSize' and 'NumSteps' values. Use jittering to improve the stability of the leapfrog integration of the Hamiltonian dynamics.

StepSizeTuningMethod — Method for tuning sampler step size

'dual-averaging' (default) | 'none'

Method for tuning the sampler step size, specified as 'dual-averaging' or 'none'.

If StepSizeTuningMethod equals 'dual-averaging', then tuneSampler tunes the leapfrog step size of the HMC sampler to achieve a certain acceptance ratio for a fixed value of the simulation length. The simulation length equals the step size multiplied by the number of steps. To set the target acceptance ratio, use the 'TargetAcceptanceRatio' name-value pair argument of the tuneSampler method.

MassVectorTuningMethod — Method for tuning sampler mass vector

'iterative-sampling' (default) | 'hessian' | 'none'

Method for tuning the sampler mass vector, specified as one of the following values.

Value	Description
'iterative-sampling'	Tune the MassVector via successive approximations by drawing samples using a sequence of mass vector estimates.
'hessian'	Set the MassVector equal to the negative diagonal Hessian of the logpdf at the startpoint.
'none'	Perform no tuning of the MassVector.

To perform the tuning, use the tuneSampler method.

LogPDF — Logarithm of target density and its gradient

function handle

Logarithm of target density and its gradient, specified as a function handle.

LogPDF returns two output arguments: [lpdf, glpdf] = LogPDF(X). Here, lpdf is the base-e log probability density (up to an additive constant) and glpdf is the gradient of

the log density at the point X . The input argument X must be a column vector with the same number of elements as the `StartPoint` property.

If you set the `'UseNumericalGradient'` value to `true` when creating the sampler, then `LogPDF` returns the numerical gradient in `glpdf`.

StartPoint — Initial point to start sampling from

numeric column vector

Initial point to start sampling from, specified as a numeric column vector.

VariableNames — Sampling variable names

{'x1', 'x2', ...} (default) | cell array of unique character vectors

Sampling variable names, specified as a cell array of unique character vectors.

Methods

<code>estimateMAP</code>	Estimate maximum of log probability density
<code>tuneSampler</code>	Tune Hamiltonian Monte Carlo (HMC) sampler
<code>drawSamples</code>	Generate Markov chain using Hamiltonian Monte Carlo (HMC)
<code>diagnostics</code>	Markov Chain Monte Carlo diagnostics

Examples

Create Hamiltonian Monte Carlo Sampler

Create a Hamiltonian Monte Carlo (HMC) sampler to sample from a normal distribution.

First, save a function `normalDistGrad` on the MATLAB® path that returns the multivariate normal log probability density and its gradient (`normalDistGrad` is defined at the end of this example). Then, call the function with arguments to define the `logpdf` input argument to the `hmcSampler` function.

```
means = [1;-3];
standevs = [1;2];
logpdf = @(theta)normalDistGrad(theta,means,standevs);
```

Choose a starting point for the HMC sampler.

```
startpoint = randn(2,1);
```

Create the HMC sampler and display its properties.

```
smp = hmcSampler(logpdf,startpoint);
```

```
smp
```

```
smp =
```

```
HamiltonianSampler with properties:
```

```
    StepSize: 0.1000
    NumSteps: 50
    MassVector: [2x1 double]
    JitterMethod: 'jitter-both'
    StepSizeTuningMethod: 'dual-averaging'
    MassVectorTuningMethod: 'iterative-sampling'
    LogPDF: @(theta)normalDistGrad(theta,means,standevs)
    VariableNames: {2x1 cell}
    StartPoint: [2x1 double]
```

The `normalDistGrad` function returns the logarithm of the multivariate normal probability density with means in `Mu` and standard deviations in `Sigma`, specified as scalars or columns vectors the same length as `startpoint`. The second output argument is the corresponding gradient.

```
function [lpdf,glpdf] = normalDistGrad(X,Mu,Sigma)
Z = (X - Mu)./Sigma;
lpdf = sum(-log(Sigma) - .5*log(2*pi) - .5*(Z.^2));
glpdf = -Z./Sigma;
end
```

“Bayesian Linear Regression Using Hamiltonian Monte Carlo” on page 7-33

Introduced in R2017a

estimateMAP

Class: HamiltonianSampler

Estimate maximum of log probability density

Syntax

```
xhat = estimateMAP(smp)
[xhat,fitinfo] = estimateMAP(smp)
[xhat,fitinfo] = estimateMAP( ____,Name,Value)
```

Description

`xhat = estimateMAP(smp)` returns the maximum-a-posteriori (MAP) estimate of the log probability density of the Monte Carlo sampler `smp`.

`[xhat,fitinfo] = estimateMAP(smp)` returns additional fitting information in `fitinfo`.

`[xhat,fitinfo] = estimateMAP(____,Name,Value)` specifies additional options using one or more name-value pair arguments. Specify name-value pair arguments after all other input arguments.

Input Arguments

smp — Hamiltonian Monte Carlo sampler

HamiltonianSampler object

Hamiltonian Monte Carlo sampler, specified as a HamiltonianSampler object.

`estimateMAP` estimates the maximum of the log probability density specified in `smp.LogPDF`.

Use the `hmcSampler` function to create a sampler.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'IterationLimit', 100, 'StepTolerance', 1e-5` estimates the MAP point using an iteration limit of 100 and a step size convergence tolerance of $1e-5$.

StartPoint — Initial point to start optimization from

`smp.StartPoint` (default) | numeric column vector

Initial point to start optimization from, specified as a numeric column vector with the same number of elements as the `StartPoint` property of the sampler `smp`.

Example: `'StartPoint', randn(size(smp.StartPoint))`

IterationLimit — Maximum number of optimization iterations

1000 (default) | positive integer

Maximum number of optimization iterations, specified as a positive integer.

Example: `'IterationLimit', 100`

VerbosityLevel — Verbosity level of Command Window output

0 (default) | positive integer

Verbosity level of Command Window output during function maximization, specified as 0 or a positive integer.

- With the value set to 0, `estimateMAP` displays no details on the optimization.
- With the value set to a positive integer, `estimateMAP` displays convergence information at each iteration.

Convergence Information

Heading	Meaning
FUN VALUE	Objective function value.
NORM GRAD	Norm of the gradient of the objective function.
NORM STEP	Norm of the iterative step, meaning the distance between the previous point and the current point.
CURV	OK means the weak Wolfe condition is satisfied. This condition is a combination of sufficient decrease of the objective function and a curvature condition.
GAMMA	Inner product of the step times the gradient difference, divided by the inner product of the gradient difference with itself. The gradient difference is the gradient at the current point minus the gradient at the previous point. Gives diagnostic information on the objective function curvature.
ALPHA	Step direction multiplier, which differs from 1 when the algorithm performed a line search.
ACCEPT	YES means the algorithm found an acceptable step to take.

Example: 'VerbosityLevel',1

GradientTolerance — Relative gradient convergence tolerance

1e-6 (default) | positive scalar

Relative gradient convergence tolerance, specified as a positive scalar.

Let $\tau = \max(1, \min(\text{abs}(f), \text{infnormg0}))$, where f is the current objective function value and infnormg0 is the initial gradient norm. If the norm of the objective function gradient is smaller than τ times the 'GradientTolerance' value, then the maximization is considered to have converged to a local optimum.

Example: 'GradientTolerance',1e-4

StepTolerance — Step size convergence tolerance

1e-6 (default) | positive scalar

Step size convergence tolerance, specified as a positive scalar.

If the proposed step size is smaller than the 'StepTolerance' value, then the maximization is considered to have converged to a local optimum.

Example: 'StepTolerance', 1e-5

Output Arguments

xhat — MAP point estimate

numeric vector

MAP point estimate, returned as a numeric vector of the same size as `smp.StartPoint`.

fitinfo — Fitting information

structure

Fitting information for the MAP computation, returned as a structure with these fields:

Field	Description
Iteration	Iteration indices from 0 through the final iteration.
Objective	Negative log probability density at each iteration. The MAP point is computed by minimizing the negative log probability density. You can check that the final values are all similar, indicating that the function optimization has converged to a local optimum.
Gradient	Gradient of the negative log probability density at the final iteration.

Data Types: struct

Examples

Estimate MAP Point of HMC Sampler

Create a Hamiltonian Monte Carlo sampler for a normal distribution and estimate the maximum-a-posteriori (MAP) point of the log probability density.

First, save a function `normalDistGrad` on the MATLAB® path that returns the multivariate normal log probability density and its gradient (`normalDistGrad` is defined at the end of this example). Then, call the function with arguments to define the `logpdf` input argument to the `hmcSampler` function.

```
means = [1;-1];
standevs = [1;0.3];
logpdf = @(theta)normalDistGrad(theta,means,standevs);
```

Choose a starting point and create the HMC sampler.

```
startpoint = zeros(2,1);
smp = hmcSampler(logpdf,startpoint);
```

Estimate the MAP point (the point where the probability density has its maximum). Show more information during optimization by setting the `'VerbosityLevel'` value to 1.

```
[xhat,fitinfo] = estimateMAP(smp,'VerbosityLevel',1);
```

```
o Solver = LBFGS, HessianHistorySize = 15, LineSearchMethod = weakwolfe
```

ITER	FUN VALUE	NORM GRAD	NORM STEP	CURV	GAMMA	ALPH
0	6.689460e+00	1.111e+01	0.000e+00		9.000e-03	0.000
1	4.671622e+00	8.889e+00	2.008e-01	OK	9.006e-02	2.000
2	9.759850e-01	8.268e-01	8.215e-01	OK	9.027e-02	1.000
3	9.158025e-01	7.496e-01	7.748e-02	OK	5.910e-01	1.000
4	6.339508e-01	3.104e-02	7.472e-01	OK	9.796e-01	1.000
5	6.339043e-01	3.668e-05	3.762e-03	OK	9.599e-02	1.000
6	6.339043e-01	2.488e-08	3.333e-06	OK	9.015e-02	1.000

```
Infinity norm of the final gradient = 2.488e-08
```

```
Two norm of the final step = 3.333e-06, TolX = 1.000e-06
```

```
Relative infinity norm of the final gradient = 2.488e-08, TolFun = 1.000e-06
```

```
EXIT: Local minimum found.
```

To further check that the optimization has converged to a local minimum, plot the `fitinfo.Objective` field. This field contains the values of the negative log density at each iteration of the function optimization. The final values are all very similar, so the optimization has converged.

```
fitinfo
```

```
fitinfo = struct with fields:
  Iteration: [7x1 double]
```

```
Objective: [7x1 double]  
Gradient: [2x1 double]
```

```
plot(fitinfo.Iteration,fitinfo.Objective,'ro-');  
xlabel('Iteration');  
ylabel('Negative log density');
```

Display the MAP estimate. It is indeed equal to the means variable, which is the exact maximum.

xhat

```
xhat = 2×1  
  
    1.0000  
   -1.0000
```

```
means
```

```
means = 2×1  
  
    1  
   -1
```

The `normalDistGrad` function returns the logarithm of the multivariate normal probability density with means in `Mu` and standard deviations in `Sigma`, specified as scalars or column vectors the same length as `startpoint`. The second output argument is the corresponding gradient.

```
function [lpdf,glpdf] = normalDistGrad(X,Mu,Sigma)  
Z = (X - Mu)./Sigma;  
lpdf = sum(-log(Sigma) - .5*log(2*pi) - .5*(Z.^2));  
glpdf = -Z./Sigma;  
end
```

Tips

- First create a Hamiltonian Monte Carlo sampler using the `hmcSampler` function, and then use `estimateMAP` to estimate the MAP point.
- After creating an HMC sampler, you can tune the sampler, draw samples, and check convergence diagnostics using the other methods of the `HamiltonianSampler` class. Using the MAP estimate as a starting point in the `tuneSampler` and `drawSamples` methods can lead to more efficient tuning and sampling. For an example of this workflow, see [Bayesian Linear Regression Using Hamiltonian Monte Carlo](#) on page 7-33.

Algorithms

- estimateMAP uses a limited memory Broyden-Fletcher-Goldfarb-Shanno (LBFGS) quasi-Newton optimizer to search for the maximum of the log probability density. See Nocedal and Wright [1].

tuneSampler

Class: HamiltonianSampler

Tune Hamiltonian Monte Carlo (HMC) sampler

Syntax

```
tunedSmp = tuneSampler(smp)
[tunedSmp,tuningInfo] = tuneSampler(smp)
[tunedSmp,tuningInfo] = tuneSampler( ____,Name,Value)
```

Description

`tunedSmp = tuneSampler(smp)` returns a tuned Hamiltonian Monte Carlo (HMC) sampler.

First, `tuneSampler` tunes the mass vector of the HMC sampler `smp`. Then, it tunes the step size and number of steps of the leapfrog integrations to achieve a certain target acceptance ratio.

You can use the tuned sampler to create Markov chains using the `drawSamples` method.

`[tunedSmp,tuningInfo] = tuneSampler(smp)` returns additional tuning information in `tuningInfo`.

`[tunedSmp,tuningInfo] = tuneSampler(____,Name,Value)` specifies additional options using one or more name-value pair arguments. Specify name-value pair arguments after all other input arguments.

Input Arguments

smp — Hamiltonian Monte Carlo sampler

HamiltonianSampler object

Hamiltonian Monte Carlo sampler to tune, specified as a HamiltonianSampler object.

Use the `hmcSampler` function to create a sampler.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'StepSizeTuningMethod', 'dual-averaging', 'MassVectorTuningMethod', 'hessian'` tunes an HMC sampler using the specified methods for tuning the step size and mass vector of the sampler.

StartPoint — Initial point to start tuning from

`smp.StartPoint` (default) | numeric column vector

Initial point to start tuning from, specified as a numeric column vector with the same number of elements as the `StartPoint` property of the sampler `smp`.

Example: `'StartPoint', randn(size(smp.StartPoint))`

StepSizeTuningMethod — Method for tuning sampler step size

`smp.StepSizeTuningMethod` (default) | `'dual-averaging'` | `'none'`

Method for tuning sampler step size, specified as the comma-separated pair consisting of `'StepSizeTuningMethod'` and `'dual-averaging'` or `'none'`.

If `'StepSizeTuningMethod'` is set to `'dual-averaging'`, then `tuneSampler` tunes the leapfrog step size of the HMC sampler to achieve a target acceptance ratio for a fixed value of the simulation length. The simulation length equals the step size multiplied by the number of steps. To specify the target acceptance ratio, set the `'TargetAcceptanceRatio'` value.

To change the simulation length, set `smp.StepSize = a` and `smp.NumSteps = b`, for some values of `a` and `b`. This gives a simulation length of `a*b`.

Example: `'StepSizeTuningMethod', 'none'`

MassVectorTuningMethod — Method for tuning sampler mass vector

`smp.MassVectorTuningMethod` (default) | `'iterative-sampling'` | `'hessian'` | `'none'`

Method for tuning the sampler mass vector, specified as the comma-separated pair consisting of `'MassVectorTuningMethod'` and one of the following values.

Value	Description
<code>'iterative-sampling'</code>	Tune the <code>MassVector</code> via successive approximations by drawing samples using a sequence of mass vector estimates.
<code>'hessian'</code>	Set the <code>MassVector</code> equal to the negative diagonal Hessian of the <code>logpdf</code> at the <code>startpoint</code> .
<code>'none'</code>	Perform no tuning of the <code>MassVector</code> .

Example: `'MassVectorTuningMethod','hessian'`

NumStepSizeTuningIterations — Number of step size tuning iterations

100 (default) | positive integer

Number of step size tuning iterations, specified as a positive integer.

If the `'StepSizeTuningMethod'` value is `'none'`, then `tuneSampler` does not tune the step size.

Example: `'NumStepSizeTuningIterations',50`

TargetAcceptanceRatio — Target acceptance ratio

0.65 (default) | scalar from 0 through 1

Target acceptance ratio of the Markov chain, specified as a scalar from 0 through 1.

`tuneSampler` tunes the step size and number of steps of the leapfrog integration to achieve the specified target acceptance ratio for a fixed value of the simulation length. The simulation length is the leapfrog integration step size multiplied by the number of integration steps.

If the `'StepSizeTuningMethod'` value is `'none'`, then `tuneSampler` does not tune the step size.

To change the simulation length, set `smp.StepSize = a` and `smp.NumSteps = b`, for some values of `a` and `b`. This gives a simulation length of `a*b`.

Example: `'TargetAcceptanceRatio',0.55`

NumStepsLimit — Maximum number of leapfrog steps

2000 (default) | positive integer

Maximum number of leapfrog steps allowed during step size tuning, specified as a positive integer.

If the 'StepSizeTuningMethod' value is 'none', then tuneSampler does not tune the step size.

Example: 'NumStepsLimit', 1000

VerbosityLevel — Verbosity level of Command Window output

0 (default) | nonnegative integer

Verbosity level of Command Window output during sampler tuning, specified as a nonnegative integer.

- With the value set to 0, tuneSampler displays no details of the tuning.
- With the value set to 1, tuneSampler displays details of the step size tuning.
- With the value set to 2 or larger, tuneSampler displays details of the step size and mass vector tuning.

Heading	Description
ITER	Iteration number.
LOG PDF	Log probability density at the current iteration.
STEP SIZE	Leapfrog integration step size at the current iteration.
NUM STEPS	Number of leapfrog integration steps at the current iteration.
ACC RATIO	Acceptance ratio, that is, the fraction of proposals which are accepted.

Heading	Description
DIVERGENT	Number of times the sampler failed to generate a valid proposal due to the leapfrog iterations generating NaNs or Infs. <code>tuneSampler</code> searches for a good value of the integration step size. While doing so, the algorithm can encounter regions of instability and report nonzero values in the DIVERGENT column. This behavior is normal and is not a problem in itself.

Example: `'VerbosityLevel',1`

NumPrint — Verbose output frequency

100 (default) | positive integer

Verbose output frequency, specified as a positive integer.

If the `'VerbosityLevel'` value is a positive integer, `tuneSampler` outputs tuning details every `'NumPrint'` iterations.

Example: `'NumPrint',50`

Output Arguments

tunedSmp — Tuned Hamiltonian Monte Carlo sampler

`HamiltonianSampler` object

Tuned Hamiltonian Monte Carlo sampler, returned as a `HamiltonianSampler` object.

tuningInfo — Tuning information

structure

Tuning information, returned as a structure with these fields.

Field	Description
<code>MassVector</code>	Tuned mass vector
<code>StepSize</code>	Tuned leapfrog step size

Field	Description
NumSteps	Tuned value of the number of leapfrog integration steps
MassVectorTuningInfo	Structure with additional information on the mass vector tuning
StepSizeTuningInfo	Structure with additional information on the step size tuning

If you tune the mass vector using the 'iterative-sampling' method, then `MassVectorTuningInfo` has the following fields.

Field	Description
MassVector	Tuned mass vector
IterativeSamplingMassVectorProfile	P -by- K matrix of mass vectors used during the K iterations, where P is the number of sampling variables
IterativeSamplingNumSamples	K -by-1 vector of the number of samples drawn for each of the K iterations

If you tune the mass vector using the 'hessian' method, then `MassVectorTuningInfo` has the following fields.

Field	Description
MassVector	Tuned mass vector
NegativeDiagonalHessian	Negative diagonal Hessian of $\log\text{pdf}$ at the tuning start point. If some elements are negative, this field can be different from the <code>MassVector</code> field.
HessianPoint	Point at which the Hessian is evaluated

If the `MassVectorTuningMethod` value is 'none', then `MassVectorTuningInfo` is empty.

If you tune the step size using the 'dual-averaging' method, then `StepSizeTuningInfo` has the following fields.

Field	Description
StepSize	Tuned step size
NumSteps	Tuned value of the number of steps
StepSizeProfile	Column vector containing the step sizes at each tuning iteration
AcceptanceRatio	Final acceptance ratio achieved during tuning

If the step size is not tuned, then `StepSizeTuningInfo` is empty.

Data Types: `struct`

Examples

Tune Hamiltonian Monte Carlo Sampler

Tune the parameters of a Hamiltonian Monte Carlo (HMC) sampler.

Define the number of parameters to sample and their means.

```
NumParams = 9;
means = [1:NumParams]';
standevs = 1;
```

First, save a function `normalDistGrad` on the MATLAB® path that returns the multivariate normal log probability density and its gradient (`normalDistGrad` is defined at the end of this example). Then, call the function with arguments to define the `logpdf` input argument to the `hmcSampler` function.

```
logpdf = @(theta)normalDistGrad(theta,means,standevs);
```

Choose a starting point and create the HMC sampler.

```
startpoint = randn(NumParams,1);
smp = hmcSampler(logpdf,startpoint);
```

It is important to select good values for the sampler parameters to get efficient sampling. The best way to find good values is to automatically tune the `MassVector`, `StepSize`, and `NumSteps` parameters using `tuneSampler`. The method:

1. Tunes the `MassVector` of the sampler.

2. Tunes `StepSize` and `NumSteps` for a fixed simulation length to achieve a certain acceptance ratio. The default target acceptance ratio of 0.65 is good in most cases.

```
[smp,info] = tuneSampler(smp, 'NumStepSizeTuningIterations',50, 'VerbosityLevel',1, 'NumP
```

```
o Tuning mass vector using method: iterative-sampling
Finished mass vector tuning iteration 1 of 5.
Finished mass vector tuning iteration 2 of 5.
Finished mass vector tuning iteration 3 of 5.
Finished mass vector tuning iteration 4 of 5.
Finished mass vector tuning iteration 5 of 5.
```

```
o Tuning step size using method: dual-averaging. Target acceptance ratio = 0.65
```

```
o Initial step size for dual-averaging = 2
```

ITER	LOG PDF	STEP SIZE	NUM STEPS	ACC RATIO	DIVERGENT
10	-1.710457e+01	1.193e+00	4	5.000e-01	0
20	-9.152514e+00	9.527e-01	5	5.500e-01	0
30	-1.068923e+01	8.856e-01	6	5.333e-01	0
40	-1.290816e+01	8.506e-01	6	5.750e-01	0
50	-1.770386e+01	8.581e-01	6	6.000e-01	0

Plot the evolution of the step size during tuning to ensure that the step size tuning has converged. Display the achieved acceptance ratio.

```
figure;
plot(info.StepSizeTuningInfo.StepSizeProfile);
xlabel('Iteration');
ylabel('Step Size');
```

```
accratio = info.StepSizeTuningInfo.AcceptanceRatio
```

```
accratio = 0.6000
```

The `normalDistGrad` function returns the logarithm of the multivariate normal probability density with means in `Mu` and standard deviations in `Sigma`, specified as scalars or columns vectors the same length as `startpoint`. The second output argument is the corresponding gradient.

```
function [lpdf,glpdf] = normalDistGrad(X,Mu,Sigma)
Z = (X - Mu)./Sigma;
lpdf = sum(-log(Sigma) - .5*log(2*pi) - .5*(Z.^2));
```

```
glpdf = -Z./Sigma;  
end
```

Tips

- After creating an HMC sampler using the `hmcSampler` function, you can compute MAP (maximum-a-posteriori) point estimates, tune the sampler, draw samples, and check convergence diagnostics using the methods of the `HamiltonianSampler` class. For an example of this workflow, see [Bayesian Linear Regression Using Hamiltonian Monte Carlo](#) on page 7-33.

Topics

[“Bayesian Linear Regression Using Hamiltonian Monte Carlo”](#) on page 7-33

Introduced in R2017a

drawSamples

Class: HamiltonianSampler

Generate Markov chain using Hamiltonian Monte Carlo (HMC)

Syntax

```
chain = drawSamples(smp)
[chain,endpoint,accratio] = drawSamples(smp)
[chain,endpoint,accratio] = drawSamples( ____,Name,Value)
```

Description

`chain = drawSamples(smp)` generates a Markov chain by drawing samples using the Hamiltonian Monte Carlo sampler `smp`.

`[chain,endpoint,accratio] = drawSamples(smp)` also returns the final state of the Markov chain in `endpoint` and the fraction of accepted proposals in `accratio`.

`[chain,endpoint,accratio] = drawSamples(____,Name,Value)` specifies additional options using one or more name-value pair arguments. Specify name-value pair arguments after all other input arguments.

Input Arguments

smp — Hamiltonian Monte Carlo sampler

HamiltonianSampler object

Hamiltonian Monte Carlo sampler, specified as a HamiltonianSampler object.

`drawSamples` draws samples from the target log probability density in `smp.LogPDF`. Use the `hmcSampler` function to create a sampler.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Example: `'Burnin', 500, 'NumSamples', 2000` generates a Markov chain by discarding 500 burn-in samples and then drawing 2000 samples.

Burnin — Number of burn-in samples to discard

1000 (default) | positive integer

Number of burn-in samples to discard from the beginning of the Markov chain, specified as a positive integer.

Example: `'Burnin', 500`

NumSamples — Number of samples to draw

1000 (default) | positive integer

Number of samples to draw from the Markov chain using the HMC sampler, specified as a positive integer.

The `drawSamples` method generates this number of samples after the burn-in period.

Example: `'NumSamples', 2000`

ThinSize — Markov chain thinning size

1 (default) | positive integer

Markov chain thinning size, specified as a positive integer.

Only one out of the `'ThinSize'` number of samples are kept. The rest of the samples are discarded.

Example: `'ThinSize', 5`

StartPoint — Initial point to start sampling from

`smpl.StartPoint` (default) | numeric column vector

Initial point to start sampling from, specified as a numeric column vector with the same number of elements as the `StartPoint` property of the sampler `smpl`.

Example: 'StartPoint', randn(5,1)

VerbosityLevel — Verbosity level of Command Window output

0 (default) | positive integer

Verbosity level of Command Window output during sampling, specified as 0 or a positive integer.

With the value set to 0, drawSamples displays no details during sampling.

With the value set to a positive integer, drawSamples displays details of the sampling. To set the output frequency, use the 'NumPrint' name-value pair argument.

drawSamples displays the output as a table with these columns.

Heading	Description
ITER	Iteration number
LOG PDF	Log probability density at the current iteration
STEP SIZE	Leapfrog integration step size at the current iteration. If the step size is jittered, it can vary between iterations.
NUM STEPS	Number of leapfrog integration steps at the current iteration. If the number of steps is jittered, it can vary between iterations
ACC RATIO	Acceptance ratio, that is, the fraction of proposals that are accepted. The acceptance ratio is calculated from the beginning of sampling, including the burn-in period.

Heading	Description
DIVERGENT	Number of times the sampler failed to generate a valid proposal due to the leapfrog iterations generating NaNs or Infs. When drawing samples, a nonzero value in the DIVERGENT column indicates that the chosen step size is above the stability threshold for some region of state space. To fix this issue, try to set the StepSize to a smaller value, draw new samples, and check that all values in the DIVERGENT column equal 0.

Example: `'VerbosityLevel',1`

NumPrint — Verbose output frequency

100 (default) | positive integer

Verbose output frequency, specified as a positive integer.

If the `'VerbosityLevel'` value is a positive integer, then `drawSamples` outputs sampling details every `'NumPrint'` iterations.

Example: `'NumPrint',200`

Output Arguments

chain — Markov chain generated using Hamiltonian Monte Carlo

numeric matrix

Markov chain generated using Hamiltonian Monte Carlo, returned as a numeric matrix.

Each row of `chain` is a sample, and each column represents one sampling variable.

endpoint — Final state of Markov chain

numeric column vector

Final state of the Markov chain, returned as a numeric column vector of the same length as `smp.StartPoint`.

accratio — Acceptance ratio

numeric scalar

Acceptance ratio of the Markov chain proposals, returned as a numeric scalar. The acceptance ratio is calculated from the beginning of sampling, including the burn-in period.

Examples

Draw Samples Using HMC Sampler

Create MCMC chains for a multivariate normal distribution using a Hamiltonian Monte Carlo (HMC) sampler.

Define the number of parameters to sample and their means.

```
NumParams = 100;  
means = randn(NumParams,1);  
standevs = 0.1;
```

First, save a function `normalDistGrad` on the MATLAB® path that returns the multivariate normal log probability density and its gradient (`normalDistGrad` is defined at the end of this example). Then, call the function with arguments to define the `logpdf` input argument to the `hmcSampler` function.

```
logpdf = @(theta)normalDistGrad(theta,means,standevs);
```

Choose a starting point of the sampler. Create the HMC sampler and tune its parameters.

```
startpoint = randn(NumParams,1);  
smp = hmcSampler(logpdf,startpoint);  
smp = tuneSampler(smp);
```

Draw samples from the posterior density, using a few independent chains. Choose different, randomly distributed starting points for each chain. Specify the number of burn-in samples to discard from the beginning of the Markov chain and the number of samples to generate after the burn-in. Set the `'VerbosityLevel'` to print details during sampling for the first chain.

```
NumChains = 4;  
chains = cell(NumChains,1);
```

```

Burnin      = 500;
NumSamples = 2000;
for c = 1:NumChains
    if c == 1
        showOutput = 1;
    else
        showOutput = 0;
    end
    chains{c} = drawSamples(smp, 'Burnin', Burnin, 'NumSamples', NumSamples, ...
        'Start', randn(size(startpoint)), 'VerbosityLevel', showOutput, 'NumPrint', 500);
end

```

ITER	LOG PDF	STEP SIZE	NUM STEPS	ACC RATIO	DIVERGENT
500	8.017202e+01	5.303e-01	4	8.820e-01	0
1000	7.756258e+01	5.303e-01	8	8.500e-01	0
1500	9.227175e+01	5.303e-01	2	8.547e-01	0
2000	8.073805e+01	3.128e-02	6	8.610e-01	0
2500	9.672952e+01	5.161e-01	2	8.600e-01	0

After obtaining a random sample, investigate issues such as convergence and mixing to determine whether the samples represent a reasonable set of random realizations from the target distribution. To examine the output, plot the trace plots of the samples for the first few variables using the first chain.

A number of burn-in samples have been removed to reduce the effect of the sampling starting point. Furthermore, the trace plots look like high-frequency noise, without any visible long-range correlation between the samples. This indicates that the chain is well mixed.

```

for p = 1:3
    subplot(3,1,p);
    plot(chains{1}(:,p));
    ylabel(smp.VariableNames(p))
    axis tight
end
xlabel('Iteration')

```

The `normalDistGrad` function returns the logarithm of the multivariate normal probability density with means in `Mu` and standard deviations in `Sigma`, specified as scalars or columns vectors the same length as the `startpoint`. The second output argument is the corresponding gradient.

```
function [lpdf,glpdf] = normalDistGrad(X,Mu,Sigma)
Z = (X - Mu)./Sigma;
lpdf = sum(-log(Sigma) - .5*log(2*pi) - .5*(Z.^2));
glpdf = -Z./Sigma;
end
```

Tips

- After creating an HMC sampler using the `hmcSampler` function, you can compute MAP (maximum-a-posteriori) point estimates, tune the sampler, draw samples, and check convergence diagnostics using the methods of the `HamiltonianSampler` class. For an example of this workflow, see Bayesian Linear Regression Using Hamiltonian Monte Carlo on page 7-33.

diagnostics

Class: HamiltonianSampler

Markov Chain Monte Carlo diagnostics

Syntax

```
tbl = diagnostics(smp,chains)
tbl = diagnostics(smp,chains,'MaxLag',maxlag)
```

Description

`tbl = diagnostics(smp,chains)` returns Markov Chain Monte Carlo diagnostics for the chains in `chains`.

`tbl = diagnostics(smp,chains,'MaxLag',maxlag)` specifies the maximum number of autocorrelation lags to use for computing effective sample sizes.

Input Arguments

smp — Hamiltonian Monte Carlo sampler

HamiltonianSampler object

Hamiltonian Monte Carlo sampler, specified as a HamiltonianSampler object.

Use the `hmcSampler` function to create a sampler.

chains — MCMC chains

matrix | cell array

MCMC chains, specified as one of the following:

- A matrix, where each row is a sample and each column a parameter.
- A cell array of matrices, where the chain `chains{i}` is a matrix where each row is a sample and each column a parameter.

The number of parameters (that is, matrix columns) must equal the number of elements of the `StartPoint` property of the `smp` sampler.

maxlag — Maximum number of autocorrelation lags

100 (default) | positive integer

Maximum number of autocorrelation lags for computing effective sample sizes, specified as a positive integer.

The effective sample size calculation uses lags of $1, 2, \dots, \text{maxlag}$ for each chain in chains that has more than `maxlag` samples.

For chains with `maxlag` or fewer samples, the calculation uses $N_i - 1$ lags, where N_i is the number of samples of chain i .

Example: 'MaxLag', 50

Output Arguments

tbl — MCMC diagnostics

table

MCMC diagnostics, computed using all the chains in `chains` and returned as a table with these columns.

Column	Description
Name	Variable name
Mean	Posterior mean estimate
MCSE	Estimate of the Monte Carlo standard error (the standard deviation of the posterior mean estimate)
SD	Estimate of the posterior standard deviation
Q5	Estimate of the 5th quantile of the marginal posterior distribution
Q95	Estimate of the 95th quantile of the marginal posterior distribution

Column	Description
ESS	Effective sample size for the posterior mean estimate. Larger effective sample sizes lead to more accurate results. If the samples are independent, then the effective sample size is equal to the number of samples.
RHat	Gelman-Rubin convergence statistic. As a rule of thumb, values of RHat less than 1.1 are interpreted as a sign that the chains have converged to the target distribution. If RHat for any variable is larger than 1.1, try drawing more Monte Carlo samples.

Examples

Compute Markov Chain Monte Carlo Diagnostics

Create MCMC chains using a Hamiltonian Monte Carlo (HMC) sampler and compute MCMC diagnostics.

First, save a function on the MATLAB® path that returns the multivariate normal log probability density and its gradient. In this example, that function is called `normalDistGrad` and is defined at the end of the example. Then, call this function with arguments to define the `logpdf` input argument to the `hmcSampler` function.

```
means = [1;-2;2];
standevs = [1;2;0.5];
logpdf = @(theta)normalDistGrad(theta,means,standevs);
```

Choose a starting point. Create the HMC sampler and tune its parameters.

```
startpoint = randn(3,1);
smp = hmcSampler(logpdf,startpoint);
smp = tuneSampler(smp);
```

Draw samples from the posterior density, using a few independent chains. Choose different, randomly distributed starting points for each chain. Specify the number of burn-in samples to discard from the beginning of the Markov chain and the number of samples to generate after the burn-in.

```

NumChains = 4;
chains     = cell(NumChains,1);
Burnin    = 500;
NumSamples = 1000;
for c = 1:NumChains
    chains{c} = drawSamples(smp, 'Burnin',Burnin, 'NumSamples',NumSamples,...
        'Start',randn(size(startpoint)));
end

```

Compute MCMC diagnostics and display the results. Compare the true means in `means` with the column titled `Mean` in the `MCMCdiagnostics` table. The true posterior means are within a few Monte Carlo standard errors (MCSEs) of the estimated posterior means. The HMC sampler has accurately recovered the true means. Similarly, the estimated standard deviations in the column `SD` are very near the true standard deviations in `standev`.

```
MCMCdiagnostics = diagnostics(smp,chains)
```

```
MCMCdiagnostics=3×8 table
```

Name	Mean	MCSE	SD	Q5	Q95	ESS	RHat
'x1'	1.0038	0.016474	0.96164	-0.58601	2.563	3407.4	1

Classification Learner

Train models to classify data using supervised machine learning

Description

The **Classification Learner** app trains models to classify data. Using this app, you can explore supervised machine learning using various classifiers. You can explore your data, select features, specify validation schemes, train models, and assess results. You can perform automated training to search for the best classification model type, including decision trees, discriminant analysis, support vector machines, logistic regression, nearest neighbors, naive Bayes, and ensemble classification.

You can perform supervised machine learning by supplying a known set of input data (observations or examples) and known responses to the data (e.g., labels or classes). You use the data to train a model that generates predictions for the response to new data. To use the model with new data, or to learn about programmatic classification, you can export the model to the workspace or generate MATLAB code to recreate the trained model.

Tip To get started, in the Classifier list, try **All Quick-To-Train** to train a selection of models. See “Automated Classifier Training” on page 23-12.

Required Products

- MATLAB
- Statistics and Machine Learning Toolbox

Note: Classification Learner does not provide data import from file, code generation, or parallel model training in MATLAB Online.

Open the Classification Learner App

- MATLAB Toolstrip: On the **Apps** tab, under **Machine Learning**, click the app icon.
- MATLAB command prompt: Enter `classificationLearner`.

Examples

- “Train Classification Models in Classification Learner App” on page 23-11
- “Select Data and Validation for Classification Problem” on page 23-20
- “Automated Classifier Training” on page 23-12
- “Feature Selection and Feature Transformation Using Classification Learner App” on page 23-49
- “Choose Classifier Options” on page 23-26
- “Assess Classifier Performance in Classification Learner” on page 23-56

Regression Learner

Train regression models to predict data using supervised machine learning

Description

The **Regression Learner** app trains regression models to predict data. Using this app, you can explore your data, select features, specify validation schemes, train models, and assess results. You can perform automated training to search for the best regression model type, including linear regression models, regression trees, Gaussian process regression models, support vector machines, and ensembles of regression trees.

Perform supervised machine learning by supplying a known set of observations of input data (predictors) and known responses. Use the observations to train a model that generates predicted responses for new input data. To use the model with new data, or to learn about programmatic regression, you can export the model to the workspace or generate MATLAB code to recreate the trained model.

Required Products

- MATLAB
- Statistics and Machine Learning Toolbox

Note: Regression Learner does not provide data import from file, code generation, or parallel model training in MATLAB Online.

Open the Regression Learner App

- MATLAB Toolstrip: On the **Apps** tab, under **Machine Learning**, click the app icon.
- MATLAB command prompt: Enter `regressionLearner`.

Distribution Fitter

Fit probability distributions to data

Description

The **Distribution Fitter** app interactively fits probability distributions to data imported from the MATLAB workspace. You can choose from 22 built-in probability distributions or create your own custom distribution. The app displays plots of the fitted distribution superimposed on a histogram of the data. Available plots include probability density function (pdf), cumulative distribution function (cdf), probability plots, and survivor functions. You can export the fitted parameter values to the workspace as a probability distribution object, and use object functions to perform further analyses. For more information on working with these objects, see “Working with Probability Distributions” on page 5-3. For the programmatic work flow of the Distribution Fitter app, see `distributionFitter`.

Required Products

- MATLAB
- Statistics and Machine Learning Toolbox

Note: Distribution Fitter does not provide printing, custom distribution defining, or code generating functionality in MATLAB Online.

Open the Distribution Fitter App

- MATLAB Toolstrip: On the **Apps** tab, under **Math, Statistics and Optimization**, click the app icon.
- MATLAB command prompt: Enter `distributionFitter`.

Examples

- “Fit a Distribution Using the Distribution Fitter App” on page 5-99

Parameters

Data

Data — Data to import from the workspace

list of variables | valid MATLAB expression

Specify the data to import by selecting a variable from the drop-down list. If the variable is a matrix, the app imports the first column of the matrix by default. To select a different column or row of the matrix, click **Select Column or Row**. Alternatively, you can enter any valid MATLAB expression in the field.

Censoring — Variable containing censoring data

list of variables

Specify the censoring data by selecting a variable from the drop-down list. If the variable is a matrix, the app imports the first column of the matrix by default. To select a different column or row of the matrix, click **Select Column or Row**. This parameter is optional.

Frequency — Variable containing frequency data

list of variables

Specify the frequency data by selecting a variable from the drop-down list. If the variable is a matrix, the app imports the first column of the matrix by default. To select a different column or row of the matrix, click **Select Column or Row**. This parameter is optional.

Data set name — Data set name

character vector

Specify a name for the data set as a character vector, or accept the default name.

Manage data sets — Manage previously imported data sets

list of data sets

Manage previously imported data sets. Click the data set of interest, then click the buttons below this pane to view the data (**View**), set the bin rules (**Set Bin Rules**), rename the data set (**Rename**), or delete the data set (**Delete**).

Data preview — Preview plot of data

histogram plot

Display a preview plot of the variable selected from the **Data** drop-down menu.

New fit**Fit name — Name of fit**

character vector

Specify a name for the fit or accept the default name.

Data — Data set to fit

list of data sets

Specify the data to fit by selecting a data set from the drop-down list.

Distribution — Distribution to fit

Normal (default) | Exponential | Weibull | Non-parametric | ...

Specify the distribution to fit by selecting a distribution name from the drop-down list.

Exclusion rule — Data exclusion rule

list of exclusion rules

Specify a rule to exclude some data values by selecting an exclusion rule from the drop-down list. To populate this drop-down list, you must first define exclusion rules by clicking **Exclude** in the main window of the app. This parameter is optional

Manage fits**Plot — Flag to plot fitted distribution**

checked (default) | unchecked

Specify which fit or fits to plot in the main window by selecting the **Plot** check box next to each fit. Clear the **Plot** check box to remove a fit from the plot.

Conf bounds — Flag to plot confidence bounds

unchecked (default) | checked

If you select **Plot** for a particular fit, you can select **Conf bounds** to display the confidence bounds for that fit on the plot in the main window. Clearing the **Conf bounds** check box removes the confidence intervals from the plot. The Distribution Fitter app displays confidence bounds only if the Display Type in the main window is set to **Cumulative probability (CDF)**, **Quantile (inverse CDF)**, **Survivor function**, or **Cumulative hazard**.

Evaluate**Fit — Fit to evaluate**

list of fits

Select one or more fits from the list to evaluate.

Function — Available functions to fit

Density (PDF) (default) | Cumulative probability (CDF) | Quantile (inverse CDF) | Survivor function | Cumulative hazard | Hazard rate

Specify the type of probability function to evaluate from the drop-down list. Available probability functions include the probability density function (pdf), cumulative distribution function (cdf), quantile (inverse cdf), survival function, cumulative hazard, and hazard rate.

At x = — Values at which to evaluate function

numeric vector

Specify a numeric vector of values at which to evaluate the function. If you specify **Function** as **Quantile (inverse CDF)**, this field name changes to **At p =** and you enter a vector of probability values.

Compute confidence bounds — Flag to compute confidence bounds

unchecked (default) | checked

Select **Compute confidence bounds** to compute the confidence bounds for the selected fit. This check box is enabled only if you specify **Function** as **Cumulative probability (CDF)**, **Quantile (inverse CDF)**, **Survivor function**, or **Cumulative hazard**. This parameter is optional.

Level — Level for confidence bounds

95% (default) | numeric value

Specify the level at which to compute the confidence bounds. This check box is enabled only if you specify **Function** as **Cumulative probability (CDF)**, **Quantile (inverse CDF)**, **Survivor function**, or **Cumulative hazard**.

Plot function — Flag to plot function

unchecked (default) | checked

Select **Plot function** to display a plot of the distribution function, evaluated at the points that you enter in the **At x =** field, in a new window. This parameter is optional.

Exclude

Exclusion rule name — Name of exclusion rule

character vector

Specify a name for the exclusion rule as a character vector.

Exclude sections — Define data exclusion rules numerically

numeric value

Specify lower and upper limits for the data numerically.

Exclude graphically — Define data exclusion rules graphically

list of variables

Specify lower and upper limits for the data by selecting a variable from the **Select data** drop-down list and clicking **Exclude graphically**. An interactive plot opens in a new window, where you can add lower or upper limits by clicking and dragging a boundary on the plot.

Existing exclusion rules — List of existing exclusion rules

list of exclusion rules

Select an existing exclusion rule from the list. You can copy, view, rename, or delete exclusion rules by clicking the appropriate button.

Programmatic Use

`distributionFitter` opens the Distribution Fitter app, or brings focus to the app if it is already open.

`distributionFitter(y)` opens the Distribution Fitter app populated with the data specified by the vector `y`.

`distributionFitter(y,cens)` uses the vector `cens` to specify whether the observation `y(j)` is censored, (`cens(j)==1`), or observed exactly, (`cens(j)==0`). If `cens` is omitted or empty, then no `y` values are censored.

`distributionFitter(y,cens,freq)` uses the vector `freq` to specify the frequency of each element contained in `y`. If `freq` is omitted or empty, then all values in `y` have a frequency of 1.

`distributionFitter(y,cens,freq,dsname)` creates a data set with the name `dsname` using the data vector, `y`, censoring indicator, `cens`, and frequency vector, `freq`. Specify `dsname` as a character vector or string scalar, for example, `'mydata'`.

Introduced before R2006a

plotPartialDependence

Package:

Create partial dependence plot (PDP) and individual conditional expectation (ICE) plots

Syntax

```
plotPartialDependence(Mdl, Vars)  
plotPartialDependence(Mdl, Vars, X)  
plotPartialDependence( ____, Name, Value)  
ax = plotPartialDependence( ____ )
```

Description

`plotPartialDependence(Mdl, Vars)` creates a PDP between features listed in `Vars` and responses predicted by using predictor data and a trained regression model in `Mdl`.

`plotPartialDependence(Mdl, Vars, X)` creates a PDP by using new predictor data in `X`.

`plotPartialDependence(____, Name, Value)` uses additional options specified by one or more name-value pair arguments in addition to any of the arguments in the previous syntaxes. For example, if you specify `'Conditional'`, `'absolute'`, the `plotPartialDependence` function creates a figure including a PDP, a scatter plot of the selected feature and predicted responses, and an ICE plot for each observation.

`ax = plotPartialDependence(____)` returns the axes of the plot using any of the input arguments combinations in the previous syntaxes.

Examples

Create Partial Dependence Plot

Train a regression tree using the `carsmall` data set, and create a PDP that shows the relationship between a feature and the predicted responses in the trained regression tree.

Load the `carsmall` data set.

```
load carsmall
```

Specify `Weight`, `Cylinders`, and `Horsepower` as the predictor variables (X), and `MPG` as the response variable (Y).

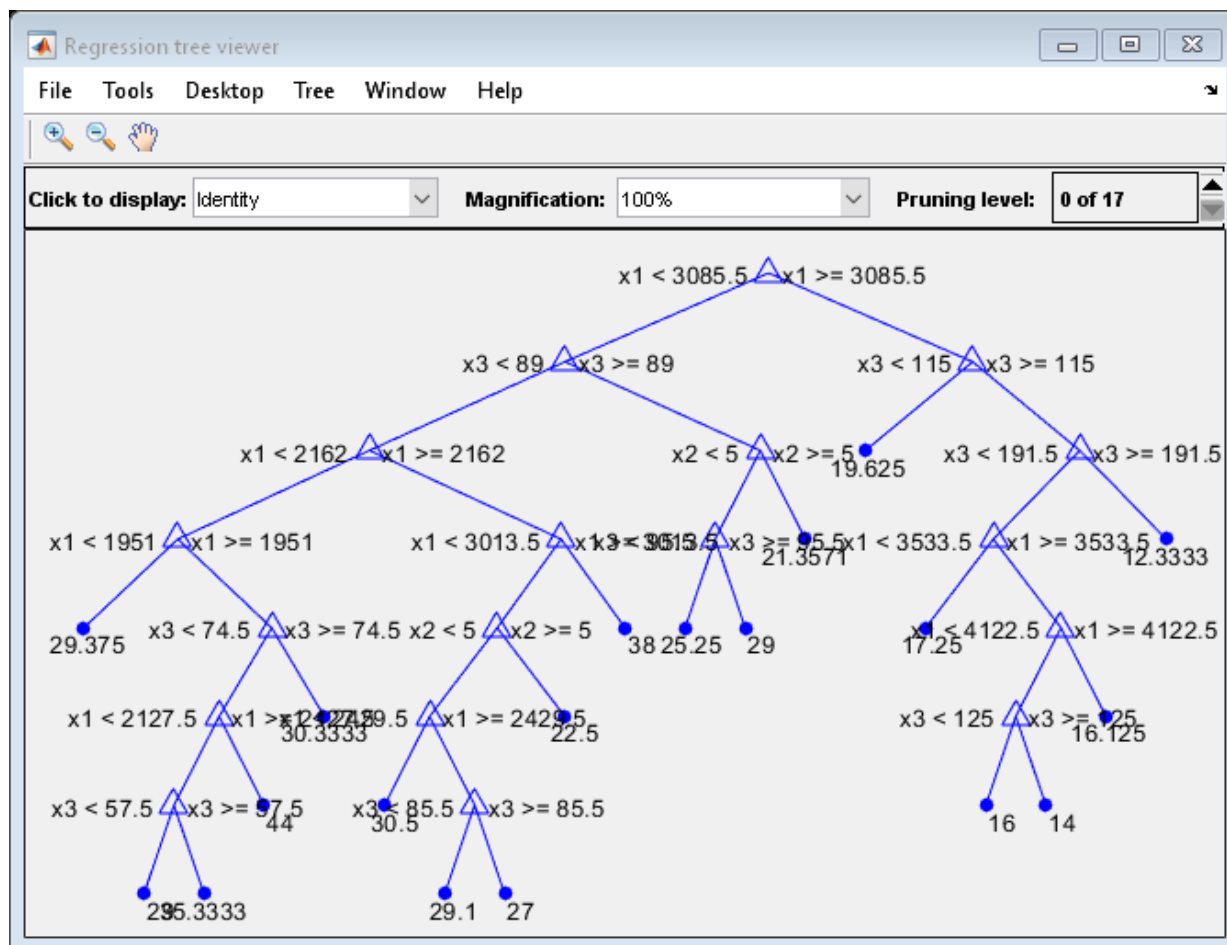

```
X = [Weight,Cylinders,Horsepower];  
Y = MPG;
```

Construct a regression tree using X and Y.

```
Mdl = fitrtree(X,Y);
```

View a graphical display of the trained regression tree.

```
view(Mdl, 'Mode', 'graph')
```

Create a PDP of the first predictor variable, Weight.

`plotPartialDependence(Mdl, 1)`

The blue line represents averaged partial relationships between Weight (labeled as x_1) and MPG (labeled as Y) in the trained regression tree MdL.

The regression tree viewer shows that the first decision is whether x_1 is smaller than 3085.5. The PDP also shows a large change near $x_1 = 3085.5$. The tree viewer visualizes each decision at each node based on predictor variables. You can find several nodes split based on the values of x_1 , but it is not easy to figure out the dependence of Y on x_1 . However, the PDP plots averaged predicted responses against x_1 , so you can clearly see the partial dependence of Y on x_1 .

The labels x_1 and Y are the default values of the predictor names and the response name. You can modify these names by specifying the name-value pair arguments

'PredictorNames' and 'ResponseName' when you train Mdl using fitrtree. You can also modify axis labels by using the xlabel and ylabel functions.

Create Individual Conditional Expectation Plots

Train a Gaussian process regression model using generated sample data where a response variable includes interactions between predictor variables. Then, create ICE plots that show the relationship between a feature and the predicted responses for each observation.

Generate sample predictor data x1 and x2.

```
rng('default') % For reproducibility
n = 200;
x1 = rand(n,1)*2-1;
x2 = rand(n,1)*2-1;
```

Generate response values that include interactions between x1 and x2.

```
Y = x1-2*x1.*(x2>0)+0.1*rand(n,1);
```

Construct a Gaussian process regression model using [x1 x2] and Y.

```
Mdl = fitrgp([x1 x2],Y);
```

Create a figure including a PDP (red line) for the first predictor x1, a scatter plot (black circle markers) of x1 and predicted responses, and a set of ICE plots (gray lines) by specifying 'Conditional' as 'centered'.

```
plotPartialDependence(Mdl,1,'Conditional','centered')
```

When 'Conditional' is 'centered', `plotPartialDependence` offsets plots so that all plots start from zero, which is helpful in examining the cumulative effect of the selected feature.

A PDP finds averaged relationships, so it does not reveal hidden dependencies especially when responses include interactions between features. However, the ICE plots clearly show two different dependencies of responses on `x1`.

Compare Importance of Predictor Variables

Train a regression ensemble using the `carsmall` data set, and create a PDP plot and ICE plots for each predictor variable using a new data set, `carbig`. Then, compare the figures to analyze the importance of predictor variables. Also, compare the results with the estimates of predictor importance returned by the `predictorImportance` function.

Load the `carsmall` data set.

```
load carsmall
```

Specify `Weight`, `Cylinders`, `Horsepower`, and `Model_Year` as the predictor variables (X), and `MPG` as the response variable (Y).

```
X = [Weight,Cylinders,Horsepower,Model_Year];
Y = MPG;
```

Train a regression ensemble using X and Y.

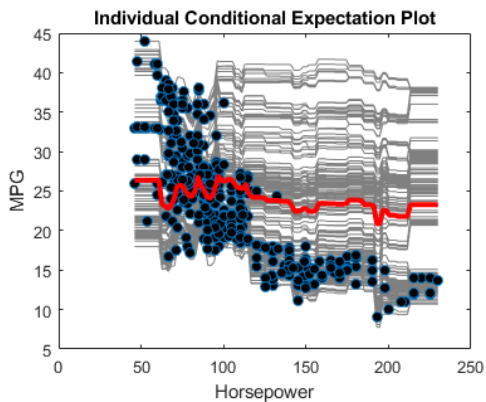

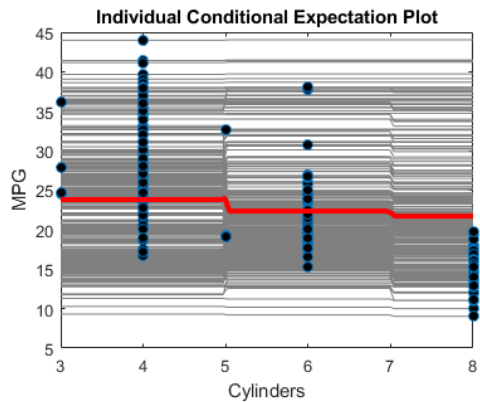

```
Mdl = fitensemble(X,Y, ...
    'PredictorNames',{'Weight','Cylinders','Horsepower','Model Year'}, ...
    'ResponseName','MPG');
```

Compare the importance of predictor variables by using the `plotPartialDependence` and `predictorImportance` functions. The `plotPartialDependence` function visualizes the relationships between a selected predictor and predicted responses. `predictorImportance` summarizes the importance of a predictor with a single value.

Create a figure including a PDP plot (red line) and ICE plots (gray lines) for each predictor by using `plotPartialDependence` and specifying `'Conditional','absolute'`. Each figure also includes a scatter plot (black circle markers) of the selected predictor and predicted responses. Also, load the `carbig` data set and use it as new predictor data, `Xnew`. When you provide `Xnew`, the `plotPartialDependence` function uses `Xnew` instead of the predictor data in `Mdl`.

```
load carbig
Xnew = [Weight,Cylinders,Horsepower,Model_Year];

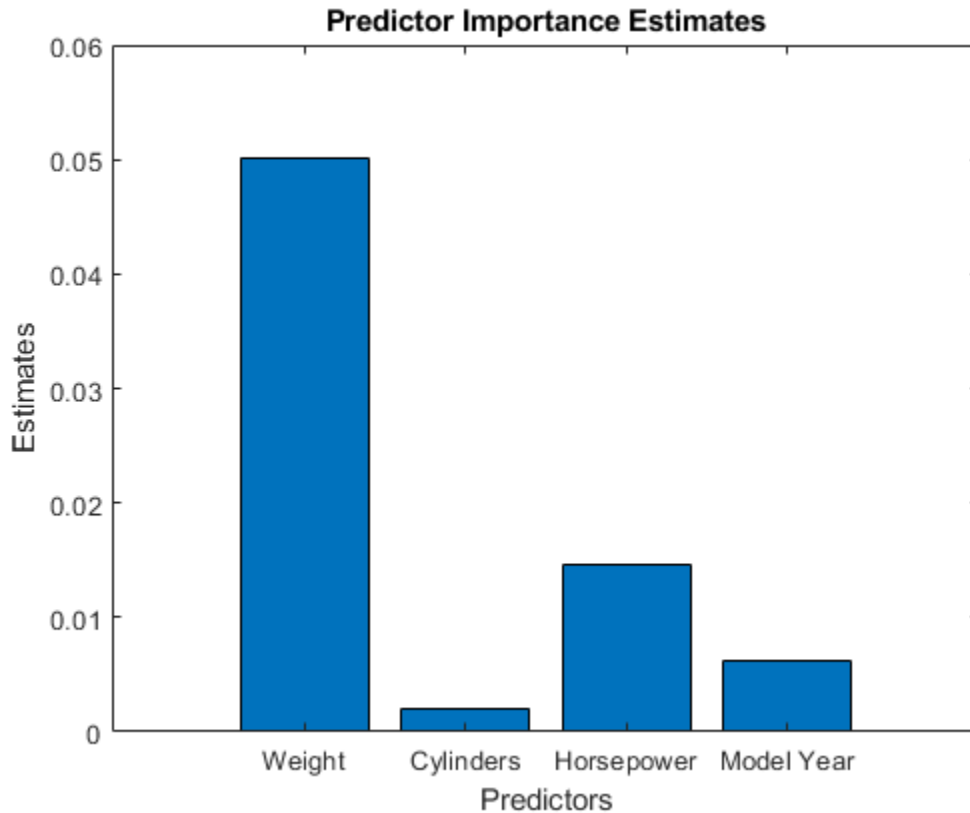

f = figure;
f.Position = [100 100 1.75*f.Position(3:4)]; % Enlarge figure for visibility.
for i = 1 : 4
    subplot(2,2,i)
    plotPartialDependence(Mdl,i,Xnew,'Conditional','absolute')
end
```

Compute estimates of predictor importance by using `predictorImportance`. This function sums changes in the mean-squared error (MSE) due to splits on every predictor, and then divides the sum by the number of branch nodes.

```
imp = predictorImportance(Mdl);
figure;
bar(imp);
title('Predictor Importance Estimates');
ylabel('Estimates');
xlabel('Predictors');
```

```
ax = gca;  
ax.XTickLabel = Mdl.PredictorNames;
```

The variable `Weight` has the most impact on MPG according to predictor importance. The PDP of `Weight` also shows that MPG has high partial dependence on `Weight`. The variable `Cylinders` has the least impact on MPG according to predictor importance. The PDP of `Cylinders` also shows that MPG does not change much depending on `Cylinders`.

Extract Partial Dependence Estimates from Plots

Train a support vector machine (SVM) regression model using the `carsmall` data set, and create a PDP for two predictor variables. Then, extract partial dependence estimates from the output of `plotPartialDependence`.

Load the `carsmall` data set.

```
load carsmall
```

Specify `Weight`, `Cylinders`, and `Horsepower` as the predictor variables (`Tbl`).

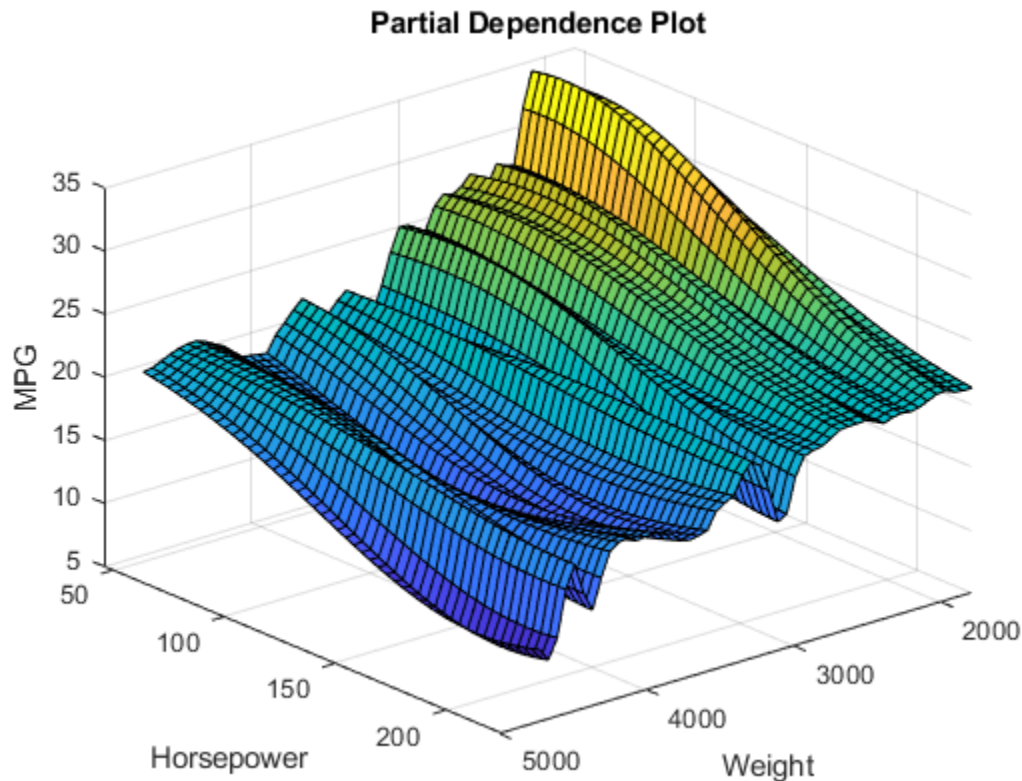

```
Tbl = table(Weight,Cylinders,Horsepower);
```

Construct a support vector machine (SVM) regression model using `Tbl` and the response variable `MPG`. Use a Gaussian kernel function with an automatic kernel scale.

```
Mdl = fitrsvm(Tbl,MPG,'ResponseName','MPG', ...  
             'KernelFunction','gaussian','KernelScale','auto');
```

Create a PDP that visualizes partial dependence of predicted responses (`MPG`) on the predictor variables `Weight` and `Horsepower`. Use the `QueryPoints` name-value pair argument to specify the points to compute partial dependence.

```
pt1 = linspace(min(Weight),max(Weight),50)';  
pt2 = linspace(min(Horsepower),max(Horsepower),50)';  
ax = plotPartialDependence(Mdl,{'Weight','Horsepower'},'QueryPoints',[pt1 pt2]);  
view(140,30) % Modify the viewing angle
```

The PDP shows an interaction effect between Weight and Horsepower.

Extract the estimated partial dependence of MPG on Weight and Horsepower. The XData, YData, and ZData values of `ax.Children` are x-axis values (the first selected predictor values), y-axis values (the second selected predictor values), and z-axis values (the corresponding partial dependence values), respectively.

```
xval = ax.Children.XData;
yval = ax.Children.YData;
zval = ax.Children.ZData;
```

If you specify 'Conditional' as 'absolute', `plotPartialDependence` creates a figure including a PDP, a scatter plot, and a set of ICE plots. `ax.Children(1)` and `ax.Children(2)` correspond to the PDP and scatter plot, respectively. The remaining

elements of `ax.Children` correspond to the ICE plots. The `XData` and `YData` values of `ax.Children(i)` are x-axis values (the selected predictor values) and y-axis values (the corresponding partial dependence values), respectively.

Input Arguments

Mdl — Trained regression model

full regression model object | compact regression model object

Trained regression model, specified as a full or compact regression model object described in the following table.

Trained Model Type	Regression Model Object	Returned By
Bootstrap aggregation for ensemble of decision trees	<code>TreeBagger</code> , <code>CompactTreeBagger</code>	<code>TreeBagger</code> , <code>compact</code>
Ensemble of regression models	<code>RegressionEnsemble</code> , <code>RegressionBaggedEnsemble</code> , <code>CompactRegressionEnsemble</code>	<code>fitrensemble</code> , <code>compact</code>
Gaussian process regression	<code>RegressionGP</code> , <code>CompactRegressionGP</code>	<code>fitrgp</code> , <code>compact</code>
Generalized linear mixed-effect model	<code>GeneralizedLinearMixedModel</code>	<code>fitglme</code>
Generalized linear model	<code>GeneralizedLinearModel</code> , <code>CompactGeneralizedLinearModel</code>	<code>fitglm</code> , <code>stepwiseglm</code> , <code>compact</code>
Linear mixed-effect model	<code>LinearMixedModel</code>	<code>fitlme</code> , <code>fitlmematrix</code>
Linear regression	<code>LinearModel</code> , <code>CompactLinearModel</code>	<code>fitlm</code> , <code>stepwiselm</code> , <code>compact</code>
Linear regression for high-dimensional data	<code>RegressionLinear</code>	<code>fitrlinear</code>

Trained Model Type	Regression Model Object	Returned By
Nonlinear regression	NonLinearModel	fitnlm
Regression tree	RegressionTree, CompactRegressionTree	fitrtree, compact
Support vector machine regression	RegressionSVM, CompactRegressionSVM	fitrsvm, compact

If `Mdl` is a compact regression model object, you must provide `X`.

`plotPartialDependence` does not support a trained model object with a sparse matrix. If you train `Mdl` by using `fitrlinear`, use a full numeric matrix for predictor data where rows correspond to individual observations.

Vars — Features to visualize

vector of positive integers | character vector | string scalar | string array | cell array of character vectors

Features to visualize, specified as a vector of positive integers, character vector or string scalar, string array, or cell array of character vectors. You can choose one or two features, as shown in the following tables.

One Feature

Value	Description
positive integer	Index value corresponding to the column of the predictor data to visualize.
character vector or string scalar	Name of a predictor variable to visualize. The name must match the entry in <code>Mdl.PredictorNames</code> .

Two Features

Value	Description
vector of two positive integers	Index values corresponding to the columns of the predictor data to visualize.
string array or cell array of character vectors	Names of the predictor variables to visualize. Each element in the array is the name of a predictor variable. The names must match the entries in <code>Mdl.PredictorNames</code> .

Example: `{'x1', 'x3'}`

Data Types: `single` | `double` | `char` | `string` | `cell`

X — Predictor data

numeric matrix | table

Predictor data, specified as a numeric matrix or table. Each row of `X` corresponds to one observation, and each column corresponds to one variable.

- If `Mdl` is a full regression model object, `plotPartialDependence` uses the predictor data in `Mdl`. If you provide `X`, then `plotPartialDependence` does not use the predictor data in `Mdl` and uses `X` only.
- If `Mdl` is a compact regression model object, you must provide `X`.

`X` must be consistent with the predictor data that trained `Mdl`, stored in either `Mdl.X` or `Mdl.Variables`.

- If you trained `Mdl` using a numeric matrix, then `X` must be a numeric matrix. The variables making up the columns of `X` must have the same number and order as the predictor variables that trained `Mdl`.
- If you trained `Mdl` using a table (for example, `Tbl`), then `X` must be a table. All predictor variables in `X` must have the same variable names and data types as the names and types in `Tbl`. However, the column order of `X` does not need to correspond to the column order of `Tbl`.
- `plotPartialDependence` does not support a sparse matrix.

Data Types: `single` | `double` | `table`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example:

```
plotPartialDependence(Mdl, Vars, X, 'NumObservationsToSample', 100, 'UseParallel', true) creates a PDP by using 100 sampled observations in X and executing for-loop iterations in parallel.
```

Conditional — Plot type

'none' (default) | 'absolute' | 'centered'

Plot type, specified as the comma-separated pair consisting of 'Conditional' and 'none', 'absolute', or 'centered'.

Value	Description
'none'	<p>plotPartialDependence creates a PDP.</p> <ul style="list-style-type: none"> If you select one numeric feature in Vars, plotPartialDependence computes partial dependence at values between the minimum and maximum of the selected feature and creates a PDP with a solid blue line. If you select one categorical feature in Vars, plotPartialDependence computes predicted responses at all categorical values and plots partial dependence with blue circle markers connected with a dotted line. If you select two features in Vars, plotPartialDependence creates a surface plot.
'absolute'	<p>plotPartialDependence creates a figure including the following three types of plots:</p> <ul style="list-style-type: none"> PDP with a solid red line Scatter plot of the selected feature and predicted responses with black circle markers ICE plot for each observation with a solid gray line <p>This value is valid when you select only one feature.</p>
'centered'	<p>plotPartialDependence creates a figure including the same three types of plots as 'absolute'. plotPartialDependence offsets plots so that all plots start from zero.</p> <p>This value is valid when you select only one feature.</p>

For details, see “Partial Dependence Plot” on page 32-7395 and “Individual Conditional Expectation Plots” on page 32-7396.

Example: 'Conditional', 'absolute'

NumObservationsToSample — Number of observations to sample

number of total observations (default) | positive integer

Number of observations to sample, specified as the comma-separated pair consisting of 'NumObservationsToSample' and a positive integer. The default value is the number

of total observations in either `Mdl` or `X`. If you specify a value larger than the number of total observations, then `plotPartialDependence` uses all observations.

`plotPartialDependence` samples observations without replacement by using the function `datasample` and uses the sampled observations to compute partial dependence. If you specify `'Conditional'` as either `'absolute'` or `'centered'`, `plotPartialDependence` creates a figure including an ICE plot for each sampled observation.

Example: `'NumObservationsToSample',100`

Data Types: `single` | `double`

ParentAxisHandle — Axes in which to plot

`gca` (default) | axes object

Axes in which to plot, specified as the comma-separated pair consisting of `'ParentAxisHandle'` and an axes object. If you do not specify the axes and if the current axes are Cartesian, then `plotPartialDependence` uses the current axes (`gca`). If axes do not exist, `plotPartialDependence` plots in a new figure.

Example: `'ParentAxisHandle',ax`

QueryPoints — Points to compute partial dependence

numeric column vector | numeric two column matrix | cell array of two numeric column vectors

Points to compute partial dependence, specified as the comma-separated pair consisting of `'QueryPoints'` and a numeric column vector, a numeric two-column matrix, or a cell array of two numeric column vectors.

The default value is a numeric column vector or a numeric two-column matrix, depending on the number of selected features, where a column contains 100 evenly spaced points between the minimum and maximum values of the selected feature.

- If you select one feature in `Vars`, use a numeric column vector.
- If you select two features in `Vars`:
 - Use a numeric two-column matrix to specify the same number of points for each feature.
 - Use a cell array of two numeric column vectors to specify a different number of points for each feature.

The default values for a categorical feature are all categorical values in the selected feature. You cannot modify 'QueryPoints' for a categorical feature. If you select one numeric feature and one categorical feature, you can specify 'QueryPoints' for a numeric feature by using a cell array consisting of a numeric column vector and an empty array.

Example: 'QueryPoints', {pt, []}

Data Types: single | double | cell

UseParallel — Flag to run in parallel

false (default) | true

Flag to run in parallel, specified as the comma-separated pair consisting of 'UseParallel' and true or false. If you specify 'UseParallel' as true, plotPartialDependence executes for-loop iterations in parallel by using parfor when predicting responses for each observation and averaging them.

Example: 'UseParallel', true

Data Types: logical

Output Arguments

ax — Axes of the plot

axes object

Axes of the plot, returned as an axes object. For details on how to modify the appearance of the axes and extract data from plots, see “Axes Appearance” (MATLAB) and “Extract Partial Dependence Estimates from Plots” on page 32-7387.

Definitions

Partial Dependence Plot

A partial dependence plot[1] (PDP) visualizes relationships between features and predicted responses in a trained regression model. plotPartialDependence creates either a line plot or a surface plot of predicted responses against a single feature or a pair of features, respectively, by marginalizing over the other variables.

Consider a PDP for a subset X^S of the whole feature set $X = \{x_1, x_2, \dots, x_m\}$. A subset X^S includes either one feature or two features: $X^S = \{x_{S1}\}$ or $X^S = \{x_{S1}, x_{S2}\}$. Let X^C be the complementary set of X^S in X . A predicted response $f(X)$ depends on all features in X :

$$f(X) = f(X^S, X^C).$$

The partial dependence of predicted responses on X^S is defined by the expectation of predicted responses with respect to X^C :

$$f^S(X^S) = E_C[f(X^S, X^C)] = \int f(X^S, X^C) p_C(X^C) dX^C,$$

where $p_C(X^C)$ is the marginal probability of X^C , that is, $p_C(X^C) \approx \int p(X^S, X^C) dX^S$. Assuming that each observation is equally likely, and the dependence between X^S and X^C and the interactions of X^S and X^C in responses are not strong, `plotPartialDependence` estimates the partial dependence by using observed predictor data as follows:

$$f^S(X^S) \approx \frac{1}{N} \sum_{i=1}^N f(X^S, X_i^C), \quad (32-1)$$

where N is the number of observations and $X_i = (X_i^S, X_i^C)$ is the i th observation.

`plotPartialDependence` creates a PDP by using “Equation 32-1”. Input a trained model ($f(\cdot)$) and select features (X^S) to visualize by using the input arguments `Mdl` and `Vars`, respectively. `plotPartialDependence` computes partial dependence at 100 evenly spaced points of X^S or the points that you specify by using the `'QueryPoints'` name-value pair argument. You can specify the number (N) of observations to sample from given predictor data by using the `'NumObservationsToSample'` name-value pair argument.

Individual Conditional Expectation Plots

An individual conditional expectation (ICE) plot[2], as an extension of a PDP, visualizes the relationship between a feature and the predicted responses for each observation. While a PDP visualizes the averaged relationship between features and predicted responses, a set of ICE plots disaggregates the averaged information and visualizes an individual dependence for each observation.

`plotPartialDependence` creates an ICE plot for each observation. A set of ICE plots is useful to investigate heterogeneities of partial dependence originating from different observations. `plotPartialDependence` can also create ICE plots with any predictor

data provided through the input argument X . You can use this feature to explore predicted response space.

Consider an ICE plot for a selected feature x_S with a given observation X_i^C , where $X^S = \{x_S\}$, X^C is the complementary set of X^S in the whole feature set X , and $X_i = (X_i^S, X_i^C)$ is the i th observation. The ICE plot corresponds to the summand of the summation in “Equation 32-1”:

$$f_i^S(X^S) = f(X^S, X_i^C).$$

`plotPartialDependence` plots $f_i^S(X^S)$ for each observation i when you specify 'Conditional' as 'absolute'. If you specify 'Conditional' as 'centered', `plotPartialDependence` draws all plots after removing level effects due to different observations:

$$f_{i, \text{centered}}^S(X^S) = f(X^S, X_i^C) - f(\min(X^S), X_i^C).$$

This subtraction ensures that each plot starts from zero, so that you can examine the cumulative effect of X^S and the interactions between X^S and X^C .

Weighted Traversal Algorithm

The weighted traversal algorithm[1] is a method to estimate partial dependence for a tree-based regression model. The estimated partial dependence is the weighted average of response values corresponding to the leaf nodes visited during the tree traversal.

Let X^S be a subset of the whole feature set X and X^C be the complementary set of X^S in X . For each X^S value to compute partial dependence, the algorithm traverses a tree from the root (beginning) node down to leaf (terminal) nodes and finds the weights of leaf nodes. The traversal starts by assigning a weight value of one at the root node. If a node splits by X^S , the algorithm traverses to the appropriate child node depending on the X^S value. The weight of the child node becomes the same value as its parent node. If a node splits by X^C , the algorithm traverses to both child nodes. The weight of each child node becomes a value of its parent node multiplied by the fraction of observations corresponding to each child node. After completing the tree traversal, the algorithm computes the weighted average by using the assigned weights.

For an ensemble of regression trees, the estimated partial dependence is an average of the weighted averages over the individual regression trees.

Algorithms

`plotPartialDependence` uses a `predict` function to predict responses. `plotPartialDependence` chooses the proper `predict` function according to `Mdl` and runs `predict` with its default settings. For details about each `predict` function, see the `predict` function in the following table. If `Mdl` is a tree-based model and 'Conditional' is 'none', then `plotPartialDependence` uses the weighted traversal algorithm instead of the `predict` function. For details, see “Weighted Traversal Algorithm” on page 32-7397.

Trained Model Type	Regression Model Object	Function to Predict Responses
Bootstrap aggregation for ensemble of decision trees	<code>CompactTreeBagger</code>	<code>predict</code>
Bootstrap aggregation for ensemble of decision trees	<code>TreeBagger</code>	<code>predict</code>
Ensemble of regression models	<code>RegressionEnsemble</code> , <code>RegressionBaggedEnsemble</code> , <code>CompactRegressionEnsemble</code>	<code>predict</code>

Extended Capabilities

Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the 'UseParallel' option to true.

Set the 'UseParallel', true name-value pair argument in the call to this function.

For more general information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

fitckernel

Fit Gaussian kernel classification model using random feature expansion

`fitckernel` trains or cross-validates a binary Gaussian kernel classification model for nonlinear classification. `fitckernel` is more practical for big data applications that have large training sets but can also be applied to smaller data sets that fit in memory.

`fitckernel` maps data in a low-dimensional space into a high-dimensional space, then fits a linear model in the high-dimensional space by minimizing the regularized objective function. Obtaining the linear model in the high-dimensional space is equivalent to applying the Gaussian kernel to the model in the low-dimensional space. Available linear classification models include regularized support vector machine (SVM) and logistic regression models.

To train a nonlinear SVM model for binary classification of in-memory data, see `fitsvm`.

Syntax

```
Mdl = fitckernel(X,Y)
Mdl = fitckernel(X,Y,Name,Value)
[Mdl,FitInfo] = fitckernel(____)
[Mdl,FitInfo,HyperparameterOptimizationResults] = fitckernel(____)
```

Description

`Mdl = fitckernel(X,Y)` returns a binary Gaussian kernel classification model trained using the predictor data in `X` and the corresponding class labels in `Y`. The `fitckernel` function maps the predictors in a low-dimensional space into a high-dimensional space, then fits a binary SVM model to the transformed predictors and class labels. This linear model is equivalent to the Gaussian kernel classification model in the low-dimensional space.

`Mdl = fitckernel(X,Y,Name,Value)` returns a kernel classification model with additional options specified by one or more name-value pair arguments. For example, you can implement logistic regression, specify the number of dimensions of the expanded space, or specify to cross-validate.

[Mdl,FitInfo] = fitckernel(___) also returns the fit information in the structure array FitInfo using any of the input arguments in the previous syntaxes. You cannot request FitInfo for cross-validated models.

[Mdl,FitInfo,HyperparameterOptimizationResults] = fitckernel(___) also returns the hyperparameter optimization results HyperparameterOptimizationResults when you optimize hyperparameters by using the 'OptimizeHyperparameters' name-value pair argument.

Examples

Train Kernel Classification Model

Train a binary kernel classification model using SVM.

Load the ionosphere data set. This data set has 34 predictors and 351 binary responses for radar returns, either bad ('b') or good ('g').

```
load ionosphere
[n,p] = size(X)

n = 351

p = 34

resp = unique(Y)

resp = 2x1 cell array
    {'b'}
    {'g'}
```

Train a binary kernel classification model that identifies whether the radar return is bad ('b') or good ('g'). Extract a fit summary to determine how well the optimization algorithm fits the model to the data.

```
rng('default') % For reproducibility
[Mdl,FitInfo] = fitckernel(X,Y)

Mdl =
    ClassificationKernel
        ResponseName: 'Y'
```

```
      ClassNames: {'b' 'g'}
      Learner: 'svm'
NumExpansionDimensions: 2048
      KernelScale: 1
      Lambda: 0.0028
BoxConstraint: 1
```

Properties, Methods

```
FitInfo = struct with fields:
      Solver: 'LBFGS-fast'
      LossFunction: 'hinge'
      Lambda: 0.0028
      BetaTolerance: 1.0000e-04
      GradientTolerance: 1.0000e-06
      ObjectiveValue: 0.2604
      GradientMagnitude: 0.0028
      RelativeChangeInBeta: 8.2512e-05
      FitTime: 0.1775
      History: []
```

`Mdl` is a `ClassificationKernel` model. To inspect the in-sample classification error, you can pass `Mdl` and the training data or new data to the `loss` function. Or, you can pass `Mdl` and new predictor data to the `predict` function to predict class labels for new observations. You can also pass `Mdl` and the training data to the `resume` function to continue training.

`FitInfo` is a structure array containing optimization information. Use `FitInfo` to determine whether optimization termination measurements are satisfactory.

For better accuracy, you can increase the maximum number of optimization iterations (`'IterationLimit'`) and decrease the tolerance values (`'BetaTolerance'` and `'GradientTolerance'`) by using the name-value pair arguments. Doing so can improve measures like `ObjectiveValue` and `RelativeChangeInBeta` in `FitInfo`. You can also optimize model parameters by using the `'OptimizeHyperparameters'` name-value pair argument.

Cross-Validate Kernel Classification Model

Load the `ionosphere` data set. This data set has 34 predictors and 351 binary responses for radar returns, either bad ('b') or good ('g').

```
load ionosphere
rng('default') % For reproducibility
```

Cross-validate a binary kernel classification model. By default, the software uses 10-fold cross-validation.

```
CVMdl = fitkernel(X,Y,'CrossVal','on')
```

```
CVMdl =
  classreg.learning.partition.ClassificationPartitionedKernel
  CrossValidatedModel: 'Kernel'
  ResponseName: 'Y'
  NumObservations: 351
  KFold: 10
  Partition: [1x1 cvpartition]
  ClassNames: {'b' 'g'}
  ScoreTransform: 'none'
```

Properties, Methods

```
numel(CVMdl.Trained)
```

```
ans = 10
```

`CVMdl` is a `ClassificationPartitionedKernel` model. Because `fitkernel` implements 10-fold cross-validation, `CVMdl` contains 10 `ClassificationKernel` models that the software trains on training-fold (in-fold) observations.

Estimate the cross-validated classification error.

```
kfoldLoss(CVMdl)
```

```
ans = 0.0940
```

The classification error rate is approximately 9%.

Optimize Kernel Classifier

Optimize hyperparameters automatically using the 'OptimizeHyperparameters' name-value pair argument.

Load the `ionosphere` data set. This data set has 34 predictors and 351 binary responses for radar returns, either bad ('b') or good ('g').

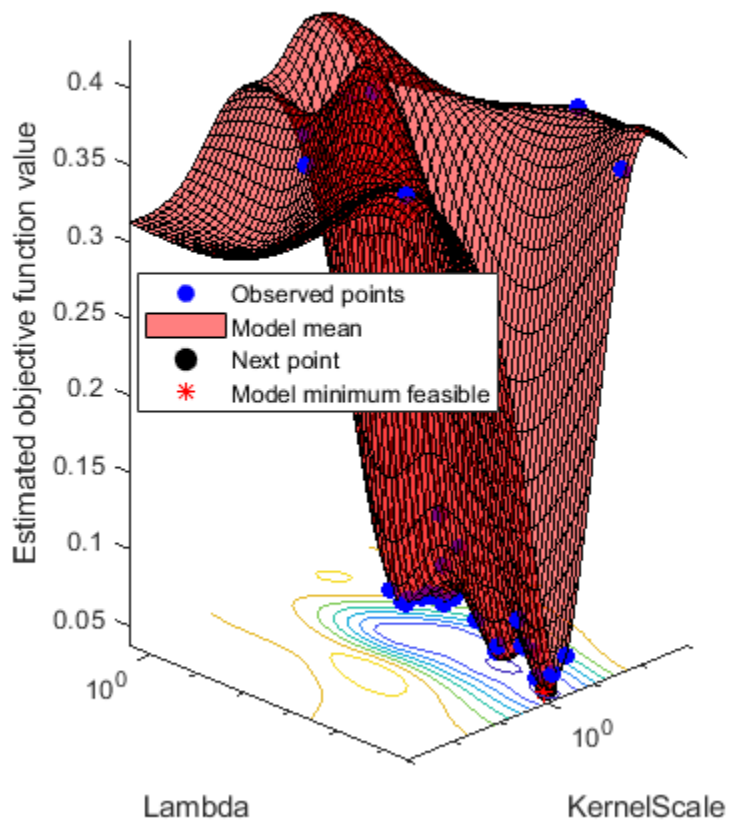

```
load ionosphere
```

Find hyperparameters that minimize five-fold cross-validation loss by using automatic hyperparameter optimization. Specify 'OptimizeHyperparameters' as 'auto' so that `fitckernel` finds optimal values of the 'KernelScale' and 'Lambda' name-value pair arguments. For reproducibility, set the random seed and use the 'expected-improvement-plus' acquisition function.

```
rng('default')  
[Mdl,FitInfo,HyperparameterOptimizationResults] = fitckernel(X,Y,'OptimizeHyperparameters',  
    'HyperparameterOptimizationOptions',struct('AcquisitionFunctionName','expected-impr
```

For big data, the optimization procedure can take a long time. If the data set is too large to run the optimization procedure, you can try to optimize the parameters using only partial data. Use the `datasample` function and specify `'Replace', 'false'` to sample data without replacement.

Input Arguments

X — Predictor data

numeric matrix

Predictor data, specified as an n -by- p numeric matrix, where n is the number of observations and p is the number of predictors.

The length of Y and the number of observations in X must be equal.

Data Types: `single` | `double`

Y — Class labels

categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Class labels, specified as a categorical, character, or string array, logical or numeric vector, or cell array of character vectors.

- `fitckernel` supports only binary classification. Either `Y` must contain exactly two distinct classes, or you must specify two classes for training by using the `ClassNames` name-value pair argument.
- If `Y` is a character array, then each element must correspond to one row of the array.
- The length of `Y` and the number of observations in `X` must be equal.
- A good practice is to specify the class order by using the `ClassNames` name-value pair argument.

Data Types: `categorical` | `char` | `string` | `logical` | `single` | `double` | `cell`

Note `fitckernel` removes missing observations, that is, observations with any of these characteristics:

- NaN, empty character vector (' '), empty string (""), <missing>, and <undefined> elements in the response (`Y`)
- At least one NaN value in a predictor observation (row in `X`)
- NaN value or 0 weight ('Weights')

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Note You cannot use any cross-validation name-value pair argument along with the 'OptimizeHyperparameters' name-value pair argument. You can modify the cross-validation for 'OptimizeHyperparameters' only by using the 'HyperparameterOptimizationOptions' name-value pair argument.

Example: `Mdl = fitckernel(X,Y,'Learner','logistic','NumExpansionDimensions',2^15,'KernelScale','auto')` implements logistic regression after mapping the predictor data to the 2^{15} dimensional space using feature expansion with a kernel scale parameter selected by a heuristic procedure.

Kernel Classification Options

Learner — Linear classification model type

'svm' (default) | 'logistic'

Linear classification model type, specified as the comma-separated pair consisting of 'Learner' and 'svm' or 'logistic'.

In the following table, $f(x) = T(x)\beta + b$.

- x is an observation (row vector) from p predictor variables.
- $T(\cdot)$ is a transformation of an observation (row vector) for feature expansion. $T(x)$ maps x in \mathbb{R}^p to a high-dimensional space (\mathbb{R}^m).
- β is a vector of m coefficients.
- b is the scalar bias.

Value	Algorithm	Response Range	Loss Function
'svm'	Support vector machine	$y \in \{-1,1\}$; 1 for the positive class and -1 otherwise	Hinge: $\ell[y, f(x)] = \max[0, 1 - yf(x)]$
'logistic'	Logistic regression	Same as 'svm'	Deviance (logistic): $\ell[y, f(x)] = \log\{1 + \exp[-yf(x)]\}$

Example: 'Learner', 'logistic'

NumExpansionDimensions — Number of dimensions of expanded space

'auto' (default) | positive integer

Number of dimensions of the expanded space, specified as the comma-separated pair consisting of 'NumExpansionDimensions' and 'auto' or a positive integer. For 'auto', the `fitckernel` function selects the number of dimensions using $2.^{\text{ceil}(\min(\log_2(p)+5, 15))}$, where p is the number of predictors.

For details, see “Random Feature Expansion” on page 32-7429.

Example: 'NumExpansionDimensions', 2^15

Data Types: char | string | single | double

KernelScale — Kernel scale parameter

1 (default) | 'auto' | positive scalar

Kernel scale parameter, specified as the comma-separated pair consisting of 'KernelScale' and 'auto' or a positive scalar. The software obtains a random basis for random feature expansion by using the kernel scale parameter. For details, see “Random Feature Expansion” on page 32-7429.

If you specify 'auto', then the software selects an appropriate kernel scale parameter using a heuristic procedure. This heuristic procedure uses subsampling, so estimates can vary from one call to another. Therefore, to reproduce results, set a random number seed by using `rng` before training.

Example: 'KernelScale', 'auto'

Data Types: char | string | single | double

BoxConstraint — Box constraint

1 (default) | positive scalar

Box constraint, specified as the comma-separated pair consisting of 'BoxConstraint' and a positive scalar.

This argument is valid only when 'Learner' is 'svm' (default) and you do not specify a value for the regularization term strength 'Lambda'. You can specify either 'BoxConstraint' or 'Lambda' because the box constraint (C) and the regularization term strength (λ) are related by $C = 1/(\lambda n)$, where n is the number of observations.

Example: 'BoxConstraint', 100

Data Types: single | double

Lambda — Regularization term strength

'auto' (default) | nonnegative scalar

Regularization term strength, specified as the comma-separated pair consisting of 'Lambda' and 'auto' or a nonnegative scalar.

For 'auto', the value of 'Lambda' is $1/n$, where n is the number of observations.

You can specify either `'BoxConstraint'` or `'Lambda'` because the box constraint (C) and the regularization term strength (λ) are related by $C = 1/(\lambda n)$.

Example: `'Lambda', 0.01`

Data Types: `char | string | single | double`

Cross-Validation Options

CrossVal — Flag to train cross-validated classifier

`'off'` (default) | `'on'`

Flag to train a cross-validated classifier, specified as the comma-separated pair consisting of `'Crossval'` and `'on'` or `'off'`.

If you specify `'on'`, then the software trains a cross-validated classifier with 10 folds.

You can override this cross-validation setting using the `CVPartition`, `Holdout`, `KFold`, or `Leaveout` name-value pair argument. You can use only one cross-validation name-value pair argument at a time to create a cross-validated model.

Example: `'Crossval', 'on'`

CVPartition — Cross-validation partition

`[]` (default) | `cvpartition` partition object

Cross-validation partition, specified as the comma-separated pair consisting of `'CVPartition'` and a `cvpartition` partition object created by `cvpartition`. The partition object specifies the type of cross-validation and the indexing for the training and validation sets.

To create a cross-validated model, you can use one of these four name-value pair arguments only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: Suppose you create a random partition for 5-fold cross-validation on 500 observations by using `cvp = cvpartition(500, 'KFold', 5)`. Then, you can specify the cross-validated model by using `'CVPartition', cvp`.

Holdout — Fraction of data for holdout validation

scalar value in the range (0,1)

Fraction of the data used for holdout validation, specified as the comma-separated pair consisting of `'Holdout'` and a scalar value in the range (0,1). If you specify `'Holdout', p`, then the software completes these steps:

- 1 Randomly select and reserve $p \times 100\%$ of the data as validation data, and train the model using the rest of the data.
- 2 Store the compact, trained model in the Trained property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: `'Holdout',0.1`

Data Types: `double` | `single`

KFold — Number of folds

10 (default) | positive integer value greater than 1

Number of folds to use in a cross-validated model, specified as the comma-separated pair consisting of `'KFold'` and a positive integer value greater than 1. If you specify `'KFold',k`, then the software completes these steps:

- 1 Randomly partition the data into k sets.
- 2 For each set, reserve the set as validation data, and train the model using the other $k - 1$ sets.
- 3 Store the k compact, trained models in the cells of a k -by-1 cell vector in the Trained property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: `'KFold',5`

Data Types: `single` | `double`

Leaveout — Leave-one-out cross-validation flag

'off' (default) | 'on'

Leave-one-out cross-validation flag, specified as the comma-separated pair consisting of `'Leaveout'` and `'on'` or `'off'`. If you specify `'Leaveout','on'`, then, for each of the n observations (where n is the number of observations excluding missing observations), the software completes these steps:

- 1 Reserve the observation as validation data, and train the model using the other $n - 1$ observations.

- 2 Store the n compact, trained models in the cells of an n -by-1 cell vector in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: `'Leaveout', 'on'`

Convergence Controls

BetaTolerance — Relative tolerance on linear coefficients and bias term

1e-5 (default) | nonnegative scalar

Relative tolerance on the linear coefficients and the bias term (intercept), specified as the comma-separated pair consisting of `'BetaTolerance'` and a nonnegative scalar.

Let $B_t = [\beta_t' \ b_t]$, that is, the vector of the coefficients and the bias term at optimization iteration t . If $\left\| \frac{B_t - B_{t-1}}{B_t} \right\|_2 < \text{BetaTolerance}$, then optimization terminates.

If you also specify `GradientTolerance`, then optimization terminates when the software satisfies either stopping criterion.

Example: `'BetaTolerance', 1e-6`

Data Types: `single` | `double`

GradientTolerance — Absolute gradient tolerance

1e-6 (default) | nonnegative scalar

Absolute gradient tolerance, specified as the comma-separated pair consisting of `'GradientTolerance'` and a nonnegative scalar.

Let $\nabla \mathcal{L}_t$ be the gradient vector of the objective function with respect to the coefficients and bias term at optimization iteration t . If $\|\nabla \mathcal{L}_t\|_\infty = \max|\nabla \mathcal{L}_t| < \text{GradientTolerance}$, then optimization terminates.

If you also specify `BetaTolerance`, then optimization terminates when the software satisfies either stopping criterion.

Example: `'GradientTolerance', 1e-5`

Data Types: `single` | `double`

IterationLimit — Maximum number of optimization iterations

positive integer

Maximum number of optimization iterations, specified as the comma-separated pair consisting of 'IterationLimit' and a positive integer.

The default value is 1000 if the transformed data fits in memory, as specified by the BlockSize name-value pair argument. Otherwise, the default value is 100.

Example: 'IterationLimit',500

Data Types: single | double

Other Kernel Classification Options**BlockSize — Maximum amount of allocated memory**4e³ (4GB) (default) | positive scalar

Maximum amount of allocated memory (in megabytes), specified as the comma-separated pair consisting of 'BlockSize' and a positive scalar.

If `fitckernel` requires more memory than the value of 'BlockSize' to hold the transformed predictor data, then the software uses a block-wise strategy. For details about the block-wise strategy, see “Algorithms” on page 32-7430.

Example: 'BlockSize',1e4

Data Types: single | double

RandomStream — Random number stream

global stream (default) | random stream object

Random number stream for reproducibility of data transformation, specified as the comma-separated pair consisting of 'RandomStream' and a random stream object. For details, see “Random Feature Expansion” on page 32-7429.

Use 'RandomStream' to reproduce the random basis functions that `fitckernel` uses to transform the predictor data to a high-dimensional space. For details, see “Managing the Global Stream” (MATLAB) and “Creating and Controlling a Random Number Stream” (MATLAB).

Example: 'RandomStream',RandStream('mlfg6331_64')

HessianHistorySize — Size of history buffer for Hessian approximation

15 (default) | positive integer

Size of the history buffer for Hessian approximation, specified as the comma-separated pair consisting of 'HessianHistorySize' and a positive integer. At each iteration, `fitkernel` composes the Hessian approximation by using statistics from the latest `HessianHistorySize` iterations.

Example: 'HessianHistorySize',10

Data Types: `single` | `double`

Verbose — Verbosity level

0 (default) | 1

Verbosity level, specified as the comma-separated pair consisting of 'Verbose' and either 0 or 1. `Verbose` controls the display of diagnostic information at the command line.

Value	Description
0	<code>fitkernel</code> does not display diagnostic information.
1	<code>fitkernel</code> displays and stores the value of the objective function, gradient magnitude, and other diagnostic information. <code>FitInfo.History</code> contains the diagnostic information.

Example: 'Verbose',1

Data Types: `single` | `double`

Other Classification Options

ClassNames — Names of classes to use for training

categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Names of classes to use for training, specified as the comma-separated pair consisting of 'ClassNames' and a categorical, character, or string array, a logical or numeric vector, or a cell array of character vectors. `ClassNames` must have the same data type as `Y`.

If `ClassNames` is a character array, then each element must correspond to one *row* of the array.

Use `ClassNames` to:

- Order the classes during training.

- Specify the order of any input or output argument dimension that corresponds to the class order. For example, use `ClassNames` to specify the order of the dimensions of `Cost` or the column order of classification scores returned by `predict`.
- Select a subset of classes for training. For example, suppose that the set of all distinct class names in `Y` is `{'a', 'b', 'c'}`. To train the model using observations from classes `'a'` and `'c'` only, specify `'ClassNames', {'a', 'c'}`.

The default value for `ClassNames` is the set of all distinct class names in `Y`.

Example: `'ClassNames', {'b', 'g'}`

Data Types: `categorical` | `char` | `string` | `logical` | `single` | `double` | `cell`

Cost — Misclassification cost

`square matrix` | `structure array`

Misclassification cost, specified as the comma-separated pair consisting of `'Cost'` and a square matrix or structure.

- If you specify the square matrix `cost ('Cost', cost)`, then `cost(i, j)` is the cost of classifying a point into class `j` if its true class is `i`. That is, the rows correspond to the true class, and the columns correspond to the predicted class. To specify the class order for the corresponding rows and columns of `cost`, use the `ClassNames` name-value pair argument.
- If you specify the structure `S ('Cost', S)`, then it must have two fields:
 - `S.ClassNames`, which contains the class names as a variable of the same data type as `Y`
 - `S.ClassificationCosts`, which contains the cost matrix with rows and columns ordered as in `S.ClassNames`

The default value for `Cost` is `ones(K) - eye(K)`, where `K` is the number of distinct classes.

`fitckernel` uses `Cost` to adjust the prior class probabilities specified in `Prior`. Then, `fitckernel` uses the adjusted prior probabilities for training and resets the cost matrix to its default.

Example: `'Cost', [0 2; 1 0]`

Data Types: `single` | `double` | `struct`

Prior — Prior probabilities

'empirical' (default) | 'uniform' | numeric vector | structure array

Prior probabilities for each class, specified as the comma-separated pair consisting of 'Prior' and 'empirical', 'uniform', a numeric vector, or a structure array.

This table summarizes the available options for setting prior probabilities.

Value	Description
'empirical'	The class prior probabilities are the class relative frequencies in Y .
'uniform'	All class prior probabilities are equal to $1/K$, where K is the number of classes.
numeric vector	Each element is a class prior probability. Order the elements according to their order in Y . If you specify the order using the 'ClassNames' name-value pair argument, then order the elements accordingly.
structure array	A structure S with two fields: <ul style="list-style-type: none"> $S.ClassNames$ contains the class names as a variable of the same type as Y. $S.ClassProbs$ contains a vector of corresponding prior probabilities.

`fitckernel` normalizes the prior probabilities in `Prior` to sum to 1.

Example: `'Prior', struct('ClassNames',
{'setosa', 'versicolor'}, 'ClassProbs', 1:2)`

Data Types: `char` | `string` | `double` | `single` | `struct`

ScoreTransform — Score transformation

'none' (default) | 'doublelogit' | 'invlogit' | 'ismax' | 'logit' | function handle | ...

Score transformation, specified as the comma-separated pair consisting of 'ScoreTransform' and a character vector, string scalar, or function handle.

This table summarizes the available character vectors and string scalars.

Value	Description
'doublelogit'	$1/(1 + e^{-2x})$
'invlogit'	$\log(x / (1 - x))$
'ismax'	Sets the score for the class with the largest score to 1, and sets the scores for all other classes to 0
'logit'	$1/(1 + e^{-x})$
'none' or 'identity'	x (no transformation)
'sign'	-1 for $x < 0$ 0 for $x = 0$ 1 for $x > 0$
'symmetric'	$2x - 1$
'symmetricismax'	Sets the score for the class with the largest score to 1, and sets the scores for all other classes to -1
'symmetriclogit'	$2/(1 + e^{-x}) - 1$

For a MATLAB function or a function you define, use its function handle for score transform. The function handle must accept a matrix (the original scores) and return a matrix of the same size (the transformed scores).

Example: 'ScoreTransform', 'logit'

Data Types: char | string | function_handle

Weights — Observation weights

positive numeric vector

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a positive numeric vector of length n , where n is the number of observations in X . The fitckernel function weighs the observations in X with the corresponding values in Weights.

The default value is ones($n, 1$).

fitckernel normalizes Weights to sum up to the value of the prior probability in the respective class.

Example: 'Weights', w

Data Types: single | double

Hyperparameter Optimization Options

OptimizeHyperparameters — Parameters to optimize

'none' (default) | 'auto' | 'all' | string array or cell array of eligible parameter names | vector of `optimizableVariable` objects

Parameters to optimize, specified as the comma-separated pair consisting of 'OptimizeHyperparameters' and one of these values:

- 'none' — Do not optimize.
- 'auto' — Use {'KernelScale', 'Lambda'}.
- 'all' — Optimize all eligible parameters.
- Cell array of eligible parameter names.
- Vector of `optimizableVariable` objects, typically the output of `hyperparameters`.

The optimization attempts to minimize the cross-validation loss (error) for `fitkernel` by varying the parameters. To control the cross-validation type and other aspects of the optimization, use the `HyperparameterOptimizationOptions` name-value pair argument.

Note 'OptimizeHyperparameters' values override any values you set using other name-value pair arguments. For example, setting 'OptimizeHyperparameters' to 'auto' causes the 'auto' values to apply.

The eligible parameters for `fitkernel` are:

- `KernelScale` — `fitkernel` searches among positive values, by default log-scaled in the range $[1e-3, 1e3]$.
- `Lambda` — `fitkernel` searches among positive values, by default log-scaled in the range $[1e-3, 1e3]/n$, where n is the number of observations.
- `Learner` — `fitkernel` searches among 'svm' and 'logistic'.
- `NumExpansionDimensions` — `fitkernel` searches among positive integers, by default log-scaled in the range $[100, 10000]$.

Set nondefault parameters by passing a vector of `optimizableVariable` objects that have nondefault values. For example:

```
load fisheriris
params = hyperparameters('fitckernel',meas,species);
params(2).Range = [1e-4,1e6];
```

Pass `params` as the value of `'OptimizeHyperparameters'`.

By default, iterative display appears at the command line, and plots appear according to the number of hyperparameters in the optimization. For the optimization and plots, the objective function is $\log(1 + \text{cross-validation loss})$ for regression and the misclassification rate for classification. To control the iterative display, set the `Verbose` field of the `'HyperparameterOptimizationOptions'` name-value pair argument. To control the plots, set the `ShowPlots` field of the `'HyperparameterOptimizationOptions'` name-value pair argument.

For an example, see “Optimize Kernel Classifier” on page 32-7404.

Example: `'OptimizeHyperparameters','auto'`

HyperparameterOptimizationOptions — Options for optimization

structure

Options for optimization, specified as the comma-separated pair consisting of `'HyperparameterOptimizationOptions'` and a structure. This argument modifies the effect of the `OptimizeHyperparameters` name-value pair argument. All fields in the structure are optional.

Field Name	Values	Default
Optimizer	<ul style="list-style-type: none"> • 'bayesopt' — Use Bayesian optimization. Internally, this setting calls bayesopt. • 'gridsearch' — Use grid search with NumGridDivisions values per dimension. • 'randomsearch' — Search at random among MaxObjectiveEvaluations points. <p>'gridsearch' searches in a random order, using uniform sampling without replacement from the grid. After optimization, you can get a table in grid order by using the command <code>sortrows(Mdl.HyperparameterOptimizationResults)</code>.</p>	'bayesopt'
AcquisitionFunctionName	<ul style="list-style-type: none"> • 'expected-improvement-per-second-plus' • 'expected-improvement' • 'expected-improvement-plus' • 'expected-improvement-per-second' • 'lower-confidence-bound' • 'probability-of-improvement' <p>Acquisition functions whose names include <code>per-second</code> do not yield reproducible results because the optimization depends on the runtime of the objective function. Acquisition functions whose names include <code>plus</code> modify their behavior when they are overexploiting an area. For more details, see “Acquisition Function Types” on page 10-4.</p>	'expected-improvement-per-second-plus'

Field Name	Values	Default
MaxObjectiveEvaluations	Maximum number of objective function evaluations.	30 for 'bayesopt' or 'randomsearch', and the entire grid for 'gridsearch'
MaxTime	Time limit, specified as a positive real. The time limit is in seconds, as measured by tic and toc. Run time can exceed MaxTime because MaxTime does not interrupt function evaluations.	Inf
NumGridDivisions	For 'gridsearch', the number of values in each dimension. The value can be a vector of positive integers giving the number of values for each dimension, or a scalar that applies to all dimensions. This field is ignored for categorical variables.	10
ShowPlots	Logical value indicating whether to show plots. If true, this field plots the best objective function value against the iteration number. If there are one or two optimization parameters, and if Optimizer is 'bayesopt', then ShowPlots also plots a model of the objective function against the parameters.	true
SaveIntermediateResults	Logical value indicating whether to save results when Optimizer is 'bayesopt'. If true, this field overwrites a workspace variable named 'BayesoptResults' at each iteration. The variable is a BayesianOptimization object.	false

Field Name	Values	Default
Verbose	Display to the command line. <ul style="list-style-type: none"> • 0 — No iterative display • 1 — Iterative display • 2 — Iterative display with extra information For details, see the <code>bayesopt</code> <code>Verbose</code> name-value pair argument.	1
UseParallel	Logical value indicating whether to run Bayesian optimization in parallel, which requires Parallel Computing Toolbox. For details, see “Parallel Bayesian Optimization” on page 10-8.	false
Repartition	Logical value indicating whether to repartition the cross-validation at every iteration. If <code>false</code> , the optimizer uses a single partition for the optimization. <code>true</code> usually gives the most robust results because this setting takes partitioning noise into account. However, for good results, <code>true</code> requires at least twice as many function evaluations.	false
Use no more than one of the following three field names.		
CVPartition	A <code>cvpartition</code> object, as created by <code>cvpartition</code> .	'Kfold', 5 if you do not specify any cross-validation field
Holdout	A scalar in the range (0, 1) representing the holdout fraction.	
Kfold	An integer greater than 1.	

Example:

```
'HyperparameterOptimizationOptions', struct('MaxObjectiveEvaluations', 60)
```

Data Types: struct

Output Arguments

Mdl — Trained kernel classification model

ClassificationKernel model object | ClassificationPartitionedKernel cross-validated model object

Trained kernel classification model, returned as a ClassificationKernel model object or ClassificationPartitionedKernel cross-validated model object.

If you set any of the name-value pair arguments CrossVal, CVPartition, Holdout, KFold, or Leaveout, then Mdl is a ClassificationPartitionedKernel cross-validated classifier. Otherwise, Mdl is a ClassificationKernel classifier.

To reference properties of Mdl, use dot notation. For example, enter Mdl.NumExpansionDimensions in the Command Window to display the number of dimensions of the expanded space.

Note Unlike other classification models, and for economical memory usage, a ClassificationKernel model object does not store the training data or training process details (for example, convergence history).

FitInfo — Optimization details

structure array

Optimization details, returned as a structure array including fields described in this table. The fields contain final values or name-value pair argument specifications.

Field	Description
Solver	Objective function minimization technique: 'LBFGS-fast', 'LBFGS-blockwise', or 'LBFGS-tall'. For details, see "Algorithms" on page 32-7430.
LossFunction	Loss function. Either 'hinge' or 'logit' depending on the type of linear classification model. See Learner.
Lambda	Regularization term strength. See Lambda.
BetaTolerance	Relative tolerance on the linear coefficients and the bias term. See BetaTolerance.

Field	Description
GradientTolerance	Absolute gradient tolerance. See GradientTolerance.
ObjectiveValue	Value of the objective function when optimization terminates. The classification loss plus the regularization term compose the objective function.
GradientMagnitude	Infinite norm of the gradient vector of the objective function when optimization terminates. See GradientTolerance.
RelativeChangeInBeta	Relative changes in the linear coefficients and the bias term when optimization terminates. See BetaTolerance.
FitTime	Elapsed, wall-clock time (in seconds) required to fit the model to the data.
History	History of optimization information. This field is empty ([]) if you specify 'Verbose', 0. For details, see Verbose and "Algorithms" on page 32-7430.

To access fields, use dot notation. For example, to access the vector of objective function values for each iteration, enter `FitInfo.ObjectiveValue` in the Command Window.

A good practice is to examine `FitInfo` to assess whether convergence is satisfactory.

HyperparameterOptimizationResults — Cross-validation optimization of hyperparameters

BayesianOptimization object | table of hyperparameters and associated values

Cross-validation optimization of hyperparameters, returned as a BayesianOptimization object or a table of hyperparameters and associated values. The output is nonempty when the value of 'OptimizeHyperparameters' is not 'none'. The output value depends on the Optimizer field value of the 'HyperparameterOptimizationOptions' name-value pair argument:

Value of Optimizer Field	Value of HyperparameterOptimizationResults
'bayesopt' (default)	Object of class BayesianOptimization

Value of Optimizer Field	Value of HyperparameterOptimizationResults
'gridsearch' or 'randomsearch'	Table of hyperparameters used, observed objective function values (cross-validation loss), and rank of observations from lowest (best) to highest (worst)

Limitations

- `fitckernel` does not accept initial conditions for the vector of coefficients β and bias term (b) used to determine the decision function, $f(x) = T(x)\beta + b$.
- `fitckernel` does not support standardization and cross-validation options.
- `fitckernel` does not accept table inputs.

Definitions

Random Feature Expansion

Random feature expansion, such as Random Kitchen Sinks[1] and Fastfood[2], is a scheme to approximate Gaussian kernels of the kernel classification algorithm to use for big data in a computationally efficient way. Random feature expansion is more practical for big data applications that have large training sets, but can also be applied to smaller data sets that fit in memory.

The kernel classification algorithm searches for an optimal hyperplane that separates the data into two classes after mapping features into a high-dimensional space. Nonlinear features that are not linearly separable in a low-dimensional space can be separable in the expanded high-dimensional space. All the calculations for hyperplane classification use only dot products. You can obtain a nonlinear classification model by replacing the dot product x_1x_2' with the nonlinear kernel function $G(x_1, x_2) = \langle \varphi(x_1), \varphi(x_2) \rangle$, where x_i is the i th observation (row vector) and $\varphi(x_i)$ is a transformation that maps x_i to a high-dimensional space (called the “kernel trick”). However, evaluating $G(x_1, x_2)$ (Gram matrix) for each pair of observations is computationally expensive for a large data set (large n).

The random feature expansion scheme finds a random transformation so that its dot product approximates the Gaussian kernel. That is,

$$G(x_1, x_2) = \langle \varphi(x_1), \varphi(x_2) \rangle \approx T(x_1)T(x_2)',$$

where $T(x)$ maps x in \mathbb{R}^p to a high-dimensional space (\mathbb{R}^m). The Random Kitchen Sink scheme uses the random transformation

$$T(x) = m^{-1/2} \exp(iZX'),$$

where $Z \in \mathbb{R}^{m \times p}$ is a sample drawn from $N(0, \sigma^{-2})$ and σ^2 is a kernel scale. This scheme requires $O(mp)$ computation and storage. The Fastfood scheme introduces another random basis V instead of Z using Hadamard matrices combined with Gaussian scaling matrices. This random basis reduces the computation cost to $O(m \log p)$ and reduces storage to $O(m)$.

The `fitkernel` function uses the Fastfood scheme for random feature expansion and uses linear classification to train a Gaussian kernel classification model. Unlike solvers in the `fitcsvm` function, which require computation of the n -by- n Gram matrix, the solver in `fitkernel` only needs to form a matrix of size n -by- m , with m typically much less than n for big data.

Box Constraint

A box constraint is a parameter that controls the maximum penalty imposed on margin-violating observations, and aids in preventing overfitting (regularization). Increasing the box constraint can lead to longer training times.

The box constraint (C) and the regularization term strength (λ) are related by $C = 1/(\lambda n)$, where n is the number of observations.

Algorithms

`fitkernel` minimizes the regularized objective function using a Limited-memory Broyden-Fletcher-Goldfarb-Shanno (LBFGS) solver with ridge (L_2) regularization. To find the type of LBFGS solver used for training, type `FitInfo.Solver` in the Command Window.

- 'LBFGS-fast' — LBFGS solver.
- 'LBFGS-blockwise' — LBFGS solver with a block-wise strategy. If `fitkernel` requires more memory than the value of `BlockSize` to hold the transformed predictor data, then it uses a block-wise strategy.

- 'LBFSG-tall' — LBFSG solver with a block-wise strategy for tall arrays.

When `fitckernel` uses a block-wise strategy, `fitckernel` implements LBFSG by distributing the calculation of the loss and gradient among different parts of the data at each iteration. Also, `fitckernel` refines the initial estimates of the linear coefficients and the bias term by fitting the model locally to parts of the data and combining the coefficients by averaging. If you specify 'Verbose', 1, then `fitckernel` displays diagnostic information for each data pass and stores the information in the `History` field of `FitInfo`.

When `fitckernel` does not use a block-wise strategy, the initial estimates are zeros. If you specify 'Verbose', 1, then `fitckernel` displays diagnostic information for each iteration and stores the information in the `History` field of `FitInfo`.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

Usage notes and limitations:

- Some name-value pair arguments have different defaults compared to the default values for the in-memory `fitckernel` function. Supported name-value pair arguments, and any differences, are:

- 'Learner'
- 'NumExpansionDimensions'
- 'KernelScale'
- 'BoxConstraint'
- 'Lambda'
- 'BetaTolerance' — Default value is relaxed to $1e-3$.
- 'GradientTolerance' — Default value is relaxed to $1e-5$.
- 'IterationLimit' — Default value is relaxed to 20.
- 'BlockSize'
- 'RandomStream'
- 'HessianHistorySize'
- 'Verbose' — Default value is 1.
- 'ClassNames'
- 'Cost'
- 'Prior'
- 'ScoreTransform'
- 'Weights' — Value must be a tall array.
- 'OptimizeHyperparameters'
- 'HyperparameterOptimizationOptions' — For cross-validation, tall optimization supports only 'Holdout' validation. For example, you can specify `fitckernel(X,Y,'OptimizeHyperparameters','auto','HyperparameterOptimizationOptions',struct('Holdout',0.2))`.
- If 'KernelScale' is 'auto', then `fitckernel` uses the random stream controlled by `tallrng` for subsampling. For reproducibility, you must set a random number seed for both the global stream and the random stream controlled by `tallrng`.
- If 'Lambda' is 'auto', then `fitckernel` might take an extra pass through the data to calculate the number of observations in X.
- `fitckernel` uses a block-wise strategy. For details, see “Algorithms” on page 32-7430.

For more information, see “Tall Arrays” (MATLAB).

Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the 'UseParallel' option to true.

To perform parallel hyperparameter optimization, use the 'HyperparameterOptions', struct('UseParallel', true) name-value pair argument in the call to this function.

For more information on parallel hyperparameter optimization, see “Parallel Bayesian Optimization” on page 10-8.

For more general information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

Introduced in R2017b

ClassificationKernel

Gaussian kernel classification model using random feature expansion

Description

`ClassificationKernel` is a trained model object for a binary Gaussian kernel classification model using random feature expansion. `ClassificationKernel` is more practical for big data applications that have large training sets but can also be applied to smaller data sets that fit in memory.

Unlike other classification models, and for economical memory usage, `ClassificationKernel` model objects do not store the training data. However, they do store information such as the number of dimensions of the expanded space, the kernel scale parameter, prior-class probabilities, and the regularization strength.

You can use trained `ClassificationKernel` models to continue training using the training data and to predict labels or classification scores for new data. For details, see `resume` and `predict`.

Creation

Create a `ClassificationKernel` object using the `fitckernel` function. This function maps data in a low-dimensional space into a high-dimensional space, then fits a linear model in the high-dimensional space by minimizing the regularized objective function. The linear model in the high-dimensional space is equivalent to the model with a Gaussian kernel in the low-dimensional space. Available linear classification models include regularized support vector machine (SVM) and logistic regression models.

Properties

Kernel Classification Properties

Learner — Linear classification model type

'logistic' | 'svm'

Linear classification model type, specified as 'logistic' or 'svm'.

In the following table, $f(x) = T(x)\beta + b$.

- x is an observation (row vector) from p predictor variables.
- $T(\cdot)$ is a transformation of an observation (row vector) for feature expansion. $T(x)$ maps x in \mathbb{R}^p to a high-dimensional space (\mathbb{R}^m).
- β is a vector of m coefficients.
- b is the scalar bias.

Value	Algorithm	Loss Function	FittedLoss Value
'logistic'	Logistic regression	Deviance (logistic): $\ell[y, f(x)] = \log \{1 + \exp[-yf(x)]\}$	'logit'
'svm'	Support vector machine	Hinge: $\ell[y, f(x)] = \max [0, 1 - yf(x)]$	'hinge'

NumExpansionDimensions — Number of dimensions of expanded space

positive integer

Number of dimensions of the expanded space, specified as a positive integer.

Data Types: single | double

KernelScale — Kernel scale parameter

positive scalar

Kernel scale parameter, specified as a positive scalar.

Data Types: char | single | double

BoxConstraint — Box constraint

positive scalar

Box constraint, specified as a positive scalar.

Data Types: double | single

Lambda — Regularization term strength

nonnegative scalar

Regularization term strength, specified as a nonnegative scalar.

Data Types: `single` | `double`

FittedLoss — Loss function used to fit linear model

'hinge' | 'logit'

Loss function used to fit the linear model, specified as 'hinge' or 'logit'.

Value	Algorithm	Loss Function	Learner Value
'hinge'	Support vector machine	Hinge: $\ell[y, f(x)] = \max[0, 1 - yf(x)]$	'svm'
'logit'	Logistic regression	Deviance (logistic): $\ell[y, f(x)] = \log\{1 + \exp[-yf(x)]\}$	'logistic'

Regularization — Complexity penalty type

'ridge (L2)'

Complexity penalty type, which is always 'ridge (L2)'.

The software composes the objective function for minimization from the sum of the average loss function (see `FittedLoss`) and the regularization term, ridge (L_2) penalty.

The ridge (L_2) penalty is

$$\frac{\lambda}{2} \sum_{j=1}^p \beta_j^2$$

where λ specifies the regularization term strength (see `Lambda`). The software excludes the bias term (β_0) from the regularization penalty.

Other Classification Properties

CategoricalPredictors — Indices of categorical predictors

[]

Indices of categorical predictors, whose value is always empty ([]) because a `ClassificationKernel` model does not support categorical predictors.

ClassNames — Unique class labels

categorical array | character array | logical vector | numeric vector | cell array of character vectors

Unique class labels used in training, specified as a categorical or character array, logical or numeric vector, or cell array of character vectors. `ClassNames` has the same data type as the class labels Y . (The software treats string arrays as cell arrays of character vectors.) `ClassNames` also determines the class order.

Data Types: categorical | char | logical | single | double | cell

Cost — Misclassification costs

square numeric matrix

This property is read-only.

Misclassification costs, specified as a square numeric matrix. `Cost` has K rows and columns, where K is the number of classes.

$\text{Cost}(i, j)$ is the cost of classifying a point into class j if its true class is i . The order of the rows and columns of `Cost` corresponds to the order of the classes in `ClassNames`.

Data Types: double

ModelParameters — Parameters used for training model

structure

Parameters used for training the `ClassificationKernel` model, specified as a structure.

Access fields of `ModelParameters` using dot notation. For example, access the relative tolerance on the linear coefficients and the bias term by using `Mdl.ModelParameters.BetaTolerance`.

Data Types: struct

PredictorNames — Predictor names

cell array of character vectors

Predictor names in order of their appearance in the predictor data X , specified as a cell array of character vectors. The length of `PredictorNames` is equal to the number of columns in X .

Data Types: cell

ExpandedPredictorNames — Expanded predictor names

cell array of character vectors

Expanded predictor names, specified as a cell array of character vectors.

Because a `ClassificationKernel` model does not support categorical predictors, `ExpandedPredictorNames` and `PredictorNames` are equal.

Data Types: `cell`

Prior — Prior class probabilities

numeric vector

This property is read-only.

Prior class probabilities, specified as a numeric vector. `Prior` has as many elements as classes in `ClassNames`, and the order of the elements corresponds to the elements of `ClassNames`.

Data Types: `double`

ScoreTransform — Score transformation function to apply to predicted scores

'doublelogit' | 'invlogit' | 'ismax' | 'logit' | 'none' | function handle | ...

Score transformation function to apply to predicted scores, specified as a function name or function handle.

For kernel classification models and before the score transformation, the predicted classification score for the observation x (row vector) is $f(x) = T(x)\beta + b$.

- $T(\cdot)$ is a transformation of an observation for feature expansion.
- β is the estimated column vector of coefficients.
- b is the estimated scalar bias.

To change the score transformation function to *function*, for example, use dot notation.

- For a built-in function, enter this code and replace *function* with a value from the table.

```
Mdl.ScoreTransform = 'function';
```

Value	Description
'doublelogit'	$1/(1 + e^{-2x})$
'invlogit'	$\log(x / (1 - x))$
'ismax'	Sets the score for the class with the largest score to 1, and sets the scores for all other classes to 0
'logit'	$1/(1 + e^{-x})$
'none' or 'identity'	x (no transformation)
'sign'	-1 for $x < 0$ 0 for $x = 0$ 1 for $x > 0$
'symmetric'	$2x - 1$
'symmetricismax'	Sets the score for the class with the largest score to 1, and sets the scores for all other classes to -1
'symmetriclogit'	$2/(1 + e^{-x}) - 1$

- For a MATLAB function, or a function that you define, enter its function handle.

```
Mdl.ScoreTransform = @function;
```

function must accept a matrix of the original scores for each class, and then return a matrix of the same size representing the transformed scores for each class.

Data Types: char | function_handle

ResponseName — Response variable name

character vector

Response variable name, specified as a character vector.

Data Types: char

Object Functions

edge Classification edge for Gaussian kernel classification model
 loss Classification loss for Gaussian kernel classification model
 margin Classification margins for Gaussian kernel classification model

predict Predict labels for Gaussian kernel classification model
resume Resume training of Gaussian kernel classification model

Examples

Train Kernel Classification Model

Train a binary kernel classification model using SVM.

Load the `ionosphere` data set. This data set has 34 predictors and 351 binary responses for radar returns, either bad ('b') or good ('g').

```
load ionosphere
[n,p] = size(X)

n = 351

p = 34

resp = unique(Y)

resp = 2x1 cell array
    {'b'}
    {'g'}
```

Train a binary kernel classification model that identifies whether the radar return is bad ('b') or good ('g'). Extract a fit summary to determine how well the optimization algorithm fits the model to the data.

```
rng('default') % For reproducibility
[Mdl,FitInfo] = fitckernel(X,Y)

Mdl =
  ClassificationKernel
      ResponseName: 'Y'
      ClassNames: {'b' 'g'}
      Learner: 'svm'
      NumExpansionDimensions: 2048
      KernelScale: 1
      Lambda: 0.0028
      BoxConstraint: 1
```

Properties, Methods

```
FitInfo = struct with fields:
    Solver: 'LBFGS-fast'
    LossFunction: 'hinge'
    Lambda: 0.0028
    BetaTolerance: 1.0000e-04
    GradientTolerance: 1.0000e-06
    ObjectiveValue: 0.2604
    GradientMagnitude: 0.0028
    RelativeChangeInBeta: 8.2512e-05
    FitTime: 0.1775
    History: []
```

`Mdl` is a `ClassificationKernel` model. To inspect the in-sample classification error, you can pass `Mdl` and the training data or new data to the `loss` function. Or, you can pass `Mdl` and new predictor data to the `predict` function to predict class labels for new observations. You can also pass `Mdl` and the training data to the `resume` function to continue training.

`FitInfo` is a structure array containing optimization information. Use `FitInfo` to determine whether optimization termination measurements are satisfactory.

For better accuracy, you can increase the maximum number of optimization iterations (`'IterationLimit'`) and decrease the tolerance values (`'BetaTolerance'` and `'GradientTolerance'`) by using the name-value pair arguments. Doing so can improve measures like `ObjectiveValue` and `RelativeChangeInBeta` in `FitInfo`. You can also optimize model parameters by using the `'OptimizeHyperparameters'` name-value pair argument.

Predict Class Labels and Resume Training

Load the `ionosphere` data set. This data set has 34 predictors and 351 binary responses for radar returns, either bad (`'b'`) or good (`'g'`).

```
load ionosphere
```

Partition the data set into training and test sets. Specify a 20% holdout sample for the test set.

```

rng('default') % For reproducibility
Partition = cvpartition(Y,'Holdout',0.20);
trainingInds = training(Partition); % Indices for the training set
XTrain = X(trainingInds,:);
YTrain = Y(trainingInds);
testInds = test(Partition); % Indices for the test set
XTest = X(testInds,:);
YTest = Y(testInds);

```

Train a binary kernel classification model that identifies whether the radar return is bad ('b') or good ('g').

```
Mdl = fitckernel(XTrain,YTrain,'IterationLimit',5,'Verbose',1);
```

Solver	Pass	Iteration	Objective	Step	Gradient magnitude	char
LBFGS	1	0	1.000000e+00	0.000000e+00	2.811388e-01	
LBFGS	1	1	7.585395e-01	4.000000e+00	3.594306e-01	1
LBFGS	1	2	7.160994e-01	1.000000e+00	2.028470e-01	6
LBFGS	1	3	6.825272e-01	1.000000e+00	2.846975e-02	2
LBFGS	1	4	6.699435e-01	1.000000e+00	1.779359e-02	1
LBFGS	1	5	6.535619e-01	1.000000e+00	2.669039e-01	4

Mdl is a `ClassificationKernel` model.

Predict the test-set labels, construct a confusion matrix for the test set, and estimate the classification error for the test set.

```

label = predict(Mdl,XTest);
ConfusionTest = confusionchart(YTest,label);

```

```
L = loss(Mdl,XTest,YTest)
```

```
L = 0.3594
```

Mdl misclassifies all bad radar returns as good returns.

Continue training by using `resume`. This function continues training with the same options used for training Mdl.

```
UpdatedMdl = resume(Mdl,XTrain,YTrain);
```

Predict the test-set labels, construct a confusion matrix for the test set, and estimate the classification error for the test set.

```
UpdatedLabel = predict(UpdatedMdl,XTest);
UpdatedConfusionTest = confusionchart(YTest,UpdatedLabel);
```

```
UpdatedL = loss(UpdatedMdl,XTest,YTest)
```

```
UpdatedL = 0.1284
```

The classification error decreases after resume updates the classification model with more iterations.

Introduced in R2017b

edge

Classification edge for Gaussian kernel classification model

Syntax

```
e = edge(Mdl,X,Y)
e = edge(Mdl,X,Y,'Weights',weights)
```

Description

`e = edge(Mdl,X,Y)` returns the classification edge on page 32-7452 for the binary Gaussian kernel classification model `Mdl` using the predictor data in `X` and the corresponding class labels in `Y`.

`e = edge(Mdl,X,Y,'Weights',weights)` returns the weighted classification edges for the observation weights supplied in `weights`.

Examples

Estimate Test-Set Edge

Load the `ionosphere` data set. This data set has 34 predictors and 351 binary responses for radar returns, either bad ('b') or good ('g').

```
load ionosphere
```

Partition the data set into training and test sets. Specify a 15% holdout sample for the test set.

```
rng('default') % For reproducibility
Partition = cvpartition(Y,'Holdout',0.15);
trainingInds = training(Partition); % Indices for the training set
testInds = test(Partition); % Indices for the test set
```

Train a binary kernel classification model using the training set.

```
Mdl = fitckernel(X(trainingInds,:),Y(trainingInds));
```

Estimate the training-set edge and the test-set edge.

```
eTrain = edge(Mdl,X(trainingInds,:),Y(trainingInds))
```

```
eTrain = 2.1703
```

```
eTest = edge(Mdl,X(testInds,:),Y(testInds))
```

```
eTest = 1.5643
```

Feature Selection Using Test-Set Edges

Perform feature selection by comparing test-set edges from multiple models. Based solely on this criterion, the classifier with the highest edge is the best classifier.

Load the `ionosphere` data set. This data set has 34 predictors and 351 binary responses for radar returns, either bad ('b') or good ('g').

```
load ionosphere
```

Partition the data set into training and test sets. Specify a 15% holdout sample for the test set.

```
rng('default') % For reproducibility
Partition = cvpartition(Y,'Holdout',0.15);
trainingInds = training(Partition); % Indices for the training set
XTrain = X(trainingInds,:);
YTrain = Y(trainingInds);
testInds = test(Partition); % Indices for the test set
XTest = X(testInds,:);
YTest = Y(testInds);
```

Randomly choose half of the predictor variables.

```
p = size(X,2); % Number of predictors
idxPart = randsample(p,ceil(0.5*p));
```

Train two binary kernel classification models: one that uses all of the predictors, and one that uses half of the predictors.

```
Mdl = fitkernel(XTrain,YTrain);  
PMdl = fitkernel(XTrain(:,idxPart),YTrain);
```

Mdl and PMdl are ClassificationKernel models.

Estimate the test-set edge for each classifier.

```
fullEdge = edge(Mdl,XTest,YTest)
```

```
fullEdge = 1.6335
```

```
partEdge = edge(PMdl,XTest(:,idxPart),YTest)
```

```
partEdge = 2.0205
```

Based on the test-set edges, the classifier that uses half of the predictors is the better model.

Input Arguments

Mdl — Binary kernel classification model

ClassificationKernel model object

Binary kernel classification model, specified as a ClassificationKernel model object. You can create a ClassificationKernel model object using fitkernel.

X — Predictor data

n-by-*p* numeric matrix

Predictor data, specified as an *n*-by-*p* numeric matrix, where *n* is the number of observations and *p* is the number of predictors used to train Mdl.

The length of Y and the number of observations in X must be equal.

Data Types: single | double

Y — Class labels

categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Class labels, specified as a categorical, character, or string array, logical or numeric vector, or cell array of character vectors.

- The data type of Y must be the same as the data type of `Mdl.ClassNames`. (The software treats string arrays as cell arrays of character vectors.)
- The distinct classes in Y must be a subset of `Mdl.ClassNames`.
- If Y is a character array, then each element must correspond to one row of the array.
- The length of Y and the number of observations in X must be equal.

Data Types: `categorical` | `char` | `string` | `logical` | `single` | `double` | `cell`

weights — Observation weights

positive numeric vector

Observation weights, specified as a positive numeric vector of length n , where n is the number of observations in X . If you supply weights, `edge` computes the weighted classification edge on page 32-7452.

The default value is `ones(n,1)`.

`edge` normalizes `weights` to sum up to the value of the prior probability in the respective class.

Data Types: `double` | `single`

Output Arguments

e — Classification edge

numeric scalar

Classification edge on page 32-7452, returned as a numeric scalar.

Definitions

Classification Edge

The classification edge is the weighted mean of the classification margins.

One way to choose among multiple classifiers, for example to perform feature selection, is to choose the classifier that yields the greatest edge.

Classification Margin

The classification margin for binary classification is, for each observation, the difference between the classification score for the true class and the classification score for the false class.

The software defines the classification margin for binary classification as

$$m = 2yf(x).$$

x is an observation. If the true label of x is the positive class, then y is 1, and -1 otherwise. $f(x)$ is the positive-class classification score for the observation x . The classification margin is commonly defined as $m = yf(x)$.

If the margins are on the same scale, then they serve as a classification confidence measure. Among multiple classifiers, those that yield greater margins are better.

Classification Score

For kernel classification models, the raw classification score for classifying the observation x , a row vector, into the positive class is defined by

$$f(x) = T(x)\beta + b.$$

- $T(\cdot)$ is a transformation of an observation for feature expansion.
- β is the estimated column vector of coefficients.
- b is the estimated scalar bias.

The raw classification score for classifying x into the negative class is $-f(x)$. The software classifies observations into the class that yields a positive score.

If the kernel classification model consists of logistic regression learners, then the software applies the 'logit' score transformation to the raw classification scores (see `ScoreTransform`).

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. For more information, see “Tall Arrays” (MATLAB).

Introduced in R2017b

loss

Classification loss for Gaussian kernel classification model

Syntax

```
L = loss(Mdl,X,Y)
L = loss(Mdl,X,Y,Name,Value)
```

Description

`L = loss(Mdl,X,Y)` returns the classification loss on page 32-7460 for the binary Gaussian kernel classification model `Mdl` using the predictor data in `X` and the corresponding class labels in `Y`.

`L = loss(Mdl,X,Y,Name,Value)` uses additional options specified by one or more name-value pair arguments. For example, you can specify a classification loss function and observation weights. Then, `loss` returns the weighted classification loss using the specified loss function.

Examples

Estimate Test-Set Classification Loss

Load the ionosphere data set. This data set has 34 predictors and 351 binary responses for radar returns, either bad ('b') or good ('g').

```
load ionosphere
```

Partition the data set into training and test sets. Specify a 15% holdout sample for the test set.

```
rng('default') % For reproducibility
Partition = cvpartition(Y,'Holdout',0.15);
trainingInds = training(Partition); % Indices for the training set
testInds = test(Partition); % Indices for the test set
```

Train a binary kernel classification model using the training set.

```
Mdl = fitckernel(X(trainingInds,:),Y(trainingInds));
```

Estimate the training-set classification error and the test-set classification error.

```
ceTrain = loss(Mdl,X(trainingInds,:),Y(trainingInds))
```

```
ceTrain = 0.0067
```

```
ceTest = loss(Mdl,X(testInds,:),Y(testInds))
```

```
ceTest = 0.1140
```

Specify Custom Classification Loss

Load the `ionosphere` data set. This data set has 34 predictors and 351 binary responses for radar returns, either bad ('b') or good ('g').

```
load ionosphere
```

Partition the data set into training and test sets. Specify a 15% holdout sample for the test set.

```
rng('default') % For reproducibility
Partition = cvpartition(Y,'Holdout',0.15);
trainingInds = training(Partition); % Indices for the training set
testInds = test(Partition); % Indices for the test set
```

Train a binary kernel classification model using the training set.

```
Mdl = fitckernel(X(trainingInds,:),Y(trainingInds));
```

Create an anonymous function that measures linear loss, that is,

$$L = \frac{\sum_j -w_j y_j f_j}{\sum_j w_j}.$$

w_j is the weight for observation j , y_j is response j (-1 for the negative class, and 1 otherwise), and f_j is the raw classification score of observation j .

```
linearloss = @(C,S,W,Cost)sum(-W.*sum(S.*C,2))/sum(W);
```

Custom loss functions must be written in a particular form. For rules on writing a custom loss function, see the 'LossFun' name-value pair argument.

Estimate the training-set classification loss and the test-set classification loss using the linear loss function.

```
ceTrain = loss(Mdl,X(trainingInds,:),Y(trainingInds),'LossFun',linearloss)
ceTrain = -1.0851
ceTest = loss(Mdl,X(testInds,:),Y(testInds),'LossFun',linearloss)
ceTest = -0.7821
```

Input Arguments

Mdl — Binary kernel classification model

ClassificationKernel model object

Binary kernel classification model, specified as a ClassificationKernel model object. You can create a ClassificationKernel model object using fitckernel.

X — Predictor data

n -by- p numeric matrix

Predictor data, specified as an n -by- p numeric matrix, where n is the number of observations and p is the number of predictors used to train Mdl.

The length of Y and the number of observations in X must be equal.

Data Types: single | double

Y — Class labels

categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Class labels, specified as a categorical, character, or string array, logical or numeric vector, or cell array of character vectors.

- The data type of Y must be the same as the data type of Mdl.ClassNames. (The software treats string arrays as cell arrays of character vectors.)

- The distinct classes in `Y` must be a subset of `Mdl.ClassNames`.
- If `Y` is a character array, then each element must correspond to one row of the array.
- The length of `Y` and the number of observations in `X` must be equal.

Data Types: `categorical` | `char` | `string` | `logical` | `single` | `double` | `cell`

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `L = loss(Mdl,X,Y,'LossFun','quadratic','Weights',weights)` returns the weighted classification loss using the quadratic loss function.

LossFun — Loss function

'`classiferror`' (default) | '`binodeviance`' | '`exponential`' | '`hinge`' | '`logit`' | '`mincost`' | '`quadratic`' | function handle

Loss function, specified as the comma-separated pair consisting of '`LossFun`' and a built-in loss function name or a function handle.

- This table lists the available loss functions. Specify one using its corresponding value.

Value	Description
' <code>binodeviance</code> '	Binomial deviance
' <code>classiferror</code> '	Classification error
' <code>exponential</code> '	Exponential
' <code>hinge</code> '	Hinge
' <code>logit</code> '	Logistic
' <code>mincost</code> '	Minimal expected misclassification cost (for classification scores that are posterior probabilities)
' <code>quadratic</code> '	Quadratic

'mincost' is appropriate for classification scores that are posterior probabilities. For kernel classification models, logistic regression learners return posterior probabilities as classification scores by default, but SVM learners do not (see `predict`).

- Specify your own function by using function handle notation.

Let n be the number of observations in X and K be the number of distinct classes (`numel(Mdl.ClassNames)`, where `Mdl` is the input model). Your function must have this signature:

```
lossvalue = lossfun(C,S,W,Cost)
```

- The output argument `lossvalue` is a scalar.
- You choose the function name (*lossfun*).
- C is an n -by- K logical matrix with rows indicating the class to which the corresponding observation belongs. The column order corresponds to the class order in `Mdl.ClassNames`.

Construct C by setting $C(p, q) = 1$, if observation p is in class q , for each row. Set all other elements of row p to 0 .

- S is an n -by- K numeric matrix of classification scores. The column order corresponds to the class order in `Mdl.ClassNames`. S is a matrix of classification scores, similar to the output of `predict`.
- W is an n -by-1 numeric vector of observation weights. If you pass W , the software normalizes the weights to sum to 1.
- $Cost$ is a K -by- K numeric matrix of misclassification costs. For example, $Cost = ones(K) - eye(K)$ specifies a cost of 0 for correct classification, and 1 for misclassification.

Example: 'LossFun',@*lossfun*

Data Types: char | string | function_handle

Weights — Observation weights

positive numeric vector

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a positive numeric vector of length n , where n is the number of observations in X . If you supply weights, `loss` computes the weighted classification loss on page 32-7460.

The default value is `ones(n,1)`.

Loss normalizes weights to sum up to the value of the prior probability in the respective class.

Data Types: `double` | `single`

Output Arguments

L — Classification loss

numeric scalar

Classification loss on page 32-7460, returned as a numeric scalar. The interpretation of **L** depends on **Weights** and **LossFun**.

Definitions

Classification Loss

Classification loss functions measure the predictive inaccuracy of classification models. When you compare the same type of loss among many models, a lower loss indicates a better predictive model.

Suppose the following:

- L is the weighted average classification loss.
- n is the sample size.
- y_j is the observed class label. The software codes it as -1 or 1, indicating the negative or positive class, respectively.
- $f(X_j)$ is the raw classification score for the transformed observation (row) j of the predictor data X using feature expansion.
- $m_j = y_j f(X_j)$ is the classification score for classifying observation j into the class corresponding to y_j . Positive values of m_j indicate correct classification and do not contribute much to the average loss. Negative values of m_j indicate incorrect classification and contribute to the average loss.
- The weight for observation j is w_j . The software normalizes the observation weights so that they sum to the corresponding prior class probability. The software also normalizes the prior probabilities so that they sum to 1. Therefore,

$$\sum_{j=1}^n w_j = 1.$$

This table describes the supported loss functions that you can specify by using the 'LossFun' name-value pair argument.

Loss Function	Value of LossFun	Equation
Binomial deviance	'binodeviance'	$L = \sum_{j=1}^n w_j \log\{1 + \exp[-2m_j]\}.$

`ClassificationKernel` | `fitckernel` | `predict`

Introduced in R2017b

margin

Classification margins for Gaussian kernel classification model

Syntax

```
m = margin(Mdl,X,Y)
```

Description

`m = margin(Mdl,X,Y)` returns the classification margins on page 32-7470 for the binary Gaussian kernel classification model `Mdl` using the predictor data in `X` and the corresponding class labels in `Y`.

Examples

Estimate Test-Set Margins

Load the ionosphere data set. This data set has 34 predictors and 351 binary responses for radar returns, either bad ('b') or good ('g').

```
load ionosphere
```

Partition the data set into training and test sets. Specify a 30% holdout sample for the test set.

```
rng('default') % For reproducibility
Partition = cvpartition(Y,'Holdout',0.30);
trainingInds = training(Partition); % Indices for the training set
testInds = test(Partition); % Indices for the test set
```

Train a binary kernel classification model using the training set.

```
Mdl = fitkernel(X(trainingInds,:),Y(trainingInds));
```

Estimate the training-set margins and test-set margins.

```
mTrain = margin(Mdl,X(trainingInds,:),Y(trainingInds));  
mTest = margin(Mdl,X(testInds,:),Y(testInds));
```

Plot both sets of margins using box plots.

```
boxplot([mTrain; mTest],[zeros(size(mTrain,1),1); ones(size(mTest,1),1)], ...  
    'Labels',{'Training set','Test set'});  
title('Training-Set and Test-Set Margins')
```

The margin distribution of the training set is situated higher than the margin distribution of the test set.

Feature Selection Using Test-Set Margins

Perform feature selection by comparing test-set margins from multiple models. Based solely on this criterion, the classifier with the larger margins is the better classifier.

Load the `ionosphere` data set. This data set has 34 predictors and 351 binary responses for radar returns, either bad ('b') or good ('g').

```
load ionosphere
```

Partition the data set into training and test sets. Specify a 15% holdout sample for the test set.

```
rng('default') % For reproducibility
Partition = cvpartition(Y,'Holdout',0.15);
trainingInds = training(Partition); % Indices for the training set
XTrain = X(trainingInds,:);
YTrain = Y(trainingInds);
testInds = test(Partition); % Indices for the test set
XTest = X(testInds,:);
YTest = Y(testInds);
```

Randomly choose 10% of the predictor variables.

```
p = size(X,2); % Number of predictors
idxPart = randsample(p,ceil(0.1*p));
```

Train two binary kernel classification models: one that uses all of the predictors, and one that uses the random 10%.

```
Mdl = fitckernel(XTrain,YTrain);
PMdl = fitckernel(XTrain(:,idxPart),YTrain);
```

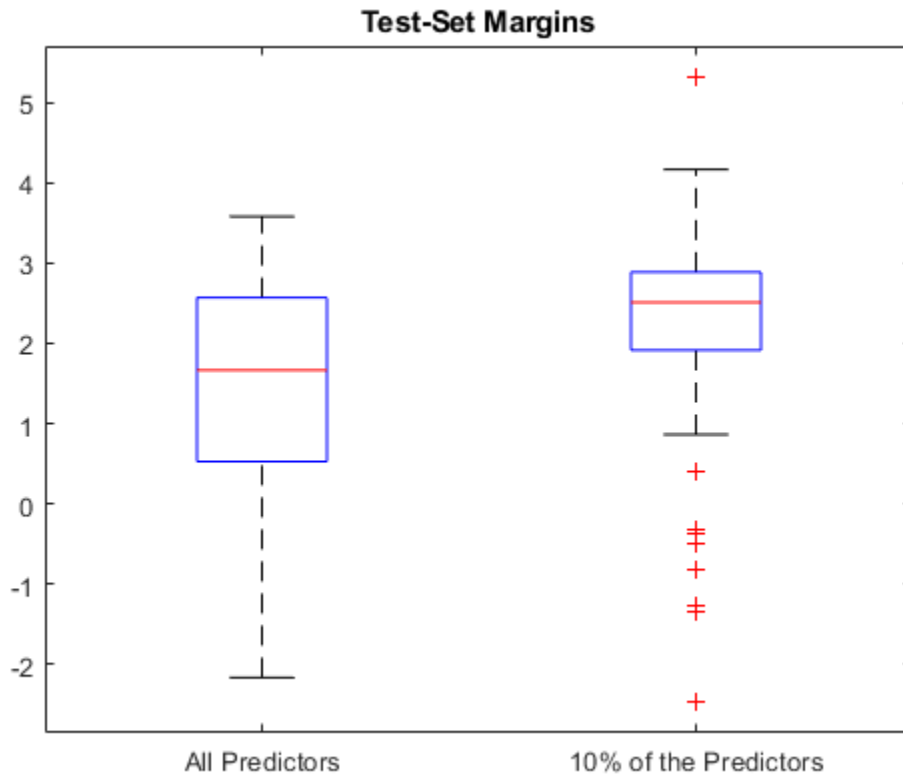

`Mdl` and `PMdl` are `ClassificationKernel` models.

Estimate the test-set margins for each classifier.

```
fullMargins = margin(Mdl,XTest,YTest);
partMargins = margin(PMdl,XTest(:,idxPart),YTest);
```

Plot the distribution of the margin sets using box plots.

```
boxplot([fullMargins partMargins], ...
        'Labels',{'All Predictors','10% of the Predictors'});
title('Test-Set Margins')
```

The margin distribution of PMdL is situated higher than the margin distribution of MdL. Therefore, the PMdL model is the better classifier.

Input Arguments

MdL — Binary kernel classification model

`ClassificationKernel` model object

Binary kernel classification model, specified as a `ClassificationKernel` model object. You can create a `ClassificationKernel` model object using `fitckernel`.

X — Predictor data

n-by-*p* numeric matrix

Predictor data, specified as an *n*-by-*p* numeric matrix, where *n* is the number of observations and *p* is the number of predictors used to train `Mdl`.

The length of `Y` and the number of observations in `X` must be equal.

Data Types: `single` | `double`

Y — Class labels

categorical array | character array | string array | logical vector | numeric vector | cell array of character vectors

Class labels, specified as a categorical, character, or string array, logical or numeric vector, or cell array of character vectors.

- The data type of `Y` must be the same as the data type of `Mdl.ClassNames`. (The software treats string arrays as cell arrays of character vectors.)
- The distinct classes in `Y` must be a subset of `Mdl.ClassNames`.
- If `Y` is a character array, then each element must correspond to one row of the array.
- The length of `Y` and the number of observations in `X` must be equal.

Data Types: `categorical` | `char` | `string` | `logical` | `single` | `double` | `cell`

Output Arguments

m — Classification margins

numeric column vector

Classification margins on page 32-7470, returned as an *n*-by-1 numeric column vector, where *n* is the number of observations in `X`.

Definitions

Classification Margin

The classification margin for binary classification is, for each observation, the difference between the classification score for the true class and the classification score for the false class.

The software defines the classification margin for binary classification as

$$m = 2yf(x).$$

x is an observation. If the true label of x is the positive class, then y is 1, and -1 otherwise. $f(x)$ is the positive-class classification score for the observation x . The classification margin is commonly defined as $m = yf(x)$.

If the margins are on the same scale, then they serve as a classification confidence measure. Among multiple classifiers, those that yield greater margins are better.

Classification Score

For kernel classification models, the raw classification score for classifying the observation x , a row vector, into the positive class is defined by

$$f(x) = T(x)\beta + b.$$

- $T(\cdot)$ is a transformation of an observation for feature expansion.
- β is the estimated column vector of coefficients.
- b is the estimated scalar bias.

The raw classification score for classifying x into the negative class is $-f(x)$. The software classifies observations into the class that yields a positive score.

If the kernel classification model consists of logistic regression learners, then the software applies the 'logit' score transformation to the raw classification scores (see `ScoreTransform`).

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. For more information, see “Tall Arrays” (MATLAB).

`ClassificationKernel` | `edge` | `fitckernel` | `predict`

Introduced in R2017b

predict

Predict labels for Gaussian kernel classification model

Syntax

```
Label = predict(Mdl,X)
[Label,Score] = predict(Mdl,X)
```

Description

`Label = predict(Mdl,X)` returns predicted class labels for each observation in the predictor data `X` based on the binary Gaussian kernel classification model `Mdl`.

`[Label,Score] = predict(Mdl,X)` also returns classification scores on page 32-7479 for both classes.

Examples

Predict Training Set Labels

Predict the training set labels using a binary kernel classification model, and display the confusion matrix for the resulting classification.

Load the `ionosphere` data set. This data set has 34 predictors and 351 binary responses for radar returns, either bad ('b') or good ('g').

```
load ionosphere
```

Train a binary kernel classification model that identifies whether the radar return is bad ('b') or good ('g').

```
rng('default') % For reproducibility
Mdl = fitckernel(X,Y);
```

`Mdl` is a `ClassificationKernel` model.

Predict the training set, or resubstitution, labels.

```
label = predict(Mdl,X);
```

Construct a confusion matrix.

```
ConfusionTrain = confusionchart(Y,label);
```

The model misclassifies one radar return for each class.

Predict Test Set Labels

Predict the test set labels using a binary kernel classification model, and display the confusion matrix for the resulting classification.

Load the `ionosphere` data set. This data set has 34 predictors and 351 binary responses for radar returns, either bad ('b') or good ('g').

```
load ionosphere
```

Partition the data set into training and test sets. Specify a 15% holdout sample for the test set.

```
rng('default') % For reproducibility
Partition = cvpartition(Y,'Holdout',0.15);
trainingInds = training(Partition); % Indices for the training set
testInds = test(Partition); % Indices for the test set
```

Train a binary kernel classification model using the training set. A good practice is to define the class order.

```
Mdl = fitkernel(X(trainingInds,:),Y(trainingInds),'ClassNames',{'b','g'});
```

Predict the training-set labels and the test set labels.

```
labelTrain = predict(Mdl,X(trainingInds,:));
labelTest = predict(Mdl,X(testInds,:));
```

Construct a confusion matrix for the training set.

```
ConfusionTrain = confusionchart(Y(trainingInds),labelTrain);
```

The model misclassifies only one radar return for each class.

Construct a confusion matrix for the test set.

```
ConfusionTest = confusionchart(Y(testInds),labelTest);
```

The model misclassifies one bad radar return as being a good return, and five good radar returns as being bad returns.

Estimate Posterior Class Probabilities

Estimate posterior class probabilities for a test set, and determine the quality of the model by plotting a receiver operating characteristic (ROC) curve. Kernel classification models return posterior probabilities for logistic regression learners only.

Load the `ionosphere` data set. This data set has 34 predictors and 351 binary responses for radar returns, either bad ('b') or good ('g').

```
load ionosphere
```

Partition the data set into training and test sets. Specify a 30% holdout sample for the test set.

```
rng('default') % For reproducibility
Partition = cvpartition(Y,'Holdout',0.30);
trainingInds = training(Partition); % Indices for the training set
testInds = test(Partition); % Indices for the test set
```

Train a binary kernel classification model. Fit logistic regression learners.

```
Mdl = fitckernel(X(trainingInds,:),Y(trainingInds), ...
    'ClassNames',{'b','g'},'Learner','logistic');
```

Predict the posterior class probabilities for the test set.

```
[~,posterior] = predict(Mdl,X(testInds,:));
```

Because `Mdl` has one regularization strength, the output `posterior` is a matrix with two columns and rows equal to the number of test-set observations. Column `i` contains posterior probabilities of `Mdl.ClassNames(i)` given a particular observation.

Obtain false and true positive rates, and estimate the area under the curve (AUC). Specify that the second class is the positive class.

```
[fpr,tpr,~,auc] = perfcurve(Y(testInds),posterior(:,2),Mdl.ClassNames(2));
auc
```

```
auc = 0.9042
```

The AUC is close to 1, which indicates that the model predicts labels well.

Plot an ROC curve.

```
figure;
plot(fpr,tpr)
h = gca;
h.XLim(1) = -0.1;
h.YLim(2) = 1.1;
xlabel('False positive rate')
ylabel('True positive rate')
title('ROC Curve')
```

Input Arguments

Mdl — Binary kernel classification model

ClassificationKernel model object

Binary kernel classification model, specified as a *ClassificationKernel* model object. You can create a *ClassificationKernel* model object using `fitckernel`.

X — Predictor data

n-by-*p* numeric matrix

Predictor data, specified as an n -by- p numeric matrix, where n is the number of observations and p is the number of predictors used to train MdL .

Data Types: `single` | `double`

Output Arguments

Label — Predicted class labels

categorical array | character array | logical matrix | numeric matrix | cell array of character vectors

Predicted class labels, returned as a categorical or character array, logical or numeric matrix, or cell array of character vectors.

Label has n rows, where n is the number of observations in X , and has the same data type as the observed class labels (Y) used to train MdL . (The software treats string arrays as cell arrays of character vectors.)

`predict` classifies observations into the class yielding the highest score.

Score — Classification scores

numeric array

Classification scores on page 32-7479, returned as an n -by-2 numeric array, where n is the number of observations in X . $\text{Score}(i, j)$ is the score for classifying observation i into class j . $MdL.ClassNames$ stores the order of the classes.

If $MdL.Learner$ is `'logistic'`, then classification scores are posterior probabilities.

Definitions

Classification Score

For kernel classification models, the raw classification score for classifying the observation x , a row vector, into the positive class is defined by

$$f(x) = T(x)\beta + b.$$

- $T(\cdot)$ is a transformation of an observation for feature expansion.
- β is the estimated column vector of coefficients.
- b is the estimated scalar bias.

The raw classification score for classifying x into the negative class is $-f(x)$. The software classifies observations into the class that yields a positive score.

If the kernel classification model consists of logistic regression learners, then the software applies the 'logit' score transformation to the raw classification scores (see `ScoreTransform`).

`ClassificationKernel` | `confusionchart` | `fitckernel` | `perfcurve` | `resume`

Introduced in R2017b

resume

Resume training of Gaussian kernel classification model

Syntax

```
UpdatedMdl = resume(Mdl,X,Y)
UpdatedMdl = resume(Mdl,X,Y,Name,Value)
[UpdatedMdl,FitInfo] = resume(____)
```

Description

`UpdatedMdl = resume(Mdl,X,Y)` continues training with the same options used to train `Mdl`, including the training data (predictor data in `X` and class labels in `Y`) and the feature expansion. The training starts at the current estimated parameters in `Mdl`. The function returns a new binary Gaussian kernel classification model `UpdatedMdl`.

`UpdatedMdl = resume(Mdl,X,Y,Name,Value)` returns a new binary Gaussian kernel classification model with additional options specified by one or more name-value pair arguments. For example, you can modify convergence control options, such as convergence tolerances and the maximum number of additional optimization iterations.

`[UpdatedMdl,FitInfo] = resume(____)` also returns the fit information in the structure array `FitInfo` using any of the previous input arguments in the syntaxes.

Examples

Predict Class Labels and Resume Training

Load the ionosphere data set. This data set has 34 predictors and 351 binary responses for radar returns, either bad ('b') or good ('g').

```
load ionosphere
```

Partition the data set into training and test sets. Specify a 20% holdout sample for the test set.

```
rng('default') % For reproducibility
Partition = cvpartition(Y,'Holdout',0.20);
trainingInds = training(Partition); % Indices for the training set
XTrain = X(trainingInds,:);
YTrain = Y(trainingInds);
testInds = test(Partition); % Indices for the test set
XTest = X(testInds,:);
YTest = Y(testInds);
```

Train a binary kernel classification model that identifies whether the radar return is bad ('b') or good ('g').

```
Mdl = fitkernel(XTrain,YTrain,'IterationLimit',5,'Verbose',1);
```

Solver	Pass	Iteration	Objective	Step	Gradient magnitude	char
LBFGS	1	0	1.000000e+00	0.000000e+00	2.811388e-01

LBFGS	1	5	6.535619e-01	1.000000e+00	2.669039e-01	4

Mdl is a `ClassificationKernel` model.

Predict the test-set labels, construct a confusion matrix for the test set, and estimate the classification error for the test set.

```
label = predict(Mdl,XTest);
ConfusionTest = confusionchart(YTest,label);
```

```
L = loss(Mdl,XTest,YTest)
```

```
L = 0.3594
```

Mdl misclassifies all bad radar returns as good returns.

Continue training by using `resume`. This function continues training with the same options used for training Mdl.

```
UpdatedMdl = resume(Mdl,XTrain,YTrain);
```

Predict the test-set labels, construct a confusion matrix for the test set, and estimate the classification error for the test set.

```
UpdatedLabel = predict(UpdatedMdl,XTest);
UpdatedConfusionTest = confusionchart(YTest,UpdatedLabel);
```

```
UpdatedL = loss(UpdatedMdl,XTest,YTest)
```

```
UpdatedL = 0.1284
```

The classification error decreases after resume updates the classification model with more iterations.

Resume Training with Modified Convergence Control Training Options

Load the `ionosphere` data set. This data set has 34 predictors and 351 binary responses for radar returns, either bad ('b') or good ('g').

```
load ionosphere
```

Partition the data set into training and test sets. Specify a 20% holdout sample for the test set.

```
rng('default') % For reproducibility
Partition = cvpartition(Y,'Holdout',0.20);
trainingInds = training(Partition); % Indices for the training set
XTrain = X(trainingInds,:);
YTrain = Y(trainingInds);
testInds = test(Partition); % Indices for the test set
XTest = X(testInds,:);
YTest = Y(testInds);
```

Train a binary kernel classification model with relaxed convergence control training options by using the name-value pair arguments 'BetaTolerance' and 'GradientTolerance'.

```
[Mdl,FitInfo] = fitckernel(XTrain,YTrain,'Verbose',1, ...
    'BetaTolerance',1e-1,'GradientTolerance',1e-1);
```

Solver	Pass	Iteration	Objective	Step	Gradient magnitude	char
LBFGS	1	0	1.000000e+00	0.000000e+00	2.811388e-01	
LBFGS	1	1	7.585395e-01	4.000000e+00	3.594306e-01	1
LBFGS	1	2	7.160994e-01	1.000000e+00	2.028470e-01	6
LBFGS	1	3	6.825272e-01	1.000000e+00	2.846975e-02	2

Mdl is a `ClassificationKernel` model.

Predict the test-set labels, construct a confusion matrix for the test set, and estimate the classification error for the test set

```
label = predict(Mdl,XTest);  
ConfusionTest = confusionchart(YTest,label);
```

```
L = loss(Mdl,XTest,YTest)
```

```
L = 0.3594
```

Mdl misclassifies all bad radar returns as good returns.

Continue training by using resume with modified convergence control training options.

```
[UpdatedMdl,UpdatedFitInfo] = resume(Mdl,XTrain,YTrain, ...
    'BetaTolerance',1e-2,'GradientTolerance',1e-2);
```

Solver	Pass	Iteration	Objective	Step	Gradient magnitude	char

LBFGS	1	18	2.579350e-01	1.000000e+00	3.202847e-02	2
LBFGS	1	19	2.570669e-01	1.000000e+00	1.779359e-02	4
LBFGS	1	20	2.552954e-01	1.000000e+00	1.769940e-03	1

Predict the test-set labels, construct a confusion matrix for the test set, and estimate the classification error for the test set.

```
UpdatedLabel = predict(UpdatedMdl,XTest);
UpdatedConfusionTest = confusionchart(YTest,UpdatedLabel);
```

```
UpdatedL = loss(UpdatedMdl,XTest,YTest)
```

```
UpdatedL = 0.1140
```

The classification error decreases after resume updates the classification model with smaller convergence tolerances.

Display the outputs `FitInfo` and `UpdatedFitInfo`.

```
FitInfo
```

```
FitInfo = struct with fields:  
    Solver: 'LBFGS-fast'  
    LossFunction: 'hinge'  
    Lambda: 0.0036
```

```
BetaTolerance: 0.1000
GradientTolerance: 0.1000
ObjectiveValue: 0.6825
GradientMagnitude: 0.0285
RelativeChangeInBeta: 0.2389
FitTime: 0.0162
History: [1x1 struct]
```

UpdatedFitInfo

```
UpdatedFitInfo = struct with fields:
    Solver: 'LBFGS-fast'
    LossFunction: 'hinge'
    Lambda: 0.0036
    BetaTolerance: 0.0100
    GradientTolerance: 0.0100
    ObjectiveValue: 0.2553
    GradientMagnitude: 0.0018
    RelativeChangeInBeta: 0.0190
    FitTime: 0.0607
    History: [1x1 struct]
```

Both trainings terminate because the software satisfies the absolute gradient tolerance.

Plot the gradient magnitude versus the number of iterations by using `UpdatedFitInfo.History.GradientMagnitude`. Note that the `History` field of `UpdatedFitInfo` includes the information in the `History` field of `FitInfo`.

```
semilogy(UpdatedFitInfo.History.GradientMagnitude, 'o-')
ax = gca;
ax.XTick = 1:25;
ax.XTickLabel = UpdatedFitInfo.History.IterationNumber;
grid on
xlabel('Number of Iterations')
ylabel('Gradient Magnitude')
```

The first training terminates after three iterations because the gradient magnitude becomes less than $1e-1$. The second training terminates after 20 iterations because the gradient magnitude becomes less than $1e-2$.

Input Arguments

Mdl — Binary kernel classification model

`ClassificationKernel` model object

Binary kernel classification model, specified as a `ClassificationKernel` model object. You can create a `ClassificationKernel` model object using `fitckernel`.

X — Predictor data used to train MdL

n-by-*p* numeric matrix

Predictor data used to train MdL, specified as an *n*-by-*p* numeric matrix, where *n* is the number of observations and *p* is the number of predictors.

Data Types: `single` | `double`

Y — Class labels used to train MdL

categorical array | character array | string array | logical vector | vector of numeric values | cell array of character vectors

Class labels used to train MdL, specified as a categorical, character, or string array, logical or numeric vector, or cell array of character vectors.

Data Types: `categorical` | `char` | `string` | `logical` | `single` | `double` | `cell`

Note `resume` should run only on the same training data (*X* and *Y*) and the same observation weights used to train MdL. The `resume` function uses the same training options used to train MdL, including feature expansion.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `UpdatedMdL = resume(MdL, X, Y, 'GradientTolerance', 1e-5)` resumes training with the same options used to train MdL, except the absolute gradient tolerance.

Weights — Observation weights used to train MdL

positive numeric vector

Observation weights used to train MdL, specified as the comma-separated pair consisting of `'Weights'` and a positive numeric vector of length *n*, where *n* is the number of observations in *X*. The `resume` function weighs the observations in *X* with the corresponding values in `Weights`.

The default value is `ones(n, 1)`.

resume normalizes `Weights` to sum up to the value of the prior probability in the respective class.

Example: 'Weights',w

Data Types: single | double

BetaTolerance — Relative tolerance on linear coefficients and bias term

BetaTolerance value used to train MdL (default) | nonnegative scalar

Relative tolerance on the linear coefficients and the bias term (intercept), specified as the comma-separated pair consisting of 'BetaTolerance' and a nonnegative scalar.

Let $B_t = [\beta_t' b_t]$, that is, the vector of the coefficients and the bias term at optimization iteration t . If $\left\| \frac{B_t - B_{t-1}}{B_t} \right\|_2 < \text{BetaTolerance}$, then optimization terminates.

If you also specify `GradientTolerance`, then optimization terminates when the software satisfies either stopping criterion.

By default, the value is the same `BetaTolerance` value used to train MdL.

Example: 'BetaTolerance',1e-6

Data Types: single | double

GradientTolerance — Absolute gradient tolerance

GradientTolerance value used to train MdL (default) | nonnegative scalar

Absolute gradient tolerance, specified as the comma-separated pair consisting of 'GradientTolerance' and a nonnegative scalar.

Let $\nabla \mathcal{L}_t$ be the gradient vector of the objective function with respect to the coefficients and bias term at optimization iteration t . If $\|\nabla \mathcal{L}_t\|_\infty = \max|\nabla \mathcal{L}_t| < \text{GradientTolerance}$, then optimization terminates.

If you also specify `BetaTolerance`, then optimization terminates when the software satisfies either stopping criterion.

By default, the value is the same `GradientTolerance` value used to train MdL.

Example: 'GradientTolerance',1e-5

Data Types: single | double

IterationLimit — Maximum number of additional optimization iterations

positive integer

Maximum number of additional optimization iterations, specified as the comma-separated pair consisting of 'IterationLimit' and a positive integer.

The default value is 1000 if the transformed data fits in memory (`Mdl.ModelParameters.BlockSize`), which you specify by using the name-value pair argument when training `Mdl`. Otherwise, the default value is 100.

Note that the default value is not the value used to train `Mdl`.

Example: 'IterationLimit',500

Data Types: single | double

Output Arguments

UpdatedMdl — Updated kernel classification model

ClassificationKernel model object

Updated kernel classification model, returned as a `ClassificationKernel` model object.

FitInfo — Optimization details

structure array

Optimization details, returned as a structure array including fields described in this table. The fields contain final values or name-value pair argument specifications.

Field	Description
Solver	Objective function minimization technique: 'LBFGS-fast', 'LBFGS-blockwise', or 'LBFGS-tall'. For details, see "Algorithms" on page 32-7430 of <code>fitckernel</code> .
LossFunction	Loss function. Either 'hinge' or 'logit' depending on the type of linear classification model. See <code>Learner</code> of <code>fitckernel</code> .
Lambda	Regularization term strength. See <code>Lambda</code> of <code>fitckernel</code> .
BetaTolerance	Relative tolerance on the linear coefficients and the bias term. See <code>BetaTolerance</code> .

Field	Description
GradientTolerance	Absolute gradient tolerance. See GradientTolerance.
ObjectiveValue	Value of the objective function when optimization terminates. The classification loss plus the regularization term compose the objective function.
GradientMagnitude	Infinite norm of the gradient vector of the objective function when optimization terminates. See GradientTolerance.
RelativeChangeInBeta	Relative changes in the linear coefficients and the bias term when optimization terminates. See BetaTolerance.
FitTime	Elapsed, wall-clock time (in seconds) required to fit the model to the data.
History	History of optimization information. This field also includes the optimization information from training MdL. This field is empty ([]) if you specify 'Verbose', 0 when training MdL. For details, see Verbose and "Algorithms" on page 32-7430 of fitckernel.

To access fields, use dot notation. For example, to access the vector of objective function values for each iteration, enter `FitInfo.ObjectiveValue` in the Command Window.

A good practice is to examine `FitInfo` to assess whether convergence is satisfactory.

Definitions

Random Feature Expansion

Random feature expansion, such as Random Kitchen Sinks[1] and Fastfood[2], is a scheme to approximate Gaussian kernels of the kernel classification algorithm to use for big data in a computationally efficient way. Random feature expansion is more practical for big data applications that have large training sets, but can also be applied to smaller data sets that fit in memory.

The kernel classification algorithm searches for an optimal hyperplane that separates the data into two classes after mapping features into a high-dimensional space. Nonlinear features that are not linearly separable in a low-dimensional space can be separable in the expanded high-dimensional space. All the calculations for hyperplane classification

use only dot products. You can obtain a nonlinear classification model by replacing the dot product $x_1 x_2'$ with the nonlinear kernel function $G(x_1, x_2) = \langle \varphi(x_1), \varphi(x_2) \rangle$, where x_i is the i th observation (row vector) and $\varphi(x_i)$ is a transformation that maps x_i to a high-dimensional space (called the “kernel trick”). However, evaluating $G(x_1, x_2)$ (Gram matrix) for each pair of observations is computationally expensive for a large data set (large n).

The random feature expansion scheme finds a random transformation so that its dot product approximates the Gaussian kernel. That is,

$$G(x_1, x_2) = \langle \varphi(x_1), \varphi(x_2) \rangle \approx T(x_1)T(x_2)',$$

where $T(x)$ maps x in \mathbb{R}^p to a high-dimensional space (\mathbb{R}^m). The Random Kitchen Sink scheme uses the random transformation

$$T(x) = m^{-1/2} \exp(iZx'),$$

where $Z \in \mathbb{R}^{m \times p}$ is a sample drawn from $N(0, \sigma^{-2})$ and σ^2 is a kernel scale. This scheme requires $O(mp)$ computation and storage. The Fastfood scheme introduces another random basis V instead of Z using Hadamard matrices combined with Gaussian scaling matrices. This random basis reduces the computation cost to $O(m \log p)$ and reduces storage to $O(m)$.

The `fitkernel` function uses the Fastfood scheme for random feature expansion and uses linear classification to train a Gaussian kernel classification model. Unlike solvers in the `fitcsvm` function, which require computation of the n -by- n Gram matrix, the solver in `fitkernel` only needs to form a matrix of size n -by- m , with m typically much less than n for big data.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

Usage notes and limitations:

- The default value for the 'IterationLimit' name-value pair argument is relaxed to 20 when working with tall arrays.
- `resume` uses a block-wise strategy. For details, see “Algorithms” on page 32-7430 of `fitckernel`.

For more information, see “Tall Arrays” (MATLAB).

fitrkernel

Fit Gaussian kernel regression model using random feature expansion

`fitrkernel` trains or cross-validates a Gaussian kernel regression model for nonlinear regression. `fitrkernel` is more practical to use for big data applications that have large training sets, but can also be applied to smaller data sets that fit in memory.

`fitrkernel` maps data in a low-dimensional space into a high-dimensional space, then fits a linear model in the high-dimensional space by minimizing the regularized objective function. Obtaining the linear model in the high-dimensional space is equivalent to applying the Gaussian kernel to the model in the low-dimensional space. Available linear regression models include regularized support vector machine (SVM) and least-squares regression models.

To train a nonlinear SVM regression model on in-memory data, see `fitrsvm`.

Syntax

```
Mdl = fitrkernel(X,Y)
Mdl = fitrkernel(X,Y,Name,Value)
[Mdl,FitInfo] = fitrkernel(____)
[Mdl,FitInfo,HyperparameterOptimizationResults] = fitrkernel(____)
```

Description

`Mdl = fitrkernel(X,Y)` returns a compact Gaussian kernel regression model trained using the predictor data in `X` and the corresponding responses in `Y`.

`Mdl = fitrkernel(X,Y,Name,Value)` returns a kernel regression model with additional options specified by one or more name-value pair arguments. For example, you can implement least-squares regression, specify the number of dimension of the expanded space, or specify cross-validation options.

`[Mdl,FitInfo] = fitrkernel(____)` also returns the fit information in the structure array `FitInfo` using any of the input arguments in the previous syntaxes. You cannot request `FitInfo` for cross-validated models.

[Mdl,FitInfo,HyperparameterOptimizationResults] = fitrkernel(____) also returns the hyperparameter optimization results when you optimize hyperparameters by using the 'OptimizeHyperparameters' name-value pair argument.

Examples

Train Gaussian Kernel Regression Model

Train a kernel regression model for a tall array by using SVM.

Create a datastore that references the folder location with the data. The data can be contained in a single file, a collection of files, or an entire folder. Treat 'NA' values as missing data so that `datastore` replaces them with NaN values. Select a subset of the variables to use. Create a tall table on top of the datastore.

```
varnames = {'ArrTime','DepTime','ActualElapsedTime'};
ds = datastore('airlinesmall.csv','TreatAsMissing','NA',...
    'SelectedVariableNames',varnames);
t = tall(ds);
```

Specify `DepTime` and `ArrTime` as the predictor variables (X) and `ActualElapsedTime` as the response variable (Y). Select the observations for which `ArrTime` is later than `DepTime`.

```
daytime = t.ArrTime>t.DepTime;
Y = t.ActualElapsedTime(daytime); % Response data
X = t{daytime,{'DepTime' 'ArrTime'}}; % Predictor data
```

Standardize the predictor variables.

```
Z = zscore(X); % Standardize the data
```

Train a default Gaussian kernel regression model with the standardized predictors. Extract a fit summary to determine how well the optimization algorithm fits the model to the data.

```
[Mdl,FitInfo] = fitrkernel(Z,Y)
```

Found 6 chunks.

```

```
BoxConstraint: 1
Epsilon: 5.9303
```

Properties, Methods

```
FitInfo = struct with fields:
    Solver: 'LBFSGS-tall'
    LossFunction: 'epsiloninsensitive'
    Lambda: 8.5385e-06
    BetaTolerance: 1.0000e-03
    GradientTolerance: 1.0000e-05
    ObjectiveValue: 30.6315
    GradientMagnitude: 0.0068
    RelativeChangeInBeta: 0.0161
    FitTime: 77.1910
    History: [1x1 struct]
```

Mdl is a `RegressionKernel` model. To inspect the regression error, you can pass Mdl and the training data or new data to the `loss` function. Or, you can pass Mdl and new predictor data to the `predict` function to predict responses for new observations. You can also pass Mdl and the training data to the `resume` function to continue training.

FitInfo is a structure array containing optimization information. Use FitInfo to determine whether optimization termination measurements are satisfactory.

For improved accuracy, you can increase the maximum number of optimization iterations ('IterationLimit') and decrease the tolerance values ('BetaTolerance' and 'GradientTolerance') by using the name-value pair arguments of fitrkernel. Doing so can improve measures like ObjectiveValue and RelativeChangeInBeta in FitInfo. You can also optimize model parameters by using the 'OptimizeHyperparameters' name-value pair argument.

Cross-Validate Kernel Regression Model

Load the carbig data set.

```
load carbig
```

Specify the predictor variables (X) and the response variable (Y).

```
X = [Acceleration,Cylinders,Displacement,Horsepower,Weight];
Y = MPG;
```

Delete rows of X and Y where either array has NaN values. Removing rows with NaN values before passing data to `fitrkernel` can speed up training and reduce memory usage.

```
R = rmmissing([X Y]); % Data with missing entries removed
X = R(:,1:5);
Y = R(:,end);
```

Standardize the predictor variables.

```
Z = zscore(X);
```

Cross-validate a kernel regression model using 5-fold cross-validation.

```
Mdl = fitrkernel(Z,Y,'Kfold',5)
```

```
Mdl =
  classreg.learning.partition.RegressionPartitionedKernel
  CrossValidatedModel: 'Kernel'
  ResponseName: 'Y'
  NumObservations: 392
  KFold: 5
  Partition: [1x1 cvpartition]
  ResponseTransform: 'none'
```

Properties, Methods

```
numel(Mdl.Trained)
```

```
ans = 5
```

Mdl is a `RegressionPartitionedKernel` model. Because `fitrkernel` implements five-fold cross-validation, Mdl contains five `RegressionKernel` models that the software trains on training-fold (in-fold) observations.

Examine the cross-validation loss (mean squared error) for each fold.

```
kfoldLoss(Mdl,'mode','individual')
```

```
ans = 5×1
```

```
13.0610
14.0975
24.0104
21.1223
24.3979
```

Optimize Kernel Regression

Optimize hyperparameters automatically using the 'OptimizeHyperparameters' name-value pair argument.

Load the `carbig` data set.

```
load carbig
```

Specify the predictor variables (X) and the response variable (Y).

```
X = [Acceleration,Cylinders,Displacement,Horsepower,Weight];
Y = MPG;
```

Delete rows of X and Y where either array has NaN values. Removing rows with NaN values before passing data to `fitrkernel` can speed up training and reduce memory usage.

```
R = rmmissing([X Y]); % Data with missing entries removed
X = R(:,1:5);
Y = R(:,end);
```

Standardize the predictor variables.

```
Z = zscore(X);
```

Find hyperparameters that minimize five-fold cross-validation loss by using automatic hyperparameter optimization. Specify 'OptimizeHyperparameters' as 'auto' so that `fitrkernel` finds the optimal values of the 'KernelScale', 'Lambda', and 'Epsilon' name-value pair arguments. For reproducibility, set the random seed and use the 'expected-improvement-plus' acquisition function.

```
rng('default')
[Mdl,FitInfo,HyperparameterOptimizationResults] = fitrkernel(Z,Y,'OptimizeHyperparameters','auto','Epsilon',0.01,'KernelScale',1,'Lambda',1,'HyperparameterOptimizationOptions',struct('AcquisitionFunctionName','expected-improvement-plus'))
```

For big data, the optimization procedure can take a long time. If the data set is too large to run the optimization procedure, you can try to optimize the parameters using only partial data. Use the `datasample` function and specify 'Replace', 'false' to sample data without replacement.

Input Arguments

X — Predictor data

numeric matrix

Predictor data to which the regression model is fit, specified as an n -by- p numeric matrix, where n is the number of observations and p is the number of predictor variables.

The length of Y and the number of observations in X must be equal.

Data Types: `single` | `double`

Y — Response data

numeric vector

Response data, specified as an n -dimensional numeric vector. The length of Y and the number of observations in X must be equal.

Data Types: `single` | `double`

Note `fitrkernel` removes missing observations, that is, observations with any of these characteristics:

- NaN elements in the response (Y)
 - At least one NaN value in a predictor observation (row in X)
 - NaN value or 0 weight ('Weights')
-

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, . . . , NameN, ValueN`.

Note You cannot use any cross-validation name-value pair argument along with the 'OptimizeHyperparameters' name-value pair argument. You can modify the cross-validation for 'OptimizeHyperparameters' only by using the 'HyperparameterOptimizationOptions' name-value pair argument.

Example: `Mdl = fitrkernel(X,Y,'Learner','leastsquares','NumExpansionDimensions',2^15,'KernelScale','auto')` implements least-squares regression after mapping the predictor data to the 2^{15} dimensional space using feature expansion with a kernel scale parameter selected by a heuristic procedure.

Kernel Regression Options

BoxConstraint — Box constraint

1 (default) | positive scalar

Box constraint on page 32-7526, specified as the comma-separated pair consisting of 'BoxConstraint' and a positive scalar.

This argument is valid only when 'Learner' is 'svm' (default) and you do not specify a value for the regularization term strength 'Lambda'. You can specify either 'BoxConstraint' or 'Lambda' because the box constraint (C) and the regularization term strength (λ) are related by $C = 1/(\lambda n)$, where n is the number of observations (rows in X).

Example: 'BoxConstraint',100

Data Types: single | double

Epsilon — Half width of epsilon-insensitive band

'auto' (default) | nonnegative scalar value

Half the width of the epsilon-insensitive band, specified as the comma-separated pair consisting of 'Epsilon' and 'auto' or a nonnegative scalar value.

For 'auto', the `fitrkernel` function determines the value of `Epsilon` as $\text{iqr}(Y)/13.49$, which is an estimate of a tenth of the standard deviation using the interquartile range of the response variable Y . If $\text{iqr}(Y)$ is equal to zero, then `fitrkernel` sets the value of `Epsilon` to 0.1.

'Epsilon' is valid only when `Learner` is `svm`.

Example: 'Epsilon',0.3

Data Types: single | double

NumExpansionDimensions — Number of dimensions of expanded space

'auto' (default) | positive integer

Number of dimensions of the expanded space, specified as the comma-separated pair consisting of 'NumExpansionDimensions' and 'auto' or a positive integer. For 'auto', the `fitrkernel` function selects the number of dimensions using $2.^{\text{ceil}(\min(\log_2(p)+5, 15))}$, where p is the number of predictors.

Example: 'NumExpansionDimensions',2^15

Data Types: char | string | single | double

KernelScale — Kernel scale parameter

1 (default) | 'auto' | positive scalar

Kernel scale parameter, specified as the comma-separated pair consisting of 'KernelScale' and 'auto' or a positive scalar. MATLAB obtains the random basis for random feature expansion by using the kernel scale parameter. For details, see “Random Feature Expansion” on page 32-7525.

If you specify 'auto', then MATLAB selects an appropriate kernel scale parameter using a heuristic procedure. This heuristic procedure uses subsampling, so estimates can vary from one call to another. Therefore, to reproduce results, set a random number seed by using `rng` before training.

Example: 'KernelScale', 'auto'

Data Types: char | string | single | double

Lambda — Regularization term strength

'auto' (default) | nonnegative scalar

Regularization term strength, specified as the comma-separated pair consisting of 'Lambda' and 'auto' or a nonnegative scalar.

For 'auto', the value of 'Lambda' is $1/n$, where n is the number of observations (rows in X).

You can specify either 'BoxConstraint' or 'Lambda' because the box constraint (C) and the regularization term strength (λ) are related by $C = 1/(\lambda n)$.

Example: 'Lambda', 0.01

Data Types: char | string | single | double

Learner — Linear regression model type

'svm' (default) | 'leastsquares'

Linear regression model type, specified as the comma-separated pair consisting of 'Learner' and 'svm' or 'leastsquares'.

In the following table, $f(x) = T(x)\beta + b$.

- x is an observation (row vector) from p predictor variables.
- $T(\cdot)$ is a transformation of an observation (row vector) for feature expansion. $T(x)$ maps x in \mathbb{R}^p to a high-dimensional space (\mathbb{R}^m).
- β is a vector of m coefficients.
- b is the scalar bias.

Value	Algorithm	Response range	Loss function
'leastsquares'	Linear regression via ordinary least squares	$y \in (-\infty, \infty)$	Mean squared error (MSE): $\ell[y, f(x)]$ $= \frac{1}{2}[y - f(x)]^2$

Value	Algorithm	Response range	Loss function
'svm'	Support vector machine regression	Same as 'leastquares'	Epsilon-insensitive: $\ell[y, f(x)] = \max[0, y - f(x) - \varepsilon]$

Example: 'Learner', 'leastquares'

Verbose — Verbosity level

0 (default) | 1

Verbosity level, specified as the comma-separated pair consisting of 'Verbose' and either 0 or 1. Verbose controls the amount of diagnostic information `fitrkernel` displays at the command line.

Value	Description
0	<code>fitrkernel</code> does not display diagnostic information.
1	<code>fitrkernel</code> displays and stores the value of the objective function, gradient magnitude, and other diagnostic information. <code>FitInfo.History</code> contains the diagnostic information.

Example: 'Verbose', 1

Data Types: single | double

BlockSize — Maximum amount of allocated memory

4e³ (4GB) (default) | positive scalar

Maximum amount of allocated memory (in megabytes), specified as the comma-separated pair consisting of 'BlockSize' and a positive scalar.

If `fitrkernel` requires more memory than the value of `BlockSize` to hold the transformed predictor data, then MATLAB uses a block-wise strategy. For details about the block-wise strategy, see “Algorithms” on page 32-7526.

Example: 'BlockSize', 1e4

Data Types: single | double

RandomStream — Random number stream

global stream (default) | random stream object

Random number stream for reproducibility of data transformation, specified as the comma-separated pair consisting of 'RandomStream' and a random stream object. For details, see “Random Feature Expansion” on page 32-7525.

Use 'RandomStream' to reproduce the random basis functions that `fitrkernel` uses to transform the data in `X` to a high-dimensional space. For details, see “Managing the Global Stream” (MATLAB) and “Creating and Controlling a Random Number Stream” (MATLAB).

Example: 'RandomStream', RandStream('mlfg6331_64')

ResponseTransform — Response transformation

'none' (default) | function handle

Response transformation, specified as the comma-separated pair consisting of 'ResponseTransform' and either 'none' or a function handle. The default is 'none', which means $@(y)y$, or no transformation. For a MATLAB function or a function you define, use its function handle. The function handle must accept a vector (the original response values) and return a vector of the same size (the transformed response values).

Example: Suppose you create a function handle that applies an exponential transformation to an input vector by using `myfunction = @(y)exp(y)`. Then, you can specify the response transformation as 'ResponseTransform', `myfunction`.

Data Types: char | string | function_handle

Weights — Observation weights

`ones(n,1)/n` (default) | numeric vector of positive values

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a numeric vector of positive values. `fitrkernel` weighs the observations in `X` with the corresponding values in `Weights`. The size of `Weights` must equal `n`, the number of observations (rows in `X`).

`fitrkernel` normalizes `Weights` to sum to 1.

Data Types: double | single

Cross-Validation Options

CrossVal — Cross-validation flag

'off' (default) | 'on'

Cross-validation flag, specified as the comma-separated pair consisting of 'Crossval' and 'on' or 'off'.

If you specify 'on', then the software implements 10-fold cross-validation.

You can override this cross-validation setting using the `CVPartition`, `Holdout`, `KFold`, or `Leaveout` name-value pair argument. You can use only one cross-validation name-value pair argument at a time to create a cross-validated model.

Example: 'Crossval', 'on'

CVPartition — Cross-validation partition

[] (default) | `cvpartition` partition object

Cross-validation partition, specified as the comma-separated pair consisting of 'CVPartition' and a `cvpartition` partition object created by `cvpartition`. The partition object specifies the type of cross-validation and the indexing for the training and validation sets.

To create a cross-validated model, you can use one of these four name-value pair arguments only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: Suppose you create a random partition for 5-fold cross-validation on 500 observations by using `cvp = cvpartition(500, 'KFold', 5)`. Then, you can specify the cross-validated model by using 'CVPartition', `cvp`.

Holdout — Fraction of data for holdout validation

scalar value in the range (0,1)

Fraction of the data used for holdout validation, specified as the comma-separated pair consisting of 'Holdout' and a scalar value in the range (0,1). If you specify 'Holdout', `p`, then the software completes these steps:

- 1 Randomly select and reserve $p \times 100\%$ of the data as validation data, and train the model using the rest of the data.
- 2 Store the compact, trained model in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: 'Holdout', 0.1

Data Types: `double` | `single`

KFold — Number of folds

10 (default) | positive integer value greater than 1

Number of folds to use in a cross-validated model, specified as the comma-separated pair consisting of 'KFold' and a positive integer value greater than 1. If you specify 'KFold', k , then the software completes these steps:

- 1 Randomly partition the data into k sets.
- 2 For each set, reserve the set as validation data, and train the model using the other $k - 1$ sets.
- 3 Store the k compact, trained models in the cells of a k -by-1 cell vector in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: 'KFold',5

Data Types: `single` | `double`

Leaveout — Leave-one-out cross-validation flag

'off' (default) | 'on'

Leave-one-out cross-validation flag, specified as the comma-separated pair consisting of 'Leaveout' and 'on' or 'off'. If you specify 'Leaveout', 'on', then, for each of the n observations (where n is the number of observations excluding missing observations), the software completes these steps:

- 1 Reserve the observation as validation data, and train the model using the other $n - 1$ observations.
- 2 Store the n compact, trained models in the cells of an n -by-1 cell vector in the `Trained` property of the cross-validated model.

To create a cross-validated model, you can use one of these four name-value pair arguments only: `CVPartition`, `Holdout`, `KFold`, or `Leaveout`.

Example: 'Leaveout', 'on'

Convergence Controls**BetaTolerance — Relative tolerance on linear coefficients and bias term**

1e-5 (default) | nonnegative scalar

Relative tolerance on the linear coefficients and the bias term (intercept), specified as the comma-separated pair consisting of 'BetaTolerance' and a nonnegative scalar.

Let $B_t = [\beta_t' \ b_t]$, that is, the vector of the coefficients and the bias term at optimization iteration t . If $\left\| \frac{B_t - B_{t-1}}{B_t} \right\|_2 < \text{BetaTolerance}$, then optimization terminates.

If you also specify GradientTolerance, then optimization terminates when the software satisfies either stopping criterion.

Example: 'BetaTolerance', 1e-6

Data Types: single | double

GradientTolerance — Absolute gradient tolerance

1e-6 (default) | nonnegative scalar

Absolute gradient tolerance, specified as the comma-separated pair consisting of 'GradientTolerance' and a nonnegative scalar.

Let $\nabla \mathcal{L}_t$ be the gradient vector of the objective function with respect to the coefficients and bias term at optimization iteration t . If $\|\nabla \mathcal{L}_t\|_\infty = \max|\nabla \mathcal{L}_t| < \text{GradientTolerance}$, then optimization terminates.

If you also specify BetaTolerance, then optimization terminates when the software satisfies either stopping criterion.

Example: 'GradientTolerance', 1e-5

Data Types: single | double

HessianHistorySize — Size of history buffer for Hessian approximation

15 (default) | positive integer

Size of the history buffer for Hessian approximation, specified as the comma-separated pair consisting of 'HessianHistorySize' and a positive integer. At each iteration, fitrkernel composes the Hessian by using statistics from the latest HessianHistorySize iterations.

Example: 'HessianHistorySize', 10

Data Types: single | double

IterationLimit — Maximum number of optimization iterations

positive integer

Maximum number of optimization iterations, specified as the comma-separated pair consisting of 'IterationLimit' and a positive integer.

The default value is 1000 if the transformed data fits in memory, as specified by BlockSize. Otherwise, the default value is 100.

Example: 'IterationLimit',500

Data Types: single | double

Hyperparameter Optimization Options**OptimizeHyperparameters — Parameters to optimize**

'none' (default) | 'auto' | 'all' | string array or cell array of eligible parameter names | vector of `optimizableVariable` objects

Parameters to optimize, specified as the comma-separated pair consisting of 'OptimizeHyperparameters' and one of these values:

- 'none' — Do not optimize.
- 'auto' — Use {'KernelScale', 'Lambda', 'Epsilon'}.
- 'all' — Optimize all eligible parameters.
- Cell array of eligible parameter names.
- Vector of `optimizableVariable` objects, typically the output of hyperparameters.

The optimization attempts to minimize the cross-validation loss (error) for `fitrkernel` by varying the parameters. To control the cross-validation type and other aspects of the optimization, use the `HyperparameterOptimizationOptions` name-value pair argument.

Note 'OptimizeHyperparameters' values override any values you set using other name-value pair arguments. For example, setting 'OptimizeHyperparameters' to 'auto' causes the 'auto' values to apply.

The eligible parameters for `fitrkernel` are:

- `Epsilon` — `fitrkernel` searches among positive values, by default log-scaled in the range $[1e-3, 1e2] * \text{iqr}(Y) / 1.349$.

- `KernelScale` — `fitrkernel` searches among positive values, by default log-scaled in the range $[1e-3, 1e3]$.
- `Lambda` — `fitrkernel` searches among positive values, by default log-scaled in the range $[1e-3, 1e3]/n$, where n is the number of observations.
- `Learner` — `fitrkernel` searches among 'svm' and 'leastsquares'.
- `NumExpansionDimensions` — `fitrkernel` searches among positive integers, by default log-scaled in the range $[100, 10000]$.

Set nondefault parameters by passing a vector of `optimizableVariable` objects that have nondefault values. For example:

```
load carsmall
params = hyperparameters('fitrkernel', [Horsepower, Weight], MPG);
params(2).Range = [1e-4, 1e6];
```

Pass `params` as the value of 'OptimizeHyperparameters'.

By default, iterative display appears at the command line, and plots appear according to the number of hyperparameters in the optimization. For the optimization and plots, the objective function is $\log(1 + \text{cross-validation loss})$ for regression and the misclassification rate for classification. To control the iterative display, set the `Verbose` field of the 'HyperparameterOptimizationOptions' name-value pair argument. To control the plots, set the `ShowPlots` field of the 'HyperparameterOptimizationOptions' name-value pair argument.

For an example, see “Optimize Kernel Regression” on page 32-7505.

Example: 'OptimizeHyperparameters', 'auto'

HyperparameterOptimizationOptions — Options for optimization

structure

Options for optimization, specified as the comma-separated pair consisting of 'HyperparameterOptimizationOptions' and a structure. This argument modifies the effect of the `OptimizeHyperparameters` name-value pair argument. All fields in the structure are optional.

Field Name	Values	Default
Optimizer	<ul style="list-style-type: none"> 'bayesopt' — Use Bayesian optimization. Internally, this setting calls bayesopt. 'gridsearch' — Use grid search with NumGridDivisions values per dimension. 'randomsearch' — Search at random among MaxObjectiveEvaluations points. <p>'gridsearch' searches in a random order, using uniform sampling without replacement from the grid. After optimization, you can get a table in grid order by using the command <code>sortrows(Mdl.HyperparameterOptimizationResults)</code>.</p>	'bayesopt'
AcquisitionFunctionName	<ul style="list-style-type: none"> 'expected-improvement-per-second-plus' 'expected-improvement' 'expected-improvement-plus' 'expected-improvement-per-second' 'lower-confidence-bound' 'probability-of-improvement' <p>Acquisition functions whose names include <code>per-second</code> do not yield reproducible results because the optimization depends on the runtime of the objective function. Acquisition functions whose names include <code>plus</code> modify their behavior when they are overexploiting an area. For more details, see “Acquisition Function Types” on page 10-4.</p>	'expected-improvement-per-second-plus'

Field Name	Values	Default
MaxObjectiveEvaluations	Maximum number of objective function evaluations.	30 for 'bayesopt' or 'randomsearch', and the entire grid for 'gridsearch'
MaxTime	Time limit, specified as a positive real. The time limit is in seconds, as measured by tic and toc. Run time can exceed MaxTime because MaxTime does not interrupt function evaluations.	Inf
NumGridDivisions	For 'gridsearch', the number of values in each dimension. The value can be a vector of positive integers giving the number of values for each dimension, or a scalar that applies to all dimensions. This field is ignored for categorical variables.	10
ShowPlots	Logical value indicating whether to show plots. If true, this field plots the best objective function value against the iteration number. If there are one or two optimization parameters, and if Optimizer is 'bayesopt', then ShowPlots also plots a model of the objective function against the parameters.	true
SaveIntermediateResults	Logical value indicating whether to save results when Optimizer is 'bayesopt'. If true, this field overwrites a workspace variable named 'BayesoptResults' at each iteration. The variable is a BayesianOptimization object.	false

Field Name	Values	Default
Verbose	Display to the command line. <ul style="list-style-type: none"> • 0 — No iterative display • 1 — Iterative display • 2 — Iterative display with extra information For details, see the <code>bayesopt</code> <code>Verbose</code> name-value pair argument.	1
UseParallel	Logical value indicating whether to run Bayesian optimization in parallel, which requires Parallel Computing Toolbox. For details, see “Parallel Bayesian Optimization” on page 10-8.	false
Repartition	Logical value indicating whether to repartition the cross-validation at every iteration. If <code>false</code> , the optimizer uses a single partition for the optimization. <code>true</code> usually gives the most robust results because this setting takes partitioning noise into account. However, for good results, <code>true</code> requires at least twice as many function evaluations.	false
Use no more than one of the following three field names.		
CVPartition	A <code>cvpartition</code> object, as created by <code>cvpartition</code> .	'Kfold', 5 if you do not specify any cross-validation field
Holdout	A scalar in the range (0, 1) representing the holdout fraction.	
Kfold	An integer greater than 1.	

Example:

```
'HyperparameterOptimizationOptions', struct('MaxObjectiveEvaluations', 60)
```

Data Types: struct

Output Arguments

Mdl — Trained kernel regression model

RegressionKernel model object | RegressionPartitionedKernel cross-validated model object

Trained kernel regression model, returned as a RegressionKernel model object or RegressionPartitionedKernel cross-validated model object.

If you set any of the name-value pair arguments CrossVal, CVPartition, Holdout, KFold, or Leaveout, then Mdl is a RegressionPartitionedKernel cross-validated model. Otherwise, Mdl is a RegressionKernel model.

To reference properties of Mdl, use dot notation. For example, enter Mdl.NumExpansionDimensions in the Command Window to display the number of dimensions of the expanded space.

Note Unlike other regression models, and for economical memory usage, a RegressionKernel model object does not store the training data or training process details (for example, convergence history).

FitInfo — Optimization details

structure array

Optimization details, returned as a structure array including fields described in this table. The fields contain final values or name-value pair argument specifications.

Field	Description
Solver	Objective function minimization technique: 'LBFGS-fast', 'LBFGS-blockwise', or 'LBFGS-tall'. For details, see "Algorithms" on page 32-7526.
LossFunction	Loss function. Either mean squared error (MSE) or epsilon-insensitive, depending on the type of linear regression model. See Learner.
Lambda	Regularization term strength. See Lambda.
BetaTolerance	Relative tolerance on the linear coefficients and the bias term. See BetaTolerance.

Field	Description
GradientTolerance	Absolute gradient tolerance. See GradientTolerance.
ObjectiveValue	Value of the objective function when optimization terminates. The regression loss plus the regularization term compose the objective function.
GradientMagnitude	Infinite norm of the gradient vector of the objective function when optimization terminates. See GradientTolerance.
RelativeChangeInBeta	Relative changes in the linear coefficients and the bias term when optimization terminates. See BetaTolerance.
FitTime	Elapsed, wall-clock time (in seconds) required to fit the model to the data.
History	History of optimization information. This field also includes the optimization information from training Mdl. This field is empty ([]) if you specify 'Verbose', 0. For details, see Verbose and "Algorithms" on page 32-7526.

To access fields, use dot notation. For example, to access the vector of objective function values for each iteration, enter `FitInfo.ObjectiveValue` in the Command Window.

Examine the information provided by `FitInfo` to assess whether convergence is satisfactory.

HyperparameterOptimizationResults — Cross-validation optimization of hyperparameters

BayesianOptimization object | table of hyperparameters and associated values

Cross-validation optimization of hyperparameters, returned as a BayesianOptimization object or a table of hyperparameters and associated values. The output is nonempty when the value of 'OptimizeHyperparameters' is not 'none'. The output value depends on the Optimizer field value of the 'HyperparameterOptimizationOptions' name-value pair argument:

Value of Optimizer Field	Value of HyperparameterOptimizationResults
'bayesopt' (default)	Object of class BayesianOptimization

Value of Optimizer Field	Value of HyperparameterOptimizationResults
'gridsearch' or 'randomsearch'	Table of hyperparameters used, observed objective function values (cross-validation loss), and rank of observations from lowest (best) to highest (worst)

Limitations

- `fitrkernel` does not accept initial conditions for the linear coefficients β and bias term (b) used to determine the decision function, $f(x) = T(x)\beta + b$.
- `fitrkernel` does not support standardization and cross-validation options.
- `fitrkernel` does not accept table inputs.

Definitions

Random Feature Expansion

Random feature expansion, such as Random Kitchen Sinks[1] and Fastfood[2], is a scheme to approximate Gaussian kernels of the kernel regression algorithm for big data in a computationally efficient way. Random feature expansion is more practical for big data applications that have large training sets but can also be applied to smaller data sets that fit in memory.

The kernel regression algorithm searches for an optimal function that deviates from each response data point (y_i) by values no greater than the epsilon margin (ϵ) after mapping the predictor data into a high-dimensional space.

Some regression problems cannot be described adequately using a linear model. In such cases, obtain a nonlinear regression model by replacing the dot product x_1x_2' with a nonlinear kernel function $G(x_1, x_2) = \langle \varphi(x_1), \varphi(x_2) \rangle$, where x_i is the i th observation (row vector) and $\varphi(x_i)$ is a transformation that maps x_i to a high-dimensional space (called the "kernel trick"). However, evaluating $G(x_1, x_2)$, the Gram matrix, for each pair of observations is computationally expensive for a large data set (large n).

The random feature expansion scheme finds a random transformation so that its dot product approximates the Gaussian kernel. That is,

$$G(x_1, x_2) = \langle \varphi(x_1), \varphi(x_2) \rangle \approx T(x_1)T(x_2)',$$

where $T(x)$ maps x in \mathbb{R}^p to a high-dimensional space (\mathbb{R}^m). The Random Kitchen Sink[1] scheme uses the random transformation

$$T(x) = m^{-1/2} \exp(iZx'),$$

where $Z \in \mathbb{R}^{m \times p}$ is a sample drawn from $N(0, \sigma^{-2})$ and σ^2 is a kernel scale. This scheme requires $O(mp)$ computation and storage. The Fastfood[2] scheme introduces another random basis V instead of Z using Hadamard matrices combined with Gaussian scaling matrices. This random basis reduces computation cost to $O(m \log p)$ and reduces storage to $O(m)$.

You can specify values for m and σ^2 , using the `NumExpansionDimensions` and `KernelScale` name-value pair arguments of `fitrkernel`, respectively.

The `fitrkernel` function uses the Fastfood scheme for random feature expansion and uses linear regression to train a Gaussian kernel regression model. Unlike solvers in the `fitrsvm` function, which require computation of the n -by- n Gram matrix, the solver in `fitrkernel` only needs to form a matrix of size n -by- m , with m typically much less than n for big data.

Box Constraint

A box constraint is a parameter that controls the maximum penalty imposed on observations that lie outside the epsilon margin (ϵ), and helps to prevent overfitting (regularization). Increasing the box constraint can lead to longer training times.

The box constraint (C) and the regularization term strength (λ) are related by $C = 1/(\lambda n)$, where n is the number of observations.

Algorithms

`fitrkernel` minimizes the regularized objective function using a Limited-memory Broyden-Fletcher-Goldfarb-Shanno (LBFGS) solver with ridge (L_2) regularization. To find the type of LBFGS solver used for training, type `FitInfo.Solver` in the Command Window.

- 'LBFSG-fast' — LBFSG solver.
- 'LBFSG-blockwise' — LBFSG solver with a block-wise strategy. If `fitrkernel` requires more memory than the value of `BlockSize` to hold the transformed predictor data, then it uses a block-wise strategy.
- 'LBFSG-tall' — LBFSG solver with a block-wise strategy for tall arrays.

When `fitrkernel` uses a block-wise strategy, `fitrkernel` implements LBFSG by distributing the calculation of the loss and gradient among different parts of the data at each iteration. Also, `fitrkernel` refines the initial estimates of the linear coefficients and the bias term by fitting the model locally to parts of the data and combining the coefficients by averaging. If you specify 'Verbose', 1, then `fitrkernel` displays diagnostic information for each data pass and stores the information in the `History` field of `FitInfo`.

When `fitrkernel` does not use a block-wise strategy, the initial estimates are zeros. If you specify 'Verbose', 1, then `fitrkernel` displays diagnostic information for each iteration and stores the information in the `History` field of `FitInfo`.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

Usage notes and limitations:

- Some name-value pair arguments have different defaults compared to the default values for the in-memory `fitrkernel` function. Supported name-value pair arguments, and any differences, are:
 - 'BoxConstraint'
 - 'Epsilon'
 - 'NumExpansionDimensions'
 - 'KernelScale'
 - 'Lambda'
 - 'Learner'
 - 'Verbose' — Default value is 1.
 - 'BlockSize'
 - 'RandomStream'
 - 'ResponseTransform'
 - 'Weights' — Value must be a tall array.
 - 'BetaTolerance' — Default value is relaxed to $1e-3$.
 - 'GradientTolerance' — Default value is relaxed to $1e-5$.
 - 'HessianHistorySize'
 - 'IterationLimit' — Default value is relaxed to 20.
 - 'OptimizeHyperparameters'
 - 'HyperparameterOptimizationOptions' — For cross-validation, tall optimization supports only 'Holdout' validation. For example, you can specify `fitrkernel(X,Y,'OptimizeHyperparameters','auto','HyperparameterOptimizationOptions',struct('Holdout',0.2))`.
- If 'KernelScale' is 'auto', then `fitrkernel` uses the random stream controlled by `tallrng` for subsampling. For reproducibility, you must set a random number seed for both the global stream and the random stream controlled by `tallrng`.
- If 'Lambda' is 'auto', then `fitrkernel` might take an extra pass through the data to calculate the number of observations in X.
- `fitrkernel` uses a block-wise strategy. For details, see “Algorithms” on page 32-7526.

For more information, see “Tall Arrays” (MATLAB).

Automatic Parallel Support

Accelerate code by automatically running computation in parallel using Parallel Computing Toolbox™.

To run in parallel, set the 'UseParallel' option to true.

To perform parallel hyperparameter optimization, use the 'HyperparameterOptions', struct('UseParallel', true) name-value pair argument in the call to this function.

For more information on parallel hyperparameter optimization, see “Parallel Bayesian Optimization” on page 10-8.

For more general information about parallel computing, see “Run MATLAB Functions with Automatic Parallel Support” (Parallel Computing Toolbox).

Introduced in R2018a

RegressionKernel

Gaussian kernel regression model using random feature expansion

Description

`RegressionKernel` is a trained model object for Gaussian kernel regression using random feature expansion. `RegressionKernel` is more practical for big data applications that have large training sets but can also be applied to smaller data sets that fit in memory.

Unlike other regression models, and for economical memory usage, `RegressionKernel` model objects do not store the training data. However, they do store information such as the dimension of the expanded space, the kernel scale parameter, and the regularization strength.

You can use trained `RegressionKernel` models to continue training using the training data, predict responses for new data, and compute the mean squared error or epsilon-insensitive loss. For details, see `resume`, `predict`, and `loss`.

Creation

Create a `RegressionKernel` object using the `fitrkernel` function. This function maps data in a low-dimensional space into a high-dimensional space, then fits a linear model in the high-dimensional space by minimizing the regularized objective function. Obtaining the linear model in the high-dimensional space is equivalent to applying the Gaussian kernel to the model in the low-dimensional space. Available linear regression models include regularized support vector machines (SVM) and least-squares regression models.

Properties

Kernel Regression Properties

Epsilon — Half width of epsilon-insensitive band

nonnegative scalar

Half the width of the epsilon-insensitive band, specified as a nonnegative scalar.

If `Learner` is not 'svm', then `Epsilon` is an empty array (`[]`).

Data Types: `single` | `double`

Learner — Linear regression model type

'svm' (default) | 'leastsquares'

Linear regression model type, specified as 'leastsquares' or 'svm'.

In the following table, $f(x) = T(x)\beta + b$.

- x is an observation (row vector) from p predictor variables.
- $T(\cdot)$ is a transformation of an observation (row vector) for feature expansion. $T(x)$ maps x in \mathbb{R}^p to a high-dimensional space (\mathbb{R}^m).
- β is a vector of m coefficients.
- b is the scalar bias.

Value	Algorithm	Loss function	FittedLoss Value
'leastsquares'	Linear regression via ordinary least squares	Mean squared error (MSE): $\ell[y, f(x)]$ $= \frac{1}{2}[y - f(x)]^2$	'mse'
'svm'	Support vector machine regression	Epsilon-insensitive: $\ell[y, f(x)] = \max$ $[0, y - f(x) - \varepsilon]$	'epsiloninsensitive'

NumExpansionDimensions — Number of dimensions of expanded space

positive integer

Number of dimensions of the expanded space, specified as a positive integer.

Data Types: `single` | `double`

KernelScale — Kernel scale parameter

positive scalar

Kernel scale parameter, specified as a positive scalar.

Data Types: `single` | `double`

BoxConstraint — Box constraint

positive scalar

Box constraint, specified as a positive scalar.

Data Types: `double` | `single`

Lambda — Regularization term strength

nonnegative scalar

Regularization term strength, specified as a nonnegative scalar.

Data Types: `single` | `double`

FittedLoss — Loss function used to fit linear model

`'epsiloninsensitive'` | `'mse'`

Loss function used to fit the linear model, specified as `'epsiloninsensitive'` or `'mse'`.

Value	Algorithm	Loss function	Learner Value
<code>'epsiloninsensitive'</code>	Support vector machine regression	Epsilon-insensitive: $\ell[y, f(x)] = \max[0, y - f(x) - \varepsilon]$	<code>'svm'</code>
<code>'mse'</code>	Linear regression via ordinary least squares	Mean squared error (MSE): $\ell[y, f(x)] = \frac{1}{2}[y - f(x)]^2$	<code>'leastquares'</code>

Regularization — Complexity penalty type

`'lasso (L1)'` | `'ridge (L2)'`

Complexity penalty type, specified as `'lasso (L1)'` or `'ridge (L2)'`.

The software composes the objective function for minimization from the sum of the average loss function (see `FittedLoss`) and a regularization value from this table.

Value	Description
'lasso (L1)'	Lasso (L_1) penalty: $\lambda \sum_{j=1}^p \beta_j $
'ridge (L2)'	Ridge (L_2) penalty: $\frac{\lambda}{2} \sum_{j=1}^p \beta_j^2$

λ specifies the regularization term strength (see Lambda).

The software excludes the bias term (β_0) from the regularization penalty.

Other Regression Properties

CategoricalPredictors — Indices of categorical predictors

[]

Indices of categorical predictors, whose value is always empty ([]) because a RegressionKernel model does not support categorical predictors.

ModelParameters — Parameters used for training model

structure

Parameters used for training the RegressionKernel model, specified as a structure.

Access fields of ModelParameters using dot notation. For example, access the relative tolerance on the linear coefficients and the bias term by using `Mdl.ModelParameters.BetaTolerance`.

Data Types: struct

PredictorNames — Predictor names

cell array of character vectors

Predictor names in order of their appearance in the predictor data X, specified as a cell array of character vectors. The length of PredictorNames is equal to the number of columns in X.

Data Types: cell

ExpandedPredictorNames — Expanded predictor names

cell array of character vectors

Expanded predictor names, specified as a cell array of character vectors.

Because a `RegressionKernel` model does not support categorical predictors, `ExpandedPredictorNames` and `PredictorNames` are equal.

Data Types: `cell`

ResponseName — Response variable name

character vector

Response variable name, specified as a character vector.

Data Types: `char`

ResponseTransform — Response transformation function to apply to predicted responses

'none' | function handle

Response transformation function to apply to predicted responses, specified as 'none' or a function handle.

For kernel regression models and before the response transformation, the predicted response for the observation x (row vector) is $f(x) = T(x)\beta + b$.

- $T(\cdot)$ is a transformation of an observation for feature expansion.
- β corresponds to `Mdl.Beta`.
- b corresponds to `Mdl.Bias`.

For a MATLAB function or a function that you define, enter its function handle. For example, you can enter `Mdl.ResponseTransform = @function`, where *function* accepts a numeric vector of the original responses and returns a numeric vector of the same size containing the transformed responses.

Data Types: `char` | `function_handle`

Object Functions

<code>loss</code>	Regression loss for Gaussian kernel regression model
<code>predict</code>	Predict responses for Gaussian kernel regression model
<code>resume</code>	Resume training of Gaussian kernel regression model

Examples

Train Gaussian Kernel Regression Model

Train a kernel regression model for a tall array by using SVM.

Create a datastore that references the folder location with the data. The data can be contained in a single file, a collection of files, or an entire folder. Treat 'NA' values as missing data so that `datastore` replaces them with NaN values. Select a subset of the variables to use. Create a tall table on top of the datastore.

```
varnames = {'ArrTime', 'DepTime', 'ActualElapsedTime'};
ds = datastore('airlinesmall.csv', 'TreatAsMissing', 'NA', ...
    'SelectedVariableNames', varnames);
t = tall(ds);
```

Specify `DepTime` and `ArrTime` as the predictor variables (X) and `ActualElapsedTime` as the response variable (Y). Select the observations for which `ArrTime` is later than `DepTime`.

```
daytime = t.ArrTime>t.DepTime;
Y = t.ActualElapsedTime(daytime); % Response data
X = t{daytime, {'DepTime' 'ArrTime'}}; % Predictor data
```

Standardize the predictor variables.

```
Z = zscore(X); % Standardize the data
```

Train a default Gaussian kernel regression model with the standardized predictors. Extract a fit summary to determine how well the optimization algorithm fits the model to the data.

```
[Mdl, FitInfo] = fitrkernel(Z, Y)
```

Found 6 chunks.

Solver	Iteration / Data Pass	Objective	Gradient magnitude	Beta relative change

```

Mdl =
  RegressionKernel
    PredictorNames: {'x1' 'x2'}
    ResponseName: 'Y'
    Learner: 'svm'
    NumExpansionDimensions: 64
    KernelScale: 1
    Lambda: 8.5385e-06
    BoxConstraint: 1
    Epsilon: 5.9303

```

Properties, Methods

```
FitInfo = struct with fields:
    Solver: 'LBFSG-tall'
    LossFunction: 'epsiloninsensitive'
    Lambda: 8.5385e-06
    BetaTolerance: 1.0000e-03
    GradientTolerance: 1.0000e-05
    ObjectiveValue: 30.6315
    GradientMagnitude: 0.0068
    RelativeChangeInBeta: 0.0161
    FitTime: 77.1910
    History: [1x1 struct]
```

Mdl is a RegressionKernel model. To inspect the regression error, you can pass Mdl and the training data or new data to the loss function. Or, you can pass Mdl and new predictor data to the predict function to predict responses for new observations. You can also pass Mdl and the training data to the resume function to continue training.

FitInfo is a structure array containing optimization information. Use FitInfo to determine whether optimization termination measurements are satisfactory.

For improved accuracy, you can increase the maximum number of optimization iterations ('IterationLimit') and decrease the tolerance values ('BetaTolerance' and 'GradientTolerance') by using the name-value pair arguments of fitrkernel. Doing so can improve measures like ObjectiveValue and RelativeChangeInBeta in FitInfo. You can also optimize model parameters by using the 'OptimizeHyperparameters' name-value pair argument.

Estimate Sample Loss and Resume Training

Resume training a Gaussian kernel regression model for more iterations to improve the regression loss.

Load the carbig data set.

```
load carbig
```

Specify the predictor variables (X) and the response variable (Y).

```
X = [Acceleration,Cylinders,Displacement,Horsepower,Weight];
Y = MPG;
```

Delete rows of `X` and `Y` where either array has NaN values. Removing rows with NaN values before passing data to `fitrkernel` can speed up training and reduce memory usage.

```
R = rmmissing([X Y]); % Data with missing entries removed
X = R(:,1:5);
Y = R(:,end);
```

Reserve 10% of the observations as a holdout sample. Extract the training and test indices from the partition definition.

```
rng(10) % For reproducibility
N = length(Y);
cvp = cvpartition(N,'Holdout',0.1);
idxTrn = training(cvp); % Training set indices
idxTest = test(cvp); % Test set indices
```

Standardize the training data and train a kernel regression model. Set the iteration limit to 5 and specify `'Verbose',1` to display diagnostic information.

```
Xtrain = X(idxTrn,:);
Ytrain = Y(idxTrn);
[Ztrain,tr_mu,tr_sigma] = zscore(Xtrain); % Standardize the training data
tr_sigma(tr_sigma==0) = 1;
Mdl = fitrkernel(Ztrain,Ytrain,'IterationLimit',5,'Verbose',1)
```

```
Mdl =
  RegressionKernel
      ResponseName: 'Y'
        Learner: 'svm'
  NumExpansionDimensions: 256
        KernelScale: 1
            Lambda: 0.0028
```

```
BoxConstraint: 1
Epsilon: 0.8617
```

Properties, Methods

Mdl is a RegressionKernel model.

Standardize the test data using the same mean and standard deviation of the training data columns. Estimate the epsilon-insensitive error for the test set.

```
Xtest = X(idxTest,:);
Ztest = (Xtest-tr_mu)./tr_sigma; % Standardize the test data
Ytest = Y(idxTest);
```

```
L = loss(Mdl,Ztest,Ytest,'LossFun','epsiloninsensitive')
```

```
L = 2.0674
```

Continue training the model by using resume. This function continues training with the same options used for training Mdl.

```
UpdatedMdl = resume(Mdl,Ztrain,Ytrain);
```

Estimate the epsilon-insensitive error for the test set using the updated model.

```
UpdatedL = loss(UpdatedMdl, Ztest, Ytest, 'LossFun', 'epsiloninsensitive')
```

```
UpdatedL = 1.8933
```

The regression error decreases by a factor of about **0.08** after resume updates the regression model with more iterations.

Introduced in R2018a

loss

Regression loss for Gaussian kernel regression model

Syntax

```
L = loss(Mdl,X,Y)
L = loss(Mdl,X,Y,Name,Value)
```

Description

`L = loss(Mdl,X,Y)` returns the mean squared error (MSE) for the Gaussian kernel regression model `Mdl` using the predictor data in `X` and the corresponding responses in `Y`.

`L = loss(Mdl,X,Y,Name,Value)` uses additional options specified by one or more name-value pair arguments. For example, you can specify a regression loss function and observation weights. Then, `loss` returns the weighted regression loss using the specified loss function.

Examples

Calculate Sample Loss for Gaussian Kernel Regression Model

Train a Gaussian kernel regression model for a tall array, then calculate the resubstitution mean squared error and epsilon-insensitive error.

Create a datastore that references the folder location with the data. The data can be contained in a single file, a collection of files, or an entire folder. Treat 'NA' values as missing data so that `datastore` replaces them with NaN values. Select a subset of the variables to use. Create a tall table on top of the datastore.

```
varnames = {'ArrTime','DepTime','ActualElapsedTime'};
ds = datastore('airlinesmall.csv','TreatAsMissing','NA',...
    'SelectedVariableNames',varnames);
t = tall(ds);
```

Starting parallel pool (parpool) using the 'local' profile ...
connected to 6 workers.

Specify DepTime and ArrTime as the predictor variables (X) and ActualElapsedTime as the response variable (Y). Select the observations for which ArrTime is later than DepTime.

```
daytime = t.ArrTime>t.DepTime;
Y = t.ActualElapsedTime(daytime); % Response data
X = t{daytime,{'DepTime' 'ArrTime'}}; % Predictor data
```

Standardize the predictor variables.

```
Z = zscore(X); % Standardize the data
```

Train a default Gaussian kernel regression model with the standardized predictors. Set 'Verbose', 0 to suppress diagnostic messages.

```
[Mdl,FitInfo] = fitrkernel(Z,Y,'Verbose',0)
```

```
Mdl =
  RegressionKernel
    PredictorNames: {'x1' 'x2'}
    ResponseName: 'Y'
    Learner: 'svm'
    NumExpansionDimensions: 64
    KernelScale: 1
    Lambda: 8.5385e-06
    BoxConstraint: 1
    Epsilon: 5.9303
```

Properties, Methods

```
FitInfo = struct with fields:
    Solver: 'LBFGS-tall'
    LossFunction: 'epsiloninsensitive'
    Lambda: 8.5385e-06
    BetaTolerance: 1.0000e-03
    GradientTolerance: 1.0000e-05
    ObjectiveValue: 31.2279
    GradientMagnitude: 0.0182
    RelativeChangeInBeta: 0.0465
    FitTime: 68.4420
```

History: []

Mdl is a trained `RegressionKernel` model, and the structure array `FitInfo` contains optimization details.

Determine how well the trained model generalizes to new predictor values by estimating the resubstitution mean squared error and epsilon-insensitive error.

```
lossMSE = loss(Mdl,Z,Y) % Resubstitution mean squared error
```

```
lossMSE =
```

```
M×N×... tall array
```

```
? ? ? ...  
? ? ? ...  
? ? ? ...  
: : :  
: : :
```

Preview deferred. Learn more.

```
lossEI = loss(Mdl,Z,Y,'LossFun','epsiloninsensitive') % Resubstitution epsilon-insensi
```

```
lossEI =
```

```
M×N×... tall array
```

```
? ? ? ...  
? ? ? ...  
? ? ? ...  
: : :  
: : :
```

Preview deferred. Learn more.

Evaluate the tall arrays and bring the results into memory by using `gather`.

```
[lossMSE,lossEI] = gather(lossMSE,lossEI)
```

```
Evaluating tall expression using the Parallel Pool 'local':
```

```
- Pass 1 of 1: Completed in 2 sec
```

```
Evaluation completed in 2.4 sec
```

```
lossMSE = 2.8508e+03
```

```
lossEI = 28.1095
```

Specify Custom Regression Loss

Specify a custom regression loss (Huber loss) for a Gaussian kernel regression model.

Load the carbig data set.

```
load carbig
```

Specify the predictor variables (X) and the response variable (Y).

```
X = [Weight,Cylinders,Horsepower,Model_Year];
Y = MPG;
```

Delete rows of X and Y where either array has NaN values. Removing rows with NaN values before passing data to `fitrkernel` can speed up training and reduce memory usage.

```
R = rmmissing([X Y]);
X = R(:,1:4);
Y = R(:,end);
```

Reserve 10% of the observations as a holdout sample. Extract the training and test indices from the partition definition.

```
rng(10) % For reproducibility
N = length(Y);
cvp = cvpartition(N,'Holdout',0.1);
idxTrn = training(cvp); % Training set indices
idxTest = test(cvp); % Test set indices
```

Standardize the training data and train the regression kernel model.

```
Xtrain = X(idxTrn,:);
Ytrain = Y(idxTrn);
[Ztrain,tr_mu,tr_sigma] = zscore(Xtrain); % Standardize the training data
tr_sigma(tr_sigma==0) = 1;
Mdl = fitrkernel(Ztrain,Ytrain)
```

```
Mdl =
  RegressionKernel
```

```

        ResponseName: 'Y'
          Learner: 'svm'
NumExpansionDimensions: 128
      KernelScale: 1
          Lambda: 0.0028
    BoxConstraint: 1
          Epsilon: 0.8617

```

Properties, Methods

Mdl is a `RegressionKernel` model.

Create an anonymous function that measures Huber loss ($\delta = 1$), that is,

$$L = \frac{1}{\sum w_j} \sum_{j=1}^n w_j \ell_j,$$

where

$$\ell_j = \begin{cases} 0.5\widehat{e}_j^2; & |\widehat{e}_j| \leq 1 \\ |\widehat{e}_j| - 0.5; & |\widehat{e}_j| > 1 \end{cases}$$

\widehat{e}_j is the residual for observation j . Custom loss functions must be written in a particular form. For rules on writing a custom loss function, see the 'LossFun' name-value pair argument.

```

huberloss = @(Y,Yhat,W) sum(W.*((0.5*(abs(Y-Yhat)<=1).*(Y-Yhat).^2) + ...
    ((abs(Y-Yhat)>1).*abs(Y-Yhat)-0.5)))/sum(W);

```

Estimate the training set regression loss using the Huber loss function.

```
eTrain = loss(Mdl,Ztrain,Ytrain,'LossFun',huberloss)
```

```
eTrain = 1.7210
```

Standardize the test data using the same mean and standard deviation of the training data columns. Estimate the test set regression loss using the Huber loss function.

```

Xtest = X(idxTest,:);
Ztest = (Xtest-tr_mu)./tr_sigma; % Standardize the test data

```

```
Ytest = Y(idxTest);  
eTest = loss(Mdl,Ztest,Ytest,'LossFun',huberloss)  
eTest = 1.3062
```

Input Arguments

Mdl — Kernel regression model

RegressionKernel model object

Kernel regression model, specified as a RegressionKernel model object. You can create a RegressionKernel model object using fitrkernel.

X — Predictor data

n-by-*p* numeric matrix

Predictor data, specified as an *n*-by-*p* numeric matrix, where *n* is the number of observations and *p* is the number of predictors. *p* must be equal to the number of predictors used to train Mdl.

Data Types: single | double

Y — Response data

numeric vector

Response data, specified as an *n*-dimensional numeric vector. The length of Y and the number of observations in X must be equal.

Data Types: single | double

Name-Value Pair Arguments

Specify optional comma-separated pairs of Name, Value arguments. Name is the argument name and Value is the corresponding value. Name must appear inside quotes. You can specify several name and value pair arguments in any order as Name1, Value1, ..., NameN, ValueN.

Example: L =

```
loss(Mdl,X,Y,'LossFun','epsiloninsensitive','Weights',weights) returns  
the weighted regression loss using the epsilon-insensitive loss function.
```

LossFun — Loss function

'mse' (default) | 'epsiloninsensitive' | function handle

Loss function, specified as the comma-separated pair consisting of 'LossFun' and a built-in loss function name or a function handle.

- The following table lists the available loss functions. Specify one using its corresponding character vector or string scalar. Also, in the table, $f(x) = T(x)\beta + b$.
 - x is an observation (row vector) from p predictor variables.
 - $T(\cdot)$ is a transformation of an observation (row vector) for feature expansion. $T(x)$ maps x in \mathbb{R}^p to a high-dimensional space (\mathbb{R}^m).
 - β is a vector of m coefficients.
 - b is the scalar bias.

Value	Description
'epsiloninsensitive'	Epsilon-insensitive loss: $\ell[y, f(x)] = \max[0, y - f(x) - \varepsilon]$
'mse'	MSE: $\ell[y, f(x)] = [y - f(x)]^2$

'epsiloninsensitive' is appropriate for SVM learners only.

- Specify your own function by using function handle notation.

Let n be the number of observations in X . Your function must have this signature:

```
lossvalue = lossfun(Y,Yhat,W)
```

- The output argument `lossvalue` is a scalar.
- You choose the function name (`lossfun`).
- Y is an n -dimensional vector of observed responses. `loss` passes the input argument Y in for Y .
- $Yhat$ is an n -dimensional vector of predicted responses, which is similar to the output of `predict`.
- W is an n -by-1 numeric vector of observation weights.

Specify your function using 'LossFun', `@lossfun`.

Data Types: char | string | function_handle

Weights — Observation weights

`ones(n, 1)/n` (default) | numeric vector of positive values

Observation weights, specified as the comma-separated pair consisting of 'Weights' and a numeric vector of positive values. `loss` weighs the observations in `X` with the corresponding values in `Weights`. The size of `Weights` must equal `n`, the number of observations (rows in `X`). If you supply the observation weights, `loss` computes the weighted regression loss, that is, the “Weighted Mean Squared Error” on page 32-7549 or “Epsilon-Insensitive Loss Function” on page 32-7550.

`loss` normalizes `Weights` to sum to 1.

Data Types: `double` | `single`

Output Arguments

L — Regression loss

numeric scalar

Regression loss, returned as a numeric scalar. The interpretation of `L` depends on `Weights` and `LossFun`. For example, if you use the default observation weights and specify 'epsiloninsensitive' as the loss function, then `L` is the epsilon-insensitive loss.

Definitions

Weighted Mean Squared Error

The weighted mean squared error is calculated as follows:

$$\text{mse} = \frac{\sum_{j=1}^n w_j (f(x_j) - y_j)^2}{\sum_{j=1}^n w_j},$$

where:

- n is the number of observations.
- x_j is the j th observation (row of predictor data).
- y_j is the observed response to x_j .
- $f(x_j)$ is the response prediction of the Gaussian kernel regression model `Mdl` to x_j .
- w is the vector of observation weights.

Each observation weight in w is equal to $\text{ones}(n, 1)/n$ by default. You can specify different values for the observation weights by using the 'Weights' name-value pair argument. `loss` normalizes `Weights` to sum to 1.

Epsilon-Insensitive Loss Function

The epsilon-insensitive loss function ignores errors that are within the distance epsilon (ε) of the function value. The function is formally described as:

$$Loss_{\varepsilon} = \begin{cases} 0, & \text{if } |y - f(x)| \leq \varepsilon \\ |y - f(x)| - \varepsilon, & \text{otherwise.} \end{cases}$$

The mean epsilon-insensitive loss is calculated as follows:

$$Loss = \frac{\sum_{j=1}^n w_j \max(0, |y_j - f(x_j)| - \varepsilon)}{\sum_{j=1}^n w_j},$$

where:

- n is the number of observations.
- x_j is the j th observation (row of predictor data).
- y_j is the observed response to x_j .
- $f(x_j)$ is the response prediction of the Gaussian kernel regression model `Mdl` to x_j .
- w is the vector of observation weights.

Each observation weight in w is equal to $\text{ones}(n, 1)/n$ by default. You can specify different values for the observation weights by using the 'Weights' name-value pair argument. `loss` normalizes `Weights` to sum to 1.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. For more information, see “Tall Arrays” (MATLAB).

See Also

`RegressionKernel` | `fitrkernel` | `predict` | `resume`

Introduced in R2018a

predict

Predict responses for Gaussian kernel regression model

Syntax

```
YFit = predict(Mdl,X)
```

Description

`YFit = predict(Mdl,X)` returns predicted responses for each observation in the predictor data `X` based on the binary Gaussian kernel regression model `Mdl`.

Examples

Predict Test Set Responses

Predict the test set responses using a Gaussian kernel regression model for the `carbig` data set.

Load the `carbig` data set.

```
load carbig
```

Specify the predictor variables (`X`) and the response variable (`Y`).

```
X = [Weight,Cylinders,Horsepower,Model_Year];  
Y = MPG;
```

Delete rows of `X` and `Y` where either array has NaN values. Removing rows with NaN values before passing data to `fitrkernel` can speed up training and reduce memory usage.

```
R = rmmissing([X Y]);  
X = R(:,1:4);  
Y = R(:,end);
```

Reserve 10% of the observations as a holdout sample. Extract the training and test indices from the partition definition.

```
rng(10) % For reproducibility
N = length(Y);
cvp = cvpartition(N, 'Holdout', 0.1);
idxTrn = training(cvp); % Training set indices
idxTest = test(cvp); % Test set indices
```

Standardize the training data and train the regression kernel model.

```
Xtrain = X(idxTrn,:);
Ytrain = Y(idxTrn);
[Ztrain, tr_mu, tr_sigma] = zscore(Xtrain); % Standardize the training data
tr_sigma(tr_sigma==0) = 1;
Mdl = fitrkernel(Ztrain, Ytrain)
```

```
Mdl =
  RegressionKernel
      ResponseName: 'Y'
          Learner: 'svm'
  NumExpansionDimensions: 128
          KernelScale: 1
              Lambda: 0.0028
          BoxConstraint: 1
              Epsilon: 0.8617
```

Properties, Methods

Mdl is a RegressionKernel model.

Standardize the test data using the same mean and standard deviation of the training data columns. Predict responses for the test set.

```
Xtest = X(idxTest,:);
Ztest = (Xtest - tr_mu) ./ tr_sigma; % Standardize the test data
Ytest = Y(idxTest);

YFit = predict(Mdl, Ztest);
```

Create a table containing the first 10 observed response values and predicted response values.

```
table(Ytest(1:10),YFit(1:10),'VariableNames',...  
      {'ObservedValue','PredictedValue'})
```

```
ans=10x2 table  
  ObservedValue  PredictedValue  
  _____  _____  
          18          17.616  
          14          25.799  
          24          24.141  
          25          25.018  
          14          13.637  
          14          14.557  
          18          18.584  
          27          26.096  
          21          25.031  
          13          13.324
```

Estimate the test set regression loss using the mean squared error loss function.

```
L = loss(Mdl,Ztest,Ytest)
```

```
L = 9.2664
```

Input Arguments

Mdl — Kernel regression model

RegressionKernel model object

Kernel regression model, specified as a RegressionKernel model object. You can create a RegressionKernel model object using `fitrkernel`.

X — Predictor data

n -by- p numeric matrix

Predictor data, specified as an n -by- p numeric matrix, where n is the number of observations and p is the number of predictors. p must be equal to the number of predictors used to train Mdl.

Data Types: single | double

Output Arguments

YFit — Predicted responses

numeric vector

Predicted responses, returned as a numeric vector.

YFit is an n -by-1 vector of the same data type as the response data (**Y**) used to train **Mdl**, where n is the number of observations in **X**.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

This function fully supports tall arrays. For more information, see “Tall Arrays” (MATLAB).

`RegressionKernel` | `fitrkernel` | `loss` | `resume`

Introduced in R2018a

resume

Resume training of Gaussian kernel regression model

Syntax

```
UpdatedMdl = resume(Mdl,X,Y)
UpdatedMdl = resume(Mdl,X,Y,Name,Value)
[UpdatedMdl,FitInfo] = resume(____)
```

Description

`UpdatedMdl = resume(Mdl,X,Y)` continues training with the same options used to train `Mdl`, including the training data (predictor data in `X` and response data in `Y`) and the feature expansion. The training starts at the current estimated parameters in `Mdl`. The function returns a new Gaussian kernel regression model `UpdatedMdl`.

`UpdatedMdl = resume(Mdl,X,Y,Name,Value)` returns a new kernel regression model with additional options specified by one or more name-value pair arguments. For example, you can modify convergence control options, such as convergence tolerances and the maximum number of additional optimization iterations.

`[UpdatedMdl,FitInfo] = resume(____)` also returns the fit information in the structure array `FitInfo` using any of the input arguments in the previous syntaxes.

Examples

Estimate Sample Loss and Resume Training

Resume training a Gaussian kernel regression model for more iterations to improve the regression loss.

Load the `carbig` data set.

```
load carbig
```

Specify the predictor variables (X) and the response variable (Y).

```
X = [Acceleration,Cylinders,Displacement,Horsepower,Weight];
Y = MPG;
```

Delete rows of X and Y where either array has NaN values. Removing rows with NaN values before passing data to `fitrkernel` can speed up training and reduce memory usage.

```
R = rmmissing([X Y]); % Data with missing entries removed
X = R(:,1:5);
Y = R(:,end);
```

Reserve 10% of the observations as a holdout sample. Extract the training and test indices from the partition definition.

```
rng(10) % For reproducibility
N = length(Y);
cvp = cvpartition(N,'Holdout',0.1);
idxTrn = training(cvp); % Training set indices
idxTest = test(cvp); % Test set indices
```

Standardize the training data and train a kernel regression model. Set the iteration limit to 5 and specify 'Verbose', 1 to display diagnostic information.

```
Xtrain = X(idxTrn,:);
Ytrain = Y(idxTrn);
[Ztrain,tr_mu,tr_sigma] = zscore(Xtrain); % Standardize the training data
tr_sigma(tr_sigma==0) = 1;
Mdl = fitrkernel(Ztrain,Ytrain,'IterationLimit',5,'Verbose',1)
```

Estimate the epsilon-insensitive error for the test set using the updated model.

```
UpdatedL = loss(UpdatedMdl,Ztest,Ytest,'LossFun','epsiloninsensitive')
```

```
UpdatedL = 1.8933
```

The regression error decreases by a factor of about 0.08 after resume updates the regression model with more iterations.

Resume Training with Modified Convergence Control Training Options

Load the carbig data set.

```
load carbig
```

Specify the predictor variables (X) and the response variable (Y).

```
X = [Acceleration,Cylinders,Displacement,Horsepower,Weight];
Y = MPG;
```

Delete rows of X and Y where either array has NaN values. Removing rows with NaN values before passing data to `fitrkernel` can speed up training and reduce memory usage.

```
R = rmmissing([X Y]); % Data with missing entries removed
X = R(:,1:5);
Y = R(:,end);
```

Reserve 10% of the observations as a holdout sample. Extract the training and test indices from the partition definition.

```
rng(10) % For reproducibility
N = length(Y);
cvp = cvpartition(N,'Holdout',0.1);
idxTrn = training(cvp); % Training set indices
idxTest = test(cvp); % Test set indices
```

Standardize the training data and train a kernel regression model with relaxed convergence control training options by using the name-value pair arguments 'BetaTolerance' and 'GradientTolerance'. Specify 'Verbose', 1 to display diagnostic information.

```
Xtrain = X(idxTrn,:);
Ytrain = Y(idxTrn);
[Ztrain,tr_mu,tr_sigma] = zscore(Xtrain); % Standardize the training data
tr_sigma(tr_sigma==0) = 1;
[Mdl,FitInfo] = fitrkernel(Ztrain,Ytrain,'Verbose',1, ...
    'BetaTolerance',2e-2,'GradientTolerance',2e-2);
```

Solver	Pass	Iteration	Objective	Step	Gradient magnitude	char
LBFGS	1	0	5.691016e+00	0.000000e+00	5.852758e-02	
LBFGS	1	1	5.086537e+00	8.000000e+00	5.220869e-02	9
LBFGS	1	2	3.862301e+00	5.000000e-01	3.796034e-01	5
LBFGS	1	3	3.460613e+00	1.000000e+00	3.257790e-01	1
LBFGS	1	4	3.136228e+00	1.000000e+00	2.832861e-02	8
LBFGS	1	5	3.063978e+00	1.000000e+00	1.475038e-02	3

Mdl is a RegressionKernel model.

Standardize the test data using the same mean and standard deviation of the training data columns. Estimate the epsilon-insensitive error for the test set.

```
Xtest = X(idxTest,:);
Ztest = (Xtest-tr_mu)./tr_sigma; % Standardize the test data
Ytest = Y(idxTest);
```

```
L = loss(Mdl,Ztest,Ytest,'LossFun','epsiloninsensitive')
```

```
L = 2.0674
```

Continue training the model by using `resume` with modified convergence control options.

```
[UpdatedMdl,UpdatedFitInfo] = resume(Mdl,Ztrain,Ytrain, ...
    'BetaTolerance',2e-3,'GradientTolerance',2e-3);
```

Solver	Pass	Iteration	Objective	Step	Gradient magnitude	char
LBFGS	1	0	3.063978e+00	0.000000e+00	1.475038e-02	
LBFGS	1	1	3.007822e+00	8.000000e+00	1.391637e-02	2

LBFGS	1	3	2.807294e+00	2.500000e-01	6.798867e-02	2
LBFGS	1	4	2.791060e+00	1.000000e+00	2.549575e-02	1
LBFGS	1	5	2.767821e+00	1.000000e+00	6.154419e-03	2
LBFGS	1	6	2.738163e+00	1.000000e+00	5.949008e-02	9
LBFGS	1	7	2.719146e+00	1.000000e+00	1.699717e-02	1
LBFGS	1	8	2.705941e+00	1.000000e+00	3.116147e-02	4
LBFGS	1	9	2.701162e+00	1.000000e+00	5.665722e-03	9
LBFGS	1	10	2.695341e+00	5.000000e-01	3.116147e-02	4
LBFGS	1	11	2.691277e+00	1.000000e+00	8.498584e-03	1
LBFGS	1	12	2.689972e+00	1.000000e+00	1.983003e-02	9
LBFGS	1	13	2.688979e+00	1.000000e+00	1.416431e-02	6
LBFGS	1	14	2.687787e+00	1.000000e+00	1.621956e-03	7

Estimate the epsilon-insensitive error for the test set using the updated model.

```
UpdatedL = loss(UpdatedMdl,Ztest,Ytest,'LossFun','epsiloninsensitive')
```

```
UpdatedL = 1.8891
```

The regression error decreases after `resume` updates the regression model with smaller convergence tolerances.

Display the outputs `FitInfo` and `UpdatedFitInfo`.

```
FitInfo
```

```
FitInfo = struct with fields:
```

```
    Solver: 'LBFGS-fast'
    LossFunction: 'epsiloninsensitive'
    Lambda: 0.0028
    BetaTolerance: 0.0200
    GradientTolerance: 0.0200
```

```
ObjectiveValue: 3.0640
GradientMagnitude: 0.0148
RelativeChangeInBeta: 0.0331
FitTime: 0.0213
History: [1x1 struct]
```

UpdatedFitInfo

```
UpdatedFitInfo = struct with fields:
    Solver: 'LBFGS-fast'
    LossFunction: 'epsiloninsensitive'
    Lambda: 0.0028
    BetaTolerance: 0.0020
    GradientTolerance: 0.0020
    ObjectiveValue: 2.6878
    GradientMagnitude: 0.0016
    RelativeChangeInBeta: 0.0071
    FitTime: 0.0322
    History: [1x1 struct]
```

Both trainings terminate because the software satisfies the absolute gradient tolerance.

Plot the gradient magnitude versus the number of iterations by using `UpdatedFitInfo.History.GradientMagnitude`. Note that the `History` field of `UpdatedFitInfo` includes the information in the `History` field of `FitInfo`.

```
semilogy(UpdatedFitInfo.History.GradientMagnitude, 'o-')
ax = gca;
ax.XTick = 1:21;
ax.XTickLabel = UpdatedFitInfo.History.IterationNumber;
grid on
xlabel('Number of Iterations')
ylabel('Gradient Magnitude')
```

The first training terminates after five iterations because the gradient magnitude becomes less than $2e-2$. The second training terminates after 14 iterations because the gradient magnitude becomes less than $2e-3$.

Input Arguments

Mdl — Kernel regression model

`RegressionKernel` model object

Kernel regression model, specified as a `RegressionKernel` model object. You can create a `RegressionKernel` model object using `fitrkernel`.

X — Predictor data used to train Mdl

n-by-*p* numeric matrix

Predictor data used to train Mdl, specified as an *n*-by-*p* numeric matrix, where *n* is the number of observations and *p* is the number of predictors.

Data Types: `single` | `double`

Y — Response data used to train Mdl

numeric vector

Response data used to train Mdl, specified as a numeric vector.

Data Types: `double` | `single`

Note `resume` should run only on the same training data (*X* and *Y*) and the same observation weights (`Weights`) used to train Mdl. The `resume` function uses the same training options, such as feature expansion, used to train Mdl.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `UpdatedMdl = resume(Mdl, X, Y, 'BetaTolerance', 1e-3)` resumes training with the same options used to train Mdl, except the relative tolerance on the linear coefficients and the bias term.

Weights — Observation weights used to train Mdl

positive numeric vector

Observation weights used to train Mdl, specified as the comma-separated pair consisting of `'Weights'` and a positive numeric vector of length *n*, where *n* is the number of observations in *X*. The `resume` function weighs the observations in *X* with the corresponding values in `Weights`.

The default value is `ones(n, 1)/n`.

`resume` normalizes `Weights` to sum to 1.

Example: 'Weights',w

Data Types: single | double

BetaTolerance — Relative tolerance on linear coefficients and bias term

BetaTolerance value used to train MdL (default) | nonnegative scalar

Relative tolerance on the linear coefficients and the bias term (intercept), specified as the comma-separated pair consisting of 'BetaTolerance' and a nonnegative scalar.

Let $B_t = [\beta_t' \ b_t]$, that is, the vector of the coefficients and the bias term at optimization iteration t . If $\left\| \frac{B_t - B_{t-1}}{B_t} \right\|_2 < \text{BetaTolerance}$, then optimization terminates.

If you also specify GradientTolerance, then optimization terminates when the software satisfies either stopping criterion.

By default, the value is the same BetaTolerance value used to train MdL.

Example: 'BetaTolerance',1e-6

Data Types: single | double

GradientTolerance — Absolute gradient tolerance

GradientTolerance value used to train MdL (default) | nonnegative scalar

Absolute gradient tolerance, specified as the comma-separated pair consisting of 'GradientTolerance' and a nonnegative scalar.

Let $\nabla \mathcal{L}_t$ be the gradient vector of the objective function with respect to the coefficients and bias term at optimization iteration t . If $\|\nabla \mathcal{L}_t\|_\infty = \max|\nabla \mathcal{L}_t| < \text{GradientTolerance}$, then optimization terminates.

If you also specify BetaTolerance, then optimization terminates when the software satisfies either stopping criterion.

By default, the value is the same GradientTolerance value used to train MdL.

Example: 'GradientTolerance',1e-5

Data Types: single | double

IterationLimit — Maximum number of additional optimization iterations

positive integer

Maximum number of additional optimization iterations, specified as the comma-separated pair consisting of 'IterationLimit' and a positive integer.

The default value is 1000 if the transformed data fits in memory (`Mdl.ModelParameters.BlockSize`), which you specify by using the 'BlockSize' name-value pair argument when training `Mdl` with `fitrkernel`. Otherwise, the default value is 100.

Note that the default value is not the value used to train `Mdl`.

Example: 'IterationLimit',500

Data Types: single | double

Output Arguments

UpdatedMdl — Updated kernel regression model

RegressionKernel model object

Updated kernel regression model, returned as a `RegressionKernel` model object.

FitInfo — Optimization details

structure array

Optimization details, returned as a structure array including fields described in this table. The fields contain final values or name-value pair argument specifications.

Field	Description
Solver	Objective function minimization technique: 'LBFGS-fast', 'LBFGS-blockwise', or 'LBFGS-tall'. For details, see the "Algorithms" on page 32-7526 section of <code>fitrkernel</code> .
LossFunction	Loss function. Either mean squared error (MSE) or epsilon-insensitive, depending on the type of linear regression model. See <code>Learner</code> of <code>fitrkernel</code> .
Lambda	Regularization term strength. See <code>Lambda</code> of <code>fitrkernel</code> .
BetaTolerance	Relative tolerance on the linear coefficients and the bias term. See <code>BetaTolerance</code> .

Field	Description
GradientTolerance	Absolute gradient tolerance. See GradientTolerance.
ObjectiveValue	Value of the objective function when optimization terminates. The regression loss plus the regularization term compose the objective function.
GradientMagnitude	Infinite norm of the gradient vector of the objective function when optimization terminates. See GradientTolerance.
RelativeChangeInBeta	Relative changes in the linear coefficients and the bias term when optimization terminates. See BetaTolerance.
FitTime	Elapsed, wall-clock time (in seconds) required to fit the model to the data.
History	History of optimization information. This field also includes the optimization information from training Mdl. This field is empty ([]) if you specify 'Verbose', 0 when training Mdl. For details, see Verbose and the “Algorithms” on page 32-7526 section of fitrkernel.

To access fields, use dot notation. For example, to access the vector of objective function values for each iteration, enter `FitInfo.ObjectiveValue` in the Command Window.

Examine the information provided by `FitInfo` to assess whether convergence is satisfactory.

Definitions

Random Feature Expansion

Random feature expansion, such as `Random Kitchen Sinks[1]` and `Fastfood[2]`, is a scheme to approximate Gaussian kernels of the kernel regression algorithm for big data in a computationally efficient way. Random feature expansion is more practical for big data applications that have large training sets but can also be applied to smaller data sets that fit in memory.

The kernel regression algorithm searches for an optimal function that deviates from each response data point (y_i) by values no greater than the epsilon margin (ϵ) after mapping the predictor data into a high-dimensional space.

Some regression problems cannot be described adequately using a linear model. In such cases, obtain a nonlinear regression model by replacing the dot product $x_1 x_2'$ with a nonlinear kernel function $G(x_1, x_2) = \langle \varphi(x_1), \varphi(x_2) \rangle$, where x_i is the i th observation (row vector) and $\varphi(x_i)$ is a transformation that maps x_i to a high-dimensional space (called the “kernel trick”). However, evaluating $G(x_1, x_2)$, the Gram matrix, for each pair of observations is computationally expensive for a large data set (large n).

The random feature expansion scheme finds a random transformation so that its dot product approximates the Gaussian kernel. That is,

$$G(x_1, x_2) = \langle \varphi(x_1), \varphi(x_2) \rangle \approx T(x_1)T(x_2)',$$

where $T(x)$ maps x in \mathbb{R}^p to a high-dimensional space (\mathbb{R}^m). The Random Kitchen Sink[1] scheme uses the random transformation

$$T(x) = m^{-1/2} \exp(iZx'),$$

where $Z \in \mathbb{R}^{m \times p}$ is a sample drawn from $N(0, \sigma^{-2})$ and σ^2 is a kernel scale. This scheme requires $O(mp)$ computation and storage. The Fastfood[2] scheme introduces another random basis V instead of Z using Hadamard matrices combined with Gaussian scaling matrices. This random basis reduces computation cost to $O(m \log p)$ and reduces storage to $O(m)$.

You can specify values for m and σ^2 , using the `NumExpansionDimensions` and `KernelScale` name-value pair arguments of `fitrkernel`, respectively.

The `fitrkernel` function uses the Fastfood scheme for random feature expansion and uses linear regression to train a Gaussian kernel regression model. Unlike solvers in the `fitrsvm` function, which require computation of the n -by- n Gram matrix, the solver in `fitrkernel` only needs to form a matrix of size n -by- m , with m typically much less than n for big data.

Extended Capabilities

Tall Arrays

Calculate with arrays that have more rows than fit in memory.

Usage notes and limitations:

- The default value for the 'IterationLimit' name-value pair argument is relaxed to 20 when you work with tall arrays.
- `resume` uses a block-wise strategy. For details, see the “Algorithms” on page 32-7526 section of `fitrkernel`.

For more information, see “Tall Arrays” (MATLAB).

Introduced in R2018a

RegressionPartitionedKernel

Cross-validated kernel model for regression

Description

`RegressionPartitionedKernel` is a set of kernel regression models trained on cross-validated folds. To obtain a cross-validated, kernel regression model, use `fitrkernel` and specify one of the cross-validation options. You can estimate the predictive quality of the model, or how well the linear regression model generalizes, using one or more of these “kfold” methods: `kfoldPredict` and `kfoldLoss`.

Every “kfold” method uses models trained on *training-fold* observations to predict the response for *validation-fold* observations. For example, suppose that you cross-validate using five folds. In this case, the software randomly assigns each observation into five groups of equal size (roughly). The training fold contains four of the groups (that is, roughly 4/5 of the data) and the validation fold contains the other group (that is, roughly 1/5 of the data). In this case, cross-validation proceeds as follows:

- 1 The software trains the first model (stored in `CVMdl.Trained{1}`) using the observations in the last four groups and reserves the observations in the first group for validation.
- 2 The software trains the second model (stored in `CVMdl.Trained{2}`) using the observations in the first group and the last three groups. The software reserves the observations in the second group for validation.
- 3 The software proceeds in a similar fashion for the third through the fifth models.

If you validate by calling `kfoldPredict`, it computes predictions for the observations in group 1 using the first model, group 2 for the second model, and so on. In short, the software estimates a response for every observation using the model trained without that observation.

Note `RegressionPartitionedKernel` model objects do not store the predictor data set.

Creation

Create a `RegressionPartitionedKernel` object using the `fitrkernel` function. Use one of the 'CrossVal', 'CVPartition', 'Holdout', 'KFold', or 'Leaveout' name-value pair arguments in the call to `fitrkernel`. For details, see the `fitrkernel` function reference page.

Properties

Cross-Validation Properties

CrossValidatedModel — Cross-validated model name

character vector

This property is read-only.

Cross-validated model name, specified as a character vector.

For example, 'Kernel' specifies a cross-validated kernel model.

Data Types: char

KFold — Number of cross-validated folds

positive integer scalar

This property is read-only.

Number of cross-validated folds, specified as a positive integer scalar.

Data Types: double

ModelParameters — Cross-validation parameter values

object

This property is read-only.

Cross-validation parameter values, specified as an object. The parameter values correspond to the name-value pair argument values used to cross-validate the kernel regression model. `ModelParameters` does not contain estimated parameters.

NumObservations — Number of observations

positive numeric scalar

This property is read-only.

Number of observations in the training data, specified as a positive numeric scalar.

Data Types: double

Partition — Data partition

cvpartition model

This property is read-only.

Data partition indicating how the software splits the data into cross-validation folds, specified as a cvpartition model.

Trained — Kernel regression models trained on cross-validation folds

cell array of RegressionKernel models

This property is read-only.

Kernel regression models trained on cross-validation folds, specified as a cell array of RegressionKernel models. Trained has k cells, where k is the number of folds.

Data Types: cell

W — Observation weights

numeric vector

This property is read-only.

Observation weights used to cross-validate the model, specified as a numeric vector. W has NumObservations elements.The software normalizes the weights used for training so that $\text{nansum}(W)$ is 1.

Data Types: single | double

Y — Observed response values

numeric vector

This property is read-only.

Observed response values used to cross-validate the model, specified as a numeric vector. `Y` has `NumObservations` elements.

Each row of `Y` represents the observed response of the corresponding observation in the predictor data.

Data Types: `single` | `double`

Other Regression Properties

CategoricalPredictors — Categorical predictor indices

`[]`

This property is read-only.

Categorical predictor indices, specified as an empty numeric value. In general, `CategoricalPredictors` contains index values corresponding to the columns of the predictor data that contain categorical predictors. Because `RegressionKernel` models can only be trained on numeric predictor data, this property is empty (`[]`).

PredictorNames — Predictor names

`{'x1', 'x2', ...}`

This property is read-only.

Predictor names in order of their appearance in predictor data (`X`), specified as a cell array of character vectors of the form `{'x1', 'x2', ...}`. The length of `PredictorNames` is equal to the number of columns in `X`.

Data Types: `cell`

ResponseName — Response variable name

`'Y'`

This property is read-only.

Response variable name, specified as `'Y'`. Because `RegressionKernel` models cannot be trained using tabular data, this property is always `'Y'`.

Data Types: `char`

ResponseTransform — Response transformation function

`'none'` | function handle

Response transformation function, specified as 'none' or a function handle. ResponseTransform describes how the software transforms raw response values predicted by the model.

For a MATLAB function, or a function that you define, enter its function handle. For example, you can enter `Mdl.ResponseTransform = @function`, where *function* accepts a numeric vector of the original responses and returns a numeric vector of the same size containing the transformed responses.

Data Types: char | string | function_handle

Object Functions

`kfoldLoss` Regression loss for cross-validated kernel regression model
`kfoldPredict` Predict responses for observations in cross-validated kernel regression model

Examples

Create Cross-Validated Kernel Regression Model

Simulate sample data.

```
rng(0, 'twister'); % For reproducibility
n = 1000;
x = linspace(-10,10,n)';
y = 1 + x*2e-2 + sin(x)./x + 0.2*randn(n,1);
```

Cross-validate a kernel regression model.

```
CVMdl = fitrkernel(x,y,'Kfold',5);
```

`CVMdl` is a `RegressionPartitionedKernel` cross-validated model. Because `fitrkernel` implements 10-fold cross-validation by default, `CVMdl.Trained` contains a cell vector of 10 `RegressionKernel` models. Display the trained property.

```
CVMdl.Trained
```

```
ans = 5x1 cell array
      {1x1 RegressionKernel}
```

```
{1x1 RegressionKernel}  
{1x1 RegressionKernel}  
{1x1 RegressionKernel}  
{1x1 RegressionKernel}
```

Each cell contains a kernel regression model trained on nine folds, then tested on the remaining fold.

Predict responses for observations in the validation folds and estimate the generalization error by passing `CVmdl` to `kfoldPredict` and `kfoldLoss`, respectively.

```
yHat = kfoldPredict(CVmdl);  
L = kfoldLoss(CVmdl)
```

```
L = 0.1887
```

`kfoldLoss` computes the average mean squared error for all the folds by default. The estimated mean squared error is 0.1887.

Introduced in R2018b

kfoldLoss

Regression loss for cross-validated kernel regression model

Syntax

```
L = kfoldLoss(CVMdl)
L = kfoldLoss(CVMdl,Name,Value)
```

Description

`L = kfoldLoss(CVMdl)` returns the regression loss obtained by the cross-validated kernel regression model `CVMdl`. For every fold, `kfoldLoss` computes the regression loss for observations in the validation fold, using a model trained on observations in the training fold.

`L = kfoldLoss(CVMdl,Name,Value)` returns the mean squared error (MSE) with additional options specified by one or more name-value pair arguments. For example, you can specify the regression-loss function or which folds to use for loss calculation.

Examples

Compute Loss for Cross-Validated Kernel Regression Models

Simulate sample data:

```
rng(0, 'twister'); % For reproducibility
n = 1000;
x = linspace(-10,10,n)';
y = 1 + x*2e-2 + sin(x)./x + 0.2*randn(n,1);
```

Cross-validate a kernel regression model.

```
CVMdl = fitrkernel(x,y,'Kfold',5);
```

`fitrkernel` implements 5-fold cross-validation. `CVMDL` is a `RegressionPartitionedKernel` model. It contains the property `Trained`, which is a 5-by-1 cell array holding 5 `RegressionKernel` models that the software trained using the training set.

Compute the epsilon-insensitive loss for each fold for observations that `fitrkernel` did not use in training the folds.

```
L = kfoldLoss(CVMDL, 'LossFun', 'epsiloninsensitive', 'Mode', 'individual')
```

```
L = 5×1
```

```
0.2812  
0.3223  
0.3073  
0.3117  
0.2576
```

Input Arguments

CVMDL — Cross-validated kernel regression model

`RegressionPartitionedKernel` model object

Cross-validated kernel regression model, specified as a `RegressionPartitionedKernel` model object. You can create a `RegressionPartitionedKernel` model using `fitrkernel` and specifying any of the cross-validation name-value pair arguments, for example, `CrossVal`.

Name-Value Pair Arguments

Specify optional comma-separated pairs of `Name`, `Value` arguments. `Name` is the argument name and `Value` is the corresponding value. `Name` must appear inside quotes. You can specify several name and value pair arguments in any order as `Name1, Value1, ..., NameN, ValueN`.

Example: `'LossFun', 'epsiloninsensitive', 'Mode', 'individual'` specifies `kfoldLoss` to return the epsilon-insensitive loss for each fold.

Folds — Fold indices to use for response prediction

1: `CVMDL.KFold` (default) | numeric vector of positive integers

Fold indices to use for response prediction, specified as the comma-separated pair consisting of 'Folds' and a numeric vector of positive integers. The elements of Folds must range from 1 through `CVMdl.KFold`.

Example: 'Folds',[1 4 10]

Data Types: single | double

LossFun — Loss function

'mse' (default) | 'epsiloninsensitive' | function handle

Loss function, specified as the comma-separated pair consisting of 'LossFun' and a built-in, loss-function name or function handle.

- The following table lists the available loss functions. Specify one using its corresponding character vector or string scalar. Also, in the table, $f(x) = x\beta + b$.
 - β is a vector of p coefficients.
 - x is an observation from p predictor variables.
 - b is the scalar bias.

Value	Description
'epsiloninsensitive'	Epsilon-insensitive loss: $\ell[y, f(x)] = \max[0, y - f(x) - \varepsilon]$
'mse'	MSE: $\ell[y, f(x)] = [y - f(x)]^2$

'epsiloninsensitive' is appropriate for SVM learners only.

- Specify your own function using function handle notation.

Assume that n is the number of observations in X . Your function must have this signature

```
lossvalue = lossfun(Y,Yhat,W)
```

where:

- The output argument `lossvalue` is a scalar.
- You specify the function name (`lossfun`).
- Y is an n -dimensional vector of observed responses. `kfoldLoss` passes the input argument Y in for Y .

- \hat{Y} is an n -dimensional vector of predicted responses, which is similar to the output of `predict`.
- W is an n -by-1 numeric vector of observation weights.

Data Types: `char` | `string` | `function_handle`

Mode — Loss aggregation level

'average' (default) | 'individual'

Loss aggregation level, specified as the comma-separated pair consisting of 'Mode' and 'average' or 'individual'.

Value	Description
'average'	Returns losses averaged over all folds
'individual'	Returns losses for each fold

Example: 'Mode', 'individual'

Output Arguments

L — Cross-validated regression losses

numeric scalar | numeric vector

Cross-validated regression losses, returned as a numeric scalar or vector. The interpretation of L depends on `LossFun`.

- If `Mode` is 'average', then L is a scalar.
- Otherwise, L is a k -by-1 vector, where k is the number of folds. $L(j)$ is the average regression loss over fold j .

To estimate L , `kfoldLoss` uses the data that created `CVMdl`.

`RegressionKernel` | `RegressionPartitionedKernel` | `fitrkernel` | `kfoldPredict`

Introduced in R2018b

kfoldPredict

Predict responses for observations in cross-validated kernel regression model

Syntax

```
YHat = kfoldPredict(CVMdl)
```

Description

`YHat = kfoldPredict(CVMdl)` returns cross-validated predicted responses by the cross-validated kernel regression model `CVMdl`. That is, for every fold, `kfoldPredict` predicts the responses for observations that it holds out in validation fold while it trains using all other observations in the training fold.

Examples

Predict Responses from Cross-Validated Kernel Regression Models

Simulate sample data:

```
rng(0, 'twister'); % For reproducibility
n = 1000;
x = linspace(-10,10,n)';
y = 1 + x*2e-2 + sin(x)./x + 0.2*randn(n,1);
```

Cross-validate a kernel regression model.

```
CVMdl = fitrkernel(x,y, 'CrossVal', 'on');
```

By default, `fitrkernel` implements 10-fold cross-validation. `CVMdl` is a `RegressionPartitionedKernel` model. It contains the property `Trained`, which is a 10-by-1 cell array holding 10 `RegressionKernel` models that the software trained using the training set.

Predict responses for observations that `fitrkernel` did not use in training the folds.

```
yHat = kfoldPredict(CVMdl);
```

yHat is a numeric vector. Display the first five predicted responses.

```
yHat(1:5)
```

```
ans = 5×1
```

```

Input Arguments

CVMdl — Cross-validated kernel regression model

RegressionPartitionedKernel model object

Cross-validated kernel regression model, specified as a RegressionPartitionedKernel model object. You can create a RegressionPartitionedKernel model using fitrkernel and specifying any of the one of the cross-validation name-value pair arguments, for example, CrossVal.

To obtain estimates, kfoldPredict applies the same data used to cross-validate the kernel regression model (see X input argument on fitrkernel page).

Output Arguments

YHat — Cross-validated predicted responses

numeric vector

Cross-validated predicted responses, returned as an n -by-1 numeric array, where n is the number of observations in the predictor data used to create CVMdl (see X input argument on fitrkernel page).

Introduced in R2018b

Sample Data Sets

Sample Data Sets

Statistics and Machine Learning Toolbox software includes the sample data sets in the following table.

To load a data set into the MATLAB workspace, type:

```
load filename
```

where *filename* is one of the files listed in the table.

Data sets contain individual data variables, description variables with references, and dataset arrays encapsulating the data set and its description, as appropriate.

File	Description of Data Set
acetylene.mat	Chemical reaction data with correlated predictors
arrhythmia.mat	Cardiac arrhythmia data from the UCI machine learning repository
carbig.mat	Measurements of cars, 1970–1982
carsmall.mat	Subset of carbig.mat. Measurements of cars, 1970, 1976, 1982
census1994.mat	Adult data from the UCI machine learning repository
cereal.mat	Breakfast cereal ingredients
cities.mat	Quality of life ratings for U.S. metropolitan areas
discrim.mat	A version of cities.mat used for discriminant analysis
examgrades.mat	Exam grades on a scale of 0–100
fisheriris.mat	Fisher's 1936 iris data
flu.mat	Google Flu Trends estimated ILI (influenza-like illness) percentage for various regions of the US, and CDC weighted ILI percentage based on sentinel provider reports
gas.mat	Gasoline prices around the state of Massachusetts in 1993
hald.mat	Heat of cement vs. mix of ingredients
hogg.mat	Bacteria counts in different shipments of milk

Distribution Reference

Bernoulli Distribution

In this section...
“Overview” on page B-2
“Parameters” on page B-2
“Probability Mass Function” on page B-2
“Mean and Variance” on page B-2
“Relationship to Other Distributions” on page B-3

Overview

The Bernoulli distribution is a discrete probability distribution with the only two possible values for the random variable. Each instance of an event with a Bernoulli distribution is called a Bernoulli trial.

Parameters

The Bernoulli distribution uses the following parameter.

Parameter	Description	Support
p	Probability of success	$0 \leq p \leq 1$

Probability Mass Function

The probability mass function (pmf) is

$$f(x|p) = \begin{cases} 1 - p & , \quad x = 0, \\ p & , \quad x = 1 \end{cases} .$$

Mean and Variance

The mean is

$$\text{mean} = p .$$

The variance is

$$\text{var} = p(1 - p) .$$

Relationship to Other Distributions

The Bernoulli distribution is a special case of the binomial distribution on page B-9, with the number of trials $n = 1$. The geometric distribution on page B-60 models the number of Bernoulli trials before the first success (or first failure).

Beta Distribution

In this section...
“Overview” on page B-4
“Parameters” on page B-4
“Probability Density Function” on page B-5
“Cumulative Distribution Function” on page B-7
“Example” on page B-7

Overview

The beta distribution describes a family of curves that are unique in that they are nonzero only on the interval (0 1). A more general version of the function assigns parameters to the endpoints of the interval.

Statistics and Machine Learning Toolbox provides several ways to work with the beta distribution. You can use the following approaches to estimate parameters from sample data, compute the pdf, cdf, and icdf, generate random numbers, and more.

- Fit a probability distribution object to sample data, or create a probability distribution object with specified parameter values. See [Using BetaDistribution Objects](#) for more information.
- Work with data input from matrices, tables, and dataset arrays using probability distribution functions. See “Supported Distributions” on page 5-20 for a list of beta distribution functions.
- Interactively fit, explore, and generate random numbers from the distribution using an app or user interface.

For more information on each of these options, see “Working with Probability Distributions” on page 5-3.

Parameters

The beta distribution uses the following parameters.

Parameter	Description	Support
a	First shape parameter	$a > 0$
b	Second shape parameter	$b > 0$

Probability Density Function

Definition

The probability density function (pdf) of the beta distribution is

$$y = f(x|a, b) = \frac{1}{B(a, b)} x^{a-1} (1-x)^{b-1} I_{[0,1]}(x)$$

where $B(\cdot)$ is the Beta function. The indicator function $I_{(0,1)}(x)$ ensures that only values of x in the range $(0,1)$ have nonzero probability.

Plot

This plot shows how changing the value of the parameters alters the shape of the pdf. The constant pdf (the flat line) shows that the standard uniform distribution is a special case of the beta distribution, which occurs when $a = b = 1$.

```
X = 0:.01:1;
y1 = betapdf(X,0.75,0.75);
y2 = betapdf(X,1,1);
y3 = betapdf(X,4,4);

figure
plot(X,y1,'Color','r','LineWidth',2)
hold on
plot(X,y2,'LineStyle','-','Color','b','LineWidth',2)
plot(X,y3,'LineStyle',':','Color','g','LineWidth',2)
legend({'a = b = 0.75', 'a = b = 1', 'a = b = 4'}, 'Location', 'NorthEast');
hold off
```

Relationship to Other Distributions

The beta distribution has a functional relationship with the t distribution. If Y is an observation from Student's t distribution with ν degrees of freedom, then the following transformation generates X , which is beta distributed.

$$X = \frac{1}{2} + \frac{1}{2} \frac{Y}{\sqrt{\nu + Y^2}}$$

If $Y \sim t(\nu)$, then $X \sim \beta\left(\frac{\nu}{2}, \frac{\nu}{2}\right)$

This relationship is used to compute values of the t cdf and inverse function as well as generating t distributed random numbers.

Cumulative Distribution Function

The beta cdf is the same as the incomplete beta function.

Example

Suppose you are collecting data that has hard lower and upper bounds of zero and one respectively. Parameter estimation is the process of determining the parameters of the beta distribution that fit this data best in some sense.

One popular criterion of goodness is to maximize the likelihood function. The likelihood has the same form as the beta pdf. But for the pdf, the parameters are known constants and the variable is x . The likelihood function reverses the roles of the variables. Here, the sample values (the x 's) are already observed. So they are the fixed constants. The variables are the unknown parameters. Maximum likelihood estimation (MLE) involves calculating the values of the parameters that give the highest likelihood given the particular set of data.

The function `betafit` returns the MLEs and confidence intervals for the parameters of the beta distribution. Here is an example using random numbers from the beta distribution with $a = 5$ and $b = 0.2$.

```
rng default % For reproducibility
r = betarnd(5,0.2,100,1);
[phat, pci] = betafit(r)

phat = 1×2

    7.4911    0.2135

pci = 2×2

    5.0861    0.1744
   11.0334    0.2614
```

The MLE for parameter a is 7.4911, compared to the true value of 5. The 95% confidence interval for a goes from 5.0861 to 11.0334, which does not include the true value. While

this is an unlikely result, it does sometimes happen when estimating distribution parameters.

Similarly the MLE for parameter **b** is 0.2135, compared to the true value of 0.2. The 95% confidence interval for **b** goes from 0.1744 to 0.2614, which does include the true value. In this made-up example you know the “true value.” In experimentation you do not.

Binomial Distribution

In this section...

“Overview” on page B-9
 “Parameters” on page B-9
 “Probability Density Function” on page B-9
 “Mean and Variance” on page B-10
 “Relationship to Other Distributions” on page B-10
 “Example” on page B-10

Overview

The binomial distribution models the total number of successes in repeated trials from an infinite population under the following conditions:

- Only two outcomes are possible on each of n trials.
- The probability of success for each trial is constant.
- All trials are independent of each other.

Parameters

The binomial distribution uses the following parameters.

Parameter	Description	Support
N	Number of trials	positive integer
p	Probability of success	$0 \leq p \leq 1$

Probability Density Function

The probability density function (pdf) is

$$f(x|N, p) = \binom{N}{x} p^x (1-p)^{N-x} \quad ; \quad x = 0, 1, 2, \dots, N,$$

where x is the number of successes in n trials of a Bernoulli process with probability of success p .

Mean and Variance

The mean is

$$\text{mean} = np .$$

The variance is

$$\text{var} = np(1 - p) .$$

Relationship to Other Distributions

The binomial distribution is a generalization of the Bernoulli distribution on page B-2, allowing for a number of trials n greater than 1. The binomial distribution generalizes to the multinomial distribution on page B-104 when there are more than two possible outcomes for each trial.

Example

Suppose you are collecting data from a widget manufacturing process, and you record the number of widgets within specification in each batch of 100. You might be interested in the probability that an individual widget is within specification. Parameter estimation is the process of determining the parameter, p , of the binomial distribution that fits this data best in some sense.

One popular criterion of goodness is to maximize the likelihood function. The likelihood has the same form as the binomial pdf above. But for the pdf, the parameters (n and p) are known constants and the variable is x . The likelihood function reverses the roles of the variables. Here, the sample values (the x 's) are already observed. So they are the fixed constants. The variables are the unknown parameters. MLE involves calculating the value of p that give the highest likelihood given the particular set of data.

The function `binofit` returns the MLEs and confidence intervals for the parameters of the binomial distribution. Here is an example using random numbers from the binomial distribution with $n = 100$ and $p = 0.9$.

```
rng default; % for reproducibility
r = binornd(100,0.9)

r = 85

[phat, pci] = binofit(r,100)
```

```
phat = 0.8500
pci = 1x2
      0.7647    0.9135
```

The MLE for parameter p is 0.8800, compared to the true value of 0.9. The 95% confidence interval for p goes from 0.7998 to 0.9364, which includes the true value. In this made-up example you know the “true value” of p . In experimentation you do not.

The following commands generate a plot of the binomial pdf for $n = 10$ and $p = 1/2$.

```
x = 0:10;
y = binopdf(x,10,0.5);
plot(x,y, '+')
```

Birnbaum-Saunders Distribution

In this section...

“Definition” on page B-13

“Background” on page B-13

“Parameters” on page B-13

Definition

The Birnbaum-Saunders distribution has the density function

$$\frac{1}{\sqrt{2\pi}} \exp\left\{-\frac{(\sqrt{x/\beta} - \sqrt{\beta/x})^2}{2\gamma^2}\right\} \left(\frac{\sqrt{x/\beta} + \sqrt{\beta/x}}{2\gamma x}\right)$$

with scale parameter $\beta > 0$ and shape parameter $\gamma > 0$, for $x > 0$.

If x has a Birnbaum-Saunders distribution with parameters β and γ , then

$$\frac{(\sqrt{x/\beta} - \sqrt{\beta/x})}{\gamma}$$

has a standard normal distribution.

Background

The Birnbaum-Saunders distribution was originally proposed as a lifetime model for materials subject to cyclic patterns of stress and strain, where the ultimate failure of the material comes from the growth of a prominent flaw. In materials science, Miner's Rule suggests that the damage occurring after n cycles, at a stress level with an expected lifetime of N cycles, is proportional to n / N . Whenever Miner's Rule applies, the Birnbaum-Saunders model is a reasonable choice for a lifetime distribution model.

Parameters

To estimate distribution parameters, use `mle` or the Distribution Fitter app.

“Burr pdf for Various Parameters” on page B-21

“Survival and Hazard Functions of Burr Distribution” on page B-23

“Divergence of Parameter Estimates” on page B-25

Definition

The Burr type XII distribution is a three-parameter family of distributions on the positive real line. The cumulative distribution function (cdf) of the Burr distribution is

$$F(x) \left| \alpha, c, k \right. = 1 - \frac{1}{\left(1 + \left(\frac{x}{\alpha}\right)^c\right)^k}, \quad x > 0, \alpha > 0, c > 0, k > 0,$$

where c and k are the shape parameters and α is the scale parameter. The probability density function (pdf) is

$$f(x) \left| \alpha, c, k \right. = \frac{\frac{kc}{\alpha} \left(\frac{x}{\alpha}\right)^{c-1}}{\left(1 + \left(\frac{x}{\alpha}\right)^c\right)^{k+1}}, \quad x > 0, \alpha > 0, c > 0, k > 0.$$

The density of the Burr type XII distribution is L-shaped if $c \leq 1$ and unimodal, otherwise.

Background

Burr distribution was first discussed by Burr (1942) as a two-parameter family. An additional scale parameter was introduced by Tadikamalla (1980). It is a flexible distribution family that can express a wide range of distribution shapes. The Burr

distribution includes, overlaps, or has as a limiting case, many commonly used distributions such as gamma, lognormal, loglogistic, bell-shaped, and J-shaped beta distributions (but not U-shaped). Some compound distributions also correspond to the Burr distribution. For example, compounding a Weibull distribution with a gamma distribution for its scale parameter results in a Burr distribution. Similarly, compounding an exponential distribution with a gamma distribution for its rate parameter, $1/\mu$, also yields a Burr distribution. The Burr distribution also has two asymptotic limiting cases: Weibull and Pareto Type I.

The Burr distribution can fit a wide range of empirical data. Different values of its parameters cover a broad set of skewness and kurtosis. Hence, it is used in various fields such as finance, hydrology, and reliability to model a variety of data types. Examples of data modeled by the Burr distribution are household income, crop prices, insurance risk, travel time, flood levels, and failure data.

The survival and hazard functions of Burr type XII distribution are, respectively,

$$S(x|\alpha, c, k) = \frac{1}{\left[1 + \left(\frac{x}{\alpha}\right)^c\right]^k}$$

and

$$h(x|\alpha, c, k) = \frac{\frac{kc}{\alpha} \left(\frac{x}{\alpha}\right)^{c-1}}{1 + \left(\frac{x}{\alpha}\right)^c}.$$

If $c > 1$, the hazard function $h(x)$ is non-monotonic with a mode at $x = \alpha(c - 1)^{1/c}$.

Parameters

The three-parameter Burr distribution is defined by its scale parameter α and shape parameters c and k . You can estimate the parameters using `mle` or `fitdist`. Both functions support censored data for Burr distribution.

Generate sample data from a Burr distribution with scale parameter 0.5 and shape parameters 2 and 5.

```
rng('default')  
R = random('burr', 0.5, 2, 5, 1000, 1);
```

Estimate the parameters and the confidence intervals.

```
[phat,pci] = mle(R, 'distribution', 'burr')
```

```
phat =
```

```
    0.4154    2.1217    4.0550
```

```
pci =
```

```
    0.2985    1.9560    2.4079
    0.5782    2.3014    6.8288
```

The default 95% confidence intervals for the parameters include the true parameter values.

The three-parameter Burr distribution converges asymptotically to one of the two limiting forms as its parameters diverge:

- If $k \rightarrow 0$, $c \rightarrow \infty$, $ck = \lambda$, then the Burr distribution reduces to a two-parameter Pareto distribution with the cdf

$$F_P = 1 - \left(\frac{x}{\alpha}\right)^{-\lambda}, \quad x \geq \alpha.$$

- If $k \rightarrow \infty$, $\alpha \rightarrow \infty$, $\alpha/k^{1/c} = \theta$, then the Burr distribution reduces to a two-parameter Weibull distribution with the cdf

$$F_W(x | c, \theta) = 1 - \exp\left[-\left(\frac{x}{\theta}\right)^c\right].$$

If `mle` or `fitdist` detects such divergence, it returns an error message, but informs you of the limiting distribution and corresponding parameter estimates for that distribution.

Fit a Burr Distribution and Draw the cdf

This example shows how to fit a Burr distribution to data, draw the cdf, and construct a histogram with a Burr distribution fit.

1. Load the sample data.

```
load arrhythmia
```

The fifth column in `X` contains a measurement obtained from electrocardiograms, called QRS duration.

2. Fit a Burr distribution to the QRS duration data, and get the parameter estimates.

```
PD = fitdist(X(:,5), 'burr');
```

PD has the maximum likelihood estimates of the Burr distribution parameters in the property Param. The estimates are $\alpha = 80.4515$, $c = 18.9251$, $k = 0.4492$.

3. Plot the cdf of the QRS duration data.

```
QRScdf=cdf('burr',sortrows(X(:,5)),80.4515,18.9251,0.4492);  
plot(sortrows(X(:,5)),QRScdf)  
title('QRS duration data')  
xlabel('QRS Duration')
```

4. Draw the histogram of QRS duration data with 15 bins and the pdf of the Burr distribution fit.

```
histfit(X(:,5),15,'burr')  
title('Histogram of QRS data with a Burr distribution fit')  
xlabel('QRS Duration')
```

Compare Lognormal and Burr Distribution pdfs

Compare the lognormal pdf to the Burr pdf using income data generated from a lognormal distribution.

Generate the income data.

```
rng('default') % For reproducibility
y = random('Lognormal',log(25000),0.65,[500,1]);
```

Fit a Burr distribution.

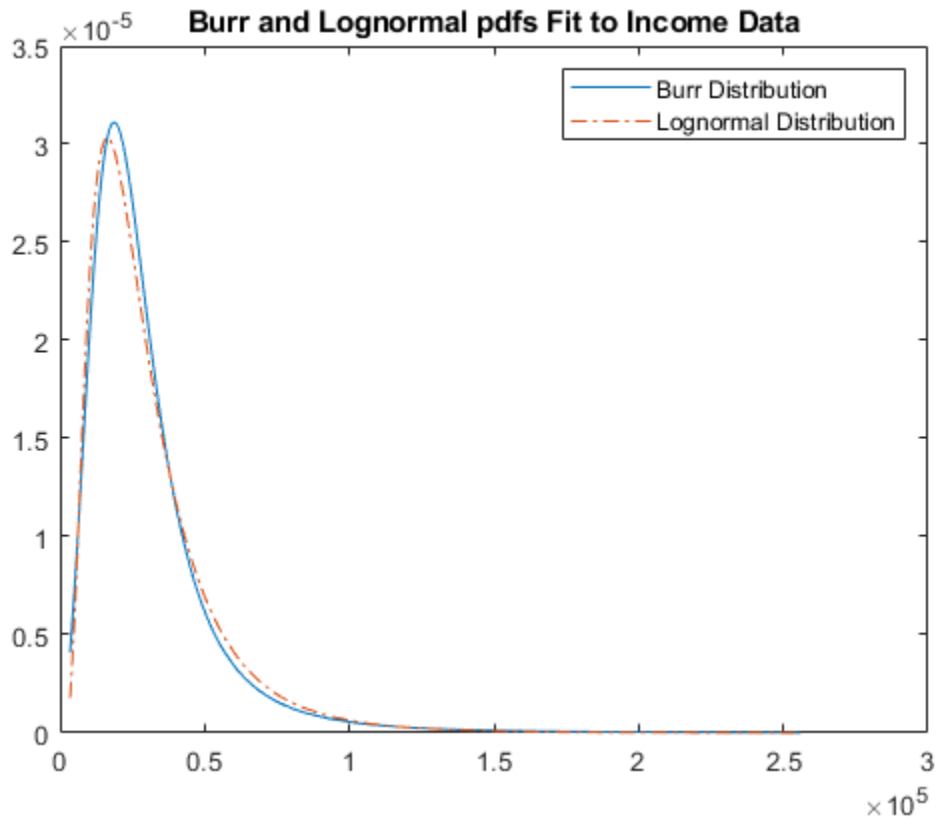

```
pd = fitdist(y,'burr')

pd =
  BurrDistribution

  Burr distribution
  alpha = 26007.2    [21165.5, 31956.4]
  c = 2.63743      [2.3053, 3.0174]
  k = 1.09658      [0.775479, 1.55064]
```

Plot both the Burr and lognormal pdfs of income data on the same figure.

```
p_burr = pdf(pd,sortrows(y));
p_lognormal = pdf('Lognormal',sortrows(y),log(25000),0.65);
plot(sortrows(y),p_burr,'-',sortrows(y),p_lognormal,'-.')
title('Burr and Lognormal pdfs Fit to Income Data')
legend('Burr Distribution','Lognormal Distribution')
```

Burr pdf for Various Parameters

This example shows how to create a variety of shapes for probability density functions of the Burr distribution.

```
X = 0:0.01:5;
c = [0.5 0.95 2 5];
k = [0.5 0.75 2 5];
alpha = [0.5 1 2 5];
colors = ['b'; 'g'; 'r'; 'k'];
```

```
figure
```

```
for i = 1:1:4
pdf1(i,:) = pdf('burr',X,1,c(i),0.5);
pdf2(i,:) = pdf('burr',X,1,2,k(i));
pdf3(i,:) = pdf('burr',X,alpha(i),2,0.5);

axC = subplot(3,1,1);
pC(i) = plot(X,pdf1(i,:),colors(i),'LineWidth',2);
title('Effect of c, \alpha = 1, k = 0.5'),xlabel('x')
hold on

axK = subplot(3,1,2);
pK(i) = plot(X,pdf2(i,:),colors(i),'LineWidth',2);
title('Effect of k, \alpha = 1, c = 2'),xlabel('x')
hold on

axAlpha = subplot(3,1,3);
pAlpha(i) = plot(X,pdf3(i,:),colors(i),'LineWidth',2);
title('Effect of \alpha, c = 2, k = 0.5'),xlabel('x')
hold on
end

set(axC,'XLim',[0 3],'YLim',[0 1.2]);
set(axK,'XLim',[0 3],'YLim',[0 2.1]);
set(axAlpha,'XLim',[0 5],'YLim',[0 1]);

legend(axC,'c=0.5','c=0.95','c=2','c=5');
legend(axK,'k=0.5','k=0.75','k=2','k=5');
legend(axAlpha,'\alpha=0.5','\alpha=1','\alpha=2','\alpha=5');
```

This figure illustrates how the shape and scale of the Burr distribution changes for different values of its parameters.

Survival and Hazard Functions of Burr Distribution

This example shows how to find and plot the survival and hazard functions for a sample coming from a Burr distribution.

Generate the data.

```
X = 0:0.015:2.5;
```

Evaluate the pdf and cdf of data in X.

```
Xpdf = pdf('burr',X,0.2,5,0.5);  
Xcdf = cdf('burr',X,0.2,5,0.5);
```

Evaluate and plot the survival function of data in X.

```
S = 1.-Xcdf; % survival function  
plot(X,S,'LineWidth',2)  
title('Survival function')  
xlabel('x')
```

Evaluate and plot the hazard function of data in X.

```
H = Xpdf./S; % hazard function  
plot(X,H,'r','LineWidth',2)
```

```
title('Hazard function')  
xlabel('x')
```

Divergence of Parameter Estimates

This example shows how to interpret the display when the parameter estimates diverge when fitting a Burr distribution to input data.

1. Generate sample data from the Weibull distribution with parameters 0.5 and 2.

```
rng('default') % for reproducibility  
X = wblrnd(0.5,2,100,1);
```

2. Fit a Burr distribution.

```
PD = fitdist(X, 'burr');
```

```
Error using addburr>burrfit (line 566)
The data are not fit by a Burr distribution with finite parameters.
The maximum likelihood fit is provided by the k->Inf, alpha->Inf
limiting form of the Burr distribution: a Weibull distribution
with the parameters below.
    a (scale): 0.476817
    b (shape): 1.96219
```

```
Error in prob.BurrDistribution.fit (line 246)
    p = burrfit(x,0.05,cens,freq,opt);
```

```
Error in fitdist>localfit (line 238)
pd = feval(fitter,x,'cens',c,'freq',f,varargin{:});
```

```
Error in fitdist (line 185)
    pd = localfit(dist,fitter,x,cens,freq,args{:});
```

The error message tells you that the Weibull family seems to fit the data better and gives you the parameter estimates from a Weibull fit. You can use those estimates directly. If you need covariance estimates for the parameters or other information about the fit, you can refit a Weibull distribution to the data.

3. Fit a Weibull distribution to the data and find the confidence intervals for the parameter estimates.

```
PD = fitdist(X, 'weibull');
paramci(PD)
```

```
ans =
```

```
    0.4291    1.6821
    0.5298    2.2890
```

These are the 95% confidence intervals of the parameter estimates for the Weibull distribution fit.

Overview

The chi-square distribution is commonly used in hypothesis testing, particularly the chi-squared test for goodness of fit.

Parameters

The chi-square distribution uses the following parameter.

Parameter	Description	Support
ν	Degrees of freedom	ν is a positive value

Probability Density Function

The probability density function (pdf) is

$$y = f(x|\nu) = \frac{x^{(\nu-2)/2} e^{-x/2}}{2^{2}\Gamma(\nu/2)}$$

where $\Gamma(\cdot)$ is the Gamma function, ν is the degrees of freedom, and $x \geq 0$.

Cumulative Distribution Function

The cumulative distribution function (cdf) is

$$p = F(x | \nu) = \int_0^x \frac{t^{(\nu-2)/2} e^{-t/2}}{2^{\nu/2} \Gamma(\nu/2)} dt$$

where $\Gamma(\cdot)$ is the Gamma function, ν is the degrees of freedom, and $x \geq 0$.

Descriptive Statistics

The mean is ν .

The variance is 2ν .

Relationship to Other Distributions

The χ^2 distribution is a special case of the gamma distribution where $b = 2$ in the equation for gamma distribution below.

$$y = f(x | a, b) = \frac{1}{b^a \Gamma(a)} x^{a-1} e^{-x/b}$$

The χ^2 distribution gets special attention because of its importance in normal sampling theory. If a set of n observations is normally distributed with variance σ^2 , and s^2 is the sample variance, then

$$\frac{(n-1)s^2}{\sigma^2} \sim \chi^2(n-1)$$

This relationship is used to calculate confidence intervals for the estimate of the normal parameter σ^2 in the function `normfit`.

Examples

Compute Chi-Square Distribution pdf

Compute the pdf of a chi-square distribution with 4 degrees of freedom.

```
x = 0:0.2:15;
y = chi2pdf(x,4);
```

Plot the pdf.

```
figure;  
plot(x,y)
```

The chi-square distribution is skewed to the right, especially for few degrees of freedom.

Exponential Distribution

In this section...
“Definition” on page B-32
“Background” on page B-32
“Parameters” on page B-32
“Examples” on page B-33

Definition

The exponential pdf is

$$y = f(x|\mu) = \frac{1}{\mu} e^{-\frac{x}{\mu}}$$

Background

Like the chi-square distribution, the exponential distribution is a special case of the gamma distribution (obtained by setting $a = 1$)

$$y = f(x|a, b) = \frac{1}{b^a \Gamma(a)} x^{a-1} e^{-\frac{x}{b}}$$

where $\Gamma(\cdot)$ is the Gamma function.

The exponential distribution is special because of its utility in modeling events that occur randomly over time. The main application area is in studies of lifetimes.

Parameters

Suppose you are stress testing light bulbs and collecting data on their lifetimes. You assume that these lifetimes follow an exponential distribution. You want to know how long you can expect the average light bulb to last. Parameter estimation is the process of determining the parameters of the exponential distribution that fit this data best in some sense.

One popular criterion of goodness is to maximize the likelihood function. The likelihood has the same form as the exponential pdf above. But for the pdf, the parameters are

known constants and the variable is x . The likelihood function reverses the roles of the variables. Here, the sample values (the x 's) are already observed. So they are the fixed constants. The variables are the unknown parameters. MLE involves calculating the values of the parameters that give the highest likelihood given the particular set of data.

The function `expfit` returns the MLEs and confidence intervals for the parameters of the exponential distribution. Here is an example using random numbers from the exponential distribution with $\mu = 700$.

```
lifetimes = exprnd(700,100,1);
[muhat, muc1] = expfit(lifetimes)
```

```
muhat =
    672.8207
```

```
muc1 =
    547.4338
    810.9437
```

The MLE for parameter μ is 672, compared to the true value of 700. The 95% confidence interval for μ goes from 547 to 811, which includes the true value.

In the life tests you do not know the true value of μ so it is nice to have a confidence interval on the parameter to give a range of likely values.

Examples

Exponentially Distributed Lifetime Data

For exponentially distributed lifetimes, the probability that an item will survive an extra unit of time is independent of the current age of the item. The example shows a specific case of this special property.

```
l = 10:10:60;
lpd = l+0.1;
deltap = (expcdf(lpd,50)-expcdf(l,50))./(1-expcdf(l,50))

deltap =
    0.0020    0.0020    0.0020    0.0020    0.0020    0.0020
```

Compute the Exponential Distribution pdf

Compute the pdf of an exponential distribution with parameter $\mu = 2$.

```
x = 0:0.1:10;  
y = exppdf(x,2);
```

Plot the pdf.

```
figure;  
plot(x,y)
```

Extreme Value Distribution

In this section...
“Definition” on page B-36
“Background” on page B-36
“Parameters” on page B-38
“Examples” on page B-39

Definition

The probability density function for the extreme value distribution with location parameter μ and scale parameter σ is

$$y = f(x|\mu, \sigma) = \sigma^{-1} \exp\left(\frac{x - \mu}{\sigma}\right) \exp\left(-\exp\left(\frac{x - \mu}{\sigma}\right)\right)$$

This form of the probability density function is suitable for modeling the minimum value. To model the maximum value, use the negative of the original values.

If T has a Weibull distribution on page B-199 with parameters a and b , then $\log T$ has an extreme value distribution with parameters $\mu = \log a$ and $\sigma = 1/b$.

Background

Extreme value distributions are often used to model the smallest or largest value among a large set of independent, identically distributed random values representing measurements or observations. The extreme value distribution is appropriate for modeling the smallest value from a distribution whose tails decay exponentially fast, such as, the normal distribution. It can also model the largest value from a distribution, such as the normal or exponential distributions, by using the negative of the original values.

For example, the following fits an extreme value distribution to minimum values taken over 1000 sets of 500 observations from a normal distribution.

```
rng default; % For reproducibility
xMinima = min(randn(1000,500), [], 2);
paramEstsMinima = evfit(xMinima);
y = linspace(-5, -1.5, 1001);
histogram(xMinima, -4.75:.25:-1.75);
```

```
p = evpdf(y,paramEstsMinima(1),paramEstsMinima(2));
line(y,.25*length(xMinima)*p,'color','r')
```

The following fits an extreme value distribution to the maximum values in each set of observations.

```
rng default; % For reproducibility
xMaxima = max(randn(1000,500), [], 2);
paramEstsMaxima = evfit(-xMaxima);
y = linspace(1.5,5,1001);
histogram(xMaxima,1.75:.25:4.75);
p = evpdf(-y,paramEstsMaxima(1),paramEstsMaxima(2));
line(y,.25*length(xMaxima)*p,'color','r')
```

Although the extreme value distribution is most often used as a model for extreme values, you can also use it as a model for other types of continuous data. For example, extreme value distributions are closely related to the Weibull distribution. If T has a Weibull distribution, then $\log(T)$ has a type 1 extreme value distribution.

Parameters

The function `evfit` returns the maximum likelihood estimates (MLEs) and confidence intervals for the parameters of the extreme value distribution. The following example shows how to fit some sample data using `evfit`, including estimates of the mean and variance from the fitted distribution.

Suppose you want to model the size of the smallest washer in each batch of 1000 from a manufacturing process. If you believe that the sizes are independent within and between each batch, you can fit an extreme value distribution to measurements of the minimum diameter from a series of eight experimental batches. The following code returns the MLEs of the distribution parameters as `parmhat` and the confidence intervals as the columns of `parmci`.

```
x = [19.774 20.141 19.44 20.511 21.377 19.003 19.66 18.83];
[parmhat, parmci] = evfit(x)

parmhat =
    20.2506    0.8223

parmci =
    19.644 0.49861
    20.857 1.3562
```

You can find mean and variance of the extreme value distribution with these parameters using the function `evstat`.

```
[meanfit, varfit] = evstat(parmhat(1),parmhat(2))

meanfit =
    19.776

varfit =
    1.1123
```

Examples

Compute the Extreme Value Distribution pdf

Compute the pdf of an extreme value distribution.

```
t = [-5:.01:2];
y = evpdf(t);
```

Plot the pdf.

```
figure;
plot(t,y)
```

The extreme value distribution is skewed to the left, and its general shape remains the same for all parameter values. The location parameter, μ , shifts the distribution along the real line, and the scale parameter, σ , expands or contracts the distribution.

The following plots the probability function for different combinations of μ and σ .

```
x = -15:.01:5;
plot(x,evpdf(x,2,1),'-', ...
      x,evpdf(x,0,2),':', ...
      x,evpdf(x,-2,4),'-.');
legend({'mu = 2, sigma = 1', ...
       'mu = 0, sigma = 2', ...
       'mu = -2, sigma = 4'}, ...
       'Location','NW')
```

```
xlabel('x')  
ylabel('f(x|mu,sigma)')
```

F Distribution

In this section...

“Definition” on page B-42

“Background” on page B-42

“Examples” on page B-42

Definition

The pdf for the F distribution is

$$y = f(x | \nu_1, \nu_2) = \frac{\Gamma\left(\frac{\nu_1 + \nu_2}{2}\right)}{\Gamma\left(\frac{\nu_1}{2}\right)\Gamma\left(\frac{\nu_2}{2}\right)} \left(\frac{\nu_1}{\nu_2}\right)^{\frac{\nu_1}{2}} \frac{x^{\frac{\nu_1 - 2}{2}}}{\left[1 + \left(\frac{\nu_1}{\nu_2}\right)x\right]^{\frac{\nu_1 + \nu_2}{2}}}$$

where $\Gamma(\cdot)$ is the Gamma function.

Background

The F distribution has a natural relationship with the chi-square distribution. If χ_1 and χ_2 are both chi-square with ν_1 and ν_2 degrees of freedom respectively, then the statistic F below is F -distributed.

$$F(\nu_1, \nu_2) = \frac{\chi_1/\nu_1}{\chi_2/\nu_2}$$

The two parameters, ν_1 and ν_2 , are the numerator and denominator degrees of freedom. That is, ν_1 and ν_2 are the number of independent pieces of information used to calculate χ_1 and χ_2 , respectively.

Examples

Compute the F Distribution pdf

Compute the pdf of an F distribution with 5 numerator degrees of freedom and 3 denominator degrees of freedom.

```
x = 0:0.01:10;  
y = fpdf(x,5,3);
```

Plot the pdf.

```
figure;  
plot(x,y)
```

The plot shows that the F distribution exists on positive real numbers and is skewed to the right.

Gamma Distribution

In this section...

“Definition” on page B-45

“Background” on page B-45

“Parameters” on page B-45

“Examples” on page B-46

Definition

The gamma pdf is

$$y = f(x | a, b) = \frac{1}{b^a \Gamma(a)} x^{a-1} e^{-\frac{x}{b}}$$

where $\Gamma(\cdot)$ is the Gamma function, a is a shape parameter, b is a scale parameter.

Background

The gamma distribution models sums of exponentially distributed random variables.

The gamma distribution family is based on two parameters. The chi-square and exponential distributions, which are children of the gamma distribution, are one-parameter distributions that fix one of the two gamma parameters.

The gamma distribution has the following relationship with the incomplete Gamma function.

$$f(x | a, b) = \text{gammainc}\left(\frac{x}{b}, a\right)$$

When a is large, the gamma distribution closely approximates a normal distribution with the advantage that the gamma distribution has density only for positive real numbers.

Parameters

Suppose you are stress testing computer memory chips and collecting data on their lifetimes. You assume that these lifetimes follow a gamma distribution. You want to know

how long you can expect the average computer memory chip to last. Parameter estimation is the process of determining the parameters of the gamma distribution that fit this data best in some sense.

One popular criterion of goodness is to maximize the likelihood function. The likelihood has the same form as the gamma pdf above. But for the pdf, the parameters are known constants and the variable is x . The likelihood function reverses the roles of the variables. Here, the sample values (the x 's) are already observed. So they are the fixed constants. The variables are the unknown parameters. MLE involves calculating the values of the parameters that give the highest likelihood given the particular set of data.

The function `gamfit` returns the MLEs and confidence intervals for the parameters of the gamma distribution. Here is an example using random numbers from the gamma distribution with $a = 10$ and $b = 5$.

```
lifetimes = gamrnd(10,5,100,1);  
[phat, pci] = gamfit(lifetimes)
```

```
phat =
```

```
    10.9821    4.7258
```

```
pci =
```

```
    7.4001    3.1543  
   14.5640    6.2974
```

Note `phat(1) = \hat{a}` and `phat(2) = \hat{b}` . The MLE for parameter a is 10.98, compared to the true value of 10. The 95% confidence interval for a goes from 7.4 to 14.6, which includes the true value.

Similarly the MLE for parameter b is 4.7, compared to the true value of 5. The 95% confidence interval for b goes from 3.2 to 6.3, which also includes the true value.

In the life tests you do not know the true value of a and b so it is nice to have a confidence interval on the parameters to give a range of likely values.

Examples

Compare Gamma and Normal Distribution pdfs

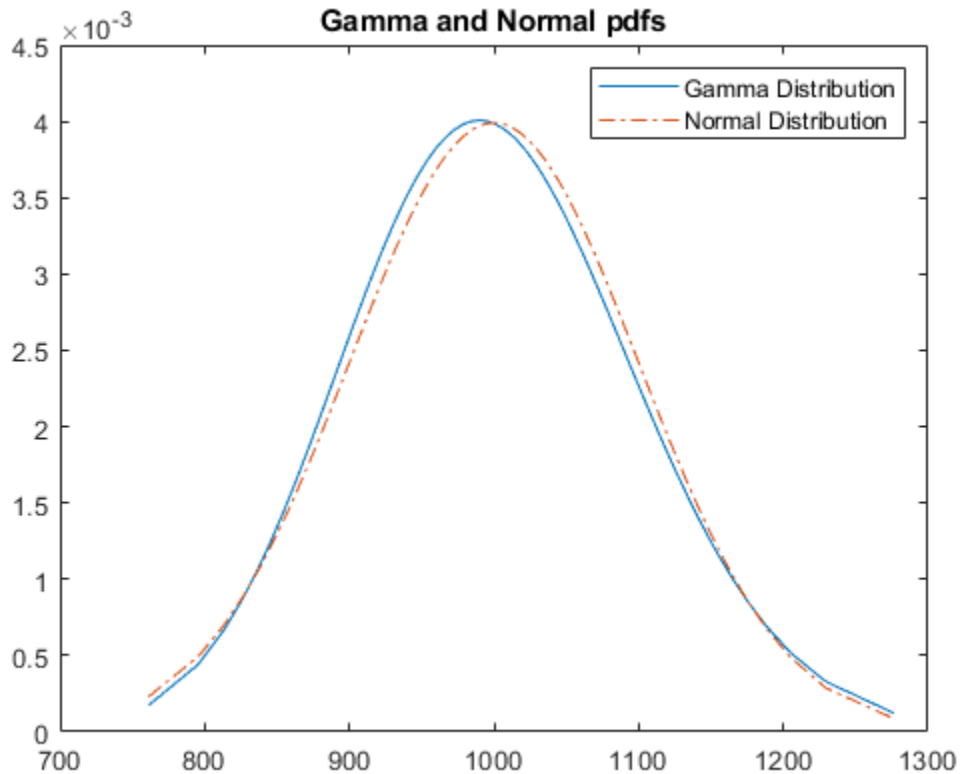

The gamma distribution has the shape parameter a and the scale parameter b . For a large a , the gamma distribution closely approximates the normal distribution with mean $\mu = ab$

and variance $\sigma^2 = ab^2$. Compute the pdf of a gamma distribution with parameters $A = 100$ and $B = 10$. For comparison, also compute the pdf of a normal distribution with parameters $\mu = 1000$ and $\sigma = 100$.

```
x = gaminv((0.005:0.01:0.995),100,10);  
y_gam = gampdf(x,100,10);  
y_norm = normpdf(x,1000,100);
```

Plot the pdfs of the gamma distribution and the normal distribution on the same figure.

```
plot(x,y_gam,'-',x,y_norm,'-.')  
title('Gamma and Normal pdfs')  
legend('Gamma Distribution','Normal Distribution')
```

Generalized Extreme Value Distribution

In this section...

“Definition” on page B-49

“Background” on page B-49

“Parameters” on page B-50

“Examples” on page B-51

Definition

The probability density function for the generalized extreme value distribution with location parameter μ , scale parameter σ , and shape parameter $k \neq 0$ is

$$y = f(x|k, \mu, \sigma) = \left(\frac{1}{\sigma}\right) \exp\left(-\left(1 + k\frac{(x-\mu)}{\sigma}\right)^{-\frac{1}{k}}\right) \left(1 + k\frac{(x-\mu)}{\sigma}\right)^{-1 - \frac{1}{k}}$$

for

$$1 + k\frac{(x-\mu)}{\sigma} > 0$$

$k > 0$ corresponds to the Type II case, while $k < 0$ corresponds to the Type III case. For $k = 0$, corresponding to the Type I case, the density is

$$y = f(x|0, \mu, \sigma) = \left(\frac{1}{\sigma}\right) \exp\left(-\exp\left(-\frac{(x-\mu)}{\sigma}\right) - \frac{(x-\mu)}{\sigma}\right)$$

Background

Like the extreme value distribution, the generalized extreme value distribution is often used to model the smallest or largest value among a large set of independent, identically distributed random values representing measurements or observations. For example, you might have batches of 1000 washers from a manufacturing process. If you record the size of the largest washer in each batch, the data are known as block maxima (or minima if you record the smallest). You can use the generalized extreme value distribution as a model for those block maxima.

The generalized extreme value combines three simpler distributions into a single form, allowing a continuous range of possible shapes that includes all three of the simpler distributions. You can use any one of those distributions to model a particular dataset of block maxima. The generalized extreme value distribution allows you to “let the data decide” which distribution is appropriate.

The three cases covered by the generalized extreme value distribution are often referred to as the Types I, II, and III. Each type corresponds to the limiting distribution of block maxima from a different class of underlying distributions. Distributions whose tails decrease exponentially, such as the normal, lead to the Type I. Distributions whose tails decrease as a polynomial, such as Student's *t*, lead to the Type II. Distributions whose tails are finite, such as the beta, lead to the Type III.

Types I, II, and III are sometimes also referred to as the Gumbel, Frechet, and Weibull types, though this terminology can be slightly confusing. The Type I (Gumbel) and Type III (Weibull) cases actually correspond to the mirror images of the usual Gumbel and Weibull distributions, for example, as computed by the functions `evcdf` and `evfit`, or `wblcdf` and `wblfit`, respectively. Finally, the Type II (Frechet) case is equivalent to taking the reciprocal of values from a standard Weibull distribution.

Parameters

If you generate 250 blocks of 1000 random values drawn from Student's *t* distribution with 5 degrees of freedom, and take their maxima, you can fit a generalized extreme value distribution to those maxima.

```
blocksize = 1000;  
nblocks = 250;  
rng default % For reproducibility  
t = trnd(5,blocksize,nblocks);  
x = max(t); % 250 column maxima  
paramEsts = gevfit(x)
```

```
paramEsts = 1×3  
  
    0.1185    1.4530    5.8929
```

Notice that the shape parameter estimate (the first element) is positive, which is what you would expect based on block maxima from a Student's *t* distribution.

```
histogram(x,2:20,'FaceColor',[.8 .8 1]);  
xgrid = linspace(2,20,1000);
```

```
line(xgrid,nblocks*...  
      gevpdf(xgrid,paramEsts(1),paramEsts(2),paramEsts(3)));
```

Examples

Compute the Generalized Extreme Value Distribution pdf

Generate examples of probability density functions for the three basic forms of the generalized extreme value distribution.

```
x = linspace(-3,6,1000);  
y1 = gevpdf(x,-.5,1,0);  
y2 = gevpdf(x,0,1,0);
```

```
y3 = gevpdf(x,.5,1,0);  
plot(x,y1,'-', x,y2,'--', x,y3,':')  
legend({'K < 0, Type III' 'K = 0, Type I' 'K > 0, Type II'})
```

Notice that for $k > 0$, the distribution has zero probability density for x such that $x < -\sigma/k + \mu$.

For $k < 0$, the distribution has zero probability density for $x > -\sigma/k + \mu$.

For $k = 0$, there is no upper or lower bound.

Generalized Pareto Distribution

In this section...

“Definition” on page B-54

“Background” on page B-54

“Parameters” on page B-55

“Examples” on page B-57

Definition

The probability density function for the generalized Pareto distribution with shape parameter $k \neq 0$, scale parameter σ , and threshold parameter θ , is

$$y = f(x \mid k, \sigma, \theta) = \left(\frac{1}{\sigma}\right) \left(1 + k \frac{(x - \theta)}{\sigma}\right)^{-1 - \frac{1}{k}}$$

for $\theta < x$, when $k > 0$, or for $\theta < x < \theta - \sigma/k$ when $k < 0$.

For $k = 0$, the density is

$$y = f(x \mid 0, \sigma, \theta) = \left(\frac{1}{\sigma}\right) e^{-\frac{(x - \theta)}{\sigma}}$$

for $\theta < x$.

If $k = 0$ and $\theta = 0$, the generalized Pareto distribution is equivalent to the exponential distribution. If $k > 0$ and $\theta = \sigma/k$, the generalized Pareto distribution is equivalent to the Pareto distribution with a scale parameter equal to σ/k and a shape parameter equal to $1/k$.

Background

Like the exponential distribution, the generalized Pareto distribution is often used to model the tails of another distribution. For example, you might have washers from a manufacturing process. If random influences in the process lead to differences in the sizes of the washers, a standard probability distribution, such as the normal, could be used to model those sizes. However, while the normal distribution might be a good model

near its mode, it might not be a good fit to real data in the tails and a more complex model might be needed to describe the full range of the data. On the other hand, only recording the sizes of washers larger (or smaller) than a certain threshold means you can fit a separate model to those tail data, which are known as *exceedences*. You can use the generalized Pareto distribution in this way, to provide a good fit to extremes of complicated data.

The generalized Pareto distribution allows a continuous range of possible shapes that includes both the exponential and Pareto distributions as special cases. You can use either of those distributions to model a particular dataset of exceedences. The generalized Pareto distribution allows you to “let the data decide” which distribution is appropriate.

The generalized Pareto distribution has three basic forms, each corresponding to a limiting distribution of exceedence data from a different class of underlying distributions.

- Distributions whose tails decrease exponentially, such as the normal, lead to a generalized Pareto shape parameter of zero.
- Distributions whose tails decrease as a polynomial, such as Student's t , lead to a positive shape parameter.
- Distributions whose tails are finite, such as the beta, lead to a negative shape parameter.

The generalized Pareto distribution is used in the tails of distribution fit objects of the `paretotails` object.

Parameters

If you generate a large number of random values from a Student's t distribution with 5 degrees of freedom, and then discard everything less than 2, you can fit a generalized Pareto distribution to those exceedences.

```
rng default % For reproducibility
t = trnd(5,5000,1);
y = t(t > 2) - 2;
paramEsts = gpfity
```

```
paramEsts = 1×2
    0.1445    0.7225
```

Notice that the shape parameter estimate (the first element) is positive, which is what you would expect based on exceedences from a Student's t distribution.

```
hist(y+2,2.25:.5:11.75);  
h = findobj(gca,'Type','patch');  
h.FaceColor = [.8 .8 1];  
xgrid = linspace(2,12,1000);  
line(xgrid,.5*length(y)*...  
      gppdf(xgrid,paramEsts(1),paramEsts(2),2));
```

Examples

Compute Generalized Pareto Distribution pdf

Compute the pdf of three generalized Pareto distributions. The first has shape parameter $k = -0.25$, the second has $k = 0$, and the third has $k = 1$.

```
x = linspace(0,10,1000);  
y1 = gppdf(x, -.25,1,0);  
y2 = gppdf(x,0,1,0);  
y3 = gppdf(x,1,1,0);
```

Plot the three pdfs on the same figure.

```
figure;  
plot(x,y1,'-', x,y2,'--', x,y3,':')  
legend({'K < 0' 'K = 0' 'K > 0'});
```

Geometric Distribution

In this section...
“Overview” on page B-60
“Parameters” on page B-60
“Probability Distribution Function” on page B-60
“Cumulative Distribution Function” on page B-63
“Mean and Variance” on page B-65
“Example” on page B-66

Overview

The geometric distribution models the number of failures before one success in a series of independent trials, where each trial results in either success or failure, and the probability of success in any individual trial is constant. For example, if you toss a coin, the geometric distribution models the number of tails observed before getting a heads. The geometric distribution is discrete, existing only on the nonnegative integers.

Parameters

The geometric distribution uses the following parameter.

Parameter	Description
$0 \leq p \leq 1$	Probability of success

Probability Distribution Function

Definition

The probability distribution function (pdf) of the geometric distribution is

$$y = f(x|p) = p(1 - p)^x \quad ; \quad x = 0, 1, 2, \dots,$$

where p is the probability of success, and x is the number of failures before the first success. The result y is the probability of observing exactly x trials before a success, when

the probability of success in any given trial is p . For discrete distributions, the probability distribution function is also known as the probability mass function (pmf).

Plot

This plot shows how changing the value of the probability parameter p alters the shape of the pdf. Use `geopdf` to compute the pdf for values at x equals 1 through 10, for three different values of p . Then plot all three pdfs on the same figure for a visual comparison.

```
x = [1:10];  
y1 = geopdf(x,0.1); % For p = 0.1  
y2 = geopdf(x,0.25); % For p = 0.25  
y3 = geopdf(x,0.75); % For p = 0.75  
  
figure;  
plot(x,y1,'kd')  
hold on  
plot(x,y2,'ro')  
plot(x,y3,'b+')  
legend({'p = 0.1', 'p = 0.25', 'p = 0.75'})  
hold off
```

In this plot, the value of y is the probability of observing exactly x trials before a success. When the probability of success p is large, y decreases rapidly as x increases, and the probability of observing a large number of failures before a success quickly becomes small. But when the probability of success p is small, y decreases slowly as x increases. The probability of observing a large number of failures before a success still decreases as the number of trials increases, but at a much slower rate.

Random Number Generation

A random number generated from a geometric distribution represents the number of failures observed before a success in a single experiment, given the probability of success p for each independent trial. Use `geornd` to generate random numbers from the

geometric distribution. For example, the following generates a random number from a geometric distribution with probability of success p equal to 0.1.

```
p = 0.1;
r = geornd(p)

r = 1
```

The returned random number represents the number of failures observed before a success in a series of independent trials.

Relationship to Other Distributions

The geometric distribution is a special case of the negative binomial distribution on page B-122, with the specified number of successes parameter r equal to 1.

Cumulative Distribution Function

Definition

The cumulative distribution function (cdf) of the geometric distribution is

$$y = F(x|p) = 1 - (1 - p)^{x+1}; \quad x = 0, 1, 2, \dots,$$

where p is the probability of success, and x is the number of failures before the first success. The result y is the probability of observing up to x trials before a success, when the probability of success in any given trial is p .

Plot

This plot shows how changing the value of the parameter p alters the shape of the cdf. Use `geocdf` to compute the cdf values at x equals 1 through 10, for three different values of p . Then plot all three cdfs on the same figure for a visual comparison.

```
x = [1:10];
y1 = geocdf(x,0.1);    % For p = 0.1
y2 = geocdf(x,0.25);  % For p = 0.25
y3 = geocdf(x,0.75);  % For p = 0.75

figure;
plot(x,y1,'kd')
hold on
```

```
plot(x,y2,'ro')
plot(x,y3,'b+')
legend({'p = 0.1', 'p = 0.25', 'p = 0.75'})
hold off
```

In this plot, the value of y is the probability of observing up to x trials before a success. When the probability of success p is large, y increases rapidly as x increases. The probability of observing a success quickly becomes very high, even for a small number of trials. But when the probability of success p is small, y increases slowly as x increases. The probability of observing a success still increases as the number of trials increases, but at a much slower rate.

Inverse cdf

The inverse cdf of a geometric distribution determines the value of x that corresponds to a probability y of observing x successes in a row in independent trials. Use `geoinv` to compute the inverse cdf of the geometric distribution. For example, the following returns the smallest possible integer x such that the geometric cdf y evaluated at x is greater than or equal to 0.1, when the probability of success for each independent trial p is 0.03.

```
y = 0.1;  
p = 0.03;  
x = geoinv(y,p)  
  
x = 3
```

Mean and Variance

The mean of the geometric distribution is

$$\text{mean} = \frac{1-p}{p},$$

and the variance of the geometric distribution is

$$\text{var} = \frac{1-p}{p^2},$$

where p is the probability of success.

Use `geostat` to compute the mean and variance of a geometric distribution. For example, the following computes the mean m and variance v of a geometric distribution with probability parameter p equal to 0.25.

```
p = 0.25;  
[m,v] = geostat(p)  
  
m = 3  
v = 12
```

Example

Compute Geometric Distribution Probabilities

Suppose the probability of a five-year-old car battery not starting in cold weather is 0.03. What is the probability of the car starting for 25 consecutive days during a long cold snap?

Model the scenario using a geometric distribution, where "failure" means the car starts, and "success" means the car does not start. Determine the probability of observing 25 failures (the car starts) without observing a single success (the car does not start). The probability of success for each trial (the car not starting on any single attempt) is p equal to 0.03.

Compute the cumulative distribution function (cdf) for x equal to 25. This returns the probability of observing success (the car not starting) in up to 25 trials.

```
x = 25;  
p = 0.03;  
psuccess = geocdf(x,p);
```

To determine the probability of not observing a success in up to 25 trials - in other words, the probability that the car starts on every one of the 25 attempts - subtract this result from 1.

```
pfail = 1 - psuccess  
  
pfail = 0.4530
```

The returned result `pfail = 0.4530` is the probability that the car will start every day for 25 days in a row during a cold snap.

The cdf plot shows that, as the number of trials (x) increases, the probability of success (y) also increases. In this example, it means that the more times you attempt to start the car, the greater the probability that it does not start on at least one of those occasions.

```
figure;  
x = 0:25;  
y = geocdf(x,0.03);  
stairs(x,y)
```

Half-Normal Distribution

In this section...
“Overview” on page B-68
“Parameters” on page B-68
“Probability Density Function” on page B-69
“Cumulative Distribution Function” on page B-70
“Descriptive Statistics” on page B-72
“Relationship to Other Distributions” on page B-73

Overview

The half-normal distribution is a special case of the folded normal and truncated normal distributions. Some applications of the half-normal distribution include modeling measurement data and lifetime data.

Parameters

The half-normal distribution uses the following parameters:

Parameter	Description
$-\infty < \mu < \infty$	Location parameter
$\sigma \geq 0$	Scale parameter

The support for the half-normal distribution is $x \geq \mu$.

Use `makedist` with specified parameter values to create a half-normal probability distribution object `HalfNormalDistribution`. Use `fitdist` to fit a half-normal probability distribution object to sample data. Use `mle` to estimate the half-normal distribution parameter values from sample data without creating a probability distribution object. For more information about working with probability distributions, see “Working with Probability Distributions” on page 5-3.

The Statistics and Machine Learning Toolbox implementation of the half-normal distribution assumes a fixed value for the location parameter μ . Therefore, neither `fitdist` nor `mle` estimates the value of the parameter μ when fitting a half-normal

distribution to sample data. You can specify a value for the μ parameter by using the name-value pair argument 'mu'. The default value for the 'mu' argument is 0 in both `fitdist` and `mle`.

Probability Density Function

The probability density function (pdf) of the half-normal distribution is

$$y = f(x|\mu, \sigma) = \sqrt{\frac{2}{\pi}} \frac{1}{\sigma} e^{-\frac{1}{2}\left(\frac{x-\mu}{\sigma}\right)^2}; x \geq \mu,$$

where μ is the location parameter and σ is the scale parameter. If $x \leq \mu$, then the pdf is undefined.

To compute the pdf of the half-normal distribution, create a `HalfNormalDistribution` probability distribution object using `fitdist` or `makedist`, then use the `pdf` method to work with the object.

PDF of Half-Normal Probability Distribution

This example shows how changing the values of the `mu` and `sigma` parameters alters the shape of the pdf.

Create four probability distribution objects with different parameters.

```
pd1 = makedist('HalfNormal');
pd2 = makedist('HalfNormal','mu',0,'sigma',2);
pd3 = makedist('HalfNormal','mu',0,'sigma',3);
pd4 = makedist('HalfNormal','mu',0,'sigma',5);
```

Compute the probability density functions (pdfs) of each distribution.

```
x = 0:0.1:10;
pdf1 = pdf(pd1,x);
pdf2 = pdf(pd2,x);
pdf3 = pdf(pd3,x);
pdf4 = pdf(pd4,x);
```

Plot the pdfs on the same figure.

```
figure;
plot(x,pdf1,'r','LineWidth',2)
hold on;
```

```
plot(x,pdf2,'k:','LineWidth',2);  
plot(x,pdf3,'b-.','LineWidth',2);  
plot(x,pdf4,'g--','LineWidth',2);  
legend({'mu = 0, sigma = 1','mu = 0, sigma = 2',...  
       'mu = 0, sigma = 3','mu = 0, sigma = 5'},'Location','NE');  
hold off;
```

As σ increases, the curve flattens and the peak value becomes smaller.

Cumulative Distribution Function

The cumulative distribution function (cdf) of the half-normal distribution is

$$y = F(x) = \operatorname{erf}\left(\frac{x - \mu}{\sqrt{2}\sigma}\right) = 2\Phi\left(\frac{x - \mu}{\sigma}\right) - 1; x \geq \mu,$$

where μ is the location parameter, σ is the scale parameter, $\operatorname{erf}(\bullet)$ is the error function, and $\Phi(\bullet)$ is the cdf of the standard normal distribution. If $x \leq \mu$, then the cdf is undefined.

To compute the cdf of the half-normal distribution, create a `HalfNormalDistribution` probability distribution object using `fitdist` or `makedist`, then use the `cdf` method to work with the object.

CDF of Half-Normal Probability Distribution

This example shows how changing the values of the `mu` and `sigma` parameters alters the shape of the cdf.

Create four probability distribution objects with different parameters.

```
pd1 = makedist('HalfNormal');
pd2 = makedist('HalfNormal','mu',0,'sigma',2);
pd3 = makedist('HalfNormal','mu',0,'sigma',3);
pd4 = makedist('HalfNormal','mu',0,'sigma',5);
```

Compute the cumulative distribution functions (cdfs) for each probability distribution.

```
x = 0:0.1:10;
cdf1 = cdf(pd1,x);
cdf2 = cdf(pd2,x);
cdf3 = cdf(pd3,x);
cdf4 = cdf(pd4,x);
```

Plot all four cdfs on the same figure.

```
figure;
plot(x,cdf1,'r','LineWidth',2)
hold on;
plot(x,cdf2,'k:', 'LineWidth',2);
plot(x,cdf3,'b-.','LineWidth',2);
plot(x,cdf4,'g--','LineWidth',2);
legend({'mu = 0, sigma = 1','mu = 0, sigma = 2',...
       'mu = 0, sigma = 3','mu = 0, sigma = 5'},'Location','SE');
hold off;
```

As sigma increases, the curve of the cdf flattens.

Descriptive Statistics

The mean of the half-normal distribution is

$$\text{mean} = \mu + \sigma \sqrt{\frac{2}{\pi}},$$

where μ is the location parameter and σ is the scale parameter.

The variance of the half-normal distribution is

$$\text{var} = \sigma^2 \left(1 - \frac{2}{\pi} \right),$$

where σ is the scale parameter.

Relationship to Other Distributions

If a random variable Z has a standard normal distribution with a mean μ equal to zero and standard deviation σ equal to one, then $X = \mu + \sigma|Z|$ has a half-normal distribution with parameters μ and σ .

Hypergeometric Distribution

In this section...
“Definition” on page B-74
“Background” on page B-74
“Examples” on page B-75

Definition

The hypergeometric pdf is

$$y = f(x) \left| M, K, n \right. = \frac{\binom{K}{x} \binom{M-K}{n-x}}{\binom{M}{n}}$$

Background

The hypergeometric distribution models the total number of successes in a fixed-size sample drawn without replacement from a finite population.

The distribution is discrete, existing only for nonnegative integers less than the number of samples or the number of possible successes, whichever is greater. The hypergeometric distribution differs from the binomial only in that the population is finite and the sampling from the population is without replacement.

The hypergeometric distribution has three parameters that have direct physical interpretations.

- M is the size of the population.
- K is the number of items with the desired characteristic in the population.
- n is the number of samples drawn.

Sampling “without replacement” means that once a particular sample is chosen, it is removed from the relevant population for all subsequent selections.

Examples

Compute and Plot Hypergeometric Distribution CDF

This example shows how to compute and plot the cdf of a hypergeometric distribution.

Compute the cdf of a hypergeometric distribution that draws 20 samples from a group of 1000 items, when the group contains 50 items of the desired type.

```
x = 0:10;  
y = hygecdf(x,1000,50,20);
```

Plot the cdf.

```
stairs(x,y)
```

The x-axis of the plot shows the number of items drawn that are of the desired type. The y-axis shows the corresponding cdf values.

Inverse Gaussian Distribution

In this section...

“Definition” on page B-77

“Background” on page B-77

“Parameters” on page B-77

Definition

The inverse Gaussian distribution has the density function

$$\sqrt{\frac{\lambda}{2\pi x^3}} \exp\left\{-\frac{\lambda}{2\mu^2 x}(x - \mu)^2\right\}$$

Background

Also known as the Wald distribution, the inverse Gaussian is used to model nonnegative positively skewed data. The distribution originated in the theory of Brownian motion, but has been used to model diverse phenomena. Inverse Gaussian distributions have many similarities to standard Gaussian (normal) distributions, which lead to applications in inferential statistics.

Parameters

To estimate distribution parameters, use `mle` or the Distribution Fitter app.

Inverse Wishart Distribution

Definition

The probability density function of the d -dimensional Inverse Wishart distribution is given by

$$y = f(X, \Sigma, \nu) = \frac{|T|^{(\nu/2)} e^{-\frac{1}{2}\text{trace}(TX^{-1})}}{2^{(\nu d)/2} \pi^{(d(d-1))/4} |X|^{(\nu+d+1)/2} \Gamma(\nu/2) \dots \Gamma(\nu-(d-1))/2},$$

where X and T are d -by- d symmetric positive definite matrices, and ν is a scalar greater than or equal to d . While it is possible to define the Inverse Wishart for singular T , the density cannot be written as above.

If a random matrix has a Wishart distribution with parameters T^{-1} and ν , then the inverse of that random matrix has an inverse Wishart distribution with parameters T and ν . The mean of the distribution is given by

$$\frac{1}{\nu - d - 1} T$$

where d is the number of rows and columns in T .

Only random matrix generation is supported for the inverse Wishart, including both singular and nonsingular T .

Background

The inverse Wishart distribution is based on the Wishart distribution on page B-204. In Bayesian statistics it is used as the conjugate prior for the covariance matrix of a multivariate normal distribution.

Example

Notice that the sampling variability is quite large when the degrees of freedom is small.

```
Tau = [1 .5; .5 2];
df = 10; S1 = iwishrnd(Tau,df)*(df-2-1)
```

```
S1 =
    1.7959    0.64107
    0.64107    1.5496

df = 1000; S2 = iwishrnd(Tau,df)*(df-2-1)

S2 =
    0.9842    0.50158
    0.50158    2.1682
```

Kernel Distribution

In this section...
“Overview” on page B-80
“Kernel Density Estimator” on page B-80
“Kernel Smoothing Function” on page B-80
“Bandwidth” on page B-86

Overview

A kernel distribution is a nonparametric representation of the probability density function (pdf) of a random variable. You can use a kernel distribution when a parametric distribution cannot properly describe the data, or when you want to avoid making assumptions about the distribution of the data. A kernel distribution is defined by a smoothing function and a bandwidth value, which control the smoothness of the resulting density curve.

Kernel Density Estimator

The kernel density estimator is the estimated pdf of a random variable. For any real values of x , the kernel density estimator's formula is given by

$$\hat{f}_h(x) = \frac{1}{nh} \sum_{i=1}^n K\left(\frac{x - x_i}{h}\right),$$

where x_1, x_2, \dots, x_n are random samples from an unknown distribution, n is the sample size, $K(\cdot)$ is the kernel smoothing function, and h is the bandwidth.

Kernel Smoothing Function

The kernel smoothing function defines the shape of the curve used to generate the pdf. Similar to a histogram, the kernel distribution builds a function to represent the probability distribution using the sample data. But unlike a histogram, which places the values into discrete bins, a kernel distribution sums the component smoothing functions for each data value to produce a smooth, continuous probability curve. The following plots show a visual comparison of a histogram and a kernel distribution generated from the same sample data.

A histogram represents the probability distribution by establishing bins and placing each data value in the appropriate bin.

```
SixMPG = [13;15;23;29;32;34];  
figure  
histogram(SixMPG)
```

Because of this bin count approach, the histogram produces a discrete probability density function. This might be unsuitable for certain applications, such as generating random numbers from a fitted distribution.

Alternatively, the kernel distribution builds the pdf by creating an individual probability density curve for each data value, then summing the smooth curves. This approach creates one smooth, continuous probability density function for the data set.

```
figure
pdSix = fitdist(SixMPG,'Kernel','BandWidth',4);
x = 0:.1:45;
ySix = pdf(pdSix,x);
plot(x,ySix,'k-','LineWidth',2)

% Plot each individual pdf and scale its appearance on the plot
hold on
for i=1:6
    pd = makedist('Normal','mu',SixMPG(i),'sigma',4);
    y = pdf(pd,x);
    y = y/6;
    plot(x,y,'b:')
end
hold off
```

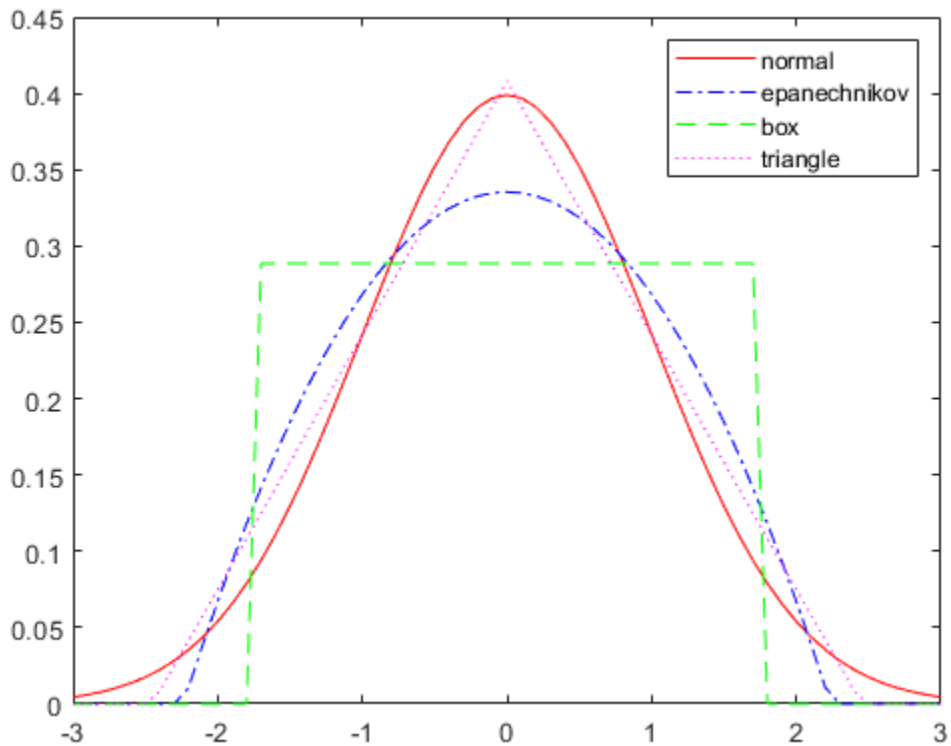

The smaller dashed curves are the probability distributions for each value in the sample data, scaled to fit the plot. The larger solid curve is the overall kernel distribution of the SixMPG data. The kernel smoothing function refers to the shape of those smaller component curves, which have a normal distribution in this example.

You can choose one of several options for the kernel smoothing function. This plot shows the shapes of the available smoothing functions.

Set plot specifications

```
hname = {'normal' 'epanechnikov' 'box' 'triangle'};  
colors = {'r' 'b' 'g' 'm'};  
lines = {'-', '-.', '--', ':'};
```

```
% Generate a sample of each kernel smoothing function and plot
data = [0];
figure
for j=1:4
    pd = fitdist(data,'kernel','Kernel',hname{j});
    x = -3:.1:3;
    y = pdf(pd,x);
    plot(x,y,'Color',colors{j},'LineStyle',lines{j})
    hold on
end
legend(hname)
hold off
```

To understand the effect of different kernel smoothing functions on the shape of the resulting pdf estimate, compare plots of the mileage data (MPG) from `carbig.mat` using each available kernel function.

```
load carbig
% Set plot specifications
hname = {'normal' 'epanechnikov' 'box' 'triangle'};
colors = {'r' 'b' 'g' 'm'};
lines = {'-', '-.', '--', ':'};

% Generate kernel distribution objects and plot
figure
for j=1:4
    pd = fitdist(MPG, 'kernel', 'Kernel', hname{j});
    x = -10:1:60;
    y = pdf(pd, x);
    plot(x, y, 'Color', colors{j}, 'LineStyle', lines{j})
    hold on
end
legend(hname)
hold off
```

Each density curve uses the same input data, but applies a different kernel smoothing function to generate the pdf. The density estimates are roughly comparable, but the shape of each curve varies slightly. For example, the box kernel produces a density curve that is less smooth than the others.

Bandwidth

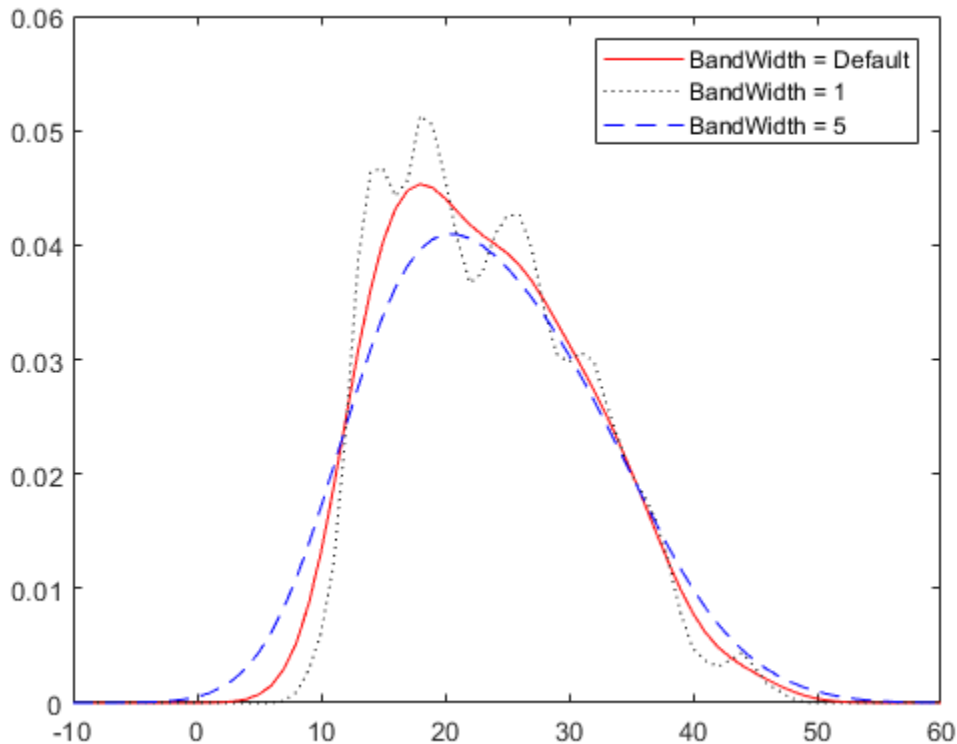

The choice of bandwidth value controls the smoothness of the resulting probability density curve. This plot shows the density estimate for the same MPG data, using a normal kernel smoothing function with three different bandwidths.

Create kernel distribution objects

```
pd1 = fitdist(MPG, 'kernel');
pd2 = fitdist(MPG, 'kernel', 'BandWidth', 1);
pd3 = fitdist(MPG, 'kernel', 'BandWidth', 5);

% Compute each pdf
x = -10:1:60;
y1 = pdf(pd1, x);
y2 = pdf(pd2, x);
y3 = pdf(pd3, x);

% Plot each pdf
plot(x, y1, 'Color', 'r', 'LineStyle', '-');
hold on
plot(x, y2, 'Color', 'k', 'LineStyle', ':');
plot(x, y3, 'Color', 'b', 'LineStyle', '--');
legend({'BandWidth = Default', 'BandWidth = 1', 'BandWidth = 5'})
hold off
```

The default bandwidth, which is theoretically optimal for estimating densities for the normal distribution [1], produces a reasonably smooth curve. Specifying a smaller bandwidth produces a very rough curve, but reveals that there might be two major peaks in the data. Specifying a larger bandwidth produces a curve nearly identical to the kernel function, and is so smooth that it obscures potentially important features of the data.

Logistic Distribution

In this section...

“Overview” on page B-90

“Parameters” on page B-90

“Probability Density Function” on page B-90

“Relationship to Other Distributions” on page B-90

Overview

The logistic distribution is used for growth models and in logistic regression. It has longer tails and a higher kurtosis than the normal distribution.

Parameters

The logistic distribution uses the following parameters.

Parameter	Description	Support
mu	Mean	$-\infty < \mu < \infty$
sigma	Scale parameter	$\sigma \geq 0$

Probability Density Function

The probability density function (pdf) is

$$f(x) \Big|_{\mu, \sigma} = \frac{\exp\left\{\frac{x-\mu}{\sigma}\right\}}{\sigma\left(1 + \exp\left\{\frac{x-\mu}{\sigma}\right\}\right)^2} ; \quad -\infty < x < \infty .$$

Relationship to Other Distributions

The loglogistic distribution is closely related to the logistic distribution. If x is distributed loglogistically with parameters μ and σ , then $\log(x)$ is distributed logistically with parameters μ and σ .

Loglogistic Distribution

In this section...

“Overview” on page B-92

“Parameters” on page B-92

“Probability Density Function” on page B-92

“Relationship to Other Distributions” on page B-93

Overview

The loglogistic distribution is a probability distribution whose logarithm has a logistic distribution. This distribution is often used in survival analysis to model events that experience an initial rate increase, followed by a rate decrease. It is also known as the Fisk distribution in economics applications.

Parameters

The loglogistic distribution uses the following parameters.

Parameter	Description	Support
mu	Mean of logarithmic values	$\mu > 0$
sigma	Scale parameter of logarithmic values	$\sigma > 0$

Probability Density Function

The probability density function (pdf) is

$$f(x | \mu, \sigma) = \frac{1}{\sigma} \frac{1}{x} \frac{e^z}{(1 + e^z)^2} ; \quad x \geq 0,$$

$$\text{where } z = \frac{\log(x) - \mu}{\sigma}.$$

Relationship to Other Distributions

The loglogistic distribution is closely related to the logistic distribution. If x is distributed loglogistically with parameters μ and σ , then $\log(x)$ is distributed logistically with parameters μ and σ . The relationship is similar to that between the lognormal on page B-94 and normal on page B-136 distribution.

Lognormal Distribution

In this section...
“Overview” on page B-94
“Parameters” on page B-94
“Probability Density Function” on page B-95
“Cumulative Distribution Function” on page B-96
“Examples” on page B-96
“Related Distributions” on page B-102

Overview

The lognormal distribution, sometimes called the Galton distribution, is a probability distribution whose logarithm has a normal distribution. The lognormal distribution is applicable when the quantity of interest must be positive, because $\log(x)$ exists only when x is positive.

Statistics and Machine Learning Toolbox offers several ways to work with the lognormal distribution.

- Create a probability distribution object `LognormalDistribution` by fitting a probability distribution to sample data (`fitdist`) or by specifying parameter values (`makedist`). Then, use object functions to evaluate the distribution, generate random numbers, and so on.
- Work with the lognormal distribution interactively by using the **Distribution Fitter** app. You can export an object from the app and use the object functions.
- Use distribution-specific functions (`logncdf`, `lognpdf`, `logninv`, `lognlike`, `lognstat`, `lognfit`, `lognrnd`) with specified distribution parameters. The distribution-specific functions can accept parameters of multiple lognormal distributions.
- Use generic distribution functions (`cdf`, `icdf`, `pdf`, `random`) with a specified distribution name (`'Lognormal'`) and parameters.

Parameters

The lognormal distribution uses these parameters.

Parameter	Description	Support
μ (μ)	Mean of logarithmic values	$-\infty < \mu < \infty$
σ (σ)	Standard deviation of logarithmic values	$\sigma \geq 0$

If X follows the lognormal distribution with parameters μ and σ , then $\log(X)$ follows the normal distribution with mean μ and standard deviation σ .

Parameter Estimation

To fit the lognormal distribution to data and find the parameter estimates, use `lognfit`, `fitdist`, or `mle`.

- For uncensored data, `lognfit` and `fitdist` find the unbiased estimates of the distribution parameters, and `mle` finds the maximum likelihood estimates.
- For censored data, `lognfit`, `fitdist`, and `mle` find the maximum likelihood estimates.

Unlike `lognfit` and `mle`, which return parameter estimates, `fitdist` returns the fitted probability distribution object `LognormalDistribution`. The object properties `mu` and `sigma` store the parameter estimates.

Descriptive Statistics

The mean m and variance v of a lognormal random variable are functions of the lognormal distribution parameters μ and σ :

$$m = \exp(\mu + \sigma^2/2)$$

$$v = \exp(2\mu + \sigma^2)(\exp(\sigma^2) - 1)$$

Also, you can compute the lognormal distribution parameters μ and σ from the mean m and variance v :

$$\mu = \log(m^2/\sqrt{v + m^2})$$

$$\sigma = \sqrt{\log(v/m^2 + 1)}$$

Probability Density Function

The probability density function (pdf) of the lognormal distribution is

$$y = f(x \mid \mu, \sigma) = \frac{1}{x\sigma\sqrt{2\pi}} \exp\left\{-\frac{(\log x - \mu)^2}{2\sigma^2}\right\}, \quad \text{for } x > 0.$$

For an example, see “Compute Lognormal Distribution pdf” on page B-96.

Cumulative Distribution Function

The cumulative distribution function (cdf) of the lognormal distribution is

$$p = F(x \mid \mu, \sigma) = \frac{1}{\sigma\sqrt{2\pi}} \int_0^x \frac{1}{t} \exp\left\{-\frac{(\log t - \mu)^2}{2\sigma^2}\right\} dt, \quad \text{for } x > 0.$$

For an example, see “Compute Lognormal Distribution cdf” on page B-97.

Examples

Compute Lognormal Distribution pdf

Suppose the income of a family of four in the United States follows a lognormal distribution with $\mu = \log(20,000)$ and $\sigma = 1$. Compute and plot the income density.

Create a lognormal distribution object by specifying the parameter values.

```
pd = makedist('Lognormal', 'mu', log(20000), 'sigma', 1)
```

```
pd =  
LognormalDistribution  
  
Lognormal distribution  
mu = 9.90349  
sigma = 1
```

Compute the pdf values.

```
x = (10:1000:125010)';  
y = pdf(pd, x);
```

Plot the pdf.

```
plot(x,y)
h = gca;
h.XTick = [0 30000 60000 90000 120000];
h.XTickLabel = {'0', '$30,000', '$60,000', ...
                '$90,000', '$120,000'};
```

Compute Lognormal Distribution cdf

Compute the cdf values evaluated at the values in x for the lognormal distribution with mean μ and standard deviation σ .

```
x = 0:0.2:10;
mu = 0;
```

```
sigma = 1;  
p = logncdf(x,mu,sigma);
```

Plot the cdf.

```
plot(x,p)  
grid on  
xlabel('x')  
ylabel('p')
```

Relationship Between Normal and Lognormal Distributions

If X follows the lognormal distribution with parameters μ and σ , then $\log(X)$ follows the normal distribution with mean μ and standard deviation σ . Use distribution objects to inspect the relationship between normal and lognormal distributions.

Create a lognormal distribution object by specifying the parameter values.

```
pd = makedist('Lognormal', 'mu', 5, 'sigma', 2)

pd =
  LognormalDistribution

  Lognormal distribution
      mu = 5
      sigma = 2
```

Compute the mean of the lognormal distribution.

```
mean(pd)

ans = 1.0966e+03
```

The mean of the lognormal distribution is not equal to the μ parameter. The mean of the logarithmic values is equal to μ . Confirm this relationship by generating random numbers.

Generate random numbers from the lognormal distribution and compute their log values.

```
rng('default'); % For reproducibility
x = random(pd, 10000, 1);
logx = log(x);
```

Compute the mean of the logarithmic values.

```
m = mean(logx)

m = 5.0033
```

The mean of the log of x is close to the μ parameter of x , because x has a lognormal distribution.

Construct a histogram of $\log x$ with a normal distribution fit.

```
histfit(logx)
```

The plot shows that the log values of x are normally distributed.

`histfit` uses `fitdist` to fit a distribution to data. Use `fitdist` to obtain parameters used in fitting.

```
pd_normal = fitdist(logx, 'Normal')  
  
pd_normal =  
NormalDistribution  
  
Normal distribution  
mu = 5.00332 [4.96445, 5.04219]
```

```
sigma = 1.98296 [1.95585, 2.01083]
```

The estimated normal distribution parameters are close to the lognormal distribution parameters 5 and 2.

Compare Lognormal and Burr Distribution pdfs

Compare the lognormal pdf to the Burr pdf using income data generated from a lognormal distribution.

Generate the income data.

```
rng('default') % For reproducibility
y = random('Lognormal',log(25000),0.65,[500,1]);
```

Fit a Burr distribution.

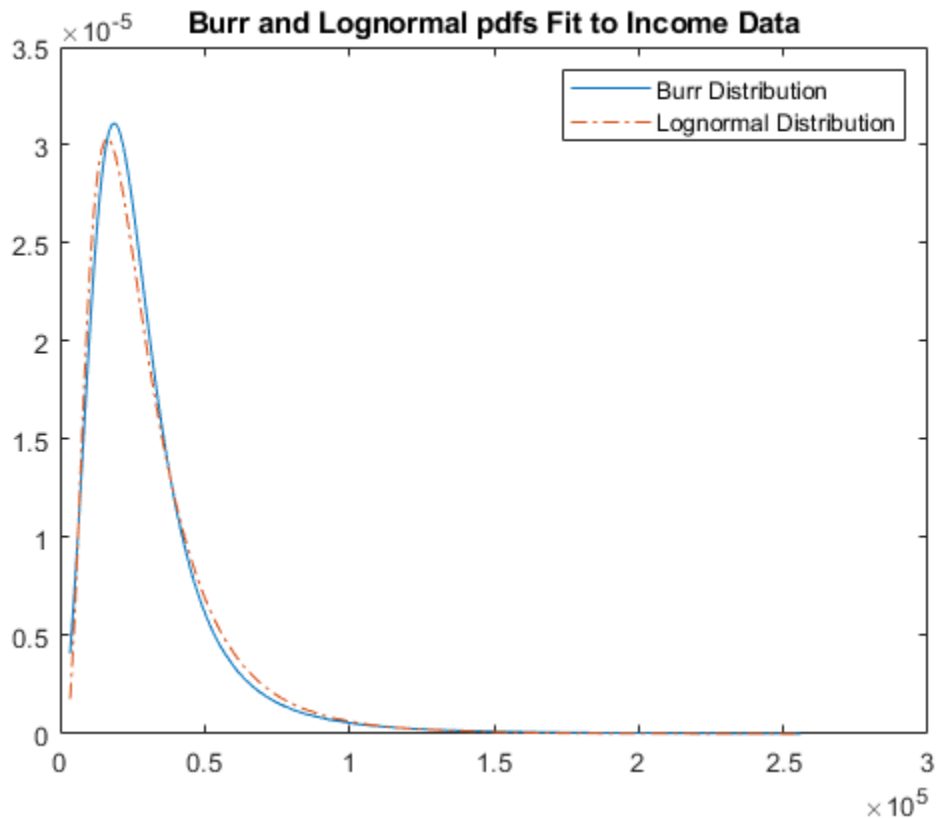

```
pd = fitdist(y,'burr')

pd =
    BurrDistribution

    Burr distribution
    alpha = 26007.2 [21165.5, 31956.4]
    c = 2.63743 [2.3053, 3.0174]
    k = 1.09658 [0.775479, 1.55064]
```

Plot both the Burr and lognormal pdfs of income data on the same figure.

```
p_burr = pdf(pd,sortrows(y));
p_lognormal = pdf('Lognormal',sortrows(y),log(25000),0.65);
plot(sortrows(y),p_burr,'-',sortrows(y),p_lognormal,'-.')
title('Burr and Lognormal pdfs Fit to Income Data')
legend('Burr Distribution','Lognormal Distribution')
```

Related Distributions

- “Normal Distribution” on page B-136 — The lognormal distribution is closely related to the normal distribution. If X is distributed lognormally with parameters μ and σ , then $\log(x)$ is distributed normally with mean μ and standard deviation σ . See “Relationship Between Normal and Lognormal Distributions” on page B-99.
- “Burr Type XII Distribution” on page B-15 — The Burr distribution is a flexible distribution family that can express a wide range of distribution shapes. It has as a limiting case many commonly used distributions such as gamma, lognormal, loglogistic, bell-shaped, and J-shaped beta distributions (but not U-shaped). See “Compare Lognormal and Burr Distribution pdfs” on page B-101.

Multinomial Distribution

In this section...
“Overview” on page B-104
“Parameter” on page B-104
“Probability Density Function” on page B-104
“Descriptive Statistics” on page B-105
“Relationship to Other Distributions” on page B-105

Overview

Multinomial distribution models the probability of each combination of successes in a series of independent trials. Use this distribution when there are more than two possible mutually exclusive outcomes for each trial, and each outcome has a fixed probability of success.

Parameter

Multinomial distribution uses the following parameter.

Parameter	Description	Constraints
probabilities	Outcome probabilities	$0 \leq \text{probabilities}(i) \leq 1 ; \sum_{\text{all}(i)} \text{probabilities}(i) = 1$

Probability Density Function

The multinomial pdf is

$$f(x | n, p) = \frac{n!}{x_1! \dots x_k!} p_1^{x_1} \dots p_k^{x_k},$$

where k is the number of possible mutually exclusive outcomes for each trial, and n is the total number of trials. The vector $x = (x_1 \dots x_k)$ is the number of observations of each k outcome, and contains nonnegative integer components that sum to n . The vector $p =$

$(p_1 \dots p_k)$ is the fixed probability of each k outcome, and contains nonnegative scalar components that sum to 1.

Descriptive Statistics

The expected number of observations of outcome i in n trials is

$$E\{x_i\} = np_i,$$

where p_i is the fixed probability of outcome i .

The variance is of outcome i is

$$\text{var}(x_i) = np_i(1 - p_i) .$$

The covariance of outcomes i and j is

$$\text{cov}(x_i, x_j) = - np_i p_j, \quad i \neq j.$$

Relationship to Other Distributions

The multinomial distribution is a generalization of the binomial distribution on page B-9. While the binomial distribution gives the probability of the number of “successes” in n independent trials of a two-outcome process, the multinomial distribution gives the probability of each combination of outcomes in n independent trials of a k -outcome process. The probability of each outcome in any one trial is given by the fixed probabilities p_1, \dots, p_k .

Multivariate Normal Distribution

In this section...
“Overview” on page B-106
“Parameters” on page B-106
“Probability Density Function” on page B-107
“Cumulative Distribution Function” on page B-107
“Examples” on page B-108

Overview

The multivariate normal distribution is a generalization of the univariate normal distribution on page B-136 to two or more variables. It is a distribution for random vectors of correlated variables, where each vector element has a univariate normal distribution. In the simplest case, no correlation exists among variables, and elements of the vectors are independent univariate normal random variables.

Because it is easy to work with, the multivariate normal distribution is often used as a model for multivariate data.

Statistics and Machine Learning Toolbox provides several functionalities related to the multivariate normal distribution.

- Generate random numbers from the distribution using `mvnrnd`.
- Evaluate the probability density function (pdf) at specific values using `mvnpdf`.
- Evaluate the cumulative distribution function (cdf) at specific values using `mvncdf`.

Parameters

The multivariate normal distribution uses the parameters in this table.

Parameter	Description	Univariate Normal Analogue
μ	Mean vector	Mean μ (scalar)

Parameter	Description	Univariate Normal Analogue
Σ	Covariance matrix — Diagonal elements contain the variances for each variable, and off-diagonal elements contain the covariances between variables	Variance σ^2 (scalar)

Note that in the one-dimensional case, Σ is the variance, not the standard deviation. For more information on the parameters of the univariate normal distribution, see “Parameters” on page B-136.

Probability Density Function

The probability density function (pdf) of the d -dimensional multivariate normal distribution is

$$y = f(x, \mu, \Sigma) = \frac{1}{\sqrt{|\Sigma|(2\pi)^d}} \exp\left(-\frac{1}{2}(x-\mu) \Sigma^{-1}(x-\mu)'\right)$$

where x and μ are 1-by- d vectors and Σ is a d -by- d symmetric, positive definite matrix.

Note that Statistics and Machine Learning Toolbox:

- Supports singular Σ for random vector generation only. The pdf cannot be written in the same form when Σ is singular.
- Uses x and μ oriented as row vectors rather than column vectors.

For an example, see “Bivariate Normal Distribution pdf” on page B-108.

Cumulative Distribution Function

The multivariate normal cumulative distribution function (cdf) evaluated at x is defined as the probability that a random vector v , distributed as multivariate normal, lies within the semi-infinite rectangle with upper limits defined by x ,

$$\Pr\{v(1) \leq x(1), v(2) \leq x(2), \dots, v(d) \leq x(d)\}.$$

Although the multivariate normal cdf has no closed form, `mvncdf` can compute cdf values numerically.

For an example, see “Bivariate Normal Distribution cdf” on page B-109.

Examples

Bivariate Normal Distribution pdf

Compute and plot the pdf of a bivariate normal distribution with parameters $\mu = [0 \ 0]$ and $\sigma = [0.25 \ 0.3; \ 0.3 \ 1]$.

Define the parameters μ and σ .

```
mu = [0 0];  
sigma = [0.25 0.3; 0.3 1];
```

Create a grid of evenly spaced points in two-dimensional space.

```
x1 = -3:0.2:3;  
x2 = -3:0.2:3;  
[X1,X2] = meshgrid(x1,x2);  
X = [X1(:) X2(:)];
```

Evaluate the pdf of the normal distribution at the grid points.

```
y = mvnpdf(X,mu,sigma);  
y = reshape(y,length(x2),length(x1));
```

Plot the pdf values.

```
surf(x1,x2,y)  
caxis([min(y(:))-0.5*range(y(:)),max(y(:))])  
axis([-3 3 -3 3 0 0.4])  
xlabel('x1')  
ylabel('x2')  
zlabel('Probability Density')
```

Bivariate Normal Distribution cdf

Compute and plot the cdf of a bivariate normal distribution.

Define the mean vector μ and the covariance matrix σ .

```
mu = [1 -1];  
sigma = [.9 .4; .4 .3];
```

Create a grid of 625 evenly spaced points in two-dimensional space.

```
[X1,X2] = meshgrid(linspace(-1,3,25)',linspace(-3,1,25)');  
X = [X1(:) X2(:)];
```

Evaluate the cdf of the normal distribution at the grid points.

```
p = mvncdf(X,mu,sigma);
```

Plot the cdf values.

```
Z = reshape(p,25,25);  
surf(X1,X2,Z)
```

Probability over Rectangular Region

Compute the probability over the unit square of a bivariate normal distribution, and create a contour plot of the results.

Define the bivariate normal distribution parameters μ and σ .

```
mu = [0 0];  
sigma = [0.25 0.3; 0.3 1];
```

Compute the probability over the unit square.

```
p = mvncdf([0 0],[1 1],mu,sigma)
```

```
p = 0.2097
```

To visualize the result, first create a grid of evenly spaced points in two-dimensional space.

```
x1 = -3:.2:3;  
x2 = -3:.2:3;  
[X1,X2] = meshgrid(x1,x2);  
X = [X1(:) X2(:)];
```

Then, evaluate the pdf of the normal distribution at the grid points.

```
y = mvnpdf(X,mu,sigma);  
y = reshape(y,length(x2),length(x1));
```

Finally, create a contour plot of the multivariate normal distribution that includes the unit square.

```
contour(x1,x2,y,[0.0001 0.001 0.01 0.05 0.15 0.25 0.35])  
xlabel('x')  
ylabel('y')  
line([0 0 1 1 0],[1 0 0 1 1], 'LineStyle', '--', 'Color', 'k')
```

Computing a multivariate cumulative probability requires significantly more work than computing a univariate probability. By default, the `mvncdf` function computes values to less than full machine precision, and returns an estimate of the error as an optional second output. View the error estimate in this case.

```
[p,err] = mvncdf([0 0],[1 1],mu,sigma)
```

```
p = 0.2097
```

```
err = 1.0000e-08
```

Multivariate t Distribution

In this section...

“Definition” on page B-114

“Background” on page B-114

“Example” on page B-115

Definition

The probability density function of the d -dimensional multivariate Student's t distribution is given by

$$f(x, \Sigma, \nu) = \frac{1}{|\Sigma|^{1/2}} \frac{1}{\sqrt{(\nu\pi)^d}} \frac{\Gamma((\nu + d)/2)}{\Gamma(\nu/2)} \left(1 + \frac{x' \Sigma^{-1} x}{\nu} \right)^{-(\nu + d)/2}.$$

where x is a 1-by- d vector, Σ is a d -by- d symmetric, positive definite matrix, and ν is a positive scalar. While it is possible to define the multivariate Student's t for singular Σ , the density cannot be written as above. For the singular case, only random number generation is supported. Note that while most textbooks define the multivariate Student's t with x oriented as a column vector, for the purposes of data analysis software, it is more convenient to orient x as a row vector, and Statistics and Machine Learning Toolbox software uses that orientation.

Background

The multivariate Student's t distribution is a generalization of the univariate Student's t to two or more variables. It is a distribution for random vectors of correlated variables, each element of which has a univariate Student's t distribution. In the same way as the univariate Student's t distribution can be constructed by dividing a standard univariate normal random variable by the square root of a univariate chi-square random variable, the multivariate Student's t distribution can be constructed by dividing a multivariate normal random vector having zero mean and unit variances by a univariate chi-square random variable.

The multivariate Student's t distribution is parameterized with a correlation matrix, Σ , and a positive scalar degrees of freedom parameter, ν . ν is analogous to the degrees of freedom parameter of a univariate Student's t distribution. The off-diagonal elements of Σ

contain the correlations between variables. Note that when Σ is the identity matrix, variables are uncorrelated; however, they are not independent.

The multivariate Student's t distribution is often used as a substitute for the multivariate normal distribution in situations where it is known that the marginal distributions of the individual variables have fatter tails than the normal.

Example

Plot PDF and CDF of Multivariate t-Distribution

Plot the pdf of a bivariate Student's t distribution. You can use this distribution for a higher number of dimensions as well, although visualization is not easy.

```
Rho = [1 .6; .6 1];  
nu = 5;  
x1 = -3:.2:3; x2 = -3:.2:3;  
[X1,X2] = meshgrid(x1,x2);  
F = mvtpdf([X1(:) X2(:)],Rho,nu);  
F = reshape(F,length(x2),length(x1));  
surf(x1,x2,F);  
caxis([min(F(:))-.5*range(F(:)),max(F(:))]);  
axis([-3 3 -3 3 0 .2])  
xlabel('x1'); ylabel('x2'); zlabel('Probability Density');
```

Plot the cdf of a bivariate Student's t distribution.

```
F = mvtcdf([X1(:) X2(:)],Rho,nu);  
F = reshape(F,length(x2),length(x1));  
surf(x1,x2,F);  
caxis([min(F(:))-0.5*range(F(:)),max(F(:))]);  
axis([-3 3 -3 3 0 1])  
xlabel('x1'); ylabel('x2'); zlabel('Cumulative Probability');
```

Since the bivariate Student's t distribution is defined on the plane, you can also compute cumulative probabilities over rectangular regions. For example, this contour plot illustrates the computation that follows, of the probability contained within the unit square shown in the figure.

```
contour(x1,x2,F,[.0001 .001 .01 .05:.1:.95 .99 .999 .9999]);
xlabel('x'); ylabel('y');
line([0 0 1 1 0],[1 0 0 1 1],'linestyle','--','color','k');
```

Compute the value of the probability contained within the unit square.

```
F = mvtcdf([0 0],[1 1],Rho,nu)
```

```
F = 0.1401
```

Computing a multivariate cumulative probability requires significantly more work than computing a univariate probability. By default, the `mvtcdf` function computes values to less than full machine precision and returns an estimate of the error, as an optional second output.

```
[F,err] = mvtcdf([0 0],[1 1],Rho,nu)
```

```
F = 0.1401
```

err = 1.0000e-08

Nakagami Distribution

In this section...
“Definition” on page B-120
“Background” on page B-120
“Parameters” on page B-120

Definition

The Nakagami distribution has the density function

$$2\left(\frac{\mu}{\omega}\right)^{\mu} \frac{1}{\Gamma(\mu)} x^{(2\mu-1)} e^{-\frac{\mu}{\omega}x^2}$$

with shape parameter μ and scale parameter $\omega > 0$, for $x > 0$. If x has a Nakagami distribution with parameters μ and ω , then x^2 has a gamma distribution with shape parameter μ and scale parameter ω/μ .

Background

In communications theory, Nakagami distributions, Rician distributions on page B-158, and Rayleigh distributions on page B-155 are used to model scattered signals that reach a receiver by multiple paths. Depending on the density of the scatter, the signal will display different fading characteristics. Rayleigh and Nakagami distributions are used to model dense scatters, while Rician distributions model fading with a stronger line-of-sight. Nakagami distributions can be reduced to Rayleigh distributions, but give more control over the extent of the fading.

Parameters

To estimate distribution parameters, use `mle` or the Distribution Fitter app.

Negative Binomial Distribution

In this section...
“Definition” on page B-122
“Background” on page B-122
“Parameters” on page B-123
“Example” on page B-124

Definition

When the r parameter is an integer, the negative binomial pdf is

$$y = f(x | r, p) = \binom{r + x - 1}{x} p^r q^x I_{(0, 1, \dots)}(x)$$

where $q = 1 - p$. When r is not an integer, the binomial coefficient in the definition of the pdf is replaced by the equivalent expression

$$\frac{\Gamma(r + x)}{\Gamma(r)\Gamma(x + 1)}$$

Background

In its simplest form (when r is an integer), the negative binomial distribution models the number of failures x before a specified number of successes is reached in a series of independent, identical trials. Its parameters are the probability of success in a single trial, p , and the number of successes, r . A special case of the negative binomial distribution, when $r = 1$, is the geometric distribution on page B-60, which models the number of failures before the first success.

More generally, r can take on non-integer values. This form of the negative binomial distribution has no interpretation in terms of repeated trials, but, like the Poisson distribution on page B-152, it is useful in modeling count data. The negative binomial distribution is more general than the Poisson distribution because it has a variance that is greater than its mean, making it suitable for count data that do not meet the assumptions of the Poisson distribution. In the limit, as r increases to infinity, the negative binomial distribution approaches the Poisson distribution.

Parameters

Suppose you are collecting data on the number of auto accidents on a busy highway, and would like to be able to model the number of accidents per day. Because these are count data, and because there are a very large number of cars and a small probability of an accident for any specific car, you might think to use the Poisson distribution. However, the probability of having an accident is likely to vary from day to day as the weather and amount of traffic change, and so the assumptions needed for the Poisson distribution are not met. In particular, the variance of this type of count data sometimes exceeds the mean by a large amount. The data below exhibit this effect: most days have few or no accidents, and a few days have a large number.

```
accident = [2 3 4 2 3 1 12 8 14 31 23 1 10 7 0];
m = mean(accident)

m = 8.0667

v = var(accident)

v = 79.3524
```

The negative binomial distribution is more general than the Poisson, and is often suitable for count data when the Poisson is not. The function `nbinfit` returns the maximum likelihood estimates (MLEs) and confidence intervals for the parameters of the negative binomial distribution. Here are the results from fitting the `accident` data:

```
[phat,pci] = nbinfit(accident)

phat = 1×2

    1.0060    0.1109

pci = 2×2

    0.2152    0.0171
    1.7968    0.2046
```

It is difficult to give a physical interpretation in this case to the individual parameters. However, the estimated parameters can be used in a model for the number of daily accidents. For example, a plot of the estimated cumulative probability function shows that while there is an estimated 10% chance of no accidents on a given day, there is also about a 10% chance that there will be 20 or more accidents.

```
plot(0:50,nbincdf(0:50,phat(1),phat(2)),'.-');  
xlabel('Accidents per Day')  
ylabel('Cumulative Probability')
```

Example

Compute and Plot Negative Binomial Distribution PDF

Compute and plot the pdf using four different values for the parameter r , the desired number of successes: .1, 1, 3, and 6. In each case, the probability of success p is .5.

```
x = 0:10;  
plot(x,nbinpdf(x,.1,.5),'s-', ...
```

```

x,nbinpdf(x,1,.5),'o-', ...
x,nbinpdf(x,3,.5),'d-', ...
x,nbinpdf(x,6,.5),'^-',);
legend({'r = .1' 'r = 1' 'r = 3' 'r = 6'})
xlabel('x')
ylabel('f(x|r,p)')

```

The plot shows that the negative binomial distribution can take on a variety of shapes, ranging from very skewed to nearly symmetric, depending on the value of r .

Noncentral Chi-Square Distribution

In this section...

“Definition” on page B-127

“Background” on page B-127

“Examples” on page B-128

Definition

There are many equivalent formulas for the noncentral chi-square distribution function. One formulation uses a modified Bessel function of the first kind. Another uses the generalized Laguerre polynomials. The cumulative distribution function is computed using a weighted sum of χ^2 probabilities with the weights equal to the probabilities of a Poisson distribution. The Poisson parameter is one-half of the noncentrality parameter of the noncentral chi-square

$$F(x | \nu, \delta) = \sum_{j=0}^{\infty} \left(\frac{\left(\frac{1}{2}\delta\right)^j}{j!} e^{-\frac{\delta}{2}} \right) \Pr[\chi_{\nu+2j}^2 \leq x]$$

where δ is the noncentrality parameter.

Background

The χ^2 distribution is actually a simple special case of the noncentral chi-square distribution. One way to generate random numbers with a χ^2 distribution (with ν degrees of freedom) is to sum the squares of ν standard normal random numbers (mean equal to zero.)

What if the normally distributed quantities have a mean other than zero? The sum of squares of these numbers yields the noncentral chi-square distribution. The noncentral chi-square distribution requires two parameters: the degrees of freedom and the noncentrality parameter. The noncentrality parameter is the sum of the squared means of the normally distributed quantities.

The noncentral chi-square has scientific application in thermodynamics and signal processing. The literature in these areas may refer to it as the “Rician Distribution” on page B-158 or generalized “Rayleigh Distribution” on page B-155.

Examples

Compute Noncentral Chi-Square Distribution pdf

Compute the pdf of a noncentral chi-square distribution with degrees of freedom $V = 4$ and noncentrality parameter $\text{DELTA} = 2$. For comparison, also compute the pdf of a chi-square distribution with the same degrees of freedom.

```
x = (0:0.1:10)';  
ncx2 = ncx2pdf(x,4,2);  
chi2 = chi2pdf(x,4);
```

Plot the pdf of the noncentral chi-square distribution on the same figure as the pdf of the chi-square distribution.

```
figure;  
plot(x,ncx2,'b-','LineWidth',2)  
hold on  
plot(x,chi2,'g--','LineWidth',2)  
legend('ncx2','chi2')
```

Noncentral F Distribution

In this section...

“Definition” on page B-130

“Background” on page B-130

“Examples” on page B-131

Definition

Similar to the noncentral χ^2 distribution, the toolbox calculates noncentral F distribution probabilities as a weighted sum of incomplete beta functions using Poisson probabilities as the weights.

$$F(x \mid \nu_1, \nu_2, \delta) = \sum_{j=0}^{\infty} \left(\frac{\left(\frac{1}{2}\delta\right)^j}{j!} e^{-\frac{\delta}{2}} \right) I\left(\frac{\nu_1 \cdot x}{\nu_2 + \nu_1 \cdot x} \mid \frac{\nu_1}{2} + j, \frac{\nu_2}{2}\right)$$

$I(x \mid a, b)$ is the incomplete beta function with parameters a and b , and δ is the noncentrality parameter.

Background

As with the χ^2 distribution, the F distribution is a special case of the noncentral F distribution. The F distribution is the result of taking the ratio of χ^2 random variables each divided by its degrees of freedom.

If the numerator of the ratio is a noncentral chi-square random variable divided by its degrees of freedom, the resulting distribution is the noncentral F distribution.

The main application of the noncentral F distribution is to calculate the power of a hypothesis test relative to a particular alternative.

Examples

Compute Noncentral F Distribution pdf

Compute the pdf of a noncentral F distribution with degrees of freedom $NU1 = 5$ and $NU2 = 20$, and noncentrality parameter $DELTA = 10$. For comparison, also compute the pdf of an F distribution with the same degrees of freedom.

```
x = (0.01:0.1:10.01)';  
p1 = ncfpdf(x,5,20,10);  
p = fpdf(x,5,20);
```

Plot the pdf of the noncentral F distribution and the pdf of the F distribution on the same figure.

```
figure;  
plot(x,p1,'b-','LineWidth',2)  
hold on  
plot(x,p,'g--','LineWidth',2)  
legend('Noncentral F','F distribution')
```

Noncentral t Distribution

In this section...

"Definition" on page B-133

"Background" on page B-133

"Examples" on page B-134

Definition

The most general representation of the noncentral t distribution is quite complicated. Johnson and Kotz [66] give a formula for the probability that a noncentral t variate falls in the range $[-u, u]$.

$$P(-u < x < u | \nu, \delta) = \sum_{j=0}^{\infty} \left(\frac{\left(\frac{1}{2}\delta^2\right)^j}{j!} e^{-\frac{\delta^2}{2}} \right) I\left(\frac{u^2}{\nu + u^2} \middle| \frac{1}{2} + j, \frac{\nu}{2}\right)$$

$I(x|\nu, \delta)$ is the incomplete beta function with parameters ν and δ . δ is the noncentrality parameter, and ν is the number of degrees of freedom.

Background

The noncentral t distribution is a generalization of Student's t distribution.

Student's t distribution with $n - 1$ degrees of freedom models the t -statistic

$$t = \frac{\bar{x} - \mu}{s/\sqrt{n}}$$

where \bar{x} is the sample mean and s is the sample standard deviation of a random sample of size n from a normal population with mean μ . If the population mean is actually μ_0 , then the t -statistic has a noncentral t distribution with noncentrality parameter

$$\delta = \frac{\mu_0 - \mu}{\sigma/\sqrt{n}}$$

The noncentrality parameter is the normalized difference between μ_0 and μ .

The noncentral t distribution gives the probability that a t test will correctly reject a false null hypothesis of mean μ when the population mean is actually μ_0 ; that is, it gives the power of the t test. The power increases as the difference $\mu_0 - \mu$ increases, and also as the sample size n increases.

Examples

Compute Noncentral t Distribution pdf

Compute the pdf of a noncentral t distribution with degrees of freedom $V = 10$ and noncentrality parameter $\text{DELTA} = 1$. For comparison, also compute the pdf of a t distribution with the same degrees of freedom.

```
x = (-5:0.1:5)';  
nct = nctpdf(x,10,1);  
t = tpdf(x,10);
```

Plot the pdf of the noncentral t distribution and the pdf of the t distribution on the same figure.

```
plot(x,nct,'b-','LineWidth',2)  
hold on  
plot(x,t,'g--','LineWidth',2)  
legend('nct','t')
```

Normal Distribution

In this section...
"Overview" on page B-136
"Parameters" on page B-136
"Probability Density Function" on page B-138
"Cumulative Distribution Function" on page B-138
"Examples" on page B-139
"Related Distributions" on page B-146

Overview

The normal distribution, sometimes called the Gaussian distribution, is a two-parameter family of curves. The usual justification for using the normal distribution for modeling is the Central Limit theorem, which states (roughly) that the sum of independent samples from any distribution with finite mean and variance converges to the normal distribution as the sample size goes to infinity.

Statistics and Machine Learning Toolbox offers several ways to work with the normal distribution.

- Create a probability distribution object `NormalDistribution` by fitting a probability distribution to sample data (`fitdist`) or by specifying parameter values (`makedist`). Then, use object functions to evaluate the distribution, generate random numbers, and so on.
- Work with the normal distribution interactively by using the **Distribution Fitter** app. You can export an object from the app and use the object functions.
- Use distribution-specific functions (`normcdf`, `normpdf`, `norminv`, `normlike`, `normstat`, `normfit`, `normrnd`) with specified distribution parameters. The distribution-specific functions can accept parameters of multiple normal distributions.
- Use generic distribution functions (`cdf`, `icdf`, `pdf`, `random`) with a specified distribution name (`'Normal'`) and parameters.

Parameters

The normal distribution uses these parameters.

Parameter	Description	Support
μ (μ)	Mean	$-\infty < \mu < \infty$
σ (σ)	Standard deviation	$\sigma \geq 0$

The standard normal distribution has zero mean and unit standard deviation. If z is standard normal, then $\sigma z + \mu$ is also normal with mean μ and standard deviation σ . Conversely, if x is normal with mean μ and standard deviation σ , then $z = (x - \mu) / \sigma$ is standard normal.

Parameter Estimation

The *maximum likelihood estimates* (MLEs) are the parameter estimates that maximize the likelihood function. The maximum likelihood estimators of μ and σ^2 for the normal distribution, respectively, are

$$\bar{x} = \sum_{i=1}^n \frac{x_i}{n}$$

and

$$s_{\text{MLE}}^2 = \frac{1}{n} \sum_{i=1}^n (x_i - \bar{x})^2.$$

\bar{x} is the sample mean for samples x_1, x_2, \dots, x_n . The sample mean is an unbiased estimator of the parameter μ . However, s_{MLE}^2 is a biased estimator of the parameter σ^2 , meaning that its expected value does not equal the parameter.

The *minimum variance unbiased estimator* (MVUE) is commonly used to estimate the parameters of the normal distribution. The MVUE is the estimator that has the minimum variance of all unbiased estimators of a parameter. The MVUEs of the parameters μ and σ^2 for the normal distribution are the sample mean \bar{x} and sample variance s^2 , respectively.

$$s^2 = \frac{1}{n-1} \sum_{i=1}^n (x_i - \bar{x})^2$$

To fit the normal distribution to data and find the parameter estimates, use `normfit`, `fitdist`, or `mle`.

- For uncensored data, `normfit` and `fitdist` find the unbiased estimates, and `mle` finds the maximum likelihood estimates.

- For censored data, `normfit`, `fitdist`, and `mle` find the maximum likelihood estimates.

Unlike `normfit` and `mle`, which return parameter estimates, `fitdist` returns the fitted probability distribution object `NormalDistribution`. The object properties `mu` and `sigma` store the parameter estimates.

For an example, see “Fit Normal Distribution Object” on page B-139.

Probability Density Function

The normal probability density function (pdf) is

$$y = f(x) \left| \mu, \sigma \right. = \frac{1}{\sigma\sqrt{2\pi}} e^{-\frac{(x-\mu)^2}{2\sigma^2}}, \quad \text{for } x \in \mathbb{R}.$$

The *likelihood function* is the pdf viewed as a function of the parameters. The maximum likelihood estimates (MLEs) are the parameter estimates that maximize the likelihood function for fixed values of x .

For an example, see “Compute and Plot the Normal Distribution pdf” on page B-139.

Cumulative Distribution Function

The normal cumulative distribution function (cdf) is

$$p = F(x) \left| \mu, \sigma \right. = \frac{1}{\sigma\sqrt{2\pi}} \int_{-\infty}^x e^{-\frac{(t-\mu)^2}{2\sigma^2}} dt, \quad \text{for } x \in \mathbb{R}.$$

p is the probability that a single observation from a normal distribution with parameters μ and σ falls in the interval $(-\infty, x]$.

The standard normal cumulative distribution function $\Phi(x)$ is functionally related to the error function `erf`.

$$\Phi(x) = \frac{1}{2} \left(1 - \operatorname{erf} \left(-\frac{x}{\sqrt{2}} \right) \right)$$

where

$$\operatorname{erf}(x) = \frac{2}{\sqrt{\pi}} \int_0^x e^{-t^2} dt = 2\Phi(\sqrt{2}x) - 1.$$

For an example, see “Plot Standard Normal Distribution cdf” on page B-140

Examples

Fit Normal Distribution Object

Load the sample data and create a vector containing the first column of student exam grade data.

```
load examgrades
x = grades(:,1);
```

Create a normal distribution object by fitting it to the data.

```
pd = fitdist(x, 'Normal')

pd =
    NormalDistribution

    Normal distribution
         mu = 75.0083    [73.4321, 76.5846]
        sigma =  8.7202    [7.7391, 9.98843]
```

The intervals next to the parameter estimates are the 95% confidence intervals for the distribution parameters.

Compute and Plot the Normal Distribution pdf

Compute the pdf of a standard normal distribution, with parameters μ equal to 0 and σ equal to 1.

```
x = [-3:.1:3];
y = normpdf(x,0,1);
```

Plot the pdf.

```
plot(x,y)
```

**Plot Standard Normal Distribution cdf**

Create a standard normal distribution object.

```
pd = makedist('Normal')
```

```
pd =  
NormalDistribution
```

```
Normal distribution  
mu = 0  
sigma = 1
```

Specify the x values and compute the cdf.

```
x = -3:.1:3;  
p = cdf(pd,x);
```

Plot the cdf of the standard normal distribution.

```
plot(x,p)
```

Compare Gamma and Normal Distribution pdfs

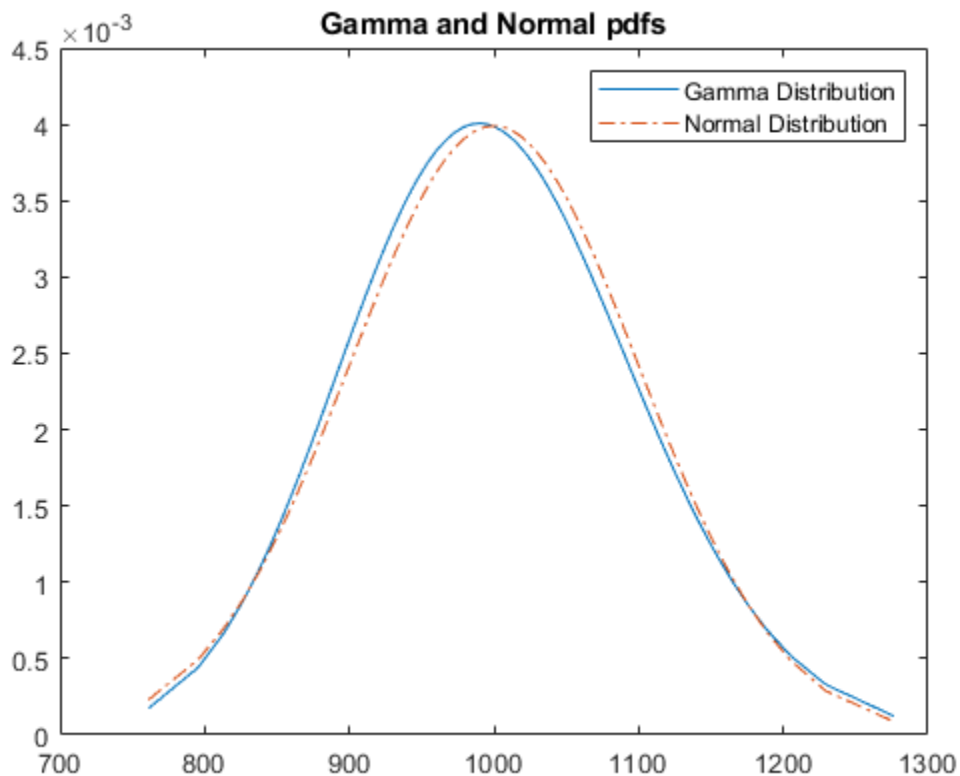

The gamma distribution has the shape parameter a and the scale parameter b . For a large a , the gamma distribution closely approximates the normal distribution with mean $\mu = ab$

and variance $\sigma^2 = ab^2$. Compute the pdf of a gamma distribution with parameters $A = 100$ and $B = 10$. For comparison, also compute the pdf of a normal distribution with parameters $\mu = 1000$ and $\sigma = 100$.

```
x = gaminv((0.005:0.01:0.995),100,10);  
y_gam = gampdf(x,100,10);  
y_norm = normpdf(x,1000,100);
```

Plot the pdfs of the gamma distribution and the normal distribution on the same figure.

```
plot(x,y_gam,'-',x,y_norm,'-.')  
title('Gamma and Normal pdfs')  
legend('Gamma Distribution','Normal Distribution')
```

Relationship Between Normal and Lognormal Distributions

If X follows the lognormal distribution with parameters μ and σ , then $\log(X)$ follows the normal distribution with mean μ and standard deviation σ . Use distribution objects to inspect the relationship between normal and lognormal distributions.

Create a lognormal distribution object by specifying the parameter values.

```
pd = makedist('Lognormal', 'mu', 5, 'sigma', 2)

pd =
  LognormalDistribution

  Lognormal distribution
      mu = 5
      sigma = 2
```

Compute the mean of the lognormal distribution.

```
mean(pd)

ans = 1.0966e+03
```

The mean of the lognormal distribution is not equal to the μ parameter. The mean of the logarithmic values is equal to μ . Confirm this relationship by generating random numbers.

Generate random numbers from the lognormal distribution and compute their log values.

```
rng('default'); % For reproducibility
x = random(pd, 10000, 1);
logx = log(x);
```

Compute the mean of the logarithmic values.

```
m = mean(logx)

m = 5.0033
```

The mean of the log of x is close to the μ parameter of x , because x has a lognormal distribution.

Construct a histogram of $\log x$ with a normal distribution fit.

```
histfit(logx)
```

The plot shows that the log values of x are normally distributed.

`histfit` uses `fitdist` to fit a distribution to data. Use `fitdist` to obtain parameters used in fitting.

```
pd_normal = fitdist(logx, 'Normal')  
  
pd_normal =  
NormalDistribution  
  
Normal distribution  
mu = 5.00332 [4.96445, 5.04219]
```

```
sigma = 1.98296 [1.95585, 2.01083]
```

The estimated normal distribution parameters are close to the lognormal distribution parameters 5 and 2.

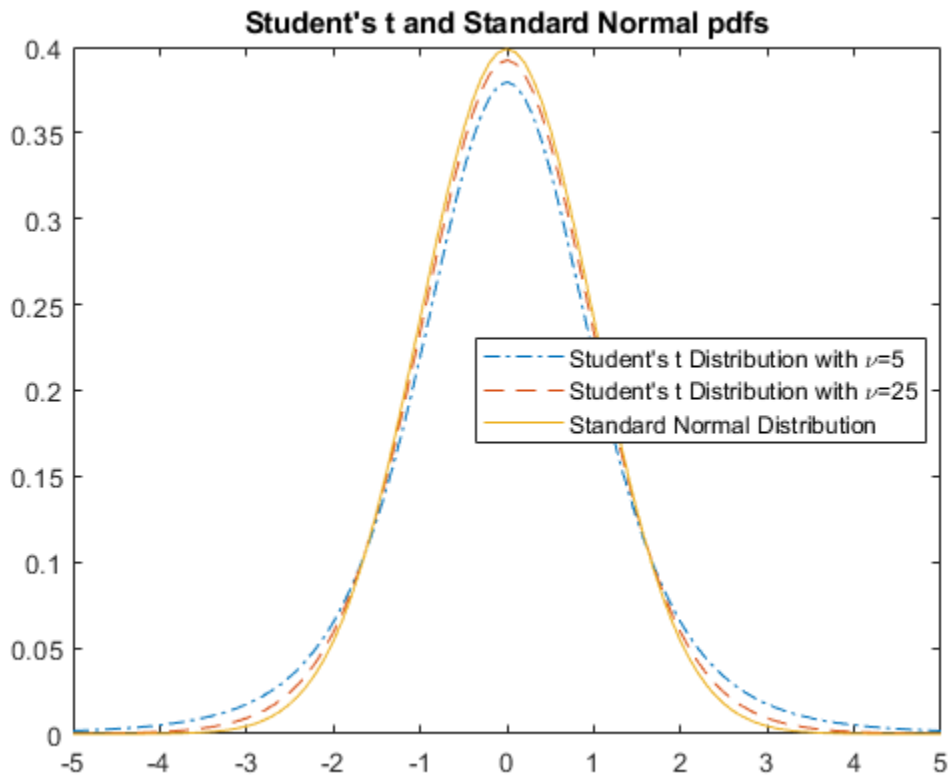

Compare Student's t and Normal Distribution pdfs

The Student's t distribution is a family of curves depending on a single parameter ν (the degrees of freedom). As the degrees of freedom ν goes to infinity, the t distribution approaches the standard normal distribution. Compute the pdfs for the Student's t distribution with the parameter $\nu = 5$ and the Student's t distribution with the parameter $\nu = 25$. Compute the pdf for a standard normal distribution.

```
x = -5:0.1:5;
y1 = tpdf(x,5);
y2 = tpdf(x,15);
z = normpdf(x,0,1);
```

Plot the Student's t pdfs and the standard normal pdf on the same figure. The standard normal pdf has shorter tails than the Student's t pdfs.

```
plot(x,y1,'-.',x,y2,'--',x,z,'-')
legend('Student''s t Distribution with \nu=5', ...
       'Student''s t Distribution with \nu=25', ...
       'Standard Normal Distribution','Location','best')
title('Student''s t and Standard Normal pdfs')
```

Related Distributions

- “Binomial Distribution” on page B-9 — The binomial distribution models the total number of successes in n repeated trials with the probability of success p . As n increases, the binomial distribution can be approximated by a normal distribution with $\mu = np$ and $\sigma^2 = np(1-p)$.
- “Birnbbaum-Saunders Distribution” on page B-13 — If x has a Birnbbaum-Saunders distribution with parameters β and γ , then

$$\frac{(\sqrt{x/\beta} - \sqrt{\beta/x})}{\gamma}$$

has a standard normal distribution.

- “Chi-Square Distribution” on page B-28 — The chi-square distribution is the distribution of the sum of squared, independent, standard normal random variables. If a set of n observations is normally distributed with variance σ^2 , and s^2 is the sample variance, then $(n-1)s^2/\sigma^2$ has a chi-square distribution with $n-1$ degrees of freedom. The `normfit` function uses this relationship to calculate confidence intervals for the estimate of the normal parameter σ^2 .
- “Extreme Value Distribution” on page B-36 — The extreme value distribution is appropriate for modeling the smallest or largest value from a distribution whose tails decay exponentially fast, such as, the normal distribution.
- “Gamma Distribution” on page B-45 — The gamma distribution has the shape parameter a and the scale parameter b . For a large a , the gamma distribution closely approximates the normal distribution with mean $\mu = ab$ and variance $\sigma^2 = ab^2$. The gamma distribution has density only for positive real numbers. See “Compare Gamma and Normal Distribution pdfs” on page B-141.
- “Half-Normal Distribution” on page B-68 — The half-normal distribution is a special case of the folded normal and truncated normal distributions. If a random variable Z has a standard normal distribution, then $X = \mu + \sigma|Z|$ has a half-normal distribution with parameters μ and σ .
- “Logistic Distribution” on page B-90 — The logistic distribution is used for growth models and in logistic regression. It has longer tails and a higher kurtosis than the normal distribution.
- “Lognormal Distribution” on page B-94 — If X follows the lognormal distribution with parameters μ and σ , then $\log(X)$ follows the normal distribution with mean μ and standard deviation σ . See “Relationship Between Normal and Lognormal Distributions” on page B-143.
- “Multivariate Normal Distribution” on page B-106 — The multivariate normal distribution is a generalization of the univariate normal to two or more variables. It is a distribution for random vectors of correlated variables, in which each element has a univariate normal distribution. In the simplest case, there is no correlation among variables, and elements of the vectors are independent, univariate normal random variables.
- “Poisson Distribution” on page B-152 — The Poisson distribution is a one-parameter discrete distribution that takes nonnegative integer values. The parameter, λ , is both the mean and the variance of the distribution. As λ increase, the Poisson distribution can be approximated by a normal distribution with $\mu = \lambda$ and $\sigma^2 = \lambda$.

- “Rayleigh Distribution” on page B-155 — The Rayleigh distribution is a special case of the Weibull distribution with applications in communications theory. If the component velocities of a particle in the x and y directions are two independent normal random variables with zero means and equal variances, then the distance the particle travels per unit time follows the Rayleigh distribution.
- “Stable Distribution” on page B-160 — The normal distribution is a special case of the stable distribution. The stable distribution with the first shape parameter $\alpha = 2$ corresponds to the normal distribution.

$$N(\mu, \sigma^2) = S\left(2, 0, \frac{\sigma}{\sqrt{2}}, \mu\right).$$

- “Student's t Distribution” on page B-173 — The Student's t distribution is a family of curves depending on a single parameter ν (the degrees of freedom). As the degrees of freedom ν goes to infinity, the t distribution approaches the standard normal distribution. See “Compare Student's t and Normal Distribution pdfs” on page B-145.

If x is a random sample of size n from a normal distribution with mean μ , then the statistic

$$t = \frac{\bar{x} - \mu}{s/\sqrt{n}}$$

where \bar{x} is the sample mean and s is the sample standard deviation, has the Student's t distribution with $n-1$ degrees of freedom.

- “ t Location-Scale Distribution” on page B-181 — The t location-scale distribution is useful for modeling data distributions with heavier tails (more prone to outliers) than the normal distribution. It approaches the normal distribution as the shape parameter ν approaches infinity.

Piecewise Linear Distribution

In this section...
“Overview” on page B-150
“Parameters” on page B-150
“Cumulative Distribution Function” on page B-150
“Relationship to Other Distributions” on page B-150

Overview

The piecewise linear distribution creates a nonparametric representation of the cumulative distribution function (cdf) by linearly connecting the known cdf values from the sample data.

Parameters

The piecewise linear distribution uses the following parameters.

Parameter	Description
x	Vector of x values at which the cdf changes slope
F_x	Vector of cdf values that correspond to each value in x

Cumulative Distribution Function

The piecewise linear distribution constructs a continuous cumulative distribution function (cdf) by connecting the empirical cdf values such that the cdf increases linearly between $x(j)$ and $x(j + 1)$.

Relationship to Other Distributions

The piecewise linear distribution is a continuous version of the discrete empirical cumulative distribution function (ecdf).

Poisson Distribution

In this section...
“Definition” on page B-152
“Background” on page B-152
“Parameters” on page B-153
“Examples” on page B-153

Definition

The Poisson pdf is

$$f(x|\lambda) = \frac{\lambda^x}{x!} e^{-\lambda}; x = 0, 1, 2, \dots, \infty .$$

Background

The Poisson distribution is appropriate for applications that involve counting the number of times a random event occurs in a given amount of time, distance, area, etc. Sample applications that involve Poisson distributions include the number of Geiger counter clicks per second, the number of people walking into a store in an hour, and the number of flaws per 1000 feet of video tape.

The Poisson distribution is a one-parameter discrete distribution that takes nonnegative integer values. The parameter, λ , is both the mean and the variance of the distribution. Thus, as the size of the numbers in a particular sample of Poisson random numbers gets larger, so does the variability of the numbers.

The Poisson distribution is the limiting case of a binomial distribution where N approaches infinity and p goes to zero while $Np = \lambda$.

The Poisson and exponential distributions are related. If the number of counts follows the Poisson distribution, then the interval between individual counts follows the exponential distribution.

Parameters

The MLE and the MVUE of the Poisson parameter, λ , is the sample mean. The sum of independent Poisson random variables is also Poisson distributed with the parameter equal to the sum of the individual parameters. This is used to calculate confidence intervals λ . As λ increase, the Poisson distribution can be approximated by a normal distribution with $\mu = \lambda$ and $\sigma^2 = \lambda$. This approximation is used to calculate confidence intervals for values of λ greater than 100.

Examples

Compute and Plot Poisson Distribution PDF

Compute and plot the pdf of a Poisson distribution with parameter $\lambda = 5$.

```
x = 0:15;  
y = poisspdf(x,5);  
plot(x,y, '+' )
```

Rayleigh Distribution

In this section...

“Definition” on page B-155

“Background” on page B-155

“Parameters” on page B-155

“Examples” on page B-156

Definition

The Rayleigh pdf is

$$y = f(x|b) = \frac{x}{b^2} e^{\left(\frac{-x^2}{2b^2}\right)}$$

Background

The Rayleigh distribution is a special case of the Weibull distribution on page B-199. If A and B are the parameters of the Weibull distribution, then the Rayleigh distribution with parameter b is equivalent to the Weibull distribution with parameters $A = \sqrt{2}b$ and $B = 2$.

If the component velocities of a particle in the x and y directions are two independent normal random variables with zero means and equal variances, then the distance the particle travels per unit time is distributed Rayleigh.

In communications theory, Nakagami distributions on page B-120, Rician distributions on page B-158, and Rayleigh distributions are used to model scattered signals that reach a receiver by multiple paths. Depending on the density of the scatter, the signal will display different fading characteristics. Rayleigh and Nakagami distributions are used to model dense scatters, while Rician distributions model fading with a stronger line-of-sight. Nakagami distributions can be reduced to Rayleigh distributions, but give more control over the extent of the fading.

Parameters

The `raylfit` function returns the MLE of the Rayleigh parameter. This estimate is

$$b = \sqrt{\frac{1}{2n} \sum_{i=1}^n x_i^2}$$

Examples

Compute and Plot Rayleigh Distribution pdf

Compute the pdf of a Rayleigh distribution with parameter $B = 0.5$.

```
x = [0:0.01:2];  
p = raylpdf(x,0.5);
```

Plot the pdf.

```
figure;  
plot(x,p)
```

Rician Distribution

In this section...
“Definition” on page B-158
“Background” on page B-158
“Parameters” on page B-158

Definition

The Rician distribution has the density function

$$I_0\left(\frac{xs}{\sigma^2}\right) \frac{x}{\sigma^2} e^{-\left(\frac{x^2+s^2}{2\sigma^2}\right)}$$

with noncentrality parameter $s \geq 0$ and scale parameter $\sigma > 0$, for $x > 0$. I_0 is the zero-order modified Bessel function of the first kind. If x has a Rician distribution with parameters s and σ , then $(x/\sigma)^2$ has a noncentral chi-square distribution with two degrees of freedom and noncentrality parameter $(s/\sigma)^2$.

Background

In communications theory, Nakagami distributions on page B-120, Rician distributions, and Rayleigh distributions on page B-155 are used to model scattered signals that reach a receiver by multiple paths. Depending on the density of the scatter, the signal will display different fading characteristics. Rayleigh and Nakagami distributions are used to model dense scatters, while Rician distributions model fading with a stronger line-of-sight. Nakagami distributions can be reduced to Rayleigh distributions, but give more control over the extent of the fading.

Parameters

To estimate distribution parameters, use `mle` or the Distribution Fitter app.

Stable Distribution

In this section...

“Overview” on page B-160

“Parameters” on page B-161

“Probability Density Function” on page B-161

“Cumulative Distribution Function” on page B-165

“Descriptive Statistics” on page B-168

“Relationship to Other Distributions” on page B-169

Overview

Stable distributions are a class of probability distributions suitable for modeling heavy tails and skewness. A linear combination of two independent, identically-distributed stable-distributed random variables has the same distribution as the individual variables. In other words, if X_1, X_2, \dots, X_n are independent and identically distributed stable random variables, then for every n

$$X_1 + X_2 + \dots + X_n \stackrel{d}{=} c_n X + d_n$$

where the constant $c_n > 0$ and $d_n \in \mathbb{R}$.

The stable distribution is an application of the Generalized Central Limit Theorem, which states that the limit of normalized sums of independent identically distributed variables is stable.

Several different parameterizations exist for the stable distribution. The implementation in Statistics and Machine Learning Toolbox uses the parameterization described in [2]. In this case, a random variable X has the stable distribution $S(\alpha, \beta, \gamma, \delta_0; 0)$ if its characteristic function is given by:

$$E(e^{itX}) = \begin{cases} \exp\left(-\gamma^\alpha |t|^\alpha \left[1 + i\beta \operatorname{sign}(t) \tan\frac{\pi\alpha}{2} \left(|\gamma| |t|^{1-\alpha} - 1\right)\right] + i\delta_0 t\right) & \text{for } \alpha \neq 1, \\ \exp\left(-\gamma |t| \left[1 + i\beta \operatorname{sign}(t) \frac{2}{\pi} \ln(|\gamma| |t|)\right] + i\delta_0 t\right) & \text{for } \alpha = 1 \end{cases}$$

Parameters

The stable distribution uses the following parameters.

Parameter	Description	Support
alpha	First shape parameter	$0 < \alpha \leq 2$
beta	Second shape parameter	$-1 \leq \beta \leq 1$
gam	Scale parameter	$0 < \gamma < \infty$
delta	Location parameter	$-\infty < \delta < \infty$

The first shape parameter, α , describes the tails of the distribution. The software computes the densities of the stable distribution using the direct integration method. As explained in [1], numerical difficulties exist with accurately computing the pdf and cdf when the α parameter is close to 1 or 0. If α is close to 1 (specifically, $0 < |\alpha - 1| < 0.02$), then the software rounds α to 1. If α is close to 0, then the densities may not be accurate.

The second shape parameter, β , describes the skewness of the distribution. If $\beta = 0$, then the distribution is symmetric. If $\beta > 0$, then the distribution is right-skewed. If $\beta < 0$, then the distribution is left-skewed. When α is small, the skewness of β is significant. As α increases, the effect of β decreases.

Probability Density Function

Definition

Most members of the stable distribution family do not have an explicit probability density function (pdf). Instead, the pdf is described in terms of the characteristic function [2].

Some special cases of the stable distribution, such as the normal, Cauchy, and Lévy distributions, have closed-form density functions. See Relationship to Other Distributions on page B-169 for more information.

Use `pdf` to calculate the probability density function for the stable distribution. The software computes the pdf using the direct integration method. As explained in [1], numerical difficulties exist with accurately computing the pdf when the α parameter is close to 1 or 0. If α is close to 1 (specifically, $0 < |\alpha - 1| < 0.02$), then the software rounds α to 1. If α is close to 0, then the densities may not be accurate.

Compare PDFs of Stable Distributions

The following plot compares the probability density functions for stable distributions with different alpha values. In each case, $\beta = 0$, $\gamma = 1$, and $\delta = 0$.

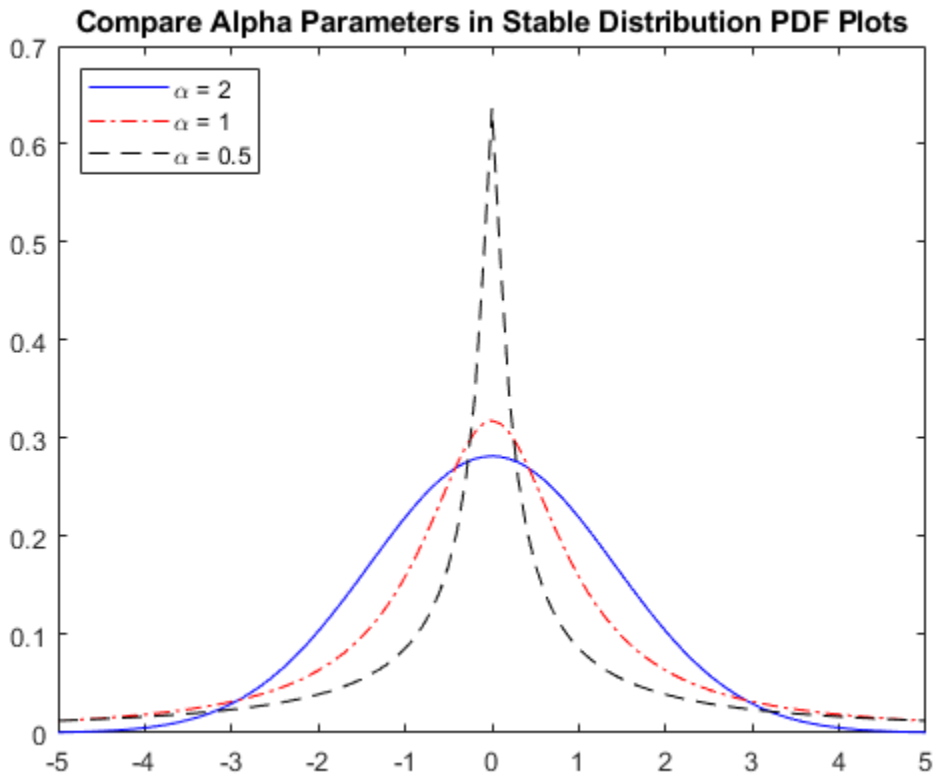

```
pd1 = makedist('Stable', 'alpha', 2, 'beta', 0, 'gam', 1, 'delta', 0);  
pd2 = makedist('Stable', 'alpha', 1, 'beta', 0, 'gam', 1, 'delta', 0);  
pd3 = makedist('Stable', 'alpha', 0.5, 'beta', 0, 'gam', 1, 'delta', 0);
```

Calculate the pdf for each distribution.

```
x = -5:.1:5;  
pdf1 = pdf(pd1,x);  
pdf2 = pdf(pd2,x);  
pdf3 = pdf(pd3,x);
```

Plot all three pdf functions on the same figure for visual comparison.

```
figure  
plot(x,pdf1, 'b-');  
hold on  
plot(x,pdf2, 'r-.');  
plot(x,pdf3, 'k--');  
title('Compare Alpha Parameters in Stable Distribution PDF Plots')  
legend('\alpha = 2', '\alpha = 1', '\alpha = 0.5', 'Location', 'northwest')  
hold off
```

The plot illustrates the effect of the alpha parameter on the tails of the distribution.

The next plot compares the probability density functions for stable distributions with different beta values. In each case, $\alpha = 0.5$, $\text{gam} = 1$, and $\text{delta} = 0$.

```
pd1 = makedist('Stable','alpha',0.5,'beta',0,'gam',1,'delta',0);
pd2 = makedist('Stable','alpha',0.5,'beta',0.5,'gam',1,'delta',0);
pd3 = makedist('Stable','alpha',0.5,'beta',1,'gam',1,'delta',0);
```

Calculate the pdf for each distribution.

```
x = -5:.1:5;
pdf1 = pdf(pd1,x);
pdf2 = pdf(pd2,x);
pdf3 = pdf(pd3,x);
```

Plot all three pdf functions on the same figure for visual comparison.

```
figure
plot(x,pdf1,'b-');
hold on
plot(x,pdf2,'r-.');
plot(x,pdf3,'k--');
title('Compare Beta Parameters in Stable Distribution PDF Plots')
legend('\beta = 0', '\beta = 0.5', '\beta = 1', 'Location', 'northwest')
hold off
```

Random Number Generation

Use `random` to generate random numbers from the stable distribution. The software generates random numbers for the stable distribution using the method proposed in [3]

Cumulative Distribution Function

Definition

Most members of the stable distribution family do not have an explicit cumulative distribution function (cdf). Instead, the cdf is described in terms of the characteristic function [2].

Use `cdf` to calculate the cumulative distribution function for the stable distribution. The software computes the cdf using the direct integration method. As explained in [1], numerical difficulties exist with accurately computing the cdf when the α parameter is close to 1 or 0. If α is close to 1 (specifically, $0 < |\alpha - 1| < 0.02$), then the software rounds α to 1. If α is close to 0, then the densities may not be accurate.

Compare CDFs of Stable Distributions

The following plot compares the cumulative distribution functions for stable distributions with different α values. In each case, $\beta = 0$, $\gamma = 1$, and $\delta = 0$.

```
pd1 = makedist('Stable', 'alpha', 2, 'beta', 0, 'gam', 1, 'delta', 0);
pd2 = makedist('Stable', 'alpha', 1, 'beta', 0, 'gam', 1, 'delta', 0);
pd3 = makedist('Stable', 'alpha', 0.5, 'beta', 0, 'gam', 1, 'delta', 0);
```

Calculate the cdf for each distribution.

```
x = -5:.1:5;
cdf1 = cdf(pd1,x);
cdf2 = cdf(pd2,x);
cdf3 = cdf(pd3,x);
```

Plot all three cdf functions on the same figure for visual comparison.

```
figure
plot(x,cdf1,'b-');
hold on
plot(x,cdf2,'r-.');
plot(x,cdf3,'k--');
title('Compare Alpha Parameters in Stable Distribution CDF Plots')
```

```
legend('\alpha = 2', '\alpha = 1', '\alpha = 0.5', 'Location', 'northwest')  
hold off
```

The plot illustrates the effect of the alpha parameter on the shape of the cdf.

The next plot compares the cumulative distribution functions for stable distributions with different beta values. In all cases, alpha = 0.5, gam = 1, and delta = 0.

```
pd1 = makedist('Stable', 'alpha', 0.5, 'beta', 0, 'gam', 1, 'delta', 0);  
pd2 = makedist('Stable', 'alpha', 0.5, 'beta', 0.5, 'gam', 1, 'delta', 0);  
pd3 = makedist('Stable', 'alpha', 0.5, 'beta', 1, 'gam', 1, 'delta', 0);
```

Calculate the cdf for each distribution.

```
x = -5:.1:5;  
cdf1 = cdf(pd1,x);  
cdf2 = cdf(pd2,x);  
cdf3 = cdf(pd3,x);
```

Plot all three pdf functions on the same figure for visual comparison.

```
figure  
plot(x,cdf1,'b-');  
hold on  
plot(x,cdf2,'r-.');  
plot(x,cdf3,'k--');  
title('Compare Beta Parameters in Stable Distribution CDF Plots')  
legend('\beta = 0', '\beta = 0.5', '\beta = 1', 'Location', 'northwest')  
hold off
```

Descriptive Statistics

The mean of the stable distribution is undefined for values of $\alpha \leq 1$. For $\alpha > 1$, the mean of the stable distribution is

$$\text{mean} = \delta - \beta \gamma \tan\left(\frac{\pi\alpha}{2}\right).$$

Use `mean` to calculate the mean of the stable distribution.

The variance of the stable distribution is undefined for values of $\alpha < 2$. For $\alpha = 2$, the variance of the stable distribution is

$$\text{var} = 2\gamma^2.$$

Use `var` to calculate the variance of the stable distribution.

Relationship to Other Distributions

The stable distribution has three special cases: The normal distribution, the Cauchy distribution, and the Lévy distribution. These distributions are notable because they have closed-form probability density functions.

Normal Distribution

The normal, or Gaussian, distribution is a special case of the stable distribution. The stable distribution with $\alpha = 2$ corresponds to the normal distribution. In other words,

$$N(\mu, \sigma^2) = S\left(2, 0, \frac{\sigma}{\sqrt{2}}, \mu\right).$$

μ is the mean and σ is the standard deviation of the normal distribution.

Although the value of β has no effect when $\alpha = 2$, the normal distribution is usually associated with $\beta = 0$.

The probability density function for the normal distribution is

$$f(x) = \frac{1}{\sqrt{2\pi}\sigma} \exp\left(-\frac{(x - \mu)^2}{2\sigma^2}\right), \quad -\infty < x < \infty.$$

A plot of the density for a normal distribution is symmetric and has a bell-shaped curve.

Cauchy Distribution

The Cauchy distribution is a special case of the stable distribution with $\alpha = 1$ and $\beta = 0$. In other words,

$$\text{Cauchy}(\delta, \gamma) = S(1, 0, \gamma, \delta),$$

where γ is the scale parameter and δ is location parameter of the Cauchy distribution.

The probability density function for the Cauchy distribution is

$$f(x) = \frac{1}{\pi} \frac{\gamma}{\gamma^2 + (x - \delta)^2}, \quad -\infty < x < \infty.$$

A plot of the density for a Cauchy distribution is symmetric and has a bell-shaped curve, but has heavier tails than the density of a normal distribution.

Lévy Distribution

The Lévy distribution is a special case of the stable distribution where $\alpha = 0.5$ and $\beta = 1$. In other words,

$$Lévy(\delta, \gamma) = S(0.5, 1, \gamma, \gamma + \delta) .$$

where γ is the scale parameter and δ is location parameter of the Lévy distribution.

The probability density function for the Lévy distribution is

$$f(x) = \sqrt{\frac{\gamma}{2\pi}} \frac{1}{(x - \delta)^{3/2}} \exp\left(-\frac{\gamma}{2(x - \delta)}\right), \delta < x < \infty .$$

A plot of the density for a Lévy distribution is highly skewed and has heavy tails.

Comparison Plot for Stable Distributions

The following plot compares the probability density functions for the standard normal, Cauchy, and Lévy distributions.

Create a probability distribution object for the standard normal, Cauchy, and Lévy distributions.

```
pd_norm = makedist('Stable', 'alpha', 2, 'beta', 0, 'gam', 1/sqrt(2), 'delta', 0);
pd_cauchy = makedist('Stable', 'alpha', 1, 'beta', 0, 'gam', 1, 'delta', 0);
pd_levy = makedist('Stable', 'alpha', 0.5, 'beta', 1, 'gam', 1, 'delta', 0);
```

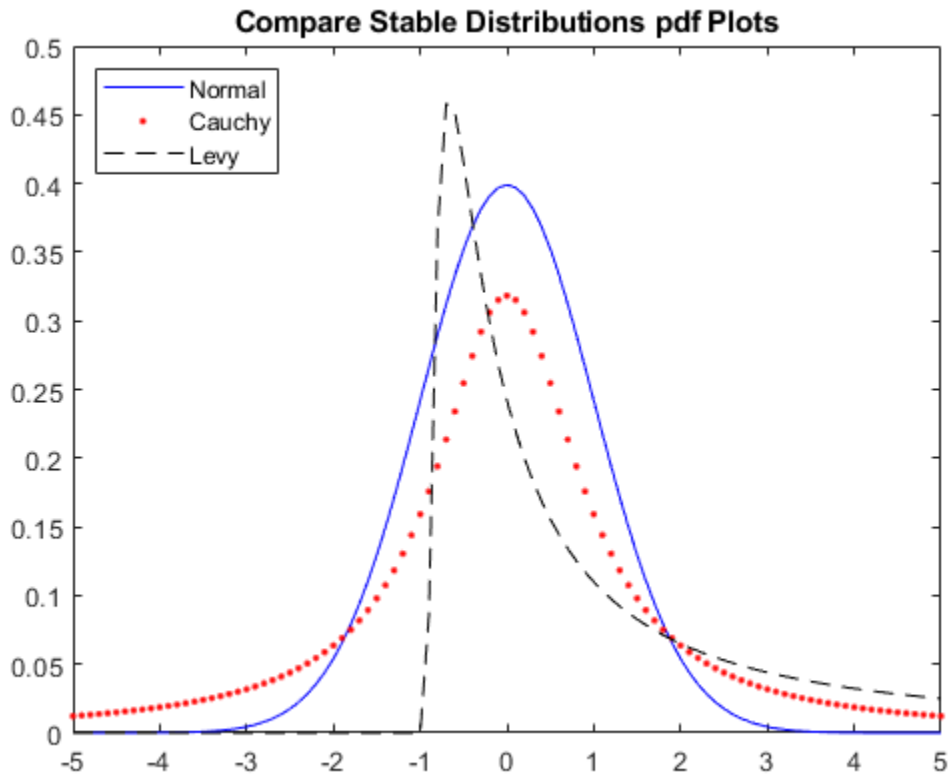

Calculate the pdf for each distribution.

```
x = -5:.1:5;
pdf_norm = pdf(pd_norm, x);
pdf_cauchy = pdf(pd_cauchy, x);
pdf_levy = pdf(pd_levy, x);
```

Plot all three pdf functions on the same figure for visual comparison.

```
figure
plot(x, pdf_norm, 'b-');
hold on
plot(x, pdf_cauchy, 'r.');
```

```
plot(x,pdf_levy,'k--');  
title('Compare Stable Distributions pdf Plots')  
legend('Normal','Cauchy','Levy','Location','northwest')  
hold off
```

Student's *t* Distribution

In this section...

“Overview” on page B-173

“Parameters” on page B-173

“Probability Density Function” on page B-173

“Cumulative Distribution Function” on page B-176

“Mean and Variance” on page B-178

“Example” on page B-178

Overview

The Student's *t* distribution is a family of curves depending on a single parameter ν (the degrees of freedom).

Parameters

The Student's *t* distribution uses the following parameter.

Parameter	Description
$\nu = 1, 2, 3, \dots$	Degrees of freedom

Probability Density Function

Definition

The probability density function (pdf) of the Student's *t* distribution is

$$y = f(x) \left| \nu = \frac{\Gamma\left(\frac{\nu+1}{2}\right)}{\Gamma\left(\frac{\nu}{2}\right)} \frac{1}{\sqrt{\nu\pi}} \frac{1}{\left(1 + \frac{x^2}{\nu}\right)^{\frac{\nu+1}{2}}}$$

where ν is the degrees of freedom and $\Gamma(\cdot)$ is the Gamma function. The result y is the probability of observing a particular value of x from a Student's *t* distribution with ν degrees of freedom.

Plot

This plot shows how changing the value of the degrees of freedom parameter ν alters the shape of the pdf. Use `tpdf` to compute the pdf for values x equals 0 through 10, for three different values of ν . Then plot all three pdfs on the same figure for a visual comparison.

```
x = [0:.1:10];
y1 = tpdf(x,5); % For nu = 5
y2 = tpdf(x,25); % For nu = 25
y3 = tpdf(x,50); % For nu = 50

figure;
plot(x,y1,'Color','black','LineStyle','-')
hold on
plot(x,y2,'Color','red','LineStyle','-')
plot(x,y3,'Color','blue','LineStyle','-')
legend({'nu = 5','nu = 25','nu = 50'})
hold off
```

Random Number Generation

Use `trnd` to generate random numbers from the Student's t distribution. For example, the following generates a random number from a Student's t distribution with degrees of freedom ν equal to 10.

```
nu = 10;  
r = trnd(nu)  
r = 1.0585
```

Relationship to Other Distributions

As the degrees of freedom ν goes to infinity, the t distribution approaches the standard normal distribution.

If x is a random sample of size n from a normal distribution with mean μ , then the statistic

$$t = \frac{\bar{x} - \mu}{s/\sqrt{n}}$$

where \bar{x} is the sample mean and s is the sample standard deviation, has Student's t distribution with $n - 1$ degrees of freedom.

The Cauchy distribution is a Student's t distribution with degrees of freedom ν equal to 1. The Cauchy distribution has an undefined mean and variance.

Cumulative Distribution Function

Definition

The cumulative distribution function (cdf) of Student's t distribution is

$$p = F(x) \left| \nu \right. = \int_{-\infty}^x \frac{\Gamma\left(\frac{\nu+1}{2}\right)}{\Gamma\left(\frac{\nu}{2}\right)} \frac{1}{\sqrt{\nu\pi}} \frac{1}{\left(1 + \frac{t^2}{\nu}\right)^{\frac{\nu+1}{2}}} dt$$

where ν is the degrees of freedom and $\Gamma(\cdot)$ is the Gamma function. The result p is the probability that a single observation from the t distribution with ν degrees of freedom will fall in the interval $[-\infty, x]$.

Plot

This plot shows how changing the value of the parameter ν alters the shape of the cdf. Use `tcdf` to compute the cdf for values x equals 0 through 10, for three different values of ν . Then plot all three cdfs on the same figure for a visual comparison.

```
x = [0:.1:10];
y1 = tcdf(x,5); % For nu = 5
y2 = tcdf(x,25); % For nu = 25
y3 = tcdf(x,50); % For nu = 50

figure;
plot(x,y1,'Color','black','LineStyle','-')
hold on
plot(x,y2,'Color','red','LineStyle','-.')
```

```
plot(x,y3,'Color','blue','LineStyle','--')  
legend({'nu = 5','nu = 25','nu = 50'})  
hold off
```

Inverse cdf

Use `tinvcdf` to compute the inverse cdf of the Student's t distribution.

```
p = .95;  
nu = 50;  
x = tinvcdf(p,nu)
```

```
x = 1.6759
```

Mean and Variance

The mean of the Student's *t* distribution is

$$\text{mean} = 0$$

for degrees of freedom ν greater than 1. If ν equals 1, then the mean is undefined.

The variance of the Student's *t* distribution is

$$\text{var} = \frac{\nu}{\nu - 2}$$

for degrees of freedom ν greater than 2. If ν is less than or equal to 2, then the variance is undefined.

Use `tstat` to compute the mean and variance of a Student's *t* distribution. For example, the following computes the mean and variance of a Student's *t* distribution with degrees of freedom ν equal to 10.

```
nu = 10;  
[m,v] = tstat(nu)
```

```
m = 0
```

```
v = 1.2500
```

Example

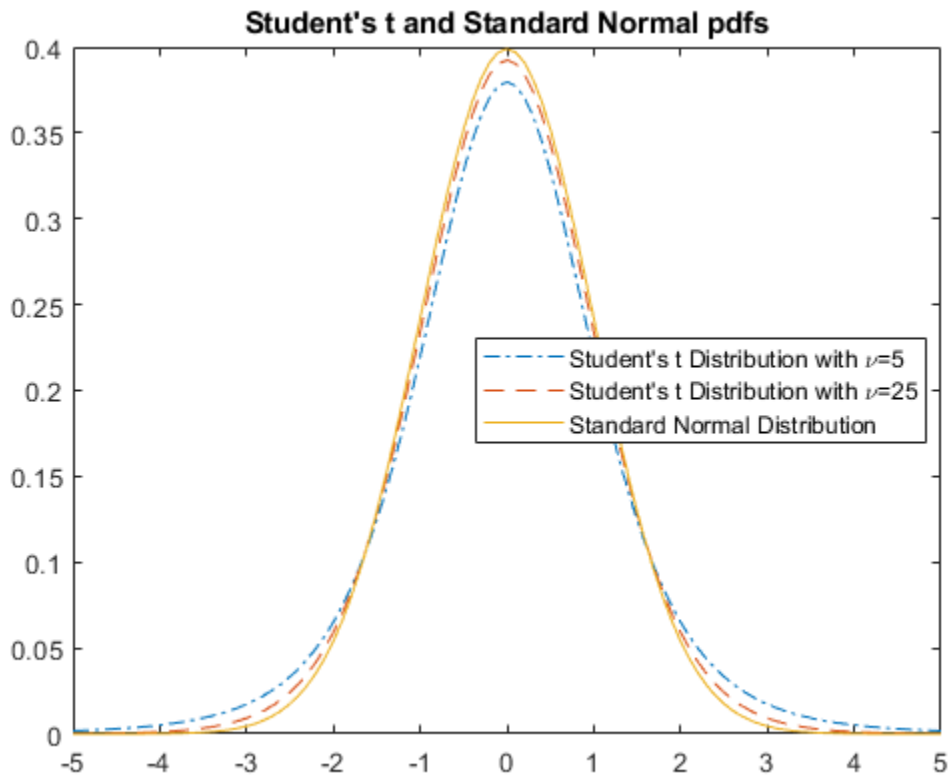

Compare Student's *t* and Normal Distribution pdfs

The Student's *t* distribution is a family of curves depending on a single parameter ν (the degrees of freedom). As the degrees of freedom ν goes to infinity, the *t* distribution approaches the standard normal distribution. Compute the pdfs for the Student's *t* distribution with the parameter `nu = 5` and the Student's *t* distribution with the parameter `nu = 25`. Compute the pdf for a standard normal distribution.

```
x = -5:0.1:5;  
y1 = tpdf(x,5);  
y2 = tpdf(x,15);  
z = normpdf(x,0,1);
```

Plot the Student's t pdfs and the standard normal pdf on the same figure. The standard normal pdf has shorter tails than the Student's t pdfs.

```
plot(x,y1,'-.',x,y2,'--',x,z,'-')
legend('Student''s t Distribution with \nu=5', ...
      'Student''s t Distribution with \nu=25', ...
      'Standard Normal Distribution','Location','best')
title('Student''s t and Standard Normal pdfs')
```

t Location-Scale Distribution

In this section...

“Overview” on page B-181
 “Parameters” on page B-181
 “Probability Density Function” on page B-181
 “Cumulative Distribution Function” on page B-182
 “Descriptive Statistics” on page B-182
 “Relationship to Other Distributions” on page B-182

Overview

The t location-scale distribution is useful for modeling data distributions with heavier tails (more prone to outliers) than the normal distribution. It approaches the normal distribution as ν approaches infinity, and smaller values of ν yield heavier tails.

Parameters

The t location-scale distribution uses the following parameters.

Parameter	Description	Support
μ	Location parameter	$-\infty < \mu < \infty$
σ	Scale parameter	$\sigma > 0$
ν	Shape parameter	$\nu > 0$

To estimate distribution parameters, use `mle`. Alternatively, fit a `tLocationScaleDistribution` object to data using `fitdist` or the **Distribution Fitter** app.

Probability Density Function

The probability density function (pdf) of the t location-scale distribution is

$$\frac{\Gamma\left(\frac{\nu+1}{2}\right)}{\sigma\sqrt{\nu\pi}\Gamma\left(\frac{\nu}{2}\right)} \left[\frac{\nu + \left(\frac{x-\mu}{\sigma}\right)^2}{\nu} \right]^{-\left(\frac{\nu+1}{2}\right)}$$

where $\Gamma(\cdot)$ is the gamma function, μ is the location parameter, σ is the scale parameter, and ν is the shape parameter .

To compute the probability density function, use `pdf` and specify `'tLocationScale'`. Alternatively, you can create a `tLocationScaleDistribution` object using `fitdist` or `makedist`, then use the `pdf` to work with the object.

Cumulative Distribution Function

To compute the probability density function, use `cdf` and specify `'tLocationScale'`. Alternatively, you can create a `tLocationScaleDistribution` object using `fitdist` or `makedist`, then use the `cdf` to work with the object.

Descriptive Statistics

The mean of the *t* location-scale distribution is

$$\text{mean} = \mu ,$$

where μ is the location parameter. The mean is only defined for shape parameter values $\nu > 1$. For other values of ν , the mean is undefined.

The variance of the *t* location-scale distribution is

$$\text{var} = \sigma^2 \frac{\nu}{\nu - 2} ,$$

where μ is the location parameter and ν is the shape parameter. The variance is only defined for values of $\nu > 2$. For other values of ν , the variance is undefined.

To compute the mean and variance, create a `tLocationScaleDistribution` object using `fitdist` or `makedist`. You can also use the **Distribution Fitter** app.

Relationship to Other Distributions

If x has a *t* location-scale distribution, with parameters μ , σ , and ν , then

$$\frac{x - \mu}{\sigma}$$

has a Student's *t* distribution with ν degrees of freedom.

Triangular Distribution

In this section...
“Overview” on page B-184
“Parameters” on page B-184
“Probability Density Function” on page B-185
“Cumulative Distribution Function” on page B-186
“Descriptive Statistics” on page B-188

Overview

The triangular distribution provides a simplistic representation of the probability distribution when limited sample data is available. Its parameters are the minimum, maximum, and peak of the data. Common applications include business and economic simulations, project management planning, natural phenomena modeling, and audio dithering.

Parameters

The triangular distribution uses the following parameters.

Parameter	Description	Constraints
a	Lower limit	$a \leq b$
b	Peak location	$a \leq b \leq c$
c	Upper limit	$c \geq b$

Parameter Estimation

Typically, you estimate triangular distribution parameters using subjectively reasonable values based on the sample data. You can estimate the lower and upper limit parameters a and c using the minimum and maximum values of the sample data, respectively. You can estimate the peak location parameter b using the sample mean, median, mode, or any other subjectively reasonable estimate of the population mode.

Probability Density Function

The probability density function (pdf) of the triangular distribution is

$$f(x) \Big|_{a,b,c} = \begin{cases} \frac{2(x-a)}{(c-a)(b-a)} & ; a \leq x \leq b \\ \frac{2(c-x)}{(c-a)(c-b)} & ; b < x \leq c \\ 0 & ; x < a, x > c \end{cases} .$$

This plot shows how changing the value of the parameters a , b , and c alters the shape of the pdf.

```
% Create four distribution objects with different parameters
```

```
pd1 = makedist('Triangular');
pd2 = makedist('Triangular','a',-1,'b',0,'c',1);
pd3 = makedist('Triangular','a',-.5,'b',0,'c',1);
pd4 = makedist('Triangular','a',0,'b',0,'c',1);
```

```
% Compute the pdfs
```

```
x = -2:.01:2;
pdf1 = pdf(pd1,x);
pdf2 = pdf(pd2,x);
pdf3 = pdf(pd3,x);
pdf4 = pdf(pd4,x);
```

```
% Plot the pdfs
```

```
figure;
plot(x,pdf1,'r','LineWidth',2)
hold on;
plot(x,pdf2,'k','LineWidth',2);
plot(x,pdf3,'b-.','LineWidth',2);
plot(x,pdf4,'g--','LineWidth',2);
legend({'a = 0, b = 0.5, c = 1','a = -1, b = 0, c = 1',...
'a = -0.5, b = 0, c = 1','a = 0, b = 0, c = 1'},'Location','NW');
hold off;
```

As the distance between a and c increases, the density at any particular value within the distribution boundaries decreases. Because the density function integrates to 1, the height of the pdf plot decreases as its width increases. The location of the peak parameter b determines whether the pdf skews right or left, or if it is symmetrical.

Cumulative Distribution Function

The cumulative distribution function (cdf) of the triangular distribution is

$$F(x) \left| a, b, c \right. = \begin{cases} 0 & , x < a \\ \frac{(x-a)^2}{(c-a)(b-a)} & , a \leq x \leq b \\ 1 - \frac{(c-x)^2}{(c-a)(c-b)} & , b < x \leq c \\ 1 & , x > c \end{cases} .$$

This plot shows how changing the value of the parameters a , b , and c alters the shape of the cdf.

```
% Create four distribution objects with different parameters
```

```
pd1 = makedist('Triangular');
pd2 = makedist('Triangular','a',-1,'b',0,'c',1);
pd3 = makedist('Triangular','a',-.5,'b',0,'c',1);
pd4 = makedist('Triangular','a',0,'b',0,'c',1);
```

```
% Compute the cdfs
```

```
x = -1.2:.01:1.2;
cdf1 = cdf(pd1,x);
cdf2 = cdf(pd2,x);
cdf3 = cdf(pd3,x);
cdf4 = cdf(pd4,x);
```

```
% Plot the cdfs
```

```
figure;
plot(x,cdf1,'r','LineWidth',2)
xlim([-1.2 1.2]);
ylim([0 1.1]);hold on;
plot(x,cdf2,'k:','LineWidth',2);
plot(x,cdf3,'b-.','LineWidth',2);
plot(x,cdf4,'g--','LineWidth',2);
legend({'a = 0, b = 0.5, c = 1','a = -1, b = 0, c = 1',...
'a = -0.5, b = 0, c = 1','a = 0, b = 0, c = 1'},'Location','NW');
hold off;
```

Descriptive Statistics

The mean and variance of the triangular distribution are related to the parameters a , b , and c .

The mean is

$$\text{mean} = \left(\frac{a + b + c}{3} \right).$$

The variance is

$$\text{var} = \left(\frac{a^2 + b^2 + c^2 - ab - ac - bc}{18} \right).$$

Uniform Distribution (Continuous)

In this section...

“Overview” on page B-190

“Parameters” on page B-190

“Probability Density Function” on page B-190

“Cumulative Distribution Function” on page B-192

“Descriptive Statistics” on page B-194

“Relationship to Other Distributions” on page B-195

Overview

The uniform distribution (also called the rectangular distribution) is notable because it has a constant probability distribution function (pdf) between its two bounding parameters. It is appropriate for representing the distribution of round-off errors in values tabulated to a particular number of decimal places, and is used in random number generating techniques such as the inversion method.

Parameters

The uniform distribution uses the following parameters.

Parameter	Description	Constraints
lower	Lower limit	$-\infty < \text{lower} < \text{upper}$
upper	Upper limit	$\text{lower} < \text{upper} < \infty$

Parameter Estimation

The maximum likelihood estimator (MLE) for *lower* is the sample minimum. The MLE for *upper* is the sample maximum.

Probability Density Function

The probability density function (pdf) of the continuous uniform distribution is

$$f(x \mid \text{lower}, \text{upper}) = \begin{cases} \left(\frac{1}{\text{upper} - \text{lower}} \right) & ; \text{ lower} \leq x \leq \text{upper} \\ 0 & ; \text{ otherwise} \end{cases} .$$

The pdf is constant between *lower* and *upper*.

This plot illustrates how changing the value of the parameters *lower* and *upper* affects the shape of the pdf.

`% Create three distribution objects with different parameters`

```
pd1 = makedist('Uniform');
pd2 = makedist('Uniform','lower',-2,'upper',2);
pd3 = makedist('Uniform','lower',-2,'upper',1);
```

`% Compute the pdfs`

```
x = -3:.01:3;
pdf1 = pdf(pd1,x);
pdf2 = pdf(pd2,x);
pdf3 = pdf(pd3,x);
```

`% Plot the pdfs`

```
figure;
stairs(x,pdf1,'r','LineWidth',2);
hold on;
stairs(x,pdf2,'k:','LineWidth',2);
stairs(x,pdf3,'b-.','LineWidth',2);
ylim([0 1.1]);
legend({'lower = 0, upper = 1','lower = -2, upper = 2',...
'lower = -2, upper = 1'},'Location','NW');
hold off;
```

As the distance between *lower* and *upper* increases, the density at any particular value within the distribution boundaries decreases. Because the density function integrates to 1, the height of the pdf plot decreases as its width increases.

Cumulative Distribution Function

The cumulative distribution function (cdf) of the continuous uniform distribution is

$$F(x|lower, upper) = \begin{cases} 0 & ; \quad x < lower \\ \frac{x - lower}{upper - lower} & ; \quad lower \leq x < upper . \\ 1 & ; \quad x \geq upper \end{cases}$$

This plot illustrates how changing the value of the parameters *lower* and *upper* affects the shape of the cdf.

```
% Create three distribution objects with different parameters
```

```
pd1 = makedist('Uniform');

Descriptive Statistics

The mean and variance of the continuous uniform distribution are related to the parameters *lower* and *upper*.

The mean is

$$\text{mean} = \frac{1}{2}(\text{lower} + \text{upper}) .$$

The variance is

$$\text{var} = \frac{1}{12}(\text{upper} - \text{lower})^2 .$$

Relationship to Other Distributions

The standard uniform distribution (`lower = 0` and `upper = 1`) is a special case of the beta distribution on page B-4 obtained by setting the beta distribution parameters `a = 1` and `b = 1`.

The inversion method uses the continuous standard uniform distribution to generate random numbers for any other continuous distribution. The inversion method relies on the principle that continuous cumulative distribution functions (cdfs) range uniformly over the open interval (0,1). If u is a uniform random number on (0,1), then $x = F^{-1}(u)$ generates a random number x from any continuous distribution with the specified cdf F .

Uniform Distribution (Discrete)

In this section...
"Definition" on page B-196
"Background" on page B-196
"Examples" on page B-196

Definition

The discrete uniform pdf is

$$y = f(x|N) = \frac{1}{N}I_{(1, \dots, N)}(x)$$

Background

The discrete uniform distribution is a simple distribution that puts equal weight on the integers from one to N .

Examples

Plot a Discrete Uniform Distribution cdf

As for all discrete distributions, the cdf is a step function. The plot shows the discrete uniform cdf for $N = 10$.

```
x = 0:10;  
y = unidcdf(x,10);  
figure;  
stairs(x,y)  
h = gca;  
h.XLim = [0 11];
```

Generate Discrete Uniform Random Numbers

Pick a random sample of 10 from a list of 553 items.

```
rng default; % for reproducibility  
numbers = unidrnd(553,1,10)
```

```
numbers = 1x10
```

```
451 501 71 506 350 54 155 303 530 534
```

Weibull Distribution

In this section...

“Definition” on page B-199

“Background” on page B-199

“Plot the Weibull Distribution Hazard Function” on page B-199

“Estimate Parameters of the Weibull Distribution” on page B-200

“Estimate Parameters of a Three-Parameter Weibull Distribution” on page B-201

Definition

The Weibull pdf is positive only for positive values of x , and is zero otherwise. For strictly positive values of the shape parameter b and scale parameter a , the density is

$$f(x|a, b) = \frac{b}{a} \left(\frac{x}{a}\right)^{b-1} e^{-(x/a)^b}.$$

Background

Waloddi Weibull offered the distribution that bears his name as an appropriate analytical tool for modeling the breaking strength of materials. Current usage also includes reliability and lifetime modeling. The Weibull distribution is more flexible than the exponential for these purposes.

To see why, consider the hazard rate function (instantaneous failure rate). If $f(t)$ and $F(t)$ are the pdf and cdf of a distribution, then the hazard rate is

$$h(t) = \frac{f(t)}{1 - F(t)}$$

Substituting the pdf and cdf of the exponential distribution for $f(t)$ and $F(t)$ above yields a constant. The example below shows that the hazard rate for the Weibull distribution can vary.

Plot the Weibull Distribution Hazard Function

The exponential distribution has a constant hazard function, which is not generally the case for the Weibull distribution. The plot shows the hazard function for exponential

(dashed line) and Weibull (solid line) distributions having the same mean life. The Weibull hazard rate here increases with age (a reasonable assumption).

```
t = 0:0.1:4.5;  
h1 = exppdf(t,0.8862)./(1-expcdf(t,0.8862));  
h2 = wblpdf(t,1,2)./(1-wblcdf(t,1,2));  
plot(t,h1,'--',t,h2,'-')
```

Estimate Parameters of the Weibull Distribution

Suppose you want to model the tensile strength of a thin filament using the Weibull distribution. The function `wblfit` gives maximum likelihood estimates and confidence intervals for the Weibull parameters.

```

rng('default'); % For reproducibility
strength = wblrnd(0.5,2,100,1); % Simulated strengths
[p,ci] = wblfit(strength)

p = 1x2
    0.4768    1.9622

ci = 2x2
    0.4291    1.6821
    0.5298    2.2890

```

The default 95% confidence interval for each parameter contains the true value.

Estimate Parameters of a Three-Parameter Weibull Distribution

This example shows how to estimate parameters of a three-parameter Weibull distribution by using a custom probability density function.

Statistics and Machine Learning Toolbox™ uses a two-parameter Weibull distribution with a shape parameter a and a scale parameter b . The Weibull distribution can take one more parameter, a location parameter c . The probability density function becomes

$$f(x) \begin{cases} \frac{b}{a} \left(\frac{x-c}{a}\right)^{b-1} \exp\left(-\left(\frac{x-c}{a}\right)^b\right) & \text{if } x > c, \\ 0 & \text{if } x \leq c, \end{cases}$$

where a and b are positive values, and c is a real value.

Generate sample data of size 1000 from a three-parameter Weibull distribution with the shape parameter 1, scale parameter 1, and location parameter 10.

```

rng('default') % For reproducibility
data = wblrnd(1,1,[1000,1])+10;

```

Define a probability density function for a three-parameter Weibull distribution.

```

custpdf = @(x,a,b,c) (x>c).*(b/a).*((x-c)/a).^(b-1).*exp(-((x-c)/a).^b);

```

The Weibull probability density function is positive only for $x > c$. This constraint also implies that a location parameter c is smaller than the minimum of the sample data. Include the lower and upper bounds of parameters by using the name-value pair arguments 'LowerBound' and 'UpperBound', respectively.

```
opt = statset('MaxIter',1e5,'MaxFunEvals',1e5,'FunValCheck','off');  
phat = mle(data,'pdf',custpdf,'start',[5 5 5],'Options',opt,...  
           'LowerBound',[0 0 -Inf],'UpperBound',[Inf Inf min(data)])
```

```
phat = 1×3
```

```
    1.0258    1.0618   10.0004
```

If `mle` does not converge with default statistics options, you can modify them by using the name-value pair argument 'Options'. Create a statistics options structure `opt` by using the function `statset`. Then use `opt` as the value of 'Options'.

The option `opt` includes the following:

- 'MaxIter', 1e5 — Increase the maximum number of iterations to 1e5.
- 'MaxFunEvals', 1e5 — Increase the maximum number of object function evaluations to 1e5.
- 'FunValCheck', 'off' — Turn off checking for invalid object function values.

For a distribution with a region that has zero probability density, `mle` might try some parameters that have zero density, and it will fail to estimate parameters. To avoid this problem, you can turn off the option that checks for invalid function values by using 'FunValCheck', 'off'.

If the scale parameter b is smaller than 1, the probability density of the Weibull distribution approaches infinity as x goes to c , where c is the location parameter. The maximum of the likelihood function is infinite. `mle` may find satisfactory estimates in some cases, but the global maximum is degenerate when $b < 1$.

Wishart Distribution

In this section...

“Overview” on page B-204

“Parameters” on page B-204

“Probability Density Function” on page B-204

“Example” on page B-205

Overview

The Wishart distribution is a generalization of the univariate chi-square distribution to two or more variables. It is a distribution for symmetric positive semidefinite matrices, typically covariance matrices, the diagonal elements of which are each chi-square random variables. In the same way as the chi-square distribution can be constructed by summing the squares of independent, identically distributed, zero-mean univariate normal random variables, the Wishart distribution can be constructed by summing the inner products of independent, identically distributed, zero-mean multivariate normal random vectors. The Wishart distribution is often used as a model for the distribution of the sample covariance matrix for multivariate normal random data, after scaling by the sample size.

Only random matrix generation is supported for the Wishart distribution, including both singular and nonsingular Σ .

Parameters

The Wishart distribution is parameterized with a symmetric, positive semidefinite matrix, Σ , and a positive scalar degrees of freedom parameter, ν . ν is analogous to the degrees of freedom parameter of a univariate chi-square distribution, and $\Sigma\nu$ is the mean of the distribution.

Probability Density Function

The probability density function of the d -dimensional Wishart distribution is given by

$$y = f(X, \Sigma, \nu) = \frac{|X|^{(\nu-d-1)/2} e^{-\frac{1}{2}\text{trace}(\Sigma^{-1}X)}}{2^{(\nu d)/2} \pi^{(d(d-1))/4} |\Sigma|^{\nu/2} \Gamma(\nu/2) \dots \Gamma(\nu-(d-1)/2)}$$

where X and Σ are d -by- d symmetric positive definite matrices, and ν is a scalar greater than $d - 1$. While it is possible to define the Wishart for singular Σ , the density cannot be written as above.

Example

If x is a bivariate normal random vector with mean zero and covariance matrix

$$\Sigma = \begin{pmatrix} 1 & .5 \\ .5 & 2 \end{pmatrix}$$

then you can use the Wishart distribution to generate a sample covariance matrix without explicitly generating x itself. Notice how the sampling variability is quite large when the degrees of freedom is small.

```
Sigma = [1 .5; .5 2];
df = 10; S1 = wishrnd(Sigma,df)/df
```

```
S1 =
    1.7959    0.64107
    0.64107    1.5496
```

```
df = 1000; S2 = wishrnd(Sigma,df)/df
```

```
S2 =
    0.9842    0.50158
    0.50158    2.1682
```
